

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

EDITORIAL COMMITTEE: S. NEWCOMB, Mathematics; R. S. WOODWARD, Mechanics; E. C. PICKERING, Astronomy; T. C. MENDENHALL, Physics; R. H. THURSTON, Engineering; IRA REMSEN, Chemistry; CHARLES D. WALCOTT, Geology; W. M. DAVIS, Physiography; HENRY F. OSBORN, Paleontology; W. K. BROOKS, C. HART MERRIAM, Zoology; S. H. SCUDDER, Entomology; C. E. BESSEY, N. L. BRITTON, Botany; C. S. MINOT, Embryology, Histology; H. P. BOWDITCH, Physiology; J. S. BILLINGS, Hygiene; WILLIAM H. WELCH, Pathology; J. MCKEEN CATTELL, Psychology; J. W. POWELL, Anthropology.

NEW SERIES. VOLUME XV.

JANUARY - JUNE, 1902.

NEW YORK
THE MACMILLAN COMPANY

41 NORTH QUEEN STREET,
LANCASTER, PA.

CONTENTS AND INDEX.

N. S. VOL. XV.—JANUARY TO JUNE, 1902.

The Names of Contributors are Printed in Small Capitals.

- A., C., Guatemala Earthquake Waves, 873
 A., J. A., Häcker's Gesang der Vögel, 98; Ridgway's Birds of North and Middle Amer., 225
 ABBE, C. Pernter's Meteorological Optics, 708; Indian Summer, 793
 Aeronautics, R. H. T., 633
 Agricultural Experiment Stations, A. C. TRUE, 939
 Agriculture and Experiment Stations, H. F. ROBERTS, 430; Graduate School of, 997
 Agriculturists, College work for, R. H. THURSTON, 534
 ALLEN, F., Injuries to the Eye caused by Intense Light, 109
 ALLEN, G. M., Boston Society of Natural History, 192, 471, 666
 American Association for the Advancement of Science: Anthropology, 121, 509, 532, 1032; Zoology, 132; Membership in, 616, 814, 982; Physics, 631; Meeting of Council, 657; Mechanical Science and Engineering, 668, 1031; Mathematics and Astronomy, 668; Pittsburgh Meeting, 801, 868, 911, 955, 998; Social and Economic Science, 827; Chemistry, 869, 1030
 AMI, H. M., Union and Riverdale Formations in Nova Scotia, 392
 Anatomists, American, Association of, 130
 Anthropological, Society of Washington, W. HUGH, 147, 391, 544, 790; Expedition to Torres Straits, J. JASTROW, 742; National, Society, F. BOAS, 804; W J M., 1035
 Anthropology, in United States, G. G. MACCURDY, 211; Twenty Years of, G. G. MACCURDY, 532
 Appointments, Scientific, under the Government, 634, 997
 Astronomical, and Astrophysical Society of America, W. S. EICHELBERGER, 255, 284; Bulletin, E. C. PICKERING, 996
 Bacteriologists, Amer. Society of, H. W. CONN, 361
 BAER, von, The Law of, O. C. GLASER, 976
 BAGG, Jr., R. M., *Discorbina rugosa* d'Orbigny, 755
 Baldwin, J. M., Dictionary of Philosophy, F. THILLY, 302; Social and Ethical Interpretations, G. TOSTI, 551
 BANCROFT, W. D., Roozeboom on Die heterogenen Gleichgewichte, 537; Ostwald's Analytic Chemistry, 538
 BANKS, N., Sjöstedt's Der Termiten Afrikas, 307
 BARNES, C. R., Némec's Die Reizleitung bei den Pflanzen, 660
 Barometry, F. H. BIGELOW, 417
 BARROWS, F. W., and L. C. NEWELL, R. E. DODGE, M. R. MILLER, H. R. LINVILLE, N. Y. State Teachers Association, 729
 BARUS, C., Graded Condensation in Benzine Vapor, 175; Amer. Jour. of Physics, 629; Properties of Nuclei, 912
 BASKERVILLE, C., Elisha Mitchell Scientific Society, 232, 312, 549, 747; and H. R. WELLER, Black Rain in North Carolina, 1034
 BATHER, F. A., 'Geology,' 747, 993
 BAUER, L. A., Magnetic Disturbance and Eruption of Mont Pelee, 873
 BEAL, W. J., What is Nature Study? 991
 BEAN, B. A., A 'Whale Shark,' 353; Conger Eel, 715
 BEEBE, C. W., A Subdermal Mite in Birds, 754
 BESSEY, C. E., Botanical Notes, 75, 274, 511, 632, 793; 'Ecology,' 593; Campbell's Botany, 900
 BIGELOW, F. H., A New Barometry, 417
 Biological Society of Washington, F. A. LUCAS, 107, 189, 269, 389, 468, 588, 709, 746, 907, 1032
 Birds, Song in, W. E. D. SCOTT, 178; W. CRAIG, 590; W. S. KELLEY, 715
 BIRGE, E. A., A Jær. Society of Naturalists, 299
 Blood-corpuscle, Red, Nodules in, G. MACLOSKE, 499; G. N. STEWART, 714
 BOAS, F., Variability of Organisms, 1; National Anthropological Society, 804
 BOLTON, H. C., Rössing's Gesehichte der Metalle, 139; Memorial Lectures at Chemical Society of London, 421; Correspondence of J. Berzelius and F. Wöhler, 740; of Liebig and Schönbein, 816
 BOOTH, E., Chemistry in California Schools, 35; Pacific Coast Assoc. of Chem. Teachers, 868
 Boston Society of Natural History, G. M. ALLEN, 192, 471, 666
 Botanical, Notes, C. E. BESSEY, 75, 274, 511, 632, 793; Garden, Missouri, 157; Section of Concilium Bibliographicum, H. H. FIELD, 357; Society of Washington, H. J. WEBBER, 895, 903, 989
 Botanists of Central States, A. SCHNEIDER, 454
 BRADLEY, W. P., Sensitive Thermostat, 510
 BRITTON, W. E., The Gray Squirrel as Twig-pruner, 950
 BROOKS, A. H., Geological Society of Washington, 150; 350, 389, 506, 545, 664, 710, 822; Northwestern America and Northeastern Asia, 909
 BROOKS, W. K., Intellectual Conditions for the Science of Embryology, 444, 481
 BROUGH, B. H., Andrew Carnegie Research Scholarship, 73
 BROWN, A. C., Ions of Electrolysis, 881
 BROWN, J. S., Injuries to the Eye by Intense Light, 433

THE RELATIONS BETWEEN THE VARIABILITY OF ORGANISMS AND THAT OF THEIR CONSTITUENT ELEMENTS.

IN a study of the varying forms of organisms we may either direct our attention to the variability of the organism as a whole, or to the variability of its constituent elements. When two organisms differ in form, their differences are necessarily founded on differences in the forms of their corresponding parts, and we are justified in assuming each of these parts as very small. The corresponding parts may consist of homologous cell groups, of individual cells, or of other small homologous elements of the two organisms. These small elements may differ in size and form, and new elements may also be added in the one or the other organism, so that there may also be a difference in the number of elements. The difference between the two organisms may then be considered as a resultant of the differences between their constituent elements. Therefore, there must be a certain definite relation between the variability of the elements and that of the whole organism.

In order to make this clear we will, for a moment, consider the elements as independent units, not as parts of an organic whole. In this case, each element would be entirely independent of the other. When we consider two organisms thus con-

stituted in which the total number of cells is the same, we find that they cannot possess any variability, because the variations of the constituent cells would compensate each other. This can be proven as follows: If we determine the form of an organism by a number of measurements taken in various directions, then each measurement may be considered as made up of many constituent elements. On the average, the variability of the combined elements will be proportionate to the square root of the number of elements, while the value of the total length of the combined elements will be proportionate to their number. If, therefore, the number of elements is very great—and there is nothing to hinder us in assuming each element as very small and their number as very great—the variability of the whole measurement must be very small, according to the small value of the proportion between the square root of the number of elements, and the number of elements. Since this contradicts the fact that all organisms are variable, it follows that the elements cannot be constant in number and mutually independent. This conclusion is obvious from a morphological point of view, but it seemed desirable to point out that the independence and constant number of elements would entail lack of variability in the whole organism.

If the elements were independent of each other but varied in number, we might assume in accordance with morphological observation that each group of elements had a certain limited period of multiplication which proceeds at a definite average rate. Then it may be said that this period undergoes certain changes that are due to chance. If this were the case, the size of the organ would increase approximately ingeometrical progression when the period increases in arithmetical progression.

It is probable that, on the whole, the periods of development of various organisms

vary around the typical period according to the laws of chance. Then the frequencies of periods belonging to different individuals would be arranged symmetrically around the typical period, while the measurements corresponding to each period and belonging to different individuals would be arranged asymmetrically around the type, in accordance with the relations between size and period. It is quite evident that the observed distributions of variations around a type do not generally conform with a law of this character, and therefore this theory must also be rejected as insufficient, although we recognize that it may explain a part of the general phenomena of variability.

It is, therefore, necessary to assume the elements of organisms to be correlated. This is entirely in accord with the evidence of morphology and of pathology. If the number of elements is assumed as constant, it is easy to determine what the results of such correlation must be. 'Correlation' means that the change in form and size of one element influences more or less the forms and sizes of other elements. Such correlated elements may either be contiguous, or they may be related in some other way. The degree of their relation may be expressed by an index of correlation.

If the correlation of all the elements were perfect, that is to say, if a change in one would necessitate a corresponding change of a certain definite amount in all the others, the variability of the whole organism would be proportioned to the average variability and number of the homologous elements. This condition is as unlikely as that of complete independence of the elements. We must draw the conclusion that the variability of the organism as a whole will always be less, in proportion to its size, than the variability of its constituent elements; or, as we might perhaps say, the

variability of the individual cells that constitute an organism must always be greater than the variability of the whole organism.

It may be well to illustrate the effects of correlation by assuming simplified conditions of correlation.

Assuming first, that the elements may be classed in a limited number of groups, each consisting of interdependent elements, so that the enlargement of one element of each group would necessitate a definite amount of enlargement of all the others. Furthermore be it assumed that the chances of a small number of these groups being enlarged are subject to accidental causes. Then the probability that one, two, three, or more of these groups are affected can be calculated according to the binomial law. Each group would contribute a definite, invariable amount to the total variability and the general variability would, therefore, also conform to the binomial law.

We will next assume a case which is somewhat nearer natural conditions. When we count and measure the total number of elements in *all* the individuals of a variable series, we obtain certain definite numbers of elements of various sizes and we can express numerically the frequency or probability of each size. In order to simplify matters, we will speak only of elements of decreased size and of enlarged size. The proportion of these two classes is definite in the total number of elements belonging to the different organisms of the series. If inside of each organism there were no correlation, then the proportion of large and small elements in each organism would, on account of the great number of elements, correspond to their proportions in the whole mass of elements. On account of the existence of correlations in each organism the occurrence of each enlarged element will have the effect, that an additional number of enlarged elements may be expected in the same organism, and the

occurrence of an element of decreased size will add to the probability of elements of this character in the organism in which it occurs. The arrangement of these elements becomes, therefore, similar to that in a mechanical mixture of elements of two sizes, which are not uniformly distributed, but in which large and small parts cluster together. It is quite clear that the variability of distribution in such a mixture must be quite different from that found in cases of even mixture. It will depend entirely upon the distribution of large and small elements, and the number of elements of both classes that are found in a unit of space, how their proportion in each unit of space will vary.

We may obtain an insight into such variabilities by a consideration of the results obtained by taking a certain number of contiguous balls out of a row containing large and small balls that are not thoroughly mixed. The two arrangements given under 1 and 2 may serve as examples:

1. ● ● ● ● ● ● ● ● ● ●
 2. ● ● ● ● ● ● ● ● ● ●

If four contiguous balls are taken out of each of these rows, we find that in the drawings made from the two series large balls occur as follows:

	Series 1.	Series 2.
4 large balls	1 Time	0 Times
3 " "	2 Times	3 "
2 " "	2 "	3 "
1 " ball	2 "	1 Time

Evidently, the distribution in cases of this kind cannot be foretold. This result may be expressed in a more general form as follows: If only one series of elements of an organism are interdependent, and all the others independent, the variability of form of all the individuals will depend primarily upon the distribution of disturbances in the interdependent elements in the whole series of individuals. Therefore the distribution of variations cannot be fore-

told. The same is true if the number of groups of interdependent elements is small.

When, however, the number of these groups of interdependent elements is somewhat greater and each group of correlations is independent of the other, then the conditions approach again those described before, when we assumed a number of groups in which the size of one element of a group determines the sizes of all the other elements of the same group. We may then expect to find a distribution the type of which is determined by the binomial law, because the combinations of groups that occur in each individual are determined by this law, while the law must be modified by the variability of the size of each correlated group, taken as a total. It is quite evident that the resultant curve must be similar in its general character to the series of binomial points, but continuous on account of the variability of each group. This phenomenon is still further complicated by the variation in the number of elements, the effect of which was discussed before.

We may reach the same result by assuming that the form of the whole organism is affected by a limited number of causes variable in intensity, each of which influences to a measurable degree the form of the organism. The combination of such groups of independent causes, limited in number and each having measurable results will bring about a distribution of variations of the same character as the one described before. The phenomenon, expressed in this manner, does not differ from the expression found before, because it does not seem probable that each cause would affect all the elements comprising the organism in the same manner. It seems much more likely that certain groups of elements will be affected more by one cause than by another. At the same time, it is possible that the same element may be subject to several causes and thus belong to various

groups of correlated elements. Karl Pearson's discussions have shown that many distributions can be explained satisfactorily by assuming that they correspond to a continuous function determined by the points binomial.

It will be noted that, on the whole, the greater a variable measurement, the more nearly will the distribution of variations be symmetrical and in conformity with the exponential law. This may be expected, because the greater the measurement, the greater will probably be the number of independent, correlated groups. The increase of their number necessitates an approach to the exponential law. On the other hand, the smaller the measurement, the more probable that a great part of its constituent elements are subject to the same causes, so that the conditions are favorable to the combination of a small number of independent causes, each of which brings about considerable variation, so that we may expect as a resultant skew distributions of variations.

It would seem, therefore, that the whole range of phenomena of variability can be understood on the basis of our conception of the relations between the variability of the small constituent elements of an organism and the variability of the organism itself. We are justified in drawing the following conclusions:

1. The elements of organisms are more variable than the organisms themselves.
2. The elements of organisms vary in correlated groups.
3. The characteristics of the variability of an organism depend upon the correlations of its constituent elements, so that a knowledge of these correlations will enable us to determine the characteristics of the variability of the organism.

It follows from this that the problem of variability may be treated by a study of the variability and of the correlations of

the constituent elements of organisms. The study of physiological and pathological variations that elucidate correlations will, therefore, be a most powerful factor in the discussion of the problem of variability.

This point of view coincides closely with that of Rudolf Virchow who has always emphasized that the clue for the problems of variability must be looked for in the study of cellular variation.

Under certain simplified assumptions the problem, as here defined, may be made amenable to statistical treatment. If all the contributory causes of variation are given equal weight, and if it is assumed that the index of correlation for all the groups is the same, then it is only necessary to determine four unknown quantities: the total number of causes (or correlated groups); the probable number of causes (or correlated groups); the amount of influence of each cause (or correlated group) upon the whole organism; the variability of the effect of each cause (or correlated group) upon the whole organism. These few data can be calculated without any great difficulty from the averages of the first four powers of the individual variations. This method may be serviceable as long as the actual correlations are unknown.

Still another conclusion may be drawn from our considerations. We have seen that the variability of an organism depends upon the correlations of its elements, and that the variability must be the greater the closer these correlations and the less the number of correlated groups. At the same time, the variations will be the more likely to have skew distributions, the less the number of correlated groups. A disturbance in one element of an organism thus constituted must, therefore, result in a considerable variation of the whole. That is to say, that in the case of skew distributions of variations we may expect sudden transformations of type due to small causes. In

organisms in which the variability is symmetrical, we may generally expect the whole form to be controlled by many independent causes, or by many independent groups of correlated elements. In this case, the changes of form due to small changes of conditions will probably be less marked.

The principal advantage of the method of considering variation that has been here suggested is that the occurrence of variations in fixed lines, that are so difficult to understand, may be considered as a result of chance variation of small elements and of physiological correlation. Both of these are much more readily understood than a variation of form that does not show any immediate relation to the causes producing the variation.

It has often been asserted, or assumed, that skew distribution of variations is a proof of the effect of selection, or of some other kind of instability of type. Our considerations have shown that this is not necessarily the case. Skew distributions may be found in stable forms. On the whole, it does not seem possible to discover by purely statistical methods the causes of skewness. The numerical material obtained by measurements can be made to fit satisfactorily many theories that would account for the skewness. It is necessary to base such theories on biological investigations and to subordinate our statistical methods to the biological point of view. Otherwise the result of statistical inquiry will be of little use and may even become quite misleading.

FRANZ BOAS.

ON THE TRUE NATURE OF TAMIOSOMA.*

In 1856 the late T. A. Conrad described a remarkable fossil from California, under the name of *Tamiosoma gregaria*, composed of large tubes with a longitudinal cellular

* Communicated by permission of the Director of the U. S. Geological Survey.

structure, closed and tapering to a relatively small point of attachment below, nearly filled with a vesicular mass of shell laminae internally, preserving a smooth-walled body cavity with a reflexed margin at the upper end, without any trace of subdivision in the walls, or dentiform processes. He pointed out some similarities in the form of the aperture to the sessile barnacles (*Balanus*) from which animals the undivided tube structure seemed to definitely separate the new organism. Subsequently he described an imperfect specimen as a *Balanus* (*B. estrellanus* Conrad, 1857), but still later (1864) he referred it to *Radiolites*, in the course of some rectifications of his earlier papers, and stated that it was characteristic of the Cretaceous of California.

In 1866 Gabb stated ('Pal. Cal.,' II., p. 62) that it was a fossil of 'the Bituminous shale, the best marked member of our Upper Miocene,' and referred it to the Hippuritida, an opinion provisionally accepted by Stoliczka in 1871,* notwithstanding the fact that the upper valve was unknown and the supposed lower valve showed no traces of muscular impressions, pallial line or tooth sockets. Tyron,† in 1884, copies Gabb's remarks without comment. Zittel‡ and Barrois, in 1887, regarded it as a problematical organism possibly referable to the corals, while in the same year Fischer expresses the opinion§ that it is more like a large barnacle than a Hippurite. Most of the manuals and check-lists prudently omit all reference to it.

During the past season Mr. Homer Hamlin of Los Angeles sent to the writer a collection of fossils from southern California containing numerous Miocene types,

*'Cretaceous Peleceypoda of India,' p. 239.

†'Structural and Systematic Conch.,' III., p. 206.

‡'Traité de Pal.,' II., p. 86.

§'Man. de Conchyl.,' p. 1064.

including *Lyropecten magnolia* and *L. Heermanni* Conrad, from a horizon of which the matrix is a cemented calcareous gravel (not the bituminous shale), containing several examples of *Tamiosoma*; not only the gregarious colonies, such as were described by Conrad, but also solitary individuals and certain flat saucer-like, concentric valves with reflected edges, which were naturally taken to be the long-sought upper valves. One solitary individual appeared to have this flat valve *in situ* and a sagittal section of it was made, to study the relations of the body cavity. It may be mentioned in passing that all the material in the beds from which these fossils came has been more or less crushed so that perfect specimens are extremely rare.

The result of the sectionizing was most unexpected. There was no body cavity and the flat saucer-like portion proved to be merely the basal portion of the tube, which in solitary individuals starts from an extremely small point of attachment to some object and grows concentrically in a flat form until it is an inch or two in diameter, after which it changes its manner of growth and rises in columnar fashion. In the gregarious groups the growth forms an inverted cone, owing to the mechanical difficulties in the way of lateral expansion. A section of the shelly matter showed that it is entirely destitute of the prismatic layer of the *Hippuritida*, and that the structure of the shell is precisely that of the sessile cirripedes. Since the tube is entire and not divided into valves, and is quite destitute of any radial structure, it was evident that the organism is not homologous with the valvular case of the sessile barnacles, which is always divided into plates more or less distinctly fused with one another, and that it cannot be a coral.

The only remaining alternative then appears to be that the fossil described by Conrad is homologous, not with the valvu-

lar portion of *Balanus*, but with the base, which in the latter genus is not only entire, but under suitable conditions assumes a tubular conical form, and in one species, the *Balanus laevis* of Darwin, sometimes has the lower portion of this tube more or less filled with a vesicular mass of shell substance closely resembling the tube of *Tamiosoma*.* This conclusion was fortified by the discovery of an undoubted species of *Balanus* in the same horizon as that of *Tamiosoma*, forming a tubular base like that of *B. laevis*, though much smaller, in the proximal portion of which a certain amount of vesicular filling had taken place. Lastly, complete confirmation was attained through the kindness of the authorities of the State Mining Bureau of California which at the intercession of Dr. J. C. Merriam, of the University of California, forwarded a unique specimen which had been supposed to exhibit an 'upper valve,' but in which the subconic base filled this rôle, while a careful cleaning of the much-crushed but otherwise nearly intact 'base' revealed the remains of six very solid valves typical of the genus *Balanus*, and the cavity, now filled with gravel and fragments of the shell, in which the soft parts of the animal had originally been enclosed. These valves were so crushed and worn that a complete figure of the valvular summit of *Tamiosoma* is not yet attainable, but the fact that the valves are smooth, except for the rude concentric rugosities due to resting stages and other exigencies of growth, and that they agree with the typical *Balanus* in number and general character, is conclusively demonstrated.†

It is interesting to discover new types of

*Darwin, Mon. Cirripedia, *Balanidae*, p. 227, 1854. See figure of the variety *coquimbensis*, Plate 4, Fig. 2a, giving a section of the tubular base, partly filled with vesicular septa.

†Since the above was written a letter from Mr. Hamlin announces the discovery of a number of complete specimens with the valves.

animal organisms, but perhaps still more so to be able to place those already known to some extent, but whose relations, in the absence of complete information, have been so differently estimated as in the present case. It only remains for systematic students of the cirripedes to determine whether the notable peculiarities of growth of this singular fossil warrant the retention of the name *Tamiosoma* in a subgeneric or sectional sense, or whether it shall be relegated to the genus *Balanus* as a synonym.

Some time since, the supposed occurrence of *Radiolites* in a bed of clay pierced for a tunnel in the city of Los Angeles was noted in SCIENCE. A further examination of fossils collected from these clays by Mr. Hamlin shows that sixty per cent. of the mollusks are recent species, and the age of the deposit therefore Pliocene. Mr. T. W. Vaughan is confident that the fossil which was taken for the smaller valve of the supposed *Radiolites* is a solitary coral; and, while the other portion still remains problematical, it is highly improbable that it belongs to the group of Rudistes.

WM. HEALEY DALL.

THE RELATIVE PROGRESS OF THE COAL-TAR INDUSTRY IN ENGLAND AND GERMANY DURING THE PAST FIFTEEN YEARS.*

THE coal-tar industry is the flower of the chemical industries. It represents the highest development of applied chemical research and chemical engineering, and a country which allows the most scientific branch of chemical industry to languish cannot expect to maintain preeminence

*From a paper by Arthur C. Green read before the British Association (Section of Chemistry) at the Glasgow Meeting, 1901. This accurate statement of the present status of the coal-tar industry, and incidentally of the whole chemical industry, is of interest, not only to the audience for which it was prepared, but also to Americans. For this reason the most important portions of the paper are here presented.

long in any simpler branch of chemical manufacture. Skill trained for attacking the difficult problems of organic chemistry is certain, sooner or later, to be brought to bear on the simpler problems, and to result in improvements along the whole line of chemical industry, resulting in better products and cheaper production. This is well exemplified in the recent revolution in the manufacture of sulfuric acid. The manufacture of alizarin colors and artificial indigo has made a strong demand for cheap sulfur trioxid. With the object of satisfying their own requirements in this respect, the Badische Anilin and Soda Works of Ludwigshafen devoted much time and research to improving the catalytic process of Winkler. This endeavor was attended with such success that by means of the process and plant which they finally evolved they were enabled to produce sulfur trioxid so cheaply that it could not only be used for a large variety of purposes, but, by combination with water, afforded a profitable source of sulfuric acid. This new method of manufacturing sulfuric acid is, for concentrated acid at least, cheaper than the chamber process, and since the product is absolutely free from arsenic and can be produced at any desired concentration, it seems likely to supplant eventually the time-honored method of manufacture.

Besides exerting a stimulating influence upon the inorganic chemical manufactures, the coal-tar industry has given birth during recent years to several important daughter industries. The manufacture of synthetic medicinal agents, artificial perfumes, sweetening materials, antitoxins, nutritives and photographic developers, are all outgrowths of the coal-tar industry, and in great part still remain attached to the color works where they originated. The requirements of the coal-tar industry have further led to great advances in the design and production of chemical plants, such as

filter-presses, autoclaves, fractionating columns, vacuum-pumps and stills, suction-filters, enameled iron, aluminum and stoneware vessels, etc., for the supply of which extensive works have become necessary.

Lord Beaconsfield said that the chemical trade of a country is a barometer of its prosperity, and it has always been regarded as a most important branch of English manufactures. Even those who might be inclined to regard our declining position in the color industry with more or less indifference would consider the loss of a material portion of our general chemical trade as nothing less than a national calamity. The two are, however, indissolubly connected.

It is with the object of ascertaining our present and future prospects in the chemical trade of the world that I propose to compare the relative development of the color industry in England and Germany during the past fifteen years. In 1886, in a paper read before the Society of Arts, Professor Mendola gave a masterly account of the position of the industry in this country at that date, and sounded a warning note to our manufacturers and business men regarding its future progress. These warnings, repeatedly given, have remained largely unheeded, and if the conclusions now forced upon us are unfortunately not of a reassuring nature for our national trade, it is well to remember that nothing is gained by burying our heads in the sand.

In no other industry have such extraordinarily rapid changes and gigantic developments taken place in so short a period—developments in which the scientific elucidation of abstract problems has gone hand in hand with inventive capacity, manufacturing skill, and commercial enterprise; in no other industry has the close and intimate interrelation of science and practice been more clearly demonstrated.

From 1858 to 1886 may be called the 'rosanilin period' of the color industry, since it was chiefly marked by the development of the colors of this group. A few individual members of other groups had been discovered, but had not attained importance. This is especially true of the 'azo' dyes, which have attained such importance that the last fifteen years may justly be called the 'azo period.' The number of individual compounds belonging to this class which have either been prepared or are at present preparable, runs into many millions, and far exceeds the members of all other groups of coloring matters put together. In commercial importance, also, they occupy a position at present far in advance of any other group; the employment of some of them, as the azo blacks, amounting to many thousands of tons annually. A great stimulus to the investigation of the azo compounds was given by the discovery by Boettger in 1884 of the first color possessing a direct affinity for cotton (Congo red), which was followed in a few years by a rapidly increasing series of colors of all shades having similar dyeing properties. The great simplification of cotton dyeing, brought about by the introduction of the new group of azo colors—'benzo' or 'diamin' colors as they are called—led to a rapid increase of their number. Simultaneously therewith proceeded the discovery and investigation of the various isomeric derivatives of naphthalene, required as raw products for the preparation of these colors.

Another method of applying azo colors to cotton, by which much faster shades are obtained, was introduced by Messrs. Read, Holliday & Co., of Huddersfield, in 1880, and consisted in producing unsulfonated azo compounds on the fiber by direct combination. Owing to technical difficulties this process has only reached its full development during the last few years, and that at other

hands than those of its discoverers. The most important color produced by this method is paranitranilin red, for which over two hundred tons of chemically pure paranitranilin are manufactured annually.

The search for direct cotton colors led the author to the discovery of primulin in 1887, and this can be used for the synthesis of various azo colors on the fiber, which are remarkable for great fastness in washing. The new principle of dyeing which this introduced has been considerably extended in other so-called 'diaz' colors. The mordant azo colors have also, with the growing demand for faster shades, recently come into much prominence. The laborious scientific investigations of Fischer and Hepp, Bernthsen, Kehrmann and others on the azins, oxazins, and thiazins, have led to the discovery of many valuable new members of these classes, such as the indulins, rosindulins, rhodulins, etc. Much investigation has also been given to the pyrone and acridin groups, leading to the rhodamins, a class of pure basic reds, and to the basic yellows and oranges.

Next to the azo group, it is in the alizarin group that the greatest progress must be recorded. The demand for fast colors for calico-printing and for dyeing chrome-mordanted wool to withstand severe milling operations, has led to a long series of investigations and patents for producing new derivatives of anthraquinone—the anthracene and alizarin colors. The 'Vidal' blacks and other colors, for the direct dyeing of unmordanted cotton, are now being rapidly developed, although thus far their constitution has resisted elucidation.

It may be fairly claimed, however, that the greatest triumph of the coal-tar industry for the past fifteen years has been the successful production of artificial indigo on a large manufacturing scale.

Returning to the economic aspect of the subject, I will ask you to consider what

share we have obtained in the great expansion of trade resulting from all these new discoveries, of which many have originated in this country. The development of the industry in Germany is well illustrated by the following figures:

Exports from Germany to the World.

	1885. Tons.	1895. Tons.	1899. Tons.
Anilin oil and salt.....	1,713	7,135
Coal-tar colors (excl. of alizarin)	4,646	15,789	17,639
Alizarin colors.....	4,284	8,927

The value of the exports of coal-tar colors from Germany in 1894 was 2,600,000 pounds sterling, in 1898 3,500,000 pounds, an increase of nearly a million in four years. The total annual value of the industry of Germany is hardly less than ten millions of pounds sterling. With the increase in the production of synthetic indigo it may be taken to-day to considerably exceed this figure.

One may well wonder what becomes of this enormous quantity of coal-tar products. According to the United States Consular reports the three and a half million pounds' worth of coal-tar colors exported by Germany in 1898 were consumed as follows:

The United States took...	750,000	pounds' worth.
The United Kingdom took.	750,000	" "
Austria and Hungary took	350,000	" "
Italy took.....	225,000	" "
China took.....	270,000	" "

whilst the rest of the world took the remainder.

The great increase in production in Germany is further shown by the growth in the capital and number of work-people employed. Thus, according to a report of the Badische Works recently issued, the capital of this company, which was increased in 1889 from 900,000 pounds to 1,050,000, will be further augmented this year by the issue of 750,000 pounds' worth of bonds. The number of work-people employed by this company in 1900 was 6,485, as against

4,800 in 1896, an increase of over thirty-three per cent. in four years. The firm of Leopold Cassella & Co., of Mainkur, near Frankfurt, have increased the number of their work-people from 545 in 1890, to 1,800 in 1900.

In England we find that the imports of coal-tar colors are steadily rising, having increased from 509,750 pounds sterling in 1886 to 720,000 pounds in 1900. Contrasted with this, the exports of coal-tar colors manufactured in England have fallen from 530,000 in 1890 to 366,500 pounds sterling in 1899. It is therefore apparent that we have had little share in the great increase which this industry has experienced during the past fifteen years, and we have not been able even to supply the expansion in our own requirements. This is well shown by the following statistics of the two Associations who together form a very large proportion of the entire dyeing trade.

Coloring-matters Used by the Bradford Dyers' Association.

English	10 per cent.	Swiss6 per cent.
German	80 per cent.	French4 per cent.

Coloring-matters Used by British Cotton and Wool Dyers' Association.

Anilin colors.....	{	English	22 per cent.
		Foreign	78 per cent.
Alizarin colors.....	{	English ..	1.65 per cent.
		Foreign ..	98.35 per cent.

Out of a total of sixty tons of coloring-matters and other dyeing materials derived from coal-tar, used by the English Sewing Cotton Company, only 9 per cent. were of English manufacture.

The following table gives a fair picture of the present dimensions of the industry in Germany.

Compared with such figures as these, the English color manufacture assumes insignificant proportions. The total capital invested in the color industry in this country does not exceed 500,000 pounds, and the

POSITION OF THE SIX LARGEST COLOR WORKS IN GERMANY IN THE YEAR 1900.

	Badische Anilin Works.	Meister, Lucius and Brüning.	Farben Fabriken Bayer and Co.	Berlin Anilin Co.	Cassella and Co.	Far werk Mühlheim Leonhardt, and Co.	Total of Six Firms about.
Capital	£1,050,000	£833,000	£882,000	£441,000	{ Private } concern	£157,000	£3,500,000
Number of Chemists...	148	120	145	55	} 60	} 450	500

Levinstein	19
Read Holliday & Co.....	28
Claus & Reß.....	9
W. G. Thompson.....	2

Total of six English firms..... 86

Nor does this represent the sum total of our losses. The new coloring matters, made chiefly in Germany, have in many cases been introduced as substitutes for natural products, which were staple articles of English commerce. Madder and cochineal have been replaced and logwood and indigo are seriously threatened. The capture of the indigo market by the syn-

thetic product, which would mean a loss to our Indian dependencies of three million pounds sterling a year is regarded by the Badische Company as so absolutely certain, that having already invested nearly a million pounds in the enterprise, they are at present issuing 750,000 pounds of new bonds to provide funds to extend their plant for this purpose.

Again, besides the loss of material wealth which the neglect of the coal-tar trade has involved to the country, there is yet another aspect of the question which is even of more importance than the commercial one. There can be no doubt that the growth in Germany of a highly scientific industry of large and far-reaching proportion has reacted with beneficial effect upon the universities, and has tended to promote scientific thought throughout the land. By its demonstration of the practical importance of purely theoretical conceptions, it has had a far-reaching effect on the intellectual life of the nation. How much such a scientific revival is wanted in our own country the social and economical history of the past ten years abundantly testifies. For in the struggle for existence between nations the battle is no longer to the strong in arm, but to those who are the strongest in knowledge to turn the resources of nature to the best account.

In 1886 it could perhaps still be maintained that we held the key to the situation if we chose to make use of it; inasmuch as the principal raw products of the color industry (tar oils, naphthalene, anthracene, soda, ammonia, iron, etc.) were in great measure imported from England. In 1878 Professor von Bayer had said: "Germany, which in comparison with England and France possesses such great disadvantages in reference to natural resources, has succeeded by means of her intellectual activity in wresting from both countries a source of national wealth. The primitive source of this wealth is in England. It is one of the most singular phenomena in the domain of industrial chemistry that the chief industrial nation, and the most practical people in the world, have been beaten in the endeavor to turn to profitable account the coal-tar which they possess. We must not, however, rest upon our oars, for we may be quite sure that England, which at present looks on quietly while we purchase her tar and convert it into colors, will unhesitatingly cut off the source of supply as soon as all technical difficulties have been surmounted by the exertions of German manufacturers."

But the initial advantages which our natural resources afforded us have been neglected, and now, in 1901, the conditions are completely changed, and Germany is no longer dependent upon England for her raw material. Through the shortsightedness, ignorance, and want of enterprise of those with whom rested the care of the color industry of this country in its earlier days, the opportunity has been allowed to pass forever. The English manufacturer considered that a knowledge of the benzene market was of far greater importance than a knowledge of the benzene theory, and little encouragement was given here to chemical investigators and discoverers. The control of the industry passed into the hands of men who had no

knowledge and absolutely no appreciation of the science upon which their business rested, and concerned only with getting the ultimate amount of present profit, discouraged all scientific investigations as waste of time and money. The chemist who devoted himself to the elucidation of the chemical constitution of a coloring matter was regarded by them as an unpractical theorist of no value to a manufacturing business. Even when he discovered new coloring matters of commercial value, they were so blind to their own interests and so incapable of believing that any practical good could come out of such theoretical work, that in many cases they refused to patent or in any way take advantage of the discoveries made by him.

During recent years this attitude has certainly undergone considerable modification. Certain firms must indeed be given the credit of endeavoring to pursue a more enlightened policy, but these attempts have always been directed too much in the expectation of realizing immediate financial results. The difficulties which must be encountered in an attempt to regain the lost ground are of necessity very great and quite unappreciated by our business men. It seems, in fact, to have been the opinion of the public and of the average financial man that this industry ought to be easily won back by the establishment of a few technical schools, the engagement of a dozen chemists, and the investment of a few thousand pounds in new plants, forgetting that the supremacy of our German competitors has been won by years of patient toil, by the work of hundreds of trained chemists, and by the outlay of millions of capital. Who can be surprised, therefore, if such expectations have not been realized, and if in spite of some notable successes the general position of the color trade in England to-day presents a gloomy aspect?

Where, then, are we to look for an improvement? Some would find a remedy in the imposition of heavy protective tariffs, but such tariffs in France have not availed to prevent a similar state of things there, and protection in coloring matters might have a very detrimental effect upon the textile industries of the country. Others expect salvation from the extension of technical schools, but laudable as is the aim of these institutions, I cannot see how they can effect much until their raw material is of a very different character from what it is at present, and until the public can be completely disabused of the fallacy that a year or two of technical training pumped into an ignorant schoolboy will produce a better works-chemist than a university course of scientific study laid upon the foundation of a good general education.

The remedy for the present state of affairs must of necessity be a slow one, and in my opinion can only be found in a better appreciation of the value of science throughout the length and breadth of the land. Until our government and public men can be brought to realize the importance of fostering the study of science, and of encouraging all scientific industries, until our schools and universities appreciate the importance of a scientific education, until the rewards for public service in science are made equal to those in other branches of public service, so long will science continue to be held in insufficient esteem in our country. It is not so much the education of our chemists which is at fault as the scientific education of the public as a whole.

When our capitalists more completely realize the importance of calling in the aid of the best scientific skill available, when our universities and technical schools are able to supply a sufficient number of highly educated chemists equal in knowledge, originality and resource to those trained

in German universities, when our professors and manufacturers are willing to work together in this and other matters, when our patent laws are rendered just to ourselves, we may confidently hope that our natural engineering skill and practical resource will once more bring us to the front.

CONCERNING CERTAIN MOSQUITOES.

DURING the season of 1901 the writer studied the mosquito problem, as it exists in the State of New Jersey, with a view to determining whether it was possible in any way to reduce or control the number of these pests in the State. It was decided that the first point of importance was to ascertain just what species was or were the most troublesome, and just where these troublesome species bred. Collections were made in all parts of the State and local boards of health were enlisted in the service everywhere. The result was the accumulation of a large amount of material, covering every county and almost every district in the State.

Based upon these collections, it was found that the most abundant species was *Culex sollicitans*, and, after this fact was determined, especial attention was paid to the life history and breeding places of this mosquito. It has been known that the species breeds in brackish water; but it has been believed, and is so stated by Dr. Howard in his book on mosquitoes, that it would not breed in water as salty as the sea itself. Collections made along shore soon proved that this general belief was incorrect: so far as noted the contrary is true, for larvæ were found in great abundance in pools and ponds in which the water was fully twenty-five per cent. more salty than ordinary sea water. The collections in the marshes along the coast demonstrated that some percentage of salt was absolutely necessary for the development of the larvæ. In no case were

they found in fresh water, even where adults occurred in enormous quantities. This was prettily illustrated on the Elizabethport meadows, from which the cities of Newark and Elizabeth get the greatest proportion of their mosquito supply during the summer. A large portion of these meadows is flooded during extra high tides, or during storms; a number of fresh water creeks run through them and rapidly freshen these salt-water-covered areas. This is especially true during the latter part of the summer after a period of moderate tides. A two days' collecting trip by an assistant failed to develop any larvæ of *sollicitans* until the shore edge of the meadows was reached, where the puddles were distinctly salty. Everywhere else, while there were plenty of other larvæ discoverable those of *sollicitans* were entirely absent. After a heavy storm causing an unusually high tide, which flooded the meadows, collections were again made and now, as salty water was found almost everywhere, there was no difficulty in obtaining larvæ of *sollicitans*. Every attempt was made to secure *sollicitans* larvæ from fresh water; but almost without success, even where the insects occurred in swarms. I feel no hesitation in claiming that under natural conditions the larva of this species is never found in fresh water; unless it is in a pool that was salty when the eggs were laid and has been freshened subsequently by rains, or otherwise.

Another fact was established by observations made during the summer: that is, the species will travel long distances from its breeding places. For miles throughout South Jersey the only species of mosquito found in any numbers is *Culex sollicitans*. On the cranberry bogs on which I spent some time countless thousands of these insects occurred. The breeding conditions for mosquito larvæ were almost ideal and plenty of larvæ were found, but none were of this species. All the specimens observed

were females; males apparently do not go away from their natural breeding places. Twenty miles back from the coast, *sollicitans* is the dominant species and occurs most of the summer. Forty miles from the coast occasional flights occur; but their period is short, rarely lasting more than a week or ten days, and there may not be more than one or two of them during the season. From observations made and information gathered along shore and back from it for some distance, it seems certain that large swarms rise during favorable evenings and are carried during the night by the wind for varying distances. The direction is determined by the direction of the wind, and may be as often out to sea as inland. Swarms have been met with fifteen miles from shore, and are common five miles from shore. These are usually if not always lost. This migration, if that term can be properly employed, is contrary to previous beliefs, my own included, and is an important factor in the question of the control of mosquitoes in the State. It takes it out of the rank of local problems and makes it a State affair. It is quite obvious that no methods adopted at a point where these mosquitoes do not breed can prevent their abundance when the wind is in the right direction to bring swarms of them from the sea coast. On the other hand, there seems to be no very great difficulty in deciding upon the character of the work that should be done to destroy the breeding places of these pests. The measures are largely of a permanent character. They consist partly of draining, partly of ditching and partly of opening ways for the free entrance of tides, and with them of certain species of small fish that feed on mosquito larvæ. At a comparatively small expense considerable areas can sometimes be freed of breeding places. Much has been done by private enterprise at seashore resorts and there will be no difficulty in se-

curing cooperation in any work that the State may undertake or may suggest.

The next species in abundance is *Culex pungens*. The history of this species has been so well written that little remains to be added to it. It is the one species of *Culex* of which we know positively that it hibernates in the adult stage. It breeds everywhere in almost all sorts of places, provided only there is water which is not salty. I have never found it in salt water; but in other respects it is not particular. It breeds in cesspools, sewage water and even in manure pits. It has no objection to remaining indoors, and the larvæ will swarm in a neglected bucket just as readily as they do in a half-filled tin can on a dump. The only point of particular interest noted in connection with this species is the fact that it breeds much later in the season than has been believed. Active larvæ were found until late in November, and even less than half-grown forms were seen at that time, indicating a comparatively recent oviposition. As against this species local work is necessary and effective; but it is far from necessary to treat indiscriminately all sorts of bodies of water. There are some places where even this insect will not breed, and unless information is generally distributed concerning the places that actually need treatment, a good deal of work will be wasted and unnecessary expense incurred.

Some very interesting information concerning the species of *Anopheles* has been gathered. It has been known that these species hibernate as adults; the places where they hibernate in the woods have been discovered; the general character of the breeding places has been established and it has been found that the larvæ may be found in salt water as well as fresh. This has been asserted of a European species but was doubted by Dr. Howard for our own. It has been also found that

these insects continue to breed until long after frost has set in. Larvæ and pupæ were taken from ponds that had been completely ice covered. On at least three separate occasions adults were bred from larvæ and pupæ after they had been confined in or under ice for a period of several hours. It is demonstrated beyond peradventure that mere cold or even an ice covering is not fatal to larval or pupal life of *Anopheles*. It is further indicated from the researches made that there is absolutely no connection between the abundance of *Anopheles* and the prevalence of malaria. In a limited district where malaria as an original disease is unknown, over two thousand specimens of *A. punctipennis* were taken from the cellar under a moderate-sized farm-house. From the outbuildings as many more were captured, in October and November. Altogether about this one group of farm buildings fully five thousand specimens were actually taken during the two months mentioned. This is, therefore, one of their commonest mosquitoes; yet patients afflicted with malaria have come there, away off in the woods, to get well; and they did so, without leaving in their trail a wake of malarial cases. I do not wish to be understood as doubting the connection between *Anopheles* and malaria, nor that the mosquito is necessary as an intermediate host in the development of the pathogenic organism. I wish only to say that my investigations point to the fact that there is some other factor involved and that, even in the presence of an existing case of malaria, *Anopheles* is not able to transmit the disease to a healthy individual, unless certain other conditions favor the transmission or the development of the malarial organism after it is introduced into the healthy subject.

UNIVERSITY REGISTRATION STATISTICS.

A KNOWLEDGE of the present condition of the status of higher education in the United States may be gleaned from the accompanying table, wherein are enumerated statistics relating to the registration at seventeen of the leading universities in the country, both

East and West. These figures have been obtained from the proper officials of the institutions concerned, and are as correct as statistics of this nature can be made. With but slight exceptions, these figures are approximately as of November 1, 1901.

The gain or loss in the enrollment in

the various departments of the universities enumerated are indicated in each instance, where obtainable, by figures within parentheses. These figures have been revised, and may not tally exactly with the figures to be found in SCIENCE published on December 21, 1900. The enrollment figures for the University of Nebraska are for the first time included in this table.

While statistics of this character may not be exactly the same for two weeks in succession, as those engaged in university administrative work well know, nevertheless such figures are general enough in import to indicate the trend of the advancement of higher education in various sections of the

country. Changes in curricula, stiffening of entrance requirements, and the inauguration of new policies, materially affect the enrollment statistics of any university.

Particular attention is called to the effect of the introduction of the new entrance requirements to the Harvard Medical School. The demand of four years' liberal training in a college previous to entrance upon the work of the Harvard Medical School has resulted in a loss of almost 100; but this change will inevitably result to the advantage of the Harvard Medical course.

Attention is also called to the increased enrollment in the summer sessions of both our eastern and western universities.

While there has been a falling off in the grand total of attendance on some of the universities tabulated, there has at the same time taken place a steady forward movement in the progress of higher education,

as revealed by these statistics of attendance.

tember, 1900, gehalten von OSCAR HERTWIG. Jena, Gustav Fischer. Pp. 31.

The advancement in knowledge of organic nature was so remarkable during the nineteenth century that it is of unusual interest to have the progress in biology summed up by one of the leaders in the movement. As might be expected from Hertwig's well-known powers of clear exposition, the reading of this lecture is enjoyable; the line of thought is not difficult to follow and the analysis of the subject is as simple and direct as it is possible to make it within the limits of thirty-one pages. It is, of course, impossible in many instances to do more than suggest the line of influence of a group of men whose work has been of epoch-making importance. The names of most of the great leaders are mentioned categorically—and the list is a long one, but it is a disappointment to miss any reference to Bichat. His influence was so

* Included under College. 170 students in law are enrolled; loss of 15.

of a blunder. However clear the general account of biological progress may be, it is inadequate if no place is found in it for such names as Cope, Marsh and Gray or for the mention of the embryological and cytological researches of American investigators.

The subject is naturally considered under two main divisions—the progress in morphology and that in physiology. In regard to progress in morphology, the four following factors are indicated as having had the greatest influence: (1) The establishment of the cell theory and the closely related protoplasm doctrine. (2) The development of the science of bacteriology. (3) Progress in embryology. (4) The doctrine of organic evolution.

The great influence of the cell theory is especially emphasized, not only as to its unifying tendency in uniting animals and plants on the broad basis of similitude of structure, but also as opening to naturalists the real problems of the living organism. The dis-

covery that fermentation, putrefaction and finally, that many diseases are due to micro-organisms, stimulated studies which led to the establishment of the science of bacteriology. The revival in the nineteenth century of the question of spontaneous generation is mentioned, and the great triumph of Pasteur in demonstrating the falsity of the position of the heterogenists. Here also one notes another omission—no reference is made to the luminous researches of Tyndall on this subject with optically pure air. The great influence of embryology as founded on the work of Pander and von Baer is sympathetically although briefly treated. The facts that all animals begin as single cells, and show every gradation between that simple condition and the more complex one of the adult, and that ontogeny is in a sense an epitome of phylogeny, are sufficiently striking to endue this subject with unusual interest. Lastly, the influence of the establishment of the theory of evolution is spoken of.

In physiology the fundamental importance of experiment is pointed out—what the microscope is for anatomy, experiment is for physiology. Among the greatest advances mentioned in the first half of the century are the demonstration of Bell's law and the elaboration of the theory of specific energy by Johannes Müller. The development of physiology along the respective lines of chemical and physical physiology is discussed, together with the opposition aroused by these researches to the old theory of vitalism. The observations as to the action of chemical substances within the bodies of lower animals were turned to practical account in medicine. While physiology was being developed along chemical lines by one school, represented by Claude Bernard, Pettinkofer, Voigt, Pflüger, Heidenhain and others, it was being advanced along physical lines by Robert Meyer, Helmholtz, Ludwig, Dubois-Reymond and others. With the latter school came exact methods of measuring and recording physiological activities, as with the kymograph, myograph, etc. The greatest triumph of the chemical and physical methods was in demonstrating that physiological processes are chemico-physical rather

than vital. But this conception has been carried too far; some physiologists look upon life, with all its complex manifestations, as being entirely chemical and physical. This is as far wrong as the old theory of vitalism. The relation of the physicist to biological questions is similar to that of the chemist. Physiological questions can not be explained on purely chemical and physical grounds. We can not find out the rôle played by albumin in vital processes by study of its chemistry, but by direct study of the protoplasm in living cells. We must return to an anatomico-biological basis and let it be modified by the chemico-physical conception. The material world must be united by biological studies with the manifestations of the immaterial world of life.

WILLIAM A. LOCY.

Comparative Physiology of the Brain and Comparative Psychology. By JACQUES LOEB. The Science Series. New York, G. P. Putnam's Sons. 1900. Pp. x+309. \$1.50.

Professor Loeb's book forcibly calls attention to the importance of the comparative method in physiology and psychology. The present work is a translation, with additions and changes, of the German edition of 1900 by Mrs. Loeb. The book has been made into English with singular skill. It is clear, concise, scientifically accurate in statement, and, withal, readable. Of it may truthfully be said 'every words counts.' Whether one agrees or disagrees with any or all of the conclusions reached, the discussion is valuable, for it pleads for opposition, contradiction, investigation. There are not so very many physiologists, we fancy, who will fully agree with all the theories which Professor Loeb seeks to maintain; fewer still are the psychologists who will find themselves in sympathy with his attitude, and among ethical thinkers scarcely any will come to the support of the new scientific construction whose possibility, nay, necessity—for our author is evidently a man of strong convictions—is hinted at. But opposition is needed for the testing of the theories in which the book abounds, although we doubt not that in the main the author's position is a safe one. Nothing is clearer than the seri-

ousness with which Professor Loeb takes himself and his work. Every sentence indicates that he realizes the importance of the study of life phenomena, and appreciates the intimate relationship of all physiological investigation to the practical problems of our work-a-day life.

The book is itself a collection of experimental discovered facts of neural physiology so arranged that they inevitably lead the reader to the definite conception of the rôle of the nervous system held by the author. Noteworthy is the fact that a majority of the experimental studies from which evidence is drawn in support of the views presented have been made by Professor Loeb himself. They form, as thus gathered together, and unified by a single purpose, a splendid monument to the energy, patience and enthusiasm of a physiologist who has well earned the praises of the scientific world. To say of most physiologists 'he has based a general discussion of the function of the nervous system solely upon the results of his own researches,' would be equivalent to characterizing and condemning the work as narrow and incomplete. But of the work in question this cannot be said, for Professor Loeb's investigations have covered such a wide range of physiological and psychological phenomena, and his problems have been selected with such rare insight into the general implications and relative importance of different aspects of his chosen work, that they furnish an excellent foundation for the theories which he presents.

The conscious and avowed goal of Professor Loeb's researches is 'the control of life phenomena.' His slogan well might be 'more life and fuller that we want.' It is not simply to understand the functions of the organism for the sake or satisfaction of understanding, but that we may be the better able to regulate our lives that we should strive toward the control of vital processes. Toward this goal we are to progress by the use of the methods of physics and chemistry. To quote, "It seems to me that living organisms are machines and that their reactions can only be explained according to the same principles which are used by the physicist." On the basis of the physical

and chemical qualities of protoplasm our author proposes to explain all activities.

'Comparative Physiology of the Brain and Comparative Psychology' may for review be divided into four parts. Of these the first deals with the relation of reflex action to the nervous system. Experimental evidence is presented to prove that such actions are not dependent upon any specific character of nerve tissue, but upon the general properties of protoplasm. This is followed by a consideration of the morphological and physiological evidence bearing upon the 'center theory' and the 'segmental theory' of the nervous system, with a defense of the latter. The third main subject is the relation of instinctive action to the rôle of the nervous system and to reflex action. Experiments are cited to show that the instinctive act is really only a chain of reflexes. Finally, in the portion of the book which comes under the title 'comparative psychology,' associative memory is pointed out as the psychic fact of prime importance. Its connection with brain functioning is discussed, and the possibility of analyzing all complex psychic phenomena into associative processes maintained.

It is common to refer all actions to nerve centers. Even the simplest reflex act is thought of by many as dependent upon the functioning of a ganglionic center. Now it is Professor Loeb's conviction that this is an erroneous view; and by an examination of experimental studies of representatives of the Cœlenterata, Echinodermata, Vermes, Arthropoda, Mollusca and Vertebrata he proves that reflexes can be executed in the absence of ganglia. A few of the instances mentioned in the book may be cited.

Study of the Medusæ has shown that the bell will make normal spontaneous, coordinated movements after the nervous system has been removed. Thus by a very simple experiment, spontaneity, coordination and reflex action are proved to be independent of the central nervous system.

Among the Ascidians, *Ciona intestinalis*, whose nervous system consists of a single ganglion, normally exhibits a peculiarly characteristic reflex in the closing of both the oral and aboral openings, when open, if either is

touched. If the ganglion be removed the animal will still carry out this reflex. But careful study shows that there are differences between the action of the normal animal and the one which lacks its ganglion. In the latter the threshold of stimulation is higher and the reaction-time greater. From this Professor Loeb concludes that 'the nerves and ganglion only play the part of a more sensitive and quicker conductor for the stimulus.'

The tentacles of *Metridium* in the food-taking activity of the animal move in such a way as to bring the object with which they are in contact to the mouth. The action is one of apparent adaptation, and one would scarcely expect to see the same kind of a reflex occur after the tentacle had been cut from the body. Such, however, is the result of the experiment; no difference between the action of the tentacle in normal relation to the nervous system and that which has been isolated is observable. We have to conclude, therefore, that the action is determined by the properties of the protoplasm of the tentacle itself, and not by special properties of the nervous tissues.

Other observations prove that certain worms when deprived of their brains are able to move spontaneously. As a case in point, the freshwater Planarian, *Planaria torva*, is sensitive to stimulation by light. To any increase in intensity it responds by movement. It also selects the darkest region of a dish in which it is left. When the anterior portion of the body is cut off it is found that the brainless portion will give the same responses to light as the normal animal. And the only significant fact in favor of the influence of the brain upon such activities is that the reaction-time of the brainless animal is longer.

Of the reflexes of higher animals that are known to be in part at least independent of the brain and cord are the movements of the iris, the bladder, rectum, blood vessels, respiratory organs, etc. Experiments upon fishes, frogs and dogs have established the independence of many of their reflexes. In one instance the whole brain and spinal cord of a larval frog were destroyed without interfering with spontaneous movements. There are so many observations of this kind for the vertebrates that

one cannot question the general truth of Professor Loeb's conclusion. As he states, those instances in which the reflex is interfered with by the destruction of the nervous system are explicable by the fact that the only existing connection between the sense organ and the muscle has been broken. Establish any kind of protoplasmic connection between the region in which the disturbance arises and the motor apparatus, and the appropriate reflex will be executed.

But the fundamental experiment for the proof of the independence of reflexes is that made by Professor Loeb upon isolated muscles. He has shown that muscles containing no ganglion cells will beat rhythmically when placed in a pure sodium chloride solution of the same osmotic pressure as the blood. To put the matter in his words, "It is not the presence or absence of ganglion cells which determines the spontaneous rhythmic contractions, but the presence or absence of certain ions. Na ions start or increase the rate of spontaneous rhythmic contractions; Ca ions diminish the rate or inhibit such contractions altogether." Now it is clear that to prove the isolated muscle capable of responding to stimuli is to establish the thesis which has been stated.

The conception of the nervous system as a series of more or less intimately related centers, each with its own special function, arose and found an observational basis in the many experiments on localization. Certain parts of the brain apparently control certain groups of muscles. This is undoubtedly true, but Professor Loeb attempts to show that the conception as a whole is false. From comparative morphology and physiology comes abundant evidence of the segmental theory of the nervous system. In the Annelids, for example, the segments, each with its ganglion and nerves, are to a certain extent independent organisms. Each ganglion in this case functions in connection with a very definite portion of the worm.

"The so-called centers of the cerebral cortex are merely the places where the fibers from single segments of the central nervous system enter." If the spinal cord of a dog be cut it will be found, after the shock of the operation

has passed, that all of the reflexes belonging to the segments of the body which are represented by the portion of the cord severed can be executed. Rubbing of the skin causes scratching movements of the hind legs, and the reflexes of bladder, rectum and respiratory organs occur in response to the appropriate stimuli.

"According to the segmental theory," writes our author, "there are only indifferent segmental ganglia in the central nervous system, and the different reactions or reflexes are due to the different peripheral organs and the arrangements of the muscles. The center theory must remain satisfied with the mere problem of localizing the apparent 'seat' of a 'function' without being able to give the dynamics of the reactions of an animal, as the latter depend in reality upon the peripheral structures, and not on the structures of the ganglia. For this reason the segmental theory alone will be able to lead to a dynamical conception of the functions of the central nervous system."

In taking up the problem of instinct Professor Loeb touches a field which he has made distinctively his own; for no one has done so much as he toward the analysis and explanation of this type of action. He holds that there can be no sharp separation of reflex action from instinctive. The reflex usually is the activity of a single organ, and the instinctive act one in which the whole organism is concerned. Instinctive actions are characterized by an apparent adaptation to a special purpose, an adaptation to the circumstances in which they occur. For this reason there is a strong tendency to regard them as results of intelligence. For years Professor Loeb has been studying, and, as it were, dissecting, instinct after instinct in order to show the absurdity of this conception.

The fly that instinctively selects for the depositing of its eggs a substance on which the larvæ can feed does so not because it has a faint notion of the utility of the action, or even because it chooses so to do, but because the chemical particles emanating from the substance stimulate it in such fashion as to cause an orientation of its body in reference to the source of the stimulus, and this orientation in turn determines the movement toward the sub-

stance. The whole is simply a mechanical problem; physics and chemistry serve to explain the instinct.

An insect comes within the range of vision of a frog and is instinctively stalked, seized and swallowed. In this event the visual stimulus initiates a series of reflexes whose result is the obtaining of food. There is no deliberate choice, no intelligence in the action. The crustacean or insect or worm that instinctively moves toward a source of light does so, experiments indicate, simply because the light forces it to take a certain orientation, just as the chemical stimulus did in case of the fly. Once having taken this position, there is only the possibility of moving toward the source of the stimulus. The 'orientation theory' is one of Professor Loeb's chief contributions to the explanation of instincts. It is based upon the assumption that when a stimulus affects symmetrical points of an animal's body unequally there is resulting inequality of muscular activity on the two sides, and as a result the organism is finally forced into that position in which symmetrical points are equally stimulated. Such a position is evidently attained when the long axis of the body is parallel with the rays of light, for example, with the head either toward or away from the source of the light. From this position it is clear the animal can move only toward or away from the light.

And again it is noticed that certain arthropods and worms 'hide' in crevices. If we study this action we learn that the animals are able to remain quiet only when the body is in contact with some object, and so long as it is not in such a position the animal moves about continuously. In the act 'hiding' plays no part. The phenomenon is merely the inhibition of movement by a stimulus, it matters not whether the stimulus be given by a board which really 'hides' the animal or by a plate of glass which leaves it fully exposed to view. And so one might go on with the enumeration of simple instinctive acts that appear to be guided by reason, but whose careful study reveals only the influence of certain environmental factors upon a definitely describable organic structure.

To the most important of these environmental factors the name 'tropism' has been applied. Heliotropism is the response to light; chemotropism, to chemicals; galvanotropism, to electricity; stereotropism, to contact; geotropism, to gravity; hydrotropism, to moisture; thermotropism, to temperature, etc. All simple instinctive acts are found to be responses to one or more such factors either external or internal; those more complex actions of which nest building and the instinctive processes of ants, bees and wasps are representative are presumably due to a number of factors working simultaneously and giving rise to a series of reflex acts, the whole of which in their interconnection is an instinctive action. No one has yet succeeded in satisfactorily analyzing any of these complex activities, but Professor Loeb has confidence that the subjecting of any of them to laboratory requirements will reveal the same kind of structure as has been discovered in the simple acts.

The chapter on instinct closes with some remarks concerning the relation of the conception presented to ethics. "The analysis of instincts from a purely physiological point of view will ultimately furnish the data for a scientific ethics. Human happiness is based upon the possibility of a natural and harmonious satisfaction of the instincts." Such are the significant statements with which we are introduced to the author's ethical philosophy. From the naturalistic point of view ethics can have no other foundation than that indicated above; and there is no doubt that he who is only a physiologist can find complete satisfaction in it. But one feels, *instinctively*, that Professor Loeb, despite his unpleasant, though appropriate, introductory words concerning the mixing of metaphysical and scientific conceptions, is of a philosophic mind, and it seems probable that physiology alone saved him from becoming a technical metaphysician.

We find upon turning to the discussion of comparative psychology that Professor Loeb considers as the central and chief problem of the physiology of the central nervous system the study of the 'mechanisms which give rise to the so-called psychic phenomena.'

As the elemental psychic fact he names 'associative memory,' by which he means neither more nor less, so far as we can see, than what the psychologist designates as an associative process. Wherever associative memory is found there is material for the psychologist. His first task must be to determine in what animals this psychic phenomenon occurs, and his second, to analyze the more complex processes of higher animals into the elements of the psychic process, much as the instinctive act is analyzed into reflexes.

An animal which can learn is said to have psychic processes. In this criterion of associative memory is seen, by Professor Loeb, the basis of a future comparative psychology. Among vertebrates it is well known that associative processes are found; even the Amphibia and Fishes profit by experience, although it is stated by the author that the frog has not yet been proved to have associative memory. Of the invertebrates in this respect little is known for they have not been studied experimentally. But at present it seems safe to say the Cœlenterata and Vermes are not known to profit by training. By this criterion of the psychic a very sharp limit for the field of psychology is indicated. Those who do not believe in what Professor Loeb describes as crises in development will not be likely to take much stock in his conception of the rôle of comparative psychology until experimentation has proved the abrupt appearance of the associative process in the animal series. For until then there will remain the possibility that the whole thing is a matter of degree of ability to profit by experience, rather than of the presence or absence of a brain mechanism which is able to mediate the association. On this point the author says, "The idea of a steady, continuous development is inconsistent with the general physical qualities of protoplasm or colloidal material. The colloidal substances in our protoplasm possess critical points."

Two chapters of great interest treat of the 'Cerebral Hemisphere and Associative Memory' and 'Anatomical and Psychic Localization.' Concerning the valuable experimental data furnished in them we may make only

a general statement. It proves that the associative process in vertebrates is dependent upon the cerebral hemisphere. "The assumption of 'centers of association,'" says the author, "is just as erroneous as the assumption of a center of coordination in the heart. Association is, like coordination, a dynamical effect determined by the conductivity of the protoplasm. Associative processes occur everywhere in the hemispheres (and possibly in other parts of the brain), just as coordination occurs wherever the connection between two protoplasmic pieces is sufficient. It is just as anthropomorphic to invent special centers of association as to invent special centers of coordination."

Finally, attention should be called to the stress which in this valuable contribution to the literature of comparative physiology is laid upon the chemical and physical study of protoplasm and its transformations. Ultimately it would appear all physiological investigations resolve themselves into problems of the physics of colloidal substances.

In this imperfect and inadequate review of Professor Loeb's book an attempt has been made to indicate a few of the general tendencies and conclusions which seem of prime importance. There are a large number of interesting experimental studies discussed in the book which have not even been mentioned here. We have taken the liberty to quote freely from the text, and it is hoped that the sentences thus selected to indicate the author's point of view will in no case misrepresent him because of their isolation.

ROBERT MEARNS YERKES.

CAMBRIDGE, MASS.

Plant Life of Alabama. An account of the distribution, modes of association and adaptations of the flora of Alabama, together with a systematic catalogue of the plants growing in the State. By CHARLES MOHR, Ph.D. Contributions from the U. S. National Herbarium. VI. Washington. 1901. 8vo. Pp. 921. 12 plates and 1 map. The 'Plant Life of Alabama' is a noteworthy addition to the list of works which treat of State floras. The book consists of two parts; one, of 127 pages, dealing chiefly with

the floristics of the vegetation, the other, of 708 pages, containing a complete catalogue of the flora. The first part will be particularly welcomed by phytogeographers as the first serious analysis of a portion of the vegetative covering of the southeastern United States. The value of this portion lies chiefly in the observations and lists which it contains, as no systematic investigation of the vegetation has yet been made. The absence of recent methods and the lack of detailed formational analysis detract much from this part, though the lapse of time between the completion of the manuscript and its publication would seem to indicate that this is not the fault of the author. It is much to be regretted that the author's death occurred before his book finally appeared.

The author sketches the history of the botanical exploration of Alabama, giving a brief account of the labors of Bartram, Peters, Buckley and others. This is followed by a summary of the general physiographical and climatic features of the State. Physiographically, the area considered falls into five regions, the coastal plain, the region of crystalline rocks, the region of the coal measures, the Coosa Valley and the Tennessee Valley. The author gives a brief discussion of the general principles underlying plant distribution, in which he has unfortunately made use of Merriam's divisions of the North American continent, which are phytogeographically incorrect. The formational treatment is based upon the work of Willkomm and Warming. The accurate classification of formations, however, as hydrophytic, mesophytic or xerophytic, is hardly to be determined otherwise than by actual physiometric investigation of formations, which have been tentatively determined by means of floristic. The formational analysis of the vegetation is neither close nor thorough, consisting for the most part of floristic lists of the various habitats, with very slight consideration of the interrelations of the species which constitute the formation. In some instances (page 65) the difficulty seems to rise from the fact that the acquaintance with the particular vegetation is at second hand.

Under biological and ecological relations, the author treats briefly of the forest flora, in which are included shrubby-plant associations and arboreal-plant associations, evergreen and deciduous, the campestrian flora, the water and swamp flora, including the hydrocharidean, lithophytic, limnæan and palustrian classes, and of the organotopic flora, comprising epiphytic, saprophytic, symbiotic and parasitic plant associations. This is followed by an interesting discussion of introduced plants, which are regarded as naturalized, adventive and fugitive. The more detailed consideration of the vegetation is taken up under plant distribution, in connection with the Carolinian and Louisianian areas. In delimiting the two the author makes use of 'truly zonal plants,' which, except in restricted formations, usually of hydrophytic stamp, are illusive. The Carolinian area falls into the mountain region, the table-lands, the region of the Tennessee Valley and the lower hill country. Under each is given a summary of the physiographical features and climate, and a discussion of the various formations, grouped as xerophile and mesophile forests, and xerophile, mesophile and hydrophytic plant associations. The Louisianian area is likewise divided into several regions, central pine belt, central prairie, maritime pine and coast plain, in which the treatment of the formations is similar.

Notwithstanding the valuable information now made available for the first time in the part just considered, the second part is a more important contribution. It contains an excellent catalogue of the entire flora, in which are enumerated more than 4,500 plants, of which 2,500 are flowering plants and upward of 2,000 cryptogams, numbers which indicate an extreme richness and diversity of vegetation. The large list of fungi, which is contributed by Professor Earle, is a testimony of the energy and industry of a few workers, notably Peters, Atkinson, Underwood and Earle. The algae are apparently little known as yet, a fact which explains the preponderance of anthrocytes in the list. The entries of the flowering plants are models of floristic cataloguing. The bibliography is full, and indications of range,

both State and continental, are given with unusual care. The type locality is indicated wherever known, as is also the disposition of the Alabama exsiccata. Altogether the catalogue is the most complete and painstaking State list so far contributed to American botany. The book closes with a list of the plants cultivated in Alabama, a tabular statement of the plants of the State, and a very satisfactory index.

FREDERIC E. CLEMENTS.

THE UNIVERSITY OF NEBRASKA.

TWO PAPERS ON ANIMAL MECHANICS.

Ueber die Bewegungen in den Handgelenken, von RUDOLF FICK; *Ueber die Bewegungen des Fusses u. s. w.*, von OTTO FISCHER; both in the 26th volume of the *Abhandlungen der Math. phys. Classe der König. Sächsischen Gesellschaft der Wissen.*, Leipzig, 1901.

These papers are alike, but in some respects quite different. In the former Fick discusses the movements of the bones of the wrist as shown by the X-rays, and though mathematics are not avoided, they are rather subordinate to the results of observation. Thus anyone who is sufficiently at home in the anatomy of the hand can follow the author provided only he take pains enough. Fischer's paper is the fourth part of his 'Gang des Menschen' in which the share of the foot in the walk is scientifically and mathematically studied. This puts it beyond the reach of most readers. Without pretending to be able to appreciate it, we think we run little risk, from the reputation of the author, in recommending it to students of this field.

The paper on the wrist is one that, while very valuable, is not of very general interest to readers other than anatomists. Since the introduction of the X-ray, hands, as convenient objects, have been photographed everywhere, and several anatomists have given attention to the movements of the bones. So far as the results obtained from the dead body go, we are not inclined to modify the opinion which we have expressed, namely, that the X-rays have done little more than confirm what was already known of the movements of the wrist. (This must however be understood

with the proviso that more was known than was found in most anatomical text-books.) But in these studies the living hand has been used, and although our contention still in the main holds good, it is to be admitted that *à priori* we really did not know how closely the movements made on a dead body reproduced the conditions which were the result of motions from within. The work has been very thorough, much attention being given to individual bones. Some of the views strike us as quite original. Thus we do not remember to have seen, in any of the monographs on this subject the position of the carpal bones in palmar and dorsal flexion shown directly from either the front or the back as in the usual view of the wrist. The objection which naturally presents itself, when such a course is proposed, is that the foreshortening of the flexed bones and the hiding of more or less of one row under the other would make the figure worthless, but this objection has by skill in technique been well met. The illustrations are admirable, and are made still more practical by being almost always accompanied by an outline drawing.

The results in the main are these: In lateral motions of the hand we may accept the theory of two oblique axes crossing each other at about the middle of the wrist with the proximal and distal angles larger than the lateral ones; but in flexion and extension we must assume a single transverse axis. A point emphasized is that the mid-carpal joint is a very important one. This is not new to anatomists, but we doubt if it is very familiar to the average student of anatomy. The work in short is both an interesting and a valuable one.

THOMAS DWIGHT.

The Teaching of Mathematics in the Higher Schools of Prussia. By J. W. A. YOUNG, Ph.D., Assistant Professor in the University of Chicago. New York, Longmans, Green & Co. 1900. Pp. xiv + 141.

The feeling that German schools have something well worth the American teacher's attention is not at all new. It has been said and written for a century, and within a few years it has given rise to the publication of several

works of genuine merit, not to speak of numerous books and articles of no merit whatever. Of the former class this one by Professor Young is unique in that it is the first to devote itself entirely to the mathematical phase of education. Furthermore, it is somewhat unique in being a well-balanced, practical book for practical and well-balanced teachers. It tells one what one wishes to know. Not many Americans have been able critically to examine the subject of mathematics in Prussia. Here is a book that answers just the questions the intelligent teacher would ask if he were there, that gives him courage to face the issues of the present, and that should make him confident of the future. And it does all this, not by preaching American or German supremacy, but by intelligently pointing out the superior features of German education and by showing us our lines for improvement.

The real interest in the book is not so much in the carefully selected general information, for this it is not difficult to find in standard works like those of Baumeister and Russell, but in the consideration of the two questions: Are the Prussian schools doing better work in mathematics than the American? If so, how is this accomplished?

When we consider that we give about ten per cent. more time to mathematics than they do, that they recognize less home study than we, and that their children leave even the classical gymnasium knowing more of mathematics than do our high-school graduates in scientific courses, there can be only one answer to the first question.

The reasons for this state of facts are, briefly, the following: (1) The teachers in the gymnasiums are men, and they enter the profession as a life work. (2) These men are university graduates, with at least two additional years of professional training. They have been rigidly examined, not by school teachers whose political pulls have given them place, but by university professors, specialists in their various subjects, appointed by the state. And in addition to all this, they have had at least one year of probationary teaching. Their examinations for the elementary classes include the calculus, and those for the high school grades

require independence of thought in the higher geometry, in analysis, and in analytic mechanics, with a good knowledge of the literature of these subjects. (3) The teacher's position is one of honor, recognized in cases of superior excellence by the title of 'Professor,' bestowed by the government, a title with us 'defamed by every charlatan and soiled by much ignoble use.' (4) The teacher has fewer classes per week than the American teacher, and when out of class instead of being set to watch a 'study hall' he has time for recreation and study. (5) Considering the purchasing power of the money, the teacher comes, after a reasonable time, to receive a somewhat better salary than is offered in America, and hence a relatively stronger set of men enter the profession. (6) His countrymen appreciate that the teacher "can do his best only in an atmosphere of financial and mental tranquility. He must himself be continually growing, and if he is embarrassed by financial cares and harassed by struggles to improve his material position, his growth is retarded and the quality of his work inevitably deteriorates." He is, therefore, accountable to no local authorities; political 'pulls' have no meaning to him; his superiors in law are his educational superiors as well. He works with the assurance that a pension awaits him when the 'rainy day' comes, and yet he is urged to progress by such manifold inducements that he does not stagnate. (7) The school year is longer than in America, the twenty-minute class periods of our lower grades are unknown, and hence the instruction means more when it is being given and is more consecutive than with us. (8) The teacher teaches; he does not merely hear a recitation. Text-books mean little; home study is not a serious matter; but the class period is a time for serious study, rapid work, heuristic teaching and general inspiration. Space does not permit of speaking of other reasons, or of the results of the system as shown by examination tests.

Professor Young does not, however, claim that Germany is all good and America all bad. Neither does he claim that we can adopt their system. He is eminently judicial in his conclusions, pointing out what we can safely use,

and where we can unquestionably improve. On the whole, the book is one of the best balanced works on German education that have appeared, and as such is recommended to every American teacher of mathematics.

DAVID EUGENE SMITH.

TEACHERS COLLEGE,
COLUMBIA UNIVERSITY.

SCIENTIFIC JOURNALS AND ARTICLES.

THE *Botanical Gazette* for November contains the following leading articles: G. T. Moore has published with three plates his second paper entitled 'New or Little-Known Unicellular Algae,' giving a detailed account of the life history of *Eremosphaera viridis*, and coming to the conclusion that for the present, at least, the genus should be classed with the Protococcoideæ; and also describing as a new genus a form which has been confused heretofore with *Eremosphaera*, and naming it *Excentrosphaera*. T. C. Frye has published with one plate an account of the development of the pollen in certain Asclepiadaceæ, his investigation having been suggested by the record that in certain members of this family there is no tetrad division. The development of the sporangium was found to be of the general type, the primary sporogenous cells passing over directly into pollen mother cells; these latter divide in the usual tetrad manner, but subsequently through mutual adjustment the four spores are arranged in a linear series. Miss F. Grace Smith has published the results of a large number of observations upon the distribution of red color in vegetative parts in the New England flora. A general conclusion is reached that the statistical observations obtained fit no one theory of color in all particulars. Mr. George A. Shull has published with illustrations the results of observations upon 'Some Plant Abnormalities.' He records instances of fasciation in *Erigeron Canadense* and *Echium vulgare*; abnormal foliage leaves in *Pelargonium* and *Hicoria*; and abnormal floral organs in *Lathyrus odoratus*, as well as in certain species of *Clematis*. Under the head of 'Briefer Articles,' E. B. Copeland has discussed Meissner's paper on evergreen needles, answering certain

criticisms of the author, and presenting new observations; M. L. Fernald publishes a final paper upon the instability of the Rochester nomenclature, being an answer to papers of Messrs. C. L. Polard, L. M. Underwood and N. L. Britton; and Charles Robertson has published a third set of observations of flower visits of oligotropic bees.

SOCIETIES AND ACADEMIES.

NEW YORK ACADEMY OF SCIENCES.

SECTION OF GEOLOGY AND MINERALOGY.

The regular meeting of the Geological Section of the New York Academy of Sciences was held on Monday evening, November 18, with the chairman, Dr. A. A. Julien, presiding. The program of the evening was begun with the reading of a memorial of Dr. Theodore G. White by Professor James F. Kemp, who said in part:

Theodore Greely White was born in New York, August 6, 1872, and was the only child of his parents, both of whom he lost but a short time before his own death. He was graduated from the School of Mines of Columbia University in the course in geology and paleontology as Ph.B. in 1894, as M.A. in 1895 and as Ph.D. in 1898. He was appointed assistant in the department of physics in 1896 and held the position until 1900, being especially in charge of the experimental work in optics. From early boyhood Dr. White was interested in natural science, and while yet an undergraduate he began investigations both geological and botanical. His bachelor's thesis was a description of the geology of Essex and Willsboro towns on Lake Champlain, and he took up the study of the faunas of the Trenton group in the Champlain valley for his doctorate. In the end he extended these faunal studies all around the Adirondack crystalline area. He also carried on work for the New York State Museum under the direction of Dr. F. J. H. Merrill; and, in association with Professor W. O. Crosby, he described the petrographical characters of the Quincy granite. During an excursion to the seashore last summer he became exhausted while bathing in the salt water, and took a cold which developed into pneumonia and caused his death on the

7th of August, after a brief illness. Dr. White was a man of indefatigable industry and of great perseverance. He has left a large circle of sincere and devoted friends who can with difficulty reconcile themselves to his loss.

The second paper was a memorial of Professor Joseph Le Conte by Professor John J. Stevenson. A memorial of Professor Le Conte having appeared in the columns of SCIENCE, an abstract of this paper will not be given here.

The next paper was by Dr. Edmund O. Hovey and was entitled 'Notes on the Triassic and Jurassic beds of the Black Hills of South Dakota and Wyoming.' In this paper the author described, with the aid of a map and a number of lantern slides, the geological characteristics, the stratigraphic relations and the topographic features of the famous Red Valley of the Hills and its inclosing rim of Jurassic shales and sandstones; the observations being, for the most part, a result of a collecting trip made for the American Museum of Natural History during the past summer.

The closing paper was by Dr. Alexis A. Julien and was a discussion of 'Erosion by Flying Sand on the Beaches of Cape Cod.' The author said in part: The physical characters of the beach sand of Cape Cod show, in general, its recent derivation from the adjacent beds of the later Tertiary and especially from sands and gravels of Glacial age. In form the sand grains are mostly angular to subangular with but small admixture of those nearly spherical grains (for which I have proposed the term 'palæospheres') the form of which would indicate long erosion and high antiquity. In constitution the sands differ somewhat from those of the Atlantic coast to the southward, *e. g.*, of Long Island and New Jersey, particularly in a smaller content of iron-oxides and garnet. Through the continual movement of the winds over the peninsula, the sand upon the beaches and dunes is in a state of constant motion. During the frequent winter storms it is even borne along in vast quantities by aerial transport, and commonly with a violence sufficient to produce sharp attrition upon fixed solid objects.

The distribution of the sand is carried on from two directions: from the west along the south shore and from the north along the east and west sides of the 'forearm' of the Cape. The result is that the elbow tends to extend farther into the ocean, and Massachusetts Bay is a pocket steadily filling up with sand from the north. With the great fall of the tide on that coast, however, broad shoals are daily offered to sun and wind and the dried sands are constantly blown up on the highest dunes of the Cape, viz., those near Barnstable. There are ancient dunes along the coast, sometimes farther inland and even covered by forests, whose aggregation may be attributed to special violence of wind action at a remote period.

The most prominent results of the erosive action of the wind-driven sand are those pertaining to the general sculpture of headlands and summits of dunes, and the eating away of the softer layers of gravel and sand of which the bluffs along the east coast consist. The fine example of such erosion at Truro was described in detail and illustrated by means of a photograph. The recession of the face of the bluff here and everywhere from a vertical plane clearly indicates that its principal erosion is being constantly carried on by aerial rather than by marine attack. On the Cape, as elsewhere along our Atlantic coast, it is a common error to attribute the ravages on bluffs and dunes, noticed after a severe storm, too much to the incursions of the sea. A very large part of the damage has been done by the violence of the wind, reinforced by vast quantities of sand and spray lifted up and hurled continuously for hours against all opposing objects.

Other effects of the natural sand blast are shown in the pitted surfaces of small bodies strewn upon the beach, in the projecting hard minerals of the beach pebbles and in the depolishing of exposed portions of bits of glass and pottery. 'Faceted pebbles' are lacking from the beaches, because there is too much motion to permit of grinding anything to a flat surface. The rapidity of the eroding action under favorable circumstances is surprising. During the great gale of November 25,

1899, one night sufficed to convert into ground-glass the window panes in the exposed sides of the life-saving station at Truro. No scratches or grooves appear in these surfaces, such as have been observed in the sand-fretted pebbles of a desert, the conditions of sand erosion on a beach tending to pit the surface rather than to produce striae.

The least obvious, but perhaps the most important, effect of this form of erosion is upon the flying sand grains themselves by mutual attrition, minute particles not being protected from wear as they are when suspended in water. By the splitting of particles from the grains and their own final reduction to the most minute size, the production of silt is constantly in progress upon these windy beaches, and it is regularly carried away in suspension by every tide.

The papers of the evening were discussed by Professors J. J. Stevenson and R. E. Dodge and Dr. A. W. Grabau.

In response to an invitation from the chair Dr. W. S. Yeates, State geologist of Georgia, gave some account of the history of the geological survey of that State and a brief statement about the work being carried on by the present organization. Appreciative comments were made by Professors J. F. Kemp and J. J. Stevenson and Mr. G. F. Kunz.

EDMUND O. HOVEY,
Secretary.

RESEARCH CLUB OF THE UNIVERSITY OF
MICHIGAN.

At a meeting of the Research Club of the University of Michigan, held November 7, 1901, the evening was taken up with the presentation of papers by Professors Rolfe and Novy.

Professor Rolfe spoke on 'The Use of Ellipsis in the Explanation of Grammatical Phenomena.'

Dr. Novy gave an account of the investigations which Dr. Freer and he had carried on during the past year. After reviewing the work hitherto done concerning the action of metals, such as gold and copper, upon bacteria, it was pointed out that the explanation of this

action as offered by Behring was insufficient, and that there was good reason for believing that such metals exerted a surface action resulting in the formation of peroxides which clearly possessed a greater germicidal action than hydrogen peroxide. The action of light upon bacteria, especially of sunlight, was discussed, and although the studies of Richardson, Dieudonné and others rendered it certain that hydrogen peroxide was formed under these conditions, nevertheless it was by no means demonstrated that this substance was the active germicidal agent. These considerations led the authors to the belief that the germicidal effect of metals and of sunlight was due to higher and more active peroxides. Accordingly a number of organic peroxides were prepared and their action on bacteria was studied. Several of these were found to be wholly inert. This was the case with acetone peroxide and dibenzoyl peroxide. On the other hand, the diacetyl and the benzoyl acetyl peroxides were found to be extremely germicidal. It was pointed out, however, that these bodies were not germicidal as such, but that in aqueous solution hydrolysis took place, resulting in the formation of acetyl hydrogen peroxide and benzoyl hydrogen peroxide respectively. The intense germicidal as well as oxidizing power of such solutions was therefore due to the products of hydrolysis.

It was pointed out that these last mentioned peroxides were capable of destroying the most resistant spores usually inside of a minute. A comparison with hydrogen peroxide showed that this substance was much more feeble in its action. In order to obtain approximately the same germicidal effects it was necessary to prepare solutions of hydrogen peroxide which contained eighty times as much active oxygen as that contained in a solution of benzoyl hydrogen peroxide. This fact was interpreted as showing that the organic peroxides exerted their germicidal action not through nascent oxygen, as is commonly held in the case of ozone and hydrogen peroxide, but rather through other means, possibly through ions. In the subsequent discussion it was pointed out that other interpretations were possible; that the oxygen liberated might possess a

higher potential energy than that from hydrogen peroxide; or that the organic peroxides might be dissociated, as in the case of alcohol, not so much into ions as into one or more active parts.

Dr. Novy also detailed at some length the investigation bearing upon the relation of the surface action of metals to the formation of benzoyl acetyl peroxide. Metals, paper and fabrics, as well as sand, originally employed by Erlenmeyer and by Nef, exert a marked favoring action which may be interpreted as due to occlusion and partial dissociation of oxygen.

FREDERICK C. NEWCOMBE,
Secretary.

THE ACADEMY OF SCIENCE OF ST. LOUIS.

At the meeting of the Academy of Science of St. Louis on the evening of December 2, 1901, the following subjects were presented:

Mr. J. Arthur Harris presented in abstract a paper on 'Normal and Teratological Thorns of *Gleditschia triacanthos* L.'

Professor A. S. Chessin, of Washington University, delivered an address on 'The harmony of Tone and Color.' The speaker said that although the idea is not new that colors, like tones, are subject to laws of harmony, he did not know that any systematic theory concerning this had thus far been presented, and the object of the paper was to establish such a theory. A color-scale was constructed and the properties of the intervals corresponding to those appearing in the musical scale were discussed, and the conclusion was reached that within the limit of an octave the laws of harmony in tone and color are identical.

A paper by Professor A. S. Chessin, on 'The true Potential of the Force of Gravity,' was presented and read by title, the author remarking that this was the first of a series of detailed papers bearing upon the general subject, the broad conclusions concerning which he had presented in synopsis at a recent meeting of the Academy.

A committee was elected to nominate officers for the year 1902.

WILLIAM TRELEASE,
Recording Secretary.

SHORTER ARTICLES.

THE SMALLEST KNOWN VERTEBRATE.

THE United States has borne the distinction of having, in certain cyprinodont fishes of the Southern States, the smallest known fishes and at the same time the smallest known vertebrates. Thus, *Heterandria formosa* Agassiz, found from South Carolina to Florida, has an average length of 25 mm. for females and 18 to 19 mm. for males. *Lucania ommata* (Jordan), recorded only from Florida, probably never exceeds an inch in length; two males, the only ones thus far found,* measured 19.5 and 20 mm., and two females from the same locality were 20 and 22 mm. long, exclusive of caudal fin. Of this species Dr. O. P. Hay† remarked that 'it may contend with *Heterandria formosa* for the honor of being the smallest known vertebrate.' Another diminutive member of the cyprinodontids is the well-known viviparous *Gambusia affinis*, the adult males of which sometimes barely exceed 12.5 mm. in length, although the females reach a length of 50 mm. In this family are several other species that are scarcely larger than those before mentioned. The pigmy percoidean, *Elassoma evergladei* Jordan, of the swamps of Georgia and Florida, ranges from less than 20 mm. to a maximum of about 33 mm. in standard length, and several of the darters are no longer. Among the marine fishes, there are a number of gobies whose length is barely 25 mm. The smallest of the known marine vertebrates, however, is probably the lancelet, *Acymmetron lucayanum* Andrews, from the Bahamas; examples taken by the *Fish Hawk* in Porto Rico are about 19 mm. long, although Dr. Andrews' types in the National Museum are nearly a third smaller.

The United States Fish Commission has recently received from the Philippine Islands numerous specimens of a species of fish now to be described which has a maximum size less than the minimum adult size of most of the foregoing species, while the minimum and average sizes for mature individuals are thought to be less than those of any other

known fish or other vertebrate. The specimens were obtained, through the courtesy of the Surgeon-General of the army, by medical officers connected with the military hospital at Buhi, southern Luzon, in the department of Camarines Sur; and were collected in Lake Buhi, to which the species is said to be peculiar.

The fish is a member of the great cosmopolitan goby family, of which upwards of 600 species are known; and exhibits peculiar characters which necessitate the creation of a new genus for its reception. The diagnostic features of this genus, for which the name *Mistichthys* (*μίστιχος*, the smallest) is proposed, are coalescent ventral fins not adnate to the abdomen, two well-separated dorsal fins of which the anterior contains three weak spines, a single series of conical teeth in each jaw, body covered with large ctenoid scales, and an elongated genital papilla by the shape of which the sexes may readily be distinguished.

This species, to which the name *Mistichthys luzonensis* is given, and which will be more fully described in a forthcoming paper in the Fish Commission Bulletin, is apparently nearly transparent in life, with a black chin, a black median line behind the anal fin, and a few black spots on the back. It is probably viviparous or ovo-viviparous; but while many of the specimens contain ripe ovarian eggs (some of which have been discharged in the preserving medium), no eggs exhibiting evidences of development have been found. The females are slightly larger than the males and average 13.5 mm. in length; the maximum for egg-bearing fish is 15 mm. and the minimum less than 12 mm. The average length of males is about 12.5 mm., the maximum is 13.5 mm., and the minimum is under 10 mm. The average length of 50 specimens taken at random, both sexes about equally represented, was 12.9 mm.

A fact of more than ordinary interest in connection with this diminutive species is that it is a food-fish of considerable importance. Dr. George A. Zeller, acting assistant surgeon U. S. A., writing from the military hospital at Buhi, says:

"I enclose herewith samples of a strange

* Woolman, *Bulletin U. S. Fish Comm.*, 1890.

† *Proc. U. S. Nat. Mus.*, 1885.

article of diet greatly relished by the Bicol, among whom I have been stationed for the past eighteen months. Rice and fish are the staple articles of diet for most Filipinos and in the provinces of the Camarines there is little variation from these two. Fishes of every size and many varieties are prepared in every conceivable form, but the samples enclosed are unique in that they are found here and nowhere else. * * * Many varieties of fish abound in the lake, but by far the most numerous are these minute specimens. They are called in the native Bicol tongue *sinarapan*, and when dried in the sun on a leaf are called *badi*. They are caught by a large sheet of close web, which is dipped under wherever a school congregates. They are put into tightly woven baskets from which the water soon drains, leaving a compact mass of fish. They are not minnows or immature fish. They are adults and attain no greater size. The natives buy them eagerly; and when the little fleet of fishermen return from their morning's quest and place their baskets upon the ground on the market place, they are instantly surrounded by a crowd of waiting children who, armed with every sort of dish, are anxious to take home the family meal. They bring three or four potato tubers, a handful or two of rice, or a few copper pennies, and in exchange receive about a pint of fish. In the kitchen the fish are made up with peppers or other spiced herbs, and they do not taste bad. The soldiers have become quite fond of this food, and liberally patronize the little native restaurants where it is served."

WASHINGTON, D. C.

H. M. SMITH.

DINOSAURS IN THE FT. PIERRE SHALES AND UNDERLYING BEDS IN MONTANA.

In the summer of 1900 I made a collection of Dinosaur and Mosasaur remains from the Ft. Pierre beds, near Fish Creek, in Sweetgrass County, in Montana. I have not noticed any account of the collecting of Dinosaurs from this horizon.

The beds are composed of dark-colored shales, with occasional very thin lenses or layers of sand. Sometimes the shales have no

grit, sometimes they contain much fine sand. There are many brown or grayish, rounded concretions or concretionary layers. These concretions are often very hard. In these are many of the fossils, both vertebrate and invertebrate. The mollusca are principally the well-known, characteristic Ft. Pierre forms such as *Ammonites*, *Baculites*, *Scaphites*, *Nautali* and many smaller forms.

In this locality the weathered surface of the beds forms a rolling, grass-clad prairie with occasional ravines cutting into the soft shales. The bones are sometimes found in these ravines and 'cut banks' and sometimes among the grass roots, some of the bones projecting above the short grass.

The harder sandstones in the formation above form a line of bluffs or 'rim-rock' which for many miles marks the southern boundary of the Ft. Pierre shales. There are also dark shales interbedded with these sandstones. This formation contains leaf impressions and many fragments of Dinosaur bones, but the fossils have not been studied and no characteristic ones were recognized.

Below the Ft. Pierre shales are hard, rather thin-bedded sandstones with interbedded shales. Still lower are hard and soft sandstones, the latter predominating. These contain plant impressions, fossil wood, a few apparently fresh-water or brackish-water shells and Turtle and Dinosaur bones. The latter, many of them, were in a beautiful state of preservation, but no nearly complete skeletons were found. In these beds are bands of peculiar black or very dark, hard nodules, that look something like basalt. These sometimes contain bones. The Dinosaur remains are of the *Claosaurus* type.

From the Ft. Pierre beds the greater part of the skeleton of one Dinosaur and a good number of bones of another were obtained, besides the skull and other parts of Mosasaurs. The more complete Dinosaur skeleton is in the museum of the University of Montana. It undoubtedly is a *Claosaurus*. The other portion of a skeleton is in my collection. It is much smaller and was undoubtedly quadrupedal in gait. The sacrum is nearly complete and is different from anything else that I have seen.

It is composed of three ankylosed vertebræ.

It is interesting to find Dinosaurs in these marine beds. The marine fossils are found mixed with the bones. While digging out the skeleton of *Claosaurus* nearly a dozen *Nautili* were found among the bones. As a rule, when bones are found a good part of the skeleton is there or there is evidence that it has been. Several skeletons had been found and the bones removed for curiosities before I had visited this region. The first skeleton I saw was shown to me by a young man, Mr. Albert Silberling, who lived on the ranch from which the others were dug. I think that very few fossil-hunters would have looked for Dinosaur bones here.

It seems that these deposits were made in a shallow inland sea or an estuary which, at least during a part of the time, was cut off from the ocean, for in places there is considerable gypsum. Perhaps we should hardly expect to find such large marine mollusca in such a place, but they evidently are not far from where they died. There is no evidence of strong tides, and if the shells had been washed up by these or the winds they would be broken, not complete as we find them.

As a rule land animals are not very perfectly preserved in marine deposits. In unearthing these animals, therefore, the question is always arising: "How did these bones get here?" Did these Dinosaurs that have been so modified, evidently fitting them for life on land, still retain their swimming habits, but occasionally suffer shipwreck and their carcasses sink to the bottom of the sea? By some invasion of the sea were they forced to stay and starve or 'swim for life' which proved in some cases to be for death? I have seen no indications that they were killed by violence or their carcasses destroyed by large carnivorous animals, though there has been a little disturbance of the bones. Did they die on some mud flat or did their carcasses float down some sluggish stream and get stranded in shallow water or get 'water-logged' and sink in deeper water? These are interesting questions, but more thorough and careful investigation is needed to decide the matter with any degree of certainty.

The University of Montana hopes before very long to publish a bulletin describing these beds and whatever is of interest in the collections obtained from them.

EARL DOUGLASS.

PRINCETON, N. J.

MAGMATIC DIFFERENTIATION OF ROCKS.

SINCE the time when the celebrated chemist Bunsen first elaborated his theory on the nature of rock magmas, the subject has been of great importance to the geologist. If one were asked to name three of the grander ideas which mark the progress of geology during the century just closed, this conception of magmatic differentiation of rocks would certainly be one of them. Of late years contributions to the subject have been numerous and important. Several of the most recent are especially noteworthy.

In the reconsideration, by H. S. Washington (*Bulletin Geological Society of America*, Volume XI.), of the 'Igneous Complex of Magnet Cove, Arkansas,' made exceptionally interesting through the elaborate efforts of J. Francis Williams, are recorded some observations on magmatic differentiation that are of unusual significance at this time. Contrary to previously expressed opinion, the several types of deep-seated rocks represented in the complex are regarded as integral parts of one great mass and as contemporaneous in origin, and therefore not due to successive intrusions. Furthermore, the structure of the whole mass is probably laccolithic in character.

A remarkable feature connected with the zonal distribution of the various rock-types is the complete reversal of the order almost invariably found among large masses of cooled magmas. Ordinarily the borders are basic and the central parts more acidie. But in the Magnet Cove mass the heavy constituents are in the center and the lighter silica, alumina and alkali components are on the edges. Notable instances of similar character are reported from Norway, Finland and Montana.

The exceptional character of the Magnet Cove mass appears to suggest unusual conditions. While the general subject of the causes of differentiation is not discussed at length, a possible explanation for the Arkansas complex

is offered. Briefly stated, the essential idea is that, just as in a highly cooled vessel of salt water the ice crystallizes at the sides, bottom and top, leaving a core of more concentrated liquid at the center, so here the solvent may have frozen out, collecting at the borders of the cavity in a more or less pure condition, as foyaité, and gradually becoming more basic (richer in the solute) as the freezing process crept towards the center.

Although the great work of the Russian petrographer, F. Loewinson-Lessing, on the Eruptive Rocks of the Central Caucasus, was issued more than two years ago, the views advanced are only beginning to get into form accessible to the majority of English students. The general interest lies in the discussions of the subjects of rock-classification and the differentiation of rock magmas.

The classification proposed for the igneous rocks is chemical. It is based primarily upon the degree of acidity of the silicate minerals. Four great groups are thus established: (1) The ultra-basic rocks, derived from a mono-silicate magma, (2) basic rocks, which had a bisilicate magma, (3) neutral rocks, with a magma which was bisilicate or normal, and (4) acid rocks, in which the magma was polysilicate. These groups are subdivided in 14 sub-groups and 34 families.

In order to find the proper systematic position of an eruptive rock from the fundamental viewpoint of the proposed classification four factors are considered: (1) The relation of the oxygen in the silica and that in all the other oxides taken together, giving what is termed the coefficient of acidity; (2) the chemical composition, which gives for each type a distinctive formula; (3) the relations between the two groups of oxides according to their molecular proportions; and (4) the relations of the soda and potash in the alkaline rocks. This consideration of the principles of classification leads to the proof of the distinct phases of fundamental magmas.

Discussion of the differentiation of rock magmas has an unusual interest. The Russian author calls special attention to the principle of Soret, the action of super-saturated solutions, the effect of gravity, the principles of

maximum work as proposed by Berthelot, and the reaction of mixed liquids, as operating in the separation of magmas.

Three distinct kinds of magmatic differentiation are recognized. They are: Static differentiation, taking place in the depths of the earth; differentiation by cooling during ascent to the surface; and crystalline differentiation. Specific gravity, pressure and temperature are the chief factors governing the course of the static kind; while chemical affinities come into play in large measure only in crystalline separation.

The rôle of inclusions of foreign rocks, which has so long been such an unsatisfactory subject to petrographers, is explained on the idea that it is only that portion of the magma yet undifferentiated which affects the introduced rocks. After thorough assimilation of limestone, for example, a separation of the modified magma takes place. One part contains very little lime and the other nearly all of it. Rock formed from the first mentioned might be a granite, while from the second would come perhaps a gabbro.

CHARLES R. KEYES.

ON THE REASON FOR THE RETENTION OF SALTS NEAR THE SURFACE OF SOILS.

VERY recently a light-colored saline incrustation was noticed by Professor Milton Whitney upon the surface of the soil in the grounds of the Department of Agriculture in Washington. This crust was collected and examined in the laboratory of the Bureau of the Soils under the direction of Dr. Frank K. Cameron. The crust contained about 1 per cent. of soluble matter, principally sulphates and nitrates of sodium and calcium. Samples were then collected at different depths and examined to determine the vertical distribution of the soluble salts. The results showed that although the soil was examined to a depth of three feet, practically all of the salt was in the surface inch, the larger part of it being in the top eighth-inch.

The crust was found at the end of a short, dry season, such as is common in the autumn months along the Atlantic coast region.

A number of similar occurrences of abnormal amounts of soluble matter on the sur-

face of the soils of humid regions have been reported, but very little has been written about them. Cameron has, in Bulletin No. 17, Division of Soils, described a number of occurrences of crusts in humid regions, and has called my attention to several others which were not known to him at the time his paper was published. All of these cases were after a short season of dry weather, but it must be admitted that their occurrence seems rather an anomaly when the heavy rainfall is considered. For what is the reason that this salt remains near the surface of the ground when the water from the rains passes down through the soil? If the salt which is soluble in water is dissolved by the downward percolating rains, why is it not continually washed deeper into the subsoil? Why is it that, in spite of the fact that more water passes downward than returns to the surface by evaporation and capillary movements upward, analyses of soils in the humid regions invariably show more soluble matter in the surface soil than in the subsoil?

There are several reasons which may account for this seemingly anomalous condition of affairs. First, in the soils of the humid region the great bulk of the decomposition of the soil minerals and the consequent liberation of soluble matter takes place within the soil proper in which the greatest aeration takes place, where the bacteria are most numerous and where tillage and sunlight and changes of temperature have a maximum influence.

A second reason which might be given is that of absorption. Very little definitely is known about the phenomenon called absorption, beyond the fact that it is a property of soil grains or of any surface by virtue of which matters in solution are held so that is difficult to wash them off, so that salts which are liberated during the processes of weathering are held near the surface by the absorption.

There is a third factor which seems to assist in accounting for the salts at the surface, and that is that there is a difference between the rates of downward and upward movements of salts within the soil.

When water falls on the soil both gravity and capillary attraction act in the downward

movement. Capillary attraction is more effective in the smaller spaces between the soil grains, while gravity is more effective in the larger openings. When water leaches through a soil in a field, by far the larger part of it passes through the larger openings—those produced by insects, worm burrows, root holes, cracks, large interstitial spaces formed by coarse grains, etc. That such is the case is very easily proven if the rate of percolation is measured through a block of soil in field condition, and the same block is broken up dry, so as to prevent puddling and the rate of percolation is measured again. A simple examination of any soil in the field will reveal the presence of these larger openings, and as the resistance to flow varies as the fourth power of the diameter of the tube, a much larger amount of water passes downward through the large openings, than passes through the smaller true capillary spaces. These larger openings might well be called the gravitational spaces, and the smaller spaces in the soil grains the capillary spaces.

When water moves upward through a soil to replace that lost by evaporation or removed by plants, the movement is entirely capillary and the entire film around the soil grains moves.

Now let us consider the action which takes place when rain falls upon a soil covered with a thin soluble crust. First of all the soluble matter is dissolved and carried down into the soil. The downward-moving wave penetrates most rapidly along the gravitational spaces, since here the resistance is least and the front of the wave is drawn laterally into the true capillary spaces by surface tension. These capillary spaces, therefore, largely fill with water from the front of the wave, and since the front of the wave contains the greater part of the salt dissolved, this salt is thus retained in the capillary spaces. As soon as the capillary spaces are filled, practically all movement in them ceases, except the slow downward percolation caused by gravity, and in a soil of average texture this movement is practically nothing. The movement in the gravitational spaces continues. The salt in the water which was drawn back from the front of the penetrating wave remains stationary or only

escapes out into the gravitational spaces by diffusion.

When the rain ceases the gravitational spaces drain of water, carrying off relatively a small part of the soluble matter, and the evaporation from the surface causes the upward movement to commence, but this movement is entirely capillary and the whole film around the soil grains moves, and as it moves so does all of the salt except possibly that portion absorbed, and there is evidence which leads one to believe that the absorbed salt moves also, but rather more slowly than the film; that is, the absorbed salt shows a tendency to lag behind.

Therefore, it will be seen that the rains do not move the salt as far down as they penetrate but leave the most of it near the surface of the soil or at least so close to the surface that capillary movements will again accumulate at the surface as soon as the dry season occurs.

This explanation of the movement of soluble salts within a soil finds application in a number of ways. In the arid regions, where the soluble salts are more abundant than in the humid climate, and where the movements of these salts, if not understood and controlled, oftentimes result in the accumulation of soluble matter this explanation of the difference in the rate of downward movement, compared with the upward movement, goes far to explain some points which were heretofore but imperfectly understood. For example, it has always been difficult for the writer to understand why alkali salts should continue to accumulate at the surface of the ground in spite of the repeated irrigations, and the maxim laid down by agriculturists in that region that 'alkali goes with the water.' In one district of especial notoriety in California the water table was thirty years ago about sixty feet below the surface of the ground and there were no indications of alkali. Irrigation was commenced and continued large and excessive quantities were used. All of the time the water table was steadily rising, showing unquestionably that more water went downward through the soil than came up for evaporation, and yet in spite of this accumulative downward movement of

the water the alkali salts, which, so far as can be gathered from adjacent unirrigated areas, was within the surface twenty feet of the soil, have been steadily creeping upward and at the present time fully ten per cent. of the area is suffering from an excess of alkali salts.

It is plain that if we desire to send the salts downward the easiest way to do it is to make the downward movement, as far as possible, capillary instead of gravitational. One way of doing this is to break up the soil gravitational spaces by deep cultivation and subsequent firming by flooding. Such has been found very effective in certain areas of Arizona. Another way is to flood the soil with frequent shallow irrigations. In this way a slow downward capillary current is kept up. Half a dozen floodings with one inch of water each will be found to carry downward much more salt than one flooding of six inches.

Another lesson taught, one well known for many years, is that if the subsurface water is alkaline it must not be allowed to rise so close to the surface that continuous upward capillary movement is possible; else the alkali will accumulate in the soil, to its detriment.

THOS. H. MEANS.

BUREAU OF SOILS,
WASHINGTON, D. C.

CHEMISTRY IN THE CALIFORNIA SCHOOLS.

THE chemistry teachers of the Pacific coast have organized an association to encourage the teaching of chemistry, to harmonize methods, to become acquainted with each other and with the needs of the country and the conditions affecting their profession; and, generally, for all those purposes for which association is good. The organization was effected last August, during the Summer School session of the University of California, at which many teachers from California and from the neighboring States were present. The headquarters of the organization are at Berkeley, which, as it is the educational center of the western part of the country, is the natural location for such a purpose. Two members of the faculty of the University of California, one in the department of chemistry and one in the department of physics, were among the organizers.

The need for such an organization is shown

by the number of schools in which chemistry is taught. A recently published list shows that there are 116 schools in California whose graduates are admitted by the University of California without entrance examination. Twenty-five of these are not accredited in chemistry, but the remaining ninety-one have chemistry courses sufficiently thorough to satisfy all University requirements. And in the twenty-five not accredited in chemistry the subject is taught in most cases, though not with the necessary thoroughness. Moreover, there are many other schools in the State whose graduates are not accorded free entrance to the University, and the names of which do not, in consequence, appear on the published list, in which chemistry is one of the subjects taught. It is probable that in the State of California alone there are at least one hundred and fifty chemistry teachers; and it would be making a very modest estimate and one undoubtedly far below the true numbers to estimate at two hundred the chemistry teachers who look toward Berkeley for their inspiration.

As yet the new organization is in a formative condition. It has been getting itself together, rather than attempting to accomplish anything. Its first circular of information, just published, contains, however, a number of interesting facts. On data, not as complete as desirable, it was shown that the high-schools of California give their students a year of chemistry, recitations being supplemented with laboratory practice. The majority of the schools report fairly good laboratory facilities, one small school in the southern part of the State claiming to have a better equipment for elementary work than does the University itself. Of books of reference there is an almost total lack. In many cases there are no reference-books whatever.

One of the interesting features of the first circular is a letter from President Ira Remsen of Johns Hopkins on the proper methods of chemistry-teaching. He writes:

I thank you for the opportunity you have given me to say a few words to the members of your association. The formation of such societies as yours will, I am sure, do much to further the study of chemistry and raise the standard of teach-

ing. As I have watched the work of teachers of our science in schools, in colleges and in universities, it has seemed to me that the chief defect is what in plain English may be called slovenliness. The students get into bad habits of work and have no clear idea in regard to what they are doing. They are often left to themselves too much and work as they ought not to, without knowing that anything is wrong. Then, too, when the students attempt to give an account of what they have done, they use language that would hardly be permitted in a recitation room or in writing about a literary or historical subject. The language and the notebooks are apt to be slovenly, especially if the work has been slovenly. Now, we shall never get what we ought to get from laboratory courses in chemistry or any other subject until this slovenliness is eliminated. The ability to state the source of an element, its properties or the law of definite proportions or any other law—this ability is of little value. This kind of knowledge is meaningless unless based upon some actual experience in the laboratory.

Courses in scientific subjects are still on trial, and we teachers of chemistry are to determine by the way we do our work whether these courses are to be recognized as valuable from a purely educational point of view. Too much of the instruction now given seems to be shaped with the idea that the pupils are all to become chemists. As a matter of fact, this is true of very few of them. But I may as well stop here. I have opened up too broad a subject to be dealt with satisfactorily at this sitting.

EDWARD BOOTH,
Secretary.

SCIENTIFIC NOTES AND NEWS.

PROFESSOR YVES DELAGE has been elected a member of the Paris Academy of Sciences in the section of zoology, in the place of the late Lacaze-Duthiers.

MR. PHILIP WATTS, F.R.S., has been appointed director of naval construction by the British Board of Admiralty, succeeding Sir William H. White, F.R.S., who has resigned in consequence of ill health.

DR. CHARLES PORTER, M.D., of Shrewsbury, has been selected for the appointment of medical officer of health to the municipality of Johannesburg. The salary is £2,000 per annum.

WE learn from the *American Geologist* that Dr. H. M. Ami, of the Geological Survey of Canada, who sustained a rather severe injury to his left arm and shoulder last September, from a fall down a steep cliff at Cap à L'Aigle, below Quebec City, is sufficiently recovered to resume his official duties at Ottawa.

DR. J. W. SPENCER is at present engaged in geological explorations in Central America.

UNDER the auspices of the astronomical department of Columbia University Sir Robert S. Ball will lecture in Havemeyer Hall, on January 10, at 3:30 P. M. His subject will be 'The Cause of an Ice Age.'

DR. SVEN ANDERS HEDIN, the Swedish traveler, who recently reached Ladakh, Cashmere, from exploring the Gobi desert and Thibet, has informed King Oscar that his party was attacked by Thibetans during his journey and that all his collections and almost the whole of his caravan was lost, but that his notes were saved.

DR. ALES HRDLICKA will start about January first on his fourth expedition among the Indians of the southwestern United States and northern Mexico. These expeditions are a part of the system of anthropological exploration and investigation known as the Hyde Expedition and are carried on under the direction of Professor F. W. Putnam for the American Museum of Natural History. The expenses of the present undertaking are generously provided for by Mr. F. E. Hyde, Jr., of New York City. Dr. Hrdlicka is in charge of the somatological work of the Hyde Expedition and his plan, now more than half fulfilled, is, in the main, to ascertain the physical characteristics of the extinct as well as the living peoples in that area which has once been occupied by the Cliff-Dwellers and Pueblos, and by the Toltec, Aztec and Chechemec peoples. It is hoped that on the present journey the somatological part of the research in the field will be completed. The principal tribes that will be studied on the present trip are the Pimas, Papagos, Yaquis, Mayos, Tepchuancos, Coras, Aztecs and Tarascos. Dr. Hrdlicka will be accompanied and assisted by Mr. Gustavus Meyers, of New York City.

THE editors of the *Botanische Centralblatt* for Great Britain are: Algae, Miss Barton, British Museum (Natural History); Fungi, Mr. Masee, Royal Gardens, Kew; Archeoniatæ, Mr. A. Gepp, British Museum (Natural History); Phanerogams, Mr. Daydon Jackson, 21 Cautley Avenue, Clapham Common, S.W.; Cytology, Professor Farmer, Royal College of Science, S. Kensington; Physiology, Professor Vines, Headington Hill, Oxford; Morphology, Dr. W. H. Lang, University, Glasgow; Paleontology, Professor Scott, Old Palace, Richmond, Surrey.

MR. CLARENCE KING, the eminent geologist, died at Phoenix, Arizona, on December 24. Born in Newport, R. I., he graduated from the Sheffield Scientific School of Yale University in 1852, and joined the California Geological Survey in 1853. He was instrumental in the organization of the U. S. Geological Survey, of which he was director from 1878 to 1881. We hope to give subsequently some account of Mr. King's geological work.

SIR JOSEPH HENRY GILBERT, the well-known agricultural chemist, died on December 23, aged 83 years. With Sir John Bennet-Laws, he was over fifty years director of the Rothamsted Laboratory, and was for some years professor of rural economy at Oxford University. He was a fellow of the Royal Society and a correspondent of the Paris Academy of Sciences.

MAJOR ROBERT TEMPLE, the well-known southern engineer, died at Richmond, Va., on December 22, at the age of seventy years.

Nature records the death of the Rev. Hugh Alexander Macpherson, of Glendale, at the early age of forty-three. Mr. Macpherson was an authority on the fauna of the lake country, and had published an elaborate work on the subject, 'A Vertebrate Fauna of Lakeland, including Cumberland and Westmoreland, with Lancashire North of the Sands.' He was also the author of a book entitled 'British Birds.'

MR. ANDREW CARNEGIE has offered the city of Akron \$70,000 for a free public library, the city to guarantee \$7,000 annually to maintain it.

THE Misses Olivia and Caroline Phelps Stokes have presented to the Board of Managers of the New York Botanical Garden, \$3,000, on condition that the interest of this fund should always be used for the investigation and preservation of native plants, or for bringing the need for such preservation before the public. The income this year is offered in three prizes for papers on the subject mentioned. The papers must be presented not later than February 1, 1902.

At a meeting of the trustees of the Connecticut Agricultural College, on December 27, a resolution was passed favoring a bill now before Congress providing for the study of forestry and mining in the agricultural colleges.

AN Anthropological Club was recently organized at Yale University. Dr. Kellar presided and Professor Sumner outlined the subjects to be treated. The attendance was eighteen.

THE Society of College Gymnasium Directors met at Columbia University on December 27 and 28. The following officers were elected: *President*, Professor Paul C. Phillips, Amherst College; *First Vice-President*, Edward Hitchcock, Jr., Cornell University; *Second Vice-President*, Dr. Frederick E. Parker, Brown University; *Secretary and Treasurer*, Dr. James A. Babbitt, Haverford College; *Executive Committee*, Dr. R. Tait McKenzie, McGill University, Montreal; Dr. Dudley A. Sargent, Harvard, and Dr. William G. Anderson, Yale; *Council and Committee on Admissions*, Dr. Casper W. Miller, University of Pennsylvania; Dr. Watson Lewis Savage, Columbia; Professor A. Alonzo Stagg, University of Chicago, and the officers of the Society, *ex-officio*. *Committee on Strength Tests and Inspection of Instruments*, Dr. Sargent, Harvard; Dr. Savage, Columbia, and Dr. Jay W. Seaver, Yale. *Committee on Nomenclature*, Dr. Anderson, Yale; Dr. Sargent, Harvard, and Professor George Goldie, Princeton.

THE twelfth annual banquet provided for in the will of the late Henry Shaw, the founder of Shaw's Botanical Garden, was given on December 7, at the Mercantile Club, St. Louis.

THE *Lancet* states that the fellows and asso-

ciates of the Institute of Chemistry assembled under Professor J. Millar-Thomson, F.R.S., the president, for their annual dinner on December 4. The president was supported by a distinguished company. The minister of agriculture emphasized the importance of scientific chemistry to agriculture. The president gave a general report on the condition of the institute, pointing to the advance that that body was steadily making in the high standard of its examinations.

THE Archeological Institute of America held its annual meeting at Columbia University, on December 27 and 28, under the presidency of Professor John W. White, of Harvard University.

At a meeting held in London on December 5, under the presidency of Dr. W. R. Smith, a medico-legal society was organized.

THE *Lancet* states that at the meeting held on November 25, M. Gaule laid before the Paris Academy of Sciences the result of some researches which had been undertaken by himself with a view to ascertain whether the results of a balloon ascent were comparable with those obtained at a high altitude on land—*e. g.*, at the top of a mountain. The most notable of these is a marked augmentation in the number of red corpuscles. Viaux and sundry observers who followed him have ascertained that at a high altitude there is a great increase in the number of red corpuscles. Thus in the Cordilleras at a height of 4,000 meters, Viaux found 8,000,000 red corpuscles per cubic millimeter. M. Gaule wished to see whether in a balloon ascent, where ascension is very rapid and entails no muscular exertion, a similar phenomenon would occur. He made two investigations at heights of 4,200 and 4,700 meters and found in himself 8,000,000 red corpuscles per cubic millimeter. Further, M. Gaule at a height of over 4,000 meters made some blood-films stained after Ehrlich's method with eosin and hæmatoxylin. He found numerous red corpuscles which showed a nucleus colored blue by the hæmatoxylin. This nucleus was in many instances segmenting, and also groups of three or four corpuscles were seen as if they had undergone subdivi-

sions. Similar preparations made before the ascent showed no such appearances. M. Gaule therefore considers that at high altitudes there is an actual formation of red corpuscles and that this takes place with great rapidity. At the following meeting M. Tissot and M. Haillon gave an account of researches on a somewhat analogous subject. On November 21 they undertook some researches at various altitudes into the physics and chemistry of the respiration. Experiments were made at the following heights: 1,350 meters, 2,600 meters, and 4,450 meters in the case of M. Tissot, and at 1,700 meters and 3,500 meters in the case of M. Haillon. The chemical phenomena of the respiration did not vary appreciably at these different altitudes. The respiratory rhythm, however, was greatly modified. Although the total quantity of air entering the lungs was less the number of respirations was not sensibly altered. It would thus appear that at high altitudes the air is purer and more completely used.

The London *Times* states that Sir Colin Scott Moncrieff, has been appointed by the Secretary of State for India to preside over a commission to consider exhaustively the possibilities of further protection against famine by means of irrigation. His colleagues will be Mr. Ibbetson (recently appointed to fill a prospective vacancy in the Viceroy's council), Mr. Higham, of the Irrigation Department, and the Hon. Mr. Rajaratna Mudaliyar, of Madras. The Punjab, Sind and Rajputana are the parts of India to be first visited as being most susceptible to the advantages of irrigation. Other provinces will then be taken one after the other, Burma alone being left unvisited. In order that the commission may be assisted in its inquiries by local knowledge, each provincial administration has been asked to nominate an experienced revenue officer to be a member of the commission for the period that it remains in the province. The terms of reference to the commission show that the inquiry will be of a most exhaustive character. The Government resolution points out that the irrigation works hitherto constructed by the State have on the whole proved directly remunerative, but it is recognized that the pro-

gram of works of this kind may be approaching completion. The great storage works required for any considerable extension of irrigation in tracts most exposed to famine must necessarily be more costly per acre protected, and therefore less remunerative than completed works, which draw unfailing and perennial supplies from the great rivers of Northern and Southern India. As regards new works, therefore, the Commission is directed to regard as the main question not whether they will be likely to prove directly remunerative, but whether the net financial burden which they may impose on the State in the form of charges for interest and maintenance will be too high a price to pay for the protection against famine which they may be relied on to afford. One of the most valuable results that may be anticipated from the labors of a Commission taking this as its guiding principle will be to authoritatively set at rest the assumption that in all cases areas liable to famine can be protected by irrigation with comparatively small cost annually to the State.

The London *Times* states that the National Association of British and Irish Millers have decided to institute an inquiry into the whole question of the relative strengths of English and American wheats, and have secured the cooperation of the Southeastern Agricultural College at Wye, Kent, in the agricultural side of the work. The question has arisen in consequence of complaints by agriculturists that English millers will not purchase English-grown wheats as they did formerly, but give the preference to American wheat, though they have to pay a higher price for it. The millers reply that, however favorably they may be situated for obtaining home-grown corn, they cannot sell for bread-making purposes flour made from English wheats, because they lack the strength of the American kinds. It is hoped that the inquiry will result in an improvement in the quality and yield of English wheat. For this season the Southeastern Agricultural College is sowing the same wheats on different soils; different manures are being tried, and the wheats in each case will be tested by milling and baking. New varieties are being obtained from Canada and

America, and selection and cross-breeding will be tried to improve the yield of the old varieties, not by increasing the size, but by increasing the number of grains in the ear.

UNIVERSITY AND EDUCATIONAL NEWS.

By the will of Mrs. S. C. Warren, about \$150,000 is given for educational and charitable purposes, including \$5,000 to Harvard University for the Peabody Museum of Archeology and \$5,000 to Williams College.

PALMER COLLEGE, at Le Grand, Iowa, has received \$30,000 from Mr. F. A. Palmer, of New York, making \$50,000 given to the institution in the last six months.

A CABLE despatch to the New York *Sun* announces that the Chinese government has decided to present to Columbia University a compilation of Chinese literature, history, maps, illustrations and official papers in acknowledgment of the establishment of a chair of Chinese history, language, customs and manners in that institution. The recommendation that such action be taken was made by Liu Kun Yi, the Viceroy of Nankin.

THE Philadelphia correspondent of the New York *Evening Post* records the buildings to be erected at the University of Pennsylvania, as follows: Engineering building and machinery, \$500,000; gymnasium building and ground, \$400,000; medical laboratories, \$500,000; veterinary building, \$150,000; and various sums for additions to the chemistry and physics laboratories. About one-half of this sum has been secured, and the plans for the new engineering building have already been completed. The equipment will cost over \$200,000, and the building \$300,000. The site for the new medical laboratories has been cleared and work begun on the foundations. The trustees plan to have the laboratories ready for use by the opening of the next college year.

MRS. GEORGE HOLT and Miss Holt have endowed a fellowship in physics in University College, Liverpool, to be associated with the name of Dr. Oliver Lodge, formerly professor of physics at the College, and now principal of Birmingham University.

Its annual value will be £100 or more. A prize to be called the 'Oliver Lodge Prize' has also been established by Dr. Lodge's friends and late colleagues, to be awarded annually to the best student in physics in the third year of the honors course.

CORNELL UNIVERSITY will hereafter confer the degree of 'Forest Engineer,' in place of 'Bachelor of the Science of Forestry.' The arguments presented in favor of this change are as follows: (1) The degree 'Forest Engineer' expresses more adequately than the academic degree now conferred, and according to precedent in other technical arts, the fact that not a science, but an art of technical character has been studied to a certain degree, namely the degree of entering the student into the profession. (2) It expresses the kind of work—namely, the application of technical scientific knowledge to a business end in a productive industry—for which the student has been prepared as a professional man. (3) It does not, as does the academic degree B. S. F., place the scientific basis and the literary accomplishment before the professional result. (4) It is, in the eyes of the world, a *prima facie* title of practical attainments, fitting for employment in practical rather than literary or scientific work. (5) There is sufficient precedent, not only in other technical arts for the form of title, but in the art of forestry, wherever a title has been given outside of this country, it has assumed the form of Engineer.

At its next session the Legislature of Pennsylvania will be asked to establish a School of Forestry.

PROFESSOR LUTHER FOSTER has resigned his position of vice-director of the experiment station and professor of agriculture in connection with the University of Wyoming at Laramie, in order to accept the presidency of the New Mexico College of Agriculture and Mechanic Arts located at Mesilla Park, and the directorship of the agricultural experiment station at the same place. Professor Foster was elected to his new position unanimously by the board of regents of the college and station on November 22, and assumed charge of the duties of the position on December 1.

THE AMERICAN SOCIETY OF NATURALISTS.

THE CHICAGO MEETING.

THE meetings of the American Society of Naturalists and of the affiliated societies held last week in Chicago were not only important for the scientific work presented, but were also noteworthy as marking an epoch in the organization of science in America. The nineteenth century is regarded on all sides as the era of science. It was also an era of individualism in science, as in business and in political institutions. Historical developments do not usually occur to fit the calendar, but it has so happened that the first year of the present century has witnessed in America an extraordinary advance toward that organization of science and that cooperation among scientific men, which will probably be typical of the century.

THE American Association for the Advancement of Science met last August in Denver, passing for the first time beyond the banks of the Mississippi, and becoming national in fact as well as in name. The Association also became at the Denver meeting truly representative, not only of the whole country, but also of all the sciences,

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

by its action in making its council the representative body for all our scientific societies. Equally important in this direction was the decision to meet next year at Washington in midwinter, making it possible for all the scientific societies to come together in a great national congress. The success of the Association in securing the adherence of our leading institutions of learning to convocation week, thus obtaining an excellent time for the meetings, must also be regarded as an event of great moment.

As the American Association met for the first time in the western half of the country, so the American Society of Naturalists met this year for the first time west of the eastern seaboard. Joining with the naturalists of the Central and Western States the society became truly national in character. Equally important was the decision of the society to meet next winter at Washington in conjunction with the American Association—a step taken not only by eastern naturalists, but also by those of the Central and Western States. The congress next year at Washington will bring together the societies that have hitherto been divided between summer and winter meetings, and will thus represent the entire domain of science, as well as the whole country. It will be a meeting from which no scientific man can afford to absent himself, while its magnitude will give science a position before the national government, before our educational institutions and before the general public that it has never hitherto obtained.

The subject chosen for discussion at Chi-

cago was 'The Relation of the American Society of Naturalists to other Scientific Societies'—a topic obviously fitted to the occasion. The result of the discussion was most satisfactory in demonstrating the desire of those representing different sciences and different regions of the country to cooperate for the common good. The speakers from the Eastern States, Professors Minot, McGee and Cattell, tended to emphasize the importance of national union, whereas the speakers from the Central States, Professors Davenport, Trelease, Birge and Forbes, laid special weight on the need for local centers; but all agreed that we must have a strong central organization with a great annual meeting, while at the same time we must provide local and sectional meetings for those unable to attend the general congress, and also for the purpose of having groups not too large for adequate discussion. There was a unanimous sentiment that arrangements should be made by which the more local societies and meetings should not rival, but support the central organization. Committees were appointed by the American Society of Naturalists, and the Naturalists of the Central and Western States to cooperate in formulating plans for future meetings, and, as has been stated, the western naturalists decided to meet next year in Washington.

No less timely than the annual discussion, was the address of the president, Professor Sedgwick, on 'The Modern Subjection of Science and Education to Propaganda, printed in the present issue of SCIENCE. The usefulness of a society such

as the Naturalists is well indicated by an address of this character, stating in a semi-official way the consensus of opinion of scientific men on a topic of great concern to the whole people. For this address, and for his leading part in the arrangements for the Chicago meeting, Professor Sedgwick has the thanks of all naturalists. The lecture by Dr. Howard, like the president's address, was a model of what the occasion required. The subject 'International Work with Beneficial Insects' was of interest to all, and the treatment was neither technical nor trivial.

The local arrangements were admirable. The University of Chicago offered every possible facility for the meetings. President Harper welcomed the societies and entertained them at his house. The local committee, headed by Professors Davenport and Jordan, left nothing undone. The hotel headquarters were probably the best ever provided, and the dinner—attended by two hundred members, fifty more than at any previous meeting—was excellent, from the point of view both of the physiologist and of the psychologist. There were no speeches except the president's address, but after the official adjournment, most of those present lingered for an hour or two in pleasant social groups.

Three hundred and three scientific men registered, and there were doubtless some who omitted this formality. The meeting was the largest in the history of the Society, and nearly as large as the meetings of the American Association when it meets in the Central States. The attendance from the

Eastern States was very satisfactory, though the journey naturally prevented the attendance of many of the younger men. The Central States, including Iowa, Nebraska and Missouri, were very fully represented.

The number of papers announced on the preliminary programs of the affiliated societies—considerably increased at the time of the meetings—was as follows: American Morphological Society, 50; American Physiological Society, 43; Association of American Anatomists, 31; Society of American Bacteriologists, 35; Botanists of the Central and Western States, 28; American Psychological Association and Western Philosophical Association, 23; Section H, Anthropology, of the American Association, 16. Adding the addresses and discussions before the Naturalists, there were thus 244 scientific papers on the preliminary programs, probably the largest number presented at any meeting of the Naturalists, and equalling the number usually presented at the meetings of the American Association. Either the official proceedings or full reports of the meetings of the different scientific societies will be published in subsequent issues of this journal.

The Council of the American Association held a well-attended meeting. The permanent secretary, Dr. Howard, made a report showing that the number of members has greatly increased during the year, and that the finances are in good condition. The membership at the end of the year was over three thousand, and the initiation fees of the new members had more than defrayed the cost of sending SCIENCE to all

members. The committee, on convocation week presented the report published in the issue of this journal for December 27, showing that both our institutions of learning and our societies are unanimously cooperating in setting aside for the meetings of learned and scientific societies the week in which the first day of January falls. A committee was appointed to consider the question of the duty imposed on scientific apparatus imported for educational institutions, a resolution was passed advocating a national health service, and other business was transacted. The most interesting feature of the meeting was perhaps the representation of Section K, Physiology and Experimental Medicine, by its first officers, Professors Welch and Lee. It was decided that the first meeting of the Section should be held in Washington a year hence, and that all scientific papers must be presented through one of the national societies devoted to the sciences falling within the scope of the Section.

While the affiliated scientific societies devoted to the biological sciences were meeting in Chicago, the other scientific societies that hold winter meetings were in session in different cities. The American Geological Society met in Rochester, the American Chemical Society in Philadelphia, the Astronomical and Astrophysical Society of America in Washington, the American Mathematical and Physical Societies and the eastern branch of the Society for Plant Morphology and Physiology in New York. So far as can be judged from the preliminary programs and from accounts that have reached us, the meetings were in all

cases successful, and this will doubtless be fully proved by the reports that will be published in this journal. It will, however, be a gain to the separate societies and especially to science as a whole when all our men of science gather in one congress as will be the case next year.

Only those who have attended the meetings of our scientific societies in recent years can fully appreciate the improvement that has taken place in the conduct of the meetings, the increase in the volume and value of scientific work, and the friendly and cordial relations almost universal among scientific men. We are entitled to enjoy great satisfaction in the advances made by the Denver and Chicago meetings, and to look forward with sure anticipation of a further advance in the great meeting to be held during convocation week next winter at Washington.

*THE MODERN SUBJECTION OF SCIENCE
AND EDUCATION TO PROPAGANDA.*

ONE of the sad pages in the history of science and education is that which relates how, on the death of Alexander the Great, the teacher of his youth, the much greater Aristotle, rightly regarded by the Middle Age as the 'master of those who know' when more than sixty years old was driven from Athens into exile by a patriotic propaganda of the anti-Macedonians. A darker and a bloody page tells how Hypatia of Alexandria, the beautiful and learned daughter of Theon, was cruelly and brutally murdered in a Christian church in the year 415 of our era as a victim of a fanatical propaganda against paganism, condoned, if not conducted, by the Christian Archbishop Cyril, Patriarch of Alexandria. Copernicus hesitated long before publish-

ing his splendid discoveries on the movements of the heavenly bodies and the heliocentric theory, for fear of ecclesiastical interference, and when soon after Galileo, more bold, promulgated the truth that Copernicus had hesitated to pronounce, both he and his discoveries fell under the severest ecclesiastical condemnation ever visited upon any man of science for the truth alone.

In our own time we have too often heard of sects which place the propaganda of a special faith before either science or education, and inquire more carefully into the orthodoxy of professors and pupils than into their scientific or educational attainments. However much we may regret such action we cannot legitimately complain so long as the sectarians in question confine their actions to sectarian schools, colleges and universities, supported exclusively by private means, for the right to regulate education within the home, the family, the private school or the private college or university, is a fundamental and inalienable right of a well-regulated democracy.

The century just closed has witnessed a remarkable liberation of natural science and education from dogma. Geology was first set free by Lyell and his school, and then biology, by the discoveries of fossil man, and the splendid inductions of Darwin. Slowly but surely the teaching of natural science, which, like all teaching, follows closely in the footsteps of discovery, has also cast off its chains and freed itself from the subjection of theology. But as the church has declined in temporal power the state has become supreme, and with the recognition of its power has come the belief in its sufficiency,—even its sufficiency to remedy all ills, real or imaginary,—and scarcely had science and education freed themselves from the bonds of the church before they began to be threatened with

subjection by the state, a subjection sought for not by theologians but by philanthropists and philozoists.

The first in the field were the philozoists, commonly known as anti-vivisectionists. In former times charges of cruelty brought against scientific men would have been referred to an inquisition when such an institution existed but now, the church being powerless in such matters, appeal must be had to the state. Accordingly, a propaganda was started, first, so far as I am aware, in England but afterwards spreading to this country, which by 1875 had succeeded in bringing into complete subjection in Great Britain animal physiology, then the principal experimental biological science. Since that time a new biological science, bacteriology, has sprung up and found itself hampered also in some of its most important and most humane investigations by the same British statute, enacted on demand of the philozoic propaganda.

Anyone may read in the 29th chapter of the admirable *Life and Letters of Professor Huxley*, edited by his son, how, in 1870, when president of the British Association, Huxley had been violently attacked for speaking in defence of Brown-Séquard, the French physiologist, and how in the same year a committee had been appointed by the British Association, and reported upon the conditions under which they considered experiments on living animals justifiable. When legislation seemed imminent Huxley, in concert with other men of science, interested himself in drawing up a petition to Parliament to direct opinion on the subject and provide a fair basis for future legislation. A Royal Commission was finally appointed, with Huxley as one of its members. Early in 1876 the Commission reported and a few months later Lord Carnarvon introduced a bill entitled 'An Act to amend the Law relating to Cruelty to Animals.' "It was," says Mr. Leonard

Huxley, "a more drastic measure than was demanded. As a writer in *Nature* (1876, page 248) puts it, 'The evidence on the strength of which legislation was recommended went beyond the facts, the report went beyond the evidence, the recommendation beyond the report, and the bill can hardly be said to have gone beyond the recommendations, but rather to have contradicted them.'"

As to the early working of this law Huxley remarked in the following year in his address on 'Elementary Instruction in Physiology' as follows ('Coll. Essays,' III, 310):

"So it comes about that, in this year of grace, 1877, two persons may be charged with cruelty to animals. One [a fisherman] has impaled a frog, and suffered the creature to writhe about in that condition for hours; the other [a teacher] has pained the animal no more than one of us would be pained by tying strings round his fingers, and keeping him in the position of a hydro-pathic patient. The first offender says, 'I did it because I find fishing very amusing,' and the magistrate bids him depart in peace—nay, probably wishes him good sport. The second pleads, 'I wanted to impress a scientific truth with a distinctness attainable in no other way on the minds of my scholars,' and the magistrate fines him five pounds. I cannot but think that this is an anomalous and not wholly creditable state of things."

Looking back over more than twenty-five years of the practical working of this law we can affirm without hesitation that under its operation both physiological science and physiological education have been kept by the State, or rather by the propaganda which secured the passage of the statute, under a needless and injurious subjection.

As early as 1865, and apparently before the scientific men of Great Britain had

seriously begun to oppose the anti-vivisection propaganda, Dr. John C. Dalton, Professor of physiology in the College of Physicians and Surgeons in New York City, delivered an address before the New York Academy of Medicine, which, for lucidity of statement, dignity of tone, wisdom and high seriousness, seems to me superior to any treatment of the subject with which I am familiar ('Vivisection: What it is, and What it has Accomplished,' Address before the New York Academy of Medicine, December 13, 1866). Many of Dr. Dalton's definitions and illustrations are worthy of quotation, *e. g.*:

"The subject of discussion is not vivisection in its narrowest sense, but the entire method of experiment upon living animals as a means of study in physiology and the kindred sciences" (p. 5).

"Experimental vivisection is no more open to the charge of cruelty * * * than the dissection of human bodies for the study of anatomy is open to the charge of sacrilege and impiety. * * * (P. 2.)

"We might as well expect to learn the phenomena of magnetism by experimenting with subjects not magnetic, as to study the phenomena of life anywhere but in the actions of the living body." (P. 7.)

Dr. Dalton published further in 1875 'Experimentation on Animals as a means of Knowledge in Physiology, Pathology and Practical Medicine,' and I cannot help feeling that it was largely his calm, fair and yet firm, attitude that caused the failure of the anti-vivisection propaganda in the State of New York in 1867 and again in 1874.

In Massachusetts repeated attempts have been made to secure legislation 'regulating' vivisection. An anti-vivisection propaganda is constantly maintained in Boston, and for several successive years bills aiming at the 'restriction' or 'regulation' of vivisection have been introduced into the

legislature by the propagandists, but, having been vigorously opposed by medical and scientific men powerfully aided by such public-spirited citizens as the president of Harvard University, the president of the Massachusetts Institute of Technology and the Bishop of Massachusetts, they have hitherto failed ignominiously. All sorts of restrictions have been suggested, and in the latest bill it was proposed to endow the agents of any society for the prevention of cruelty to animals with powers of entrance and search, so that they might visit any laboratory at any time, taking names and otherwise interfering with the freedom of research and instruction, as well as infringing upon the individual liberty of persons engaged in experimentation upon animals. If such a law had been passed, the subjection of science to propaganda in Massachusetts would to-day be even more complete and more intolerable than it has been in England since 1875.

I need not recount the recent attempt of those engaged in this propaganda to secure restrictive legislation for the District of Columbia. Suffice it to say that the attempt was one of the boldest and most dangerous attacks upon the freedom of research which has ever been made in America.

Nor is this all. Some of those engaged in the anti-vivisection propaganda seek, at the same time that they would abolish vivisection, to do away with all dissection of whatever sort in public schools of whatever grade. No one in his senses desires vivisection in the public schools except, perhaps, in normal schools devoted to the education of teachers. But dissection of clams, oysters, lobsters, starfish, sea-urchins, worms, snails and possibly fishes and frogs, are not only not necessarily out of place but may even be very useful and desirable in high schools and normal schools. My own feeling is that in grammar schools and all schools lower than high schools instruc-

tion should be confined almost wholly to the external structure of plants and animals, with their occurrence, habits, habitats and the like; but I see no good reason why in high schools and normal schools the elements, at least, of the internal structure of invertebrates and even of certain vertebrates may not well be taught. I have taken some pains to secure upon this point the opinion of a number of teachers of natural science in normal schools, most of whom have also been teachers in schools of lower grade, and with one or two exceptions I find that they are strongly of the opinion that a moderate amount of dissection is not only desirable but almost indispensable.

Yet in 1895 the American Humane Association published in Chicago a report on vivisection and dissection in public schools, in which various excellent persons unhesitatingly affirmed that dissection in public schools is superfluous, and that physiology can be well enough taught by means of manikins, pictures and the like. In particular, several bishops, apparently regarding themselves as qualified to give evidence on this subject, stated without hesitation that all that is necessary in the practical teaching of physiology is illustrated books, manikins, etc., some even going further and saying that dissection must inevitably blunt the sensibilities and corrupt the character of the young. Cardinal Gibbons, of Baltimore, however, was more cautious when he said: "I am inclined to think that sufficient instruction can be imparted by the use of illustrations and manikins. I think it advisable to give children the knowledge, as Scripture does, of the God-given power of man over the lower forms of life; but they should be warned that this power is not absolute, arbitrary or cruel." In reading the pronouncements of the American bishops referred to, one is reminded of the occasions for Huxley's frequent and contemptuous sneers at the

bishops of his own land with whom he so often did battle with delight.

As a specific illustration of the need of watchfulness concerning the privilege of dissection in the public schools I may cite what took place in Boston a few years ago. Those who happened at the time to be living in that city awoke one morning in January, 1894, to find that on the previous evening a member of the Boston School Committee had offered the following order and that it had been unanimously passed.

“ORDERED: That the dissection of animals be prohibited in the public school buildings of the city of Boston.”

Realizing how damaging a rule of this sort must inevitably be to the best interests of science in the public schools, I hastily drew up the following petition to the School Committee and secured for it the signatures of President Eliot, General Walker, Professor Agassiz and a few other leaders in science or education in or near Boston:

“To the School Committee of the city of Boston:

“We have learned with surprise and regret of the prohibition which you have placed upon the dissection of animals in the public school buildings of Boston. We earnestly protest against this action and urge its immediate reversal, believing that such a prohibition will seriously weaken the efficiency of science-teaching in the schools and completely cripple the courses in zoology and physiology. As the order stands, no one, not even a head-master, is allowed to dissect, in any of the school buildings, so much as a fish or an oyster.”

(Signed) Charles W. Eliot, Francis A. Walker, A. Agassiz, Mrs. Louis Agassiz, Josiah P. Cooke, Augustus Lowell, Alice Freeman Palmer, Samuel Eliot, Mary Hemenway, Mrs. W. B. Rogers, H. P. Bowditch.

I also took pains to make the matter known through the press, and the result

was that at the next meeting of the School Committee the order was reconsidered, amended and finally passed in a less objectionable form, as follows:

“ORDERED: That dissection of red-blooded animals be confined to normal and high schools when approved by the superintendent and masters.”

This perhaps is as good a place as any in which to urge upon all those within sound of my voice, or before whom this subject may come upon the printed page, and who desire to keep intact the freedom of science and education, the necessity of watching, in season and out of season, to repel the attacks of that propoganda which would not only compel all practical instruction in physiology to be based upon pictures and manikins, but would also prohibit altogether all experimentation upon animals, whether in physiology, bacteriology or experimental medicine. Science in Great Britain, as has already been stated, has been brought under an almost intolerable subjection by the anti-vivisection propoganda. In America, though long threatened, this has not yet come to pass; but unless naturalists everywhere are on their guard they will some day be taken by surprise, very much as the English naturalists seem to have been, and be brought under a similar subjection to the same hostile propoganda.

But if in America we can rejoice that we have thus far resisted the onslaughts of philozoists upon experimental science, we must confess with sorrow that we have been less fortunate in dealing with philanthropists, in an important department of elementary education. When, in 1842, Horace Mann published his still excellent essay on ‘The Study of Physiology in Schools,’ he seems, judged by recent school statutes of the several United States, to have made one serious omission, for he nowhere mentions or even fore-shadows that remarkable creation of our

own times, 'temperance physiology,' and very likely, with some old-fashioned people of to-day, he regarded 'temperance' as chiefly a moral question.

The discovery of this new and entirely modern branch of 'science' and 'education' seems to have been the joint work of Dr. (afterwards Sir) Benjamin W. Richardson of England, an able but erratic physician, and Mrs. Mary H. Hunt, formerly of Hyde Park, Massachusetts, and now of Boston. At any rate, Mrs. Hunt refers to Dr. Richardson as the author from whom she drew some of her original inspiration, but her own achievements, in organizing and directing the propaganda now associated with her name, have so far outrun anything done for it at the outset by Dr. Richardson that we must regard her, and not him, as the true creator of this astonishing movement. Mrs. Hunt says that her mind was turned to the subject in the early seventies and that she soon found in Dr. Richardson's 'Cantor Lectures on Alcohol in its relation to Man,' the exact data she had been groping for. These lectures seemed to her to prove 'the dangerous difference between the demonstrated fact that it is the nature of a little alcohol to create an uncontrollable appetite for more, and the popular idea of the harmlessness of using alcohol in small quantities,' and the corollary seemed to her to be 'that intemperance could never be prevented until the people were taught to really know the effects of alcoholic drinks, and that this must be done through the schools.' From 1880 until the present time this really remarkable woman has given her life with intense devotion and extraordinary success to a national, and even world-wide, propaganda of her faith.

The movement is variously called 'scientific temperance instruction,' 'temperance physiology' or 'physiological temperance,' and it has now grown to such proportions and has gained such power as to dominate,

almost absolutely, all instruction in elementary physiology and hygiene in America. It is of course right and proper that pupils in all grades of the public schools should be taught the dangers of alcoholic beverages as fully and as earnestly as other dangers lurking in food or drink. We may even grant that more stress should be laid upon this subject than upon some others. But an examination of the present status of elementary education in physiology and hygiene in the United States shows that in many cases the instruction demanded by this propaganda, and given according to law, in reference to alcohol goes much further. It even appears that all instruction in physiology and hygiene in the public schools has passed to a great and unjustifiable extent into the virtual control and under the subjection of the 'temperance physiology' propaganda. Mrs. Hunt, as early as 1888, boldly announced: "We are the recruiting officers, and the teachers the drill-masters, for training the coming total-abstinence army that is to banish alcohol from human beverages."

Authoritative sources of information for testing these statements are easily accessible to all. They consist of the statutes of the several States requiring instruction, often of prescribed and peculiar kinds, regarding alcohol; of the text-books on elementary physiology and hygiene actually in the hands of the pupils; of the teachers,—many of whom groan in spirit even when they do not dare to complain openly; and last, but not least, of the boastful 'histories' of the propaganda prepared by Mrs. Hunt herself and published, one in 1891 (or earlier) and the other in 1897.*

* 1. 'A History of the First Decade of the Department of Scientific Instruction in Schools and Colleges of the Woman's Christian Temperance Union.' By Mary H. Hunt, Superintendent for the United States and the World's W. C. T. U. Second Edition. Boston, 1891.

From these latter it appears that largely through her personal efforts statutes now exist in nearly every one of the United States requiring instruction in physiology and hygiene with special reference to the nature and effects of alcoholic drinks; that in some states a penalty clause is attached for non-enforcement; that in some the amount of space to be given in text-books is prescribed, and in the same or in others, the time to be devoted to the subject. In some States it is also required that the subject shall not be treated in an appendix, or in a separate chapter at the end of the book.

In 1897 Mrs. Hunt stated that 'a combination of the Illinois law with the penalty [clause] of the New York law would be an ideal statute.' It is therefore easy to see at what she aims, for the Illinois law requires that all pupils 'below the second year of the high school and above the third year of school work' counting from the lowest primary, 'shall be taught and shall study this subject every year, from suitable text-books in the hands of all pupils, for not less than four lessons a week, for ten or more weeks of each year.' For students below the high school 'such text-books shall give at least one fifth their space,' and for high-school students "not less than twenty pages, to the nature and effects of alcoholic drinks and other narcotics. The pages on this subject in a separate chapter at the end of the book shall not be counted in determining the minimum." The New York law of 1896 is very lengthy and likewise contains an important provision that 'this subject must be treated in the text-books in connection with the various divisions of physiology

2. 'An Epoch of the Nineteenth Century. An Outline of the Work for Scientific Temperance Education in the Public Schools of the United States.' By Mary H. Hunt, National and International Superintendent of the Department of Scientific Temperance Instruction, and Life Director of the National Educational Association. Boston, 1897.

and hygiene, and pages on this subject in a separate chapter at the end of the book shall not be counted in determining the minimum.'

The effect of these peculiar laws closely defining instruction in physiology and hygiene has been to create a correspondingly peculiar class of text-books. Some of these have been prepared by competent writers, but most of them are inferior and some are distinctly bad. One chapter in Mrs. Hunt's 'History' is entitled 'The Text-Book War.' It is not agreeable reading, either for scientific men or for educators. In a so-called 'Great Petition to Publishers,' which reads more like a threat than a petition, it is stated: "This is not a physiological, but a temperance, movement. In all grades below the high school this instruction should contain only physiology enough to make the hygiene of temperance and other laws of health intelligible. Temperance should be the chief and not the subordinate topic, and should occupy at least one fourth the space in text-books for these grades." In the same 'Great Petition to Publishers' we find it also stated that "Those text-books that are largely physiology with a minimum of temperance matter * * * do not meet the requirements of the law, and do not satisfy those who secured its enactment, and *are determined to secure its enforcement.*" Further on, publishers are told exactly what is wanted, in great detail and in no uncertain tones.

Text-books conforming with these requirements of the propaganda may be officially 'indorsed' by a 'Committee of the Advisory Board' sitting in council for the purpose. In another chapter, entitled the 'Text-book War Over,' it is stated that 'in response to the Great Petition most of the publishers have expressed the desire to have their books revised, on condition that the National Superintendent of the Scien-

tific Department of the Woman's Christian Temperance Union would revise them or supervise their proposed revision.' That is to say many publishers were naturally eager to have their books 'indorsed' by Mrs. Hunt, doubtless hoping thereby to increase their sale. On August 10, 1888, Mrs. Hunt 'with secretaries and helpers returned to Hyde Park, Massachusetts and opened again 'Hope Cottage' which became the local base of operations for text-book revision.' "That these revised books might be distinguished at a glance from the unrevised and unworthy books a committee was chosen * * * to indicate upon each its character. * * * The position of the chairman (Mrs. Hunt) of this committee chosen to extend the indorsement to school text-books of this kind in behalf of the signers of the Great Petition to Publishers and of the Woman's Christian Temperance Union has proved a very trying one and a most severe test of loyalty to principle."

I may remark in passing that one is frequently reminded in Mrs. Hunt's 'histories' that the United States Commissioner of Education is, or was, a member of the Advisory Board which has conducted this remarkable propaganda. As to the propriety of the Commissioner's connection with this movement I make no comment.

It would be tedious, though not uninteresting, to give many more quotations from the extraordinary documents which recount the history of the 'scientific' temperance movement. Those who desire to inform themselves more fully should not fail to consult the original authorities referred to above. As an illustration of the almost hysterical scenes accompanying the work of securing favorable legislation by this particular propaganda, I cannot forbear quoting the 'Report of an Eyewitness' describing the passage of the Pennsylvania law: "As the work of widening the temperance sentiment goes on we come now and then,

would that it were more frequently, to the place where the only thing to do seems to be to raise an Ebenezer, and the only thing to say is 'Hitherto hath the Lord helped us.' * * * Upon a great tide of womanly support that buoyed her up on wave after wave of prayer and of faith in her powers, has the leader of this work (Mrs. Hunt) been borne from city to city like a brave ship, laden with the treasure of knowledge and blessing to be spread out before the listening people. * * * Then follows a description of the State Capitol, and of the gathering legislators, of their good-natured reception of Mrs. Hunt, of her address and its effect, after which the writer passes on to the opening of a following session: "Almost before the amen of the opening prayer had been uttered, a dozen members were on their feet offering the petitions sent in from their various districts in behalf of the bill for 'scientific temperance education'; the dozens swelled to scores, and the scores multiplied all in a moment, until so many boy-messengers were flying down the aisles with the papers, and so many arms were waving in the air, that from every seat there seemed suddenly to have sprung a great, fluttering, white blossom of petition. * * * I make no mistake when I call Mrs. Hunt the mother of the bill. * * * Behind this mother of the bill stood some of those who have borne it so closely upon their hearts that they may properly be called its god-mothers, its sisters, its consins and its aunts." The bill was passed and signed by the Governor and the writer remarks, 'It was a God-given victory and to Him be all the praise.'

One of the humors of the passage of a national law requiring 'scientific' temperance instruction at West Point, at Annapolis, in the District of Columbia and for all schools under Federal control, was a debate in the Senate in which "A certain senator declared that 'rum-sellers or patrons

of rum-sellers have as good a right to have their views on temperance education printed by the National Government as any woman.' * * * The following extract," says Mrs. Hunt, "from a letter a lady from his own State wrote that senator is a fair illustration of the reception his ideas received among his constituency: 'When I knew you, sir, in our state, you were a chivalric Southern gentleman. Imagine my indignation at the audacity of the reporter who dares to report you as saying that "liquor men have as good a right to be heard in the Congress of the United States on the education of the children as any lady.' * * * I am sure you must be misrepresented, for no man who would say such a thing in the national Senate could represent a white man's government from this State.'" 'Many such letters,' adds Mrs. Hunt, 'reached that senator, and thus his opposition died.'

No wise educator who has given any attention to the subject can deny that the influence of this powerful propaganda has been in most respects injurious to the proper teaching of physiology and hygiene in the lower schools. Teachers, principals, superintendents, and even school committees, are seldom able to speak with perfect frankness on the subject, from fear of the influences which may be brought to bear against them or of the intemperate criticism to which they may be exposed; and in my opinion it is time for a body of scientific men like the American Society of Naturalists or the American Association for the Advancement of Science to put on record its opinion that the subjection under which science and education are to-day suffering from the 'temperance physiology' propaganda has become intolerable.

I lately examined with some care a good text-book of elementary physiology and was shocked on opening it to find at the

very beginning, and in a most prominent place, an entire page devoted to an 'indorsement' of the book by the self-constituted oligarchy which has the assurance to 'approve' or not, as it sees fit, text-books on physiology and hygiene for use in secondary and lower schools. In the case I mention this committee did not even confine their 'approval' to the alcoholic and narcotic portions of the book but 'indorsed' also its 'amount of matter on general hygiene,' as well as the 'presentation of matter with regard to its adaptability to the class of students for which it is designed'; or, in other words, passed upon its scientific and pedagogical merit, as well as upon its alcoholic value. If, as would sometimes seem to be the case, it has actually come to pass, at the beginning of this twentieth century, that a writer who desires to publish an elementary text-book on physiology and hygiene, before he can obtain a publisher or a market, may have to secure the 'indorsement' of 'Mrs. Mary H. Hunt, World's and National Superintendent of Scientific Temperance Instruction of the Woman's Christian Temperance Union,' of 'the Rev. Daniel Dorchester, D.D., Vice-President of the Massachusetts Total Abstinence Society,' and the rest of this self-constituted committee, it is high time that cognizance should be taken of the fact by scientific men and educators and a protest entered.

On further examining the book to which I have just referred, I was even more disturbed to find that this author, like some other recent writers on elementary physiology and hygiene, doubtless with the New York law before his eyes (which requires that 'this subject must be treated in the text-books in connection with the *various divisions* of physiology and hygiene, and pages on this subject in a separate chapter at the end of the book shall not be counted') had actually felt bound to

weave in a lesson on alcohol with his discussion of the physiology of muscle, of nerve, of digestion, of vision, and each of several other sections of the subject, so that all his work seemed literally tainted with alcohol.

It is a notorious and a disgraceful fact, that, apparently with a view of pleasing this self-constituted oligarchy, some writers have even made alcoholic instruction the beginning, the middle, and the end, of their text-books. Of such books it may truly be said that they have no permanency of their own, and are only with difficulty preserved by alcohol.

What I have said thus far of this subject applies mainly to elementary education; but those who have witnessed the virulent attacks upon a conscientious chemist and physiologist, who has recently made important physiological experiments upon the oxidation of alcohol within the human body, because his experiments have seemed to confirm the earlier statements that alcohol in minute quantities is more like a food than a poison, do not need to be told that this same propaganda is quite as eager to bring science, as it has already brought education, under its powerful dominion. Signs are not wanting, however, which indicate that its control has already reached its climax, and even begun to decline.

An attempt in 1899 on the part of Mrs. Hunt and others to make the Massachusetts law conform more closely to the ideas of those interested in 'scientific temperance' was stoutly resisted by the Massachusetts Medical Society, as well as by various scientific men and educators, with the result that the statute of 1885 remains unchanged. This prescribes that 'physiology and hygiene, which in both divisions of the subject shall include special instruction as to the effect of alcoholic drinks, stimulants and narcotics on the human system,

shall be taught as a regular branch of study to all pupils in all schools supported wholly or in part by public money, except special schools maintained solely for instruction in particular branches, such as drawing, mechanics, art and like studies.' With the exception of the clause 'to all pupils' this statute is not unreasonable, for, as I have said above, it is right and proper that the youth of the land should be taught, plainly and thoroughly, the dangers which lurk in alcoholic drinks, in narcotics, etc. What is unnecessary and objectionable is that the exact amount of such teaching should be prescribed by law; and that the method of teaching (by text-books in the hands of the pupils), the space devoted to it, and its treatment, in text-books, should be legally regulated. That, in addition, the particular text-books used should be largely determined by a self-constituted and unofficial oligarchy, leaders of a propaganda, which, in any right use of the terms, is neither educational nor scientific, is both odious and intolerable.

In Connecticut, in 1901, a statute of the objectionable sort referred to above was repealed, and one to which but little exception can be taken was enacted in its place. It is gratifying to note, also, that the Department of Superintendence of the National Educational Association, at a meeting in Chicago in the early part of the same year, adopted a report containing the following significant, if guarded, paragraphs:

"The questions of highest importance for teachers and superintendents of schools to consider [concerning 'temperance physiology'] are those which relate to the methods by which temperance instruction shall be imparted, the extent to which it shall be carried, and the subject-matter to be presented.

"The educational side of this question is vitally important, and demands thor-

ough and systematic study.' This action is timely and welcome in view of the existence of an opinion like the following, expressed in a letter to me by a representative of a prominent publishing house: "I feel that we can not be too emphatic in expressing sympathy with your movement and in denouncing the intimidation of teachers and other educators which has gone on for some years. The whole so-called temperance physiology movement of the W. C. T. U. seems to have fallen into the hands of blackmailers and schemers, who pull the wool over the eyes of the rank and file of the organization, and work both schools and publishers for their own financial benefit. You are quite right in saying that the school teachers are 'bullied'; they are, and they do not dare resent such action as it should be resented."

Time fails to deal, as I would be glad to do, with other forms of propaganda which seek to bring under their special subjection various departments of science or education. One of these is that known as the anti-vaccination movement, which is widely supported not only in England, but of late also in America, and has already succeeded in both countries in modifying very materially those requirements of compulsory vaccination indicated by science, experience and common sense. It is true that compulsory vaccination should be undertaken only after the most careful consideration, for it constitutes a serious trespass upon the fundamental right of personal and individual liberty. But I have no idea that this movement will ever seriously subvert the cause of vaccination, for the reason that a lively epidemic of small-pox will generally bring the majority of the people to their senses, and such epidemics are tolerably sure to come if anti-vaccinationists become too numerous or too active. I must, however, enter a protest against those medical practitioners who after

merely prescribing powders for children give them certificates of 'vaccination' which will enable them to attend the public schools. Such lying and deceit merit only the condemnation and contempt of all lovers of science and truth.

Naturalists should also be on their guard against the influence of that new but rapidly growing sect, known as Christian Scientists, which virtually denies the existence of disease and accordingly, logically enough, disapproves of all teaching of physiology and hygiene. It has recently come within my own knowledge that a Christian Scientist refused to attend a lecture on domestic economy by an expert because the latter happened to be at the time attending a meeting of the American Public Health Association, alleging that no one could be worth hearing on the subject appointed who had anything to do with an Association devoted to a purpose so useless.

With propagandists besieging more or less successfully our halls of legislation, the time has come when bodies like the American Society of Naturalists and the American Association for the Advancement of Science should have standing committees on legislation, to take care, as far as possible, that unwise, extravagant or fanatical ideas regarding science and education shall not be given the force of law by the several States or by the Federal Congress.

If to-day we have little to fear from dogma or theology we may still have much to dread from foolish or needless legislation; and I desire to urge upon all those to whom these words may come, the duty, alike of individual watchfulness and of united effort, to resist everywhere and always the statutory subjection of science and education to propaganda.

WILLIAM T. SEDGWICK.

MASS. INSTITUTE OF TECHNOLOGY.

*A SUMMER'S DREDGING ON THE COAST
OF SOUTHERN CALIFORNIA.**

A CONSIDERABLE piece of marine biological exploration was carried on along the coast of southern California during the past summer by the Zoological Department of the University of California. This was made possible financially by the augmentation of University funds that could be devoted to the undertaking chiefly through the efforts and generosity of Mr. H. W. O'Melveny, Mr. J. A. Graves and Mr. Jacob Baruch of Los Angeles; but to numerous other gentlemen and ladies of that city the warmest thanks are due both for financial assistance and for intelligent interest in and encouragement of the work.

The purpose of the undertaking was investigation. As, however, a little formal teaching could be done without greatly increasing the expenditure or hindering the main work of the summer, it was thought best to offer a few courses of instruction. Three of these were consequently given. One in general marine zoology, one in physiology, and a third for students sufficiently advanced to work under guidance on special problems.

The scientific staff, all from the University of California, consisted of:

William E. Ritter, Ph.D., Associate Professor of Zoology, in charge.

J. W. Raymond, B.S., Assistant Professor of Physics, Hydrography and Conchology.

C. A. Kofoid, Ph.D., Assistant Professor of Histology and Embryology, Zoology and Hydrography.

F. W. Bancroft, Ph.D., Instructor in Physiology.

*A portion of the Preliminary Report to the President of the University of California on the Marine Biological Explorations conducted by the Zoological Department of the University on the coast of southern California, during the summer of 1901.

H. B. Torrey, M.S., Instructor in Zoology.

Alice Robertson, M.S., Le Conte Fellow in Zoology. In charge of the collections.

In addition there were present at the laboratory for longer or shorter periods during the summer, for the prosecution of independent studies:

Mr. W. C. Adler-Mereschkowsky, a Russian diatomist, now of Los Angeles.

T. D. A. Cockerell, Entomologist of New Mexico Agricultural Experiment Station, East Las Vegas, New Mexico.

W. R. Coe, Ph.D., Assistant Professor of Zoology of Sheffield Scientific School, Yale University.

S. J. Holmes, Ph.D., Instructor in Zoology, University of Michigan.

Miss Sarah I. Monks, Instructor in Zoology, State Normal School, Los Angeles.

Miss G. R. Crocker, graduate student, University of California.

Mrs. Ida Oldroyd, Los Angeles, California.

Fourteen persons, mostly teachers of biological subjects in colleges and high schools of California, were enrolled in the elementary courses.

In view of the importance of the field, and the meagerness of previous investigations in it, it seemed best to plan the summer's work as though it were to be the beginning of a detailed biological survey of the coast of California, even though no assurance could be had of the possibility of continuing the work beyond this season.

Such a survey would of necessity comprehend the investigation, not merely of the life of the area, but as well of the physical conditions under which it exists. It would have to be hydrographic as well as biological. The limitations of the equipment and the force of workers determined what might be undertaken for the summer. Soundings, temperature and specific gravity determinations, and the character of

the bottom were practicable on the hydrographic side. Current investigations, fundamental in importance as they are, could be prosecuted to but a very limited extent.

The dredge and trawl were chiefly relied upon in the collecting. For various reasons it was found both impracticable and unwise to attempt deep plankton work to any considerable extent; neither could surface plankton collecting be extensively carried on, though the limited efforts in this direction were productive of interesting and valuable results.

Both the hydrographic and the biological explorations were extended from the shore line to the hundred-fathom curve. The general purposes of the summer's undertaking dictated that the explorations should be carried out with as much accuracy and detail as possible within these bathymetric limits, and that the geographical range over which they should extend should be made secondary to this aim. San Pedro was selected as the base of operations, on account both of its central location in the area to be surveyed and its natural advantages as a site for a marine station. The plan was to explore the coast immediately contiguous to this place and then extend the work to the south and north as far as the time would permit. It was hoped before operations began that they might reach to San Diego at the south, Point Conception at the north and various of the islands off the coast. Experience proved, however, the impossibility of accomplishing so much. The areas actually covered are about thirty miles of coast in the vicinity of San Pedro, viz., from Redondo pier on the northwest to Newport Bay on the southeast; around Santa Catalina Island; and the vicinity of San Diego from the Los Coronados Islands on the south to La Jolla on the north.

The following table, compiled from the

field records, shows something of the amount and distribution of the summer's work:

Locality.	Stations.	Hauls.			Tem.	Soundings.	Salinity.
		Dredge or Plankton.					
		Trawl.	Surface.	Deep.			
San Pedro	27	40	66	3			
Catalina							
Island	17	31		4			
San Diego	41	88		4		23-	
Total.	85	159	66	11	194+	170+	
						19	

EQUIPMENT.

Vessel.—The new gasoline launch *Elsie*, forty feet in length over all, with a 17-horse-power engine, was hired for three months, from May 15 to August 15. The boat proved to be excellently adapted for the purpose, although not built for such service. Contrary to the usual practice in the construction of boats of this type, her entire middle and after portions are without cabin, and are consequently available for working space. The hoisting gear was placed in the middle. The after-deck was supplemented by a temporary structure, extending between it and the hoisting winch, to be used for receiving and sorting the contents of the dredge.

One of the most serious obstacles in the way of successful dredging and trawling with a vessel propelled by a gasoline engine is always found in reducing the speed of the boat sufficiently to keep the trawl on the bottom during the towing without unduly weighting the apparatus. The problem was solved in this instance by using a battery instead of the engine's dynamo for exploding the gasoline, and by casting out a sea-anchor under some conditions.

HOISTING GEAR AND COLLECTING APPARATUS.

A hand winch was used for handling the collecting apparatus. With this the strength of four men was sufficient for accomplishing the dredging aims of the expedition, although it was found that a

depth of a hundred fathoms for the dredge, and three hundred fathoms for the deep plankton net, reached about the limits of practicability. Manila rope nine sixteenths of an inch in diameter was used for all the dredging and deep plankton work.

HYDROGRAPHIC APPARATUS.

The sounding apparatus consisted of the ordinary leads of twelve and twenty pounds weight, galvanized steel wire, No. 10, of the American Steel and Wire Company's grading, and a hand reel, used both for paying out and for reeling in, and for registering the depth. The Miller-Casella thermometer was used for all temperatures below the surface. Surface and atmosphere temperatures were mostly taken by an ordinary chemical instrument. The bucket for taking subsurface samples of water consists of a brass tube 47 mm. in diameter and 500 mm. in length. The closed lower end is provided with a valve opening inward. The upper end is open during the descent of the instrument, so that the water may pass freely through it. The bucket is attached to the sounding-line above the lead and thermometer, the line being passed through the length of the tube and the middle of its bottom. The instrument having been sent down to the depth from which the water sample is desired, is then closed by a messenger sent down on the line. The apparatus was not satisfactory, but was the best obtainable under the circumstances. No observations on the composition of the water were attempted, beyond the determination of its specific gravity. For this work the most sensitive hydrometer available was one with a range of scale 1.000 to 1.040. This not being sufficiently accurate for wholly reliable results, the main dependence was placed upon weighing the water samples.

It was, of course, impossible to use either

salinometer or scales on board the launch, but precautions were taken not to allow the water samples to remain long in the bottles before being tested. Temperature corrections were made in all cases. The salinity observations are the least satisfactory, probably, of any of the work seriously attempted. The difficulties of this phase of hydrographic investigation are well known to all experienced in it; and greater refinement of both appliances and methods than the funds at our disposal this summer would permit would be necessary to make it satisfactory.

THE LOCATION OF STATIONS.

An essential feature in such a survey as is here contemplated must be a study of the change in the life of particular localities with the passage of time. The displacement of species and groups of species by others through physical or biological influences; their increase in numbers of individuals; their migrations, etc., are among the most important, but least understood, questions of marine biology. Data for sound generalizations on these questions must meet two general conditions: First, they must be gathered at fairly frequent intervals throughout an entire year at least; second, they must be gathered from the same identical spot, so far as this is possible. The locating and picking up of stations becomes, consequently, a matter of prime importance. After consultation with several experienced hydrographers, particularly to be mentioned being Professor George Davidson, Mr. Otto Von Goldern, U. S. Engineer Corps, and Lieut. Commander G. C. Calkins, U. S. N., it seemed best to depend upon the sextant for this work. It was believed that greater accuracy could be secured than with the compass, and that it would be more practicable and less expensive than the range-pole method. In the hands of Professor Raymond for the first portion of

the season, and of Professor Kofoed for the second portion, it proved as satisfactory as any method could, I am convinced. The difficulties in the way of making the haul with the dredge or trawl over precisely the desired course were found to be wholly independent of the method of locating the station. Of these, the drift due to wind and current, which frequently renders it impossible to get the dredge to the bottom at precisely the point after this has been located, is the most serious. It was found practicable to approach within fifty yards of a desired point two or three miles off shore at the first trial; and by maneuvering once or twice, giving careful heed to the currents and wind, the point may be reached almost exactly. This requires, of course, considerable practice with the sextant, and skill in handling the engine and wheel of the boat.

The procedure consists, as is well known, in locating two angles from three points on shore that are shown on the Coast and Geodetic Survey charts and are as near the level of the water as possible, and not near the circumference of a circle the center of which is the observer; and then of plotting the station on the chart by the use of a tracing-paper protractor.

This method could not be used, of course, at any considerable distance from land, nor on a coast devoid of prominent headlands or other permanent conspicuous objects, nor where fogs are prevalent. Within the geographical and bathymetric limits, however, set for the summer's operations, none of these restrictions applied. At no point is the one-hundred-fathom curve more than ten miles off shore; and in only a few places is it more than five or six miles off.

LABORATORY.

Two small wooden buildings at East San Pedro were rented for the summer and rebuilt to adapt them to the purposes of a

laboratory. These buildings were situated on the breakwater near the pier belonging to the Salt Lake, Los Angeles, and Terminal R. R. This location was selected because of its convenience on the one hand to the inner harbor, and on the other to the open sea. On the harbor side a landing for the launch was at hand within a few yards of the laboratory, and the freight and express offices were equally near by. On the ocean side sea water entirely unpolluted by refuse from shore or shipping came to the very door of the laboratory.

Of the two buildings, one, an old bathhouse, was fitted with seven small private rooms for the use of the investigators, though one of these had to be set aside for the library.

The second building, a larger one, was used for the summer-school classes, for storage and for some of the investigators who could not be provided with private rooms. Accommodation was supplied for a class of fifteen students.

The laboratory equipment, consisting of the usual sort for seaside work, as also the library, were sent from the University at Berkeley.

INVESTIGATIONS PROSECUTED AT THE STATION.

'The Classification and Structure of Diatoms': MR. WM. CONSTANTIN ADLER-MERESCHKOWSKY.

'The *Peridinium* Visitation that took place on the Southern Coast during the Summer': MR. H. B. TORREY.

'Speiographic and Ecological Studies on the Actinians of the Region': MR. H. B. TORREY.

'The Systematic Position and Variation of various species of Echinoderms': MISS G. R. CROCKER.

'The Variation and Autotomy of the star-fish *Phataria unifascialis*': MISS SARAH P. MONKS.

'The Nemertean of the Region': DR. W. R. COE.

'The Opisthobranch Molluscs of the Region': PROFESSOR T. D. A. COCKERELL.

'Classification and Distribution of the gastropod and bivalve Mollusca': PROFESSOR J. W. RAYMOND and MRS. IDA OLDROYD.

'Speciographic and Anatomical Studies on Bryozoa': MISS ALICE ROBERTSON.

'The decapod and amphipod Crustacea': DR. S. J. HOLMES.

'Selection in the Mortality of *Hippa* due to the Peridinium Visitation': DR. F. W. BANCROFT.

SOME OF THE SCIENTIFIC RESULTS OF THE
SUMMER'S WORK.

Hydrographic.—On this side it was not felt that the data collected are sufficient in quantity to warrant any statement about them in a preliminary report, beyond the mere presentation given above, of what was done.

Geological-Biological.—The observations made corroborating the view that Santa Catalina Island has recently been undergoing subsidence have already been published in this journal, October 11, 1901, p. 575, and need not be repeated.

Special interest, from the biological side, was attached to the exploration of the peculiar 'submarine valleys' that are so characteristic a feature of the coast of California, Lower California and Mexico. As,

however, a complete study of them will lead into deeper water (at their seaward ends into at least eight hundred fathoms*) than we were this year fitted to penetrate, and will go beyond the limits to which detailed soundings have been carried by the Coast and Geodetic Survey, our observations are yet too few and fragmentary to warrant any general conclusions. Two points may, however, be mentioned as having been brought out by our work. *First*, that the bottom deposits of some, at least, of the valleys, for example that at Redondo, even at the distance of several miles from shore, are of a character to prove that close inshore material is carried into them in large quantities. Shore-worn shells of strictly littoral, and even fresh-water species; fragments of drift-wood; kelp hold-fasts, of which none grow in the immediate vicinity, etc., were taken in abundance by the dredge.† *Second*, various species of deep-water fishes, crustaceans and molluscs were taken much nearer shore in these valleys than elsewhere.

The first mentioned observation suggests, though of course does not prove, that the valleys are natural channels through which currents flow, at times at least, *from the shore out to deeper water.*

*The U. S. S. *Albatross*, surveying the Monterey submerged valley with a view to its possible termination for a transpacific cable, found 868 fathoms sixteen and one half miles from shore.

†Professor Davidson gives something on the character of the bottom in most of the valleys, as determined, presumably, by the soundings. This method cannot be relied upon for the detection of such deposits as are here described. It is a suggestive fact, however, that the author mentions, in connection with the Cape Mendocino submerged valley, that "the valley itself has green mud, and yet in two places at depths of three hundred and twenty fathoms broken shells were brought up with gravel." ('The Submerged Valleys of the Coast of California, U. S. A., and of Lower California and Mexico,' *Proc. Calif. Acad. Sci.*, 3d ser., Geol., Vol. I., No. 2, 1897.)

It cannot be doubted that future study will prove these valleys to play an interesting part in the local distribution of marine life, particularly in the bathymetric distribution. Whether currents ever flow through them *from the deeper waters toward land* or not, certain it is that the temperature and pressure conditions within them are the same as for corresponding depths elsewhere; they must, consequently, form natural roads whereby deeper water species may reach nearer shore than they otherwise would.

BIOLOGICAL.

Diatomes.—Mr. Adler-Mereschkowsky came to California for the purpose of studying the diatomes of the West American coast. He has already published a list of California species. The summer's work at the San Pedro laboratory resulted, so far as the studies have yet gone, in identifying fifty known species and ten new ones, with one new genus.

But the most fruitful part of Mr. Adler-Mereschkowsky's work was that on the endochrome of these organisms. His observations here have led him to conclusions widely different from the prevailing views concerning these bodies.

Protozoa.—There occurred during the summer on the coast of southern California what might be called a *Peridinium* epidemic, for the people even, who resort in large numbers to many sea-shore points during the summer months, did not escape the noxious effects of the visitation.

No similar occurrence of this organism on the Pacific coast of North America is recorded so far as I am aware. Indeed, inquiry among many old fishermen, and longshore seamen, who have been familiar with the region for many years, elicited the affirmation, in every instance, that such a thing had never before taken place within the period of their acquaintance with the coast. As full a study of the phenomenon

was made as the facilities at our command would permit, and the results as brought together by Mr. H. B. Torrey are now with the *American Naturalist* for publication. A summary only of these results is, consequently, given here:

1. The duration of the visitation of the organism in sufficient quantity to appreciably color the water was from about July 7 to September 1, 1901.

2. The geographical extent of the phenomenon was from Santa Barbara at the north to San Diego at the south, at least (it may have extended farther south, but we have no reports from more southerly points); and in general from the shore out from four to six miles.

3. Nowhere were the organisms distributed uniformly over considerable areas, but were confined more or less completely to bands or strips varying from a few to many meters in width. They extended to the bottom at a depth of six fathoms at least; but the appliances for determining the bathymetric range were not sufficiently accurate to produce wholly reliable results.

4. The color imparted to the water varied from a light brown, where the organisms were in moderate numbers, to a vermilion, where they were in greatest abundance. The red coloration was due to material of this color contained in the nucleus. At night the phosphorescent display, at the slightest agitation of the water, was truly wonderful.

5. The presence of the organisms in such enormous numbers disturbed the biological equilibrium to a marked degree through the whole area. Several species of fishes, crustaceans, holothurians, star-fishes, and molluses, in particular, suffered a severe mortality, and showed various unmistakable evidences of discomfiture.

6. The injurious effects were apparently due entirely to crowding and the contamination of the water. The odor at times on

the lee shore, and for a considerable distance inland, was very offensive. This was due to the *Peridinium* itself, and not to animals killed by it. In character it was a modification of the ordinary odor of decomposing organic matter, and was mostly due to the dead organisms cast up on the shore.

7. A considerable list of other species of chlorophyl-bearing dinoflagellates were present in the water mingled with the *Peridinium*, and these, particularly several species of *Ceratium*, largely increased in numbers simultaneously with the increase of *Peridinium*, though to a comparatively slight extent.

8. The only pelagic organism that seemed to take advantage of the great abundance of *Peridinium*, as a food supply, was *Noctiluca*, which towards the end of the visitation became abundant, and fed upon the *Peridinium* in large numbers.

9. But a single species constituted almost the entire mass, this apparently belonging to the genus *Gonyaulax* Diesig.

10. It was impossible to correlate the enormous multiplication of the organism with any physical or chemical condition of the water. The cause of such a phenomenon remains for future investigation.

Cœlenterata.—Siphonophores and ctenophores were taken in far greater abundance, as to both species and individuals, in the plankton this year than we have ever before seen in the waters of our western coast. Worthy of mention, also, is the fact that *Varella*, which at rare intervals appears in enormous abundance on the coast, was found to be throwing off medusa buds in great numbers during May and June.

Whether the richness in pelagic metazoan life, seen not only in the groups here mentioned, but also in the Pteropoda, Heteropoda, *Sagitta*, *Salpa*, *Doliolum*, etc., may have been correlated with the conditions which resulted in the enormous de-

velopment of *Peridinium*, it is impossible to say owing to the lack of data from previous observations.

Perhaps the most interesting observations on the Cœlenterata were those made by Mr. Torrey on the longitudinal fission, from the base oralward, of a species of *Sagartia*.

Echinodermata.—Of the several interesting questions in connection with the speciology and ecology of the echinoderms, which received attention, mention may be made of two. The representatives of this branch of the animal kingdom, the most common and generally distributed over the area in which work was carried on, are an *Astropecton* (*A. erinaceus* Gray?) and a *Toxopneustes* (*T. pileolus* Ag.?). Few hauls were made anywhere that did not secure specimens of these species, the *Toxopneustes* being particularly abundant. A single haul of the dredge on Station XIII. off Point Vicente in thirty-five fathoms brought up about twelve thousand specimens, by a careful estimate, and little else! Now the type of *Toxopneustes pileolus* is a littoral animal occurring everywhere on rocky shores. The forms dredged are of a different style. They are somewhat flatter, the spines are more slender; and the color is lighter; yet the two grade into each other. It is almost certain that we have here the differentiation of two species in progress and nearly complete, bathymetric range being the chief differentiating factor.

A large quantity of material and considerable data for the further study of this point were gathered. In a somewhat similar way *Astropecton* is a distinctly bifurcate species. Indeed, one of the forms has sometimes been considered as a *Psilaster*. Their intergradation is, however, from our summer's observations proved to be complete. Longer spines with intermarginal plates, purplish and bluish color and

larger-sized individuals, are the characters usually distinctive of *A. erinaceus*. But these all fail to furnish differential marks for many specimens.

With these two forms, contrary to what we find in *Toxopneustes*, *bathymetric range appears to play no part*, as they occur together everywhere in from eight to ten fathoms, to the greatest depths reached in our work. We have thus far been unable to correlate these two varieties with any environmental peculiarities whatever. The general distribution of these two species, as contrasted with the restricted distribution of some other species of both Echinoids and Asteroids in this locality, is noteworthy and is all the more interesting when the variability—as contrasted with the lack of variability in other species localized in their distribution—is regarded. *Mediaster equalis* Verrill, for example, may be cited as a species of great rigidity in type. The individuals of this species all have the appearance of having been cut out by the same die, so alike are they in form; and having been dipped in the same paint-box, so similar are they in color. This species was taken at only two or three stations, and in any abundance at only one. Such facts as these strongly impress one who comes face to face with them with the scantiness of our knowledge of the deeper meaning of the relation of organisms to their environment.

Miss Monk's studies on *Phataria*, a starfish remarkable even among its close allies within the family Linckiidae, for the variability in the number of its rays, and the readiness with which it parts with them and then regenerates them, led to the following results:

1. The observations proved conclusively that the casting off of the rays is, in most cases at least, *not accidental, but a true self-amputation*.

2. As the breakage usually occurs at

some distance from the disk, and as the 'comet' stars are found abundant in nature, it appears as though the autotomy is for the purpose of asexual reproduction, and hence that the severed arm to which no part of the disk adheres has the power of reproducing the entire animal. But absolute certainty on this point is still to be reached.

A species of *Antedon* closely related to, if not identical with, *A. rosacea* was taken off San Diego in about one hundred fathoms. So far as I am aware, this is the first record of the occurrence of any species of this genus on the Pacific coast north of Panama.

Bryozoa.—Under the name of *Ascorhiza Californica*, Dr. Walter Fewkes described a new genus and species of Bryozoan dredged by him in Santa Barbara channel in 1886. The colony consisted of a well-defined capitulum, to which the polypides are restricted, and a long, slender, flexible stem. From the general resemblance of the stem to that of *Urnatella*, the author surmised the species to be related to the Endoprocta. In the capitulum, however, he recognized some resemblance to *Alcyonidium*. He, consequently, suggested that the form might stand intermediate between the Endoprocta and the Ectoprocta. As he did not, however, make out much about the polypides, he was unable to support the suggestion with much evidence.

Several specimens of this unique species were dredged during the summer, and from these Miss Alice Robertson has been able to establish definitely that its affinities are undoubtedly with *Alcyonidium*, and that its resemblances to *Urnatella* are wholly superficial. It is, nevertheless, a very interesting form, especially in the nature of the stem. Miss Robertson will shortly publish a paper on this and one or two other species of *Alcyonidium* of the Pacific coast.

A noteworthy fact in connection with the

Bryozoa of the regions worked in during the summer is the great abundance of the Endoproct *Ascopodaria macropes*. At no other point on our shores have we found this or any other Endoproct very plentiful. At San Pedro, however, nearly every rock one turns over presents a continuous moving field of this or a closely related species.

Mollusca.—No group of marine invertebrates of the Pacific coast of North America has been so extensively studied, systematically, as the shell-bearing mollusca. For this reason, then, if for no other, these animals are of special importance for studies on geographic and bathymetric distribution.

The expedition was fortunate in having for nearly the entire summer two such enthusiastic and well-informed conchologists as Professor Raymond and Mrs. Oldroyd in its membership; and a vast amount of material was secured, the detailed examination of which is, of course, still far from complete. Some idea of the wealth of the collections in the group may be gained from the statement that in the San Pedro and Santa Catalina Island areas alone two hundred and thirty species, exclusive of the Polyplacophora and Pteropoda, have been identified, and it is certain that the number will be largely increased by more detailed study. A few species are almost certainly new to science, though just how many it is not yet possible to say.

The total number of species of mollusca of the Pacific coast of Canada contained in the list published by Rev. G. W. Taylor in 1897 is two hundred and seventy-nine. The total number in the list of species of Los Angeles County, now in course of preparation and nearly complete, by Mrs. Oldroyd, is something over five hundred.

The familiar, though nevertheless striking, general rule of the occurrence in comparatively deep water off shore of species that are strictly littoral to the northward,

receives many illustrations in this group. A good example is furnished by *Priene oregonensis* Redfield, which occurs in a few fathoms at Sitka, Alaska, and was taken this summer in about one hundred fathoms off San Diego. *Cryptochiton stelleri*, also found in this locality for the first time this year, I believe, is another example of the same sort.

Professor Raymond has elsewhere* expressed the view that Point Conception marks a dividing line between molluscan faunæ to the north and south of it that are quite distinct; and Dall† affirms that Point Conception is the northern limit of the Panamic fauna.

The results of the summer's work, so far as they can yet be seen, confirm these views. To harmonize the apparent fact of this faunal delimitation with the view that the Davidson inshore current flows out of the Santa Barbara channel around Point Conception and then on northward, is only one of the many problems presenting themselves for solution on our coast.

Worthy of note is the discovery made by Mrs. Burton Williamson during the summer while at work at the laboratory, that at least two species of *Pecten* occurring on the southern coast, viz., *P. equisulcatus* and *P. diegensis* are hermaphroditic. A species of gymnosmatous pteropod related to *Pneumodermon pacificum* Dall, though probably a different species, was taken with the deep plankton net in San Pedro channel in considerable numbers. No species of this genus, excepting *pacificum*, has been reported hitherto from the California coast, so far as I have been able to ascertain.

Many of the specimens of a species of

*'The California Species of the genus *Nutalina*,' *Nautilus*, Vol. VII., 1894, p. 133.

†'Synopsis of the Family Tellinidæ and of the North American Species,' *Proc. U. S. Nat. Mus.*, Vol. XXIII., 1900.

Carinaria, apparently new, taken in considerable abundance off San Pedro, were found to be headless, though still alive and well, thus presenting a condition that has been observed by a number of naturalists in *Fivola*. This decapitate state was so common, and so uniform in character—*i. e.*, as to the size of the portion lost and the character of the wound—that it can hardly be supposed to have been due to mere accident. The meaning of this case is as difficult to understand as is that of the self-amputation of the posterior third of *Prophysaon* which has been noted by several observers, and which I have myself seen.

Of the opisthobranch and nudibranch mollusca, about twenty species were recognized in the San Pedro district by Professor Cockerell. Of these, five at least are almost certainly new.

Crustacea.—Of the seventy or more species of decapod crustacea taken at San Pedro during the summer (the San Diego collections have not yet been worked over), five, according to Dr. Holmes' preliminary examinations, are probably new to science, the presumably new forms all coming from deep waters. Among them may be mentioned as of special interest a Pagurid inhabiting the tube of the Annelid *Pectinaria*.

A noteworthy extension of geographic range in this group is that of three species of *Pandalus*, viz., *P. Danæ* St., *P. pubescentulus* Dana, and *P. franciscorum* Kingsley. None of these were before known to occur south of San Francisco and *pubescentulus* was not known farther south than the coast of Oregon.

The beautiful *Navanax inermis* Cooper, which is not uncommon in San Pedro harbor, is the residence of an interesting copepod which has the curious habit of using the slime of its host's external surface not merely for clinging so closely as to make its removal quite difficult, but also as

a medium in which to move about with great freedom and rapidity. Professor Cockerell, in particular, gave considerable attention to this curious case of commensalism.

The summer's work brought to light one new Enteropneust, making thus three species representing as many genera, from the San Pedro district. *Ptychodera occidentalis* Ritter MS. and *Dolichoglossus pusillus* Ritter MS. occur together in San Pedro inner harbor, while the one now added belonging, apparently, to the restricted genus *Balanoglossus*, was taken by the dredge in from seventeen to thirty fathoms off Newport, California.

The new species is related to *Balanoglossus canadensis*. Unfortunately, we were able to get only three specimens.

It is my intention to include the description of this species in my forthcoming monograph of the Enteropneusta of the Pacific coast of North America, now nearly ready for publication, and to appear in the scientific results of the Harriman Alaska Expedition.

About thirty species of simple and compound Ascidians were collected during the summer, the larger proportion of them being taken by the dredge only. At least four of these have not been taken before on the Pacific coast, and are almost certainly new to science. Even the deepest dredging failed to bring to light much of anything in common between the Ascidian fauna of this region and that of the Pacific coast north of Puget Sound. At the present time I identify two species, viz., *Amaroucium californicum* and *Distaplia occidentalis*, and possibly a third, *Styela montereyensis*, as ranging from western Alaska to southern California.

The work of Dr. Baneroff and Mr. Esterly on the heart-beat of *Ciona*, while still incomplete, arrived at the follow definite conclusions:

(1) The results confirm those of Schultz that isolated pieces from the center of the heart can contract in sea water. (2) They have established the new facts, (a) that in the intact animal the heart may sometimes beat *from the center towards both ends*; also, (b) that when the heart is tied near the center, the *isolated pieces may sometimes beat from the center towards the ends*; and (c) in *such pieces there may even be a regular alteration in the direction of the heart-beat*. These last results will probably necessitate a complete change in our conception of the character of the Ascidian heart-beat.

This is a proper place to record the occurrence of *Branchiostoma Californiense* at San Pedro, hitherto not known farther north than San Diego. About a dozen specimens were dredged during the summer, some in the inner harbor, and others outside but near its mouth.

It may also be noted here that the Point Loma blind fish, *Typhlogobius Californiensis*, hitherto not reported north of San Diego, was found at San Pedro. At White's Point it was found in holes in the soft rock and under stones; while during the *Peridinium* visitation a considerable number of specimens were cast ashore, some alive and others dead, along the breakwater at San Pedro.

WM. E. RITTER.

UNIVERSITY OF CALIFORNIA,
BERKELEY, October 29, 1901.

SCIENTIFIC BOOKS.

A Treatise on Hydraulics. By HENRY T. BOVEY, M. Inst. C.E., LL.D., F.R.S.C. Second edition, rewritten. New York, John Wiley and Sons. 1901. Pp. xviii + 583. Figs. 330. Price, \$5.00.

The second edition of Dr. Bovey's well-known text-book is practically a new work, having been largely rewritten, rearranged and nearly doubled in extent; forming a very important and valuable addition to the literature

of engineering education. It contains 583 pages and 330 figures, as against 337 and 196, respectively, in the first edition; embodying also some improvements in mechanical execution, such as the substitution of clear-cut line engravings for the few (but hazy) half-tones illustrating certain water-meters in the first edition, and the use of bold-faced type for important formulæ. Being printed on thinner paper the present volume possesses no more weight or bulk than the earlier book.

As in the earlier edition, the statements of many numerical examples, with their answers, are placed at the end of each chapter, and these have been greatly increased in number (*e. g.*, at the end of Chapter I. we find 106 examples as against 76 in the first edition); but a new and special feature in this respect consists in the insertion, in the body of the text in connection with each topic, of numerical examples fully worked out in all their details. This added feature will be heartily welcomed by engineering students possessing only average mathematical ability, and hence needing careful guidance in the principles of correct numerical substitution.

Among additions to the subject-matter the following are prominent:

A description of the elaborate apparatus in the Hydraulic Laboratory of McGill University, for experimentation with jets of water (as to coefficients of efflux, form of jets and impact of jets on vanes and cups of various shapes); with methods of use and results obtained.

An illustrated abstract (ten pages of fine print) of Bazin's papers in the *Annales des Ponts et Chaussées* on experiments with weirs; including the phenomena of depressed, drowned and adhering nappes.

In connection with flow in pipes, the formulæ of Darcy, Hagen, Thrupp, Reynolds, Lévy, Vallot, Manning, Tutton, Flamant, Foss and Lampe.

Many of the results obtained by Mr. C. H. Tutton in 1896 in his careful and extended collation, and logarithmic plotting, of the elements of some 1,000 recorded experiments on the flow of water in pipes; with diagrams and formulæ.

For uniform flow in open channels, the formulæ of St. Venant, Bazin, Manning, Tutton, Humphreys and Abbot, and Gauckler; and extensive tables of the coefficients to be employed with the formulæ of Bazin, Ganguillet and Kutter and Manning.

A practically new and well-illustrated chapter (Chapter IV., of 25 pages and 22 figures), on hydraulic rams, presses, accumulators and water-pressure engines.

Some of the results of Freeman's experiments with nozzles, jets and hose for fire-engines.

Considerable extra matter in the theoretical treatment of vertical water-wheels and turbines.

A new chapter (of 30 pages and 22 figures) devoted exclusively to centrifugal pumps; giving much practical detail as well as theoretical treatment.

References (on pp. 168 and 206) to the recent experiments made at Detroit by Prof. G. S. Williams and others on the flow of water in pipes; as regards the loss of head due to curves in pipes from 12 to 30 inches in diameter, and the distribution of velocity in the cross-section. (See *Proc. Am. Soc. Civ. Engineers* for May, 1901, and later discussion.)

It is seen that much of the above added matter has to do with the practical and experimental side of the subject; and in this connection it is perhaps to be regretted, from a practical standpoint, that the author had not omitted a large part of the theoretical treatment of unimportant and nearly obsolete forms of vertical water-wheels, substituting therefor some account of recent modern turbines and their appurtenances such as the wheels at Niagara Falls and the prominent American makes known as 'Victor,' 'New American,' 'Hercules,' 'McCormick,' etc.; with a chapter giving methods and results of tests of efficiency.

Criticism and comment on a few incidental points may perhaps be permitted. 'American' readers of the book may need to be reminded that the gallon employed in the numerical examples (gallon of water) is the Imperial gallon of 271 cubic inches used in England

and weighing 10 pounds. The weight of the United States gallon (8.32 lbs.) is not mentioned in the work, although its volume (231 cubic inches) is given in the preliminary table of 'Useful Constants.'

As to the compressibility of water (see p. 5) and corresponding modulus of elasticity of volume, the author might have mentioned the experiments described by Mr. Stillman on p. 236 of *Engineering News* of October 4, 1900. In these water was subjected to a pressure of 65,000 pounds per square inch, with a resulting reduction of volume of 10 per cent.

In the treatment of problems involving the steady flow of water in branching pipes the reader might have been reminded of the great saving in time and trouble that can be accomplished by the use of diagrams of friction-heads in pipes, such as are given in Collignon's 'Hydraulique' and in Coffin's 'Graphical Solution of Hydraulic Problems,' and incidentally in engineering periodicals. (On p. 415 of the *Engineering Record* for November 3, 1900, Mr. J. H. Gregory presents such a diagram; which, having a logarithmic basis, covers a wide range of values both of diameter of pipe and friction-heads.) Although many results of experiments with pipes are stated in graphic form (Tutton) in the work before us, the diagrams are not arranged with a view to giving aid in the solution of problems. Since only the logarithms, and not the quantities themselves, are figured along the edges of these diagrams, the latter are not available for ready use.

There would seem to be some inconsistency in presenting the numerical example of p. 161 as apparently an illustration of the theory given in article 12 ('Pressure Due to Shock') of p. 160. In article 12 the closing of the stop-gate is instantaneous, and the kinetic energy of the moving water is absorbed by the elastic compression of the water itself (the pipe being supposed fixed and its possible distension neglected). In the numerical example, however, the stop-gate is gradually closed and is supposed to be handled in such a way as to make the retardation of the cylinder of water *uniform*; and as the kinetic energy of the great mass of the water is gradually given up a

nearly equal amount of kinetic energy is generated in the smaller mass passing (with high velocity) through the narrowing sectional area under the edge of the gate. Here the compression of the water is not considered, the pressure being small; as is shown by the fact that neither the modulus of elasticity (of volume) nor the velocity of sound enters the equation employed. It would have been well to remind the student at this point that in the gradual closing of a stop-gate, if the motion of the gate is uniform the rate of retardation of the water can not be uniform, and that the pressure induced just behind the gate is consequently variable and reaches a maximum value which may be many times as great as the average pressure (which average is equal to the pressure produced when the gate is so managed as to make the retardation uniform, the whole time of closing remaining unchanged).

As to the discussion of the impact of a jet upon a flat plate or vane (p. 378), one cannot help thinking that it would have been preferable to substitute for this rather lengthy and involved treatment (where the reader must be uncertain whether the plate is furnished with borders parallel to the paper or not) the simple and direct analysis given by Rankine in Case V. of § 144 of his 'Steam Engine and Other Prime Movers' (also given by Cotterill).

On page 500, in the theory of the turbine, the term 'velocity of flow' is used in a sense entirely different from that specially defined on page 498; and on the same page (500) obscurity of language results from the apparent statement that impulse equals momentum (instead of change of momentum).

The author is evidently (p. 96) of the same opinion as Collignon (see 'Hydraulique,' p. 146) when he designates as 'gratuitous' the assumption that in the case of a flat-topped weir the flow adjusts itself to such a depth on the weir as to bring about a maximum discharge. Several authors have noted that experiment gives results not very wide of this relation. Unwin (p. 472, article 'Hydromechanics, Encyclop. Brit.) is rather non-committal on this point, though giving the same analysis; whereas Mr. J. P. Frizell (see *Engineering*

News of September 29, 1892) is plainly of the opinion that the flow should theoretically adjust itself to a maximum discharge.

I. P. CHURCH.

Dragons of the Air, an Account of Extinct Flying Reptiles. By H. G. SEELEY, Professor of Geology in King's College, London. London, Methuen & Co.

When so accomplished a student of extinct life as is Professor Seeley writes in so pleasing a way as he has of a group of animals to which he has devoted many years of study, the results can only be happy. Divested so far as is possible of technicalities, accurate in statement, lucid in presentation, and enriched by patiently gathered facts from many sources, his present work upon the 'Dragons of the Air' summarizes for the paleontologist, as well as for the general reader, about all that is known of those strange fossil reptiles called pterodactyls or ornithosaurs. The book contains a discussion of reptilian characters, the range and distribution of pterodactyls, a review of the known forms, and a thorough comparison of them with other vertebrated animals, part by part, a history of their development, inferences as to their habits, and conclusions as to their place in the animal kingdom.

It is illustrated by many figures and plates of the bones or skeletons of pterodactyls and allied animals, and by many restorations of the creatures as the author and others have conceived them. In a few words, the work, while popularized, is a critical review of this extinct order of reptiles from many sides, interesting because of the strangeness of the animals and valuable to the student of vertebrate morphology, as well as to the geologist.

However, with the fullest respect for the author's anatomical erudition and admitting the force of his reasoning in many cases, the present writer can not always agree with his conclusions. To review them all would be out of place here; the curious reader may expect a wider discussion elsewhere. Many of the bird-like or mammal-like characters which he sees in the pterodactyl, Professor

Seeley would ascribe to ancestral, fundamental impressions, and not to adaptation. The present writer believes that the elongation of the wing finger, the progressive weakening of the middle fingers and the peculiar shape of the first finger are all purely adaptive, together with the shape of the humerus, the peculiar form of the sternum, the anchylosis of bones, the shortening of tail and concomitant increase in length of the sacrum, the diminution and loss of the fibula, the loss of teeth, retreat of the nostrils, etc. The bone in the lizard commonly called the squamosal extends to, or nearly to, the brain surface in the mosasaurs. If the determination of the bone be right, this character loses its value as an avian index in the pterodactyls; if wrong, there is the same possibility in the pterodactyls. *Dimorphodon* had the fifth toe peculiarly modified for the sustentation of the patagial membrane. What good reason then has Professor Seeley for supposing that this specialization was lost in later forms; that the membrane was restricted to the sides of the body only? The rudimentary fifth toe in *Ornithostoma* was divergent. What use had it unless that of *Dimorphodon*? In bats the membrane extends to the ankle and over the tail. It is reasonable to suppose that such were its relations in all the pterodactyls, the later as well as the earlier.

Especially does the writer disagree with Professor Seeley in his opinion that the quadrupedal position of the body in ambulation was a normal one. He doubts very much whether the peculiar articulation of the humerus would permit such a position of the bones in some of the pterodactyls. And what use were the loosely attached middle fingers of some pterodactyls as ambulatory organs? In a specimen of *Ornithostoma* recently acquired by the University of Kansas, the small fingers are in position, from which it is evident that they could not have been brought to the surface of the ground in a state of pronation. Nor does it seem reasonable that the animals walked upon the knuckles of the fifth fingers. In those animals in which the body is carried more or less erect, as in birds and dinosaurs, there

occurs elongation of both sacrum and ilium. In the early pterodactyls there were three or four sacral vertebrae; in *Nyctodactylus*, one of the latest, there were six true sacral vertebrae and one coossified lumbar. It thus would seem that some or all pterodactyls walked erect when upon the ground, with the knees probably much flexed. The pelvis of *Nyctodactylus*, with an expanse of outstretched wings of fully eight feet was less than seven eighths of an inch in diameter at the brim, and not three fourths of an inch at the outlet. The heads of the femora in the largest species measuring twenty feet in expanse were less than two and a half inches apart. If the legs were knock-kneed, as seems probable, both of the feet in such animals would have rested upon a space smaller than one's hand. In the posture I have indicated, with the body erect, the wing metacarpal bones would have rested upon the ground at the sides.

The eggs of *Nyctodactylus* could not have been three fourths of an inch in diameter, and of *Ornithostoma* not over two inches. How big would the young have been recently hatched from such eggs? Were they cared for by their parents after birth? Did the pterodactyls build nests?

S. W. WILLISTON.

PAPERS ON ENGINEERING.

The *Proceedings* of the Royal Society, just issued (Vol. XVI., Part II., Lond., Nov., 1901), contain a number of papers of peculiar interest in the field of applied science and engineering.

The opening article is by Lord Rayleigh, on 'Flight.' In this paper it is stated that the main problem in flight is that of the aeroplane, as in the case of the kite. But the kite is anchored and at rest relatively to the earth; while the aeronaut, the aviator, whether human or other, is adrift. No bird can maintain itself in motion in a uniform wind-current without active exertion, any more than in an atmosphere at rest. Soaring is thus evidently the outcome of utilization of internal movements of the atmosphere surrounding the bird. The albatross presumably takes advan-

tage of such movements where strata move in proximity with differing motions. Langley has shown the possibility of taking advantage of the gustiness of the wind when soaring. Attention is called to the fact that the horizontal motion of an aeroplane greatly increases the pressure beneath it when falling, tending thus to sustain it effectively. On this fact depends the possibility of flight. The sustaining pressure is also reinforced by an important complementary suction above, with similar effect in supporting the falling mass. Artificial flight is a question of speed of horizontal motion; no man can raise himself from the ground by any mechanism operated by muscular power except with preliminary acceleration in the horizontal direction. Lord Rayleigh is inclined to agree with Sir Hiram Maxim that the problem of artificial flight is mainly one of time and money. It would presumably be mainly a military problem. He does not think it will prove a safe method of conveyance; but, as Maxim has remarked, we have not even yet succeeded in making war quite safe.

The Hon. Charles A. Parsons, in the second paper, discusses motive power and the steam turbine. He commences with a paraphrase of a page in the introductory section of Thurston's 'History of the Steam Engine,' in which the account of the steam turbine in Hero's 'Spiritalia' is presented, and goes on to say that an experiment made years ago in the production of a redesigned Hero engine enabled him to obtain twenty horse-power on a consumption of but forty pounds of steam per horse-power-hour, which is a very fair performance for engines of the simpler modern forms and of similar power. A later model illustrated his system of compounding, but without commensurate advantage. Branca's turbine of 1629, similar in principle and general construction to the impact waterwheel, had been reproduced successfully by Dr. La Val and is in extensive use in a form illustrating modern scientific construction. In 1884, Mr. Parsons began his work on his now familiar form of compound turbine, adopting the type of wheel known in hydraulics as the impact turbine. This proved practically suc-

cessful, ultimately, and is now made in large numbers for electric 'plants.' It has been proved to be capable of as high economy as the reciprocating engines of the best modern constructors.

In 1894, the same plan was adopted for engines supplied to the *Turbinia*. The outcome was the redesigning of the screw-propeller and its method of application and the attainment of a higher speed than had ever before been recorded, 32½ knots, 38 miles, an hour. The steam consumption was 14½ pounds per horse-power-hour, a result better than was usually obtained in similar craft with even triple-expansion engines and under similar conditions of steam supply. About 28 pounds of steam were vaporized per square foot of heating surface of boilers.

The *Viper* and the *Cobra* have been later built on the same general plan and the former became the record-breaking vessel for the world, attaining above forty miles an hour (37,118 knots, 43 miles) on the dimensions of the regular 30-knot torpedo boat destroyer, a length of 210 feet, a beam of 21 feet and with 350 tons displacement. Water-tube, safety-boilers were fitted and the engines were of the compound turbine type.

A design for a war-vessel is hypothetically proposed on this plan and Mr. Parsons considers it possible to build a ship of 420 feet length, 42 feet beam and 14 feet draught, having 2,800 tons displacement, which should develop *eighty thousand* horse-power and a speed of 44 knots (over 51 miles) an hour. This represents a concentration of power never before dreamed of by the engineer, far less attempted or approximated, although an American designer, Mr. Mosher, has rivalled the work of Parsons in smaller craft.

Papers by Professor Ewing on the 'Structure of Metals' and by Sig. Marconi on wireless telegraphy fall into the same general category of work in applied science, and those of Lord Kelvin, Professor Dewar and others are in the field of pure science and have special interest through their promise of later utilization. Sir Andrew Noble presents a remarkable and illuminating discussion of the modern explosives.

R. H. THURSTON.

SCIENTIFIC JOURNALS AND ARTICLES.

The American Naturalist for December completes the thirty-fifth volume of this journal and contains the index for the year. The first article, by T. H. Morgan, is a discussion of 'Regeneration in the Egg, Embryo and Adult,' including the use of the term 'polarity' in organic beings and inorganic substances. The writer considers that the reorganization of living beings is an entirely different phenomenon from that of inorganic substances and one of the peculiar properties of what we call living matter. C. M. Child tells of 'The Habits and Natural History of *Stichostemma*, a small fresh-water nemertean, and W. M. Wheeler contributes another of his important papers on the history of ants under the title of 'An Extraordinary Ant-Guest,' this being a phorid larva which fastens itself to the neck of the larvæ of a large ponerine ant and feeds with its host on food prepared by the workers. Herbert W. Rand gives an extended abstract of 'Friedenthal's Experimental Proof of Blood Relationship'; this is found in the fact that the blood serum of vertebrates undeniably related to one another has no injurious effect on the corpuscles of the different species, while it dissolves those of unrelated species. Similarly the transfusion of blood of species of one family is harmless, while blood transfusion among species of different species is harmful and may cause death. The number contains the 'Quarterly Record of Gifts, Appointments, Resignations and Deaths'; Mr. Carnegie still continues prominent in the founding of libraries.

The Popular Science Monthly for January commences the sixtieth volume, and opens with a description of 'The Minnesota Seaside Station' by Conway MacMillan. The station is on the Straits of Fuca in a favorable locality for varied research. The problems of 'Antarctic Exploration' are considered by J. W. Gregory who notes the objects of the four expeditions now on the sea, and Francis Galton discusses 'The Possible Improvement of the Human Breed under existing Conditions of Law and Sentiment,' concluding that

this is not only desirable but possible. Charles V. Chapin writes of 'The End of the Fifth Theory of Disease,' but adds that we should not become too closely wedded to the germ theory which has replaced it. 'Recent Eclipses of the Sun' are described by Solon I. Bailey, Edward S. Holden contributes a sketch of 'Friar Roger Bacon,' and W. H. Dall briefly reviews 'Lamarck, the Founder of Evolution,' a biography by A. S. Packard. The final article is on 'Comet's Tails, the Corona and Aurora Borealis' by John Cox, being a detailed review of Arrhenius' theory concerning them.

The Plant World for November contains the 'Rooting of Oxalis Leaves' by John L. Shelton, 'The Blooming of Twining Honey-suckles' by Byron D. Halsted, 'Fairy Rings' by E. M. Williams, 'You Will Have to Hurry' by Aven Nelson, and 'Field Notes of a Mid-summer Tramp' by Charles C. Pitt. In 'The Families of Flowering Plants' Charles L. Pollard treats of the Order Parietales.

Popular Astronomy for January gives an account of observations on the recent Leonids, and an article by William H. Pickering upon the 'Period of Revolution of the Leonids.' R. G. Aitken, of the Lick Observatory, contributes an article entitled 'The Sources of Standard Time in the United States.' Shorter articles are 'An Asteroid Orbit of Great Eccentricity,' by E. C. Pickering; 'Eclipse Aid to Chronology,' by the Rev. Q. A. Wheat; 'The Period of Algol,' 'Transformation of the Differentials of Area and Volume,' by Asaph Hall; 'Motion in the Faint Nebula surrounding Nova Persei,' by C. D. Perrine, and a continuation of Dr. Wilson's 'Light Curve of the New Star in Perseus.'

BEGINNING with the new year *The Forester*, the official organ of the American Forestry Association and *National Irrigation*, the organ of the National Irrigation Association, will be combined and published under the name of *Forestry and Irrigation*.

DR. GEORGE B. SHATTUCK, of the Johns Hopkins University, has lately been elected on the Board of Collaborators of the *Annales de Géographie* to take the place of Professor Wm. M.

Davis, of Harvard University, who has recently resigned.

SOCIETIES AND ACADEMIES.

NEW YORK ACADEMY OF SCIENCES, SECTION OF ASTRONOMY, PHYSICS AND CHEMISTRY.

The Section met at the Chemists' Club on the evening of December 2. The following papers were presented:

Professor M. I. Pupin described an experimental investigation of 'Energy-Dissipation' in a weak magnetic field. The substance experimented upon was a toroid of square cross-section made up of iron plates .010 in. thick. The magnetizing force was supplied by a helix uniformly distributed over the core. The force applied was simple harmonic of 1,800 periods per second, and its amplitude could be varied from 0 to .1 C.G.S. unit. The inductance and resistance of the helix was determined in a Wheatstone bridge. The results obtained were compared with theory. According to the theory worked out by the author, inductance (L) and Foucault resistance (R) is given by the formulæ:

$$L = 2s^2 \mu h \log \frac{b}{a}$$

$$R = \frac{4}{3\sigma} \pi^2 \mu d^2 f^2 L$$

where

s = number of turns in the helix.

μ = permeability of the iron.

σ = specific resistance of the iron in C.G.S. units.

f = frequency of the magnetizing force.

h = height of the core in cm.

d = thickness of the plates in cm.

a = internal diameter of the plates.

b = external diameter of the plates.

Up to about .05 C.G.S. units of the magnetizing force μ is constant and equal to about 80 in the samples of iron employed; there is no hysteresis, and the theory agrees very well with experiment. Beyond that limit both L and R increase; the increase of R is very rapid on account of hysteresis.

When the core is magnetized by a steady force and then after removal of this force L and R are measured it is found that they both

change on account of the change of μ . Their values still agree with the theory within the above limits of magnetization. Hence weak magnetizations are not accompanied by hysteresis, both when the iron is neutral and also when it is already, even strongly, magnetized.

An increase of the permanent magnetization diminishes μ , and *vice versa*. The maximum change in μ thus obtained was 22 per cent.

Professor J. K. Rees presented some notes and lantern illustrations on observations of Leonids made at Bayport by C. A. Post and himself. The observations were made at Mr. Post's observatory during the nights from November 13 to 16 (both inclusive).

For the purpose of photographing meteor trails four cameras were fastened to the equatorial. Exposures for known times were made on identified parts of the sky. The results showed meteor trails on the plates taken between midnight and sunrise of November 15. Quite a remarkable meteor was shown on plates taken with the Willard and the Anthony lenses. This meteor appeared at 3.58 a. m. near the radiant point and exhibited a fine head and trail, which remained visible for a minute or more. A lantern slide of this meteor (made by Mr. Post) was thrown on the screen, and attention was called to the peculiar details of the head and trail. Considering the number and the brilliancy of the meteors which fell during the morning of the 15th, the trails on the plates are unexpectedly few.

Only during the night of November 14-15 was a careful attempt made to count the meteors. Miss Edith Post and Miss Greenough watched the northeastern and the southeastern sky. The observers at the telescope occasionally aided in counting. Four hundred and eighteen meteors, of which all but a very few were well-defined Leonids, were counted. Of these the greatest number was seen between 4.30 and 5.55 a. m., November 15, when 273 were counted. During the last hour the shower was evidently increasing.

The notes on 'Individual Meteors' show that many bright Leonids fell, showing trails which lasted many seconds, and extended 10 to 30 degrees.

Two very brilliant meteors fell at 5.28 a. m., November 15, and their paths crossed each other. One came from the radiant and the other from below Leo and cut the trail of the first under Canes Venatici. The trails were 30 degrees long.

The hope was expressed that next year we would be favored with a shower more brilliant and comparable to the showers of 1833 and 1866.

F. L. TUFTS,
Secretary.

TORREY BOTANICAL CLUB.

The first paper on the scientific program on December 10, 1901, was by Professor L. M. Underwood on 'The Genus *Gleichenia*.' This was illustrated by specimens and sketches, showing the principal natural types. The paper will be published in full in an early number of the *Bulletin*.

Mrs. N. L. Britton presented 'Notes on Macoun's Recent Collections of Canadian Mosses,' speaking of collections made by Professor J. Macoun during the past summer in the lower peninsula of Ontario between Lake Erie and Lake Ontario. Special mention was made of *Seligeria campylopora* Kindh., previously known only from Owen Sound, but now collected at Niagara Falls. This moss ordinarily grows in pockets in limestone rocks and being very small is easily overlooked. Mrs. Britton alluded also to the synonymy of *Polytrichum Ohioense* Ren. & Card. This species was distributed by Drummond in his *Musci Americani* as *Polytrichum pallidisetum* and is apparently the same as what was afterwards recognized in the Manual of Lesquereux and James as *Polytrichum formosum*, var. *pallidisetum*, but whether the original *Polytrichum pallidisetum* of Funk is identical remains to be determined.

Dr. P. A. Rydberg in 'A Review of a Recent Monograph of the Ranunculaceæ' discussed the work recently written by Dr. K. C. Davis.

The final paper was by Mr. S. H. Burnham and was entitled 'Notes on the Flora of the Lake George Region.' Mr. Burnham referred especially to *Bidens Beckii*, an aquatic plant

growing in five or six feet of water in muddy streams, and to his experiences in collecting it through the ice during the last week of November of the present year. He also alluded to the restriction of *Castalia tuberosa* to the streams flowing directly into Lake Champlain while *Castalia odorata* alone is found in the Lake George Basin.

MARSHALL A. HOWE,
Secretary pro tem.

NORTHERN SECTION OF THE AMERICAN CHEMICAL SOCIETY.

The regular monthly meeting of the Section was held on Tuesday evening, December 17, in the Kidder lecture room of the Massachusetts Institute of Technology. Professor C. F. Chandler, of Columbia University, addressed the Society on 'The Electro-chemical Industries at Niagara Falls.' After tracing the historical development of electro-chemistry, Professor Chandler proceeded to discuss the development of the Castner process for the manufacture of sodium, sodium hydroxide, peroxide and cyanide, and the utilization of the chlorine from the salt for the manufacture of bleaching powder. The Hall process for the manufacture of aluminium together with the electrolytic purification of bauxite was then discussed and illustrated by a large number of beautiful specimens. The preparation and applications of carborundum, graphite, phosphorus and calcium carbide were considered in detail and were used to illustrate the rapid development of the electro-chemical industries at Niagara Falls.

HENRY FAY,
Secretary.

DISCUSSION AND CORRESPONDENCE.

THE MEASUREMENT OF WIND AT SEA.

TO THE EDITOR OF SCIENCE: In conducting at sea the meteorological observations with kites that have been described in SCIENCE, it was necessary to deduce from the observations on the ship and from the record of velocity at the kite the true direction and velocity of the wind at sea-level and in the upper air, respectively. Knowing the resultant direction

and velocity of the wind on the ship or at the kite, as well as the speed of the ship, the triangle of forces gave the true velocity of the wind and its direction relative to the course of

the vessel. For example, let AB be the wind due to the motion of the steamer in the opposite direction and let AC be the wind observed on board, the direction relative to the vessel being indicated by the drift of the smoke and its velocity measured by an anemometer. Then the third side, BC , of the triangle represents the direction of the natural wind and its velocity on the same scale. The problem is not new, for in Abbe's 'Treatise on Meteorological Apparatus and Methods' (*Report of the Chief Signal Officer for 1887, Part 2*), several graphical and mathematical solutions that have been proposed since 1847 are cited, and in the November *Pilot Chart* of the United States Hydrographic Office, a table shows the true direction of the wind with regard to the ship and its force, when there are known, the speed of the ship, the angle that the apparent wind makes with it (points off the bow) and the force of this wind.

It does not seem to be understood, however, that the same result may be reached without any measurement whatever of wind velocity or estimation of force by merely measuring, in addition, the angle that the true wind makes with the ship, which is easily done by watching from the weather side the wave-crests as they approach the vessel. If, in the figure, AB again represent in direction and speed the ship's wind, and AC , in direction only, the resultant wind, then by measuring the angle DBA that the true wind makes with the ship we have, as before, the third side, BC , of the triangle. The method fails when the wind is in line with the ship's course and becomes inaccurate when the angle between them is small. In other cases, since the speed

and course of the ship are always sufficiently known and the two angles BAC and DBA can be measured with precision, the method is better than the first because of the difficulty in measuring the resultant velocity, arising from the upward deflection of the wind on striking the ship. When steaming through calm air, experiments with Dines' portable pressure anemometer demonstrated that in few localities on board was the speed of the vessel indicated by the horizontal movement of the air, one such place being just aft of the bow. Elsewhere a less speed was usually recorded, though under the bridge the compressed vein of air flowed astern faster than the boat moved ahead. In view of this difficulty of measuring the apparent wind velocity on a moving vessel, any method of ascertaining the true velocity with considerable accuracy, without employing an anemometer, is desirable from a scientific as well as from a practical standpoint, and, therefore, the simple method last described, which may usually replace the other, is now published for the first time, so far as the writer is aware.

A. LAWRENCE ROTCH.

BLUE HILL METEOROLOGICAL

OBSERVATORY, December 10, 1901.

THE ANDREW CARNEGIE RESEARCH SCHOLARSHIP.

A RESEARCH scholarship or scholarships, of such value as many appear expedient to the Council of the Iron and Steel Institute, from time to time founded by Mr. Andrew Carnegie (Vice-President), who has presented to the Iron and Steel Institute sixty-four one-thousand dollar Pittsburg, Bessemer and Lake Erie Railroad Company 5 per cent. Debenture bonds for the purpose, will be awarded annually, irrespective of sex or nationality, on the recommendation of the council of the institute. Candidates, who must be under thirty-five years of age, must apply, on a special form before the end of March to the secretary of the institute.

The object of this scheme of scholarships is not to facilitate ordinary collegiate studies, but to enable students, who have passed through college curriculum or have been trained in industrial establishments, to con-

duct researches in the metallurgy of iron and steel and allied subjects, with the view of aiding its advance or its application to industry. There is no restriction as to the place of research which may be selected, whether university, technical school, or works, provided it be properly equipped for the prosecution of metallurgical investigations.

The appointment to a scholarship shall be for one year, but the council may at their discretion renew the scholarship for a further period instead of proceeding to a new election. The results of the research shall be communicated to the Iron and Steel Institute in the form of a paper to be submitted to the annual general meeting of members, and if the council consider the paper to be of sufficient merit, the Andrew Carnegie Gold Medal shall be awarded to its author. Should the paper in any year not be of sufficient merit, the medal will not be awarded in that year.

By Order of the Council,

BENNETT H. BROUGH,
28, VICTORIA STREET, LONDON. *Secretary.*

CURRENT NOTES ON PHYSIOGRAPHY.

THE WASHINGTON FOLIO.

THE Washington double-sheet folio, by Darton and Keith, embraces a district in which the Potomac flows from its gorge in the Piedmont plateau to its estuary in the Coastal plain. Along the junction of the two areas is an 'inner lowland' similar to that so well developed in New Jersey, but of less breadth. It is determined on one side by the descending floor of crystallines on which the Coastal plain strata rest, and on the other by a pale and ragged 'cuesta' whose sinuous crest appears to be held up by the Matawan formation, overlapped by abundant later deposits, while the lowland itself is opened out on the clays and sands of the Potomac (Cretaceous) formation. The economic sheets give the underground contours of water-bearing strata. The structural sections exhibit the wonderfully even truncation of the steep-dipping crystallines in the Piedmont area. A novel feature is presented on the physiographic geology sheet, where the existing planes and slopes are colored according to the date of their production, and

not that of the rocks on which they are carved. This brings out clearly the pre-Columbia dissection of the Lafayette plain, as well as the Columbia and later terraces, the latter having their greatest extension along the inner lowland between the old land and the cuesta.

PHYSIOGRAPHIC ECOLOGY.

'THE Physiographic Ecology of Chicago and Vicinity, a study of the origin, development and classification of plant societies,' by Cowles (*Botan. Gazette*, XXXI., 1901, 73-108, 145-182), and 'The Genetic Development of the Forest of Northern Michigan, a study in physiographic ecology,' by Whitford (*ibid.*, 289-325), are essays in which the relation of plant distribution to land forms is carried to much more than ordinary detail. Not only is the existing distribution of plants traced out, but the extension of one plant society and the corresponding restriction of another, with the slow advance of physiographic development, as previously suggested by Woodworth, are here clearly pointed out, as in the discussion of the flora of ravines, valley sides and flood plains.

Studies of this kind are of especial interest to the physiographer from the use that they make of physiographic details; they are encouraging in the evidence that they give that the real intention of physiography is coming to be recognized. It is not so much an end in itself as a means to a larger end; hence it must concern itself not only with large features of earth form and climate, but with local details as well. It is particularly in these applications of physiography that an effective terminology will be demanded, for when the distribution of plant societies is followed out on so gently modulated a surface as that of a flood plain, nothing less than a systematic and detailed method of description will suffice. When not only biologists, but geographers and even travelers come to avail themselves of the results of physiographic study, the need of a careful terminology will be still more apparent.

THE COAST-PLAIN OF NORWAY.

UNDER the title 'Søndre Helgelands morfologi' (*Norges geol. undersøgelse*, No. 29,

1900, 1-61; German abstract, 160-170), Vogt describes the leading features of a part of mid-western Norway, including a typical portion of the coast plain whose general occurrences and origin by marine abrasion were first announced by Reusch in 1894, and whose forms were further illustrated by Richter (see SCIENCE, June 26, 1896). Between latitudes $63\frac{1}{2}^{\circ}$ and $66\frac{1}{2}^{\circ}$, the coast plain, now much dissected and mostly submerged, has a breadth of about 45 kil., or a third of that of Norway in this district. It bears some large unconsumed eminences here and there. Its inner border lies along a tolerably direct line at an altitude of from 20 to 50 met., and is well defined by the rather abrupt ascent to the highlands whose altitude shows that some 400 met. of rock was worn away in abrading the inner part of the plain. Further inland, the highlands are too uneven to be regarded as an uplifted peneplain; but they have been heavily denuded, their summits are composed of their hardest rocks, and their summit heights show a marked accordance with a plane sloping seaward at an angle of $40'$. Belts of limestone have been worn down in longitudinal valleys by which inland communication is favored. Transverse valleys, now occupied by fiords, lead to the coast. Returning to the coast plain, it slopes gently westward, and as it gradually dips under the sea thousands or tens of thousands of skerries fringe the shore line. Its outer edge is now at a depth of from 10 to 30 met., beyond which the bottom descends more rapidly. The slope of the plain is ascribed in part to post-glacial tilting ($2\frac{1}{2}'$), in part to an original declivity due to abrasion as the land slowly sank. The date of abrasion is given as pre-glacial, and the fiords and other channels by which the plain is intersected are ascribed largely to glacial erosion acting on lines of previously established valleys. The fiords reach depths of from 400 to 600 met. beneath the sea, or from 1,250 to 1,500 met. below the adjoining highlands; their depth decreases forward in the coast plains. The shore lines (strandlinjen) that were cut during the post-glacial submergence stand somewhat higher

than the inner border of the abraded plain, with which they should not be confused.

SWEDISH GLACIAL LAKES.

HANSEN has shown that the shore lines of extinct lakes occur in deep east-discharging valleys that occupy a belt next east of the general watershed of the Scandinavian highlands, and that the barriers by which the lake waters were held consisted of residual ice masses; thus confirming the generalization that the ice-sheet of the glacial period (as determined by striations and boulders) lay somewhat east of the watershed. A special account of some of these lakes is given by Gavelin ('On the glacial lakes in the upper part of the Ume river valley.' *Bull. Geol. Inst. Univ. Upsala*, IV., 1900, 231-242, map). One of these lakes in lat. 66° was over 100 kil. long, with a width up to 9 kil., and a depth of 150 or 200 met. Its outlet was westward across a pass at an elevation of 534 met. Wave-cut terraces in till and stream-built deltas of gravel are traceable round the shore line, which rises eastward with a gradient of about 1:2,000. A higher water level is found at altitudes varying between 700 and 760 met. Many other shore lines of this kind await the attention of the explorer.

W. M. DAVIS.

BOTANICAL NOTES.

POPULARIZING FORESTRY INFORMATION.

MR. ABBOT KINNEY, of Los Angeles, California, has rendered forestry a good service by bringing out a pretty book entitled, 'Forest and Water,' in which he discusses in a non-technical way many things which bear upon our forests and their management as well as their mismanagement. In a series of short chapters the author discusses enthusiastically and earnestly, if not always learnedly, many things pertaining to trees and their environment. Thus he takes up the origin and continuance of forests, forest fires, pasturage in forests, need of government control, forests in relation to torrents, study of the pines, cedars and other trees, some relations between forests and water supply, forest reservoirs, etc. In speaking of forest fires the author says, "Fire is more dreaded than any

other destroying agent by those interested in forests." In regard to the pasturing of sheep in the public forests Mr. Kinney speaks very plainly, denouncing the practice in strong terms, as most destructive to the forests. The book is illustrated with half-tone reproductions of striking photographs, which cannot fail to arrest attention. While the literary side of the book leaves something to be desired, there is no question that it will do much good, and the author is to be commended for his effort.

TITLES OF RECENT ARTICLES AND PAMPHLETS.

Under the title 'Beitraege zur Kenntniss der Grasroste' Fritz Mueller discusses in 'Beihefte zum Botanischen Centralblatt,' Band X., a new species of *Puccinia* (*P. symphyti-bromorum*) related to Ericksson's *P. dispersa*, and in the course of his paper gives the details of many cultural experiments. The latter will be of much interest to students of the Uredineae who are engaged in similar work.—Dr. Th. Valetou, in the 'Bulletin de L'Institut Botanique de Buitenzorg' (VIII.), in an article entitled 'Die Arten der Gattungen *Coffea* L., *Peristomeria* Thw., und *Lachnastoma* Korth., gives the results of a critical study of these genera in the form of careful diagnosis, followed by notes on certain species. *Coffea* is divided into two subgenera, viz., *Eucoffea* (which includes among others the well-known *C. arabica*), and *Paracoffea*, containing six to eight Asiatic and African species.—Robert Hegler's paper, 'Untersuchungen ueber die Organization der Phytochromaccenzelle,' in Pringsheim's 'Jahrbuecher' (Bd. XXXVI.), is important as a contribution to our knowledge of the structure of the cell of Proto-phytes. He distinguishes what he regards as a genuine nucleus in every cell, and is able to separate this from the cytoplasm. In each he makes out a ground-mass in which is a more deeply staining granular part. In division he describes what appears to be a crude imitation of the karyokinetic stages as seen in higher plants, but his photographs do not certainly sustain this statement.—In the last number of *Hedwigia* (Bf. XL., Hft. 5) Georg Bitter brings to a close his paper, 'Zur Mor-

phologie und Systematic von *Parmelia*,' in which he has discussed in particular the subgenus *Hypogymnia*.—A notable paper in the September *Annals of Botany* is Margaret C. Ferguson's 'Development of the Egg, and Fertilization in *Pinus strobus*,' in which she notes the similarity between fertilization in the pines and processes known to take place during fertilization in some animals. Three plates of about ninety figures illustrate the paper.—V. S. White's paper, 'The Tylostomaceae of North America,' in the August *Bulletin of the Torrey Botanical Club*, is a valuable contribution to our knowledge of these curious puff-balls. The paper is illustrated with ten plates, including seventy-eight figures.—Dr. Walter Migula, the well-known German botanist, has undertaken to bring out a new 'Kryptogamen Flora' of Germany, which is to constitute the fifth, sixth and seventh volumes of Thome's 'Flora von Deutschland, Oesterreich und der Schweiz.' The first Lieferung takes up the Bryophyta. A feature of the work is to be the use of colored plates for illustrating the text, and the examples given in the first number indicate that this part of the work is to be well done.—Numbers 209 and 210 of Engler and Prantl's 'Pflanzenfamilien' are devoted to the Selaginellaceae, and the fossil members of this family and of the Lycopodiaceae, and in addition, the Lepidodendraceae.—The sixth 'Heft' of Engler's 'Pflanzenreich' has appeared, and we may now judge of the magnitude and importance of the work which Engler has undertaken. These six Heften have treated of the families Musaceae, Typhaceae, Sparganiaceae, Pandanaceae, Monimiaceae, Rafflesiaceae, Hydroceae, and Symplocaceae, and to these about four hundred and fifty pages have been given. The illustrations and text maintain the high standard of the earlier numbers.

SUPPLEMENT TO NICHOLSON'S DICTIONARY OF GARDENING.

BOTANISTS and horticulturists will find much of value in the two volumes which constitute the supplement to this well-known work. In 747 pages the editor has succeeded in adding a great amount of new and supplemental mat-

ter, and in fact brings the work fairly up to the present. The volumes have the appearance of those which preceded them, and the typography and illustrations are of the high order with which we were familiar in the earlier volumes. The colored plates, which are quite lavishly used, are very fine, indeed; in fact they are not to be excelled anywhere in works of this class. Many of the black illustrations are from photographs which have been reproduced with unusual fidelity. In the text the topics which attract one on account of full treatment are: *Adiantum*, where many additions are made; *Alsophila*, to which two beautiful illustrations are added; *Aquatic Plants*, covering eight pages, and including five fine photographs; *Asplenium*, with forty figures, and covering thirteen pages; *Bedding Plants*, nine pages; *Cacti*, eight pages; *Chrysanthemum*, ten pages; *Cypripedium*, twelve pages; *Ferns*, six pages; *Landscape Gardening*, eleven pages; *Sphingidae*, six pages; *Tulipa*, four pages.

CHARLES E. BESSEY.

UNIVERSITY OF NEBRASKA.

THE CARNEGIE INSTITUTION.

MR. ANDREW CARNEGIE'S great gift of \$10,000,000 for scientific research has been transferred to a corporation to be known as 'The Carnegie Institution.' The original incorporators are Secretary Hay, Dr. D. C. Gilman, lately president of Johns Hopkins University and director of the Washington Memorial Institution; the Hon. Chas. D. Walcott, director of the U. S. Geological Survey and president of the Board of Trustees of the Washington Memorial Institution; Dr. John S. Billings, U. S. A. (retired), director of the New York Public Library; the Hon. Edward D. White, associate justice of the Supreme Court of the United States, and the Hon. Carroll D. Wright, U. S. Commissioner of Labor. The original incorporators will select a board of from 27 to 30 trustees.

The preamble of the articles of incorporation is as follows:

We, the undersigned, persons of full age and citizens of the United States and a majority of whom are citizens of the District of Columbia, be-

ing desirous to establish and maintain in the City of Washington, in the spirit of Washington, an institution for promoting original research in science, literature and art, do hereby associate ourselves as a body corporate for said purposes under an act to establish a code of law for the District of Columbia, approved March 3, 1901, Sections 599 to 604 inclusive.

The objects of the institution, in addition to the promotion of research, are set forth as follows:

To acquire, hold and convey real estate and other property necessary for the purpose of the institution and to establish general and specific funds.

To conduct, endow and assist investigation in any department of scientific literature or art, and to this end to cooperate with governments, universities, colleges, technical schools, learned societies and individuals.

To appoint committees of experts to direct special lines of research.

To publish and distribute documents, to conduct lectures and to hold meetings.

To acquire and maintain a library and, in general, to do and perform all things necessary to promote the objects of the institution.

SCIENTIFIC NOTES AND NEWS.

SOME account of the recent meeting of the American Society of Naturalists and the affiliated societies will be found at the beginning of the present issue of SCIENCE. The address of the president, Professor Sedgwick, is also printed above. It may be added that the society took action commending a national board of health and the preservation of the remains of the cliff-dwellings in Arizona. The sum of \$50 was appropriated toward the University table at the Naples Zoological Station. A committee was appointed, consisting of Professors Minot (chairman), Sedgwick, Cattell, Wilson and McGee, to confer with a similar committee to be appointed by the naturalists of the Central and Western States in regard to the relations of the two societies. The officers elected for next year are as follows: *President*, J. McKeen Cattell, Columbia University; *Vice-Presidents*, C. D. Wolcott, U. S. Geological Survey, L. O. Howard, Department of Agriculture, and D. P. Penhallow, McGill University; *Secretary*, R. G. Har-

Prison, Johns Hopkins University; *Treasurer*, M. M. Metcalf, Woman's College, of Baltimore; *Members of Executive Committee*, W. T. Sedgwick, Massachusetts Institute of Technology, and E. B. Wilson, Columbia University.

A MEETING of naturalists of the Central States was held at Chicago, January 2, 1902, and it was voted to organize a society of naturalists of the Central States. A committee of five was ordered to be appointed by the presiding officer, Professor S. A. Forbes, to confer with a committee to be appointed by the American Society of Naturalists, and also to report a form of organization and to nominate members in accordance with the constitution of the American Society of Naturalists. It was voted to meet next year during convocation week at Washington.

A MEETING of zoologists of the Central and Western States was held at Kent Theater, Chicago, January 2, 1902. Professor Davenport was chosen moderator. A committee of three was appointed, consisting of Professors Forbes, Reighard and Davenport, to draw up a constitution. It was voted to meet next convocation week at Washington.

THE American Morphological Society elected the following officers for 1902: *President*, H. C. Bupmus; *Vice-President*, G. H. Parker; *Secretary* and *Treasurer*, M. M. Metcalf; *Executive Committee*, H. S. Jennings and R. G. Harrison.

THE officers elected by the Association of American Anatomists are as follows: *President*, G. S. Huntington, New York; *Vice-President*, D. S. Lamb, Washington; *Secretary* and *Treasurer*, G. Carl Huber, Ann Arbor; *New Members of Executive Committee*, C. A. Hamann, Cleveland, George A. Piersol, Philadelphia, and F. H. Gerrish, Portland, Me.

THE American Psychological Association elected officers as follows: *President*, E. A. Sanford, Clark University; *Secretary* and *Treasurer*, Livingston Farrand, Columbia University; *New Members of the Council*, G. S. Fullerton, University of Pennsylvania, and G. T. W. Patrick, Iowa State University.

At the recent Rochester meeting of the Geological Society of America the following officers were elected: *President*, N. H. Winchell, Minneapolis; *First Vice-President*, S. F. Emmons, Washington; *Second Vice-President*, J. C. Branner, Stanford University; *Secretary*, H. L. Fairchild, Rochester, N. Y.; *Treasurer*, I. C. White, Morgantown, W. Va.; *Editor*, J. Stanley-Brown, Washington; *Librarian*, E. P. Cushing, Cleveland, O.; *Councillors*, C. W. Hayes, Washington, and J. P. Iddings, Chicago.

CAPTAIN ALFRED T. MAHAN, U. S. N. (retired), known for his publications on naval and military problems, has been elected president of the American Historical Association. The Association will meet next year at Philadelphia.

COL. JACOB L. GREENE, of the Connecticut Mutual Life Insurance Co., has been elected president of the Hartford Scientific Society, in place of Dr. Geo. L. Parmele, who declined reelection.

PROFESSOR VIRCHOW, while stepping from a trolley car in Berlin on January 5, fell and was so much injured that it was necessary to carry him to his house.

MAYOR Low has appointed Mr. Ernst J. Lederle health commissioner of New York City, with Dr. Herman M. Biggs as medical officer, having charge of the medical affairs of the board. J. M. Woodbury, M.D., has been appointed street cleaning commissioner.

DR. ARTHUR SMITH WOODWARD, F.R.S., has been appointed keeper of geology in the British Museum in succession to Dr. Henry Woodward, F.R.S., who recently retired. It is rumored that Dr. A. S. Woodward is likely to be succeeded in the assistant keepership by Dr. Francis Arthur Bather, who has been an assistant in the museum since 1887. Dr. Bather is one of the most distinguished members of the modern school of paleontology in Europe, and is a frequent contributor to SCIENCE. He is personally known and esteemed by a large circle of scientific friends in this country.

DR. WILLIAM SOMERVILLE, late professor of agriculture at the University of Cambridge,

has been appointed to be an assistant secretary to the board of agriculture on the retirement of Sir Jacob Wilson.

MR. FRANCIS J. E. SPRING, senior inspector of railways in India, has been given the degree of Master of Engineering at Dublin University. It is doubtful whether Mr. Spring's valuable services for thirty years on the railways and other engineering works in India enabled him to understand the Latin oration given on the occasion by the public orator, Dr. R. Y. Tyrrell.

MR. WILLIAM HUNTER, assistant to the bacteriologist to the London hospital, has been appointed government bacteriologist to the Colony of Hong Kong.

DR. SAMUEL CALVIN, state geologist of Iowa, recently delivered a lecture on the 'Ice Age in Iowa' before the science teachers at the Iowa State Teachers' Association.

PROFESSOR T. D. A. COCKERELL has been elected a correspondent of the Philadelphia Academy of Natural Sciences.

DR. H. M. SAVILLE, of the American Museum of Natural History, left Mexico City on December 31, to continue explorations of the ruins in the Oaxaca Valley.

PROFESSOR LAWRENCE BRUNER, who has on several former occasions visited the warmer portions of North and South America for similar purposes, is contemplating a trip to Costa Rica during the months of February, March and April for the purpose of collecting material for his and other departments in the University of Nebraska. While primarily thus employed, he would be pleased to undertake the collection of material for other institutions when such collecting would not too greatly interfere with the outlined work of the expedition. Other members of the party have also had experience in field work. This expedition is not undertaken entirely in the interests of the University of Nebraska and the funds to pay the expenses of the same are to be supplied only in part by that institution, and it is expected that the commissions undertaken for others would in a measure meet this deficiency. Any person or institution wishing to learn further particulars con-

cerning this proposed expedition is requested to correspond with Mr. Bruner at the University of Nebraska. It is planned to sail from New Orleans on or about February 14, 1902.

A CABLEGRAM to the New York *Sun* from St. Petersburg reports that the expedition under Dr. Herz, which was sent to Kolymsk by the St. Petersburg Academy of Science, has arrived at Srednokokolynsk with the remains of a male mammoth. The hide is in an almost complete state of preservation. In the stomach and teeth the remains of undigested food were discovered.

WE learn from *The British Medical Journal* that on December 10 a bronze medallion portrait of the late Professor Thomas Jones, which has been placed in Owens College Medical School, was unveiled in the presence of a large gathering of friends and students. At the same time a brass tablet bearing the names of Professor Jones and those of Dr. Davies, Mr. Eames and Dr. Aldred, former medical students of the college, who also lost their lives in the South African war, was unveiled. The total sum contributed by 275 subscribers to the memorial was £978, and Professor Wright, the treasurer, after defraying the cost of the medallion and tablet, was able to hand over £852 to the college authorities for the foundation of an exhibition in anatomy.

MR. EDMUND WILLIAM SMITH, archeological surveyor of the northwestern provinces of India, died of cholera on November 21, at the age of forty-three years. He had an important work in preserving archeological remains and in publishing descriptions and drawings.

MR. HENRY GEORGE MADAN, senior fellow of Queen's College, Oxford, and for twenty years head of the science department at Eton, died at Gloucester on December 21. He was a fellow of the Chemical Society and was joint author with Mr. A. G. V. Harcourt, of Christ Church, of 'Exercises in Practical Chemistry,' now in its fifth edition, and of other smaller works on chemistry and physics.

WE regret also to record the deaths of Professor J. H. Chievitz, director of the Anatomical Museum at Copenhagen, of Dr. Carl

Cramer, professor of botany in the Technical College at Zurich, and of Professor Henry Settegast, director of the Agricultural Institute at Jena.

SIR ERNEST CASSEL has given through King Edward £200,000 for a sanitarium for consumptives. The King has appointed an advisory committee, composed of leading physicians, including Sir William Henry Broadbent, Sir Richard Douglas Powell, Sir Francis Henry Lacking, and Sir Felix Semon. Three prizes of £500, £200 and £100, respectively, have been offered in connection with this scheme, for the best essays on, and plans for, the construction of the sanitarium. The competition is open to medical men of all nationalities.

By the will of Miss C. B. De Peyster, the New York Historical Society, will, on the death of her sisters, receive an estate of \$130,000.

UNIVERSITY AND EDUCATIONAL NEWS.

OBERLIN COLLEGE has collected the \$300,000 necessary to secure the \$200,000 offered by Mr. John D. Rockefeller a year ago, and thus increases its endowment by \$500,000. Barnard College, Columbia University, has not been so fortunate in fulfilling the terms of Mr. Rockefeller's offer of \$200,000, but Mr. Rockefeller has extended the time to April 1.

FOUR trustees of the Worcester Polytechnic Institute, Messrs. S. Salisbury, C. H. Whitcomb, C. H. Morgan and C. G. Washburn, have given \$30,000 to the institute. Part of the money will be devoted to the erection of a new foundry and forge shop.

SIR WILLIAM MACDONALD has placed \$125,000 at the disposal of the Ontario Government to be used in the erection of buildings at the Guelph Agricultural College, for the purpose of giving instruction to school teachers in the elements of nature-study and domestic science.

LORD STRATHCONA has given £25,000 to Aberdeen University.

THE sum of about \$80,000 has now been contributed toward the endowment of the chair of

political economy and social science at Washington and Lee University in memory of the late William L. Wilson. \$100,000 must be collected, and it is hoped that subscriptions will be sent to the treasurer of the fund, Mr. Herbert Welch, 1305 Arch Street, Philadelphia, Pa.

IT is said that M. Robert Lebaudy has offered \$25,000 towards the establishment of a French industrial school in connection with the University of Chicago. The new school is to be an integral part of the University and the necessary buildings will be located on the campus. The purpose of the school is the systematic study of American industrial and business methods. The students will consist of 600 graduates of French colleges, who will be selected by the French Government.

A DEPUTATION, representing the English university colleges of Bristol, Dundee, Leeds, Liverpool, London, Manchester, Newcastle (Durham College of Science), Nottingham and Sheffield, recently visited the chancellor of the exchequer to urge an increase in the grant of £25,000 distributed among the colleges. No hope, however, was given that the grant would be increased, except in so far as new colleges may receive small grants.

MR. WALTER PALMER, M.P., has given £2,000 to the University of London to provide the apparatus required for the proposed post-graduate courses of lectures in physiology.

AT the University of London, university scholarships have been awarded as the result of the recent B.A., B.Sc., and M.B. examinations to the following: Classics, H. G. Wood; mathematics, F. Slatore; chemistry, G. Tattersall; zoology, H. M. Woodcock; experimental physics, J. Satterly; medicine, C. J. Thomas; obstetric medicine, A. E. Jones; forensic medicine, E. M. Sharp.

DR. G. E. FELLOWES, assistant professor of history in the University of Chicago, has been elected president of the University of Maine.

DR. D. A. WELSH, senior assistant to the professor of pathology in the University of Edinburgh, has been appointed to the chair of pathology in the University of Sydney.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

EDITORIAL COMMITTEE: S. NEWCOMB, Mathematics; R. S. WOODWARD, Mechanics; E. C. PICKERING, Astronomy; T. C. MENDENHALL, Physics; R. H. THURSTON, Engineering; IRA REMSEN, Chemistry; CHARLES D. THE GEOLOGICAL SOCIETY OF AMERICA.

THE fourteenth annual meeting of the Geological Society of America was held in Rochester, N. Y., from Tuesday, December 31, 1901, to Thursday, January 2, 1902. An informal session of the Council, to canvass the ballots for officers and fellows, was held on Monday night, December 30, at the Whitecomb House, the headquarters of the Society. A formal session of the Council was held at 9 o'clock Tuesday morning in Sibley Hall, University of Rochester.

Owing to the unavoidable absence of President Walcott, the meeting was called to order by Professor Newton H. Winchell, shortly after 10 o'clock, in the geological lecture room of the University of Rochester, and the address of welcome and response were postponed until the arrival of the president. The report of the Council and officers having been printed and distributed to the members, its consideration was laid over until Thursday. Professor R. E. Dodge and Dr. E. O. Hovey were then appointed auditing committee. The vote for officers for 1902 was declared as follows:

President, N. H. Winchell, Minneapolis, Minn.; *First Vice-President,* S. F. Emmons, Washington, D. C.; *Second Vice-President,* J. C. Branner, Stanford University, Cal.; *Secretary,* H. L. Fairchild, Rochester, N. Y.; *Treasurer,* I. C. White, Morgantown, W. Va.; *Editor,* J. Stanley-Brown,

Washington, D. C.; *Librarian*, H. P. Cushing, Cleveland, O.; *Councillors*, C. W. Hayes, Washington, D. C., J. P. Iddings, Chicago, Ill.

The following were declared elected fellows of the Society:

Ermine Cowles Case, A.B., A.M. (Kansas State University, 1893), M.S. (Cornell Univ., 1895), Ph.D. (Univ. of Chicago, 1896), Instructor in State Normal School, Milwaukee, Wis.; Arthur Gray Leonard, A.B., A.M. (Oberlin), Ph.D. (Johns Hopkins Univ.), Des Moines, Iowa, Assistant State Geologist, Iowa Geological Survey; Charles Hyde Warren, Ph.B. (Yale, 1896), Ph.D. (Yale, 1899), Boston, Mass., Instructor in Geology, Mass. Inst. Technology.

The following memorials were read: George M. Dawson, by Frank D. Adams; Ralph D. Lacey, prepared by David White, read by the secretary; Theodore G. White, prepared by J. F. Kemp, read by R. E. Dodge.

The following memorials were not read, owing to the absence of the authors: Edward W. Claypole, by Theo. B. Comstock; Joseph Le Conte, by W J McGee.

President Walcott, having meanwhile arrived, took the chair, and the address of welcome was delivered by Dr. Rush Rhees, president of the University of Rochester. He complimented the Society on its work, and the city and University of Rochester on the honor conferred by the meeting of the Society within their confines. He saw no special reason why Rochester should be so favored, but hoped that this meeting would stimulate its citizens to take a deeper interest in higher education. Finally he welcomed the Society most cordially to the University and the city. President Walcott, in responding, offered many reasons why the Society should meet in Rochester, for that city was intimately connected with the early study of geology in this country, and from it have proceeded many eminent members of the Society.

The following scientific papers were then read:

The Ordovician Succession in Eastern Ontario: H. M. AMI, Ottawa, Canada.

This paper dealt with the succession of paleozoic sediments in that portion of the province of Ontario, Canada, which is traversed by the Frontenac axis or ridge of Archæan rocks which crosses the St. Lawrence river between the city of Kingston and Brockville and connects with the great Adirondack massif to the south.

The Frontenac axis divides the Ordovician strata, to the east as well as to the west, into two series, which, though not very distant, geographically speaking, are nevertheless marked by important features.

On the east side of the axis the normal succession of strata from the Potsdam to the Medina is found, but on the west side of the axis the pre-Cambrian rocks are overlain by the Rideau sandstone, succeeded without stratigraphic break by the Birdseye, Black River and Trenton strata. Fossils, except *Scolithus*, are absent in the Rideau sandstone and the problem of the equivalency of this sandstone was stated.

In the discussion Mr. Bailey Willis considered that the Rideau sandstone is the formational equivalent of the Potsdam, but not its equivalent in age. Professor W. M. Davis considered it pre-Black-river in time, but of unsettled age. Mr. Walcott, emphasizing the shifting character of the deposits around the Adirondacks, suggested that the Rideau was the shore equivalent of the Calciferous (Beekmantown) and Chazy.

Stratigraphic and Faunal Succession in the Hamilton Group of Thedford, Ontario: HERVEY W. SHIMER and A. W. GRAEAU, New York, N. Y. Read by Mr. Shimer.

The Thedford Hamilton admits of a three-fold division, closely corresponding to that of the Hamilton of western New York. The limitations of the characteristic

species correspond in a remarkable degree to those observed in western New York. The ennerinal limestone is the central member in both localities, and the chief coral zone lies just above this stratum in both. A striking dissimilarity exists between the Hamilton of Thedford and the corresponding horizon (Traverse group) of Alpena, Michigan, the next important outcrop of this formation to the northwest. The difference is shown chiefly in the faunas. The paper was discussed by J. M. Clarke, H. S. Williams and A. W. Grabau.

The Traverse Group of Michigan: AMADEUS W. GRABAU, New York, N. Y.

Two sections, one on Thunder Bay and the other on Little Traverse Bay, show the strongly calcareous facies of the strata, which is most marked in the western section. In both sections the upper limit of the Traverse groups is marked by the St. Clair Black shale, and the lowest portion of the group is a bed of blue clay 80 feet thick. The fauna varies with the rock. The reef character of the limestone strata was discussed. The faunal character of the strata was discussed by Professor H. S. Williams, and the reef structure by Mr. Chas. D. Walcott. The Society then adjourned for lunch, many members availing themselves of the opportunity offered to inspect Ward's Natural History establishment, where a lunch was provided.

The afternoon session was called to order at 2 o'clock. The following papers were read:

The Lower Carboniferous Area in Indiana:

T. C. HOPKINS, Syracuse, N. Y.

The Lower Carboniferous strata in west central Indiana undergo quite marked changes along the strike. The outcrops have been traced in detail and represented on the State map. The heavy calcareous deposits of the southern part of the area thin out to the northward and give way to

argillaceous and sandy deposits. This transition has an important bearing on the geological history of this region.

The following subdivisions, based on lithologic but not paleontologic features, were discussed. *Kaskaskia, Mitchell, Bedford; Harrodsburg and Knobstone.*

The paper was briefly discussed by W. B. Scott, J. B. Wolf and W. M. Davis. Dr. A. C. Lane discussed the relations of similar beds in Michigan, and raised the question as to the origin of the silica in the beds under consideration, and its value as a horizon marker. He suggested that it might be supplied by volcanic eruptions, even from a distance. Mr. Walcott briefly discussed the economic importance of the limestones of these formations. Brief remarks were also made by Dr. A. F. Foerste, and responded to by Dr. Hopkins.

Geological Horizon of the Kanawha Black

Flint: I. C. WHITE, Morgantown, W. Va.

The first comprehensive description of the Kanawha Black Flint was given by W. B. Rogers, and besides this, the works of Stevenson, the Platt Brothers and H. M. Chance were considered as having added most to our knowledge of the details of the Appalachian carboniferous stratigraphy. The name Conemaugh, proposed by Franklin Platt, has, according to W. B. Clark, priority over Elk River series applied to the 'Barren measures' of Rogers, by White. Platt's name was accepted for the beds lying between the Pittsburg coal and the Upper Freeport coal. The position of the Kanawha Black Flint is at the base of the Conemaugh series, though David White places it some 200 feet down in the Alleghany series from paleobotanic evidence. The work of Messrs. Campbell and Mendenhall was reviewed, the speaker disagreeing with their interpretations. The problem was attacked anew by the speaker and from a new standpoint, by tracing the

basal coalbed, and the accompanying Mahoning sandstone, as well as the Red bed series with its included erinoidal limestone, from the Pennsylvania line to West Virginia. The results of this new work were in close agreement with those arrived at by the speaker in previous studies. The speaker concluded with the following corollaries:

A. Some coal beds, limestones and sandstones may be followed for hundreds of miles.

B. Stratigraphy is superior to paleobotany in correlations.

C. Paleobotany should be used merely as an aid to stratigraphy.

The paper brought out a warm discussion, in which Professor Stevenson, Bailey Willis, I. C. White and others participated.

President Walcott read a telegram of greeting from the Cordilleran section of the Society, in session in San Francisco, Cal. On motion of Professor Stevenson a similar greeting was returned.

The next paper read was:

Correlation of the Coal Measures of Maryland: WM. B. CLARK and G. C. MARTIN, Baltimore, Md. Read by Professor Clark.

The object of this paper was to show the equivalency of the coal seams of Maryland with those of adjacent regions in Pennsylvania and West Virginia. The determination of this equivalency is based not only on the parallelism of lithologic sequence over wide areas, as shown both by the structure of the seams themselves and of the intervening beds, but also on the fossiliferous zones which have been found at numerous points throughout this district. The similarity of the chemical composition in each vein over wide areas is also strikingly shown.

Local names, heretofore used by the Maryland survey, were abandoned, and

those used in Pennsylvania and West Virginia were adopted. The paper was discussed by I. C. White, J. J. Stevenson and Bailey Willis.

Areal Distribution of the Potomac Group in Maryland: W. B. CLARK and A. BIBBINS, Baltimore, Md. Read by W. B. Clark.

The lowest member of the Atlantic coastal plain series is the Potomac group, so named by W J McGee, who considered it a single unit. The age of this group was considered to be Cretaceous by paleobotanists, and Jurassic by Marsh and other vertebrate paleontologists. The authors have described a fourfold division of the Potomac into Patuxent, Arundel, Patapsco and Raritan beds, and indicated the distinctive characters of each. The areal distribution, which varies for the different members, was briefly discussed by the speaker. Marsh found Dinosaur remains in the Arundel, which, with the underlying Patuxent beds, is Jurassic. The plant remains were found in the upper or Raritan beds, and these are cretaceous. The lower members gradually die out northward, the Patuxent and Arundel not occurring in New Jersey, though some of the lower members appear to be present in Pennsylvania. The disappearance is due to a northward transgression of the sea and a consequent overlap of the newer upon the older beds. The paper was briefly discussed by Professors Hopkins and Holmes, and questions answered by Professor Clark.

On some Joint Veins: G. K. GILBERT, Washington, D. C.

A limestone stratum between beds of Cambrian shale from western Utah shows innumerable veinlets of the segregation type. In a small hand specimen passed around, 180 veins were counted. These belong to 22 systems, which are grouped in two groups, the minor of which is aligned

with the dip of the strata (which is from 10 to 15 degrees) and the major group with the strike. They are believed to be formed along joints. The dip joint-veins are normal to the plane of stratification, the strike veins vary from normal to the stratification, to verticality, and appear to have been formed at different periods. The grouping of the joint-veins in two directions appears in all the beds examined. The scale of the jointing is related to that of the bed, which is a thin one.

Professor J. E. Wolf discussed the origin of the jointing by contraction of the rock on loss of water.

Professor B. K. Emerson considered that they had all the aspect of torsion joints as produced in glass artificially. He referred to Crosby's theory, according to which an earthquake shock, passing through a stratum in which a slight torsion was induced, would produce the joints of the type described. Gilbert considered Crosby's theory the most plausible, and that the shrinkage theory was not applicable here. Bailey Willis thought that expansion of the rocks may have been a cause in the fracturing. Gilbert emphasized the fact that no apparent cracks existed. N. H. Winchell mentioned similar phenomena in the Minnesota mica schists, which apparently were basic sediments. A. C. Lane recalled joints of similar type but larger scale in the diabase sheet of Nahant, Mass.

Regeneration of Clastic Feldspar: N. H. WINCHELL, Minneapolis, Minn.

The literature was reviewed and the speaker's own observations given. Three phases of alterations of elastic feldspars occur: (1) Decay, (2) secondary enlargement, (3) secondary enlargement but the newly added material extended so as to grow into crevices between the other grains of the rock.

The Society then adjourned.

The evening session of the Society was opened at 8:40 o'clock in the college chapel, Anderson Hall. President Charles D. Walcott delivered the annual address, his subject being: 'The Outlook of the Geologist in America.' He reviewed the work now in progress in this country, and sketched a bright future for American geology.

Second day, Wednesday, January 1, 1902. The Council of the Society met in session at Sibley Hall at 9 o'clock.

The meeting of the Society was called to order at 9:50 by President Walcott. The motion was made that the previously distributed report of the Council be accepted. Carried.

The report of the photograph committee, prepared by N. H. Darton, was read by the secretary. The report was accepted, and the usual appropriation voted.

Professor Dodge presented the report of the auditing committee, stating that the committee had examined the treasurer's accounts and found them correct. The report was accepted. The Council recommended that the name of the western section of the Society be pronounced Cordil-ya'ran, which is the Spanish pronunciation, used in California. The recommendation was adopted.

The Society then proceeded to the reading of papers:

Geology of the Snake River Plains, Idaho: ISRAEL C. RUSSELL, Ann Arbor, Mich.

In the Snake river basin are many old rhyolitic cones covered by lava flows of later origin. The extent and thickness of the Snake river lava and its relation to the Columbia river lava were discussed. There is a decided lack of evidence of fissure eruption in the Snake river area. The distinction between the cinder and lava cones was illustrated, and various types of lava from the flows were shown.

The characteristic ridges on the older lava streams are due to basal compression of folds on the surface of the stream, these folds sometimes being hollow at the top, though compressed below. Lantern views and specimens illustrated these features. Along cracks in the lava streams, parasitic cones are built up and these and numerous other characters of the lava stream were illustrated by lantern views. Where the lava stream has come in contact with a body of water, the base of the sheet expands and becomes cellular, although the character of the lava is glassy from rapid cooling. The sand of the lake or river bottoms into which the lava stream entered is often cemented into the base of the sheet, and gives it a white color.

The canyon of Snake river owes its peculiarities to many of the features discussed. Shoshone falls are due to a cone or mass of hard rhyolite beneath the basalt, discovered by the river. Heavy lava sheets overlie the finely stratified, unconsolidated lake beds exposed in the canyon, which are scarcely altered by the lava. The base of the latter is glassy, with a few steam holes, but at a short distance above, the sheet has its normal granular character. From beneath the lava stream or from a porous layer, numerous powerful springs issue along the side of the canyon below Shoshone falls. These may be called 'canyon springs,' a new term introduced in the classification of springs. In the northern wall of the canyon occur remarkable spring-formed alcoves or side canyons, which widen out amphitheater-like, and have no stream at their head. Powerful springs, issuing from the fine lacustrine beds underlying the lava, undermine the latter and cause recession of the walls. Numerous lantern views were used in illustration of the paper.

Professor Emerson discussed the origin of these lava beds and their surface char-

acters. He pointed out the similarity of many features of these lavas to those of the Hawaiian volcanoes. He compared the base of the Snake river lava, resting on fine lake beds, with that of the Triassic trap of the Connecticut Valley, resting on the Triassic sands.

Professor Wolff discussed the age of the lava flows and cones.

Structure of the Front Range, Northern Rocky Mountains, Montana: BAILEY WILLIS, Washington, D. C.

The Front Range of the northern Rockies consists of a series of limestones, quartzites and silicious argillites somewhat exceeding 9,000 feet in thickness, and gently flexed in a synclinal form. The width of the range is approximately twenty miles from foothill to foothill, and the synclinal structure has practically a corresponding extent. The trend of the range is from northwest to southeast, and the strike of the rocks is essentially parallel to it. The mass is, however, not exactly symmetrical in cross section, the rocks outcropping on the northeastern side comprising probably 3,000 feet of strata lower in the series than the lowest on the western side.

Approached from the east, the margin of this synclinal mass is found to rest discordantly upon black clays and sandstones. These strata appear at some little distance from the range in the Great Plains, dipping deeply southwestward, but where they pass beneath the great limestone and quartzite series they correspond very nearly in attitude with the overlying rocks. The relation of the overlying to the underlying series is, however, that of an overthrust mass. In many places the black shales and sandstones were found to contain *Inoceramus* and *Ostrea* characteristic of the Cretaceous. In the overlying rocks Mr. Weller fortunately found fragments of

fossils which have been determined by Mr. Walcott as identical with those discovered by him in the pre-Cambrian Belt formation. Thus the discordance corresponds to an hiatus of all of the Paleozoic and part of the Mesozoic. The plane of overthrust dips gently to the southwest, and is exposed at right angles to its strike throughout a section seven miles in length, which is equivalent to a displacement of that amount. There are interesting details of structure in the overthrust and underthrust masses.

On the western side of the range parallel to the valley of the North Fork of the Flat Head the ancient limestones and quartzites present a bold face, and the stratigraphic relations of rocks found west of the Flat Head valley indicate that this face is a deeply eroded fault scarp of the normal type. The valley of the North Fork of the Flat Head contains lake beds, which are by analogy with similar formations in Montana tentatively referred to the Miocene or Pliocene.

From these data it is inferred that the structural history of the range comprises:

First. Deposition of Cretaceous sediments of very considerable thickness adjacent to a shore not far from the present site of the range and upon a land whose surface consisted of the pre-Cambrian limestones and quartzites.

Second. That in some post-Cretaceous epoch compressive strains resulted in a fold overturned toward the northeast, and ultimately in the development of a corresponding overthrust fault.

Third. That at some later date, probably Miocene, normal faulting resulted in relative uplift of the mass of the front range and downthrow of the mass of the Flat Head valley.

The next paper was a continuation and illustration of the preceding one, numerous lantern views being shown:

Physiography of the Northern Rocky Mountains: BAILEY WILLIS, Washington, D. C.

Professor Coleman discussed the physiography and origin of the structure of the region to the north of that described by Bailey Willis. Professor Davis discussed the structure and physiography of the region described. Mr. Walcott compared the section of pre-Cambrian rocks of the Belt Mountain terrane with that given by Willis in the Northern Rockies, and considered the probability that the entire series involved in the front range is Algonkian.

The Walls of the Colorado Canyon: W. M. DAVIS, Cambridge, Mass.

The general profile of the canyon walls depends on rock structure, and not on a pause in the elevation of the plateaus. The variation of profile from the narrow canyon in the Uinkaret plateau to the wide canyon in the eastern Kaibab is due to variation in the character of the strata. The pattern of spurs and recesses varies with the stage of dissection. The pattern commonly seen in the Red-wall cliffs is repeated in the Tonto cliffs where the latter are much worn. The pattern usually seen in the Tonto is repeated in the Red-wall where it is less worn. Brief mention was made of details connected with the unconformities seen in the canyon walls.

The paper was illustrated by lantern views, and was briefly discussed by Mr. Walcott and others.

The Society then adjourned for the noon recess.

The papers of the afternoon session were:

Rock Basins at the Helen Mine, Michipicoton: A. P. COLEMAN, Toronto, Canada.

Two small lakes or ponds, each a quarter of a mile long and two-thirds as wide, just west of the Helen iron mine near

Michipicoton on the north shore of Lake Superior, present very interesting examples of rock basins. Unlike most of the smaller rock basin lakes of Canada, they are not of glacial origin and probably were not even scoured out by the ice, since they are narrowly enclosed by steep, rocky ridges rising about 150 feet to the north and south and 450 feet toward the east. The shape of the valley is somewhat like that of an armchair with its back to the east, the two ponds, called Boyer and Sayers lakes, occupying the narrow seat. They had a depth of from 125 to 150 feet in the beginning, but Boyer lake, the higher one, is now partially pumped out to facilitate mining operations. From Boyer to Sayers lake the fall is 25 feet; and from Sayers to Talbot lake, which is beyond the high rock walls of the valley, there is a drop of 75 feet.

The valley of the two ponds is cut from rocks belonging to the iron range, chiefly siderite and granular silica banded with magnetite or heavily charged with pyrite, and the lowest point of the rim of each consists of silicious siderite containing much pyrite. The side walls of the valley are of greenish schists. The hollowing of the basins must have been due to solution, perhaps of parts of the iron range rocks which had been shattered; and the deposit of the large ore body at the eastern end of Boyer lake, where a high hill, consisting largely of impure siderite, drops steeply down to the basin, probably has a bearing on their formation, the decomposition of pyrite perhaps furnishing the solvent.

The next paper was:

The Effect of the Shore Line on Waves:
W. M. DAVIS, Cambridge, Mass.

The paper was a statement of the transformations of waves as they run in upon shore lines of different forms, with special reference to the refraction of waves on

headlands and in bays, and to the formation of surf.

The breaking of waves is not so much due to a retardation by friction of the base of the wave in shallow water, as generally assumed, as to the absence of water in front of the wave near the shore.

The next paper was:

Variation of Geothermal Gradient in Michigan: ALFRED C. LANE, Lansing, Mich.

The geothermal gradient in Michigan appears to vary from 1° F. in 107 feet to 1° in 54 feet. Among the different causes of variation, the varying diffusivity of the rocks appears to be important.

Diffusivity varies with the density; the more porous the rock, the smaller the diffusivity. The limestones of Cheboygan have a diffusivity paralleling that of the copper-bearing rocks of Kewenaw Point. The diffusivity of the shales of Michigan is widely at variance with that of the limestones.

The next two papers were presented together and illustrated by lantern views:

Origin and Distribution of the Loess in Northern China and Central Asia:
GEORGE FREDERICK WRIGHT, Oberlin, O.

Detailed observations in China, Mongolia, and Turkestan were presented which bear upon the fluvio-glacial theory of the origin of the loess of these regions, and of its distribution by wind or water.

No evidence of glaciation is found where Geikie and Krapotkin assumed it.

The Age of Lake Baikal: GEORGE FREDERICK WRIGHT, Oberlin, Ohio.

The region about Lake Baikal is covered with strata of Tertiary (and possibly Triassic) age, containing coal. These beds are derived from the sediments which were carried by now existing streams into the basin from the surrounding mountains, before the present lake came into existence. At the

estimated rate of erosion the entire lake would be filled in 400,000 years, whereas it is not a quarter full, and probably not one tenth full. The age of Lake Baikal is perhaps 100,000 years or less. That this region was formerly connected with the sea is shown by the species of seal found in Lake Baikal, which are also found in the Caspian sea. Other evidence of recent submergence followed by relevation exists. A period of increased precipitation caused the freshening of all the waters of the inland lakes of this region.

Professor Scott discussed the importance of æolean action in the formation of stratified beds, referring to those of Santa Cruz in Patagonia, in which vertebrate remains have been found finely preserved.

On Some Anticlinal Folds: T. C. HOPKINS and MARTIN SMALLWOOD, Syracuse, N. Y. Read by Professor Hopkins.

A number of unique folds occur in several small and rather deep ravines in the vicinity of Meadville, Pa. They are of limited extent both vertical and linear, and so far as known occur only in the bottom of the ravines. The relation of the folds to certain land-slip terraces, suggests a cause for these folds which are often asymmetrical.

Professor I. C. White referred to similar folds in other portions of Pennsylvania. He considered that gas formed below found an opportunity to escape in the relatively weak bottoms of canyons, causing an upward pushing of the strata. Professor Brigham mentioned the occurrence of similar folds in western New York. Professor Russell recalled folds, in the bottoms of canyons in western Idaho, where the strata are sharply arched. Land-slip terraces occur on both sides, there being thus no unequal pressure. He considered that the downward pressure of the wall rocks of the canyons, and the relief of pressure in the

bottom, caused the arching. Professor Stevenson discussed other folds in Pennsylvania. Mr. C. J. Sarle mentioned folds in the Clinton beds at Rochester and other localities.

The following papers were then read by the author:

Distribution of the Internal Heat of the Earth: T. C. CHAMBERLIN, Chicago, Ill.

Has the Rate of Rotation of the Earth Changed Appreciably During Geological History? T. C. CHAMBERLIN, Chicago, Ill.

The papers were a discussion of the mathematical and physical principles involved, and the available experimental data. The geological application to the phenomena of volcanoes, mountain foldings, etc., and to the great questions of physical geology was discussed.

In discussion some remarks were made by Professor Coleman.

The Society then adjourned until the next day.

The annual dinner was served at eight o'clock at the Whitcomb House. President Walcott occupied the head of the table, which was graced by the presence of a number of ladies. The after-dinner speeches touched upon the future policy of the Society and other topics, and contributed largely to the enjoyment of the dinner, which was voted one of the best ever attended by those present.

Third day, Thursday, January 2, 1902. The Council met at 9 o'clock in Sibley Hall. The meeting of the Society was called to order at 10 o'clock, Vice-President Winchell in the chair. Professor Clarke asked for a statement from the secretary concerning the relation of the Society to Section E of the American Association, especially in regard to next winter's meeting in Washington.

The following papers were read:

Use of the terms Linden and Clifton Limestones in Tennessee Geology: AUG. F. FOERSTE, Dayton, Ohio.

The Lower Helderberg was named in Tennessee from its exposure at Linden, where it is but 12 feet thick, while the maximum thickness is between 75 and 100 feet. Foerste questioned the advisability of naming a formation from the place of its minimum exposure. Faunal and stratigraphic characteristics were given.

Bearing of the Clinton and Osgood Formations on the Age of the Cincinnati Anticline: A. F. FOERSTE, Dayton, Ohio.

In continuation of former studies the author developed his interpretation of the Cincinnati anticline. The Devonian axis of the anticline was northeast and southwest, while the present axis is north and south. The Clinton strata over the central portion of the anticline are coarse lime-sands with wave marks and crossbedding, and beds of conglomerates. North and south of this area, the material is a fine lime-mud. The relation of these features to those formerly described was discussed.

J. M. Clarke discussed the subdivision of the Lower Helderberg of Tennessee. The fauna has a Silurian facies. I. C. White called attention to the importance of the Clinton Iron Ore bed, and its extension in Maryland and Pennsylvania. Brief remarks were also made by H. M. Ami and B. K. Emerson.

Notes on the Catalogue of Types in the Geological Department of the American Museum of Natural History: E. O. HOVEY, New York.

The paper was an exposition of the great work recently completed at the Museum in the cataloguing of the large number of types and figured specimens in the Museum, and of looking up references for each specimen. Complimentary remarks

were made by J. M. Clarke, H. M. Ami, and others.

The New Carboniferous Age of the Union and Riverdale formations in Nova Scotia: H. M. AMI, Ottawa, Ont.

In Colchester county lower Carboniferous beds are thrust over the newer Union and Riverdale beds, which by their fossils are known to be middle Carboniferous. In Pietou county the Lower Carboniferous rest unconformably upon the upturned Eo-Devonian, with which the Union and Riverdale beds were formerly correlated by stratigraphers. The evidence of the overthrust is, however, complete. The Union and Riverdale beds of Nova Scotia are equivalent respectively to the Mispeck and Lancaster formations of New Brunswick.

Origin of the Faunas of the Marcellus Limestones of New York: JOHN M. CLARKE, Albany, N. Y.

The Marcellus fauna is characteristically a bituminous mud fauna. Two prominent limestone beds, the Goniatic and Stafford limestones, carry, the one an upper Onondaga fauna, and the other a lower Hamilton fauna. The former makes its appearance near the meridian of Rochester, and extends eastward, rising relatively higher and higher in the bituminous shales. The other ends at the same meridian and thickens westward. The fauna of the Goniatic limestone (fauna of *Agoniatites expansus*) represents an eastward migration of the upper Onondaga fauna, which had persisted in the west, while the bituminous mud fauna had already become established in the east. The Stafford limestone fauna is a pre-nuncial Hamilton fauna, which persisted for a time and then was overwhelmed again. The Onondaga and Hamilton faunas appear to have come from the northwest, while the bituminous mud fauna of the typical Marcellus shales came from the southwest.

In discussion, brief remarks were made by I. C. White, A. P. Brigham and A. W. Grabau.

In the absence of the authors the following papers were read by title:

Notes on Mts. Hood and Adams and their Glaciers: H. F. REID.

Keewatin and Laurentide Ice Sheets in Minnesota: A. H. ELFTMAN.

Devonian Interval in the Ozarks: C. R. KEYES.

Devonian Fish-Fauna of Iowa: C. R. EASTMAN.

Geological Section in Northern Alaska, along the 152d Meridian: FRANK C. SCHRADER.

Notes on the Geology of Southeastern Alaska: ALFRED H. BROOKS.

Geology of the Virgilina Copper District in Virginia and North Carolina: THOMAS L. WATSON.

Cuttyhunk Island: F. P. GULLIVER.

The Mohokea caldera on Hawaii: C. H. HITCHCOCK.

A resolution of thanks to the president and trustees of the University of Rochester and to the professor of geology, the secretary of the Society, was offered by Professor Emerson, and after some remarks by Professor Coleman was unanimously adopted. After some closing remarks by the vice-president, the Society adjourned until December, 1902.

A large proportion of the fellows remained in Rochester to attend the evening reception given by President and Mrs. Rush Rhees, of the University of Rochester. The afternoon was devoted to short excursions to the Genesee gorge and other localities about Rochester, and to an inspection of the establishments of Ward's Natural Science Bureau, the Bausch and Lomb Optical Company, etc.

AMADEUS W. GRABAU.

COLUMBIA UNIVERSITY,
DEPARTMENT OF GEOLOGY.

FORESTRY IN NEW YORK STATE.

THE New York State School of Forestry, located at the New York Land Grant College, with its laboratories in the form of trained man in this department in the Adirondacks, is discovering that the difficulties which have attended so generally the promotion of pure science in our colleges and schools, during the past generation and earlier, are not necessarily evaded or lessened when the question becomes one of promotion of applied science and the utilization of scientific method directly in the promotion of the highest interests of the State and of its people.

New York was the first of the States of the Union to provide, on a suitable working scale, for the introduction of the art of forestry into this country by systematic and scientific instruction in a technical college, purely and professionally devoted to that work. It established the 'College of Forestry' as a department of the State college, Cornell University, authorized the purchase of a large tract of forested land, gave directions that the work should be done under the supervision of an expert, scientific and practically trained forester, and conferred ample authority upon the College of Forestry, its director and the university board of trustees, to establish and permanently sustain the college and its work. The primary purpose of the college was the education of professionally trained foresters. This provision was made in 1898 and was at once put into operation. Land was purchased—outside the State Reservation and thus not subject to the constitutional limitations affecting that reservation—and work promptly begun.

Hardly had this long-needed and immensely important enterprise been inaugurated by the appointment of Director Fernow, the most experienced, professionally trained man in this department in the country, and the schedule of work and

study and laboratory practice determined upon than an opposition arose, on the part of interested and ignorant persons, that was as well organized and as savage as any attack upon Cornell University in its earlier days of *Sturm und Drang*. The management was accused of seeking to make the Adirondack tracts 'as barren as the top of Mount Mareh,' of 'methods under which everything in the shape of wood, right down to shrubs, is being sold and cut,' of infringing upon the State preserve and the State Constitution. It was asserted that 'the land is being stripped as clean as ever it would be stripped by wood-pulp men, * * * cleared of everything but brush,' that one company is taking all the soft wood and another is 'taking the rest of the growth, right down to saplings'; and numberless other equally false and foolish tales reinforced the bill of complaint.

To this curious and unintelligent assault it became necessary to reply, as the newspapers had taken it seriously in many instances and a hue and cry was being raised which might very probably do much injury to the new enterprise, to the best interests of the State and to the reputation of the university and the college. Director Fernow has prepared an open letter regarding the matter from which we abstract the following:

The introduction in the United States of forestry methods in managing forest properties has been delayed by just such misconceptions, misstatements and misdirected attacks as characterize the lucubrations lately published in various newspapers regarding the doings of the College of Forestry in the Adirondacks.

THE SITUATION.

Cornell University was, by the State, invited to establish a College of Forestry, in which professional foresters were to be

educated, and at the same time there was given to it, as an experiment station in charge of the College of Forestry, a tract of land in the Adirondacks, from which the lumbermen had culled the pine and spruce. On this tract it was to show how such a culled hardwood forest might be managed under forestry principles.

The College of Forestry does *not* control the State forest reserve, has not even a voice in its management, nor is it operating on any State lands, the tract at its disposal having been deeded directly from the owners to Cornell University. While it would have a perfect right to cut the timber down to saplings, it does *not* do so, for good reasons.

WHAT IS FORESTRY?

Forestry, in simplest terms, means no more nor less with reference to wood crops than agriculture means with reference to food crops. It is a business which is concerned in the production of useful material, the most important and most widely used material, next to food materials. It is, then, entirely utilitarian. It is not concerned, at least directly, with the beauty of trees or with the shelter for game, although these aspects may be incidentally looked after. Also incidentally and more prominently must the influence of a forest cover on soil and water conditions be kept in view. This latter interest is directly important to the forester himself, since he must keep his ground in satisfactory productive condition, if he expects to be successful with his crop. The forester, then, looks on the forest as a crop and that involves *reaping as well as planting*.

THE FORESTER A HARVESTER.

He is a logger as well as a sower; he uses the axe as well as the spade and dibble. He uses the axe even more than the planting tools, for under certain conditions he

may, by judicious management in the cutting of the old crop, secure the new crop by the seeds falling from the old trees before he removes them.

This is the difference between the lumberman and the forester. The lumberman simply reaps nature's product, takes the best trees, the best cuts, and leaves the rest in possession of the soil for nature to do with it as it pleases, either to let it grow up to weeds and brush or to recover the soil, in due time reproducing another crop. The forester has the obligation, when he reaps, to provide *systematically* for a new crop; not the chance volunteer crop of nature, but one of economic value, of species that are most useful, in larger quantity and better form and in shorter time than nature, unaided, could or would produce.

If the College of Forestry were only logging its tract as the lumberman does, it would, indeed, be remiss in doing its duty.

If the college were only doing what is proposed to be done on certain parts of the State Forest Reserve, namely, to cull out the valuable spruce and leave the hardwoods altogether, it would still be remiss in its duty, for while, to be sure, the charge of denuding the land could not be brought, there would not be any good forestry practice in merely reducing the most valuable part of the crop and its chances of reproduction.

REPRODUCTION THE KEY-NOTE OF FORESTRY.

The forester may not harvest his crop without systematically providing for reproduction, replacing the harvested crop by a crop, if possible, superior in composition. This can be accomplished in more than one way, and the choice of method depends on many considerations which have reference not only to the condition in which the forest manager finds the forest property that he is to manage, but also to the con-

dition of the finances which are to back him in this business of forest cropping.

Where the lumberman has culled the desirable kinds and left the inferior, or comparatively less valuable ones, in possession of the soil, as is the case in most parts of the college tract, it stands to reason that, if the former are to be reestablished, it can only be done by reducing the latter and replanting artificially those we would wish to be most prominent in our new crop. Where the desirable kinds are still present, a new crop may be reproduced from the seeds of these, gradually removing the old trees as the young crop needs light. The College of Forestry proposes to use both methods, separately and in combination, taking advantage of any volunteer growth present, and leaving the volunteer growth of young saplings of hardwoods, conifers and older seed trees where desirable, and planting in pines and spruces to fill up the natural reproduction.

FOREST PRESERVATION BY REPRODUCTION.

The operations of the college last year extended over an area of less than 500 acres, of which it is estimated about 300 need planting. Owing to the unfavorable winter, operations were delayed, so that planting ground could be made ready only to the extent of 105 acres, which were planted. The nurseries established contain now material sufficient to plant 500 acres next spring, if the means for doing this planting can be had. Burnt and waste lands have also been planted, so that some 225 acres are now planted. In fact, counting by numbers, the college has, so far, planted 100 trees for every four trees cut. These are as many as its scanty resources permitted. It is, therefore, following the main precept of forestry to reproduce the crop. The charge that it is cutting down to mere saplings is truly puerile, for, while there would be no impropriety in doing

this, provided the crop were properly replaced, there is no market for such saplings. The story comes probably from the observation that small brushwood of the felled trees has been cut and bundled as an experiment, to see whether it could not be made useful.

THOROUGH UTILIZATION.

The lumberman, it is well known, cuts and utilizes only the logs, and those of the best trees and kinds, leaving a large part of the trees he has felled on the ground as *debris*, to feed the fires and prevent young growth. The forester is forced, by the mandates of his business, to utilize as much as possible not only the poor trees, but all that is in a tree; not only the logs of the best, but of the weed trees as well, and the cordwood and the brush, if he can; or else he may have to burn the brush later. Thorough utilization, instead of the wasteful one which the mere logger practices, distinguishes the forester's work. Unfortunately, there is no market for this inferior material, which a satisfactory silviculture requires to have removed. The College of Forestry is at least trying to satisfy, as far as possible, this requirement.

WHERE THE PROFITS GO.

The charge that the logging operations are carried on for the financial benefit of Cornell University is even more puerile, for, if there were any profits to be derived from the sale of the crop, the State has carefully guarded against having them applied for any other purpose than the one in hand, namely, the running of this demonstration or experiment station and the replacement of the crop. It is absolutely impossible for Cornell University to make any profits from the College Forest, since all returns are at once turned over to the State Treasurer for the purpose aforesaid. As a matter of fact, the finances of the college experiment station are not such as

to make anyone who knows them envious. Much more work in planting and improvement generally would have been done if finances permitted; that is, if the State had appropriated a more liberal working fund, such as had been asked for. Any business man knows that a certain working capital is required to carry on a given business; if this is below a certain figure, the business can only be carried on in a lame way and at a disadvantage.

INSUFFICIENT FUNDS.

This is the condition of the College Forest management; it is trying with an insufficient capital to earn what is necessary to pay for the administration and the improvements, including planting. A lumberman, logging these hardwoods, would find it difficult to make a satisfactory margin; a forester, who is obliged to log with more care and to replace the crop he has cut, necessarily works under greater financial disadvantages, and, so far, it has only been possible with great economy and care of the finances to secure any margin which can be applied to the forestry work.

The wise policy for the State, if it wished this experiment in forest management properly carried on, would have been either to make provision for annual appropriations for its conduct or to provide a sufficient working fund on which to run the experiment as a business. In my last annual report I stated that the modest fund of \$50,000 was asked, but only \$30,000 was allowed, which would hardly suffice to carry on a logging operation. To place the experiment on a proper basis, to permit the development of means of transportation from all parts of the property, which alone would make possible the method of gradual removal and reproduction by natural means, a working capital of not less than \$150,000 should be placed at the disposal of the management.

WHO ARE THE OBJECTORS?

It remains, then, to state that the College of Forestry is doing what it is set to do. It is harvesting from an area from which the valuable part has been already removed, the old, decrepit hardwood crop which is rotting and becoming less and less valuable, and is replacing it by a young, vigorous crop of better composition. It is doing this by trying to make the old crop pay for the new; that is, carrying on the experiment like a business venture.

It may be of interest to inquire whence the opposition to its procedure comes.

There are those who have used this property as a hunting ground, and naturally desire to preserve it as such for their own personal benefit. They are opposed to the change from old timber to young plantation, which only in years will again give them a hunting ground.

Again, there are those sentimentalists who consider it a sin to cut a tree, overlooking that their houses could not be built and their homes furnished without the utilization of the forest.

There are those who mistake the situation and think it is the State's Forest Reserve that is being cut over. Moreover, as they have made up their minds that forest preservation is only to be had from non-use, the forest preservation practiced by the college, which lies in the philosophy that all life is efficiently preserved only by reproduction, does not appeal to them.

There may also be those who know only one way of treating a forest, and hence, differing as doctors do, criticise the method of artificial reproduction by planting, which the college is in part forced, in part has chosen, to follow. These recognize only the culling process, which the lumberman has practiced with the softwoods, as legitimate; and advocate even that the State practice it in the Forest Reserve on its virgin lands, and cull out the valuable

spruce in order to make the reserve of financial use.

While, no doubt, the gradual removal system has some advantages, if properly applied, it means, when applied to hardwoods, which cannot be transported by water, the development of an extensive system of railroad transportation, which requires funds such as the college has not had at its disposal.

NO FEAR FOR THE PRESERVE.

The college is doing what it can do, under the circumstances surrounding the problem, on practical business lines. It was set to doing a definite, limited task. It has no control of, no voice in, no relation to, the management of the State Forest Preserve, and would not, if it had, advocate the application of its methods to the State Preserve. For the objects of the State Preserve are entirely different from those which the college tract is to serve, and hence what is proper to do on an area set aside for demonstration is by no means proper to do or directly applicable on an area set aside primarily for soil protection and recreation.

Hence no fear need be entertained that the State Preserve is in danger of being denuded through the agency of the college. On the contrary, the college hopes to influence the management of the Adirondack Preserve in the very opposite direction. It hopes that its success in reforesting burnt and waste areas will stimulate the State authorities to do likewise. This fall the college presented to the Forest, Fish and Game Commission several thousand pine and spruce seedlings, which were planted by an agent of the Commission and by interested landholders in the Catskill Reserve.

As a result of this first beginning the Forest Commission has just contracted with the College of Forestry for 420,000

conifer seedlings to be furnished from the nurseries of the College Forest and to be planted on waste areas in the Adirondack Preserve.

Dr. Fernow's explanation should suffice not only to convince the intelligent but misled reader of the shameful attack against which he protests—and which, we observe, was telegraphed from Watertown—but even to instruct the most ignorant and thoughtless, if not to silence the selfish, obstructors of a policy which has commenced none too soon its endeavor to remedy the apparently irretrievable and fatal mischief which has done so much to bring upon the State and the nation all the grievous results of deforestation. This is one of those matters of applied science which is of such overwhelming importance as to justify the nation in making any sacrifice of time and money, the State in meeting every minutest requirement of its Forester and the people in silencing promptly and effectively every unpatriotic citizen who seeks to make the highest interests of the State subservient to his own individual petty desires.

FIELD WORK OF THE ETHNOLOGICAL DIVISION OF THE AMERICAN MUSEUM OF NATURAL HISTORY IN 1901.

IN the past year the principal part of the field work of the Jesup North Pacific Expedition, which was organized in 1897, has been brought to a close. Parties were in the field in the interior of British Columbia, on Vancouver Island, on Queen Charlotte Islands, and in northeastern Siberia. Mr. James Teit continued his studies and collections among the Thompson Indians and their neighbors. Mr. George Hunt was at work in northern Vancouver Island.

The principal undertaking of the expedi-

tion on the Pacific coast of America was a thorough investigation of the Haida Indians of Queen Charlotte Islands, which was intrusted to Dr. John R. Swanton. Dr. Swanton went to Queen Charlotte Islands in September, 1900, and stayed among the Haida for more than a year. His work was eminently successful. He succeeded in unravelling the intricate social organization of the tribe, and in giving, for the first time, thoroughly satisfactory explanations of the significance of totem poles. He also collected much information on the customs and beliefs of the people, and brought back an immense mass of mythology, recorded in both dialects of the native language, as well as grammatical notes sufficient to give a clear insight into its structure.

Unfortunately the interesting art of the Indians of Queen Charlotte Islands has practically disappeared. The raids of collectors such as Swan, Jacobsen, not to mention the later inroads of traders and other collectors, have been such that hardly an article of the old objects of this tribe is left. This condition hampered Dr. Swanton very considerably, in so far as it made his work of obtaining interpretations and explanations of objects impossible. Although he took with him a large number of sketches and photographs of masks, rattles and other objects of Haida provenience, it was found almost impossible to obtain explanations for any of these, because the owners and users of these objects either were dead or could not be found.

The Siberian department of the expedition was in charge of Mr. Waldemar Joehelson. The party consisted of Mr. and Mrs. Joehelson, Mr. and Mrs. Bogoras, and Mr. Alexander Axelrod. The party was accompanied by Mr. Buxton, who was in charge of the zoological work. The expedition took the field in the spring of 1900. Mr. and Mrs. Bogoras, Mr. Axelrod and Mr. Buxton returned a few weeks ago,

while Mr. and Mrs. Joehelson will continue their researches until the summer of 1902.

Mr. Joehelson investigated the Koryak and Lamut. In the fall of 1901 he crossed the Stanovoi Mountains, and is at present engaged in researches among the Yukaghir, among whom he is continuing work previously undertaken by him among the western branch of this tribe. From here he is going to proceed westward, and will spend a considerable time among the Yakut. Mr. Joehelson reports that the culture of the Koryak has many features in common with the culture of the Indians of the north Pacific coast. Particularly is the mythology and folk-lore of these Siberian tribes and of the northwestern American Indians very much alike. Their arts are in some respects related to the arts of the tribes of southeastern and central Siberia, while in other respects there are strong resemblances to the Eskimo of Alaska. At the present time the natives of northeastern Siberia do not make any pottery; but Mr. Joehelson reports that remains of pottery were found in prehistoric sites. He collected very thorough information on the ethnology and physical characteristics of the tribe among whom he was working. The collection made by Mr. Joehelson among the Koryak has reached the Museum, and will be exhibited at an early date.

Mr. Waldemar Bogoras studied the Chukchee, Eskimo and Kamtchadal tribes. His previous studies among the Chukchee enabled him to make a thorough investigation of the languages of this district. He finds the Kamtchadal and Chukchee to be closely related languages. He has collected a large number of mythological and shamanistic texts, and much information of ethnological value. He reports that his collections are very extensive.

The various field parties of the Jesup North Pacific Expedition that have been at

work during the last four years have accumulated information on all the important tribes between Columbia River in America and the Amur River in Asia. The work of the expedition has been planned in such a way as to cover the whole area as thoroughly as possible. Since Nelson made a thorough study of the Alaska Eskimo, and Lieutenant Emmons had accumulated a wealth of material on the Tlingit of Alaska, no work was undertaken among those two tribes. Ethnological investigations were made in the State of Washington by Livingston Farrand; in British Columbia by Franz Boas, Livingston Farrand, Roland B. Dixon, John R. Swanton, George Hunt and James Teit. This work covered the whole province, with the exception of the Athapascan tribes north and east of Chilitin River. Archeological work in British Columbia and Washington was carried on by Harlan I. Smith. The work in Arctic Asia was described before; but, besides, investigations were made on the Amur River, where Berthold Laufer studied the Gold and the Gilyak, and where Gerard Fowke carried on archeological researches.

It would be premature to express an opinion, at the present time, in regard to the final results of a comparison of the material accumulated by the Jesup Expedition. It is, however, evident that the material collected proves early cultural relations between the tribes of northeastern Asia and northwestern America.

The results of the expedition are being published as rapidly as possible, in the form of monographic descriptions. Up to the present time the following have been published:

'Facial Paintings of the Indians of Northern British Columbia': FRANZ BOAS.

'The Mythology of the Bella Coola Indians': FRANZ BOAS.

'The Archeology of Lytton, British Columbia': HARLAN I. SMITH.

'The Thompson Indians of British Columbia': JAMES TEIT. Edited by FRANZ BOAS.

'Basketry Designs of the Salish Indians': LIVINGSTON FARRAND.

'Archeology of the Thompson River Region': HARLAN I. SMITH.

'Traditions of the Chilcotin Indians': LIVINGSTON FARRAND.

'Cairns of British Columbia and Washington': HARLAN I. SMITH and GERARD FOWKE.

'Traditions of the Quinault Indians': LIVINGSTON FARRAND.

'Kwakiutl Texts': FRANZ BOAS and GEORGE HUNT.

'The Decorative Art of the Amur Tribes': BERTHOLD LAUFER.

The manuscript for a number of additional monographs is completed, and others are in preparation. It is estimated, at the present time, that the results of the expedition will fill eight volumes of the Museum Memoirs.

The Museum is also carrying on work in China, which has been provided for by the generosity of a friend of the institution who desires his name to be withheld. This work has been placed in charge of Dr. Berthold Laufer, who went to China in July, 1901, and is carrying on work at the present time in the southern part of that country. The first part of the collection of Dr. Laufer has arrived at the Museum, and will soon be exhibited. The studies of an expert collector and investigator in that country cannot fail to give important scientific as well as practical results. Dr. Laufer's collections from China will be supplemented by collections made by Dr. C. C. Vinton in Korea.

Work has also been carried on in North America. In the beginning of the year Dr. A. L. Kroeber collected among the western Algonquin tribes. This work was in continuation of his work among the

Arapaho, and has yielded much valuable material. Dr. Kroeber's investigations were directed principally to the study of the conventionalism of the western Algonquin tribes, and to their religious ceremonies. In both these lines he collected information of great scientific interest. This investigation was provided for by the liberality of Mrs. Morris K. Jesup.

In 1901 Dr. Roland B. Dixon returned from his investigations in northern California, which were supported by the late Mr. C. P. Huntington. Later in the year Dr. Dixon was engaged in the preparation of the scientific results of his inquiry, the publication of which has been provided for by Mr. Archer M. Huntington.

During the summer two investigators were sent out to carry on work among Indian tribes. Mr. William Jones spent four months among the Sac and Fox, and brought back with him much linguistic and ethnological information. Mr. H. H. St. Clair, 2d, studied the northwestern Shoshone. His investigations were partly of a linguistic character, partly ethnological. He directed his attention to the study of the conventionalism of this tribe.

The results of the studies of North American Indians, carried on by the Museum, are in progress of publication. The first volume of these researches is devoted to the Eskimo of Hudson Bay and Baffin Bay, and is in press. The first part of the descriptions of Dr. Dixon is also nearly completed. It is expected that in the coming year the results of Dr. Dixon's and Dr. Kroeber's work may be published.

SCIENTIFIC BOOKS.

Der Gesang der Vögel, seine anatomischen und biologischen Grundlagen. Von DR. VALENTIN HÄCKER. Jena, Gustav Fischer. 1900. Gr. 8vo. Pp. viii+102. Mit 13 Abbild. im Text.

In the first chapter of this interesting brochure Dr. Häcker describes in detail the

anatomical structure of the vocal apparatus in birds, which, with the accompanying illustrations, gives a fair idea of the parts concerned and their functions. Chapter II. treats of the differences in the development of the vocal muscles in different groups of birds, and especially among different groups of song birds (Oscines), as well as of the differences in the vocal apparatus in the two sexes of the same species. In the female the parts are similar to those in the male, but much more feebly developed.

Chapter III. deals with the development of the song instinct, and discusses at some length the theories of Darwin, Wallace, Groos and others, and finally presents his own views on the subject, based in part on new material. The original call-notes, from which song has been developed, he believes were originally signal or recognition sounds, and that these have become specialized according to sex and as an aid to the male in attracting the female. He recognizes four stages or phases in the development of birds' calls and songs, namely: (1) A simple, uniform call, serving as a signal and recognition note for the species, developed by natural selection; (2) varied sexual calls or pairing calls, and (3) singing and warbling, or pairing songs, serving for the mutual attraction of the sexes, and developed through natural unconscious sexual selection; (4) summer, autumn and winter songs of Palearctic birds, expressive of the ordinary emotions of the species ('allgemeine Wirkung auf die Psyche'), and due, at least in part, to natural selection.

Chapter IV. treats of other love-making demonstrations, as the 'clapping' of the stork, the 'drumming' of woodpeckers (forms of 'instrumental music'), the 'bleating' of snipe, song-flights, dances, display of color-marking and other ornamentation, etc., and of their relation to voice and song. In this connection the evolution of courtship or love-making is also considered.

Finally there is a convenient summary of the author's evidence and conclusions, the whole forming a highly original and suggestive treatment of a very interesting subject.

J. A. A.

Catalogue of the Lepidoptera Phalaenæ in the British Museum. By SIR GEORGE F. HAMPTON, Bart. Vol. III., Arctiadae (Arctianæ) and Agaristidae. London. 1901.

This volume of 690 pages is published in the same style as Volume II. of this series, already noted in these pages. The Arctiadae subfamily Arctianæ comprises 946 species from the entire world, of which 83 are here first described. Fifty new generic names are proposed. The small family Agaristidae, which are, as the author rightly observes, an outgrowth of the Noctuidæ, comprises 225 species, of which eight are here first described. Eleven new generic names are proposed in this group. The author has made some orthographical changes. *Westwoodi*, *whiteleyi*, *kinkelini*, *blakei*, etc., appear in a scarcely recognizable guise as *vestwoodi*, *whiteleyi*, *cincelini*, *blacei*, etc. But *loewi* on page 226 escaped, doubtless by inadvertence. We think these changes scarcely advisable. The woodcuts in the text and the volume of 19 colored plates accompanying the book are up to the author's usual standard, if not slightly superior to it, and add greatly to the usefulness of the work. Owing to the author's method of selecting the types of the older genera, his refusal to recognize some of the names proposed by Jacob Hübner, and to his ideas of the extent of genera, we find the familiar names of the North American species sadly changed. We hope to become accustomed to these changes; but it emphasizes the fact that the concept of the genus is very largely a personal one. With this in view I have catalogued the specimens in the National Museum by specific names, as being the more stable. We miss the genera *Cydosis*, *Doa*, *Cerathosia*, *Psychomorpha*, *Eupseudomorpha* (*Edwardisia* Neum.), *Eudryas* and *Ciris*; but these the author doubtless regards as Noctuidæ. We hope they will not fail to find place in the succeeding volumes, as seems to have happened to the genus *Pygocnucha* with the species *harrisii* Bd., *funerea* Grt. and *robinsonii* Bd., and to *Ptychoglene coccinea* Hy. Edw., which do not appear in either Vol. II. or III., and certainly cannot come in the Noctuidæ which will follow. Our large and handsome Arctian, *Platyrepria virginialis* Bd., has been quite omitted. Equally

surprising is the absence of the familiar genus *Callimorpha* with its European and Asiatic species. If this genus belongs to the Noctuidæ by the author's classification, we think the scheme is some way at fault, for the insects are certainly Arctains in their broad characters. *Holomelina (Eubaphe) immaculata* Reak. has escaped notice, doubtless owing to Kirby's erroneous reference of it to the genus *Eudule* (Geometridæ). The species *Euhalesidota otho* Barnes, *Dodia albertæ* Dyar and *Pseudalypia geronimo* Barnes, appeared too late in description to be included. Most of these omissions are, we presume, intentional, but some seem due rather to the method by which the work has progressed, by which one family is completed before the critical study of the next one has been begun. Thus species which have been wrongly referred by cataloguers are liable to be overlooked. On page 79 *Bertholdia braziliensis* is described as new. The name must fall before *B. soror* Dyar (*Proc. Ent. Soc. Wash.*, IV., 391, May 3, 1901), which seems unquestionably the same species. On page 267 our author places *Spilosoma congrua* Walk. as a synonym of *Diacrisia virginica* Fab. We cannot agree to this, since it has been shown that a part of Walker's types were a distinct species, *antigone* Streck., and to this his description applies. *Arctia complicata* Walk. is made a synonym of *A. quenseli* Payk. We had always supposed it to be a form of *ornata*, which occurs in the same region (British Columbia), whereas *quenseli* is an Alpine form from the Alps, Labrador, White Mts., etc. But the author has Walker's type and should know. We shall be interested to see if *quenseli* can be found again in Vancouver Island.

Condensed descriptions of the larvae of several species are given, but in a sporadic manner. Most of the life histories published within the last few years are included, but practically all the older ones published more than ten years ago are omitted. Doubtless it would have added greatly to the author's labors to have made a thorough search for all larval descriptions, but surely the North American species might have been included as they have been very completely catalogued in a bulletin issued by the U. S. National Museum in 1889.

We do not, of course, desire to depreciate the value of this work, which, as we have before remarked, is a great boon to working entomologists, enabling us to identify our species far more readily than ever before. For, unlike many published synopses, Hampson's tables are practicable, not containing contradictions nor hair-splitting differences. Variation within specific limits may invalidate some of the characters which he uses, but we find this a very minor objection.

HARRISON G. DYAR.

GAUPP'S ANATOMY OF THE FROG.*

THIS is not the first time that the present work has been noticed in this journal. The other parts as they have appeared have been reviewed as follows: Parts I. and II., SCIENCE, Vol. VII., p. 463; Part III., SCIENCE, Vol. X., p. 491.

The present part deals with the viscera, the next and concluding 'Heft' is to take up the integument and sense organs. The organs are discussed in the following order: Digestive tract, respiratory organs, thyroid gland, derivations of the pharyngeal region, urogenital organs, cloaca, and the cœlomic cavities. As with the portions of the work already published it is impossible with this to analyze the facts presented and to point out the features which are novel. Attention, however, must be called to the broadly morphological aspects of the work. Dr. Gaupp has given us not only the anatomy of the adult frog but has emphasized the bearings of the various structures. Thus at the beginning we have an account of the developmental history of the head-gut region without which the account of the derivatives of the branchial region would lose much of its interest. In the same way the urogenital structures are introduced by a longer account of their history. Then there is a valuable summary of what is known concerning hermaphroditism in the frogs. The illustrations throughout illustrate the frequent use of the

*A. Ecker's und R. Weidersheim's 'Anatomie des Frosches auf Grund eigener Untersuchungen durchaus neu bearbeitet,' von Dr. Ernst Gaupp. Dritte Abtheilung, erstes Hälfte. Lehre von den Eingeweiden. Braunschweig, Fr. Vieweg und Sohn. Pp. 438. 95 figures. Mk. 15.

color making them more readily intelligible, and the German is everywhere easy of comprehension.

In general terms we can say of this part, as of those which have previously appeared, that it maintains the highest standard of descriptive anatomical work, and when the treatise is completed we shall have in accessible form details of the structure of the frog only exceeded in anatomical literature by those relating to man. One can only wonder how a man, turning out so much research in other lines, can find time to produce such a monumental work as this. Not only has practically all of the existing literature been analyzed (the list of papers relating to the viscera includes 877 titles, some of course duplicate), but every point has been, as the title page says, 'neu bearbitet.' It is not possible to hope for a translation of such an extensive work, but the original must have a place in every biological laboratory in the country.

J. S. KINGSLEY.

A Laboratory Guide to the Study of Qualitative Analysis. By E. H. S. BAILEY, Ph.D., Professor of Chemistry, and HAMILTON P. CADY, A.B., Assistant Professor of Chemistry in the University of Kansas. Fourth edition. Philadelphia, P. Blakiston's Son & Co. 1901.

In the preface to this edition the authors say, "At the present time there seems to be an opportunity to broaden the methods of instruction in qualitative analytical chemistry, and to teach not only the facts and the mechanical methods of carrying out the various operations of analysis, but also to render them more intelligible and interesting to the student by a proper application of the theory of electrolytic dissociation and of the mass law. * * * The aim of the authors has been to produce a book which would enable the careful student to successfully carry on the work without the constant assistance of the instructor."

Several of the current manuals in their latest editions open with an introduction pointing out the significance of these theories for analysis, and in some the dissociation of

the text has begun, as evinced by the furtive appearance of ions here and there throughout their pages.

The present authors are thorough; their introduction of twenty pages explains the theory of dissociation and the mass law, and the entire book is written in terms of ions; for example, "Antimony forms the positive antimonous Sb^{+++} ion, and the negative antimonite SbO_3^{---} , this antimonite, SbS_3^{---} , ortho-antimonate, SbO_4^{--} , this antimonate SbS_4^{--} , and antimonyl tartrate, $\text{SbOC}_4\text{H}_4\text{O}_6^-$ ions." Instead of acid or metal groups, we find groups of anions and cations.

The serious question is—are the operations of qualitative analysis rendered more intelligible to the student by this method? It seems to the reviewer that they are made more intelligible to an advanced student, but less intelligible to a beginner; but the authors intend this book for beginners.

For example the application of the phenomena of hydrolysis of salts of weak acids to the reactions occurring in the precipitation of basic salts is doubtless a help to a riper student. Again, while the following explanation of another reaction might be clear to an older student, might it not confuse a beginner? "If to a solution containing magnesium as ion, a solution containing hydroxyl ions in considerable concentration be added, a precipitate of magnesium hydroxid $\text{Mg}(\text{OH})_2$ is produced. Ammonium hydroxid is a much weaker base than magnesium hydroxid, and consequently if an ammonium salt, such as ammonium chlorid, be added to a solution containing magnesium hydroxid, the hydroxyl ions from the latter will combine with the ammonium ions to form the slightly dissociated ammonium hydroxid, thereby decreasing the amount of the magnesium hydroxid in solution. Therefore the precipitate of magnesium hydroxid is readily dissolved on the addition of ammonium salts."

In connection with the clause quoted, it may be noted that in the separation of the groups Al, Cr, Fe—Co, Ni, Mn, Zn—Ba, Sr, Ca—Mg, the authors give directions with each group to add ammonium chloride if it is not already present, but give no reason for

the use of this reagent, excepting the one statement in separating Ba, Sr, Ca—from Mg, that 'advantage is taken of the fact that magnesium carbonate is not precipitated in the presence of ammonium salts and ammonium hydroxid.' Surely the common explanation of these group separations—the successive breaking down ammonium double-salts in order of their instability by the reagents ammonia, ammonium sulphide, ammonium carbonate and disodium phosphate—is better than no explanation. It may be objected that recent research has disproved, or at least rendered improbable, the existence in solutions of ions indicating ammonium double-salts. At all events, an explanation on the lines of the above quotation regarding magnesium ion might be given.

In brief, this book can be cordially recommended to those students who are trained from the start by lectures based on Ostwald's 'Grundlinien der anorganischen Chemie,' and are taught to look at chemical phenomena chiefly in the light afforded by the dissociation theory.

E. RENOUF.

Laboratory Companion for Use with Thurston's Inorganic Chemistry. By W. A. THURSTON, F.R.S., Lecturer on Chemistry in Clifton College, London, Edward Arnold, 1901. Pp. 110.

The author says in his preface that this little book is a reprint of most of the experiments in Part 1 of his 'Inorganic Chemistry' and is to be used only as a laboratory companion. It is intended to be used before the study of qualitative analysis is commenced, 'and may replace such work altogether in the

Evidently it is impossible to criticise this case of those who leave school at an early age,' book without a knowledge of the text-book which it accompanies. It is very different from American laboratory manuals. The author holds it 'most important that the connection between physics and chemistry should be insisted on from the earliest stages.' The first thirty-nine experiments are purely physical with exception of one on the hardness of water, which explains permanent and temporary hardness, and gives methods for deter-

mining the hardness of water; and this before a single experiment on chemical change has been made.

The experiments given in the remainder of the book are of more chemical nature, and are interesting, but seem to lack logical sequence; it is to be supposed, however, that this seeming fault would disappear if the book was used in connection with the author's lectures, and that we have in the book those experiments which he considers to be of particular theoretic or practical interest to young students. However, the book cannot be recommended as a manual in connection with the text-books in actual use in this country.

E. RENOUF.

Chemical Lecture Experiments. By FRANCIS GANO BENEDICT, Ph.D., Instructor in Chemistry in Wesleyan University. New York, The Macmillan Company, 1901.

This book of 435 pages contains brief, clear instructions for performing a great number of lecture experiments. The instructor who has little apparatus at his disposal and turns to Newth or Heumann for help in illustrating his lecture often finds it impossible to show the experiments described, for lack of apparatus. The author has rigorously excluded all costly apparatus, and has yet succeeded in giving so many brilliant and instructive experiments as practically to cover the whole course. This renders his book invaluable to instructors in schools and in the smaller colleges. But this is not all; any lecturer who glances through the book will find much that is new and striking. Especially is this true of the experiments on metals, which have received such scant attention in the earlier books. The reviewer has Dr. Benedict's book in use and finds it a valuable supplement to Newth and Heumann.

EDWARD RENOUF.

GENERAL.

'THE Fauna and Geography of the Maldive and Laccadive Archipelagoes, being the account of the work carried on and of the collections made by the expedition during the years 1899 and 1900,' is now in course of publication in 'Cambridge at the University Press.' Part I. of the first volume appeared

several months ago, and Part II, it is announced, 'will be published on April 15, 1902.' The work is edited by 'J. Stanley Gardiner, M.A., fellow of Gonville and Caius College and Balfour student of the University of Cambridge.' The part issued contains, besides the introduction, excellent reports on the physiography of the archipelagoes in question and on the Hymenoptera, Land Crustaceans and Nemerteans. The work will be more fully noticed when completed.

SCIENTIFIC JOURNALS AND ARTICLES.

The *Journal of Comparative Neurology* for December. 1. Shinkishi Hatai, 'On the Mitosis in the Nerve Cells of the Cerebellar Cortex of Fœtal Cats,' shows: (1) The germinal cells of the nervous system of the fœtal cat present a modified form of the heterotypical mitosis of Flemming, (2) the number of the chromosomes represented by internodes of segmental filaments is 16, (3) all of the 'Halospindel' and a part of the central spindle are derived from the nucleolar substance, the central spindle containing the linin in great abundance. 2. Alice Hamilton, M.D., 'The Division of Differentiated Cells in the Central Nervous system of the White Rat.' The number and position of the dividing cells in later developmental stages (at and near birth) are described and compared with the results of other workers. Regarding the nature of the dividing cells, the author concludes: (1) There are at least two kinds of dividing cells in the central nervous system of the white rat, one small the other large, (2) neuroglia cells are derived from the small cells, nerve cells from the large ones, (3) dividing cells found in the gray matter and fiber tracts of the brain and cord are not indifferent cells, but are partly differentiated and it is possible to tell which are to become neuroglia cells and which nerve cells, (4) mitotic figures are occasionally found in multipolar nerve cells and in spongioblasts. 3. C. H. Turner, 'The Mushroom Bodies of the Crayfish and their Histological Environment.' A description of the supra-oesophageal ganglion of the crayfish, in the course of which it is shown that the mushroom bodies and the central bodies of the brains of crayfish and in-

sects are homologous structures and that both of these organs are also present in worms. The first article is illustrated by one plate, the second by two, and the third by four.

PLANS have been made for a new engineering quarterly, which is to be known as the *Harvard Engineering Journal*. The first number, which will appear on March 1, will consist largely of a description of Pierce Hall, the new engineering building, and of the engineering department.

THE two journals devoted to geographical education that have hitherto existed in this country have been merged, and will appear, beginning with January, as the *Journal of Geography*, devoted to the advancement of geographical education. The new journal will be edited by Richard E. Dodge, professor of geography, Teachers College, Columbia University, and hitherto editor of the *Journal of School Geography*; Edward M. Lehnerts, professor of geography, State Normal School, Winona, Minn., and formerly editor of the *Bulletin of the American Bureau of Geography*, and Dr. J. Paul Goode, instructor in geography, University of Pennsylvania, Philadelphia, Pa. The *Journal of Geography* will appear ten times a year, with 480 pages to the volume. It will be 7 x 10 inches in size, and extensively illustrated. The editors will be aided by a large number of associate editors, representing different phases of geography. The journal will be published by the J. L. Hammett Co., Boston and New York, and will be printed at Lancaster, Pa.

SOCIETIES AND ACADEMIES.

AMERICAN MATHEMATICAL SOCIETY.

THE eighth annual meeting of the American Mathematical Society was held at Columbia University on Friday and Saturday, December 27-28, 1901. A single day's sessions no longer suffice for the extensive programs of the Society's more prominent meetings. In providing for a two-day meeting it was hoped to gain ample time for the presentation of papers, but the long program completely filled the four sessions. Fifty-nine members were in attendance, a number exceeding all

previous records. An enjoyable social feature of the meeting was the dinner at the Hotel Marlborough on Friday evening attended by fifty persons, including representatives of the American Physical Society, which was in session on Friday.

At the annual election, on Saturday morning, the following officers and members of the Council were chosen: Vice-Presidents, Maxime Böcher, Frank Morley; Secretary, F. N. Cole; Treasurer, W. S. Dennett; Librarian, D. E. Smith; Committee of Publication, F. N. Cole, Alexander Zivert, Frank Morley; Members of the Council to serve until December, 1904, Pomeroy Ladue, G. A. Miller, P. F. Smith, E. B. Van Vleck. The President of the Society, Professor E. H. Moore, holds office for a term of two years expiring at the annual meeting of 1902. Resolutions were adopted by the Council expressing appreciation of the services of the retiring Librarian, Professor Pomeroy Ladue, who has held that office since 1895.

The following persons were elected to membership in the Society: R. E. Allardice, Stanford University; Miss Grace Andrews, Columbia University; S. E. Brasefield, Michigan Agricultural College; W. E. Brooke, University of Minnesota; T. C. Esty, University of Rochester; L. L. Jackson, State Normal School, Brockport, N. Y. Seven applications for membership were received and laid over, under the by-laws, for action at the February meeting.

Reports were received from the secretary, treasurer and librarian. These reports will appear in the Society's Annual Register now in preparation. The Society has now 378 members, a net gain of 21 over last year. There are 17 life members. The total attendance of members at the meetings of 1901 was 230, the number of papers read 140, in both cases a large increase over previous years. The Treasurer's report shows a balance of over two thousand dollars. The *Transactions* has just initiated its third annual volume; the *Bulletin* has been issued since 1891. An especially important event of the past year was the deposit of the library of the Society in the charge of Columbia University, through

whose generous action the books will now become available for the use of the members. A catalogue will soon be issued and steps will be taken to extend and complete the collection.

Following is a list of the papers read at the annual meeting. It may be added that the Chicago Section of the Society issued a preliminary program of nineteen papers for its meeting at Evanston, Ill., on January 2-3, 1902.

- (1) 'Further types of unicursal sextic scrolls,' by Virgil Snyder.
- (2) 'On the nature and use of the functions employed in the recognition of quadratic residues,' by Emory McClintock.
- (3) 'A theorem concerning the method of least squares,' by Harold Jacoby.
- (4) 'The theory of maxima and minima in n variables,' by Harold Jacoby.
- (5) 'Recent researches in the theory of screws,' by Sir R. S. Ball.
- (6) 'On surfaces whose geodetic lines are represented by curves of the second degree when represented conformably upon the plane,' by H. F. Stecker.
- (7) 'A recent method for treating the intersection of plane curves,' by C. A. Scott.
- (8) 'Two principles in the theory of multiple forms,' by Edward Kasner.
- (9) 'On the invariants of a homogeneous quadratic differential equation of the second order,' by D. R. Curtiss.
- (10) 'Some applications of the theory of assemblages,' by Arnold Emch.
- (11) 'On a method for constructing all the groups of order p^n ,' by G. A. Miller.
- (12) 'Note on the transformation of a group into its canonical form,' by S. E. Slooem.
- (13) 'On the characteristics of differential equations,' by E. R. Hedrick.
- (14) 'On the circuits of plane curves,' by C. A. Scott.
- (15) 'On the plane quartic curve,' by F. Morley and A. B. Coble.
- (16) 'On the real solutions of systems of two homogeneous linear differential equations of the first order,' by Maxime Böcher.
- (17) 'The projective axioms of geometry,' by E. H. Moore.
- (18) 'Remarks on the sufficient conditions in the calculus of variations,' by E. R. Hedrick.
- (19) 'Note on isotropic congruences,' by L. P. Eisenhart.

(20) 'Lines of length zero on surfaces,' by L. P. Eisenhart.

(21) 'Concerning the class of a group of order p^m that contains an operator of order p^{m-2} or p^{m-3} , p being a prime,' by W. B. Fite.

(22) 'A characteristic property of the parabolic curve of n th order,' by Edward Kasner.

(23) 'On the content or measure of assemblages of points,' by Carl Gunderson.

(24) 'On the holomorphisms of a group,' by J. W. Young.

(25) 'On the resolution of orthogonal transformations,' by P. F. Smith.

(26) 'Proof that the group of an irreducible linear differential equation is transitive,' by Saul Epstein.

(27) 'On the uniform convergence of Fourier's series,' by W. B. Ford.

The next meeting of the Society will be held in New York City on February 22. The Chicago Section will meet at the University of Chicago in April.

F. N. COLE,
Secretary.

COLUMBIA UNIVERSITY.

THE ACADEMY OF SCIENCE OF ST. LOUIS.

At the meeting of the Academy of Science of St. Louis on the evening of December 16, the Nominating Committee reported a list of candidates for the offices of the Academy for the year 1902.

A paper by K. K. MacKenzie and B. F. Bush, entitled, 'The Lespedezas of Missouri,' was presented by title.

Professor F. L. Solden delivered an address on the advance made in education during the nineteenth century, stating that the most characteristic feature of the century's progress lay in the epoch of expansion and organization which it marked. The influence of Pestalozzi, Froebel, Horace Mann, William T. Harris and other distinguished educators was traced, the marked change in opinion concerning the commercial value of education brought out by the Centennial exposition of 1876 was indicated, and the establishment of a true university grade in this country with the opening of the Johns Hopkins University, the year following, was commented on.

Professor F. E. Nipher stated that he had continued his experiments on the production

of ether disturbances by explosions, and by the motion of masses of matter. He had apparently succeeded in eliminating the effects of the shock of the air-wave upon the magnet needle. The needle is adjusted to a condition approaching maximum sensitiveness. There is no iron about the apparatus, except what is contained in the needle and in the compensating magnets. The latter are clamped in place so that the structure on which they are mounted may be pounded by a mallet without disturbing the needle. Rowland effects due to convection of electrified particles have also been eliminated. There remains a marked deflection of the needle, seeming to indicate that an ether distortion or wave originates in a sharp or violent explosion. This result is so amazing that it is announced with the statement that the whole subject is yet under the most searching examination. The coherer and the receiver of the telephone are to be used in two wholly different plans of experiment, in one of which the effects along the entire track of a leaden bullet are to be summed up in an alternating current. The results which seem to have been reached are in entire harmony with the well-known experiment of Michelson and Morley, who found that the ether within the building in which they worked was being carried along with the building and with the earth in its orbital motion.

WILLIAM TRELEASE,
Recording Secretary.

NORTH CAROLINA SECTION OF THE AMERICAN
CHEMICAL SOCIETY.

The fall meeting of the North Carolina Section was held on Saturday, November 23, 1901, at 11 a. m., in the office of the State Chemist, Agricultural Building, Raleigh, with presiding officer, W. A. Withers, in the chair. Eighteen (18) members and visitors participated in the meeting.

After the reading and adoption of the minutes of the previous meeting and the transaction of some minor miscellaneous business, the following program was presented and discussed:

'Notes on Instruction in Dyeing': G. S. Fraps.

The author gave a brief account of methods used and results obtained, in teaching dyeing at the North Carolina College of Agriculture and Mechanic Arts. Scrap books, which had been prepared by students, containing dyed samples and tests made on them were exhibited, to show the methods pursued.

'Systematic Acid Analysis': A. S. Wheeler.

The plan suggested by Abegg and Herz (*Zeit. für Anorg. Chem.*, 23, 236) is being tried with certain modifications with his classes in qualitative analysis in the University of North Carolina with considerable success. He finds it to be the nearest approach to a separation similar to that used with bases that he has cognizance of.

'Recent Work on the Phthaleins': Charles E. Brewer.

This was a review of the several articles that have recently appeared. The first of these was by Orndorff and Brewer on the constitution of gallein. The other three articles, in the current volume of the *Berichte* contributed by Liebermann, Thiele and Jaeger and Feuerstein and Dutoit, were on dioxyfluorescein or oxyhydroquinone phthalein. In every case the view that the phthaleins react as tautomeric compounds was sustained. All the contributors agree that those derivatives which have color should have given the quinoid structure, while those which are colorless are properly represented by the lactoid structure. A number of new compounds belonging to each of these two classes were reported.

'A Constant High-Temperature Bath': Charles Baskerville.

An ordinary enameled iron water-bath is made use of, surrounded by asbestos with a copper cover and a second asbestos top projecting in the bath and a wrought-iron float constructed to hold crucibles of various sizes. The liquid of the bath is composed of a mixture of the more fusible alloys. A specially constructed thermostat, made of very infusible glass, controls the flame of a large lamp. A glass tube, open at the bottom, penetrates the dual cover and is placed within one of the crucible receptacles. A mercury thermometer under 20 degrees atmospheric pressure is used.

'New Apparatus: (1) Soil Digestion Bath

and (2) A Modified Condensing Bulb Tube for Nitrogen Determinations': C. B. Williams.

Drawings of these two pieces of apparatus, designed for use in the Chemical Laboratory of the North Carolina Department of Agriculture, were submitted; also, a description was read. Mr. Williams stated that these two pieces of apparatus had proved very helpful, both in point of economy of time and reliability.

'Nitrification of Ammonium Sulphate and Cotton-Seed Meal': W. A. Withers and G. S. Fraps.

The conclusions drawn by the authors from their pot experiments on nitrification are:

(a) Ammonium sulphate in some cases hinders nitrification.

(b) In nitrification of ammonium sulphate, sulphuric acid is produced and hinders the process unless neutralized.

(c) Soils differ in their action, depending upon the kinds of bacteria present.

(d) The relative number of organisms in the soil capable of nitrifying ammonium sulphate may be increased by continued addition of the substance and lime if such germs were originally present.

(e) Calcium carbonate is very helpful in nitrification.

CHARLES BURGESS WILLIAMS,
Secretary.

THE SECTION OF GEOLOGY AND MINERALOGY OF
THE NEW YORK ACADEMY OF SCIENCES.

THE Section met December 16, at 8:15 P. M. Mr. D. W. Johnson gave a paper on 'Notes on the Geology of the Saline Basins of Central New Mexico.' He said that in the Antonio Sandoval Grant, near the center of the Territory of New Mexico, are noted saline deposits which have served as important sources of a very pure salt in past years. The character of these basins was discussed in some detail, and points concerning their historical interest briefly touched upon. The general geology of the central portion of the Territory was then briefly reviewed, while the local geology of the Antonio Sandoval Grant was presented more in detail. It was shown that the saline lakes occur in the Red Beds of Jura-triassic or Per-

mian age. These beds are separable, on lithological grounds, into three divisions, designated as the Red Series, the Chocolate Series, and the Vermillion Series. Lenticular deposits of salt and gypsum are frequently found at the top of the lower or Red Series, and evidence was produced to show that the Saline Basins under consideration occur at this horizon. The facts were noted that Triassic types have been described from some part of the Red Beds (presumably the upper), while a characteristic Permian fauna has been recently found near the base of the Red Series. In view of these facts, and since no horizon of marked transition other than the salt and gypsum deposits occurs, it was suggested that these deposits might possibly mark the boundary line between the Jura-triassic and Permian in central New Mexico.

Dr. D. S. Martin presented a paper entitled 'Some Geological Notes on the Neighborhood of Buffalo, N. Y., made in the Summer of 1901.' Dr. Martin did not claim any special novelty for the data presented, but judged that they might be of interest to any members not acquainted with that region. Dr. Martin first outlined roughly the distribution of the series from the Medina to the Corniferous Limestone, and then mentioned in detail certain special features. He particularly noted certain joint seams in the Niagara Limestone near Lockport, N. Y., which have been much eroded and decomposed, and which are now filled with a dark brown claylike material, containing numbers of half decayed modern land shells, such as *Helix albolabris*. He then described the series of rocks exposed in the quarries found on North Main street, Buffalo, which are the source of the famous *Euryp-terus* specimens. This series extends from the Corniferous Limestone to the Saline series and is divisible into five members, known as the Corniferous Limestone, the Blue Limestone, the Bulkhead Rock, the Water Limestone, and the Salina. Dr. Martin particularly emphasized the contact between the Bullhead Rock and the overlying Blue Limestone, and noted the occurrence of a sandstone dike extending to the top of the Bullhead series.

Mr. A. J. Queneau, in a paper entitled 'The Grain of Igneous Rocks,' said that a general observation might be made in regard to intrusive dikes. Near the margin the rock is dense, often glassy without any appreciable grain, whereas the grain begins to grow coarse according to some definite law, progressively as the distance from the wall increases. The present paper is based on the study of the laws governing such increase. It appears that the loss of heat is of paramount importance.* The problem taken up is very analogous to the one presented by the cooling of a slab of finite thickness and of great length and depth with respect to the first dimension, viz., the thickness. The method followed rests on the *Théorie de la Chaleur* of Fourier, and on the general theory of cooling by Professor R. S. Woodward.† The following laws have been deduced: (1) The zone of varying grain will vary indirectly as the initial temperature. From this follows that (a) Plutonic rocks very deeply seated will not present a zone of varying grain to any extent. (b) Rocks which come to rest at a temperature nearing their consolidation point will present a wide zone of varying grain. (2) The time of cooling, other conditions being the same, varies as the square of the thickness of the dike.‡ From this last law it is assumed that the size of the crystals vary as the square of their distances from the nearest margin; then the square root of their area, which can be measured, varies directly as the distances from the margin. Thus we have a simple law of easy application.

RICHARD E. DODGE,
Secretary pro tem.

BIOLOGICAL SOCIETY OF WASHINGTON.

The 345th meeting was held on Saturday evening, December 14.

Mr. W. H. Holmes spoke on 'Finds of Fossil Remains and Indian Implements in a Spring at Afton, Indian Territory.' The spring was situated in a level country and the superficial strata consisted of four feet of sand overlying

* Alfred C. Lane, *Geol. Surv. of Michigan*, Vol. VI.

† *Annals of Mathematics*, Vol. III.

‡ Riemann, 'Partielle Differential Gleichungen.'

a gravel bed about sixteen feet in thickness. In the gravel at the bottom of the spring were found several hundred finely made flint arrow-heads and spear-points, such as were used by the buffalo-hunting tribes, flakers of deer antlers, bones of recent wolf, horse, bison and elk, and teeth and fragments of bone of fossil bison, horse, mammoth and mastodon, teeth of these latter being present in considerable numbers and in an excellent state of preservation. In the gravel all about were similar fossil remains, but somewhat widely scattered. It had been learned from an old Indian chief that the arrow heads and other implements were cast into the spring as offerings, but it was difficult to account for such large numbers of fossil teeth and broken bones and their mixture with those of recent animals. It was suggested by Mr. Gilbert in the discussion which followed Mr. Holmes' paper, that possibly these teeth were offerings also, having been gathered from time to time, as they might have been washed out, and cast into the spring.

W. A. Orton described 'The Wilt Disease of the Cow Pea and its Control,' stating that the disease was caused by the clogging of the water tubes by bacteria, and that it was very prevalent among all save one of the varieties of the cow pea. This variety, known as the Iron, was resistant to the wilt bacillus as well as to the nematode, causing root-knot; that it was thus doubly resistant was an additional reason for hoping that similar cases might be found among other plants.

Theo. Gill presented a paper, in conjunction with C. H. Townsend, on 'The Largest Deep-Sea Fish,' this being the species described in *Science* for December 13, under the name of *Macrius amissus*.

William Palmer gave 'A Study of Two Ghosts,' explaining the manner in which spectral appearances had been caused on two occasions. In one instance the shadow of a person had been thrown on a cloud of mist by a light shining through a window of an adjacent house, and in the other a similar shadow had been cast on a passing dust cloud by an electric light. The disappearance of the mist and of the dust gave the impression of a vanishing figure.

F. A. LUCAS.

SHORTER ARTICLES.

ARE HUMMING-BIRDS CYPSELOID OR CAPRIMULGOID?

IN the *Proceedings* of the Zoological Society of London, for April 2, 1901, there is a most interesting paper by Professor D'Arcy Thompson 'On the Pterylosis of the Giant Humming-bird (*Patagona gigas*).' It is illustrated by some excellent figures and the description is detailed and accurate. In his concluding paragraph the writer says: "On the balance of evidence, I am inclined to think that the facts of pterylosis, so far as they go, tend to justify the association of the humming-birds with the goat-suckers and swifts, and, if anything, to bring them somewhat nearer the former than the latter of the last two." But he adds that 'the evidence is confused and the judgment far from clear.'

In the *Journal of the Linnean Society*, 1888, Dr. R. W. Shufeldt published his well-known 'Studies of the Macrochires.' He, too, had investigated the pterylography of humming-birds, goat-suckers and swifts, and he reached these conclusions: The *Caprimulgi* "have their nearest kin in the owls, and they have no special affinity with the *Cypseli*, much less with the *Trochili*. * * * The true swifts must have a group or an order created for them, as the order *Cypseli*, * * * just outside the enormous Passerine circle, but tangent to a point in its periphery opposite the swallows. * * * For the *Trochili*, I have already proposed a separate order * * * and am to-day more convinced than ever of the correctness of that proposal." On page 369 Dr. Shufeldt says further regarding humming-birds and swifts: "They differ essentially in their pteryloses and in the number of their secondaries."

I have just completed a careful examination of 23 humming-birds, representing 11 species, ranging in size from *Mellisuga humilis* to *Coeligena clemenciae*, and 15 swifts, representing 10 different species, including *Collocalia*, *Hemiprocne*, and *Macropteryx*. I have also studied carefully the pterylography of 17 goat-suckers, representing 8 species. I have, therefore, had a considerably larger number of species at my disposal than even Dr. Shufeldt

had, and it seems to me worth while to state what conclusions my studies have led me to.

No group of birds with which I am acquainted shows such remarkable uniformity in their pterylography as do the humming-birds. So far as I can see Professor Thompson's figures of *Patagona* would answer, almost without change, for any of the 11 species I have examined. The only important difference is the absence of anything like what he calls the 'lateral' tract; I have found this in none of the specimens before me. In the feathering of the occipital region, moreover, my specimens do not agree with his figure, though they answer well to his description. Even nestlings and embryos (removed from the egg before hatching) of *Mellisuga* have precisely the same pattern of pterylosis, as in all adults. The swifts are not so constant to a single pattern as the hummers, and show some considerable generic diversity, but they nevertheless possess a very characteristic type of pterylosis. I am utterly unable to agree (however much we may allow for individual diversity in the birds and the personal equation of the observer) to either Dr. Shufeldt's account, or Professor Thompson's figure, of the cypseline pterylosis. This is not the place to enter into details, but one point at least must be mentioned. The posterior cervical apterium, so conspicuous in the humming-birds, is present in every swift I have examined, and I have not seen it in any other birds. Professor Thompson failed to find it in *Collocalia* and Dr. Shufeldt says it is *never* present in the swifts!

In the feathering of the head, the humming-birds do show a slight resemblance to the goat-suckers, but this is really not so close as appears at first sight. The swifts differ from both, but some species have the feathers on the occiput few and far between, as in the hummers. It must be borne in mind, however, that the pterylosis of the head is quite variable, perhaps more so than that of any other part of the body. In the pterylosis of the neck, the swifts and humming-birds are very similar, especially on the upper side, while the goat-suckers are strikingly different. The feathering of the back shows considerable re-

semblance between swifts and humming-birds, for while some swifts have the femoral tracts separate, others have them more or less united with the dorsal, as they are in the humming-birds. The dorsal tract of the *Caprimulgi* is obviously different, and the femorals are always well defined and free from the dorsal. The humeral tracts in both swifts and hummers are near the dorsal, and their posterior ends tend to run into either the dorsal or the anterior end of the femorals. In the goat-suckers, the humerals are narrow and some distance from the dorsals. On the ventral side, we find the sternal tracts in the goat-suckers are more or less abruptly narrowed to form the rather long ventrals, while in the swifts and the humming-birds, the sternals pass imperceptibly into the short ventrals. As far as the number of secondaries is concerned, that is chiefly a matter of size; humming-birds have 5-7, swifts 8-11, and goat-suckers 12-14.

For these, and very similar reasons, I am led to disagree with Professor Thompson that the humming-birds are nearer to the goat-suckers than to the swifts, and I must dissent quite as strongly from Dr. Shufeldt's opinion that the pteryloses of swifts and humming-birds are 'essentially different.' To my mind, the swifts and humming-birds are pterylographically nearer each other than are grouse and guans, and almost as nearly allied as grouse and quail. I cannot see that the *Caprimulgi* have any close relationship to either.

HUBERT LYMAN CLARK.

OLIVET, MICH.,

INJURIES TO THE EYE CAUSED BY INTENSE LIGHT.

THERE may be some general interest in the following cases of optical phenomena brought about by exposure of the eye to intense light.

Professor M., while working in a rather dark corner of his laboratory, accidentally broke a low-resistance circuit in which an electric current at a pressure of five hundred volts was flowing. The arc formed was about a foot from his eyes and appeared like a ball of fire rather more than six inches in diameter. Immediately there was a feeling that something had 'given way' in his right eye, though no

pain was experienced. Shortly afterwards he noticed that a part of the retina was permanently affected, the injured portion being in the form of a square, with the center of vision in one corner. The sharp outlines of this field could be easily distinguished, and upon closing the eye, fan-shaped flashes of a violet color spread out from one corner over the injured area at equal intervals of several seconds, their recurrence being entirely involuntary. After being some time in the dark the flashes of color ceased.

There was in general an apparent lack of illumination over this part of the retina, accompanied by a loss of power to properly distinguish colors, more especially green. The outlines of objects were blurred, their dimensions also appearing to be reduced by about one quarter. Printed letters could not be recognized at more than half the distance at which they were easily read by the uninjured eye. Parallel lines seemed to converge over the injured portion. In walking and riding he noticed at a short distance ahead what seemed to be a spot a few inches in diameter and about two inches high, which he often turned his wheel aside to avoid. The injured eye was also very defective in estimating distances. The effect lasted several weeks with almost undiminished intensity, but has since been gradually disappearing.

The second case is that of Mr. R., who in May, 1900, imprudently observed for some time the partial eclipse of the sun with his eyes unprotected in any way. No effect was noticed until late in the day, when in looking over the hillside he saw apparently a flock of eight or ten red birds whose movements were very erratic. Since the birds appeared wherever he looked, he carefully examined the field of vision, and discovered that the sun had formed a crescent image on the center of the retina of the left eye. The color of the image was green with a narrow red border. The injured area seemed to be quite blind, and parallel lines diverged around it, this effect being just the opposite of the previous case. The injury is always noticeable and very annoying, especially in reading. In making observations in the physical laboratory he had to discontinue

the use of his left eye, which he had been accustomed to use constantly. The effect is still noticeable after a year, though it causes much less annoyance.

A case exactly similar to this has been described, in which the injury had lasted ten years.

CORNELL UNIVERSITY.

CURRENT NOTES ON METEOROLOGY.

RAINFALL, COMMERCE AND POLITICS.

A SUGGESTIVE paper by H. H. Clayton in the *Popular Science Monthly* for December, on 'The Influence of Rainfall on Commerce and Politics,' forcibly emphasizes the interest and value of the studies that may be made along the lines of human, or economic, meteorology. In pointing out that 'every severe financial panic (in the United States) has been closely associated with a protracted period of deficient rainfall,' and that 'there has been no period of protracted drought without a severe financial panic except a period, the effects of which were masked by the large disturbances attending our Civil War,' the author has clearly indicated how closely national crises are related to the changing meteorological conditions of successive years. The sequence of deficient rainfall—deficient food supply—financial panics—changes in the dominance of political parties,—is also considered. There is much in this discussion that might well occupy the attention of those who take pleasure, not only in studying the correlations of meteorological conditions and politics in the past, but who also wish to try their luck at forecasting the political changes of the future. Mr. Clayton rightly calls attention to the value of such investigations on the economic side of meteorology, and to the need of more opportunity in our universities for the study of the influences of the atmosphere upon health, upon commerce and upon politics.

This interesting paper suggests a number of other, somewhat similar, examples of the influence of weather upon political movements of greater or less importance. Among the causes of the 'Boxer' outbreak in China, which

involved several nations in war, was the scarcity of rain during the preceding autumn, and the consequent impoverishment and discontent of the people. In this very Chinese war, the allies at Tientsin (July 3, 4) are reported to have been saved from total defeat by a torrential rainfall which obliged the Chinese to retire. A severe winter precipitated the outbreak of the French Revolution. The Russian saying that the Russian Generals January and February are invincible dates from the time of Napoleon's terrible retreat from Moscow, and again suggests the historical importance of a severe winter. Going back much farther, into more ancient history, we find that in the year 54 B. C., Cæsar's legions in Gaul had been scattered about in separate winter quarters, because of the scanty harvest following a drought. Under these circumstances a defeat at the hands of the enemy was natural, and actually took place.

The number of such cases might be extended almost indefinitely, but anyone who reads history with his eyes open to the controls which lie behind the military and political movements of the past will be able to collect an abundance of illustrations for himself.

ECONOMIC EFFECTS OF LAST JULY'S HEAT AND DROUGHT.

ANOTHER recent paper, by the compiler of these Notes, published in the *Bulletin of the American Geographical Society* for October, under the title, 'Some Economic Aspects of the Heat and Drought of July, 1901, in the United States,' brings out certain additional features in connection with the economic side of meteorology. Trade in the United States throughout the greater part of July showed some very marked effects of the high temperatures and of the drought. There was, on the one hand, a stimulation of retail trade in all kinds of light-weight summer clothing, and the continuance of the heat carried this sale beyond the usual time. On the other hand, there was commonly noted a depression of retail trade other than that in summer goods. The heat of the first week of July caused a practical suspension of industrial activity in

many cities, thus interfering with the output along the several lines affected by the shut-downs. The drought caused a lack of pasturage in the Southwest, and this led to record-breaking shipments of cattle and hogs to market at Kansas City. Thus the market became overstocked; buyers dictated prices; the situation in hides was much complicated. Prices of cereals and of railroad stocks showed marked fluctuations throughout the hot spell, the damage to corn being the chief control in the case. Reports of rain in the corn belt sent up the prices of corn, and of the stocks of the corn-carrying railroads. Under the influence of the July drought, the number of failures in August was larger than usual. Building was interfered with, and trade in building materials was checked. Meat was in less, and fruit and vegetables were in greater, demand than usual. The demand for ice was so great that there was difficulty in chartering vessels enough in which to ship the ice from Maine.

SNOW CRYSTALS.

MR. WILSON A. BENTLEY, of Nashville, Vt., who has spent some twenty years in the critical study of snow crystals by means of micro-photography, contributes a paper under the title, 'The Story of the Snow Crystals,' to *Harper's Monthly Magazine* for December. This article does not differ essentially from one by the same writer in the *Monthly Weather Review* for May last. Since January, 1885, 800 photographs of snow crystals have been taken, and no two of them are alike. The conditions under which the different forms of crystals fall have been carefully studied, and it is stated to be possible to read the character of a storm directly from its crystals. Mr. Bentley's micro-photographs rank with any that have been obtained in Europe. Several of the most beautiful types are reproduced with the article.

WEATHER AND TETANUS.

NUMBERS of cases of tetanus have recently followed vaccination in different sections of the eastern States where there have been outbreaks of smallpox, and the blame has usually been laid upon the impurity of the vaccine matter. In at least one case, however, a study

of the conditions seems to lead to another conclusion. The recent epidemic of tetanus in Camden, N. J., prompted the local Board of Health to send out a circular giving the facts collected by the Board. From this circular it appears that a bacteriological examination of the vaccine matter used in Camden showed it to be free from tetanus germs. The reason for the epidemic is found in the prevailing weather conditions, combined with carelessness on the part of persons recently vaccinated. There had been a long spell of dry weather, accompanied by high winds, which raised the dust, so that there were tetanus germs constantly present in the atmosphere. Infection resulted when the scabs had been removed, and the germs gained access to the wound.

R. DEC. WARD.

WIRELESS TELEGRAPHY.

THE readers of SCIENCE may be interested in the following editorial taken from the London *Electrician* of December 20. It seems to us also that the Marconi system cannot be expected to replace submarine cables, which form at present a network which appears almost as complicated on a small map of the world as the network of railways on an ordinary map of the State of Illinois. An attempt to substitute the Marconi system for existing cables would lead to a state of affairs closely analogous to the confused din in a stock exchange where each person makes more noise than all the rest. This analogy enables one to appreciate the limitations of wireless telegraphy. In the one case we have electrical waves and in the other case sound waves spreading in all directions from each sending station; and we must remember that Marconi's receiver is far inferior to the human ear in its ability to analyze a complicated system of waves falling upon it, or, in other words, to respond selectively to certain types of waves.

W. S. FRANKLIN.

"The current week opened with the startling announcement throughout the world that Mr. Marconi had succeeded in transmitting wireless signals across the Atlantic. By means of a

kite he had contrived, at St. John's, Newfoundland, to intercept waves transmitted from Cornwall, the actual receiver being a telephone and the actual 'message' the Morse letter 'S' at intervals of five minutes, as prearranged. The sounds were very faint, though they are declared by Mr. Marconi himself to have been unmistakable. Thursday, December 12, 1901, may prove, therefore, to be a date to be remembered in the history of wireless telegraphy. Within this apparently feeble result—three very faint clicks repeated at intervals of five minutes—there is to be seen the germ of ocean wireless telegraphy, and, perhaps, telephony. It is a germ that promises to develop into abundantly fruitful maturity. It is not in the interlinking of continents divided by an ocean, but rather in the overspreading of the ocean itself with telegraphic facilities that the power and fruitfulness of this latest achievement of Mr. Marconi is to be perceived. Submarine cables already link ocean-divided continents far better than wireless telegraphy can ever do. Long ago we pointed out that the true field of wireless telegraphy is across comparatively short distances of water—that, in fact, it is really a disadvantage to wireless telegraphy to be able to take in such a wide compass as an entire ocean. Indeed, when such immense areas are covered the probabilities of confusion and clashing of signals is a thousandfold increased.

Let any section of the public should be disposed to regard Mr. Marconi's latest experiment as foreshadowing the replacement of submarine telegraph cables by wireless apparatus, we hasten to bid them dismiss the idea. No serious competition with submarine telegraphy can ever take place on a commercial basis, at any rate until the Marconi system is evolved into something very different from what it now is. This raises the interesting but thorny question of patent rights. Others besides Mr. Marconi will have something to say on this head. We do not say that Mr. Marconi will not succeed in sending messages between this country and America; but, having regard to the uncommercial conditions under which they must be sent, it is clear that the wireless channel of transmission will be rigorously avoided by business men, to whom a guarantee of secrecy and the certainty of a recorded message are absolutely indispensable. Wireless signals in the ether can never be secret; it must always be possible to intercept them. And messages received in no more permanent form than by sounds in a telephone are too evanescent and uncertain to commend themselves

to the purposes of commerce. Nor must it be overlooked that the speed of transmission by Marconi telegraphy must be extremely limited compared with the possibilities of the cable. It is, therefore, not the territory of the telegraph and cable companies that Mr. Marconi can successfully invade with his wireless telegraphy."

CLARENCE KING.

A MEETING of all the scientific men engaged in the work of the U. S. Geological Survey was held in Washington on Saturday, December 28, to express their profound sorrow at the death of Mr. Clarence King, first Director of the Survey. Short but appreciative addresses, eulogistic of the life and work of Mr. King were made by Major J. W. Powell, the successor of Mr. King as director of the survey; Hon. Charles D. Walcott, the present director, and Mr. S. F. Emmons. At the request of the director Mr. Arnold Hague read the following tribute to the character and achievements of Mr. King, which was unanimously adopted by those present as an expression of their admiration of his life and their bereavement in his death:

"It is with profound sorrow that we learn of the death of Clarence King, the first director and, in a sense, the founder of the Geological Survey. In him we have lost not only a great scientific leader, but a genial and accomplished gentleman, whose personal qualities endear him to all who knew him, and whose many acts of loving kindness have left a wide circle of friends in all walks of life to mourn his untimely death.

"As organizer and, during ten years, Chief of the United States Geological Exploration of the Fortieth Parallel, he set higher standards for geological work in the United States and laid the foundations of a systematic survey of the country. He gave practical recognition to the fact that a good topographical map is the essential basis for accurate geological work.

"As first director of the present Geological Survey, he laid down the broad general lines upon which its work should be conducted and which, as followed by his able successors, have led to its present development. He established the principle that a geological survey of

the United States should be distinguished among similar organizations by the prominence given to the direct application of scientific results to the development of its mineral wealth.

"In that essential quality of an investigator—scientific imagination—no one surpassed King, and his colleagues have all profited by his suggestiveness. He was never content with the study of science as he found it but always sought to raise the standard of geology as well as to apply known principles to the survey of the country.

"King first introduced microscopical petrography into American geology and, as early as his Fortieth Parallel work, he foreshadowed the application of exact physics to questions of geological dynamics. Early in the history of the present survey he established a physical laboratory. One result of this step was a paper on the 'Age of the Earth' which takes very high rank among modern scientific memoirs. Although in his last years circumstances rendered it necessary for him to devote most of his time to other occupations, he had by no means abandoned plans for geological investigation on a scale worthy of his reputation.

"In Clarence King geological science in America will miss a pioneer and a leader; the Geological Survey loses its broad-minded founder and adviser, and its older members a beloved friend."

MAP OF THE PHILIPPINES.

THE *National Geographic Magazine* publishes as a supplement to its January number a map of the Philippines—5 feet 2 inches by 3 feet. The map is on the scale of 15 miles to an inch and was prepared by the U. S. Signal Office. Every town or hamlet known by the Jesuits or reported to the War Department by its many officers throughout the islands is indicated on the map. It is a compilation of everything now known about the Philippine Archipelago. Sheet I. gives the Northern Philippines and Sheet II. the Southern Philippines, as officially divided by the United States Government. A glance at the map shows how much exploration is needed

in large sections. For instance, on the Island of Mindoro only a few names along the coast are given. The interior of the island is a blank. The progress made by the American Government in the islands is graphically illustrated by the red lines, indicating cables, telegraphs, and telephones, which penetrate to nearly all corners of the archipelago. Nearly seven thousand miles of wire are now strung, whereas three years ago there was not one mile in service. All the telegraph lines are owned by the government and operated by a government department—the United States Signal Corps. The stations noted as commercial stations are open to messages of a private and commercial character, while from the stations noted as military only messages of a military nature can be sent. This map is the first map of the Philippines that has been prepared by American officers. The spelling of the names is that adopted by the United States Board on Geographic Names. The War Department printed an edition of only 400. The demands of the army posts in the Philippines and in the United States exhausted nearly the entire edition, so that only a few remain for public distribution. The National Geographic Society was, however, granted the use of the plate and has printed a large edition, so that each of its members may receive a copy of what is the only up-to-date presentation of all that is now known of the geography of these islands.

THE CARNEGIE INSTITUTION.

The trustees of the institution elected by the incorporators are as follows:

The president of the United States.
 The president of the United States Senate.
 The speaker of the House of Representatives.
 The secretary of the Smithsonian Institution.
 The president of the National Academy of Sciences.
 Grover Cleveland, New Jersey.
 John S. Billings, New York.
 William N. Frew, Pennsylvania.
 Lyman J. Gage, Illinois.
 Daniel C. Gilman, Maryland.
 John Hay, District of Columbia.
 Abram S. Hewitt, New Jersey.
 Henry L. Higginson, Massachusetts.

Henry Hitchcock, Missouri.
 Charles L. Hutchinson, Illinois.
 William Lindsay, Kentucky.
 Seth Low, New York.
 Wayne MacVeagh, Pennsylvania.
 D. O. Mills, California.
 S. Weir Mitchell, Pennsylvania.
 W. W. Morrow, California.
 Elihu Root, New York.
 John G. Spooner, Wisconsin.
 Andrew D. White, New York.
 Edward D. White, Louisiana.
 Charles D. Walcott, District of Columbia.
 Carroll D. Wright, District of Columbia.

The official statement of the plans of the institution is as follows:

“It is proposed to found in the city of Washington, in the spirit of Washington, an institution which, with the cooperation of institutions now or hereafter established, there or elsewhere, shall, in the broadest and most liberal manner, encourage investigation, research and discovery, encourage the application of knowledge to the improvement of mankind; provide such buildings, laboratories, books and apparatus as may be needed, and afford instruction of an advanced character to students whenever and wherever found, inside or outside of schools, properly qualified to profit thereby. Among its aims are these:

“1. To increase the efficiency of the universities and other institutions of learning throughout the country, by utilizing and adding to their existing facilities, and by aiding teachers in the various institutions for experimental and other work, in these institutions as far as may be advisable.

“2. To discover the exceptional man in every department of study, whenever and wherever found, and enable him by financial aid to make the work for which he seems specially designed, his life work.

“3. To promote original research, paying great attention thereto, as being one of the chief purposes of this institution.

“4. To increase facilities for higher education.

“5. To enable such students as may find Washington the best point for their special studies to avail themselves of such advantages as may be open to them in the museums,

libraries, laboratories, observatory, meteorological, piscicultural and forestry schools and kindred institutions of the several departments of the government.

"6. To insure the prompt publication and distribution of the results of scientific investigation, a field considered to be highly important.

"These and kindred objects may be attained by providing the necessary apparatus, by employing able teachers from various institutions in Washington and elsewhere, and by enabling men fitted for special work to devote themselves to it, through salaried fellowships or scholarships, or through salaries, with or without pensions in old age, or through aid in other forms to such men as continue their special work at seats of learning throughout the world."

The meeting for organization of the board of trustees and the election of officers has been called for January 29, at the office of the Secretary of State in Washington.

SCIENTIFIC NOTES AND NEWS.

PRESIDENT IRA REMSEN, of the Johns Hopkins University, has been elected president of the American Chemical Society.

PROFESSOR H. W. CONN, of Wesleyan University, has been elected president of the American Society of Bacteriologists.

THE Society for Plant Morphology and Physiology held a successful meeting at Columbia University on December 31, 1901, and January 1, 1902, of which a full account will soon appear in SCIENCE. Officers for the ensuing year were elected as follows: *President*, V. M. Spalding, University of Michigan; *Vice-President*, Byron D. Halsted, Rutgers College; *Secretary-Treasurer*, W. F. Ganong, Smith College. The Society will meet next year at Washington with the other scientific societies.

AT the annual election of officers of the California Academy of Sciences, held January 6, 1902, the following were elected to serve in the various offices of the Society during the ensuing year: *Presi-*

dent, David Starr Jordan; *First Vice-President*, M. W. Haskell; *Second Vice-President*, H. H. Behr; *Corresponding Secretary*, J. O'B. Gunn; *Recording Secretary*, J. W. Hobson; *Treasurer*, L. H. Foote; *Librarian*, Louis Falkenau; *Director of Museum*, Levrett M. Loomis; *Trustees*, William M. Pierson, James F. Houghton, William H. Crocker, C. E. Grunsky, E. J. Molera, George C. Perkins, George W. Dickie.

CASWELL GRAVE, Ph.D. (Johns Hopkins), now instructor in zoology at the Johns Hopkins University, has been appointed director of the United States Fish Commission Station at Beaufort, N. C.

DR. J. KRIECHBAUMER, senior curator of the zoological collections at Munich, has retired.

A ROYAL commission has been appointed to inquire into the question of the coal supplies of the United Kingdom. It includes among its members H. B. Dixon, M.A., professor of chemistry and metallurgy in the Owens College, Manchester; J. S. Dixon, mining engineer and coalmaster, president of the Mining Institution of Scotland, and president of the Institution of Mining Engineers of Great Britain; C. Le Neve Foster, D.Sc., B.A., F.R.S., professor of mining in the Royal College of Science, South Kensington, and lately one of his majesty's inspectors of Mines; Edward Hull, M.A., LL.D., F.R.S., lately director of the Geological Survey of Ireland; Charles Lapworth, LL.D., F.R.S., professor of geology and physiography in the Birmingham University, and J. J. H. Teall, M.A., F.R.S., president of the Geological Society of London and director of the Geological Survey of the United Kingdom.

A FUND is being raised to perpetuate the memory of the late Professor Tate, for twenty-six years professor of natural science in the Adelaide University. It is proposed to erect a memorial tablet and to establish a Tate medal for geology.

MR. C. L. A. DE NICÉVILLE died at Calcutta on December 3, of malarial fever contracted in the Terai in pursuit of his investigations as state entomologist of India, an appointment which had been created for him. He was the

author of 'The Butterflies of India, Burmah, and Ceylon,' and other contributions to entomology.

THE death is announced of M. Charles Maunoir, for thirty-seven years secretary of the Paris Geographical Society, and the author of annual reports on geographical discoveries.

MR. and MRS. HAROLD S. McCORMICK, of Chicago, have founded a memorial institute for infectious diseases to commemorate their son who died recently from scarlet fever. The endowment of the institute is said in the daily papers to be \$1,000,000. Dr. Frank Billings is president of the board of trustees and Dr. Ludvig Hektoen has been appointed director of the institute.

It is reported that Secretary Long will renew his request to Congress for an appropriation of \$230,000 for the purchase of land and the erection of a building for the use of the naval hydrographic service.

MR. ANDREW CARNEGIE has offered \$25,000 for a public library building at Melrose, Mass.; \$20,000 for a library building at Saratoga Springs, N. Y., and the same sum for a similar building at St. Catherine's, Ont.

SUBSCRIPTIONS amounting to over \$105,000 were announced at the annual meeting of the New York Historical Society toward the new building, which is to be erected at Central Park West, between Seventy-sixth and Seventy-seventh Streets.

THE library of the late Baron von Nordenskjöld has been purchased by the University of Helsingfors for about \$50,000.

A REUTER'S telegram states that Mr. William Bruce, the leader of the Scottish Antarctic expedition, has purchased the Norwegian steam whaler *Hecla* for his forthcoming expedition. The vessel will shortly be brought over to be refitted on the Clyde, where Mr. Bruce is availing himself of the guidance of Mr. G. L. Watson, the yacht builder. The *Antarctic*, with Professor Nordenskjöld's South Polar expedition on board, left Buenos Ayres on December 20 for the Falkland Islands. The *Discovery* left Lyttleton on De-

ember 21. The leakage has been stopped, except in the fore-peak, where eight minutes' pumping daily is sufficient.

THE Arctic Club held its eighth annual dinner at Hotel Marlborough, New York City, December 28, Professor William H. Brewer presiding.

At the recent Columbia meeting of the Society for Plant Morphology and Physiology, it was pointed out that the American members of the Association Internationale des Botanistes will soon be called upon to vote by ballot for two members of the general committee. It was felt that in the absence of nominations the votes would be scattering and perhaps in many cases not cast at all. No body of botanists appears to have authority to make such nominations, but it was suggested that as this Society had managed the correspondence with the former owners of the *Botanisches Centralblatt*, and later with the officers of the Association Internationale, it might not seem inappropriate for this Society to suggest such nominations. Accordingly, on this basis, the Society nominated Professors C. E. Bessey and W. F. Ganong.

THE Archeological Institute of America has this year established a traveling fellowship for researches in Central America, and Mr. Alfred M. Tozzer, who was last year a graduate student at Harvard, taking Professor Putnam's research course in American Archeology and Ethnology, has been appointed to the fellowship. During the past summer Mr. Tozzer accompanied Professor Putnam to New Mexico where he was successful in a study of the language and ceremonies of the Navajo Indians. During the summer of the previous year he was engaged in similar research among the Indians of California. He is thus in many ways especially qualified for this research in Central America. Mr. Tozzer is now on his way to Yucatan for the purpose of studying the language and customs of the Mayas, preliminary to a study of the Maya hieroglyphs, and with the hope that there may possibly be some tradition which would give a clue to some of the glyphs. The Institute Committee on this fellowship consists of

Messrs C. P. Bowditch, F. W. Putnam and Franz Boas.

DR. J. B. MATTISON, of Brooklyn, has offered a prize of \$400 for the best paper on the subject: 'Does the Habitual Subdermic Use of Morphine cause Organic Disease? If so, What?' The contest will be open for two years from December 1, 1901, to any physician in any language.

THE Senate Committee on Commerce has reported a bill creating a department of commerce. It makes the secretary of commerce a member of the Cabinet and transfers to the new department the following bureaus: Life Saving Service, Lighthouse Board, Lighthouse Service, Marine Hospital Service, Steamboat Inspection Service, Bureau of Navigation and United States Shipping Commissioners, Bureau of Immigration, Bureau of Statistics, the United States Coast and Geodetic Survey, the Commission of Railroads, the Census Office, the Patent Office, the Department of Labor, Commission of Fish and Fisheries and the Bureau of Foreign Commerce of the State Department. A Bureau of Manufactures and a Bureau of Mines and Mining are to be established in the new department.

THE Association for Promotion of Scientific Research by Women announces that applications should be received before March 1 for the American Woman's Table at the Zoological Station at Naples and for the Investigators' Table at the Marine Biological Laboratory at Wood's Holl. Further information may be obtained from the secretary, Miss Cornelia M. Clapp, Mount Hadley College, Mass.

THE thirty-sixth annual winter course of Sheffield Lectures in the Sheffield Scientific School of Yale University has been announced. The following are the subjects and lecturers:

January 17—'The Future of South Africa': MR. JOHN HAYS HAMMOND.

January 24—'The Mosquito Story': DR. L. O. HOWARD.

January 31—'Animal Intelligence': PROFESSOR L. B. MENDEL.

February 7—'Engineering Feats in Bridge Construction': FRANK W. SKINNER, C.E.

February 14—'Through the First Antaretic Night': DR. F. A. COOK.

February 21—'The Life History of a Lake': PROFESSOR H. E. GREGORY.

February 28—'The Water Resources of the Country, and their Importance to the Community': MR. F. H. NEVELL.

March 7—'The Wild Bird at Arm's Length; new methods in the Study and Photography of Birds': PROFESSOR F. H. HERRICK.

March 14—'Some Recent Doings in Astronomy': DR. F. L. CHASE.

March 21—'Niagara Falls, in Relation to Social and Economic Problems': PROFESSOR W. H. BREWER.

THE Harben Lectures of the Royal Institute of Public Health were given in King's College, London, on January 13, 14 and 15, by Dr. Max Gruber, professor of hygiene, and director of the hygienic institute in the University of Vienna. The subject of the lectures was the 'Anti-bodies of the Blood.'

IN the new Budget for the German Imperial Home Office, a sum of 12,000 Marks is allocated for the institution of researches on protozoa and one of 150,000 Marks for the prosecution of researches on tuberculosis and the means of preventing its spread.

A COMMITTEE has been appointed to consider the question of making the museum at Cardiff a national museum for Wales.

AT a recent meeting of the Archeological Section of the Wisconsin Natural History Society, a committee was appointed to investigate the feasibility of preserving a small group of three dome-shaped mounds located in the city of Waukesha.

THE *British Medical Journal* states that according to a custom, which is doubtless less out of place in Spain than it would be elsewhere, the Royal Academy of Medicine of Madrid recently attended in a body a solemn mass for the repose of the souls of deceased members, of Spanish physicians and surgeons whose work had reflected luster on their country, and of benefactors of the Academy.

OVER 200 persons have already enrolled for membership in the proposed American Electro-Chemical Society. The first meeting for definite organization and reading of papers

and discussion will probably be held in Philadelphia about Easter. A gathering of electrochemists from all parts of the United States is assured.

At the annual meeting of the Montana State Teachers' Association, held at Missoula, Mont., during the holidays, a Montana Academy of Sciences, Arts and Letters was organized. The following officers were elected: *President*, Morton J. Elrod, Professor of Biology, University of Montana; *Vice-President*, Department of Science, B. E. Tollman, Professor of Mathematics, Montana College of Agriculture and Mechanic Arts; *Vice-President*, Department of Arts, L. S. Footh, State School of Mines; *Vice-President*, Department of Letters, H. H. Swain, president of State Normal; *Secretary-Treasurer*, W. D. Harkins, Professor of Chemistry, University of Montana; *Librarian and Custodian*, B. E. Toan, Butte High School. The location of the academy is at Missoula.

THE Des Moines Geographical Exposition, held under the auspices of the Science Teachers of Iowa in connection with the meeting of the State Teachers' Association, was very successful. Its scope comprised the apparatus and appliances needful to the teaching of physical geography. Some forty models were on exhibition by Howell, Ward, Ginn and Andrews, including a series from the laboratory of Cornell College, showing methods of building models in various materials. About 1,000 lantern slides were shown from selected lists of American and British dealers, with several of the best lanterns for high schools. Besides physical wall maps of all the leading series, a large exhibit was made in this section of topographic maps from the United States Geological Survey, the Mississippi river commission, the coast survey and the surveys of several European countries. Sets of rocks and minerals suitable for high schools were shown. In the section devoted to literature the publications of the Iowa Geographic Survey were placed, together with the books and periodicals, American and foreign, most needful for the school library, or for that of the teacher. In photographs the

exposition was especially rich. Hoelzel, of Vienna, sent the well-known 'Charakterbilder' and the Detroit Photographic Co. the series of typical color photographs in physiography selected by Professor Norton, of Cornell College. Other exhibitors in this section were Haynes, the U. S. Geological Survey, Stoddard and Notman and James. In meteorology an exhibit was made by the U. S. Hydrographic office and by Queen & Co. The exposition was directed by Professor W. H. Norton, of Cornell College, and Mr. A. W. Brett, of the West Des Moines High School.

THE public health bulletin for last week contains reports to Surgeon General Wyman from officers of the Marine Hospital Service on the theory that the germs of malarial and yellow fevers are transmitted by the bite of the mosquito. Dr. Gorgas, chief sanitary officer at Havana, reports no cases of yellow fever deaths from that disease in the Cuban capital during the month of November, a condition not obtaining for years. This result Dr. Gorgas attributes to the system introduced last February of killing mosquitoes in the neighborhood of each point of infection, with the result that the mosquitoes in Havana this year are only about one tenth as numerous as last year.

A BILL has been introduced into Congress by Mr. Hepburn calling for many changes in the Marine Hospital Service. It is proposed, says the *New York Medical Record*, to alter the name to the United States Health Service, in order to bring the title more into harmony with the work which the evolved service is now doing. The officers of the new service will be the same as of the old, except that those in charge of the administrative departments in Washington will be called assistant surgeons-general, and the pay of the surgeon-general will be increased to equal that of the surgeon-general of the army. A consulting board is to be created to advise the surgeon-general of the new service in matters relating to public health, and this officer will also consult with delegates from the health departments of the various States and territories of the Union. Uniformity in the registration of vital statistics is provided for by the bill. It

will be the duty of the surgeon-general of the new service to prepare proper forms for collecting the data, in conjunction with the State boards of health, and to compile and publish them as a part of the reports of the service. The consulting board above mentioned will consist of the surgeons-general of the army and navy, the Chief of the Bureau of Animal Industry in the Agricultural Department, and the director of the laboratory in that bureau, and five other members not regularly in government employ. The service will remain a bureau of the Treasury Department.

THE new Health Board of New York City, at its first meeting, made an important departure from precedent by creating a medical advisory board of twelve prominent physicians with Professor Charles F. Chandler, of Columbia University, at the head, with the title of consulting sanitarian. The Board is to serve without pay. Its other members are:

Dr. Edward G. Janevay, Dean of the Faculty of the University of Medicine and Bellevue Hospital Medical College, and former Commissioner of Health.

Dr. Joseph D. Bryant, Professor of Surgery, University and Bellevue Hospital Medical College, and former Commissioner of Health.

Dr. T. Mitchell Prudden, Director of the Department of Pathology, College of Physicians and Surgeons; Vice-President of the Rockefeller Institute for Medical Research.

Dr. William M. Folk, Dean of the Faculty of Medicine, Cornell Medical College.

Dr. A. Jacobi, former President of the Academy of Medicine; Professor of the diseases of children, College of Physicians and Surgeons.

Dr. John Wintres Braman, President Board of Governors of the Minturn Hospital; President Medical Board of the hospitals of the Department of Health.

Dr. Richard H. Derby, surgeon, New York Eye and Ear Infirmary.

Dr. I. Emmet Holt, President of the Medical Board, Babies' Hospital; Secretary Board of Trustees, Rockefeller Institute for Medical Research.

Dr. Alexander Smith, Professor of the Principles and Practice of Medicine, University and Bellevue Hospital Medical College.

Dr. Francis P. Kinnicutt, Clinical Professor of Medicine, College of Physicians and Surgeons.

Dr. Henry R. Loomis, Professor of Materia Medica and Therapeutics, Cornell University Medical College.

As its medical adviser the Board selected Dr. Herman M. Biggs.

THE *Lancet* states that Professor Virchow's eightieth birthday was celebrated with much enthusiasm in Bahia, Brazil. In honor of the occasion a very numerous attended public meeting was held on October 13, the company present including the Governor of the State, the President of the Municipal Council, the German Consul and the Director of the Schools of Medicine, Jurisprudence and Engineering. The arrangements were made by the *Gremio dos Internos dos Hospitales da Bahia*, an association of the internes of the hospitals, and the meeting took place in the handsomely decorated hall of the *Gremio Literario*. M. Pontes, the president of the association, opened the proceedings with an address, after which the Governor of the State took the chair. Professor Juliano Moreira, speaking in the double capacity of a member of the medical profession and one of the editorial staff of the *Gazeta Medica* of Bahia, gave a comprehensive review of Professor Virchow's achievements, not only as a physician and a pathologist, but also as a biologist and as a *savant* whose methods of research had influenced every branch of human knowledge. He concluded by reading aloud a Latin address to Professor Virchow written on parchment for the purpose of being sent to him. M. Paranhos, speaking in the name of the *Revista do Gremio*, gave a sketch of the vast amount of work which Professor Virchow had contrived to crowd into the space of 60 years. Addresses were also delivered by M. Oscar Freire, representing the *Gremio dos Internos*, and by Dr. Egas Moniz, speaking in the name of the *Gremio Literario* and of a number of German journals of Paraná and Rio Grande do Sul. Poems in honor of Germany and Professor Virchow were recited by the last-named gentleman and by M. Damasceno Vietra, after which the national airs of Germany and Brazil were played by the band. The October issue of the *Gazeta Medica* of Bahia, the *doyen* of the

medical press of North Brazil, is entirely a "Virchow number," in which the life and work of the venerable *savant* are treated in six elaborate articles by Professor Juliano Moreira, Dr. Alfredo de Andrade, Professor Pacifico Pereira, Dr. Americo Fróes, Professor Matheus dos Santos and Dr. Afranio Peixoto. The *Revista do Gremio dos Internos dos Hospitales* has also published a special Virchow number.

UNIVERSITY AND EDUCATIONAL NEWS.

DR. NICHOLAS MURRAY BUTLER, professor of philosophy and education, and since the resignation of Dr. Seth Low acting-president of Columbia University, was elected president of the University on January 6 by unanimous vote of the trustees.

THE University of Wooster, at Wooster, O., will replace the building recently destroyed by fire. Dr. D. K. Pearsons of Chicago has given \$100,000 to the institution for this purpose on condition that Wooster and Wayne Counties raise \$40,000 and the Synod of Ohio \$10,000 by February.

COLUMBIA UNIVERSITY has received an anonymous gift of \$100,000, and a gift of \$3,000 from Mr. Adolph Lewisohn for the purchase of a complete set of German dissertations for the doctorate.

WILLIAM H. CHAPMAN, president of the Savings Bank of New London, has presented to the city, through the board of school visitors, \$100,000 for the building and equipment of a manual training school for use in connection with the public school system.

MR. JOHN D. ROCKEFELLER has offered to give Brown University \$75,000 for the erection and furnishing of a building to be used for social and religious purposes, on condition that \$25,000 be secured as an endowment fund for the building before the next commencement.

By subscriptions from the alumni, \$50,000 have been collected for the new Hall of Commons at Hamilton College. It will be built during the summer.

WASHINGTON UNIVERSITY, St. Louis, receives, by the will of Colonel George E. Leighton, \$25,000, and by that of Mr. William E. Huse, \$20,000. Both these gentlemen were members of the board of directors of that institution.

THE 'New England Building,' at Vassar College, containing laboratories for the departments of biology, physiology and geology, was formally opened on January 8, when a reception was given there by the board of trustees. The name commemorates the fact that the building fund of \$50,000 was the gift of alumnae residing in New England.

DR. CHARLES W. DABNEY, president of the University of Tennessee, Knoxville, has received a proposition from eastern philanthropists to establish a summer school at the University, the school to be free for teachers from all over the South.

DR. HERBERT A. GILES, professor of Chinese at Cambridge University, will give the first course of lectures for the new Chinese department of Columbia University.

THE following appointments have been made at the University of Toronto: Dr. W. H. Piersol, instructor in biology and histology; C. M. Fraser, assistant in zoology; R. B. Thompson, class assistant in botany; Dr. S. H. Westman, laboratory assistant in histology; Dr. R. E. Hooper, Dr. J. A. Roberts, Dr. W. J. McCallum, and Dr. A. F. Adams to be class assistants in histology; M. H. Embree and E. A. McCallum, class assistants in biology.

MR. HENRY STEWART MACRAN, fellow of Trinity College, Dublin, has been elected professor of mental and moral philosophy in the University of Dublin in the room of Mr. Swift Paine Johnston, who has been appointed one of the assistant commissioners of the board of intermediate education.

THE general board of studies of Cambridge University will during the Lent term proceed to the appointment of a Sidgwick University lecturer in moral science. It is desired that psychology should be one of the subjects on which the lecturer is prepared to lecture. The appointment will be for five years.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

EDITORIAL COMMITTEE: S. NEWCOMB, Mathematics; R. S. WOODWARD, Mechanics; E. C. PICKERING, Astronomy; T. C. MENDENHALL, Physics; R. H. THURSTON, Engineering; IRA REMSEN, Chemistry; CHARLES D. WÄLCOTT, Geology; W. M. DAVIS, Physiography; HENRY F. OSBORN, Paleontology; W. K. BROOKS, C. HAET MERRIAM, Zoology; S. H. SCUDDER, Entomology; C. E. BESSEY, N. L. BRITTON, Botany; C. S. MINOT, Embryology, Histology; H. P. BOWDITCH, Physiology; J. S. BILLINGS, Hygiene; WILLIAM H. WELCH, Pathology; J. MCKEEN CATTELL, Psychology; J. W. POWELL, Anthropology.

FRIDAY, JANUARY 24, 1902.

SECTION II, ANTHROPOLOGY.

THE winter meeting of Section II was held in the lecture hall of Field Columbian Museum, Chicago, on December 31, 1901, and January 1-2, 1902; Dr. J. Walter Fewkes, of the U. S. National Museum, presiding.

At the opening session, Dr. Geo. A. Dorsey was chosen press secretary. Professor Franz Boas was appointed to represent the Section on a committee to revise the schedule for measurements used in gymnasia. This committee, made up of members of various societies interested in physical education, is to report at the next meeting of the American Association for the Advancement of Physical Education.

A committee to confer with delegates from the Anthropological Society of Washington, D. C., and the American Ethnological Society, with special reference to increasing the usefulness of the *American Anthropologist*, as well as facilities for anthropological publication in general, was chosen as follows: Dorsey (chairman), Starr, Culin, Dixon, MacCurdy, Russell.

At the winter meeting in Baltimore one year ago a committee, consisting of F. W. Putnam (chairman), J. W. Powell and Geo. A. Dorsey, was appointed to take preliminary steps for the reception of the

International Congress of Americanists' on the occasion of its first meeting in the United States. The committee reported that it had performed the duty assigned, and respectfully requested to be discharged. The Section voted to discharge the Committee and to extend grateful appreciation for its labors. According to the circular accompanying Chairman Putnam's report, the thirteenth session of the International Congress of Americanists will be held in the halls of the American Museum of Natural History, in the City of New York, beginning at noon on Monday the 20th, and continuing until Saturday, the 25th of October, 1902.

The titles of papers presented before the Section are accompanied by brief abstracts in so far as these have been secured from the authors.

The Beginnings of Anthropology: W J MCGEE.

Discussion: Boas, Russell, Fewkes.

Twenty Years of Section II, Anthropology: GEORGE GRANT MACCURDY.

An analysis of the work done by the Section since its organization, and a comparison of the same with that done by European societies of a similar nature. The conclusion reached is that, while American anthropologists have been working in relatively greater isolation than have European anthropologists, they are now at the threshold of a new epoch destined to be marked by vast progress in correlative and synthetic anthropology. This paper will be printed in SCIENCE.

Discussion: Newell, McGee, Starr, Peet, MacCurdy, Russell, Dorsey, Hartzell, Thompson, Boas.

The Exhibit of Hopi Ceremonies in the Field Columbian Museum: GEO. A. DORSEY.

Dr. Dorsey kindly consented to supplement his paper by an explanatory talk in

the exhibition rooms on the closing day of the session. The following Hopi ceremonies as they occur at Oraibi have been reproduced on a magnificent scale for the Museum by Mr. Voth: Oq̄ol, Marau and Soyal Altars; Powalawu Sand Mosaic; Powamu Altar and Sand Mosaic; Kateina Initiation and Sand Mosaic; Masililantu Altar; Cho Altar and Sand Mosaic; Teob Altar and Sand Mosaic; Balulukon Screen; Hemis Kateina Dancers; Aña Kateina Dancers. The Museum also possesses a large collection of Hopi dolls, masks and head dresses.

Discussion: Fewkes, McGee.

Some Painted Stone Slabs from the Graves of the Ruins of Walpi: CHAS. L. OWEN.

Mr. Owen's paper was descriptive, his hearers having also the satisfaction of seeing the objects described. The stone slabs were only recently installed.

Basketry Designs in Northern California: ROLAND B. DIXON.

The California Indians were confined almost exclusively to basketry for the expression of their artistic sense, and to this concentration of effort is due, in part at least, the perfection to which the art of basket-making was carried. There are several more or less clearly marked areas, each of which has its own type of basketry and basketry designs. In northern California alone there are three such type areas: (1) Northwestern (Hupa, Karok, Yurok, of Powers with perhaps the Shasta). (2) Northeastern (Klamath, Modoc, Pit River, Yana, Wintu and Maidu). (3) Pomo and perhaps neighboring stocks. In his paper the author refers only to the second and third areas. Often two or more stocks show the same designs but slightly differing one from another. As a whole, however, it appears that each stock is in possession of a body of designs peculiar to itself. The author also had something to say on

the questions of origin of designs and their transmission from tribe to tribe.

Discussion: Peet, McGee, Dixon, Boas, Dorsey and Hudson who gave reasons for favoring *Poma* as against *Pomo* for the name of one of the stocks in question.

Pueblo Indian Settlements near El Paso, Texas: J. WALTER FEWKES.

A study of the social organization, officers, dances, social and other customs, and linguistics of the Tiwan Indians of Ysleta; the Piros Indians of Senecu and Socorro; the Mansos and Sumas.

Discussion: Dorsey, Starr, Kinner, Fewkes.

Variability of Anthropometric Types:

FRANZ BOAS.

The variability of organisms depends upon the correlation of their elements. The variability of the whole organism may, therefore, be considered largely an expression of correlation of its constituent parts. The greater the correlation of the parts constituting an organ, or included in a measurement, the greater will be its variability. Generally it is assumed that indices are expressions of correlation. The author demonstrated that they are not necessarily so, but that regression is the only sure test of correlation. The importance of the pathological method of studying correlation is emphasized. Professor Boas made free use of the blackboard as a means of illustration.

The Somatological Investigations of the Hyde Expedition: ALES HRDLICKA.

The Hyde Expedition comprises a variety of anthropological investigations on the peoples of the southwest, the whole being carried on under the direction of Professor Frederiek W. Putnam for the American Museum of Natural History, New York City. The object of the somatological work of the Hyde Expedition, of which Dr. Hrdlička is in charge, is to carry out a sys-

tematic investigation, mainly of a physical nature, on the extinct and living peoples of that part of the United States and Mexico which had once been occupied by the Pueblos with Cliff-Dwellers, and the Toltees, Chichimecs and Aztecs. It is hoped that these studies will establish the physical types of these peoples and show their racial relations or diversities. The region over which this research extends is bounded approximately by the 38th parallel in the north, by the Rio Grande and the foothills of the Sierra Madre in the east, the Colorado River and Pacific Ocean in the west, and the States of Mexico and Michoacan in the south. It interlaces in the south with the region, the tribes of which were examined by Professor Starr and, in the north and northwest, connects with the field of work of the Jesup Expedition under Professor Boas. Dr. Hrdlička began the outlined investigations in 1896, on the osteological material, principally Tarasco, collected by Dr. Humboldt. In 1898 the field work was begun by the study of the tribes of Tarahumaras, Huichols and Tepecanos in Mexico. On the second expedition, in 1899, the research was carried on among the Utes and the Navahos, and on the third trip, in 1900, the investigation comprised the Mokis, Zuñis, Rio Grande Pueblos, all the divisions of the Apaches, Mohaves and a branch of the Piutes. At this moment Dr. Hrdlička is starting on the fourth expedition, on which probably the field work will be completed. There will be visited the Suppays and Hualapais, Yumas, Pimas, Papagos, Yaquis, Tepehuanas, Coras, Aztecs, Tarascos and several smaller tribes. The work of the expedition will probably occupy the larger part of the coming year. The expenses of this as well as those of the 1900 and 1899 expeditions are generously provided for by Mr. Frederiek E. Hyde, Jr., of New York city.

Some Observations concerning the Navaho Blanket Industry: FRANK RUSSELL.

The lantern slides not arriving in time, Dr. Russell did not read his paper. He, however, very kindly authorized the secretary to make use of the abstract. Some tendencies in the progress of the Navaho blanket industry are described. The most noticeable changes are in the kind of yarn, the quality of the work and in the designs. Styles vary in different localities so that a little experience will enable one to name the district from which a given specimen comes. Methods of cheating the trader are described and an account given of the imitation Navaho blankets now offered for sale. The author tells how to identify imitations.

The Beginnings of Lithoculture: W J McGEE.

Discussion: Fewkes, Thompson, Grimes, McGee, Hudson.

Certain Forms of 'Winged-perforated' Slate Objects: WARREN K. MOOREHEAD.

Mr. Moorehead's paper was fully illustrated by means of numerous originals and drawings. He called attention to the necessity of an archeological nomenclature for the various 'unknown forms' in slate and granite which have hitherto been called 'ceremonials'—a meaningless term in the opinion of the author. The paper is purely descriptive, dealing with form, type, distribution, etc.

Discussion: Culin, Moorehead.

A Voice Tonometer: CARL E. SEASHORE.

An exact and ready method of determining the pitch of tones in singing is described. The apparatus is a modified form of that described by Scripture, *Yale Studies in Psychology*, IV., 135. It works on the principle of the stroboscope and furnishes a direct reading of the vibration

frequency of any tone sung within the range of two octaves. The reading is accurate to the twenty-fifth of a tone. Illustrations of results are given from measurements on the manner and the accuracy of striking a tone, singing the scale, singing the chromatic scale, singing an air, the singing of two notes in unison or in parts, and the singing of the least producible difference in pitch. The last named measurement is the most important because it furnishes a unit for the study of motor processes in singing and speaking.

The Psychological Elements of Visual Space Orientation about a Horizontal Axis: ROBERT MACDOUGALL.

The paper is a summary statement of the results of experimental work carried on in the Harvard Psychological Laboratory during 1900-1901. Its problem is the determination of factors—and their values—of resident and transient sensation which enters into the location, by the human subject, of points in the horizontal plane of the eyes. The experimental variations involved comprise the characteristics of visual determination in an ordinary illuminated field, of the location of a luminous point in an otherwise dark field, and of orientation in complete darkness, in the case of both binocular and monocular vision. The points of greater importance here are the characteristic positive or negative errors of displacement in the subjective plane of the horizon, and the range of the normal mean variation; the influence of the cooperation and disjunction of the two eyes in the act of vision; and the general function of eye strain in such forms of space orientation. Special conditions of body strain are taken up, and an analysis made of the typical errors introduced into the process of space orientation by interferences with the normal body-relations. Of these artificially induced conditions the

chief are the rotation of the eyes about their horizontal axis, the rotation of the head about its lateral horizontal axis, and the rotation of the whole body about a similar axis. A consideration of the influence exerted by the general distribution of intensities in the visual field, and of object planes and lines of perspective upon the subjective location of points in the horizontal plane of the eyes. The paper concludes with an examination of the phenomena of coordination between eye and hand in determining the plane of the eye's horizon by the index finger, the significance of this series of determinations lying in the characteristic displacement of the located point due to changes in the fundamental axes of the head and eyes. Dr. MacDougall's paper will be printed in the Publications of Harvard Psychological Laboratory, Vol. I.

The Sherman Anthropological Collection of Holyoke, Massachusetts: GEORGE GRANT MACCURDY.

Mr. Gardner M. Sherman, of Springfield, Mass., an indefatigable collector for twenty-five years, has supplemented his own finds by exchanges and judicious purchases until the collection which bears his name now numbers from 12,000 to 16,000 specimens. The material is confined almost wholly to American archeology, representing geographically twenty-one States and Territories. Massachusetts, Georgia, Illinois and Tennessee are the largest contributors. The Connecticut River valley is particularly well represented. The collection was purchased last July by the Holyoke Scientific Society, and is to be installed in the new Public Library building. It is at present in the care of Mr. J. T. Draper, head of the science department of the Holyoke High School. This paper will be published in the *American Anthropologist*.

Filial Piety in China: PAUL CARUS.

A study of a pair of wall pendants, ornamental mottoes designed as decorations for the sitting-rooms of the Celestials. The paper and art work are crude enough to allow the assumption that the prints must be very cheap in China, and are designed not for the rich, but for the common people. They may cost in Peking or Hong Kong not more than one or two cents apiece. Evidently they serve two purposes: First, of ornament, and, secondly, of instruction. The Chinese are a moralizing people, even more so than we: while we dislike abstract moralizing, they delight in it and do not tire of impressing upon their children the praiseworthiness of filial devotion. Filial devotion is in Chinese *hsiao*; the character consists of two symbols showing a child supporting an old man, and filial piety is supposed to be the basis of all virtue. The moral relations are regarded as mere varieties of *hsiao*; and the original significance of the word, which means chiefly the devotional attitude of a child toward his parents, includes such relations as the obedience of the subject to his ruler, of the wife to her husband, of the younger brother to his elder brother, and of any one's relations to his superiors, including especially man's relation to God. The Chinese ornament their rooms, not as we do with pictures of beauty, but with moral sayings; and the two pendants described, which unfortunately cannot be reproduced here for lack of space, are typical of the national character of the Chinese.

The Significance of the Cross: PAUL CARUS.

Symbols pass through three stages, the magic, the emblematic and the ornamental. The Christian cross is unique in its conception. Prehistoric crosses are the same in form, but different in interpretation. The difference in meaning is important. For

the sake of distinguishing between the two, let us call the figure of intersecting lines a thwart, and reserve the word cross for its original significance, viz., a martyr instrument. The old cross, the Roman martyr instrument for capital punishment by exposure to the inclemency of the weather, Latin *crux*, Greek *staurus*, had sometimes the form of an irregular thwart, but not necessarily so. Whether or not Christ's cross was a thwart is doubtful; it is possible, however, since he is reported to have borne his cross, which obviously means the *patibulum*. Christianity adopted the thwart as the form of Christ's cross because the thwart was an old religious symbol of deep significance. Thwarts were used in all countries—Egypt, Assyria, India, among the Teutons, the Indians, etc. Their significance varies, and is frequently obliterated. By promiscuously calling all thwarts crosses, we are surprised at finding the Christian symbol universally adopted by pre-Christian religions. The fact is the reverse. Thwarts were used in different meanings by almost all the nations of the world, and then the thwart was identified with the cross to such an extent that, at present, cross has come to mean any figure of intersecting lines. How misleading this identification may be we can see in the Dakota story of the Susbea, which is a thwart and like the Latin cross in shape, but which means dragon-fly. A missionary mistook the word in the Christian sense, so he gloried in his sermons with St. Paul in the susbea of Christ. Translations of the New Testament and the Creed in the Dakota language, according to which Christ was crucified on a dragon-fly, are still extant. To the Dakotas the susbea is a sacred religious symbol, and the missionary's mistake may have helped to recommend to them the Christian faith; but undoubtedly the confusion served to render more mysterious to them

the mystery of the cross. The two papers by Dr. Carns were both fully illustrated, and will be published in *The Open Court*.

On Wednesday and Thursday mornings, the Section met with the American Folk-Lore Society, which, like Section H, is one of the Societies affiliated with the American Society of Naturalists.

GEORGE GRANT MACCURDY,
Secretary.

THE AMERICAN CHEMICAL SOCIETY.

The annual winter meeting of the American Chemical Society, the twenty-fifth general meeting of the Society, was held in Philadelphia on the thirtieth and thirty-first of December, the assembly place being the University of Pennsylvania. The opening session was in Houston Hall at half past nine on Monday morning, when the usual felicitous words of welcome on behalf of the city, the university and the Philadelphia Section of the Society were spoken and duly responded to. The reports of the officers of the Society were read, those of the secretary and treasurer being particularly gratifying, showing large increase in membership and a considerable balance in the treasury. Including the members elected at the present meeting, the membership of the Society has passed the two thousand mark; with a very few exceptions, all the prominent chemists of the country are enrolled, and no inconsiderable number of foreigners as well. The value of the *Journal* of the Society is being more and more appreciated. Thirteen Sections of the Society are already established, and a fourteenth is now being formed on the Pacific slope.

Owing to the fact that most of the business is transacted through the Council, little came before the general meeting, but a resolution was passed memorializing the United States Government to pass a law making compulsory the use of the metric

system of weights and measures in all the departments except the Land Office. As is well known, its use is now optional, but outside of the scientific departments it is little used. In the Post Office and Treasury Departments its use is particularly desirable.

The remainder of the forenoon and the next morning were devoted to the reading of papers. The time for this was unfortunately so limited that hardly more than half of those on the program could find a place, and many of these were given only in abstract. The most interesting paper was of the nature of a lecture by Dr. Charles F. Chandler, of New York, on the 'Electrochemical Industries at Niagara Falls.' This was illustrated by a copious supply of specimens of the products of these industries, a very considerable portion of which was afterward presented to the museum of the chemical department of the University of Pennsylvania. Another paper which attracted much attention was by Professor Louis Kahlenberg, of the University of Wisconsin, on 'Instantaneous Chemical Reactions, and the Theory of Electrolytic Dissociation,' with experiments. The experiments illustrated facts brought to light by Dr. Kahlenberg which seem to controvert the ordinarily accepted theory of electrolytic dissociation, and no little interest was aroused by them. A list of the papers read is appended to this report.

At the close of each morning session a bountiful lunch was provided by the university authorities, after which the time till dark was occupied by excursions to various places of interest to chemists. There is no city in the country where there are so many industries in which chemistry plays an important part, and the time was well used by the visiting chemists. Indeed there was such a superfluity of trips that the members had to be grouped in six or seven sections each afternoon. The following list

of places visited gives an idea of the wealth of opportunities for the study of industrial chemistry:

Baldwin Locomotive Works.
 United States Mint.
 City Filtration Experiment Station.
 Bergner & Engel's Brewery.
 Midvale Steel Company's Works.
 Barrett Manufacturing Co., Working up of Coal-tar Oils.
 United States Arsenal, Special Laboratory Equipment and Testing House.
 John B. Stetson Company, Manufacturers of Hats.
 Dungan & Hood, Glazed Kid and Morocco Works.
 C. H. Masland & Sons, Carpet Mills.
 Cramp's Shipyard.
 Harrison Bros. & Company, Inc., Manufacturers of Chemicals and Paints, Electrolytic Method for the Production of Sodium.
 Philadelphia Navy Yard.
 United Gas Improvement Co., Works, Point Breeze.
 Gillinder & Sons, Glass Works.
 Quaker City Dye Works.
 Wetherill & Bro., White Lead.
 J. Eavenson & Son, Soap Works.
 Girard College.

On Monday evening the address of the retiring president, Dr. F. W. Clarke, of Washington, was delivered at the rooms of the Acorn Club. His subject was 'The Development of Chemistry.' A rapid and graphic review of the past of chemistry gave indications of the lines along which chemistry may be expected to progress in the immediate future. The speaker dwelt particularly upon the desirability of co-operation in chemical research, rather than the present plan where every chemist works in his own field independent of the work of all others. Especially in inorganic chemistry are there many problems, too large for solution by single workers, which might be successfully attacked by the co-operative efforts of a number of chemists. Dr. Clarke also called attention to the mutual benefits accruing between technical

chemistry and pure chemistry, research work in each helping the other.

Immediately after the address, a reception was tendered by the Club to the members of the Society and their wives. A little later in the evening a smoker was held at the University Club where memories of German student life were renewed. On Tuesday evening the annual banquet was held at the Bingham House, the decorations and the *ménu* having a decided flavor of the laboratory. Dr. H. W. Wiley, of Washington, acted as Master of the Feast, and toasts were responded to by the mayor of the city, Theodore C. Search of the School of Industrial Art, and by several members of the Society. According to one of his colleagues, Professor Chandler had the honor of making the longest speech on record. He began in 1901 and did not close till the next year!

Dr. Ira Remsen, president of Johns Hopkins University, was elected president of the Society for the ensuing year.

A meeting of the Council of the Society was held on Tuesday afternoon, at which the resignation of Dr. Edward Hart as editor of the Society's *Journal* was regretfully accepted, and Dr. W. A. Noyes, of Rose Polytechnic Institute, was elected to succeed him.

Nearly two hundred were enrolled at the meeting, and probably not less than two hundred and fifty were present, making this the largest general meeting the Society has ever held. It was in every respect one of the most successful.

The following is a list of the papers read at the meeting:

Review of Metallography: HENRY FAY.

A résumé of the recent work which has been done on alloys, especially of those using the methods of physical chemistry and the microscope.

Naturally Occurring Tellurid of Gold: VICTOR LEHNER.

The only occurrence of gold in nature combined with another element is the tellurid. A crystallographical and chemical study of these tellurids throws much doubt upon their being anything other than a mixture of the elements.

Action of Selenic Acid on Gold: VICTOR LEHNER.

Doubt has been cast upon the oft repeated text-book statement that gold dissolves in selenic acid. It was found that gold does dissolve with considerable readiness in concentrated selenic acid at 230°-300°, forming an auric selenate. This is the only single acid, as far as known, in which gold is soluble.

The Quantitative Blowpipe Assay of Tellurid Gold Ores: JOSEPH W. RICHARDS.

Contrary to the general opinion, this assay presents no difficulty. In the muffle assay, however, if much tellurium is present, the gold 'spits' and often sinks completely into the cupel. This may be obviated by adding antimony.

A New Blowpipe Reaction for Germanium: JOSEPH W. RICHARDS.

Argyrodite gives a white sublimate like molybdenum, which becomes an intense blue when heated with cobalt nitrate.

Contributions to the Chemistry of the Rare Earths of the Yttrium Group: L. M. DENNIS and BENTON DALES.

A review of the various methods of separation of the rare earths, and the announcement of several new ones, which promise well.

Preliminary Note on a New Separation of Thorium: F. J. METZGER.

Thorium may be separated from the other rare earths almost quantitatively by

fumaric acid. This reaction seems to be connected in some way with the molecular asymmetry of the acid molecule.

Sodium: J. D. DARLING.

Description of the electrolytic method in use at the works of Harrison Bros. & Co., for the production of sodium. This method was introduced primarily for the manufacture of nitric acid. A diaphragm four inches thick, made of magnesite and Portland cement, separates the two electrolytes. On the outside of this, fused sodium nitrate is at the anode, while the inner electrolyte surrounding the kathode is sodium hydroxid. As the current passes, this soon becomes sodium oxid, and then metallic sodium is formed. A current of about six hundred amperes at seven volts is used. The supply of metallic sodium on hand in storage is now so great that the city authorities have had the operation of the process stopped, fearing accident.

The Determination of Silica: W. F. HILLEBRAND.

The results of the analyses of a set of cement samples by a large number of chemists revealed great discrepancies in the amount of silica. This is chiefly due to the fact that one evaporation is not sufficient to render the silica insoluble. Further, the silica must be heated by a blast lamp before weighing.

Electro-Chemical Industries at Niagara Falls: C. F. CHANDLER.

A review of the history and a description of the processes used, illustrated by a large number of specimens. The manufacture of sodium, aluminum and carborundum was most fully considered.

Instantaneous Chemical Reactions, and the Theory of Electrolytic Dissociation (with experiments): LOUIS KAHLBERG.

The oleates of the metals are soluble in perfectly dry benzene, and from these solu-

tions the anhydrous chlorids are instantly precipitated by a dry benzene solution of hydrochloric acid. These solutions in benzene are practically non-conductors of electricity, consequently electrolytic dissociation cannot be supposed to have taken place; yet the reactions appear to be exactly parallel to those in aqueous solutions, to account for which the electrolytic dissociation theory is invoked.

What are the Requirements of a Course to Train Men for Work in Industrial Chemistry? W. A. NOYES.

It cannot be generally told what line of industrial chemistry a student will follow after graduation, and there are so many different fields that it would be impossible to train a man in the special technical requirements of every industry, and there should be no attempt to do this. Students should be thoroughly grounded in the general fundamental principles and have extended practice along several different lines of practical work. The special minutæ of any branch the student may enter will then be readily learned after graduation.

The Volumetric Estimation of Alumina, and Free and Combined Sulfuric Acid in Alums: ALFRED H. WHITE.

A method depending upon the proper choice of indicators.

Aqua Ammonia: Its Impurities and Methods of Analysis: J. D. PENNICK and D. A. MORTON.

A Method of Analyzing Oil Varnishes: PARKER C. McILHINEY.

The Oxygen Bases: A Review: JAS. LEWIS HOWE.

An outline of the recent work of Collie, Baeyer, Kehrman, Werner and others, on compounds in which oxygen appears to be quadrivalent, forming salts with acids, as do ammonia and its derivatives.

Electrolytic Deposition of Lead from P_2O_5
Solution: A. F. LINN.

Lead can be deposited electrolytically in a form suitable for weighing from a solution containing free phosphoric acid.

Latest Types of Formaldehyde Regenerators (with demonstration): WM. DREYFUS.

An exhibition of the various types of apparatus with a discussion of their relative merits.

Some Pyridin Derivatives: J. ARTHUR HAYES.

Report of Committee on Atomic Weights: F. W. CLARKE, Chairman.

Attention was called to the atomic weight determinations which have been made during 1901.

Sixteen other papers on the program were omitted from lack of time for presentation; most of these will be later published.

J. L. H.

THE ASSOCIATION OF AMERICAN ANATOMISTS.

THE fifteenth session of the Association, meeting with the American Society of Naturalists and affiliated societies, was held at Chicago, Ill., December 31, 1901, to January 2, 1902. The Association met in the Hull Laboratory of Anatomy, Chicago University.

The following extracts are made from the report of the secretary for 1900-01:

There are copies of the printed proceedings on hand from the 6th to the 14th volumes, inclusive, which are available to those who request them, and are especially so for presentation to libraries. A republication of the first five proceedings under one cover is being made.

At the last report there were 125 mem-

bers, 116 of whom were active and nine honorary. During the year twelve active members were elected, two died, one resigned, and three have been dropped for non-payment of dues. The present number is 131 total members, 122 active, 9 honorary.

Dr. Frederick John Brockway, assistant demonstrator of anatomy, Columbia University, New York, died April 21, and Dr. Geo. Wm. West, late professor of anatomy and physiology, medical department, National University, Washington, D. C., died July 24.

The following new members were elected:

Dr. R. R. Bensley, Asst. Prof. Anat., University of Chicago.

Dr. John L. Bremer, Harvard University.
Benson A. Cohoe, A.B., M.D., Asst. in Anat., Cornell University.

Henry H. Donaldson, Prof. Neurology, University of Chicago.

Dr. W. T. Eckley, Prof. Anatomy, College Physicians and Surgeons, Chicago, and Dr. Corinne B. Eckley, Demonstrator of Anatomy, same college.
Albert C. Eyeleshymer, Instructor in Anat., University of Chicago.

Irving Hardesty, Ph.D., Instructor in Anat., University of California.

J. Ralph Harris, M.D., Asst. in Anat., Cornell University.

Basil C. Harvey, Asst. in Anat., University of Chicago.

Dr. Arthur E. Hertzler, Halstead, Kansas.
Dr. C. M. Jackson, Prof. Anat., University of Missouri.

Dean D. Lewis, Asst. in Anat., Univ. Chicago.
Dr. Warren H. Lewis, Instructor in Anat., Johns Hopkins.

Andrew H. Montgomery, A.B., M.B., Associate in Anat., Cornell.

Charles Aubrey Parker, Instructor in Anat., Rush Med. College.

Daniel G. Revell, Associate in Anat., University of Chicago.

Dr. Fredrick C. Waite, Prof. Histology, Western Reserve University.

Dr. J. Clarence Webster, Prof. Obstetrics, Rush Med. College.

Dr. F. A. Woods, Harvard University.

The following were reelected:

Dr. T. S. Lee, University of Minnesota.

Dr. S. W. Williston, Prof. Vertebrate Anatomy and Paleontology, Kansas University, Lawrence, Kansas.

The total new members was 22, making a total membership of 153, of whom 9 are honorary.

The following recommendations of the executive committee were adopted by the Association:

1. That Section V. of the constitution be amended to read that the management of the affairs of the Association shall be delegated to an executive committee consisting of seven members, including the president and secretary, *ex officio*.

2. That three new members of the executive committee be elected at this meeting, one for three years, one for four years, and one for five years.

3. That the Association accept the offer of the editorial committee of the *American Journal of Anatomy* to furnish each member of the Association with the *Journal* at \$4.50 per year; the *Journal* to publish the proceedings of the meetings of the Association, including an abstract of the papers read.

4. That the committee on circular on anatomical peculiarities of the negro be discharged.

5. That after this meeting the maximum limit of time of reading a paper shall be twenty minutes, and two papers shall not be read consecutively by the same writer.

The following officers were elected: President, Dr. Huntington, New York; First Vice-President, Dr. Lamb, Washington; Second Vice-President, Dr. Piersol, Philadelphia; Secretary and Treasurer, Dr. Huber, Ann Arbor; Executive Committee, Dr. Hamann (three years), Cleveland, Ohio; Dr. Barker (four years), Chicago; Dr. Gerrish (five years), Portland, Me.

The following was adopted, on motion of

Dr. Gerrish: "The thanks of the Association are hereby given to the retiring secretary and treasurer, Dr. Lamb (who has positively declined a reelection), for his long, faithful and eminently satisfactory service." Dr. Lamb has been secretary-treasurer since 1890.

The following papers were read:

1. 'Models illustrating the Development of the Arm in Man': DR. W. H. LEWIS, Baltimore. Discussed by Drs. McMurrich, Huntington, Terry, Chas. Hill and Harrison.

2. 'A One Year Anatomical Course; its Arrangement, Merits and Disadvantages': DR. TERRY, St. Louis. Discussed by Drs. Barker and Huntington.

3. 'Factors and Stages in the Evolution of the Stomach': DR. BENSLEY, Chicago. Discussed by Dr. Huntington.

4. 'Sections of the Decalcified Body,' illustrated by specimens: DR. TERRY. Discussed by Drs. Jackson, Huber and Huntington.

5. 'A Case of Breech Presentation in a Monkey,' with specimen: DR. TERRY.

6. 'Note on the Structure of the Motor Endings in Striated Muscles': DR. HUBER, Univ. Mich. Discussed by Drs. Huntington and Bensley.

7. 'Neuro-muscular Spindles in the Intercostal Muscles': DR. HUBER. Discussed by Drs. Ingbert and Terry.

8. 'A Note on the Supracondylar Process,' illustrated by specimens: DR. TERRY. Discussed by Drs. Bensley and Huntington.

9. 'The Development of the Pulmonary Artery': DR. J. L. BREMER, Boston. Discussed by Drs. Huber and Huntington.

10. 'Skeleton with Rudimentary Clavicles, Divided Parietal Bones and other Anomalous Conditions': DR. TERRY. Discussed by Drs. Huntington, W. H. Lewis and Barker.

11. 'Skull Showing Many Wormian Bones': DR. PARKER, Chicago. Discussed by Drs. Huntington and Terry.

12. 'The Neuroglia of the Optic Nerve and Retina of Certain Vertebrates': DR. HUBER. Discussed by Drs. Minot and Barker.

13. 'Present Problems of Myological Research and the Significance and Classification of Muscular Variations': DR. HUNTINGTON, New York City. Discussed by Drs. McMurrich and Huber.

14. 'The Phylogeny of the Long Flexor Muscles': DR. McMURRICH, Ann Arbor. Discussed by Dr. Huntington.

15. 'Note on the Occurrence and Significance of the Musculus Tibio-astragalus': DR. McMURRICH. Discussed by Dr. Huntington.

16. 'Nuclear Changes in the Muscle Cell': DR. EYLESIYMER, Chicago. Discussed by Dr. Barker.

17. 'The Plesiosaurian Skull': DR. WILLISTON, Lawrence, Kansas. Discussed by Dr. Huntington.

18. 'The Shape of the Pyloric Glands of the Cat': DR. DEWITT. Presented by Dr. Huber, Ann Arbor.

19. 'An Illustration of the Value of the Functional System of Neurons as a Morphological Unit in the Nervous System': DR. HERRICK, Denison University, Ohio.

20. Dr. Terry showed his specimen of *Situs inversus*.

21. 'The Sphincter superior': DR. R. C. BOURLAND, University of Michigan. Read by Dr. McMurrich. Discussed by Dr. Huntington.

22. 'Development and Variation in Distribution of the Thoracic-abdominal Nerves': DR. BARDEEN, Baltimore. Discussed by Dr. Huntington.

23. 'The Ducts of the Pancreas': DR. D. G. REVELL, Chicago. Discussed by Dr. Huntington.

24. 'Variations in the Distribution of the Bile Ducts of the Liver of the Cat': DR. HORACE JOHNSON, Madison, Wis. Discussed by Dr. Huntington.

25. 'Contribution to the Morphology of the Cerebellum': DR. STROUD, Cornell University. Read by the Secretary.

26. 'Histogenesis of the Sensory Nerves of Amphibia': DR. HARRISON, Baltimore. Discussed by Drs. Huber and Herrick.

27. 'The Growth of the Mammalian Spinal Ganglion': DR. DONALDSON, Chicago. Discussed by Drs. Huber and Huntington.

28. 'The Frontal Fissures in the Brains of Two Natives of British New Guinea': DR. HUNTINGTON.

The following papers were read by title:

1. 'On the Development of Connective Tissue Fibrils': DR. MALL, Baltimore.

2. 'Unusual Forms of Placentation': DR. WEBSTER.

3. 'Contribution to the Anatomy of the Scapula': DR. HRDLICKA, New York City.

4. 'Certain Racial Characteristics of the Base of the Skull': DR. HRDLICKA.

5. 'On Certain Anomalies of Bones': DR. DORSEY, Chicago.

6. 'Some Anomalies of Blood-vessels': DR. BLAIR, St. Louis.

7. 'Two Specimens of Anomalous Viscera with Left-sided Appendix': DR. HOLMES, Philadelphia.

8. 'Models of Human Pharynx of First Six Weeks' Development': DR. SUDLER, Baltimore.

9. 'The Ducts of the Submaxillary Glands': DR. FLINT, San Francisco.

10. 'Contribution to the Encephalic Anatomy of the Races': E. A. SPITZKA, New York City.

11. 'Description of the Brain of a Regentide': MR. SPITZKA.

A PLEA FOR GREATER SIMPLICITY IN THE LANGUAGE OF SCIENCE.*

SCIENTIFIC ideas are with difficulty soluble in human speech. Man, in his contemplation of the flux of phenomena at work all about him, is embarrassed by the want of a vehicle of thought adequate for expression, as a child whose stammering accents do not permit him to tell his mother the new ideas which suddenly crowd upon him when he meets with something alien to his experience.

Our knowledge of the mechanism of nature has been undergoing a process of growth, much of which has been sudden. It is not surprising, therefore, that the incompletely formed ideas of science should become translated into clumsy language and that inexact thinking should be evidenced by vagueness of expression. This inexactness is often veiled by the liberal use of sonorous Greek-Latin words.

The growth of knowledge has required an increase in the medium of intellectual exchange. New conceptions have called for new terms. Sir Courtenay Boyle has pointed out that the purity of a nation's coinage is properly safeguarded, while the verbal coinage of its national language is subject to no control. Specially qualified persons prepare the standards of gold and silver. This insures the absolute purity of the measures of commercial exchange and gives the English sovereign and the American gold piece, for example, an assured circulation along all the ave-

*A paper read before Section E of the American Association for the Advancement of Science, August 28, 1901.

nues of commerce. It is not so with the standards of speech. The nation debases its language with slang, with hybrid and foreign words, the impure alloys and the cheap imports of its verbal coinage, mere tokens which should not be legal tender on the intellectual exchanges. France has an academy which in these matters has much of the authority given to the Mint, whose assayers test our metal coins; but in our country the mintage of words is wholly unrestricted, and, as a consequence, the English language, circulating as it does to all the four corners of the globe, has received an admixture of fragments of speech taken from various languages, just as the currency with which one is paid at the frontier, where empires meet, includes the coinage of several governments, each of which passes with an equally liberal carelessness.

Science ignores geographical lines and bemoans the babel of tongues which hinders the free interchange of ideas between all the peoples of the earth. Nevertheless, the international character of technical literature is suggested by the fact that three languages, French, German and English, are practically recognized as the standard mediums of intellectual exchange. One of these affords the most lucid solvent of thought, another is the speech of the most philosophical of European people and the third goes with world-wide dominion, so that each has a claim to become the recognized language of science. The brotherhood of thinking men will have been fully recognized when all agree to employ the same tongue in their intercourse, but such a 'far-off divine event' is not within the probabilities of the present, consequently there remains only for us to make the best of our own particular language and to safeguard its purity, so that when it goes abroad the people of other countries may at least be assured

that they are not dealing with the debased currency of speech.

Barrie has remarked that in this age the man of science appears to be the only one who has anything to say—and the only one who does not know how to say it. It is far otherwise in politics, an occupation which numbers among its followers a great many persons who have the ability for speaking far beyond anything worth the saying that they have to say. Nor is it so in the arts, the high priests of which, according to Huxley, have 'the power of expression so cultivated that their sensual caterwauling may be almost mistaken for the music of the spheres.' In science there is a language as of coded telegrams, by the use of which a limited amount of information is conveyed through the medium of six-syllabled words. Even when not thus overburdened with technical terms it is too often the case that scientific conceptions are conveyed in a raw and unpalatable form, mere indigestible chunks of knowledge, as it were, which are apt to provoke mental dyspepsia. Why, I ask, should the standard English prose of the day be a chastened art and the writing of science, in a great scientific era, merely an unkempt dressing of splendid ideas? The luminous expositions of Huxley, the occasional irradiating imagery of Tyndall, the manly speech of Le Conte, and of a very few others, all serve simply to emphasize the fact that the literature of scientific research as a whole is characterized by a flat and ungainly style, which renders it distasteful to all but those who have a great hunger for learning.

To criticism of this sort the professional scientist can reply that he addresses himself not to the public at large, but to those who are themselves engaged in similar research, and he may be prompted to add to this the further statement that he cannot pitch the tone of his teaching so as

to reach the unsensitive intelligence of persons who lack a technical education. Furthermore, he will claim that he cannot do without the use of the terms to which objection is made. However, in condemning the needless employment of bombastic words of classical origin, in place of plain English, I do not wish to be understood as attacking all technical terms. They are a necessary evil. Some of them are instruments of precision invented to cover particular scientific ideas. Old words have associations which sometimes unfit them to express new conceptions and therefore fresh words are coined. The complaint lodged against the pompous, ungainly wordiness of a large part of the scientific writing of the day is that it is an obstacle to the spread of knowledge.

Let us consider the subject as it is thus presented. In the first place, does the excessive use of technical terms impede the advancement of science? I think it does. It kills the grace and purity of the literature by means of which the discoveries of science are made known. Ruskin, himself a most accurate observer of nature, and also a geologist, said that he was stopped from pursuing his studies 'by the quite frightful inaccuracy of the scientific people's terms, which is the consequence of their always trying to write mixed Latin and English, so losing the grace of the one and the sense of the other.' But grace of diction is not needed, it may well be said; that is true, and it is also true that a clear, forceful, unadorned mode of expression is more difficult of attainment and more desirable in the teaching of science than either grace or fluency of diction. One must not, as Huxley himself remarks, 'varnish the fair face of Truth with that pestilent cosmetic, rhetoric,' and Huxley most assuredly solved the problem of how to avoid rhetorical cosmetics and yet convey deep reasoning on the most complex of

subjects in addresses which are not only as clear as a trout stream, but are also brightened by warm touches of humanity, keen wit and the glow of his own courageous manhood. Nevertheless, though clearness of expression be the first desired, yet grace is not to be scorned. When you have a teaching to convey, it is well to employ all the aids which will enable you to get a sympathetic hearing. Man lives not by bread alone, much less by stones. He likes his mental food garnished with a sauce. Let the cooking be good, of course, but a *chef* knows the value of a well-seasoned adjunct to the best dish.

Our language is capable of a grace and a finish greater than we give it credit. That it is possible to write on geology, for instance, in the most exquisite simple English has been proved by Ruskin, whose 'Deucalion' and 'Modern Painters' contain many pages describing accurately the details of the structure of rocks and mountains, and dealing with their geological features in language which is marked by the most sparing use of words which have not an Anglo-Saxon origin.

The next aspect of the enquiry is whether the language of science, apart from the view of mere grace of style in literature, is not likely, in its present everyday form, to delay the advance of knowledge by its very obscurity. Leaving the reader's feelings out of the argument, for the present, it seems obvious that the whole purpose of science, namely, the search after truth, which is best advanced by accuracy of observation and exactness of statement, is hindered by a phraseology which sometimes means very much but oftener means very little, and, on the whole, is most serviceable when required as a cloak for ignorance. To distinguish between what we know and what we think we know, to comprehend accurately the little that we do know, surely these are

the foundations of scientific progress. If a man knows what a thing really is, he can say so, describing it, for example, as being black or white; if he does not know, he masks his ignorance by stating in a few Greek or Latin terms that it partakes of the general quality of grayness. Writers get into the habit of using words that they do not clearly understand themselves and which, as a consequence, must fail in conveying an exact meaning to their readers. Many persons who possess only the smattering of a subject are apt to splash all over it with words of learned sound which are more quickly acquired, of course, than the reality of knowledge. Huxley said that if a man does really know his subject "he will be able to speak of it in an easy language and with the completeness of conviction, with which he talks of an ordinary everyday matter. If he does not, he will be afraid to wander beyond the limits of the technical phraseology which he has got up." If any scientific writer should complain that simplicity of speech is impracticable in dealing with essentially technical subjects, I refer him to the course of lectures delivered by Huxley to workmen, lectures which conveyed original investigations of the greatest importance in language which was as easily understood by his audience as it was accurate when regarded from a purely professional standpoint.

Science has been well defined as 'organized common sense'; let us then express its findings in something better than a mere jargon of speech and avoid that stupidity which Samuel Johnson, himself an arch-sinner in this respect, has fitly described as 'the immense pomposity of sesquipedalian verbiage.' George Meredith, a great mint-master of words, has recorded his objection to 'conversing in tokens not standard coin.' Indeed the clumsy latinity of much of our scientific talk is an inherit-

ance from the schoolmen of the past; it is the degraded currency of a period when the vagaries of astrology and alchemy found favor among intelligent men.

Vagueness of language produces looseness of knowledge in the teacher as well as the pupil. Huxley, in referring to the use of such comprehensive terms as 'development' and 'evolution,' remarked that words like these were mere 'noise and smoke,' the important thing being to have a clear conception of the idea signified by the name. Examples of this form of error are easy to find. The word 'dynamic' has a distinct meaning in physics, but it is ordinarily employed in the loosest possible manner in geological literature. Thus, the origin of a perplexing ore deposit was recently imputed to the effects produced by the 'dynamic power' which had shattered a certain mountain. 'Dynamic' is of Greek derivation and means powerful, therefore a 'powerful power' had done this thing; but in physics the word is used in the sense of active, as opposed to 'static' or stationary, and it implies motion resulting from the application of force. In the case quoted, and in many similar instances, the word 'agency' or 'activity' would serve to interpret the hazy idea of the writer, and there is every reason to infer, from the context, that he substituted the term 'dynamic power' merely as a frippery of speech. It is much easier to talk grandiloquently about a 'dynamic power' which perpetrates unutterable things and reconstructs creation in the twinkling of an eye than it is to make a careful study of a region, trace its structural lines and decipher the relations of a complicated series of faults. When this has been done and a writer uses comprehensive words to summarize activities which he has expressly defined and described, then indeed he has given a meaning to such words which warrants him in the use of them.

In this connection it is amusing to remember how Ruskin attacked Tyndall for a similar indiscretion. The latter had referred to a certain theory which was in debate, and had said that it, and the like of it, was 'a dynamic power which operates against intellectual stagnation.' Ruskin commented thus: "How a dynamic power differs from an undynamic one, and, presumably, also, a potestatic dynamis from an unpotestatic one—and how much more scientific it is to say, instead of—that our spoon stirs our porridge—that it 'operates against the stagnation of our porridge,' Professor Tyndall trusts the reader to recognize with admiration."

Among geological names there is that comfortable word 'metasomatosis' and its offspring of 'metasomatic interchange' 'metasomatic action,' 'metasomatic origin,' etc., etc. To a few who employ the term to express a particular manner in which rocks undergo change, it is a convenient word for a definite idea, but for the greater number of writers on geological subjects it is a wordy cloud, a nebular phrase, which politely covers the haziness of their knowledge concerning a certain phenomenon. When you don't know what a thing is, call it a 'phenomenon'! Instances of mere vulgarity of scientific language are too numerous to mention. 'Auriferous' and 'argentiferous' are ugly words. They are unnecessary ones also. The other day a metallurgical specialist spoke of 'auriferous amalgamation' as though any process in which mercury is used could be gold-bearing unless it was part of the program that somebody should add particles of gold to the ore under treatment. A mining engineer, of the kind known to the press as an expert, described a famous lode as traversing 'on the one hand a feldspathic tufaceous rock' and 'on the other hand a metamorphic matrix of a somewhat argillarenaceous composition.' This is scientific

nonsense, the mere travesty of speech. To those who care to dissect the terms used it is easily seen that the writer of them could make nothing out of the rocks he had examined, save the fact that they were decomposed and that the rock which he described last might have been almost anything, for all he said of it; for his description, when translated, means literally a changed matter of a somewhat clayey-sandy composition, which, in Anglo-Saxon, is m-u-d! The 'somewhat' is the one useful word in the sentence. Such language may be described in the terms of mineralogy as metamorphosed English pseudomorphic after blatherskite. Some years ago, when I was at a small mine near Georgetown, in Colorado, a professor visited the underground workings and was taken through them. He immediately began to make a display of verbal fireworks which bewildered the foreman and the other miners whom he met in the mine, all save one, a little Cornishman, who, bringing him a bit of the clay which accompanied one of the walls of the lode, said to him, 'What do 'ee call un, you?' The professor replied, 'It is the argillaceous remnant of an antediluvian world.' Quick as a flash came the comment, 'That's just what I told me pardner.' He was not deceived by the vapor of words.

Next consider the position of the reader. It is scarcely necessary at this date to plead for the cause of technical education and the generous bestowal of the very best that there is of scientific knowledge. The great philosophers of that New Reformation which marked the era of the publication of 'The Origin of Species' have given most freely to all men of their wealth of learning and research. When these have given so much we might well be less niggardly with our small change and cease the practice of distributing, not good wholesome intellectual bread, but the mere stones of

knowledge, the hard fossils of what were once stimulating thoughts. In the ancient world the Eleusinian mysteries were withheld from the crowd and knowledge was the possession of a few. Do the latter day priests of science desire to imitate the attendants of the old Greek temples and confine their secrets to a few of the elect by the use of a formalism which is the mere abracadabra of speech? Among certain scientific men there is a feeling that scientists should address themselves only to fellow scientists, and that to become an expositor to the unlearned is to lose caste among the learned. It is the survival of the narrow spirit of the dark ages, before modern science was born. There are not many, however, who dare confess to such a creed, although their actions may occasionally endorse it. On the whole, modern science is nothing if not catholic in its generosity. 'To promote the increase of natural knowledge and to forward the application of scientific methods of investigation to all the problems of life' was the avowed purpose of the greatest of the philosophers of the Victorian era.

There are those who are full of a similar good will, but they fail in giving effect to it because they are unable to use language which can be widely understood. In its very infancy geology was nearly choked with big words, for Lyell, the father of modern geology, said, seventy years ago, that the study of it was 'very easy, when put into plainer language than scientific writers choose often unnecessarily to employ.' At this day even the publications of the Geological Surveys of the United States and the Australian colonies, for example, are occasionally restricted in usefulness by erring in this respect, and as I yield to none in my appreciation of the splendid service done to geology and to mining by these surveys, I trust my criticism will be accepted in the thoroughly

friendly spirit with which it is offered. It seems to me that one might almost say that certain of these extremely valuable publications are 'badly' prepared because they seem to overlook the fact that they are, of course, intended to aid the mining community in the first place and the public, whether lay or scientific, only secondarily. From a wide experience among those engaged in mining I can testify that a large part of the literature thus prepared is useless to them and that no one regrets it more deeply than they, because there is a marked tendency among this class of workers to appreciate the assistance which science can give. Take, for example, a sentence like the following, extracted from one of the recent reports of the U. S. Geological Survey. "The ore forms a series of imbricating lenses, or a stringer lead, in the slates, the quartz conforming as a rule to the carunculated schistose structures, though occasionally breaking across laminae, and sometimes the slate is so broken as to form a reticulated deposit." This was written by one of our foremost geologists and, when translated, the sentence is found to convey a useful fact, but is it likely to be clear to anyone but a traveling dictionary? A thoroughly literary man might know the exact meaning of the two or three very unusual words which are employed in this statement, but the question is, will it be of any use whatever even to a fairly educated miner, or be understood by those who pay for the preparation of such literature, namely, the taxpayers? An example of another kind is afforded by a Tasmanian geologist who recently described certain ores as due to 'the effects of a reduction in temperature of the hitherto liquefied hydroplutonic solutions, and their consequent regular precipitation.' These solutions, it is further stated, presumably for the guidance of those who wield the pick,

'ascended in the form of metallic super-heated vapors which combined eventually with ebullient steam to form other aqueous solutions, causing geyser-like discharges at the surface, aided by subterranean and irrepressible pressure.' At the same time certain 'dynamical forces' were very busy indeed and 'eventuated in the opening of fissures'—of which one can only regret that they did not swallow up the author as Nathan and Abiram were once engulfed in the sight of all Israel.

It will be well to contrast these two examples of exuberant verbosity because the first begs the statement of a scientific observation of value, made by an able man, while the second cloaks the ignorance of a charlatan, who masquerades his nonsense in the trappings of wisdom. Here you have an illustration of the harmfulness of this kind of language, which obscures truth and falseness alike, to the degradation of science and the total confusion of those of the unlearned who are searching after information.

Let the writer on scientific matters learn the derivation of the words he uses and then translate them literally into English before he uses them, and thereby avoid the unconscious talking of nonsense. If he knows not the exact meaning of the terms which offer themselves to his pen, let him avoid them and trust to the honest aid of his own language. 'Great part of the supposed scientific knowledge of the day is simply bad English, and vanishes the moment you translate it,' says Ruskin. The examples already given illustrate this. 'Every Englishman has, in his native tongue, an almost perfect instrument of literary expression,' so says Huxley, and he illustrated his own saying. Huxley and Ruskin were wide apart in many things and yet they agreed in this. Ruskin proved abundantly that the language of Shakespeare and the Bible can be used as

a weapon of expression keen as a Damascus saber when it is freed from the rust of classic importations, which make it clumsy as a crowbar.

There is yet another reason against the excessive use of Greek-English words, in particular. Greece is not a remnant of extinct geography, but an existing land with a very active people and a living language. The terms which paleontology has borrowed from the Greek may be returned by the Greeks to us. And, as Ruskin points out, "What you, in compliment to Greece call a 'Dinotherium,' Greece, in compliment to you, must call a 'Nasty-beastium,' and you know the interchange of compliments can't last long."

In all seriousness, however, is it too much to ask that such technical terms as are considered essential shall not be used carelessly, and that in publications intended for an untechnical public, as are most government reports, an effort be made to avoid them and, where unavoidable, those which are least likely to be understood shall be translated in footnotes. Even as regards the transactions of scientific societies, I believe that those of us who are active members have little to lose and much to gain by confining the use of our clumsy terminology to cover ideas which we cannot otherwise express. By doing so we shall contribute, I earnestly believe, to that advancement of science which we all have at heart.

The words which, at first, are the exclusive privilege of the specialist, gradually extend into wider use, following in the wake of that diffusion of scientific knowledge which is one of the objects of this Association. We believe that to get alongside facts, to apply the best knowledge available, to seek truth for its own sake, is as essential to the well-being of the individual life as it is to the success of a

machine shop, and as beneficial to the community as it is to a smelting works.

In furtherance of this principle we must remember that language in relation to ideas is a solvent, the purity and clearness of which affect that which it bears in solution. Whewell, in 'The Philosophy of the Inductive Sciences,' has expressed this view of the matter with noble eloquence. 'Language,' he said, 'is often called an instrument of thought, but it is also the nutriment of thought; or rather, it is the atmosphere in which thought lives; a medium essential to the activity of our speculative powers, although invisible and imperceptible in its operation, and an element modifying, by its qualities and changes, the growth and complexion of the faculties which it feeds.'

In considering the subject from this standpoint, there is borne in upon the mind a suggestion which carries our thought far beyond the confines of the matter under discussion. Such power of speech as man possesses is a faculty which appears to divide him from all other living things, while at the same time the imperfection of it weighs him down continually with the sense of an essential frailty. To be able to express oneself perfectly would be divine, to be unable to make oneself understood is human. In 'Man's Place in Nature,' Huxley points out that the endowment of intelligible speech separates man from the brutes which are most like him, namely, the anthropoid apes, whom he otherwise resembles closely in substance and in structure. This endowment enables him to transmit the experience which in other animals is lost with each individual life; it has enabled him to organize his knowledge and to hand it down to his descendants, first by word of mouth and then by written words. If the experience thus recorded were properly utilized, instead of being largely disre-

garded, then man's advancement in knowledge and conduct would enable him to emphasize, much more than it is permitted him at present, his superiority over the dumb brutes. Considered from this standpoint language is a factor in the evolution of the race and an instrument which works for ethical progress. It is a gift most truly divine which should be cherished as the ladder which has permitted of an ascent from the most humble beginnings and leads to the heights of a loftier destiny, when man, ceasing to stammer forth in accents which are but the halting expression of swift thought, shall photograph his mind in the fulness of speech, and, neither withholding what he wants to say nor saying what he wants to withhold, shall be linked to his fellow by the completeness of a perfect communion of ideas.

DENVER.

SCIENTIFIC BOOKS.

Geschichte der Metalle. Vom Verein zur Beförderung des Gewerbfleißes mit dem ersten Tornow-Preise gekrönte Preisschrift. Von ADELBERT RÖSSING. Berlin, Verlag von Leonhard Simon. 1901. 8vo. Pp. vi+274.

This 'History of Metals' forms a great contrast to the 'History of the Precious Metals' by Alex. Del Mar, reviewed in SCIENCE for December 6, 1901. The latter, as we have shown, is a philosophic study of the sources and history of the two metals, silver and gold, the work under review deals with the occurrence (in nature), the history of discovery the chemical, metallurgical and electrical preparation, the statistics of production and the cost price of all the known metals, fifty-five in number. Dr. Rössing's treatise forms, consequently, a most timely and valuable complement to that by Del Mar.

The arrangement of matter is very convenient for reference; after an introduction occupying twenty-one pages, the metals are discussed in alphabetic order, the treatment

being as indicated above, but limited by circumstances in many instances. The metals that have been in use from earliest times, either in native state or in ores, naturally occupy more space than those of comparatively recent origin; especially since in the former class is included the development of metallurgical operations used at different periods to make the metals available.

The occurrence in nature of many of the metals is very fully shown by lists of localities and of ores, or minerals, the latter accompanied in many cases by formulæ giving their chemical composition. References to authorities cited occupy footnotes on nearly every page, and as an example of their thoroughness may be mentioned a note calling attention to a 'peculiarly American and wonderful' company for extracting gold from sea-water, formed in Connecticut. The history and exposure of this fraud is well known to the readers of SCIENCE.

In sketching the history of processes for extracting metals from their ores, the modern extensive application of electricity has not been neglected, especially with reference to aluminium, antimony, gold, copper, silver and zinc. In this connection German, British and American patents are occasionally cited.

Unusual forms or conditions of some metals are named, and their chemical preparation described—colloidal mercury discovered by Lottermoser, and Leo's colloidal silver, but the researches of Carey-Lea seem to be unknown to the author.

Among the most valuable features of this work should be mentioned the statistics of production and the prices; when possible the figures are given for the entire nineteenth century in five-year averages; and a study of them brings out some striking features. The contrasts in production and price of aluminium are especially notable; from 1858 (three years after the labors of St. Clair Deville had made it an article of commerce) to 1884 a kilogram of aluminium was quoted at 100 marks, during the year 1890 the price per kilo fell from 27.6 to 15.2 mks., and in the following year it fell to 5 mks.; the price in 1897 was 2.5 mks., and the output amounted to three and four tenths millions of kilos, of

which nearly two millions were produced in the United States. Sodium was quoted at 32.5 mks. per kilo in 1866, and at 5 mks. in 1897. Manganese has suffered an extraordinary fall in price, showing that as soon as an article is positively demanded by commerce, means for securing it cheaply are devised; in 1886 manganese was quoted at 550 mks. per kilo, and four years later at 40 mks.; it fell in 1896 to 16 mks. per kilo.

The price of metallic sodium in 1879 was 20. mks. per kilo, and it had fallen to 5 mks. in 1897. Some metals of minor importance maintain a relatively uniform price, as antimony and palladium; while that of platinum has risen from 500 mks. per kilo in 1870 to 1297 mks. in 1895, and largely owing to the demand made for it by electrical apparatus.

In pleasing contrast to these rapid fluctuations in price is the steady behavior of the king of metals—gold; the figures (in part) are as follows:

1801-05,	2736.8	mks.	per	kilo.
1846-50,	2736.3	"	"	"
1876-80,	2730.7	"	"	"
1891,	2736.3	"	"	"
1892,	2743.2	"	"	"

The important bearing of this is obvious to students of monetary science.

The author is to be commended for the pains he has taken to prepare a valuable work of reference; the reviewer regrets that he feels obliged to point out a blemish in the manufacture of the volume, for which the publisher is primarily responsible. The running-head lines, particularly important in a dictionary or a book on the alphabetic plan, have been omitted and their place is inadequately filled by the page numbers; this makes it difficult to find a given metal readily, although in alphabetic order, except by scanning the text closely on a given page, or by examining the table of contents. This economy by publishers is to be deprecated. HENRY CARRINGTON BOLTON.

Practical Marine Engineering, for Marine Engineers and Students, and with Aids for the Applicants for Marine Engineers' Licenses. By WM. F. DURAND, Professor of Marine Engineering, Cornell University. New York, Marine Engineering Co. 8vo.

It too seldom occurs that men of high attainments and experts in their professions, possessed of both technical and scientific, practical and 'theoretical,' knowledge, are either able or willing to give time and thought to the production of works of this sort, and the task of provision of much-needed text-books and hand-books is too generally left either to the man of science without expert knowledge in the practical field or to the practitioner lacking sound and extensive scientific culture and training. This, which is a text-book for those desiring to secure practical knowledge of marine engineering with, at the same time, accurate understanding of its scientific foundations, is a model which it is to be hoped will furnish stimulus to many other able men in as many other departments. Its field is well laid out, its scheme and details well planned and handled and it is concise, simple, clear and satisfactorily full. Dr. Durand is an authority in his department, expert in its practice and familiar with its scientific basis, accustomed to combine science with practice, an experienced engineer, a trained and successful educator. The book is authoritative and cyclopedic and in it practical marine engineering is reduced to its simplest and most exact terms.

Its chapters discuss the materials of engineering, including the fuels, their methods of preparation and production, and their characteristics and qualities; boilers and their construction; marine engines, auxiliaries and accessories, their operation, management and repair. Special topics and problems illuminate and render usefully applicable the principles enunciated, and the second part of the work is devoted particularly to 'Computations for Engineers,' carefully selected and skilfully solved problems.

The introduction on board the modern steamship of refrigerating and other special machinery leads to the study, in appropriate chapters, of the apparatus of electric light and power distribution and of refrigeration, their care and management. These chapters are admirably concise and yet complete for their purpose.

The book is well made, the type excellent

and the illustrations clear and freely supplied, especially as illustrating the details of construction of marine machinery. So far as can be seen at a first review of its contents, the book is thoroughly up to date and very accurate, a credit alike to author, publisher and printer. It has its origin, apparently, in the public spirit and enterprise of the publishers of the technical journal, *Marine Engineering*, under whose imprint it appears.

R. H. T.

Studies in Physiological Chemistry. Edited by R. H. CHITTENDEN, Ph.D. New York, Scribner's Sons. 1901.

This volume of 424 pages, one of the Yale Bicentennial publications, contains reprints of the more important studies issued from the laboratory of physiological chemistry of Sheffield Scientific School of Yale University, during the years 1897-1900.

The twenty-six papers, representing the work of Professor Chittenden and his pupils during this time, are simply reprints from the *American Journal of Physiology*, the *Journal of Experimental Medicine* and *Zeitschr. f. physiol. Chemie*, Bd. XXIX., and form a valuable sequel to the three volumes of studies previously issued from this laboratory in 1885, 1887 and 1889. A complete bibliography of the Sheffield Laboratory of Physiological Chemistry from its commencement in 1875 until the end of the year 1900 is also given.

As these studies are more or less familiar and as they have been reviewed in the original, it is hardly necessary to enter into any detailed criticism of them. In viewing the work coming recently from this laboratory, one is struck with the radical change in direction in the line of research from the earlier investigations. It would be most interesting to have researches from the Sheffield laboratory on the products of proteolysis, in view of the recent researches of Kutscher, Siegfried, Balke, Lawrow, Pick and others. This line of work, so ably carried out by Kühne and Chittenden in 1883-4, has undergone such radical modifications in latter years that the views and investigations of one of the

pioneers would be most valuable to science. Although Professor Chittenden attempts to reconcile his views in regard to antipeptone with modern investigations, in an addendum to 'a chemico-physiological study of certain derivatives of the proteids,' page 321, still we think he fails to make his point very clear.

JOHN A. MANDEL.

Primitive Man. By DOCTOR MORIZ HOERNES. Translated into English by JAMES H. LOEWE, London, 1900. Dent and Co. Pp. 136, Figs. 48.

This handy little 16mo volume forms the twenty-third number in the series of Temple Primers designed by the publishers to furnish, for a shilling a copy, the best and latest results of scholarship to the average reader who cannot afford the costly encyclopedias. Beginning with the subject of man's place in nature the author sums up the characteristics of culture, the earliest traces of man, the ages of stone, bronze and iron; and the primitive history of the Aryans and Semites. Small space is given to the Western Hemisphere, but that is fortunate in two ways, for some wild guessing has been done on that topic, and, secondly, American readers will be glad to have a handy little guide book to European archeology. Not one American authority is mentioned in the bibliography and no European work later than 1894.

O. T. MASON.

Anleitung zur mikroskopischen Untersuchung der vegetabilischen Nahrungs- und Genussmittel. By DR. A. F. W. SCHIMPER, ö. Professor der Botanik an der Universität Basel. Second revised edition. Jena, Verlag von Gustav Fisher. 1900.

A melancholy interest attaches to the consideration of this book owing to the recent death of Dr. Schimper in the prime of life. Here in a space of 150 pages we have a very attractive and useful introduction to the microscopic appearance of flours, starches and their adulterants; of coffee and its adulterants; cocoa, chocolate, tea, tobacco, pepper, cloves, allspice, red pepper, mustard, saffron, cinnamon, vanilla, cardamon, nutmeg, mace, ginger and turmeric. There is also a chapter on the

adulterants of fruit jellies, and one on honey. The book contains a good index and 134 figures, which are well drawn and very attractive. Among the substances used for adulterating coffee Schimper mentions the following: Chickory, beets, carrots, figs, various cereals, lupin seeds, acorns, carobs, dates, vegetable ivory, potatoes. These are described in a space of twenty pages with seventeen illustrations. Under fruit jellies, we learn that agar-agar is frequently employed for their adulteration and that this substance may be detected readily by means of the microscope, owing to the fact that these seaweeds always have numerous diatoms clinging to their surface, as any one may determine readily by burning a small quantity of agar-agar in a platinum dish, adding to the ashes a few drops of water rendered acid by HCl and then examining under high powers of the microscope. When jellies are suspected of adulteration with agar-agar, the author recommends that the mass of jelly be boiled with about five per cent. dilute sulphuric acid, and then that a few crystals of permanganate of potash be carefully added. The previously suspended diatom shells now fall to the bottom and form a more or less rich sediment, which may be examined without any further preparation.

In this age of haste to be rich at any cost, the extension of the adulteration of food products has become very great, and the knowledge contained in books of this kind increases yearly in importance, not only to the special worker, but to the general public. The moderate price of four Marks in paper covers, or five Marks, bound, puts the book within the reach of every one.

ERWIN F. SMITH.

Use-Inheritance illustrated by the Direction of Hair on the Bodies of Animals. By WALTER KIDD, M.D., F.Z.S. London, Adam and Charles Black. 1901.

This is an interesting contribution to the dynamic or Lamarckian principles of evolution. Dr. Kidd has first treated of the formation of whorls in the hairy coats of mammals; and second, the slope of hair in certain selected regions of the bodies of animals and

man. In the domestic horse there are five regions where whorls occur—*i. e.*, the frontal, inguinal, pectoral, post-humeral or axillary, and cervical. These are due, the author shows, to the traction of the underlying muscles. It is interesting to observe that they are absent in the zebra, and are apparently the result of the movements and work done by the horse in a state of domestication. 'It is difficult,' the author concludes, 'to see any explanation of the formation of whorls, featherings and crests in the hairy coats of mammals other than a dynamical one.' His reasons for the dynamical view are as follows:

1. They all occur, except that on the vertex, in regions where opposing traction of underlying muscles is found.

2. They never occur over the middle of a large muscle, and seldom in any place where there is not a hollow or groove in the superficial anatomy.

3. They are most uniform and most marked in animals with very strong muscles, and those that are actively locomotive.

4. Their constancy appears to depend upon range of action and activity of function of the muscles in the part and individual animal affected. This is especially shown in the three regions of the domestic horse—pectoral, post-humeral and inguinal.

As regards the hair slope, the author arrives at the following conclusions:

1. To understand the disposition of hair on living animals, it is necessary to look upon it as a stream, and this is very plastic.

2. In man, and various groups of animals, the great majority of the peculiarities here noted are congenital.

3. Certain peculiarities of hair-slope are at present in process of development.

4. The hair streams are disposed in the lines of least resistance.

5. The mechanical conditions required for the production of both the general and the special hair-slopes are in present operation.

6. The hair-slope can be modified during the life of an individual.

7. Selection (whether natural, sexual or germinal) is incompetent to produce these peculiarities of hair-slope.

8. If these are not originally created with the forms of life which present them, they must have been produced in ancestors by use or habit.

The author seems to have made out a good case and to have been led by the legitimate use of the inductive method to what seem to be valid and natural conclusions.

A. S. P.

Some Fossil Corals from the Elevated Reefs of Curaçao, Arube and Bonaire. By T. WAYLAND VAUGHAN. *Sammlungen des Geologischen Reichs-Museums in Leyden*, Ser. 11, Bd. 11, Heft. 1901.

Mr. Vaughan makes his report upon the fossil corals from the Dutch West Indies, collected by Professor K. Martin, director of the Leyden Geological Museum, part of an elaborate study of the history and synonymy of the West Indian corals. The paper is companion to another by the same writer, shortly to appear, upon the stony corals of Porto Rico collected by the recent survey of the U. S. Fish Commission. The latter will contain photographic reproductions of most of the living species of West Indian corals. Both papers are subsidiary to a larger work upon the post-Eocene Corals of the United States, now in the course of preparation.

The author is preeminently qualified for the task he has undertaken. In addition to having access to the large accumulations of corals at the U. S. National Museum and Geological Survey, including the type specimens of Dana, he has visited the collections in London, Paris, Berlin, Turin and other centers, where are contained the types of Milne-Edwards and Haime, Ehrenberg, Klunzinger, Duncan, Duchassaing and Michelotti, and other workers on the corals. In some way the present revision is a continuation of the work of Professor J. W. Gregory on the fossil corals of Barbados.

The result is what might have been expected. With the further accumulation of material for study, enabling the possible variations within the limits of a species to be estimated, and the comparison of the type specimens of different investigators, either side by side, or by the aid of photographs, it

has been possible to bridge over a large number of the gaps which separate certain so-called species, and to demonstrate that many of the latter are but varieties of growth in a somewhat protean group. Thus, to take a couple of instances: *Orbicella acropora* (Linnaeus) now embraces ten species, and has been known under the same number of genera; *Meandrina meandrites* (Linnaeus) has a synonymy in which are represented seven genera and thirteen species.

Unfortunately the revision of the synonymy reveals the necessity for several important changes in long-established names if the rules of nomenclature are to be strictly followed. Vaughan now shows that the true *Meandrina* is not the brain coral which students, from the time of Milne-Edwards, have been accustomed to associate with the name, but is the *Pectinija* of Milne-Edwards, while the *Meandrina* of the 'Coralliaires' has for the future to be known as *Platygyra*. It is with a sigh that one relinquishes *Madrepora* for the corals so long associated with this name. As was first pointed out by Geo. Brook, in the British Museum Catalogue of the Madreporaria, none of the species at present included under *Madrepora* were embraced by Linnaeus when he instituted the term in 1758. Vaughan now suggests its replacement by *Isopora*, a name first used in the subgeneric sense by Studer in 1870.

The writer follows Brook in regarding all the forms of the West Indian *Madrepora* as but one species, the three Lamarckian species—*palmata*, *cervicornis* and *prolifera*—being reduced to formæ or varieties. Gregory in 1895 had come to the same conclusion as Brook, but in 1900, following upon a visit to the West Indies, and the opportunity of seeing the different representatives in situ, he reverts to the Lamarckian arrangement, and endeavors to dispose of the specimens which Brook regarded as intermediate in form.

In the immense coral flats around the various Antillean islands the three types of *Madrepora* growth usually retain a remarkable distinctness of form, though often growing side by side; and from a study of these alone one would be far from induced to admit their

specific unity. The polyps, however, are practically alike in form and color, and anatomically and histologically they reveal no important differences. Vaughan also believes that he possesses colonies which should be regarded as intermediate in habit between the three recognized types. In his forthcoming Porto Rican paper the author proposes in like manner to unite under two groups the many and varied West Indian representatives of the allied genus *Porites*.

It might have been supposed that the study of the polyps themselves, both in their living condition and anatomically and histologically, would have revealed distinctions tending to strengthen the specific separations founded upon the skeletal form. But such is not the case. A comparative study of the polyps of many so-called species of *Madrepora*, *Porites*, *Orbicella*, etc., now in progress reveals very few differences within each genus. Compared with those of *Madrepora* the polyps of *Porites* vary greatly in color, often on the same colony, but except for slight variations in size no other differentiations of importance can be established in any part of their structure.

Extensive studies like those now being undertaken by Vaughan indicate that the greater the number of specimens of Madreporarian corals which are studied, with regard both to the skeleton and soft parts, the greater will be the tendency to lessen the number of species. As it has been expressed by the author: "The number of species is very often a function of the amount of the material studied." The same tendency has already reached its climax in the case of the Hydrozoan coral, *Millepora*. In the course of a study of both polyps and skeleton of this genus, extending over many years, and embracing specimens from all parts of the world, Professor Sidney Hickson has recently come to the conclusion that it is impossible to maintain any specific distinction. All the numerous skeletal forms, hitherto included under about thirty-nine names, are, from Hickson's researches, to be regarded as but so many varieties of growth, which presumably may be assumed by any one individual under like conditions.

Zoologically the tendency is healthy. For the student's time will be set free to investigate collections of specimens from other standpoints than that of assigning each its name, animated by the desire to produce the longest possible list. Variations in a form will be studied as modifications adapted to particular environments. In museums the specimens can then be arranged, not as objects with so many long names as appendages, but as illustrating vital principles of natural history.

J. E. DUERDEN.

JOHNS HOPKINS UNIVERSITY,
BALTIMORE, MD.

GENERAL.

A NEW edition of Stieler's Handatlas to contain 100 copper-plate maps is now in course of publication by Perthes of Gotha, in fifty parts; the price of the complete work being 30 Marks. Half the maps are newly projected and engraved. All of them have relief in brown, in order to make the names in black more legible. In preparation for binding, each sheet has its title printed on the right corner of the back, with on outline map that indicates the location of the sheet and of the neighboring sheets with their numbers. The present edition is the ninth of this valuable work; the first having been completed by Stieler in 1831. Later editions were by Stülpnagel. Petermann, Berghaus and Vogel.

SCIENTIFIC JOURNALS AND ARTICLES.

THE January (opening) number of Vol. III. of the *Transactions of the American Mathematical Society* contains the following papers: 'On a Class of Automorphic Functions,' by J. I. Hutchinson; 'Concerning the Existence of Surfaces Capable of Conformal Representation upon the Plane in such a Manner that Geodesic Lines are Represented by a Prescribed System of Curves,' by H. F. Stecker; 'Zur Erklärung der Bogenlänge und des Inhaltes einer krummen Fläche,' by O. Stolz; 'The Groups of Steiner in Problems of Contact,' by L. E. Dickson; 'Quaternion Space,' by A. S. Hathaway; 'Reciprocal Systems of Linear Differential Equations,' by E. J.

Wilczynski; 'On the Invariants of Quadratic Differential Forms,' by C. N. Haskins; 'The Second Variation of a Definite Integral when One End-point is Variable,' by G. A. Bliss; 'On the Nature and Use of the Functions Employed in the Recognition of Quadratic Residues,' by E. McClintock; 'A Determination of the Number of Real and Imaginary Roots of the Hypergeometric Series,' by E. B. Van Vleck; 'On the Projective Axioms of Geometry,' by E. H. Moore.

THE December number (Vol. VIII, No. 3) of the *Bulletin of the American Mathematical Society* contains the following articles: 'The October Meeting of the American Mathematical Society,' by Edward Kasner; 'Modern Methods of Treating Dynamical Problems and in Particular the Problem of Three Bodies,' by E. W. Brown; 'The Hamburg Meeting of the Deutsche Mathematiker-Vereinigung,' by C. M. Mason; 'Some Curious Properties of Conics Touching the Line Infinity at One of the Circular Points,' by E. V. The January number of the *Bulletin* contains: 'Note on Mr. George Peirce's Approximate Construction for π ,' by Emile Lemoine; 'Concerning the Elliptic $\varphi(g_1, g_2, z)$ -Functions as Coordinates in a Line Complex, and Certain Related Theorems,' by H. F. Stecker; 'On the Abelian Groups, which are Conformal with Non-Abelian Groups,' by G. A. Miller; 'The Infinitesimal Generators of Certain Parameter Groups,' by S. E. Sloocum; 'Shorter Notices'; 'Notes' and 'New Publications.'

SOCIETIES AND ACADEMIES.

CHEMICAL SOCIETY OF WASHINGTON.

THE 130th regular meeting was held December 12. The following program was presented: 'The Solubility of Mixtures of Sodium Chloride and Sodium Sulphate': A. SEIDELL. The author first gave a brief summary of the status of solubility work in solutions other than very dilute ones, and described in detail the experimental difficulties which have to be met in this kind of work. He then presented

a diagram illustrating the solubility curves for the system $\text{NaCl}-\text{Na}_2\text{SO}_4-\text{H}_2\text{O}$ at 10° , 21.5° , 25° , 27° , 30° , 33° and 35° . It was shown that at temperatures above 33° the curves represented equilibrium conditions between sodium chloride and anhydrous sodium sulphate, and no abnormalities presented themselves. Between 33° and 17° , however, it was found that in solutions containing but small amounts of sodium chloride and in contact with solid sodium sulphate, the equilibrium conditions were determined by the solid salt being in the form of the decahydrate, and the solubility curves for this decahydrate are very much flatter than the corresponding curves for the anhydrous salt. But as the amount of sodium chloride in the solution increased, at temperatures between 33° and 17° , there was always a sudden change in the direction of the solubility curve for sodium sulphate, which was found to be caused by the sodium sulphate present as solid phase, having gone over to the anhydrous form. In order to check this view, the experiment was made of placing large well-formed crystals of sodium sulphate decahydrate in two test-tubes, one containing a saturated solution of sodium sulphate alone, and the other a solution nearly saturated with sodium chloride, as well as sodium sulphate. Both test-tubes were fitted with cork stoppers carrying thermometers. They were then immersed in a water-bath and the temperature gradually raised. At 28° the crystals in the sodium chloride solution gradually became opalescent around the edges, then rather rapidly became entirely opaque and showed a tendency to fall apart in a loose powder. The material had undoubtedly gone over to the anhydrous salt, although the crystals which were in the tube containing only water and sodium sulphate showed no change until the temperature reached 33° . It thus appeared that the transition temperature for the change of sodium sulphate decahydrate to anhydrous salt had been displaced by the presence of sodium chloride. This was regarded as of considerable significance, and is important in connection with the suggestions on this subject in the study of the change of gypsum to

calcium sulphate hemihydrate, made by Van't Hoff and Armstrong, Vater and Cameron.

The solubility curves for sodium sulphate heptahydrate in solutions of sodium chloride were shown to be very similar to those for the decahydrate. In the case of the decahydrate at lower temperatures and the heptahydrate, the curves were shown to have minimum points, the significance of which is not apparent at the present time.

'The Evolution of Metallic Retorts' (with samples): W. H. SEAMAN.

Before commencing the paper the speaker showed a very perfect copy, just received from England, of Boerhaave's 'New Method of Chemistry,' in two volumes, second edition, 1741. Boerhaave was born in 1668, died in 1738, was famous as a physician, botanist and chemist, and was one of the first to recognize the independence of the latter science.

The first metallic retorts were copper flasks just like the olive-oil flasks of the early chemists with a gallows screw added. In a lot of scrap of Professor Henry's apparatus about to be sold thirty years ago, the author found two wrought-iron retorts with walls a centimeter thick, and shaped just like a glass tubular retort that are types of this class.

The next retort exhibited was a pear-shaped vessel. It had a feed wheel on top, and was set in an egg stove, the bottom made red hot and KClO_3 fed in by the wheel. The O was taken off by the side pipe.

Next was a kettle-shaped retort patented by the author. Its peculiarity is that all parts draw together by the gallows screw, while the top is durable with ground joint, and the bottom, being thin, heats quickly and can be cheaply renewed.

Next we have the cylindrical sheet metal retort which admits of moving the bunsen burner along its length so as to decompose the charge in successive portions.

The latest development is the little frustrum of a cone, with gallows screw top and two pipes, one for delivery and one for the introduction of an inert gas or other purpose that may be desired. In this oxygen may be made, coal distilled, etc. They are sold by the Chicago Laboratory Supply Co., price one

dollar, and are one of the most useful acquisitions we have lately had made to laboratory apparatus.

'Starch as an Adulterant or Drier in Butter, and a Study of Glucose in Butters': G. E. PATRICK and D. STUART.

1. The paper describes first a 'canned butter' which was found to contain, besides about 15 per cent. of glucose, 3.15 per cent. of starch, either potato starch or a variety closely resembling it. The starch was probably added as a drier; it is said to be sometimes used for this purpose in remanufactured butter. The complete analysis of this butter was: water, 27.19; fat, 40.36; ash, 12.65 (all NaCl except .65 impurities); casein ($N \times 6.25$), 0.86; starch, 3.15; other organic matter, 15.8. Assuming .3 per cent. of lactose, there remains 15.5 per cent. of organic matter which was set down as glucose, since no other organic substance was identified. The aqueous extracts, of 100 cc. volume, from 26.05 grams of the butter, that is, a 'normal sugar solution,' polarized 26.2 degrees on the cane sugar scale (Soleil-Ventzke).

2. With four glucosed butters studied, whole 'normal sugar solutions' polarized respectively 7.0, 11.0, 18.5 and 26.2 degrees, and whose percentages of organic matter designated glucose (as in the case above) were respectively 7.0, 7.9, 10.6 and 15.5 per cent., the rotary and copper reducing powers of the aqueous extracts being referred to these amounts of dry matter, the copper reducing power was in every case (possibly excepting one) too low to correspond to the rotary power, according to Rolfe and Defren, if the entire matter were pure glucose. Sucrose was suspected and inversion was tried by means of saccharine, following the method of Tolman. In only two of the four cases was the rotation appreciably lowered. In these two—and these two butters were canned by the same firm—there was a marked reduction of rotation, indicating (of course not proving) the presence of cane sugar to the amount of about 1.3 per cent. on the butters. The increase of copper reduction, by inversion, was not determined at the time; but several weeks later, the small residual samples having been

meantime at laboratory temperature, one was tested, and the increased copper reduction after inversion was found to correspond to .83 per cent. sucrose in the butter, while the decrease of rotation by inversion at this time corresponded to only 1.0 per cent. sucrose. As glucose is added to butters in the form of a sirup, and as there are upon the market glucose sirups containing admixture of cane sugar, the presence of the latter in a glucosed butter need not be so very surprising. Aqueous extracts, 'normal sugar solutions' of 49 non-glucosed butters polarized from 0 to .5 degree, averaging .22 degree. Five ladled butters out of 15 examined polarized from 3.4 to 5.7 degrees, showing admixture of glucose. Glucose is frequently used by ladders to improve the appearance of their product.

L. S. MUNSON,
Secretary.

ANTHROPOLOGICAL SOCIETY OF WASHINGTON.

THE 324th meeting was held December 7. Mr. Paul Beckwith presented a type series of Philippine swords, from the National Museum, with description of their use, and stated the rank and people to which each sword belongs.

President W. H. Holmes presented some rare examples of ancient Mexican art, lately acquired by the National Museum. These consisted of pottery and stone carvings, showing exceptional artistic feeling in their treatment.

The paper of the evening was on 'Le Culte des Pierres en France,' by M. Paul Sebillot, translated and read by Mr. Jos. D. McGuire. Some months ago an arrangement was made between the Société d' Anthropologie de Paris and the Anthropological Society of Washington to exchange communications for one meeting during the winter. M. Sebillot's paper is the result of this intersociety comity. M. Sebillot has made extensive historical and observational researches on the great body of folk-lore and customs connected with the megalithic monuments of France, which really constituted a cult of stones coming down from ancient times. In general the customs are divinitory and may be grouped under the head of lithomancy, the idea being to look into the

future, for instance, the maids as to marriage and the matrons as to fecundity. On the whole the Cult des Pierres seems to be feminine. The strange customs long inhibited are still secretly practiced in France and M. Sebillot has handled this delicate subject with great detail and frankness. The paper was illustrated by a large series of photographs of the megalithic monuments, lent by Dr. Thomas Wilson.

Dr. J. Walter Fewkes in discussing the paper said that he appreciated this great contribution to knowledge, and further that a number of customs among the Zuni and Moki are similar to those mentioned by M. Sebillot. Mr. W J McGee and Dr. Thomas Wilson also discussed the question of the worship of stoues in America.

The Society passed a vote of thanks to M. Sebillot and requested the publication of the paper in the *Anthropologist*.

WALTER HOUGH.

DISCUSSION AND CORRESPONDENCE.

NOTES ON CUBAN FOSSIL MAMMALS.

TO THE EDITOR OF SCIENCE: The reported occurrence in Cuba of certain fossil mammals has been used by several geologists, the first of whom was Manuel Fernandez de Castro, as evidence of former land connection between Cuba and the continent of North America in Pleistocene time.

The fossil mammals reported from this island belong to the genera *Hippopotamus*, *Equus*, *Mastodon* and *Megalocnus*, a subgenus of *Megalonix*. Leidy* examined specimens sent him by Poey, and published the opinion that the remains of the horse appear not to differ from the corresponding parts of the recent animal, and it is even doubtful if they are to be considered indigenous fossils. Concerning the hippopotamus remains, which consisted of isolated canines, he says that 'they probably also belong to the recent animal.' The same opinion was expressed by Pomel.† Vertebrate pa-

leontologists do not consider isolated horse teeth sufficient data for the determination of species. So far as I have been able to glean from the literature, the remains of the so-called fossil horses from Cuba, reputed to be of Pleistocene age, are fragmentary, and therefore cannot be considered as possessing any paleontologic value. It has been shown that the *Mastodon** remains were not indigenous to Cuba, but were contained in a box of fossils from Honduras sent by del Monte to the Royal Academy of Sciences of Havana.

These notes seem to show conclusively that the three mammals considered above were not indigenous to the island of Cuba.

The fourth genus, *Megalocnus*, remains to be considered. According to de Castro's first notice,‡ this specimen was collected at Ciego Montero, a place noted for warm baths, in the jurisdiction of Cienfuegos, by José Figueroa, a young student of the Royal University. This reference is given as a quotation from a note read by Poey to the Havana Academy in 1861. I have not seen this note by Poey in print. The subsequent publications until 1892 are simply quotations of the above given locality. In the *Anales de la Real Academia de la Habana*, Vol. III., page 656, April, 1871, a note is inserted by Poey asking for information concerning the locality of certain large fossils which were sent to de Castro. On page 698 of the same volume it is stated that this box of fossils was sent by Leonardo del Monte to the Havana Academy of Sciences and contained three fossils from Honduras. According to the note of Poey‡ this box contained specimens of *Mastodon humboldti*, but Poey himself does not verify the locality whence the *Megalocnus* came.

As there have been so many extraneous fossils confused in the so-called Cuban fossil mammalian fauna, it has occurred to me that

* For note by Poey regarding the original locality of the *Mastodon*, *M. humboldti*, see *Anal. Real. Acad. Cien. Habana*, Vol. VIII., pp. 124-126, August, 1871.

† *Anal. Real. Acad. Cien. Habana*, Vol. I., p. 58, Sept., 1864.

‡ *Anal. Real. Acad. Cien. Habana*, Vol. VIII., pp. 124-126.

* *Proc. of the Acad. of Nat. Sci. Phila.*, Vol. XX., 1868, pp. 179.

† *Comptes Rendus*, Paris, Vol. LXVII., 1868, p. 850.

the specimens of *Megalocnus* might have been contained in this box of fossils from Honduras, or they may have come from some locality not in Cuba.

The only evidence which seems to contradict this expression of doubt is that given by de la Torre* in his 'Observaciones Geológicas y Paleontológicas en la región central de la Isla (Cuba).' In this article additional localities, the vicinity of Cárdenas and between Santo Domingo and Sagua, are recorded. I am not able to express an opinion as to the correctness of these localities or on Torre's ability to determine fossil vertebrates. I am inclined to doubt because there has been so much error regarding those fossils concerning which we have subsequently been able to procure definite data.

The question which I wish here to bring to the attention of vertebrate paleontologists is: Are vertebrate fossils of the genus *Megalocnus* found in Central America, especially in Honduras?

A note may be added upon the question of the priority of the name *Megalocnus* Leidy, and *Myomorphus* Pomel. The note by Leidy was published in the *Proceedings of the Academy of Natural Sciences of Philadelphia*, Volume XX., pages 179-180. The date given at the bottom of the page is June-July, 1868. The article by Pomel was published in the *Comptes Rendus de l'Académie des Sciences*, Paris, Vol. LXVII., for the second half, July to December, 1868, pp. 665-668. This is the account of the proceedings of the session of Monday, September 28, 1868. Apparently Leidy's name antedates that of Pomel by several months.

The recent mammalian fauna of Cuba consists of only two genera, a rodent, *Capromys*, which possesses species in several other West Indian Islands. It is a peculiar genus, having its nearest relatives in the Octodont rodents of South America. There are no relatives at all on the North American continent. The other genus is a peculiar large insectivore, *Solenodon*. This animal is entirely different from anything found in any other part of America.

* *Anal. Real. Acad. Habana*, Vol. XXIX., pp. 121-124, August, 1892.

It is most closely related to a genus, which is very different, found in Madagascar. If there had been any Pleistocene connection between North America and Cuba it would have inevitably caused a considerable similarity between the mammalian faunas of the two regions. However, none of the common mammalian types of the continent, such as cats, raccoons, hares, etc., are found in that island.

SHORTER ARTICLES.

NEJED: AN ARABIAN METEORITE.

AMONG a considerable number of important specimens lately added to the Ward-Cooley Collection of Meteorites, now on display at the American Museum of Natural History in New York, is a mass or single bolide of iron from Western Australia called the Youndegin or Penkaring Rock Meteorite. It is one and one half feet in greatest diameter, and weighs between 300 and 400 pounds. Its companion piece, which is in the Royal Museum of Vienna, weighs 910 kilogrammes (half a ton) and is with Cranbourne, also from Australia, one of the largest two meteorites from the entire Eastern Hemisphere.

But of even more interest is the subject of the present notice: the Nejed Meteorite from Central Arabia. It is a siderite or iron meteorite, whose form is rudely triangular, flattened in its longest diameter, which is about fourteen inches, while its thickness below is eleven inches, and its breadth, or height, about nine inches. Its surface is completely and very handsomely covered with the pittings so frequent in meteorites, whether of iron or of stone. The sharpness of these depressions and the bright-

ness of the iron—with entire absence of weathering—are noticeable features, as strongly indicating the recentness of the fall. Nejed was a meteorite which fell in two masses, one of 131 pounds, the other of 136½ pounds. The former was brought to Europe in 1885, and was sold to the British Museum, where it has since been on display. Mr. Fletcher has given (*Mineralogical Magazine*, 1887) some interesting points as to its finding. It was brought to London by a Persian agent who delivered it at the Museum, at the same time submitting a letter from his Excellency Hajee Ahmed Khanee Sarteeep, Ex-Governor General of Bunder Abbas, Persian Gulf, and Grand Vizier of Muscat. The letter sent from Bushire, and with the Persian date 14th Di Koodah, 1301, A. H., says:

“In the year 1282, after the death of Mahomed, when Maime Faisole Ben Saoode was Governor and General-Commander-in-Chief of the Pilgrims, residing in a valley called Yakki, which is situated in Nagede (Nejed) in Central Arabia, Schiek Kolaph Ben Essah, who then resided in the above-named valley, came to Bushire, Persian Gulf, and brought a large thunderbolt with him for me, and gave me the undermentioned particulars concerning it.

“In the spring of the year 1280, in the valley called Wadee Bance Kholed in Nagede, there occurred a great storm, with thunder and lightning; and during the storm an enormous thunderbolt fell from the heavens accompanied by a dazzling light, similar to a large shooting star, and it sank deep into the earth. During its fall the noise of its descent was terrific. I, Schiek Kolaph Ben Essah, procured possession of it and brought it to you, it being the largest that ever fell in the district of Nagede. These thunderbolts, as a rule, only weigh two or three pounds, and fall from time to time during tropical storms.”

“The above concludes the narrative of Schiek Kolaph Ben Essah. The said Schiek, who brought me this thunderbolt, is still alive and under Turkish Government control at Hoodydah near Jeddah. I myself saw in Africa, four years after the above date, a similar one, weighing about 135 pounds, to that

which Schiek Kolaph Ben Essah brought to me.

“The Sultan of Zanzibar, Sayde Mazede, obtained possession of it and sent it to Europe, for the purpose of having it converted into weapons, as when melted and made into weapons they were of the most superior kind and temper. For this reason I have forwarded my thunderbolt to London, considering it one of the wonders of the world, and may be a benefit to science.”

(Signed)

HAJEE AHMED KHANEE SARTEEPEP,

Ex-Governor of Bunder Abbas, and Grand Vizier of Muscat.

Any reader of the above letter will be impressed with its straightforward narrative, even though the writer gives credence to the popular idea—not at all confined to Arabia—that meteorites fall during thunder storms. His remark that thunderbolts in his country usually weigh only two or three pounds is also of an ingenuous naïveté not incompatible with truthful sincerity. There is a similarity like to that of general human nature—which marks tales of meteorites in every part of the world, the phenomena accompanying their fall, which are also strikingly similar, helping toward this. In this present case the meteorite itself was forthcoming to justify the narrative, and its fellow followed closely after: the piece which the Grand Vizier mentions having seen in Zanzibar and which the Sultan of Zanzibar, at that time also Sultan of Muscat (which district borders close upon that of Nejed), sent also to Europe to have converted into weapons. It reached London, and also went to the British Museum, where, they being already provided, Director Fletcher sent them with this second piece to Mr. James R. Gregory—a celebrated collector of meteorites, who promptly added it by purchase to his collection. From the heirs of Mr. Gregory I a few months ago obtained it, and gave it a place of honor, becoming its uniqueness, in the Ward-Coonley Collection. In view of the fact that Sayde Mazede, the Sultan of Zanzibar, duly received his weapons, and that they were *not* made from his meteorite, the story

that 'they were of the most superior kind and temper' has a rather amusing sound. It is well known to scientists that meteoric iron quite refuses to yield to successful forging—its grain being too 'short' for a durable cutting edge. The excellency of the weapons returned to the Sultan confirms the suspicion that his messenger pocketed the proceeds of the sale, yet had the grace to visit Sheffield for the swords and simitars. The two masses of Nejed were identical in composition, as they were closely similar in size, weight and general external appearance. When a polished section of this iron is etched with acid or with bromide-water its surface displays excellently the Widmanstätten figures, the straight long beams of Kamacite forming the approximately equilateral triangle pattern according with the octahedral crystallization of the mass.

Mr. Fletcher has analyzed the iron, and has shown its near similarity in composition to the iron of Trenton (Wisconsin), Toluca (Mexico) and Verchne Udinsk (Siberia). The relation of the four irons is as follows:

	Nejed.	Trenton.	Toluca.	V. Udinsk	
Iron	91.04	91.03	90.74	91.05	
Nickel	7.43	7.20	7.78		} 8.52
Cobalt	0.66	0.53	0.72		
Copper	trace	trace	0.03		
Phosphorus	0.10	0.14	0.24	trace	
Sulphur	trace		0.03	trace	
Insol. Residue	0.59	0.45	0.34	0.58	
	99.79	99.35	99.88	100.15	

This close similarity of composition in masses fallen in widely separated parts of our earth, at different dates, and coming perhaps from heavenly bodies infinitely distant from each other in space, is one of the many wonders revealed by these cosmic messengers. Lockyer has also shown that the spectra of the two meteorites, Nejed and Obernkirchen, closely agree as to both the number and the intensity of the lines. The specific gravity of the Nejed was determined by Fletcher at 7.863. Cohen and Brezina both speak of its very slight *veränderungszone*. This surface decomposition being less than 1 mm. in thickness, together with the general sharpness and bright-

ness of the iron, lends probability to the story of the Arabian that Nejed was seen to fall. Indeed Fletcher says of it in his earliest description, "The mass is thus one of the small group of meteoric irons, numbering at most nine or ten, of which the fall has been actually observed; and of these it is the largest." But in a later paper he expresses doubt as to the fall having been seen. We at least know that it fell in some quite recent period, and at the point where it was found. And Nejed, attractive in its peculiar history, is also interesting as being like Veramin of Persia (described by the writer in the December number of the *American Journal of Science*), one of the isolated, outlying meteorites. The great countries of Arabia and of Persia have each received, so far as recorded, but one of these celestial gifts. India, of almost exactly the area of these two countries combined, has the full number of fifty. The density of population in the Indian peninsula has doubtless something to do with the observing of these falls and the preserving of the stones. But this cannot account for the enormous disparity of the meteoric distribution. Nejed remains a grand and unique representative of isolated individuality.

HENRY A. WARD.

ROCHESTER, N. Y.

PRECAUTION IN THE USE OF GASOLINE.

IN those laboratories where gasoline is in use, it is necessary to observe a certain precaution with regard to the employment of rubber tubing, to which so far as I know, attention has never been directed. This precaution is that tubing which has been in use on burners should not be used afterwards for conducting gases, unless it has been very thoroughly washed out, or left to stand for some time. Serious accidents may result if, for example, a piece of tubing which has been used for some time on a burner, is immediately connected to a gasometer containing oxygen, for transferring that gas to cylinders or flasks for experiments. It would be natural to suppose that in such a case the washing out of the gasoline would be complete enough after one had passed through the tubing a volume of

oxygen say two or three times as large as the capacity of the tubing itself. But under certain circumstances this is found to be by no means sufficient, as the following experiment illustrates.

Ten feet of thin-walled gray tubing having an internal diameter of one fourth of an inch, was used on a burner for half an hour, and was from there transferred immediately to a gasometer of oxygen; the gas was then allowed to pass through the tubing and fill over water a cylinder the capacity of which was 560 cc.

As might have been expected the gas so obtained in the cylinder exploded violently. The volume of such a piece of tubing is about 95 cc., and hence the gas drawn off would contain something less than one sixth of the mixed hydrocarbons.

A second cylinder was then drawn off, and when a taper was thrust into it an explosion was produced which was as violent as the first.

The third cylinder also exploded, though less violently; the fourth flashed back slowly to the bottom, and the fifth behaved like pure oxygen.

This in this case 2,240 cc. were used to wash out a tube whose volume was less than 100 cc. That is, the contents of the tubing were displaced more than twenty times before the gas was removed.

The experiment obviously points to a solubility of the gas in rubber, and this is not surprising in view of the ready absorption by rubber of the low-boiling paraffin hydrocarbons in the liquid state.

That a certain amount of gasoline is absorbed in rubber may also be shown by passing a piece of rubber tubing up into a tube filled with the gas and inverted over mercury. It is of course to be remembered that the gas supplied by such machines as that in use here (Springfield Gas Machine) consists of a mixture of the vapors of the hydrocarbons with a very considerable proportion of air, so that such absorption experiments as these can only be relative. An evident absorption takes place even with gasoline which does not show any abnormal behavior when conducted through the tubing; but when such behavior was mani-

fest, the absorption was more than doubled.

The danger arising from this source lasts for only a short time after the gasoline tank has been filled; and indeed the results recorded above were obtained only twice, although four attempts were made immediately after the filling of the tank; this irregularity is probably due to the varying demands made upon the gasoline machine at different times.

The rubber tubing employed in the experiments was such as is furnished under the catalogue number 8012 by Messrs. Eimer and Amend. The gasoline was that supplied by the Gilbert and Barker Manufacturing Company; hence it is of normal quality; the phenomenon in question was observed both with the 86° and 90° products (degrees Baumé, equivalent to the specific gravities 0.66 and 0.65).

On the whole these observations point to the conclusion that gasoline of the kind described contains a small amount of more volatile components, which are given off mainly at first, and being perhaps more soluble in rubber than those which come over later, cause the abnormal behavior above described.

It would be interesting to know whether others who use gasoline have had occasion to notice this peculiarity.

HAMILTON COLLEGE, CLINTON, N. Y.

ON THE SIPHON.

THE writer wishes to call attention to an error that has crept into the text-books on general physics, written for high school and university classes. Most of the books either state explicitly that a siphon will not work if the shorter of its two legs is longer than the column of liquid that would be supported by the air pressure, or else give explanations of the siphon, from which this follows as a legitimate conclusion. As a matter of fact, a siphon can be made to work and draw the liquid to a height considerably greater than that representing atmospheric pressure.

The writer usually illustrates this fact in his lectures by means of the following simple experiment: Let *ABC* in the figure be a glass

siphon tube, both legs of which are 10 cm. or 15 cm. longer than the barometric column. The bore of the tube should be small (about $\frac{1}{10}$ sq. mm.) to work well. Let one of the legs, *BC*, dip down into a larger tube *CD*, partly filled to *D* with mercury. Fill *ABC* with mercury, and start the siphon drawing mercury from *C* over to *A* in the usual way. In order to start the siphon the vertical height of *B* above the surface *D* of the mercury should be less than the length of a mercury barometer column, but as the flow continues, the mercury surface descends and keeps on descending until its vertical distance below *C* is considerably greater than this length.

To make this experiment work sufficiently well for demonstration purposes, excessive care in purifying the mercury and cleaning the glass is not necessary. Boiling the mercury in the actual tubes used, for instance, is superfluous. With ordinary redistilled commercial mercury and tubes cleaned with alcohol the writer has made the siphon work to a height of 70 cm. As the altitude of the University laboratory, where the experiment was performed, is a little over one mile, and the barometer pressure, therefore, only about 61 cm., this means that the siphon worked 9 cm. above the barometric height.

The most plausible explanation of the above fact is that the atmospheric pressure is not the only force pushing the mercury up the shorter leg. It is drawn up partly by the cohesive attraction of parts of the mercury for each other, and the column is kept from

dwindling by the adhesive force exerted by the sides of the tube on the mercury.

It follows from the above that if a mercury siphon is placed under the receiver of an air pump, it can be made to work over a height of several centimeters, even though the air pressure is reduced to only a few millimeters. This experiment also has been shown to the writer's students. The apparatus was similar to that described above, except that the tubes were much shorter.

Fossil Shells of the John Day Region.

SINCE the publication about a year ago* of my paper on the 'Fossil Land Shells of the John Day Region,' etc., I have received from Professor John C. Merriam, of the University of California, a small collection of molluscan remains obtained by him in the same general locality. Professor Merriam's collection includes examples of the several species of land shells heretofore described,† namely, *Epiphragmophora fidelis anticedens*, *Polygyra Dalli*, *Ammonitella Yatesi præcursor* and *Pyramidula perspectiva simillima*. Of these four species there are numerous specimens and fragments. Dr. White's *Unio Condoni* apparently escaped detection. The foregoing represent all of the molluscan forms thus far reported from the John Day beds. Dr. White received his material from the late Professor E. D. Cope and Professor Thomas Condon, of the University of Oregon. Cope's specimens were obtained by Mr. Jacob L. Wortman, of the Army Medical Museum. These two collections included the same species.

Professor Merriam has made some interesting additions to the above brief list which are described below.

HELIX (EPIPHRAGMOPHORA?) DUBIOSA NOM. PROV.

Shell orbicular, flattened, discoidal, periphery angulated or obtusely carinated; whorls

* *Proc. Washington Acad. Science*, Vol. II., Dec. 28, 1900, pp. 651-658, pl. XXXV.

† Vide Dr. Charles A. White's paper 'On Marine Eocene, Fresh Water Miocene and other Fossil Mollusca of Western North America'; Bulletin No. 18, U. S. Geol. Survey, Washington, 1885, with two plates.

six or more, deeply sutured and exhibiting strong growth striae. Apex whorls closely and slightly pitted. Aperture and umbilical region covered by a portion of the matrix in which the shell was imbedded.

Diameter (maximum), 24 mm., probably 26 to 26½ mm. when perfect. Elevation, about 10 mm. A sufficient portion of the shelly substance intact admits of the above description. Number of specimens, six; of these the individual described is the largest and most perfect. The smaller examples consist mainly of the upper whorls.

With more and better material it is quite probable the foregoing might prove to be an angulated, dwarfed, depressed aspect of the living *fidelis*, or *mormonum*; it also suggests the form known as *Hillebrandi*. Nearly all of the material is in a very unsatisfactory condition, with no color indications to assist in determination. While for these reasons the conclusions may be regarded as more or less arbitrary, the general character and relationship is believed to be fairly well pointed out.

PYRAMIDULA LECONTEI N. S.

Shell small, orbicularly depressed, widely and deeply umbilicated; whorls four and a half to five, rounded, closely and conspicuously ribbed except on the apex, which is nearly smooth; the ribbing extending into the umbilical cavity; the grooves between the ribs nearly as wide as the ribs are thick; the suture deep; aperture nearly circular or rounded lunate; edge of lip simple. Diameter (maximum), 8½ mm. Elevation, nearly 5 mm. A single example; the last whorl has been broken back somewhat; the maximum diameter was probably 9 to 9½ mm. The specimen appears to be scarcely mature. The number, prominence and regularity of the ribs make this a very pretty shell. The general facies suggests relationship with the extraordinary group of helicoid forms that are so widely distributed throughout the vast area denominated by Mr. W. G. Binney* the 'Central Province,' and listed by Dr. Pilsbry in his recent catalogue, as number 340† (*P. strigosa* and numerous

* 'Manual of American Land Shells,' Bull. 18, U. S. National Museum.

† 'Classified Catalogue of Land Shells of North America,' etc., Philadelphia, April, 1898.

racces or varieties). A comparison of *P. Lecontei* kindly made for me by Professor Dall, with the large series of the *strigosa* group in the National Museum, determines it, as he says, to be 'different from anything we have in the collection.'

In memory of the late Professor Joseph Le Conte, I have attached his name to the above form.

In addition to the species herein described, the material submitted to me by Professor Merriam included a small globose form about the size of a small pea; there are several examples, so disguised by adherent particles of matrix as to make it doubtful whether they belong to terrestrial or aquatic groups, with a presumption in favor of the first.

Partially exposed in portions of a fine compressed sediment of lacustrine origin are several casts of a very large *Limnæa*, suggestive in a general way of the circumboreal *L. stagnalis*, but so much distorted as to preclude a more definite description. For convenience this may be known provisionally as *L. maxima*.

Professor Merriam has now in preparation a paper on the paleontology of the John Day region, which will contain in detail the special data relating to the occurrence of the various forms above referred to as well as figures of the species I have described.

ROBT. E. C. STEARNS.

CURRENT NOTES ON PHYSIOGRAPHY.

THE ISTHMUS OF PANAMA.

AN essay on the 'Geology of the Central Portion of the Isthmus of Panama,' by Hershey (*Bull. Dept. Geol. Univ. Cal.*, II., 1901, 231-267), includes an account of the surface features in terms of the two chief cycles of denudation that have had effect there. The axial Cordillera de Veraguas, trending east and west, is described as a dissected plateau whose general surface, once a lowland of degradation, consisting in part of syenite and intrusive volcanic rocks, is now raised to an altitude of 3,000 feet. The valleys in it are deep, narrow, and steep-sided. Eliminating them, the district would be a high plateau with a width of 20 or 25 miles, arched a little along an east-west medial line, but otherwise

remarkably even. The ridges often have nearly level crest-lines for several miles, and rise to similar altitudes; and there are some extended flats at the height of the ridge tops. Southward from the mountains there is a lower and younger and much better preserved peneplain, uplifted a few hundred feet, sloping gently toward the sea and sharply trenched by young valleys 'the most beautiful and perfectly base-leveled land' that the writer has seen. The interfluves are very slightly arched and are remarkable for their long gentle slopes. Many low monadnocks rise above the plain, and these, together with a 10- or 20-mile belt of irregular ridges and peaks bordering the mountains, are taken to be the remnants of the older peneplain, here less preserved than in the harder rocks of the Cordillera. The border of the younger peneplain, determined by the ending of its gently undulating strata, is followed by a young coastal plain, trenched like the peneplain by narrow valleys and cliffed along the shore; here the interfluves are flat, instead of being gently arched as further inland. The coastal plain, as an area of marine deposition, is the equivalent of the younger peneplain as an area of subaerial degradation. On the northern side of the isthmus, a narrow, dissected peneplain slopes gently from the Cordillera to the seacoast. This plain bears auriferous gravels near the mountain base. The slopes of the two younger peneplains, north and south of the Cordillera, and the greater height that is believed to have been gained by the older peneplain along the mountain axis, suggest a repeated up-arching of the isthmus along an east-west line. A recent depression has occurred, especially noticeable along the southern coast, where there are several good examples of partly drowned valleys.

THE GRECIAN ARCHIPELAGO.

PHILIPPSON'S latest studies in classic lands concern the Cyclades or southern island group of the Grecian archipelago ('Beitr. zur Kenntniss der griech. Inselwelt,' *Pet. Mitt. Ergänzungsheft*, 134, 1901, 172 pp., 4 maps). The islands are, in the most general statement, the remains of an old-mountain region

(Rumpfgebirge) reduced to moderate but not faint relief, then elevated and much dissected by streams and waves during slow depression, finally more rapidly submerged and again vigorously attacked by the sea. The geological structure is irregular and not clearly related to the distribution of the individual islands. The old-mountain uplands are best preserved where the rocks are somewhat uniformly resistant, as on Andros; elsewhere, variety of structure leads to variety of form, Naxos being of most rugged relief. The valleys are rather sharply incised beneath the uplands; the author parenthetically notes that they would be called 'young' by American morphologists. They represent the headwater parts of what was once a much more extensive drainage system, developed while the land stood higher than at present. During that time the sea is believed to have actively abraded the coast, producing a platform of tolerably even surface from three to fifteen miles wide, with greater breadth on the exposed than on the protected sides of the islands. The depth of the platform decreases from about 200 met. at its outer border to about 80 or 50 met. near the islands; and hence a slow depression is inferred during abrasion. Then came the more rapid submergence, bringing the sea about to its present level on the steep coast that had previously been cut around the remnant islands, and transforming the valleys into bays whose depth corresponds to that of the inner border of the submerged platform. The exposed parts of the present shore line are usually bold and ragged. Few of the islands have lowland plains, those on the western side of Naxos being the largest.

In not making explicit mention of the work of subaerial erosion during the inferred abrasion of the now submerged platform, Philippson's summary may give the impression that the greater part of the old-mountain uplands were consumed by the sea. It is probable, however, that many deep and broad valleys were eroded in the original uplands by streams, while the outer border of the platform was cut away by the waves; and that the further abrasion by the sea was aided not only

by slow depression but also by the work already then accomplished by subaerial erosion. Only by supposing an extensive system of open valleys to have been developed during the earlier advance of wave work on the retreating coast can satisfactory explanation be given for the scattered arrangement of the remnant islands on the abraded platform.

THE SOUTHERN URALS.

The excursion of the Russian geological congress turned attention to the Urals as an example of an uplifted and dissected peneplain. Further information on this subject is found in some 'Topographic notes on the Ural Mountains,' by Purington (*Bull. Amer. Geogr. Soc.*, XXXIII., 1901, 103-111). The southern extension of this old chain, where the structure is as greatly disordered as elsewhere, is for the most part a gently undulating plain, the Orenburg steppe, hundreds of miles in extent. Its surface is compared to that of a calm sea, swept by huge, flat, crossing swells, 100 or 200 feet high and from two to four miles from crest to crest. The general cover of the nearly treeless plain is frequently broken by low reefs of quartzitic schists, traceable for long distances, and thus revealing something of the underground structure. Some of the more decomposable schists are weathered so deeply that mine shafts have been dug 100 feet deep before blasting was necessary. Water-worn gold-bearing gravels are abundant on the undulating plain, but are frequently too far from the streams for profitable washing. Low monadnocks of the more resistant rocks occur in the region of the steppe; further north in the forested Urals the higher extension of the same peneplain is dominated by dome-shaped monadnocks, rising 3,000 and 4,000 feet over the uplands. The rivers of the steppe have now eroded broad and shallow valleys from 50 to 200 feet deep; the sides of the valleys are well defined where they rise to the upland, whose borders are dissected by ravines for a few hundred feet. The valley floors are sheeted with gravels in which the rivers meander freely.

W. M. DAVIS.

THE STRECKER COLLECTION OF LEPIDOPTERA AND THE AMERICAN MUSEUM OF NATURAL HISTORY.

SINCE the death of Dr. Herman Strecker, many representatives of large museums have visited his former home in Reading, Pennsylvania, and commendable zeal has been displayed in their efforts to secure the Strecker collection of lepidoptera for their respective institutions. The heirs, however, have insisted that no deviation would be made from the original valuation placed upon the collection by Dr. Strecker, namely \$20,000. The Right Reverend Dean Hoffman has authorized the American Museum to purchase the collection. This is not the first time that Dean Hoffman has benefited the people of New York by gifts of like character, and the silent appreciation of the thousands that visit the superb exhibition of butterflies and moths which his generosity has made possible is itself a testimonial of public gratitude.

The growth of the Department of Entomology within the last few years has been phenomenal. In 1890 Mrs. M. S. Elliot donated the 'Elliot Collection,' consisting of six thousand local specimens, all reared from caterpillars, and consequently as nearly absolutely perfect as specimens can be—butterflies that are captured in the field are almost invariably injured. In 1892 friends of the Museum contributed some \$15,000 toward the purchase of the 'Harry Edwards Collection.' This was a general collection of insects, but contained some forty to fifty thousand butterflies and moths from various parts of the world; among these were some three hundred which were absolutely new to science. For a long time this has remained the principal part of the Museum collection. In 1891 a collection of insects numbering some ten thousand, and containing at least three thousand North American Lepidoptera, was donated by Mr. James Angus. Mr. Angus had made a specialty of one genus of moths, the *Catocala*, and in this one genus alone he had upwards of fifteen hundred specimens. In 1897 Mr. William Schaus, then of New York, but now of England, donated a remarkably complete collection of Old World Lepidoptera, numbering

some five thousand specimens, all authoritatively named, and many representing most remote localities.

The arrival of the Strecker material will increase the Museum collections by fully one hundred thousand specimens, among which are several hundred 'types.' Mr. William Beutenmüller, the curator of entomology, will personally attend to the details of transportation. The Museum will also receive the 'Strecker Library.'

THE MISSOURI BOTANICAL GARDEN.

FROM advance sheets of the administrative report of the Garden for 1901, it appears that during the past year \$44,409 was spent on the maintenance and improvement of the establishment, \$5,287.60 less than the net income for the year after providing for publications and certain fixed events designated in Henry Shaw's will, the total gross receipts being \$125,690.73.

91,262 persons visited the Garden, about 45 per cent. of this number on the first Sunday afternoon each in June and September, the only two holidays on which the Garden can be opened to the public.

The collection of living plants, which in 1900 contained 9,194 species or varieties, has been increased to 9,967. Nearly 3,000 surplus plants were distributed to hospitals and schools. Exchange relations were maintained with other botanical establishments, and in addition to what was derived from these sources the living collections were increased by an expenditure of \$2,829.61.

16,256 sheets of specimens were incorporated in the herbarium, on which \$1,175.39 was spent, and the herbarium is stated to consist now of about 365,000 specimens, valued at \$54,743.00.

\$2,688.71 was spent on the library, to which 929 books and 254 pamphlets were added, and the library now contains about 36,000 books and pamphlets, valued at \$60,305.00, in addition to which there are about 275,500 index cards.

The extent of the exchange relations of the Garden is shown by the Director's statement that 1,184 serial publications are received at

the library, of which 1,083 are received in exchange for the Reports of the Garden.

THE NATIONAL GEOGRAPHIC SOCIETY.

SEVERAL announcements of plans and progress are made by the National Geographic Society. A handsome building, costing \$50,000, is being erected for the Society and as a memorial to its first President, Hon. Gardiner Greene Hubbard. The building is located on the corner of M and 16th Streets, in the central part of the city.

The annual meeting of the Society was held on the 10th of January, Alexander Graham Bell in the chair. The membership of the Society is now about 2,700, representing every State in the Union. The following directors were elected for three years:

Alexander Graham Bell, General A. W. Greely, chief signal officer of the War Department; Henry Gannett, chief geographer of the U. S. Geological Survey; Angelo Heilprin, Academy of Natural Sciences, Philadelphia; Gifford Pinchot, forester of the U. S. Government; O. H. Tittmann, director of the Coast and Geodetic Survey; W J McGee, ethnologist in charge of the Bureau of American Ethnology, and Russell Hinman, New York City.

The National Geographic Society is already forming plans for the great International Congress of Geographers which will be held under its auspices in Washington in 1904. It is the first time the Congress has met in the Western Hemisphere. These geographic Congresses are of international importance and it is expected that representatives from all parts of the world will attend.

SCIENTIFIC NOTES AND NEWS.

AT the meeting of the Paris Academy of Sciences on January 6, M. Bouquet de la Grye, the engineer, succeeded to the presidency. M. Albert Gaudry, the paleontologist, was elected vice-president, and will be elected president next year.

THE Lavoisier medal of the Paris Academy of Sciences has been awarded to Dr. Emil Fischer, professor of chemistry in the University of Berlin.

DR. JOHN C. SMOCK, for many years state geologist of New Jersey, has been given the degree of LL.D. by Rutgers College.

MR. WILLIAM MARCONI was entertained by the American Institute of Electrical Engineers on January 15.

DR. T. C. CHAMBERLIN, professor of geology at the University of Chicago, has been re-elected president of the Chicago Academy of Sciences.

LORD KELVIN expects to visit the United States at the end of next month.

DR. B. O. PEIRCE, Hollis professor of mathematics and natural philosophy at Harvard University, has returned from Europe. He expects to resume the duties of his professorship at the beginning of next year.

PROFESSOR C. H. EIGENMANN has leave of absence during March, and will visit some of the caves of western Cuba to secure a series of the cave fauna and especially specimens of the cave fishes *Stygicola* and *Lucifuga*.

PROFESSOR MORTIMER E. COOLEY, head of the department of mechanical engineering in the University of Michigan, was nominated for the presidency of the Michigan Engineering Society, at the session of January 8, held at Grand Rapids.

PROFESSOR WILLIAM HALLOCK, of Columbia University, has been elected president of the New York State Teachers' Science Association.

PROFESSOR KOSSEL, who holds the chair of physiology at Heidelberg, has been elected a member of the Stockholm Academy of Sciences.

PROFESSOR SADEBECK, director of the Botanical Museum at Hamburg, has retired.

THE Colonial Museum at Harlem has arranged to commemorate, on June 15, the two-hundredth anniversary of the death of the naturalist, Rumphius, who for forty years carried on work in botany and other branches of natural history on the Island Amboina, one of the Molucca Islands. A medal will be struck which can be obtained, silver or bronze, and a memorial book will be issued.

A COMMITTEE has been formed at Cromarty, the birthplace of Hugh Miller, the purposes of which are to erect a museum and library to celebrate the centenary of Hugh Miller's birth.

DR. ALPHEUS HYATT, curator of the Boston Society of Natural History, assistant in invertebrate paleontology in the Harvard Museum of Comparative Zoology and professor of biology and zoology in Boston University, one of the most eminent of American naturalists, died suddenly from apoplexy at Cambridge on January 15, aged sixty-three years.

MR. J. F. WARD, a well-known engineer, died on January 16, aged seventy-one years.

T. T. T. THORELL, a distinguished arachnologist, died at Helsingborg, Sweden, on December 23, in his seventy-second year.

DR. C. P. TIELE, professor of comparative religions at the University at Leyden, died on January 13 at the age of seventy-one years.

DR. HUGO VON PERGER, professor of applied chemistry in the Technological Institute in Vienna, has died at the age of fifty-nine years.

MR. JAMES P. SHIPMAN, who published a number of papers on the geology and paleontology of the region about Nottingham, recently died at the age of fifty-three years.

THE position of chief mechanic in the National Bureau of Standards at a salary of \$1,400 will be filled by civil service examination on February 26.

WE learn from *Nature* that Dr. W. A. Herdman, F.R.S., professor of zoology at University College, Liverpool, sailed for Ceylon on December 26, 1901, to undertake for the government an investigation of the pearl oyster fisheries of the Gulf of Manaar. He is accompanied by an assistant, and in Ceylon the inspector of the fisheries and his staff will cooperate and provide boats and divers. A suitable steamer for dredging and trawling will be placed at Professor Herdman's disposal by the Government of Ceylon; and the necessary gear and apparatus for collecting and observational work, and for biological experiments, have been sent out in advance. Professor Herdman has arranged to take samples

of the plankton throughout the voyage to Ceylon, and to launch current-floats at particular parts of the course.

REUTER'S representative has had an interview with Captain J. E. Bernier, the Canadian explorer, who is organizing an arctic expedition. Since his last visit to England, when he lectured before the Colonial Institute, he has been in Canada, where he has secured the active support and cooperation of the Dominion Government for his scheme. Captain Bernier, who is devoting his services gratuitously, estimates the cost of his expedition at £30,000. Of this he has already secured £20,000, including a contribution of £1,250 from the Dominion Government, and £1,000 from Lord Strathcona, besides large donations from Canadian ministers, members of Parliament, merchants and others. Captain Bernier is now in London with the object of procuring from English subscribers the balance of £10,000 necessary for his scheme.

THROUGH the kindness of Mr. B. Talbot B. Hyde, there was an exhibition of the weaving of Navajo blankets and of beaten silver ornaments by Navajo Indians from New Mexico in the Educational Museum of Teachers College, Columbia University, on January 13.

THE Montreal correspondent of the New York *Evening Post* reports that the Hon. E. H. Monson, of Ottawa, has given a sum of money to the medical faculty for researches into possible cures for tuberculosis. They are to be carried on by Dr. A. G. Nicholls, lecturer in pathology, under the direction of Dr. J. G. Adami, professor of pathology.

A BACTERIOLOGICAL institute has been established at Davos, Switzerland.

THE trustees of the estate of the late Nathan Haskell Dole have given \$100,000 for the Boston Public Library.

THE membership of the New York Zoological Society, according to the report of the executive committee, submitted at the sixth annual meeting on Jan. 14, is now 1,063, and is steadily increasing. The total attendance at the park in the past year was 527,145, the greatest attendance on one day being 20,206,

on Sunday, August 24. The important work done included the erection of the Primates' House, at a cost of \$64,160; the beginning of the Lion House, to cost, when complete, about \$150,000; the extension of the sewer and water systems of the park, at a cost of \$10,406, and the development of Mountain Sheep Hill and enclosures, at a cost of \$2,500. Director Hornaday reported that the Zoological Park now contains 1,674 live exhibits, of which 416 are mammals, 659 birds and 599 reptiles.

A PETITION has been presented to King Edward for the incorporation of the British Academy for the Promotion of Historical, Philosophical and Philological Studies, and has been referred to a committee of Lords in Council.

REPRESENTATIVE SOUTHARD, of Ohio, chairman of the House Committee on Coinage, has sent invitations to a number of the chief manufacturers, merchants and others engaged in mercantile pursuits, to appear before the Coinage Committee on February 6 at a hearing on the bill for the adoption of the metric system of weights and measures.

THE Treasury agents state that during the past season an epidemic has prevailed among the murrelets, of the Pribilof Islands, and that the birds, which are found there in vast numbers, have perished by thousands. The first intimation of disease was the presence of birds about the village of St. Paul, close in shore, so weak that they were readily taken by the children. Later dead birds washed ashore in such numbers that 212 were counted in 150 yards, while steamers from St. Michaels reported passing through large quantities of dead birds. This recalls the epidemic which has twice prevailed among the cormorants of the Commander Islands, greatly reducing their numbers.

THE following lectures before the Franklin Institute, of Philadelphia, are announced:

January 17—'The Austrian and Italian Tyrol': DR. CHARLES L. MITCHELL, Philadelphia.

January 24—'The Aborigines of the Arid Region': PROFESSOR W. J. MCGEE, Bureau of American Ethnology, Washington, D. C.

January 31—'Porto Rico': MAJOR GEO. G. GROFF, late Superintendent of Public Instruction in Porto Rico, Lewisburgh, Pa.

February 7—'The Gases of the Atmosphere': DR. H. F. KELLER, Central High School, Philadelphia.

February 14—'The Canyons and Sierras of the Great Southwest': MR. ROBERT T. HILL, U. S. Geological Survey, Washington, D. C.

WE have already noted the bequest to the Natural History Museum, London, by Mr. Philip Crowley, of the valuable collection of birds' eggs. In accordance with the terms of the will the trustees were permitted to take four clutches of eggs of each species, or more, should any species be useful or interesting by reason of variety or locality. The selection, the *London Times* states, has recently been completed, with the result that 15,200 eggs of birds have been added to the series of eggs preserved in the zoological department of the museum. The Crowley bequest falls only a few specimens short of the series of Indian birds' eggs presented to the nation by Mr. Allan Hume in 1885. Mr. Crowley began to form his collection more than forty years ago, one of his great acquisitions being Canon Tristram's fine collection, which contained an egg of the great auk and one of the Labrador duck. These two rare eggs now pass into the possession of the national museum—a matter of some satisfaction, as hitherto the great auk has been represented in Cromwell Road by two very poor and broken specimens. The Crowley great auk's egg was bought in 1853 for £35. A very fine specimen which came into the market last year realized 315 guineas. One of the most interesting features of the Crowley collection is the remarkable series of cuckoo's eggs with those of the foster-parents. Of these there are as many as 87 different clutches, while 37 species are represented. As regards Australian birds the museum series has hitherto been markedly deficient, and as the Crowley collection was particularly rich in the eggs of that continent the increase in this respect is very appreciable. From a rough estimate it appears that the series of eggs in the Natural History Museum has been increased by nearly a third in respect of numbers, and as regards the species represented, by at least 15 per cent. Mr. Crowley also left the museum the pick of his valuable collection

of exotic butterflies. The number of specimens retained for the museum was nearly 27,000, representing about 9,900 species. The selection made will enable the museum authorities to fill important gaps in the collection, which was most deficient in examples from the localities in which the Crowley collection was especially rich—namely, West Africa, the Moluccas, and Central and Southern America.

UNIVERSITY AND EDUCATIONAL NEWS.

AMONG the gifts recently received by the University of Pennsylvania are: Mr. William Ivins, \$2,500 for the new Medical Laboratories; Mr. James Hay, \$2,500 for the Engineering Departments; Mr. Ralph C. Stewart, '99 C. and '02 L., \$5,000 towards the new building of the Department of Law.

GENERAL ISAAC J. WISTAR has paid \$12,000 for a triangular lot of ground at Thirty-seventh Street and Woodland Avenue, on which a city police station now stands. The land will be presented to the University of Pennsylvania, so that the Wistar Institute of Anatomy and Biology, which adjoins on the east, and which is also a gift of General Wistar to the University, may be enlarged.

MR. JOHN D. ROCKEFELLER has promised to double all sums of money given to Vassar College up to \$200,000, between this time and June, 1902.

DR. HENRY HOPKINS, a congregational clergyman, has been elected president of Williams College. He is the son of Mark Hopkins, who was president of the college from 1836 to 1872.

DR. SAMUEL WEIR, formerly of New York University, has accepted a lectureship in pedagogy at the University of Cincinnati, for the remainder of this year.

DR. HANS DORFF, docent in astronomy and mathematics in the University at Leipzig, has been appointed to an assistant professorship. Dr. K. Zeissig has been appointed assistant professor of physics at the Technical Institute at Darmstadt, and Dr. Parmentier assistant professor of botany at the University of Besançon.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE DEVELOPMENT OF CHEMISTRY.*

THE American Chemical Society exists for the advancement of chemical science, and the betterment of the chemical profession. Every member of it is supposed to contribute his share of thought and energy to the accomplishment of these ends; and so its work is prosecuted along many lines of activity. During the past ten years the growth of the Society has been most remarkable, and the diversity of its interests is well shown in the pages of its *Journal*. The once doubtful experiment of organization has justified itself by success, and there are no longer any apprehensions as to the future. The Society now stands before the world well established, well recognized, active and vigorous; its days of weakness and danger are over; we can look forward with confidence to greater prosperity, to larger growth, to steadily increasing usefulness. All chemistry is our province, whether it be organic, inorganic, theoretical, physical or applied; and the narrowness of specialism finds its best antidote in the varied interests of our meetings. To promote science and to uphold the dignity of our common profession are the objects which bind us together.

Optimism is a good thing, but it needs to

* Presidential address delivered at the Philadelphia meeting of the American Chemical Society, December 30, 1901.

be tempered by reason. Hopefulness and enthusiasm are fine qualities, but the restraint of common sense should keep them within bounds. Too much complacency is dangerous, and on occasions like this we may well pause in our congratulations over past achievements, to ask ourselves whither we are tending. As chemists, we owe something to the science which we represent, and the debt is one which can never be discharged absolutely. That we have done much is evidence that we can and should do more; as a society and as individuals we may well look about us and strive to see which way the path of duty lies. We cannot appraise the future, but we must help to make it. Only by acting with intelligent forethought can we hope to advance creditably.

Retrospection is the one safe basis for prophecy. The history of science is full of suggestions for the days to come, and even if we do no more than to avoid the repetition of mistakes, we shall gain much from the study. Great as the past has been, we can make sure of something better still, looking confidently forward to more perfect knowledge, to larger opportunities for research and to wider recognition in the republic of learning. Let us see how chemistry has developed hitherto, and how we can improve her present condition.

A little over a century ago chemistry was hardly more than an empirical art—a minor department in the broad field of natural philosophy. There were no chemists in the professional sense of the term, and no laboratories worthy of the name; that is, no buildings were planned and erected for chemical purposes alone; but chemical investigations were conducted in any room which happened to be available, with a disregard for convenience which would be intolerable to-day. Even at a later period the marvelous researches of Berzelius were performed in a laboratory

which was essentially a kitchen. If we use the word in its true sense, the earlier chemists were amateurs; that is to say, men who labored for the love of truth and without ulterior professional motives. Priestley was a clergyman, who regarded his voluminous theological writings as more important than his contributions to science. Scheele was an apothecary; Lavoisier was a public official with multifarious duties; Dalton was a schoolmaster and arithmetician. Before these men and their contemporaries, a vast unexplored territory was outspread; and no one could suspect what hidden riches might lie beneath its surface. Lavoisier, with his emphasis upon quantitative methods; Dalton, with the atomic theory; Davy, the discoverer and definer of elements; and Berzelius, with his genius for system and his untiring industry in the accumulation of details, opened the main roads into the new empire. Specialism in chemistry was practically unknown; all portions of its domain seemed to be equally inviting; but inorganic problems were perhaps the most obvious, and, being easiest to grasp, received the greater share of attention.

There were, from the beginning, two great stimuli to chemical research; the intellectual interest of the problems to be solved, and the practical utility of many discoveries. Both forces were essential to the rapid development of our science; neither one alone would have been adequately effective. Economic considerations, taken by themselves, help but little towards the symmetrical organization of scientific knowledge, for the practical man has usually a limited, although very direct, purpose in view, and may not wander far from his main issue. On the other hand, the purely scientific investigator can rarely exercise his full powers without a certain measure of popular support and encouragement, to which the expectation of useful

ness contributes. That discovery must precede application is obvious; that systematic knowledge outranks empiricism is also clearly true; but theory and practice react upon each other, and it is only when they work harmoniously side by side that the best results are attainable. The purist in science too often overlooks this fact, and fails to recognize his enormous debt to industry. The commercial demand for chemical data was an important factor in the establishment of our profession, and from it we derive a large part of our resources. At bottom, however, the demand is essentially selfish; and the manufacturer who seeks chemical aid, nay, even the technical chemist himself, is not uncommonly forgetful of his obligations to pure research. Every chemical occupation is based upon discoveries which were made without thought of material profit, and which sprang from investigations undertaken in the interests of truth alone. Even theory, which the ignorant worker affects to despise, has its place in the economic world, and the indebtedness of the coal-tar industry to Kekulé can hardly be overestimated. Without theory science is impossible; we should have, instead, only a chaotic anarchy of disconnected facts, a body without a soul. Theory is to science what discipline is to an army; it implies system, method and the intelligent direction of affairs; it is the coordination of knowledge, through which the experience of others becomes best available to us. The victories of research are rarely accidental; if they were, then the untrained tyro would have an equal chance of success with the greatest masters. Among ourselves, these considerations may be commonplace, but they are opposed by certain popular misconceptions which hinder our advancement and work mischief to our cause. *Cui bono* is the one question which science cannot ask.

Four agencies have been chiefly instrumental in building up the chemical structure of to-day, namely, private enterprise, the commercial demand, governmental requirements, and the extension of scientific teaching in the universities. Under the first of these headings the foundations of chemistry were laid, and the researches of Cavendish upon the composition of the atmosphere, may be taken as types of the class. Unfortunately, however, the men who combine the requisites of wealth, leisure, the inclination and the ability for scientific investigation are few in number, and the output of their labors is relatively small. Still, we must admit that the work so accomplished is often far above the average in quality, and that if it were to cease, our science would be much the poorer. Its motive is always high, and unaffected by any annoying pressure from necessity; its objects are purely scientific.

Seen from the commercial side, chemistry presents quite another aspect. Questions of utility are now paramount, and the advancement of science as such has become a secondary affair. The manufacturer seeks to improve his products or to cheapen his processes, and calls for information which shall enable him to do so; specific industrial problems require immediate attention, and each one is taken by itself, regardless of its broader philosophical bearings. From these conditions a certain narrowness must follow; no time can be wasted over considerations not directly related to the matters in hand, for the success or failure of a great enterprise may depend upon the quickness with which the obviously essential work is done. As against this urgency of demand, no just criticism can be offered; we may only ask that it shall be reasonable, and that science shall be treated less as a servant, and more as a faithful ally. The commercial chemist owes something to his profession,

as well as to his employer; and his industrial duties ought not to be incompatible with his responsibilities as a scientific man. The education of the manufacturer is one of the functions which he has to perform, and it is one which is not always easy of accomplishment. Two points of view have to be reconciled; self-interest is on the one side, the benefit of science on the other.

Several difficulties beset the pathway of applied science, and interfere with the work of its practitioners. The limitations of the field have already been suggested; but a more serious obstacle to progress is found in the secretiveness of the employer. The industrial chemist can not publish his researches, or at best can publish little; he therefore fails to receive before the world the credit which is his due, and science as a whole is the loser. A secret process, an unpublished investigation, adds nothing to the sum of human knowledge, and it represents a policy which is both short-sighted and unwise. It often covers ground which has been well covered before, and in that case it stands for misdirected effort, for wasted energy. I have seen, under the seal of confidence, a 'secret process' which had been in print for twenty years; its too practical inventor, ignorant of the literature of his subject, had worked out his methods independently; had he consulted others, he might have saved both expense and time. On still broader grounds I believe we may claim that the publicity of science is more economical than the current exclusiveness. Where several competing establishments produce the same class of goods, each one tries to hide its workings from the others. Each, therefore, gains only that new knowledge which it can develop by itself, whereas with greater wisdom it might profit by the experience of all. Secrets will leak out, in spite of precautions; a full interchange of thought merely anticipates the danger, and at last the manufacturer may find that in-

stead of suffering loss, he has really received much for little. Possibly the combination of industries under the so-called 'trusts' may act favorably upon scientific research, for when rivalry ceases, the incentive to secrecy disappears also.

If we study the reaction between science and industry at all closely, I think we shall find that an economic revolution of remarkable importance is well under way. Like all the greater social movements, it is going on quietly, without noise or bluster, but it is nevertheless far-reaching in its effects. Manufacturing, once a matter of empirical judgment and individual skill, is more and more becoming an aggregation of scientific processes, a system in which accurate quantitative methods are replacing the old rules of thumb. Exact weight and measure are taking the place of guesswork, and by their means waste is diminished and economy of production is insured. I can remember the day when few establishments in America gave regular employment to chemists; now laboratories are maintained in connection with nearly all productive enterprises, and the demand for scientific service, which was formerly sporadic, has become well-nigh universal. A railway system, making contracts for supplies, does so upon the basis of chemical reports; and the work is performed in its own offices by experts who are permanently retained. In the management of an iron furnace, ore, flux, fuel and product are analyzed from day to day, by methods of amazing rapidity and considerable exactness. Fertilizers are sold upon chemical certificate after preparation under chemical rules; sugar is refined by chemical processes, and taxed according to chemical standards; medicine is enriched by new remedies of chemical origin; in short, our science touches every productive industry at many points, and aids in its transformation. Metallurgy is becoming more and

more a chemical art; photography, a modern science, rests upon chemical foundations; with the aid of the electric furnace new chemical industries are springing into existence; and every one of these agencies reacts upon the chemist, by increasing the demand for his services and his wares. In Germany this development of applied science has gone the farthest; and in that country a single establishment may employ from fifty to more than a hundred chemists in its regular work. Some of these men are analysts merely, but others are engaged in systematic research, which has both science and industry in view. This appreciation of research as such is something to which few of our American manufacturers have attained; and it marks the highest step yet taken in the line of industrial progress. The modern era began when hand labor, which means individualism, gave way to machinery; but the machine is a symbol of organized intellectual power, and science is the bed-rock of its foundation. Chance and supposition are out of place in the industrial world of to-day.

Turning now to the governmental side of science, we find that the services of the chemist are everywhere in demand. Every civilized government now maintains chemical laboratories, and for purposes of the most varied kind. The accuracy of the coinage is determined by the assayer; supplies for public use are tested by analytical methods; taxes are assessed in terms which need chemical interpretation; the armor of the battleship and the explosive of the torpedo depend for their efficiency upon the skill with which our work is done. The sanitation of cities; their water supply; the disposal of sewage; the effectiveness of antiseptics; the quality of gas for lighting or of asphalt for paving; the warfare against the adulteration of food—all of these questions are essentially chemical in character, and are, or should be, settled in

the official laboratory. The aggregate of this work is something enormous; and yet, like commercial chemistry, it has utility, not science, in view. Science may advance because of it, but that is not the main purpose; the application of existing knowledge to public uses, and the creation of new knowledge are two distinct things. Here again chemistry is a servant, nothing more.

Throughout the scientific bureaus of the government this secondary character of chemistry appears. In the Geological Survey it is an aid to geology; in the Department of Agriculture, agriculture is to be advanced; in the medical service of the army or the navy, the interests of medicine come first. Chemistry for its own sake has as yet little or no governmental support; astronomy is encouraged, geology receives assistance, the biological sciences are given opportunities for growth; but our profession is merely utilized, without thought of its significance, its laborers being too often overworked and underpaid.

In an incidental way, however, the governmental laboratories accomplish something for pure science, albeit with little direct encouragement and in spite of difficulties. The official chemist, unlike his commercial brother, is not always crowded for time; his work can be done in a somewhat more leisurely manner, for it is unaffected by any demand for immediate financial returns; and so abstract researches, if they bear in any way upon the problems which are assigned him, are sometimes within his reach. Chemistry owes much to investigations of this class; and the papers which issue from official laboratories are by no means to be despised. Good work is done, but there ought to be more of it; research should become a recognized duty, rather than an employment for spare time. It would be well if every government could be made to see that the use of science implies the encouragement of

science; for then we might hope for the establishment of laboratories for purposes of investigation alone. To this proposition I shall recur later.

We now come to the fourth of the agencies by which chemistry has been developed, the educational, and this is the most important of all. Scientific research has become a definite function of the modern university, wherein the creation of knowledge is given equal rank with the distribution thereof. Education to-day differs from the education of former times, in that a lower place is given to mere authority; it goes more to the foundation of things, and so secures a foothold from which it can build much higher. Research, both for its own sake and as an example to the student, is now expected of the teacher; his pupils, coming face to face with the limitations of knowledge, are shown the problems which demand solution, and are taught something, by practice and by precept, of the manner in which they can be solved. The student learns that science is a living growth, and that every earnest, sincere, well-trained scholar can do something towards its development. If we examine the chemical journals of the nineteenth century, we shall find that by far the larger part of the discoveries therein recorded were made in the laboratories of universities or schools. Even in our own journal, with all its contributions from technical and official sources, over sixty per cent. of the communications published are of this class. The significance of this fact, however, must not be overestimated; we should remember the restrictions under which the technical chemist labors, whereas to the university professor publication is almost as the breath of life. His professional standing, his chances of promotion, are profoundly affected by the amount and character of the work which he puts forth; silence, to him, means the possible reproach

of inactivity; he must publish or remain obscure. Furthermore, we must not forget that the teacher owes a debt to technology which can never be repaid. The commercial demand for applications of science has enlarged the field of education, by compelling the establishment of polytechnic schools. These institutions, all of them of recent date, give employment to thousands of instructors; they supplement the universities, they multiply the facilities for scientific work, and from them, too, there flows a steady stream of contributions to knowledge, to which the chemist is adding his full share.

Apart from the freedom to publish, the university teacher has one great advantage over the technical man. He is not confined to any limited field of operations, such as the chemistry of soap, or iron, or coal-tar; the whole domain of the science lies open before him to explore where he will. The possible utility of the work need not occupy his mind; he can attack any problem he chooses, and from any point of view. And yet, with all incentives to breadth, his researches may still be tainted with narrowness, for the inevitable tendency to specialize puts its restrictions upon him. It is much easier to be a physical chemist, an organic chemist, an agricultural chemist or an analyst, than it is to be a chemist; and chemists, in the larger sense, are few. It was Berzelius, I think, who said that he was the last man who could ever know all chemistry, and the saying was both wise and true. Sixty years ago our science could be mastered in its entirety by one industrious student; to-day it is so vast that subdivision is necessary. Still, special research is not incompatible with breadth of view; every chemist should understand the nature of the great central problems; he should stand high enough to overlook the field, no matter how small a corner of it he may prefer to cultivate per-

sonally. Broadness of mind does not imply a scattering of resources, a futile waste of opportunity; it means an intelligent appreciation of all good scientific work, whether it be within our own bailiwick or elsewhere. To exalt one specialty at the expense of others, to claim supremacy for our own small interests, indicates a self-conceit which is both mischievous and absurd.

With so many opportunities for research, and with numberless problems in sight, chemistry should have grown according to some law of symmetry, giving us to-day a well-balanced and harmonious whole. History, however, tells a different tale. The science has expanded enormously in some directions, and advanced slowly in others; a glaring disproportion is the result. For this condition of affairs there are two reasons: lack of coordinated labor and the influence of fashion; for there are fashions in thinking, just as there are in dress, and only the most original minds can escape from their domination. Theoretically, every investigator is free to follow his own bent; practically, his course is shaped by a complexity of circumstances. The line of least resistance is the easiest line to take, and in science that is determined by temporary conditions. Certain researches have been fruitful; and so, like miners flocking to a new camp, we are tempted to enter the same field, rather than to play the pioneer elsewhere. The greatest prospect of immediate success is the power which attracts us. Through influences of this kind chemistry has developed unevenly, with one side over-cultivated and another suffering from neglect.

To illustrate my meaning. I do not wish to underrate the importance of organic chemistry, nor to question, in the smallest degree, the value of its achievements. Its interest, its attractiveness, the beauty of its methods, its profound influence upon

chemical theory, are all admitted; and yet it has received, it seems to me, an undue share of attention. During fifty years a large majority of all chemical investigators devoted themselves to this one branch of chemistry, leaving only a few workers to occupy other fields. Organic chemistry was the fashion; in it reputations were easiest made; the great professional prizes, the best positions, went to its devotees.

Now, in spite of all that organic chemistry has accomplished, we may fairly admit that chemical research should have a broader scope. Carbon is but one element among many; and all must be considered before we can be sure that our interpretations of chemical phenomena are sound. Special cases are easily mistaken for general laws; and to such errors we become liable when we confine our studies within too narrow bounds. Fortunately for chemistry, a broadening process has begun; and the prospects for the future are most encouraging.

During the past ten or fifteen years two movements have gained headway in the chemical world. One is marked by the revival of interest in inorganic problems, the other by the development of physico-chemical research. To a certain extent the two have much in common; each one is aided, I might say fertilized, by conceptions borrowed from the organic field; both are already fruitful to a remarkable degree. Independent journals devoted entirely to inorganic or physical chemistry, have come into existence, and investigators of the highest rank fill them with contributions. It is not my purpose to discuss either movement in detail; I mention them as symptoms of a more liberal spirit in research, as indicating the commencement of a new era. Physical chemistry in particular is becoming the center of interest; laboratories are built and equipped for its benefit alone; it bids fair to surpass even organic chemistry in

its dominion over chemical thought. One danger, however, confronts it—the danger of self-exaggeration, stimulated by over-popularity. Physical chemistry, to achieve the best results, has need of data drawn from other lines of chemical research; if they are neglected, it in turn will suffer. Even now too large a proportion of its votaries are working in one field; that is, on questions growing out of the current theory of solutions, and other subjects fail to receive the attention which they deserve. This state of affairs, this lack of proportion, is doubtless only temporary, for towards physical chemistry all chemical theories converge, and no phase of it, therefore, can long escape consideration. The very nature of physical chemistry implies the prohibition of narrowness; broad conceptions and deep insight are essential to its being.

When we consider the complex influences, the varied demands, through which chemistry has developed hitherto, we can only wonder at the outcome. Under the circumstances, a symmetrical growth was impossible; the marvel is that so much could have been accomplished. Out of unorganized, uncoordinated, individual efforts a true science has come into existence, equal in dignity to any other within the domain of learning. All science is defective, but in its very imperfections we find its greatest charm. Through them alone effort becomes possible; a wise discontent on our part is the first condition for progress. If all were known, research would come to an end; nothing could arouse our curiosity; the human mind would atrophy for want of exercise. The search for truth is better than the truth itself—if I may be allowed thus to paraphrase the well-known words of Lessing. In what direction, then, shall we pursue our search, and with what promise for the future? What are the needs of chemistry?

Pardon me, now, if I apparently indulge

in commonplace; if I cite some considerations of almost alphabetic simplicity. Fundamental principles lie so close to our eyes that they are easily overlooked; and from negligence of that kind, misdirected effort may follow. We must review our lessons sometimes in order to make sure of what we really know. In the first place it is well to bear in mind that chemistry and physics are not sharply distinct; that they are two parts of the same great body of truth; and that neither can be studied to the best advantage without aid from the other. Both rest upon the same two basic doctrines—the conservation of energy and the persistence of matter—conceptions which supplement each other and which give our work its philosophical validity.

If we try to consider chemistry by itself, to conceive of it as an independent branch of learning, we shall find that it has but one fundamental problem, namely, the study of chemical reactions. From certain kinds of matter certain other kinds are produced; and we merely investigate the laws which govern the transformations. If we prepare new compounds, we discover that such and such reactions are possible, and we describe their products. If we are interested in chemical equilibrium, we seek to determine the limits between which a given change can occur. Even our notions of chemical structure and atomic linking are but devices through which reactions and their products may be coordinated. In every case the reaction is the ultimate object of purely chemical research, and we try to ascertain its laws. Beyond this we enter the realm of physics; we describe each kind of matter in thermal, optical, electrical, mechanical and gravitational terms, and we discuss the phenomena of chemical change in similar phraseology.

Let us take, for example, any reaction whatever, and see what its *complete* investigation signifies. At once the problem will

resolve itself into four parts, two statical and two dynamical, not one of which can logically be neglected. First, there are the substances which enter into the reaction; secondly, the physical stimulus, thermal, electrical or actinic, which starts the reaction; thirdly, the phenomena which occur during the reaction; and finally, the substances produced by the reaction. An initial state of equilibrium is disturbed by some application of energy; transformations of energy take place, and in a final state of equilibrium the process comes to an end. Through a mixture of gases having certain physical properties we pass an electric spark; they unite to form a liquid with different physical properties, the process being attended by a change of volume and great evolution of heat. The fact of union is chemical; the other phenomena are physical; and the two sets of considerations are so interlaced that we are compelled to take them together. Intellectually we can discriminate between them, but the line of demarcation is essentially ideal. The chemical composition of matter cannot be studied apart from its physical relations, nor discussed without the aid of physical terminology.

It is easier to preach than to practice; to say what should be done than to do it. Between the theoretical statement of a problem and the practical method by which it may be solved there is a profound gulf, over which a direct passage is perhaps impossible. No reaction has yet been exhaustively studied on the lines which I have laid down, and possibly none ever will be, for the difficulties in the way of such a research are almost insuperable. Of all the snares which nature sets before our unwary feet, that of apparent simplicity is the most deceptive. Honest complexity, evident at sight, we may hope to overcome; it is the unseen obstacle which baffles us. In the present instance a prime difficulty is the

definition, the isolation of a reaction by itself, apart from other chemical changes. Nearly every reaction which we can observe is, in reality, a complex of several reactions—a series of steps, some of which may easily escape our notice. We measure certain phenomena, only to find at last that our result is an algebraic sum, and that we have more unknown quantities than equations. We cannot solve our problem until these factors have been recognized and separated.

To study individual reactions, then, except for the determination of definite, special phases, is not the best mode of procedure; chemistry would advance but slowly were we restricted to such a method. In ordinary chemical research, in the work of the compound-maker, for example, the initial and final stages of a series of reactions are investigated, and in that way valuable data are obtained. But the aim of science is not so much to amass facts as to connect them by laws and principles; and the more general the latter become, the greater is their intellectual value. We can not build, of course, until we have the materials, but between brick-making and architecture the difference is great indeed.

Leaving now the apparently simple, and turning to the visibly complex, let us see whether we cannot attack all reactions collectively, and in that way reach a more general statement of our real experimental problems. All reactions display the same fundamental phenomena, namely, changes of composition, changes of properties and transformations of energy; if we can classify our data under these categories, we shall begin to see more clearly the road we are to follow.

Now, recurring for a moment to the analysis of a single reaction, we may consider its two statical terms, the nature of the substances with which we begin and end. In any particular instance these ques-

tions are special and limited; but through them we discover facts which may be grouped with others of like kind. Presently we shall reach the discrimination between elements and compounds; and sooner or later we shall find ourselves face to face with one of the ultimate problems of all science—the nature of matter itself. In this problem all questions of chemical composition come to a focus; it goes back of the reaction to the substances which react; but it belongs equally to physics, and its essential details admit of description only in physical terms. Chemistry, however, is doing the most towards its solution, for it is through chemical researches that variations in the composition of matter are best explained. The indebtedness of chemistry to physics is thus fully repaid.

What is matter? Is it continuous or discrete, atomic or made up of vortex rings in the ether? These questions admit of only partial answers, and doubtless their final solution is unattainable by man. They are, nevertheless, perfectly legitimate questions for science to ask; and a tentative reply, of great practical value, is given by the atomic theory. Whether it be true or false, whether the chemical atoms are ultimate or divisible, this doctrine is the connecting thread upon which our profoundest generalizations are strung, and it is hard to see how we could do without it. Once a mere speculation of philosophy, Dalton gave it quantitative meaning; and from his day to the present every great advance in chemical theory has found its clearest statement in atomic terms. Chemical equations and formulæ; the laws which correlate the density of a gas with its composition; the law of Dulong and Petit; our ideas of valency and molecular structure; the periodic law; and the relations of stereochemistry, are all connected by the atomic theory, whose retention in science is therefore fully justified. It may not be beyond

criticism; indeed, it should be criticized; but it would be the utmost folly to abandon the theory before something better has been framed to take its place. Vague and unsatisfactory are the attempts which have so far been made to supplant it. Physics, unaided by chemistry, may reach the conception of molecules; but the subdivision of the latter, the identification of their parts, is the function of the chemist alone.

If the nature of matter is the first element in the study of chemical reactions, the nature of chemical union is the second. If combination consists in a juxtaposition of atoms, what is the force which draws and holds them together? Whether we can answer this question or not, we may investigate the laws under which chemical action is operative, and so develop an important portion of physical chemistry. Problems of chemical equilibrium, of limiting conditions, of affinity and the speed of reactions, all come under this heading, and these are fit subjects for investigation in the laboratory. For instance, chemical action is impossible at very low temperatures, and at sufficiently high temperatures all compounds dissociate; each reaction, therefore, is confined to a certain part of the thermometric scale, which in many cases is measurable. In other words, chemical change is a function of temperature, no matter what additional factors its complete study may involve. It may also be effected through the agency of electrical or actinic impulses; and here again experimental research has a wide field. Were physical chemistry restricted, as it is not, to this class of investigations alone, it would still have abundant occupation. These illustrations are enough for my immediate purpose, but they could be multiplied indefinitely.

Directly growing out of these two fundamental questions, and partly identifiable with them, are two other problems of great

generality and importance. First, what laws connect the properties of compounds with their composition? Secondly, what laws govern the transformations of energy during chemical change? Along each of these lines a large amount of work has been done, mostly empirical; and some regularities, some minor laws, are already recognized. Systematically, however, neither field is well known, and both offer rich prizes to the investigator. Great masses of more or less available data now exist; but rarely do we find any group adequately developed. The determination of constants or the measurement of thermochemical relations is tedious in the extreme; but a vast amount of such work needs to be done under some definite system or plan. At present we have a datum here and a datum there; some one in Germany makes a few measurements, some one in France, or England, or America makes a few more; but seldom is there any attempt at cooperation, and the isolated facts do not always fit together. The thermochemical data are especially difficult to determine accurately, and still more difficult to discuss in such a way as to develop any clearly defined law. Indeed, thermochemistry, of late years, has fallen out of favor; for to many chemists, despite its promise, it seems to lead nowhere. But laws must exist under all these troubling questions, and we cannot despair of their discovery. We can accomplish little, however, unless we consider each of the four great fundamental problems with reference to the others, for they are separable only in theory. Scientific research is not linear, step following step in regular succession; it is a network, rather, whose interlacing threads are woven into patterns of infinite variety. We trace individual fibers, we see, more or less clearly, a part of the design; and this is the most that any one of us can ever hope to do.

Now, whether we regard the fundamental

questions of chemistry as four in number, or condense them into two, we can use our classification as an aid to research. Success in the latter means a wise selection of problems, a choice which is conditioned by our strength and our resources; but the first step is to understand the bearings of what we are trying to do. Whether our purposes are modest or ambitious, our work must have an influence upon that of others, and the broader the plan upon which it is conceived, the better the outcome will be. One bullet well aimed is worth more than a volley at random. One fact with a purpose outweighs a hundred scattering observations. We may well ask, therefore, what investigations are most needed by chemistry to-day?

First, as to the nature of matter, with all that that question implies. Taking all kinds of matter into consideration, and starting with the established distinction between elements and compounds, it would seem to be obvious that work is most imperatively needed where our information is least complete. Some elements, some classes of compounds, have been much more exhaustively studied than others; they, therefore, can best bear a temporary neglect, our attention, in the meanwhile, being concentrated elsewhere. I do not mean by this that any kind of research should cease, only that each department should assume something like reasonable proportions. To organic chemistry, for example, we are indebted for many methods of research, and for theoretical conceptions of great fertility; but it is now time to apply them to inorganic substances, and to see whether they are generally valid. Whatever result is reached, organic chemistry itself will be the gainer; enriched by new suggestions and resting upon firmer foundations, its future advancement can be made all the more certain. Meanwhile, carbon compounds, by virtue of their serial relations,

are of peculiar value in certain lines of physico-chemical investigations; and they may also be profitably studied along the vague boundary which separates organic from inorganic chemistry. What we may call the contact phenomena between any two departments of knowledge are always interesting.

In the present revival of inorganic chemistry, a limited number of subjects have received the most attention. Among them I may name the study of double salts, of the rare earths and of complex acids and bases. All this work is of value; some of it is fundamental; but more urgent, probably, is a revision of the older data concerning much simpler bodies. This task is not attractive; it is far from brilliant in character and promises no startling discoveries; but it is none the less essential if we wish to establish the foundations of chemistry more securely. Consider any group of inorganic compounds, as, for example, the anhydrous metallic halides, and we soon find that our knowledge of them is full of gaps, and that the descriptions of many presumably well-known substances are wretchedly incomplete and defective. To remedy this condition of affairs is no small matter; there are errors to eliminate and careless work to be done over; but with modern resources a great improvement is possible. Now, thanks to physical chemistry, we can determine molecular weights, either by cryoscopic or ebullioscopic methods; and in the periodic law we have a basis for scientific classification. With these aids to research the new data should assume a theoretical value which formerly was lacking. For instance, the structural side of inorganic chemistry has been woefully defective; but now, knowing the molecular weights of substances, problems of structure may be attacked to advantage. The conception of valency can thus be tested to the uttermost degree.

Underlying all work upon compounds, however, is the study of the elements themselves. We may speculate as to their ultimate nature, or we may condemn speculation as useless; but we must agree that accurate knowledge of their relations and properties is most desirable, and especially so with respect to physico-chemical researches. In order to correlate the properties of compounds with those of their components, we must first determine the latter, and our present knowledge in this direction is exceedingly incomplete. Not one element is thoroughly known on the physical side, and some, indeed, have not as yet been definitely isolated. What we require is the exact measurement of all the physical properties of all the chemical elements at all available temperatures; from such data laws are sure to follow. Here again the periodic law can guide us; for in its curves the measured constants are easiest compared. In this scheme, evidently, the accurate determination of atomic weights is an important feature, for with them all else is coordinated. We also need to know, more completely than we do at present, the molecular weights of the free elements, because the reactions which we really observe are between molecules and not between atoms. Thus, when monatomic mercury unites with octatomic sulphur, the phenomena which occur involve the breaking down of the sulphur molecule. If, instead of mercury, we have diatomic oxygen or tetraatomic arsenic, the reaction with sulphur becomes still more complex, for in each case, before combination, two molecules must be dissociated. The dissociation, of course, implies a loss of energy, of unknown amount; and in thermochemical discussions this undetermined factor is the chief obstacle to progress. If we could study reactions between monatomic molecules alone, we should have ideally the

simplest conditions for thermochemical measurement. But such reactions might be difficult to identify, if indeed, they are possible at all. These considerations are obvious enough, but, unfortunately, they are sometimes overlooked.

Of the second great problem of chemistry, the nature of chemical combination, I need say little more. Some of the subordinate questions which grow out of it have been already mentioned, and each of them is a center of activity in the chemical research of the day. The entire field, however, is not covered, and here and there we can see evidences of neglect. First, we need to know under what conditions chemical change is possible. Then, if we would truly understand what chemical attraction means, we must study much more fully than hitherto its relations to other forces. How do heat, or light, or electricity inaugurate a reaction, and how are they produced by it? Questions of equilibrium are important, but they are subordinate to these. Furthermore, is chemical union of one kind only, or do we confuse different phenomena under the single name? Some authors write of atomic and molecular combinations as if they were distinct; are they really so, or is the separation nothing more than a confession of ignorance? For example, what is water of crystallization? Here is one of the commonest phenomena of chemistry entirely unexplained.

Up to this point I have considered the needs of chemistry from the theoretical side alone, as if we had only a matter of pure science to deal with. But the question has other aspects, of equal importance to us, and these now claim our attention. In order to enlarge the possibilities of research, what more do we need in the way of opportunities and resources?

To the sporadic, the piecemeal, the almost accidental character of scientific investigation I have already referred. Rarely

do we find a man who can take up a large problem in a large way, with all its ramifications and details; even the most favored investigator must confine his personal work within narrow bounds, and do the best he can in his own corner. The greater part of chemical discovery has been the result of individual effort—the work of men who labored independently of one another, with rare cooperation, and often under conditions of the least favorable kind. By an army of volunteers, undisciplined and unofficered, the victories of science have been won. The time is now ripe for something better—how to organize research is the problem to be solved.

I do not mean to imply, by this suggestion, that any existing agency for research should be destroyed, or even supplanted; for such a proposition would be foolish in the extreme. Individual initiative, personal enthusiasm, are too precious to be lost; they have their part to play in the development of science; and the smallest fact, discovered by the humblest worker, will always be welcome. I do believe, however, that present conditions may be improved; that the efficiency of the individual can be increased; and to this end I urge upon your consideration the possibility of cooperation between those investigators who happen to be laboring in the same field. Ten men, pulling together, can do more than twenty who are apart. Duplication of effort, the useless repetition of work, can at least be avoided.

On several former occasions I have advocated, as the most urgent need of science, the regular endowment of research. By this I do not mean the payment of salaries to men working at random, who shall each choose his own small problem and attack it in his own way. Such a procedure would increase facilities, no doubt, but it might prove to be wasteful in the end. I look rather to the establishment of institutions,

wherein bodies of trained men should take up, systematically and thoroughly, the problems which are too large for individuals to handle. Suppose that some of the wealth which chemistry has created should return to it in the form of a well-built, well-equipped, and well-endowed laboratory, devoted to research alone—what might we not expect from such a foundation! Libraries, museums, schools and universities receive endowments by the score; observatories are equipped for astronomical research; why should not chemistry come in for her share of the benefactions? Are our achievements so great that we seem to need no aid? In this hint there is a modicum of truth; the users of chemistry, the great industrial leaders, see the wonderful resources of our science, and do not realize that she can require more. That the giver of help should herself demand assistance is a hard thing to explain.

This, then, is our greatest need; the endowment of laboratories for systematic research, wherein chemistry and physics shall find joint provision. I say 'systematic research,' in order to distinguish it from the uncorrelated work of separate individuals. In physics, or for physics primarily, a beginning has already been made; the Reichsanstalt, at Berlin, the new physical laboratory in London, and the Bureau of Standards, at Washington, can cover a part of the ground. But it is only a part; for in each case, and in other like institutions, the researches are undertaken mainly in response to industrial demands; to furnish methods and standards rather than to develop principles and laws. The advancement of science as science is quite another affair. Neither does the Davy-Faraday Laboratory in London exactly meet our requirements. It is organized to help individuals, by giving facilities for work; but it does not provide for the system-

atic investigation of large problems, through the combined efforts of a body of chemists operating under a common plan. These institutions are all steps in the evolution of the research laboratory; but the development, as yet, is incomplete. Laboratories for instruction have been lavishly provided, but in them research is subordinate to teaching. The thesis of the student may represent good work; the leisure of the instructor may be fruitful also; but organized research is a different thing, and must have its own independent resources.

Either at public expense or by private enterprise, laboratories for research should be established in all of the larger civilized countries. By conference between them their work could be so adjusted as to avoid repetition, each one reinforcing the others. Their primary function should be to perform the drudgery of science; to undertake the tedious, laborious, elaborate investigations from which the solitary worker shrinks, but which are nevertheless essential to the healthy development of chemistry. Brilliant discoveries might be made in them, but incidentally, and not as their main purpose. Such discoveries would surely follow if the fundamental work was well done; but the latter should come first as being the most essential. Whether we serve pure science or applied science, we all feel the need of data which are as yet undetermined, and whose ascertainment we cannot undertake ourselves. How often are we baffled in our own researches for want of just such material! In the verification of methods and the determination of constants, the research laboratory would have plenty to do, even were nothing more attempted.

By the creation of laboratories such as I have suggested, the independent scholar might be aided in many ways. The antecedent data, without which his researches are crippled, could often be furnished, thus

opening pathways where obstacles now exist. Furthermore, the desirable cooperation between investigators would become a much simpler matter to arrange than it is now. Every laboratory for research would become a nucleus around which individual enterprises might cluster, each giving and receiving help. A great work, wisely planned, always attracts collaborators; its mere suggestiveness is enough to provoke widespread intellectual activity. Here there is no monopoly, no limit to competition, no harmful rivalry; every research is the seed of other researches, and every advance made by one scholar implies the advance of all. In the realm of thought we gain by giving; and the more lavish our offerings, the richer we become.

We glory in the achievements of chemistry, and we find merit also in its imperfections, for they give us something more to do. Never can the work be finished, never can all its possibilities be known. Hitherto the science has grown slowly and irregularly, testing its strength from step to step, and securing a sure foothold in the world. Now comes the time for better things; for system, for organization, for transforming the art of investigation itself into something like a science. The endowment of research is near at hand, and the results of it will exceed our most sanguine anticipations.

F. W. CLARKE.

U. S. GEOLOGICAL SURVEY.

GRADED CONDENSATION IN BENZINE VAPOR, AS EVIDENCED BY THE DISTORTED CORONAS AND MARKED AXIAL COLOR EFFECTS ATTENDING CLOUDY CONDENSATION.

1. It would be difficult to read the admirable work on the relation of rain and atmospheric electricity which has issued from the Cavendish Laboratory, without being convinced of the strength of the arguments put forth. That in a repetition of

these researches, in particular of the experiments of C. T. R. Wilson* on the comparative efficiency as condensation nuclei of positively and negatively charged ions, one would but reproduce his results admits of no doubt.

In so important a question, however, it is none the less desirable to reach identical conclusions from entirely different methods of approach. It has been part of my purpose to be driven to like inferences; in other words, to reach a point in my work where I should have to abandon the nucleus as an agency which for purely mechanical or thermodynamic reasons facilitates condensation, and be compelled to recognize the special activity due to its charge.

I had hoped to accomplish this in the following experiments with benzene when contrasted with the corresponding behavior of water; but the results, contrary to my expectation, are so curious and pronounced an accentuation of the nuclear theory that it seems worth while to specially describe them.

2. The work originated in the following point of view: if the action promoting condensation is in any degree of a chemical nature (such suppositions have been made; the production of hydrogen superoxide, for instance, has been suggested), then there should be a marked difference in the efficacy of the same nucleus when the saturated water vapor is replaced by the vapor of some electrolytically neutral liquid, like a hydrocarbon. I accordingly made a series of experiments with benzene, endeavoring at first to utilize benzene jet and color tube in the usual way. In this I failed for reasons without much relevant interest here. I then adopted the method of adiabatic cooling, partially exhausting a spherical receiver (Coulier, Kiessling) about 23 cm. in diameter, illuminated by

*C. T. R. Wilson, *Phil. Trans.*, London, Vol. CXIII, pp. 289-308, 1899.

white light diverging from an external point. In this way not only were copious fogs obtained, but the coronas* produced were additionally available as evidence.

In the benzine jet, particles are probably cooled too suddenly, and at once attain a size incompatible with axial color effects. Using the exhaustion method, however, these axial colors appearing in benzine are not only of pronounced depth, but they run into higher orders than in the case of moist air subjected to like exhaustions. Sequences passing through blue, green, yellow, brown, purple, etc., green, brown, etc., may be seen in the axis of a column only 23 cm. long. The reason, no doubt, is the lower latent heat of benzine, insuring the formation of drops not less uniform, but of a size, *cæt. par.*, regularly larger than for water vapor. The fact that axial colors are producible both with water and with a pronounced insulator like benzine, is a result of fundamental importance in its bearing on any theory adduced to account for the axial absorption in question.

3. The exhaustion experiments were thus at once successful. Cloudy condensation was as densely produced in benzine vapor as in water vapor, with phosphorus, flame and other nuclei. Care was taken to insure dryness of vessel by test experiments both before the benzine was introduced and after it had been quite removed by evaporation. The exhaustion of about one sixth, say 13 cm., seemed best adapted to bring

*For some time I have been making experiments with the coronas of cloudy condensation on a large scale, with the purpose of comparing the diffraction colors so produced with the axial colors of the steam jet. The latter are almost complementary to the colors of the central patches of the corresponding coronas, betraying a difference of origin in the two cases of great theoretical interest. One is tempted to infer that the light axially absorbed illuminates the colored inner circle of the corona, but the proof of such an assertion is a long stride.

out the following phenomena. When the receiver was left standing overnight no marked condensation occurred in the absence of nucleation, or else the condensation was rain, like a fine mist, falling about 2 or 3 cm. per second.

The introductory experiments were made with light nearly in parallel, the sun's image being used as a coronal center. The even dense tawny benzine fog after the first nucleation was expected to develop on subsequent exhaustions (each followed by an influx of filtered air) into the magnificent coronas which characterize this experiment in the case of water vapor. On the contrary, however, the fogs were more fleeting, showed a more rapid descent than aqueous fogs, and the color fields obtained were not ring-shaped as expected, but *sharply stratified horizontally*, roughly speaking, in alternations of green and red.

Moreover, if the exhaustions were made successive without influx of air between each, the colors rose in strata from below, as they fell in strata when left to themselves. On mounting, the strata grew successively wider and thinner till they vanished from sight, brown, yellow-white being the last colors observed. Uniform color fields (strata of limiting width) were eventually producible in this way. Yellow, brown, crimson, arose from a whitish blue base, then descended again on completed exhaustion, reminding one of the extension of an accordion. The speed of apparent viscous subsidence of the top bands has no direct meaning, since fall (or rise) is here complicated by evaporation.

On entrance of air, vortices were evidenced by ring-shaped threads of color so that mixture was at first inevitable. One must wait till this ceases before again exhausting. Convection currents due to local reheating of the adiabatically cooled gas by the walls of the receiver, were equally apparent, stringy colors rising on the out-

side and descending into the middle of the receiver. It is the phenomenon which interferes with the usefulness of narrow tubular apparatus.

4. As this subsidence of color bands in benzine vapor is an observation of importance, I resolved to repeat the work under more normal conditions. Accordingly I used as my source of light the bright area of the mantle of a Welsbach burner, seen through a small hole in the metallic screen by an eye, looking centrally through the receiver containing saturated benzine vapor and nucleated air. Punk nuclei replaced the phosphorus nuclei. On exhaustion (without nucleation) after standing overnight, the coronas were white centered fringed with brown, about as large as ordinary lycopodium coronas seen under like conditions. These large drops are a proof of the relative absence of nuclei initially.

After nucleation the first dense fogs were vaguely annular during the first five successive exhaustions, filtered air being supplied between each. The next five exhaustions produced more nearly, finally very fully stratified colors, in spite of the point source of light. Shaking the receiver violently at any time, so as to scatter the liquid benzine within, always reproduced a nearly perfect corona, which on standing became distorted again, in color at least. I now made special experiments, shaking the receiver before each observation, bringing out successive coronal effects* never as perfect as with water, however, always showing the tendency to stratification. The characteristic coronas succeeded each other so rapidly that it would be difficult to make them out. Nuclei, however, were still present after over two hours, the eventually white centered coronas showing a continued shrinkage to smaller diameters in accordance with the diminishing number of nuclei

*These will be described for water vapor in a subsequent paper.

present. Twenty exhaustions did not remove them.

Here, as above, therefore, the fleeting character of the coronas, their tendency to depart from the normal annular character into stratification, the speed of descent of the color bands, their rise upward on exhaustion like a fog from a lake, are the special characteristics of the colored cloudy condensation occurring in benzine. To these are to be added the striking axial colors mentioned above.

5. To explain the above phenomena in their variation from the normal aqueous corona, it is first necessary to account for the more rapid subsidence of nuclei. I am not aware of appreciable differences of viscosity in the two vapors; but benzine has the smaller latent heat of evaporation by over seven times. Hence under identical conditions of nucleation and for like exhaustions or like adiabatic cooling of a given mass of saturated air, the drops would be larger, the colors more advanced in benzine than in water; and since the square of radius is in question, this would point to subsidence of the loaded nuclei in benzine nearly four times more rapid. It would also account for more rapid evaporation or more fleeting colors, which is the case.

Again, if the loaded nuclei be regarded as mechanical particles, the largest will eventually be found in the lower strata, the smallest in the upper strata, as in a case of ordinary subsidence of suspended matter in water. It is well known, moreover, that smaller droplets wane, larger droplets grow. Hence on increasing exhaustion condensation takes place first at the bottom and last at the top, since the smallest nuclei correspond to greatest vapor pressure or difficulty in condensation, and since the largest nuclei have been loaded with condensed liquid first, have parted with it last, have had greater time

in falling and have therefore sunk deepest before losing their liquid load. The strata mount upward as fresh exhaustion proceeds. The last colors to appear are the browns and yellows of the first order, also seen in the steam tube for vanishing condensations. The whole phenomenon is thus the result of strata of invisible nuclei, *graded in virtue of the loading mechanism*, and partakes throughout of a mechanical character to the extent that the nuclei are *not even a uniform product*. The forced distribution is sufficiently powerful to entirely mask the elementary optical phenomenon.*

On shaking the liquid benzene in the receiver uniform distribution is again promoted, with the result that annular coronas reappear. It is particularly to be noticed that subsidence is due to loaded nuclei. The free nucleus does not appreciably descend. Even with water vapor, loading does not produce stratification. Water fogs when exceptionally dense may sometimes

* Since writing the above I have made similar experiments with benzol, reaching the additional result that nuclei are produced by the liquid itself, *spontaneously*, in the dark. They ascend against gravity in horizontal strata, at the rate of 2 or 3 cm. per sec. in the lower hemisphere. They may be completely precipitated by partial exhaustion, leaving the air in the vessel free from nuclei (but the above flask will be refilled to saturation in 10 or 20 minutes). The experiment may be repeated any number of times. The sharp demarcation of the pure air above from the rising surface of nuclei is beautifully evidenced by the coronas, which are annularly perfect for axial beams below the surface, asymptotically *bow-shaped* at the surface, and absent for axial beams above the surface. Shaking produces the coronas from pure air instantly, but these are usually smaller. In so far as the spontaneous coronas have fixed diameters for fixed exhaustions (supersaturation), the number of nuclei eventually reaches a maximum or saturation. Among many interesting problems growing out of the present observations, the corresponding behavior of water is most important.

be seen to rise, but the diffraction pattern is always annular and usually without color distortion.

BROWN UNIVERSITY,
PROVIDENCE, R. I.

DATA ON SONG IN BIRDS: THE ACQUISITION OF NEW SONGS.

The purpose of this paper is to set forth the evidence that has come under the writer's personal observation regarding the propensity of birds to acquire new methods of expression in song.

This faculty may be properly divided into three categories: First, the disposition of wild birds to interpolate new phrasing into what may be called their normal song, or *to acquire new songs*. Second, education of expression, by direct teaching from man to birds in confinement. Third, the propensity of caged birds to imitate, voluntarily, sounds that attract their attention.

The evidence under the first division of this thesis is absolute and also well known. However, a few special cases may serve to emphasize the matter.

Every trained field ornithologist discriminates individuality in song, and some have been so fortunate as to have noted wide and radical departures from what I have distinguished as the normal song. The slight variation from the normal is of too common occurrence to be dwelt on here. Suffice to say that as set forth in a previous paper in this journal,* most observers recognize degrees of excellence in the songs of wild birds of the same kind.

Again, a few observers have heard wild birds imitate or produce not only the songs of other birds, but also the barking of dogs, human speech and mechanically produced sounds such as the creaking of a wheel, the filing of a saw and the like. The facility

* See SCIENCE, October 4, 1901, p. 522.

of the mocking-bird in this particular is traditional. A few other instances seem worthy of record.

A catbird (*G. carolinensis*) that nested in the immediate vicinity of my house in the season of 1900 reproduced the call of the whip-poor-will (*A. vociferus*) so perfectly that it was difficult to induce members of my family and visitors who heard the reproduction to credit the fact that it was not the whip-poor-will singing. A friend who knew nothing about the catbird as an agent in the performance and who had not had her attention called to the matter in any way told me that she had heard a whip-poor-will singing near my house repeatedly in *the day time*, and wished to know if this was the ordinary habit of the bird. In a residence of some twenty years in this locality I have never heard whip-poor-wills nearer to the point in question than three miles.

The following case of a wild rose-breasted grosbeak (*Z. ludoviciana*) *talking* is well attested. I quote from Emily B. Pellet, Worcester, Mass., in *Bird-Lore*, Vol. III., No. 5, p. 174, October, 1901, as follows: "Early last summer, while standing on my back steps, I heard a cheerful voice say, 'You're a pretty bird. Where are you?' I supposed it to be the voice of a parrot, but wondered how any parrot could talk loud enough to be heard at that distance, for the houses on the street back of us are quite a way off.

"Almost before I had done laughing, the voice came again, clear, musical and strong—'You're a pretty bird. Where are you?'

"For several days I endured the suspense of waiting for time to investigate. Then I chased him up. There he was in the top of a walnut tree, his gorgeous attire telling me immediately that he was a rose-breasted grosbeak.

"At the end of a week he varied his

compliment to 'Pretty, pretty bird, where are you? Where are you?' With a kind of impatient jerk on the last you.

"He and his mate stayed near us all last summer, and though I heard him talk a hundred times, yet he always brought a feeling of gladness and a laugh.

"Our friend has come back again this spring. About May 1 I heard the same endearing compliment as before.

"Several of my friends whom I have told about him have asked, 'Does he say the words plainly? Do you mean that he really talks?' My reply is, 'He says them just as plainly as a bird ever says anything, so plainly, that even now I laugh whenever I hear him.'"

Space will not allow the further elaboration of this part of the subject.

The second division, that of education of birds in song and speech by man, is also well known. The bullfinch's (*Pyrrhula europæa*) ability to learn to whistle airs with great accuracy and precision, as well as the peculiar quality and charm of its voice, has arrested the attention of all observers and has been cultivated for more than a century. Few of us, however, realize that only *wild birds* hand-reared from a very early age are educated in this accomplishment, and it is worthy of special notice that wild bullfinches have little or no song, and may be compared with the European sparrow (*P. domesticus*) as a songster. Starlings (*Sturnus vulgaris*) are well known as birds susceptible not only of learning to whistle simple melodies, but as rivals of parrots in reproducing with great distinctness short sentences. Parrots are proverbial as talkers, singers and whistlers. Canary birds have frequently been recorded as learning to whistle simple tunes, and there are a number of well-attested accounts of their reproducing with precision short sentences. Jays, crows and magpies also talk and whistle with

great facility. The voices of jays in reproducing speech are particularly melodious and lack the peculiar phonographic timbre characteristic of most parrots and of starlings.

Mention must be made here of the minos (genus *Mainatus*) of India as on the whole the most receptive among birds in learning to talk, sing and imitate all sounds of a mechanical kind. All these results have been achieved by education, that is, direct teaching with intent on the part of the human instructor.

The third part of this discussion, that which deals with the propensity of caged birds to imitate or reproduce, voluntarily, sounds that attract their attention, needs a few words of explanation.

No direct effort or intention on the part of a human agent is a factor in this category. All but one instance that I shall adduce of this kind of ability have occurred in an experience covering some six or seven years with birds obtained in ways, and kept under conditions, that require brief consideration. These birds are all hand-reared wild species; birds taken from the nest when very young and raised by hand. As soon as such birds were able to feed and care for themselves they were liberated in large rooms having as near freedom as confinement would allow. No instruction was given to them. In a word, it was an effort to observe *what birds would do if left to themselves and supplied with food and water*. No effort was made to keep these birds from hearing the song of wild birds out of doors. The species dealt with in this way are comprised in the following list:

- 12 bluebirds (*Sialia sialis*).
- 14 robins (*Merula migratoria*).
- 6 wood thrushes (*Hylocichla mustelina*).
- 7 catbirds (*Galeoscoptes carolinensis*).
- 2 thrashers (*Harporhynchus rufus*).

- 2 yellow-breasted chats (*Icteria virens*).
- 2 rose-breasted grosbeaks (*Zamelodia ludoviciana*).
- 1 cardinal (*Cardinalis cardinalis*).
- 6 Baltimore orioles (*Icterus galbula*).
- 7 orchard orioles (*Icterus spurius*).
- 1 bobolink (*Dolichonyx oryzivorus*).
- 2 cowbirds (*Molothrus ater*).
- 4 crow-blackbirds (*Quiscalus quiscula*).
- 5 red-winged blackbirds (*Agelaius phoeniceus*).
- 1 meadow-lark (*Sturnella magna*).
- 6 blue jays (*Cyanocitta cristata*).

It will be sufficient for us to consider only the very marked acquirement shown by individuals among these birds, none of whose songs are quite normal. A number of the robins have peculiar songs that in no way resemble wild robins' songs. I should call them *invented* songs, for lack of a better name.

The wood thrushes' song varies much from the normal, but can hardly be regarded as invented or original.

Catbirds did much mimicry of the songs of other birds.

A yellow-breasted chat is worthy of particular mention. This was a bird taken with another from a nest in May. In September of the same year I was busy in correcting proof for a forthcoming book of some size, so that for at least three months a part of each day was devoted to this work. The manuscript and proof were delivered by a postman. There were three deliveries each day. Ordinarily the postman dropped the mail into a slot in the door, but when he had a package of proof this was not feasible and he sounded a call or postman's whistle for some one to come to relieve him. One afternoon in September, about the time I was expecting proof the whistle sounded and I went to the door. No one was there. My first impression was that some boy in the neighborhood was up to mischief. The experi-

ence occurred four or five times in the next day or two and I began to regard it as mysterious, never thinking of the birds in such a connection. Some four days later while watching the birds—I was in the room with them—a chat came and alighted on my shoulder and shrill in my ear sounded the exact reproduction of the postman's call. The very direction and distance from which the call came and its exact tone were reproduced. I heard it many times afterward, friends and other members of the family became familiar with the call, and even after I was aware of it, when I was expectant, I have heard the postman, gone to the door and finding no one, knew how realistic was the reproduction of the postman's call by a yellow-breasted chat.

One of a brood of red-winged blackbirds (*A. phoeniceus*), a male, crows constantly for all but two months in the year. The crow is an imitation of the crow of the common bantam rooster. Distance and direction are clearly indicated. The sound always appears to come from the rear of the house, at some little distance, and is a very clever imitation of the crow of a bantam rooster. This is the only song this bird has.

A blue jay (*C. cristata*) reproduces the song of the cardinal (*C. cardinalis*) so perfectly as to deceive any one. It is copied from a cardinal in the room, and distance and direction are not indicated.

A European jay (*Garrulus glandarius*) has learned from a cockatoo to say 'How do you do,' 'How do, pretty polly,' 'Pretty polly' and some whistles and calls.

"Last summer on a Wisconsin farm there was a duck hatched out with thirteen turkeys by a hen as a foster-mother. This duck followed the turkeys around and wavered a very long time before it went into the water, and it still imitates the *turkey's note* with its *duck voice*. It sleeps under the

turkeys' roost at night now, although it is quite an old duck, and scorns the company of the other ducks on the plantation. This interesting family is on the farm of Mr. Clinton D. Stewart, whose post-office address is Dousman, Wisconsin. Mrs. Merrick first called my attention to the duck's turkey call; but I was not entirely satisfied until I heard it myself." (Extract from letter of Edwin T. Merrick, 836 Gravier street, New Orleans, La., October 19, 1901, to W. E. D. Scott.)

This call of the turkey given by a duck is of special interest as precocial birds appear to have much less receptivity than altricial birds. The reason seems obvious.

In concluding a word is necessary as to the probable reason why birds in confinement diverge from the normal in the habits of song. Presuming that wild birds are pretty constantly employed in obtaining a food supply, it would seem that they *do not have much leisure*. On the contrary, birds in captivity with all their physical wants carefully looked after, *have leisure* and employ it in giving their attention to occurrences about them, particularly such as are accompanied by any noise.

Of this factor of leisure among animals in confinement little is known, and a broad field is presented for those investigators who have opportunities in zoological gardens or, better still, in special laboratories equipped for this and kindred studies.

WILLIAM E. D. SCOTT.

PRINCETON UNIVERSITY.

MUSEUM STUDY BY CHICAGO PUBLIC SCHOOLS.

THE Field Columbian Museum is often visited by classes from the Chicago public schools for purposes of instruction obtained by studying the illustrations there afforded of different subjects taught in the schools. The character and value of such

work vary of course with the age and standing of the pupils, and doubtless as well with the individuality of the teacher.

The teachers with whom I have talked are unanimous in saying that the pupils enjoy study at the Museum, not having to be urged to it as to book study, partly, of course, because of the change it affords from the routine of school work, but largely because the objects of study are so tangible and interesting of themselves. Many of the scholars spend considerable time in voluntary study at the Museum outside of school hours. The teachers also say, however, that as might be expected, no immediate results are realized from such work unless the pupils know that some report of their studies will be called for. Such report may be made orally or as a written report on some department of study, or on topics previously assigned. I have sometimes examined such written reports and have found their perusal of considerable interest and value. They furnish as accurate a test as could be devised, probably, of the amount and kind of instruction which pupils are likely to obtain from study of objects in a museum and as well also of that likely to be obtained by those 'children of a larger growth' who visit the Museum with a less definite desire for instruction, but who imbibe it nevertheless. The particular lot of reports now lying on my desk is one of about twenty made by pupils in a class in physiography in the first year in high school, ages say 13 to 15 years. The reports or essays as they might also be called, are descriptive of a visit to the geological department of the Museum for the purpose of finding and noting illustrations of the text-book study of physiography. The pupils were expected to make drawings as well as notes of the objects which they deemed important and such drawings accompany the essays. Some suggestions had previously been given the

pupils by the teacher as to topics for study, such as the description of fossils from each of the great geological periods; the study of crystals, meteorites, some special relief maps, etc.

Some points noted in the perusal of the essays may be worthy of comment. The ideas gained by the pupils from the study of the collection of fossils were isolated and fragmentary. Single forms were drawn and described with considerable accuracy, but there seemed to be little conception gained of the march and development of life as a whole, although the collection is sufficiently large and complete to make this manifest. Still, several noted the introduction of fishes in the Devonian age and the excess of vegetation in the Carboniferous. None of the pupils mentioned the animals of larger size, although many skeletons and restorations of these are exhibited. It is curious that while the average visitor of maturer age devotes his attention almost exclusively to these, I have never noticed young people take much interest in them. They take more interest in small objects, such as shells, impressions of ferns, etc. The color of the fossils or matrix was often noted and throughout the essays observation of color is the one thing prominent. The remarks on crystals contained few observations calculated to encourage the modern crystallographer. Almost anything in the mineral collection was regarded as a crystal and the observations made were chiefly on differences of color. From a collection of crystals arranged according to the six systems, one scholar drew the sweeping conclusion that 'isometric crystals are green, yellow-green or cream color; those of the tetragonal system generally red, those of the hexagonal system vermilion,' etc. This was a conclusion from scanty data, but the scoffer may be reminded that the whole world did not do

much better in its study of crystals up to the beginning of the seventeenth century, as witness its reasoning that because quartz was found on the high Alps and sometimes contained water that *ergo* it must be ice frozen so hard it could not melt. A few of the pupils, however, distinguished crystal forms quite accurately and drew excellent representations of them. I believe distinctions of form might be easily taught to pupils of this age and even younger if more attention was paid to it. In nearly all lines of scientific study form is far more important than color.

In their study of meteorites nearly all noticed the 'thumb marks' and gave a reasonable explanation for them. They also noticed the composition of meteorites as made up of iron and stone in different amounts. The finer details of structure were entirely overlooked, however. Only one noticed the Widmanstätten figures, describing them as 'scratches,' and the chondritic structure was not noted at all.

The observations drawn from a study of the relief maps excelled all others in accuracy and fullness.

The region of the Grand Cañon of the Colorado, for instance, was correctly described as a valley worn to a profile of equilibrium into which a subsequent cañon had been cut by the rise of the land. This had doubtless been stated in the text-book, but the relief map evidently gave the subject a vividness and reality. So also from a map showing the extent of the continental glacier, the southern limit of the glacier was correctly traced and a permanent impression, doubtless, of an important fact gained. On other relief maps the positions and relations of plateaus, divides and slopes were correctly noted and single geologic features accurately described. One could not read over the portions of the essays devoted to this subject without being convinced that relief maps are most

desirable adjuncts for the teaching of geography.

Some glaciated surfaces were noted by all, but few gave a correct explanation for the markings on them although the origin of the markings was stated in an accompanying label. One thought they were due to running water, another to 'undulations in the ground moraine.' I doubt if the young mind is able to conceive fully of the physical effects of a continental glacier.

Graphite was studied by many of the pupils, their interest in it presumably being aroused by their familiarity with it in lead-pencils. The fact that it was black was the principal point noted, although some listed the localities whence it is obtained. From some inconceivable source one lad drew the information that "graphite is used for egg coal, because it contains a great deal of oil, so that it is used where a fire is needed. Coal dust moulded by pressure forms graphite."

The accounts of petroleum and its uses were generally full and accurate and must have been drawn almost entirely from observations on the collection. Such a knowledge of petroleum could not have been gained by reading a dozen books. Asbestos, salt, gypsum, mica and sulphur were among other substances noted, some account being given of the appearance and uses of each. The statements were partly second-hand and partly original, with no evidence of any particular skill in observation. One girl, for instance, stated she could see no difference in appearance between gypsum and asbestos, though the distinction should have been plain. It was evident that the pupils had not as a whole been trained to careful observation, for many obvious distinctions were overlooked.

On the whole the essays showed the need of museum study rather than important results from it. They painfully evinced the fact that copied labels and statements

of text-books furnished the material out of which they were chiefly made. Doubtless many of the labels were copied without a glance at the specimen which it accompanied. There was far too little evidence of individual, independent observation. Let it be noted, however, that the essays which contained the most personal observations were the most accurate. It was in the essays most largely made up of copied labels that such strangely conglomerated statements as those I have quoted were to be found. This inculcated slavery to print is to my mind one great weakness of modern instruction in the elementary schools, so far as any hope of the promotion of science is concerned, and it is in museum study that one of the best remedies for it is to be found. In order that independent study may be encouraged it may be questioned whether the museum label should aim to give very extended information. To be sure, the mere copying or reading of the label serves to some extent to fix the information it contains upon the mind, but the knowledge would take firmer hold if this information could be gained by a study of the specimen. I have often noticed visitors of all ages studying an unlabeled collection with the greatest persistency and interest, and then have seen them finish it in a glance after it was labeled. They seemed to feel that they were relieved of any further responsibility in regard to it as soon as they saw the labels. Hence, Goode's well-known aphorism that 'a museum should consist of a collection of instructive labels illustrated by specimens' has its limitations. Uttered to call attention to the need for system and as a protest against the lumber room, it had a profound value, but modern experience will hardly consider it a final ideal. It is possible to so prepare and arrange collections that they will tell their own story without more labels than are needed to serve as

hints or indexes. Such collections or exhibits will promote the spirit of observation, study and inquiry, and the more they do this the more will they contribute to the advancement of science.

OLIVER C. FARRINGTON.

FIELD COLUMBIAN MUSEUM.

*THE BOUNDARY LINE BETWEEN TEXAS
AND NEW MEXICO.*

THE boundary line between Texas and New Mexico along the 103d meridian was the chief theme of a talk before the National Geographic Society on November 15 by Dr. Marcus Baker. This boundary, created in 1850, was surveyed and monumented, in part, in 1859 by John H. Clark, and his survey was confirmed by Congress in 1891. Recent official maps place this boundary two or three miles west of the 103d meridian, where the law declares it to be. The paper read before the Society was a summary of the results of an enquiry undertaken to discover and weigh the reasons for this discrepancy.

The original monuments set by a survey to mark a boundary in accordance with law, become, when confirmed, the boundary, even when followed by more accurate surveys which show the original monuments not to be where they were designed to be. The more accurate survey does not alter the boundary. It merely shows how well or ill the original survey was done. Of this line, 310 miles long, 180 miles were traced out and marked by mounds of earth or stone in 1859; the remaining 130 miles have not been surveyed. Of the 180 miles surveyed and marked, 24 are at the south end marked by 3 mounds and 156 at the north end marked by 23 mounds. The longitude of the south end of the line was determined by chaining eastward from El Paso along the 32d parallel 211 miles, the initial station being

Frontera of the Mexican boundary survey. Obviously this is a very weak longitude determination. It was not checked by astronomical observations originally, nor has it been since. Nor has it been checked in any other way. According to present knowledge the three monuments at the south end are on the 103d meridian and should be so shown on our maps until subsequent and better surveys shall find these monuments and show that they are not on the 103d meridian. As to the 130 miles of unsurveyed line north of the short piece, at the south end of the boundary, this part is obviously coincident with the meridian.

The longitude of the 23 mounds on the northern part of the line depends upon the one at the N.W. corner of Texas. That corner monument was set in August, 1859. Its longitude was obtained by transfer from some point on the 37th parallel, 35 miles to the northward. In 1857 a surveying party under Lieutenant-Colonel Johnston measured westward along the 37th parallel from the west boundary of Missouri 471 miles to the 103d meridian. Clark was the astronomer in Johnston's party and determined by moon culminations the longitude of the monument set by Johnston to mark the intersection of the 103d meridian and 37th parallel. The longitude of the mound at the N.W. corner of Texas, set by Clark in 1859, therefore depends upon the longitude of a point determined by himself, astronomically, two years previously on the 37th parallel. How accurate was Clark's determination? Nobody knows. Various surveys under the direction of the Land Office have been made in this vicinity since Clark's original one, but his monument has not been found. Two monuments have since been established to mark the point which Clark intended to mark and which he supposed he did mark. One of these was set by John J. Major, in 1874, and another by Rich-

ard O. Chaney, in 1881. Major searched for Clark's monument, failed to find it and 'reestablished' it, *i. e.*, set a new one. The evidence is conclusive that Major's monument was set more than two miles west of Clark's. Chaney's monument is some four or five miles east of Major's. Chaney did not find either Clark's or Major's. Thus three monuments or mounds have been built to mark the N.W. corner of Texas, one by Clark in 1859, another by Major in 1874, and a third by Chaney in 1881. Clark's alone marks the boundary and that one is lost.

Of the 22 remaining mounds marking the northern part of the boundary two, and only two, are known to still exist. These two are in sight of one another and on opposite banks of the Canadian River. They were found and reported to the General Land Office by the land surveyors Taylor and Fuss in 1883. We have no information as to their longitude other than that furnished by Clark himself, who reported them on the 103d meridian.

In the present state of our knowledge it seems highly desirable that the boundary should appear on our maps on the 103d meridian. At the same time it is even more important that topographic surveys be made along this line and as many as possible of the original Clark monuments identified and accurately placed on the map. This done the whole line should be run out, old monuments restored and new monuments built. If this is done before the discovery of oil, mineral or things coveted, a costly and bitter boundary dispute can be avoided.

Since the above was written I have learned of a recent survey which has materially added to our knowledge of the present state of this boundary. Mr. E. D. Preston, U. S. Deputy Surveyor, retraced the Clark line on the 103d meridian from

the Canadian river northward to the corner, a distance of about 75 miles, in the summer of 1900. This was done by direction of the General Land Office and his MS. report is now on file in that office. Of the 12 monuments set by Clark in 1859 on this part of the line Preston identified 3 certainly and, doubtfully, 4 in all. Clark's line, according to Preston, bears N. 0° 08' W.

In 1882 W. S. Mabry, county surveyor of Dallam county, the northwesternmost county of Texas, retraced a part of the Clark line and assisted in building a pasture fence for the XIT or Capital Land and Cattle Company. The corner of that pasture was established at the point supposed by Mabry to be Clark's corner. This XIT corner is now locally recognized as the N. W. corner of Texas. According to Preston's survey it is 'within 150 links of the proper position east of the Johnston monument.' It is about 2½ miles east of the lost Major monument of 1874 and is 2 miles 14.05 chains west of the Chaney monument of 1881. Clark's monument, according to Clark, is in longitude 103°. Chaney's monument, according to Chaney, is in longitude 103°. These monuments differ in longitude by more than 2 miles. Which one is the better determination is unknown. Both longitudes are weak—Clark's is a fair determination by a weak method, Chaney's a weak determination by a strong method. A new and strong determination by a strong method is much to be desired.

SCIENTIFIC BOOKS.

Biologia Centrali-Americana, Insecta, Lepidoptera-Rhopalocera. By FREDERICK DUCANE GODMAN, D.C.L., F.R.S., and OSBERT SALVIN, M.A., F.R.S., etc. Vol. I., Text, pp. i-xlvi + 1-487; Vol. II., Text, pp. 1-782; Vol. III., Plates, I.-CXII. and XXIVa. Published by the authors. Royal 4to. 1879-1901.

In the present age it is recognized as one of the functions and duties of wealth to minister at the altar of learning. The upbuilding of great institutions, the object of which is the ascertainment of truth and the diffusion of knowledge, is regarded as one of the high prerogatives of those who have command of material resources. Splendid have been the achievements in recent years of those who have consecrated their wealth to founding or aiding in the endowment of colleges, universities, libraries and museums; but perhaps no enterprise undertaken by wealth is likely in coming years to be regarded as more important and monumental in its character than the great work to which Messrs. Frederick Ducane Godman and Osbert Salvin addressed themselves when they conceived the idea of preparing and giving to the world the encyclopedic work known as the *Biologia Centrali-Americana*. Of this work it may be said that it constitutes *monumentum aere perennius*.

It is with profound satisfaction that we welcome the appearance in final form of the three volumes devoted to the Rhopalocera of Mexico and the Central American republics. For twenty-two years these volumes have been slowly appearing in parts. The delay is most reasonably explained by the surviving editor and author, Mr. Godman, as due 'to the constant pressure of other work, the ever-increasing amount of material, the gradually failing health and subsequent death of Mr. Salvin, and the great difficulty of dealing with the *Hesperiidæ*.' The work, however, has not lost, but has rather profited by delay. The exceedingly satisfactory treatment of the *Hesperiidæ*, which a few years ago would have been impossible, and the supplementary pages and plates cause the student, now that the work is completed, to feel thankful that the editors followed the good maxim, *festina lente*. Had they completed the work before the region had been traversed by the various collectors whom their munificence placed in the field, and had they not been able to profit by the researches in the family of the *Hesperiidæ* made by Captain E. Y. Watson, the work would not have been the eminently satisfactory work which it now proves to be. There is yet much to be

learned in reference to the lepidopterous fauna of Central America, and the last word has not been spoken even by the learned authors in the three stately volumes before us, but a foundation has been laid so broad and solid and enduring that all who come hereafter will be compelled to build upon it. These three volumes in a peculiar sense reflect the intelligence as well as the generosity of the two lifelong collaborators, Messrs. Godman and Salvin. With the exception of the volume upon the avifauna of the region, written by the same two gentlemen, they most strongly illustrate their learning. Other volumes in the great work reflect the excellence of their editorial supervision, as well as their munificence, but the parts of the 'Biologia' which have issued from their own hands and most strikingly display their scientific accuracy and the vastness of their learning are the volumes dealing with the birds and these three volumes treating of the butterflies.

Eighteen hundred and five species of butterflies are enumerated in the work as occurring within the region, three hundred and sixty of them being described as new to science. Of these species about twelve hundred and fifty are figured in the one hundred and thirteen hand-colored plates drawn by Rippon and by Purkiss. It will be seen from the foregoing statement that the region chosen is far richer in the number of the species of *Rhopalocera* than the continent of North America north of Mexico or the Palearctic region, the latter covering Europe and northern Asia. The last published list of the diurnal lepidoptera north of Mexico cites but six hundred and forty-five species, a few of which, however, are doubtful, to which must be added a few others recently described. There are probably not more than seven hundred valid species of butterflies to be found on the entire continent of North America from Florida and the Rio Grande of Texas to the Arctic Ocean. Staudinger & Rebel's Catalogue, which has just appeared, enumerates seven hundred and sixteen species as found in the Palearctic region, covering the Barbary States, Europe, Asia Minor and temperate Asia north of the Himalayan ranges. Within the comparatively small area of Mexi-

có and Central America more species of butterflies occur than are found in all temperate North America, Europe, North Africa, and temperate Asia put together.

Compared with the fauna of the West Indian Islands so far as known, the latter are exceedingly poor in the number of genera as well as species of butterflies. While strictly correct lists of the species of *Rhopalocera* found on the various West Indian Islands are not available for purposes of comparison, enough is positively known to make it certain that all of these islands together do not contain more than one third of the number of species which are accredited to the region covered by the 'Biologia.' In fact, it is doubtful whether these islands have more than one fourth as many species as are found in the territory of which we are speaking, provided the Leeward Islands and Trinidad be excluded, as appears to the writer proper, in view of their close contiguity to the South American mainland.

An examination of the exceedingly interesting table given in the introduction to the work, which is devoted to the display of the geographical distribution of the various species, shows that the region in and about Panama is probably the most prolific, Costa Rica and Guatemala following closely. It is here, in the humid tropical forests, that we have the fullest development of the *Rhopalocercous* fauna of the territory. The table of distribution is summarized as follows:

Nymphalidæ,	588	species
Libytheidæ,	1	"
Erycinidæ,	240	"
Lycænidæ,	234	"
Papilionidæ,	186	"
Hesperiidæ,	556	"

Making a total of 1805 "

Comparing this list with the great list of the '*Rhopalocera Ethiopica*,' recently published by Professor Aurivillius, and adding the *Hesperiidæ* from the Ethiopian subregion, which number about three hundred and seventy-five species, we find that the continent of Africa and the adjacent islands have up

to the present time only yielded us about two thousand species of Rhopalocera. It is evident, therefore, that the Neotropical region, which includes tropical South America as well as Mexico and Central America, is likely to prove to possess, when a final and exhaustive catalogue of the species is made, the richest Rhopaloceros fauna in the world. The family of the Hesperidae is far richer in species in this region than anywhere else. More species of these interesting and often puzzling insects occur in Mexico and Central America than are found either in the tropics of the Indo-Malayan region or in the tropics of Africa. The Erycinidae are also characteristic of the region, and the number of species of this family in the total vastly exceeds the number of species found in all other regions of the globe combined. The Nymphalidae lead all other families in the number of species, but the number of species, while great, is not equal to the number that is found in the Ethiopian subregion, nor is the number of species as great as that known to occur in the Indo-Malayan subregion.

The general conclusions reached by Mr. Godman as to the distribution of species within the territory are best expressed in his own language. He says: "Our study of the Central American butterflies proves conclusively (1) that the fauna is mainly a northern extension of that of tropical South America, extending on the Pacific side to Mazatlan and on the Atlantic to a little beyond Ciudad Victoria in Tamaulipas, some few species on each coast reaching the southern United States, with, of course, many peculiarly modified forms in the region; (2) that there are a considerable number of Nearctic genera and species coming down the central plateau a certain distance into Mexico, and some even into Guatemala, as *Argynnis*, *Vanessa*, *Limenitis*, *Grapta*, various *Colibris*, etc.; (3) that there are no strictly alpine forms, the insects met with above the tree-line being mostly stragglers from below, such species as occur at the highest limits of the forest being very like those of similar Andean localities, these mostly belonging to the genera *Euptychia*, *Archonias*, *Catantacta*, *Pereute*, *Enantia*, etc.;

(4) that the fauna of the Atlantic slope to perhaps as far south as Costa Rica is incomparably richer than that of the Pacific, this being particularly noticeable in the Ithomiina, the Erycinidae, the genera *Thecla* and *Papilio*, etc.; and (5) that some of the purely tropical genera do not reach north of Nicaragua, Costa Rica or Panama, as *Eutresis*, *Scada*, *Cerois*, *Callitera*, *Hetera*, *Oressinoma*, *Narope*, *Panacea*, *Megistanis*, *Hypna*, *Zeonia*, *Ithomeis*, etc."

Within the limits of a brief review such as this it is impossible to take up and consider many of the interesting details in reference to distribution which present themselves to view upon a careful study of the work. The writer commends to the careful attention of all students of entomology the introductory chapter of Volume I., which epitomizes in a masterly manner the results of the years of study which have been devoted by the learned authors to the subject in hand. To the comparatively few who are devoting themselves to a critical study of the Hesperidae that portion of the work devoted to this family is of extreme value. It is no exaggeration to say that it is one of the most perfect examples of careful monographic work which has ever appeared in the English language. The amount of painstaking and microscopic research which has been performed in order to attain the results which are given has been prodigious. It is certainly to be hoped that the work will find a place in all the great libraries of the New World, for without access to it the student of entomology in America is certain to find his labors greatly retarded.

W. J. HOLLAND.

CARNEGIE MUSEUM, PITTSBURGH.

A Laboratory Course in Bacteriology, for the use of Medical, Agricultural and Industrial Students. By FREDERIC P. GORHAM, A.M. Philadelphia and London, W. B. Saunders & Co. 1901. 8vo. Pp. 192.

In this unpretentious laboratory guide the author has succeeded in combining technical accuracy with sound pedagogy in a manner which will commend the book to teaching bacteriologists. The directions for even the commonest processes have very obviously stood the

test of actual use with classes before being crystallized into their present form. The particular merit of the book lies in the fact that the author has carefully described small points of technique which too many other writers have left for the student to learn for himself through experience more or less bitter.

The contents of the book are as follows: Chapter I., Microscopical Examination of Bacteria, with a description of the ordinary processes of staining; II. and III., Morphology and Reproduction, with methods of straining flagella and capsules; IV., Classification of Bacteria—a synopsis of Migula's genera; V. and VI., Sterilization, and Preparation of Culture media; VII., Cultures of Bacteria—a description of the ordinary culture methods, with full tables of descriptive terms; VIII., Determination of Species, contains a list of diagnostic characters, a standard chart for full description of a species, a key for tracing the more common forms, and a synopsis of Chester's scheme of classification by groups; IX., Bacterial Analysis of Water, Milk, Air and Soil; X., Pathogenic Bacteria—directions for the study of eleven typical pathogenic organisms. The appendix contains an account of Wilson and Randolph's method of measurement by photography, a description of the common contaminating moulds and yeasts, and a very useful list of synonyms.

Not a few points and methods are described which have hitherto appeared only in monographs; some are here published for the first time. The text is fully illustrated, and many of the cuts are new.

On account of its thoroughly modern and in many respects original treatment of the ordinary technique of bacteriology this book will prove useful not only to the bacteriologist, but to the botanist who employs bacteriological methods in pathological or systematic work.

HAVEN METCALF.

THE UNIVERSITY OF NEBRASKA.

SOCIETIES AND ACADEMIES.

THE GEOLOGICAL SOCIETY OF WASHINGTON.

The 122d meeting of the Society was held on Jan. 8. The first paper was by Mr. Charles D. Walcott on 'The Outlook of the Geologist

in America.' This was the substance of the presidential address, before the Geological Society of America, at Rochester.

Mr. M. R. Campbell then presented a paper on 'Recent Geological Work in Pennsylvania.' The author summarized briefly the character and scope of the mapping of the Pennsylvania coal fields which is now being carried on by the United States Geological Survey in co-operation with the State. Up to the present time seven quadrangles, embracing an area of 1,600 square miles in the bituminous coal fields, have been geologically surveyed.

It is generally admitted that the weakest point of the Second Geological Survey of Pennsylvania was its lack of adequate base maps on which to portray the geological data gathered in the field. It was impossible to locate geological boundaries correctly upon the crude county maps, which were the only ones available. With the aid of the recent detailed topographic maps, it is believed that the geological boundaries have been determined within an error of a few feet. The importance of such close mapping is self-evident from the fact that land underlain by the Pittsburg coal is valued at from \$300 to \$1,100 per acre. The investigations have also brought out many details of structure not previously known, which are of the utmost importance to mine and oil and gas well operators. In closing Mr. Campbell expressed a high appreciation of the labors of the geologists who had preceded him in this field, and stated that their results can only be superseded by the most careful detailed work and by the use of a topographic base map producing a high degree of accuracy.

ALFRED H. BROOKS,
Secretary.

BIOLOGICAL SOCIETY OF WASHINGTON.

The 347th meeting was held on Saturday evening, January 11.

F. A. Lucas exhibited a malformed tooth of Mastodon, of an irregular shape, and with about twice the normal number of cusps, the extra cusps having been mostly added on one side of the tooth.

M. B. Waite presented 'A Problem in Plant

Pathology and Physiology,' stating that last fall he had been called upon to examine a large pear orchard belonging to Mr. A. S. Newson of Alcoa, Texas, that was said to be suffering from the effects of blight. On examination it was found, in addition, to be suffering from leaf blight, from lack of cross fertilization and from unfavorable environment, having been planted on prairie soil without any proper natural drainage. Steps had been taken to combat the pear blight, but the result was very doubtful, as the disease could be readily brought in from surrounding orchards. The leaf blight could be remedied by spraying and the cross fertilization supplied by planting other varieties of pear, but it remained to be seen whether or not the locality was too far south for the successful cultivation of pears. These trees, like the peach, needed the rest gained by lying dormant during cold weather.

Wilfred H. Osgood spoke of 'The Supposed Occurrence of Caribou on the Queen Charlotte Islands,' saying that a new species, *Rangifer dawsoni*, had been described on the strength of a single imperfect skull, said to have been brought from Graham Island. Mr. Osgood reviewed the evidence relating to this skull and read extracts from a number of letters concerning it, concluding that in all probability caribou had never been seen in that locality.

Jacob Kotinsky read a paper on 'Present Opinion concerning the Home of the San José Scale,' briefly reviewing the history of the pest from the time of its appearance in California and the attempts to find its original habitat. It was supposed quite recently that Japan was the native place of the scale, but investigation showed that it did not occur in elevated portions of Japan, nor on native trees, while Mr. Marlatt had subsequently located it in China, south of the Great Wall.

F. A. LUCAS.

PHILOSOPHICAL SOCIETY OF WASHINGTON.

The 31st annual meeting was held Dec. 21, 1901, President Walcott in the chair.

The report of the secretaries was presented by Mr. J. F. Hayford. During the year the principal event has been the incorporation of

the Society; 16 meetings have been held for the presentation of papers; Vol. XIII. of the *Bulletin* has been completed and distributed, and 78 pages of Vol. XIV. At present the *Bulletins* are sent regularly as issued to about 300 societies, libraries, etc. A tabulation of the membership for about 20 years, during which time several other scientific societies have been formed at Washington, showed that the loss in membership due to these had now ceased and the Society has reached a steady regime. The present membership is 107. The treasurer's report presented by Mr. B. R. Green showed a healthy financial condition.

Mr. Richard Rathbun, Assistant Secretary of the Smithsonian Institution, was elected President for 1902, and the other officers were reelected.

The 544th meeting was held Jan. 4, 1902.

Mr. D. B. Wainwright, of the Coast and Geodetic Survey, described the experiments made in October last between Nantuxet Light ship and the shore, a distance of 48 miles, by the aid of the Marconi apparatus in regular use there, to determine 'Longitude by Wireless Telegraphy.' It was found possible to secure chronograph records of the chronometer beats and the signals from the ship, and then to eliminate the lag of the instruments by causing the chronometer-break to excite the coherer and obtain new chronograph records. Time observations were made and the data were obtained for what is probably the first determination of longitude by wireless telegraph. In the discussion that followed, participated in by several geodesists, the opinion was expressed that even for the short distances through which the new method could now be used, the precision of observation was greater than that of any other method except the telegraphic; its special value would probably be found in work among islands and in unsettled countries like Alaska.

Professor Updegraff then discussed the 'Stability of Astronomical Piers.' The first astronomical instrument was only a pier, the Gromon; and by its aid the ancients determined a surprisingly large number of constants. A pier should be built on soil rather than on rock; brick was now in favor rather

than stone: at the Cape of Good Hope the piers of the meridian circle were iron cylinders filled with water. At the Naval Observatory the marble piers of the six-inch meridian circle had shown a change in azimuth of $0'.3$ for 10° Fahr., and had recently been replaced by brick.

CHARLES K. WEAD,
Secretary.

NEW YORK ACADEMY OF SCIENCES.
SECTION OF BIOLOGY.

A REGULAR meeting of the Section of Biology was held on Dec. 9, Professor Bashford Dean presiding. The following papers were presented:

'The Action of Alcohol on Muscles': F. S. LEE and W. SALANT.

'Instincts of Lepidoptera': A. G. MAYER.

'The Natural History of some Tube-forming Annelids': H. R. LINVILLE.

The first paper, presented by Professor Lee, consisted of an account of an investigation carried out by the two authors jointly, by very exact methods, pure ethyl alcohol being used, and isolated muscles of the frog in the normal and in the alcoholized condition being compared. It is found that the muscle which has absorbed a moderate quantity of pure alcohol will contract more quickly, relax more slowly, perform a greater number of contractions in a given time, and become fatigued more slowly than a muscle without alcohol. The effect is most pronounced in from one half to three quarters of an hour after the liquid has begun to be absorbed, and later diminishes. Whether the alcohol exerts this beneficial action upon the muscle substance itself or on the nerves within the muscle is not yet certain. The results allow no conclusion regarding the question whether the alcohol acts as a food or in some other manner. In larger quantities its presence is detrimental, diminishing the whole number of contractions, inducing early fatigue, and diminishing the total amount of work that the muscle is capable of performing, even to the extent of abolishing the contractile power entirely. In such quantities the action is distinctly poisonous. The after-effects of either small or large doses have not yet been studied.

Dr. Mayer reported upon a number of experiments designed to determine the nature and duration of associative memory in lepidopterous larvæ. In one series the larvæ were placed in a wooden box divided into two compartments by a central partition, which was pierced by a small opening. On one side of the partition was placed moist earth containing growing food-plants, while the other chamber was barren. The larvæ were placed in the latter and found their way through the opening to the food. Apparently they never learned the path to the food, but always wandered aimlessly about, never shortening their paths. When the food was removed, however, they rarely entered this side of the box, showing that it was the presence of the food that attracted them. Individual temperament is very well shown by the larvæ, for some quickly find the food, while others are much slower. This quickness is not due to superior intelligence, however, but is owing to the fact that these larvæ remain quiet for shorter periods of time than the slower ones. A number of experiments were made upon larvæ which devour only special kinds of leaves. These can be induced to eat sparingly of previously uneatable food if the sap of their proper food-plant be rubbed into the previously distasteful leaves. Similarly, they can be prevented from devouring their proper food-plant if the juices of uneatable plants be rubbed into the substance of the leaves. However, they can always be induced to bite at or devour any foreign substance if one allows the larva to commence eating its proper food, and then slides up in front of it a distasteful leaf, sheet of paper, tinfoil, etc. The larva will take a few bites of the foreign substance, but will soon draw back its head, snapping its mandibles with apparent disgust or aversion. Very soon, however, it recommences to eat in a normal manner. If, now, the foreign substance be presented to the larva at intervals of one and one half minutes or more, about the same number of bites is taken at each presentation, thus showing that the larva does not remember its disagreeable experience for this interval. If, however, the interval be about thirty seconds the larva will take fewer and

fewer bites of the disagreeable leaf, soon refusing it altogether. Here again individual temperament is shown in the reaction of larvæ in this respect. When spinning their cocoons the larvæ of *Samia cynthia* and *C. promethea* are geotropic, for if the cocoon be inverted soon after the completion of the outer envelope, the pupæ are sometimes found reversed also, and may thus be imprisoned in the cocoon; for the densely-woven (normally lower) end of the cocoon is probably impenetrable to the issuing moth. A series of experiments are now being tried to determine whether the peculiar coloration of male moths in dimorphic species is due to sexual selection on the part of the female. In the case of *Callosamia promethea* there appears to be none, for males are accepted even when female wings are pasted upon them, or when their wings or scales are entirely removed. In the case of *O. dispar*, however, there is a decided selection against males whose wings have been cut off; 57 per cent. of the perfect males succeed in mating with the females, while only 19 per cent. of the wingless males are successful. The peculiar coloration of the males in these cases has probably not been brought about through the agency of sexual selection on the part of the female, but may be due to race-tendency toward variation in a definite direction unchecked by natural selection.

Dr. Linville, in his paper, showed that the investigation of the habits of *Amphitrite ornata* and *Diopatra cuprea* brings to light many interesting adaptations. The first named lives in U-shaped tubes in sand and mud, access to food and water being possible at either end. Additions to the tube are made at the ends by the tentacles, which are continually drawing in small masses of sand. However, there is every indication that in this animal, where no occasion exists for a protecting tube, continued tube-building is merely incidental to food-getting. Food is brought to the mouth, which is always concealed, in the masses of sand and in water currents created by the inward-lashing cilia which thickly cover the tentacles. *Diopatra* lives in a tough, mucous-lined tube, with its deeper end bare and serving as an anchor, while its outer free end is

studded with bits of shell and gravel. The animal may expose its anterior portion while searching for food and for suitable material to add to its tube. Observations made in the laboratory indicate that the animal chooses these materials by tactile sense-organs in the cephalic cirri. The particle is grasped between the palps or by the mandibles, or by both, and is then conveyed with a fair degree of precision to a place at the edge of the tube. During the construction, *Diopatra* periodically ceases to build in order to 'glue' the gravel and shell together. The mucous-secreting organs are pads upon the ventral surface near the head. These organs are brought in contact with the inner surface of the tube by long and vigorous contractions and expansions of the trunk segments. All or nearly all of the newly constructed portions are gone over in this way before the animal renews its search for new bits of gravel and shell.

HENRY E. CRAMPTON,
Secretary.

THE BOSTON SOCIETY OF NATURAL HISTORY.

AN interesting exhibition of lantern slides of New England Birds was given by Mr. Reginald Heber Howe, Junior, at the meeting of December 4, 1901. Among the more interesting views shown was one of a phœbe's nest built inside a barrel, and a series taken on Seal Island, Maine, illustrating the breeding-grounds and nesting-tunnels of the Leach's petrel. A unique photograph was that of a male chestnut-sided warbler standing on the edge of its nest, in the act of removing excrement of the young. A number of views were shown of ospreys' nests, some built, as along the Maine coast, in trees by the shore, others, as commonly in Rhode Island, on cartwheels, elevated on the ends of poles for the use of the birds.

At the meeting of December 18, Mr. John G. Jack gave an account of forestry and grazing in the Bighorn Reserve, Wyoming. The great value of the forest for holding water, and thus insuring a permanent water supply, was pointed out, and the disastrous effects of forest fires were illustrated by a series of lan-

tern slides. Englemann's spruce and lodgepole pine were the chief timber trees noted on the reserve. An interesting view was shown of a valley, running east and west, on whose sunny southern slope grew the *Pinus flexilis*, while the cooler slope with the northerly exposure supported a growth of Englemann's spruce. A view of especial interest was shown, of a group of trees on whose sides were long and deep-worn scars, made years before and partially healed over, where elk had persistently rubbed their antlers while in the velvet.

Mr. Henry L. Clapp gave an account of school gardens in Europe and in this country. There are in Europe over 80 such gardens, from Sweden to Switzerland. The methods of laying out the gardens, preparing the soil, and planting of the flowers and vegetables by the children were explained by the speaker and illustrated by a fine series of lantern slides. Only recently has this practical and interesting method of teaching botany to children been introduced into this country, but the results have already been noteworthy, and more such gardens should be established for our own schools.

GLOVER M. ALLEN,
Secretary.

THE KANSAS ACADEMY OF SCIENCE.

THE Kansas Academy of Science held its thirty-fourth annual meeting at Iola, Kansas, on December 30 and 31, 1901, Professor E. Miller, of the Kansas State University, in the chair. While the meeting did not have an attendance equal to that of some former years, there was much interest manifested in its work and an unusually full program presented. Fourteen new active members were elected, and seven active members advanced to life membership. About forty papers, mainly on biological, geological and chemical topics, were presented, many of the more technical ones being read by title only.

A paper by Professor J. T. Lovewell, formerly chemist in Washburn College, Topeka, on 'Gold in Kansas Shales,' provoked considerable discussion. The author announced as the result of a very large number of assays, that gold in paying quantities exists in the

vast beds of shales which cover such a large section of western Kansas. The chemists and geologists of the State University and many others have positively denied that gold exists in these shales. A warm discussion followed the reading of the paper, with the result that the Academy appointed a commission of three of its members to investigate the matter further, and to report at the next meeting of the Academy.

On Tuesday evening, December 31, President Miller gave the retiring president's annual address, choosing for his topic, 'The Growth of Science during the Nineteenth Century.'

'A New Plesiosaur' was described by Dr. S. W. Williston, of the State University. The remains of this animal, as well as those of many others, were discovered during the past season by Mr. Charles H. Sternberg, of Lawrence. Mr. Sternberg spent several months in the field, part of the time in the employ of a noted foreign museum, which thus obtained many of his most valuable discoveries. He read before the Academy an interesting paper on 'The Permian Beds of the Big Wichita Valley of Texas.' At the conclusion of his paper much interest was manifested in deploring the loss of these rapidly disappearing paleontological specimens to American institutions, and especially to those of Kansas. A lack of funds for employing explorers or buying the specimens is responsible for this condition.

The members of the Academy were shown every courtesy by the people of Iola, who interested themselves in showing their visitors through the vast industrial plants located there. These include several large zinc smelters, an acid manufactory, cement works, etc., all made possible by the vast field of natural gas which underlies this beautiful part of Kansas.

The following is a list of the officers for the ensuing year: President, J. T. Willard, of the State Agricultural College, Manhattan; First Vice-President, Edward Bartow, of the State University, Lawrence; Second Vice-President, J. A. Yates, of Ottawa University, Ottawa; Secretary, G. P. Grimsley, of Washburn Col-

lege, Topeka; Treasurer, E. C. Franklin, of the State University.

The next annual meeting will be held in Topeka.

D. E. LANTZ,
Secretary.

THE ACADEMY OF SCIENCE OF ST. LOUIS.

At the meeting of the Academy of Science of St. Louis on the evening of January 6, 1902, about forty persons present, the following officers for 1902 were installed: President, Henry W. Eliot; Vice-Presidents, D. S. H. Smith, William E. Guy; Recording Secretary, William Trelease; Corresponding Secretary, Ernest P. Olshausen; Treasurer, Enno Sander; Librarian, G. Hambach; Curators, G. Hambach, Julius Hurter, Hermann von Schrenk; Directors, Amand Ravold, Adolf Alt.

On behalf of herself and a considerable number of other persons, Mrs. William Bouton presented to the Academy a collection of 633 butterflies mounted on Denton tablets, on condition that the collection should be made accessible to the public.

The following papers were presented by title:

'New Species of Plants from Missouri': K. MACKENZIE and B. F. BUSH.

'Revision of the North American Species of *Triodia*': B. F. BUSH.

Professor A. S. Chessin exhibited a gyroscope and explained how an accurately constructed and rapidly rotated gyroscope might be made to indicate the position of the meridian plane, the direction of the polar axis of the earth and the latitude of the place of observation, thus serving the purpose of the mariner's compass, but more accurately, because of the fact that the compass indicates the magnetic pole and not the true pole. The following formulæ pertaining to the subject were furnished:

$$T = \pi \sqrt{\frac{A + C_1 + A_2}{C\omega\Omega \cos \lambda}} \quad T' = \pi \sqrt{\frac{A + C_1 + A_2}{C\omega\Omega}}$$

where T and T' are the durations of a complete oscillation of the gyroscope when its axis is made to remain in the horizontal and the meridian planes, respectively; ω and Ω the angular velocities of rotation of the earth and

the gyroscope, respectively; A , A_1 , A_2 and C , C_1 , C_2 the equatorial and the axial moments of inertia of the gyroscope and the two rings on which it is mounted. From these formulæ the latitude (λ) of the place of observation is derived, namely:

$$\cos \lambda = \frac{T'^2}{T^2}.$$

Professor F. E. Nipher made a further statement concerning his results in the attempt to produce ether waves by the explosion of dynamite. He had obtained some results which seemed to show that magnetic effects could be thus produced. "There is apparently no doubt that great solar outbursts like the one which Professor C. A. Young saw at Sherman in 1872* produce enormous distortions of the ether. Why should it not be possible to reproduce this result? It goes without saying that large sun-spots may be slowly formed, without such disturbance; and certainly we can hardly expect to reproduce solar velocities. But terrestrial explosions do yield tremors and sound vibrations, and these lead to experimental difficulties. The nickel-silver coherer can be operated by the sound-waves from a tuning-fork. The coherer can be either opened or closed, by sound-waves, when the coherer is properly placed in a magnetic field. The same result may be produced by changes in the magnetic field, due to the slow approach of a horseshoe magnet. After the coherer circuit has been closed by a spark, the slow approach of a horseshoe magnet will often open the circuit, precisely as it does when the coherer has been closed by the magnet held in a position of reversed polarity. When the magnet fails to open the coherer circuit, the cause is either a too rapid approach, which causes the coherer to close by reversal of magnetic polarity, or a wrong presentation of the magnet, which confirms the condition produced by the spark discharge. The conditions under which experiments are made as yet, with the jarring due to the street traffic and the explosions, and the changing magnetic field due to the electric cars, have proven to be a source of some perplexity. It throws some doubt

*The Sun,' p. 156.

upon the results reached. However, there seems to be a residual effect which cannot thus be accounted for, and it may be due to an ether displacement. This matter is being carefully studied, and it is intended to use more violent explosives."

WILLIAM TRELEASE,
Recording Secretary.

DISCUSSION AND CORRESPONDENCE.

AN AMERICAN GEOGRAPHICAL SOCIETY.

As has been announced, the next meeting of the International Geographical Congress is to be held in Washington, D. C., in 1904. It must be apparent, I think, to every one familiar with the status of geography in America, that we are not prepared for such an invasion, and that a better organization of our geographical ranks is highly desirable.

There are now at least ten geographical societies in the United States. How many more there are in other parts of the two Americas I am not informed. Each of these societies is a local organization and there is no tangible bond of union between them. It needs no argument to show that some form of cooperation or of union between these various societies is much to be wished, not only that we may make a creditable showing at the coming meeting of the International Congress, but what is much more important, in order that mutual assistance may be had, and the science of geography advanced in a more efficient way than is practicable at present. This matter is not new, and at the risk of seeming to assume undue responsibility, I venture to state a plan of reorganization which embodies ideas gathered from various sources.

My thesis is: There should be an American Geographical Society having for its territorial limits the New World. The aims of this society should be in the main threefold:

- 1st. The holding of a general meeting each year, preferably during convocation week.
- 2d. The publication of an illustrated monthly magazine, devoted to geography in its widest aspects.
- 3d. The promotion of geographical exploration and research.

In reference to the first of these aims, I

need not enlarge on the desirability of an annual meeting at which the results reached by various students of geography may be presented and discussed, and acquaintances made or renewed, since abundant justification for such a course is known to every one, from the success that has attended the annual meetings of several national and international scientific organizations during the past decade. Geographers certainly need to know their fellow workers as much as geologists, chemists, etc., need to know each other. This would be one of the chief results of an annual meeting of geographers, held perhaps at the same time and place as the annual winter meeting of the Geological Society of America.

The greatest gain to be expected from the proposed reorganization lies in the second of the aims to be fostered by the new society, namely, the publication of a strong, attractive, well-illustrated monthly magazine, in the place of the several publications now issued by existing societies. Some of the reasons for this are: The saving of expense in editing, and in duplication, especially of news items, reviews, etc.; concentration and ready reference. The concentration of American geographical literature would be a blessing to future generations, in view of the fact that complete files of the present publications are not readily accessible, and to find all of them in one library is seldom possible. With a central bureau of publication, also, it is to be hoped that the standard of the articles published would be higher. While the expense of a monthly magazine representing the interests of all classes of geographers, and well edited and well printed, would perhaps be greater than that of any one of the single publications referred to, it would be much less than all of them combined. It would also, I venture to assert, reach a wider audience than all of the publications combined which it would replace. Such a magazine would place American geography in a far more favorable light than it now enjoys, in the eyes of the geographers of other continents.

While a few of the existing societies have assisted in geographical research, their efforts

have been local and the results attained, while creditable, have not been such as could be legitimately expected from a stronger and more widely extended organization. With all geographers in America united, influence in favor of exploration could be brought to bear upon legislative bodies which would command attention.

PLAN OF REORGANIZATION.

To attain the desirable ends referred to above, the following plan for uniting the existing geographical societies into one organization, with power to increase its membership and broaden its efficiency, is proposed for discussion:

Let each of the existing societies become a section of the new organization to be known as the American Geographical Society. Each section to manage its own affairs, independently, have its own officers, its own property, etc., but pay a sum, in proportion to its membership, in support of the magazine to be published by the united sections.

All members of the various sections to be fellows of the larger organization, and at their annual meeting to elect a president, secretaries, treasurer and editor. The president of each of the various sections to be *ex officio* vice-president of the main society.

The various sections to choose their own names, but it is to be hoped these names would be geographical, as for example, Boston Section, New York Section, Washington Section, San Francisco Section, etc., of the American Geographical Society. Such a broadening and enlargement of aims would be a compliment to the Society now bearing the name which it is desirable should be given to the representative Society of the two Americas.

The arguments for a truly American geographical society are far greater than I have attempted to show. The objections to the plan outlined seem to refer entirely to local pride or, more accurately, local self-interest. That the existing societies should be proud of the results they have attained and love their present methods is not only natural, but commendable. A broader view, however, must convince one that each local society by union with all other similar societies in America,

without losing its own individuality, would bring to itself renewed strength and vigor.

My aim in presenting this outline of a method by which all students of geography in America may be induced to cooperate and mutually assist in enlarging the boundaries of geographical knowledge, is to invite discussion. I am sure that the editor of SCIENCE will give space for the expression of the opinion of any one in this connection. I wish especially to invite the Council of each existing society to discuss this matter and express its views. If we can arrange for a meeting of delegates from each society, a mutual agreement beneficial to all can no doubt be reached. This should be done in time to effect a reorganization before the convening of the International Geographical Congress.

ISRAEL C. RUSSELL.

ANN ARBOR, MICH.,

Jan. 13, 1902.

THE INTERNATIONAL CENTRALBLATT FOR BOTANY.

As we have already noted the president of the *Association Internationale des Botanistes* has appointed the following American editors for the *Botanisches Centralblatt*:

D. H. Campbell, Stanford University, California, 'Morphology.'

C. J. Chamberlain, University of Chicago, 'Cytology.'

D. T. MacDougal, New York Botanical Garden, 'Physiology.'

G. T. Moore, Department of Agriculture, Washington, D. C., 'Algae, Lichens, Archegoniates' (systematic).

D. P. Penhallow, McGill University, Montreal, 'Paleobotany.'

H. von Schrenk, Washington University, St. Louis, Mo., 'Fungi (systematic) and Vegetable Pathology.'

Wm. Trelease, Missouri Botanical Garden, St. Louis, Mo., 'Phanerogams' (systematic).

For the coordination of the editorial work, the two editors last named have been asked to serve respectively as secretary and chairman of the American Board.

Professor William Trelease, chairman of the Board has sent out the following directions, which we quote as of interest to all workers in science.

In order that the *Centralblatt* may be given the greatest possible value for American botanists and that the least possible delay may be experienced in securing the publication of abstracts of American papers, the authors of such papers are requested to promptly send copies of the same (marked 'for review,' if convenient) to the editor in charge of the subject dealt with in each paper, or, if authors' separates are not available, to call the appropriate editor's attention to the paper.

Each editor is requested to make a regular examination of current journals, proceedings of societies, etc., for papers dealing with his subject, so that occasional failure to receive an author's separate may not deprive the users of the *Centralblatt* of prompt reviews of all papers published in this country. In case an editor has not regular access to any specified serial publication, the chairman will keep him informed as to its contents, if asked to do so. Each editor is requested to consider the subject assigned to him in the broadest possible sense, and, in case of a paper doubtfully lying in his field, to err on the side of noticing it rather than in the other direction, or to specifically refer it to the editor to whom, in his judgment, it should go, or to the chairman of the board.

The management of the *Centralblatt* asks that abstracts (which may be in English), rather than commendatory reviews, be prepared; that the more important publications be first noticed, title and place of publication of current papers not reviewed being likewise sent in; and that attention be given to *quality, promptness and brevity*, in the sequence indicated, in the preparation of abstracts.

The chairman of the American Board suggests, with endorsement of the preceding paragraph, that his colleagues adopt the general form and marking for printers of the accompanying model,* in the heading of abstracts, following the Madison rules for abbreviations when such are considered necessary; that names of all new genera, species and varieties (which, like latinized names in general, should

* CAMPELL, D. H. 'On the affinities of certain anomalous dicotyledons.' (*American Naturalist*, 36: 7-12. *f.* 1-2. Jan., 1902.)

be italicized) be included in abstracts of systematic papers; that especial care be given to legibility, punctuation and the spelling of geographic and scientific names and technical words, and that 'copy' and entries for papers not reviewed be sent to the chairman regularly at the end of each week, a memorandum of postage and other necessary expense being kept and sent in at the end of each quarter year.

The editor of the *Centralblatt* desires to have each abstract signed by the person who prepares it, and, subject to approval and correction of reviews before transmittal to the chairman, each editor has the privilege of assigning any papers in his department to suitable persons, in case he does not wish to abstract them himself.

SCIENTIFIC NOTES AND NEWS.

At a recent meeting of the American Academy of Arts and Sciences of Boston, the following were elected: E. B. Wilson of New York, as associate fellow; Julius Hann of Vienna, E. R. Lankester of London, V. A. H. Horsley of London, F. Delitzsch of Berlin, and S. R. Gardiner of Sevenoaks as foreign honorary members.

JOHNS HOPKINS UNIVERSITY will celebrate on February 21 and 22 its twenty-fifth anniversary, when President Remsen will be formally inaugurated. Dr. D. C. Gilman, president emeritus, will deliver the commemorative address in the afternoon of Feb. 21. This will be followed by an official reception to the delegates, and at eight o'clock in the evening there will be a general reception. President Remsen will make his inaugural address on Feb. 22, in the afternoon. In the evening the annual banquet of the Alumni Association will be held.

THE medals and funds of the Geological Society of London will this year be awarded as follows: The Wollaston medal to M. Friedrich Schmidt of St. Petersburg, the Murchison medal to Mr. F. W. Harner, and the Lyell medals to Mr. R. Lydekker and Professor Anton Fritsch, of Prague; the Wollaston fund to Mr. L. J. Spencer, the Murchison fund to Mr. T. H. Holland, the Lyell fund to Dr.

Wheeldon Hind, and the Barlow-Jameson fund to Mr. W. M. Hutchings.

DR. EUGEN WARMING has been appointed director of the Geological Survey of Denmark.

PROFESSOR J. H. MARSHALL, who has recently been engaged in archeological researches at Athens, has been appointed director-general of the Archeological Survey of India.

WE learn from the *American Anthropologist* that a committee has been appointed at the instance of the Société d'Excursions Scientifiques, to solicit funds for the erection in Paris of a monument in honor of the late Gabriel de Mortillet. Favorable response is being made, and the names of a number of American subscribers appear in the printed list distributed by the committee. M. Louis Giroux, 22 rue Saint Blaise, Paris, is the treasurer.

WE learn from *Nature* that a medallion bust of Sir George Airy is to be placed in the northeast wall of St. Alphage Parish Church, Greenwich, by his daughters. The bust has been copied from the one in the Royal Observatory, Greenwich.

DR. WILLIAM LEROY BROWN, president of the Agricultural and Mechanical College of Auburn, Ala., died on January 23.

PROFESSOR EMIL SCHEFFER, a chemist, died at Louisville, Ky., on January 22, at the age of ninety years.

DR. HUGO VON ZIEMSEN, the eminent German pathologist, professor in the University at Munich, died on January 20, at the age of seventy-two years.

MR. CHARLES ROBERTS, a British surgeon and the author of contributions to anthropometry and natural history, died on January 8.

THE annual meeting of the board of regents of the Smithsonian Institution was held on January 22. There were present Chief Justice Fuller, chancellor, in the chair; William P. Frye, president pro tempore of the United States Senate; Senator S. M. Cullom, Senator O. H. Platt, Senator F. M. Cockrell, Representative Robert Adams, Jr., Representative

Hugh A. Dinsmore, Dr. J. B. Angell, Richard Olney, George Gray, J. B. Henderson, Dr. Alexander Graham Bell and Secretary Langley. Dr. Andrew D. White, ambassador at Berlin, and Representative R. R. Hitt were unable to be present. The secretary presented his annual report for the fiscal year ending June 30, 1901, of which we hope to give some account when it has been published. The needs of the United States National Museum were considered and a resolution was adopted providing for a committee, consisting of six members of the board, whose duty it shall be to represent to Congress the pressing necessity of additional room for the proper exhibition of specimens belonging to the National Museum, and of additional appropriations to carry on the work of the museum. The chancellor appointed as members of the committee Senators Platt, Cullom and Cockrell and Representatives Hitt, Adams and Dinsmore.

It is said that M. de Witte, the Russian minister of finance, has drawn up a decree making the metric system obligatory in Russia. The decree is now under the consideration of the Imperial Council.

MAJOR RONALD ROSS announces that Dr. Dutton has found a new kind of parasite, which causes fever in human beings. The parasite is said to be like the one which causes the fly-disease among horses in South Africa.

THE Department of Superintendence will hold its annual meeting at Chicago on February 26 and 27 under the presidency of Mr. G. R. Glenn, state school commissioner of Georgia. Among the papers to be read and discussed are: 'Obstacles to Educational Progress,' Paul H. Hanus, professor of theory and practice of education, Harvard University; 'The Danger of using Biological Analogies in Reasoning on Educational Subjects,' Dr. W. T. Harris, U. S. Commissioner of Education, Washington, D. C.; 'The High School as the People's College versus Fitting Schools,' Dr. G. Stanley Hall, president of Clark University, Worcester, Mass. Evening addresses will be made by Dr. F. W. Gunsaulus, president of the Armour Institute, Chicago, Ill., and Dr. Charles W. Dabney, president of the

University of Tennessee, Knoxville, Tenn. The National Society for the Study of Education, of which President Nicholas Murray Butler of Columbia University is president, will meet in conjunction with the Department of Superintendence on February 27 and 28.

THE ninety-sixth annual meeting of the Medical Society of the State of New York was held at Albany on January 28, 29 and 30, 1902, under the presidency of Dr. Henry L. Elsner of Syracuse.

THE conference of science teachers, which has been arranged in recent years by the Technical Education Board of the London County Council, was held on January 9 and 10, with about 400 teachers in attendance.

THE twenty-third annual meeting of the German Balneological Congress will be held this year at Stuttgart from March 7 to 11, under the presidency of Professor Oscar Liebreich.

THE eleventh Congress of Russian Naturalists and Physicians was opened at St. Petersburg on January 2. We learn from *Nature* that the number of people taking part in the Congress was very large, more than 3,250 members' tickets having been taken on the day of opening. The Minister of Public Instruction has given a sum of 500*l.* to defray the expenses of the Congress, and both the municipality of St. Petersburg and the university have contributed large sums for the same purpose. At the first general meeting of the Congress, the president (Professor Menshutkin) spoke about the foundation of a Russian Association for the Advancement of Science, which would hold regular congresses every year. This proposal was accepted by a congress held eleven years ago; but the Ministry of Public Instruction was hostile to the idea, and only now the new Minister, General Vannovsky, has agreed not to oppose it. At the same general meeting Professor S. M. Lukianoff delivered an address on the limits of cytological research under normal and pathological conditions, in which he endeavored to establish the limits of psycho-physiology; and Professor N. A. Umoff delivered a brilliant address on a physico-mechanical model of living matter.

PLANS are being made for the establishment of a national institute of hygiene in Spain. The State has offered a site for the building, and it is hoped that sufficient funds will be raised by public subscription.

THE *British Medical Journal* states that an institute for the application of the light treatment has been established in Vienna. At a recent meeting of the Medical Society of that city Professor Lang announced that, in conjunction with a number of medical practitioners and philanthropists, he had founded an institute on the model of that of Professor Finsen at Copenhagen. The institute would be to a certain extent under the control of the municipality. Among the founders is the Emperor, who has contributed 10,000 crowns.

MR. CHARLES T. HAM has presented \$5,000 to the Rochester Academy of Medicine, to be used to further medical research.

PROFESSOR J. B. SMITH, New Jersey state entomologist, expects to ask the legislature next week to appropriate \$10,000 for the investigation and extermination of the New Jersey mosquito.

WE called attention recently to the Woman's Table at the Naples Zoological Station, maintained by a number of women's colleges and individuals. Those desiring further information in regard to the conditions under which the table may be occupied should address the secretary, Miss Cornelia M. Clapp, Mt. Holyoke College, South Hadley, Mass.

UNIVERSITY AND EDUCATIONAL NEWS.

MR. ANDREW CARNEGIE and the descendants of Peter Cooper have respectively given \$300,000 to Cooper Union, New York City, doubling the gifts made by them to the Union three years ago. The total income will now be about \$90,000, which will not enable the trustees to greatly enlarge the work of the Union, but there will no longer be a deficit, and the efficiency of the work will be increased. It is said that the entire building will now be used for the work of the Cooper Union, that the salaries of the teachers will be somewhat increased, and that the work in physics and electrical engineering will be enlarged.

CHANCELLOR JAMES R. DAY, of Syracuse University, has announced that Mr. John D. Rockefeller has given \$100,000 to the university endowment fund. This insures the raising of \$400,000 to meet the offer of Mr. John D. Archbald, of New York, to double that amount. Among the new buildings that will be erected will be a biological laboratory.

THROUGH the death of Mrs. Charlotte L. Sibley Phillips Exeter Academy will receive \$50,000 and the Massachusetts Historical Society \$100,000.

THE University of Aberdeen has received £25,000 from Lord Strathcona and £30,000 in smaller subscriptions.

SIR W. O. DALGLEISH has given £10,000 to St. Andrew's University, half of which is for the new building of the Medical School.

THE Drapers Company has voted a donation of £30,000 to the new University of London.

At a meeting of the executive committee of the Carnegie Trust held in Edinburgh, the secretary and treasurer submitted their reports for the period ended December 31, 1901, showing that fees have been paid by the Trust to 2,441 students, amounting to the sum of £22,941. It was arranged to hold the annual meeting of the trustees in London, at which the first report of the executive will be submitted.

THE second annual court of governors of Birmingham University was held on January 8. Mr. Chamberlain, the chancellor, made an address describing the progress of the University. Plans have been drawn up for buildings to cost about \$5,000,000, and three groups, to cost about \$1,500,000, will be erected with the money that has been subscribed. As has been already reported, the Birmingham City Council had made a grant equal to a halfpenny in the pound on the borough rate, producing £5,750 in the financial year, and directed that a similar grant should be provided for in its annual estimates until it should otherwise order. The Staffordshire County Council had similarly identified itself with the aims of the University by making a grant of £500 a year for five years, in aid of the School of Mining and Metallurgy.

ABOUT a year ago Mr. H. Melville Hanna founded in the medical department of Western Reserve University a research fellowship for the promotion of original work in medicine, especially in physiology and pathology. Applications for the fellowship are now invited. The income of the fellowship is about \$600 a year. It is tenable, in the first instance, for one year, but a fellow who has done exceptionally good work may be reappointed for a second term. All communications should be addressed to Dr. G. N. Stewart, professor of physiology, or Dr. B. L. Milliken, dean, medical department of Western Reserve University.

PROFESSOR EDMUND J. JAMES, professor of public administration in the University of Chicago, has been elected president of Northwestern University.

DR. R. E. JONES has resigned from the presidency of Hobart College.

DR. JULIUS SACHS, head of a well-known preparatory school in New York City, has been elected professor of secondary education in Teachers' College, Columbia University.

At the January meeting of the board of trustees of Syracuse University, the following changes in the faculty of science were announced: Associate Professor H. Monmouth Smith was made full professor of chemistry. Instructor Edward H. Kraus was made associate professor of mineralogy; W. M. Smallwood, professor of biology in Allegheny College, was elected associate professor of zoology. Professor Smallwood is now on leave of absence, doing graduate work in Harvard University. He will assume the duties of his new position in September next.

At Columbia University Mr. John Cabor, Jr., M.E., has been appointed assistant in the department of physics, to succeed George B. Pegram, promoted, and Mr. Wilson E. Davis, A. B., assistant in the department of mining.

DR. W. H. THOMPSON, Dunville professor of physiology, Queen's College, Belfast, has been elected to the chair of institutes of medicine (physiology and histology) in the Royal College of Physicians of Ireland, rendered vacant by the resignation of Professor J. M. Purser.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE first meeting of the trustees of the Carnegie Institution was held in Washington on the 29th and 30th of January. Nearly all the members of the board were present and two sessions were devoted to a consideration of the important business entrusted to them by Mr. Carnegie. The Hon. John Hay, Secretary of State, presided on the first day and, at the second session, the Hon. Abram S. Hewitt, who had in the meantime been made permanent chairman of the board. The most interesting incident of the meeting was the appearance of the founder who in a very clear and modest way read the deed of trust by which he conveyed to the Carnegie Institution ten millions of dollars in five per cent. bonds of the United States Steel Corporation. After reading this deed, he proceeded to unfold in more familiar language the purposes that he had in view, which are not different from those already indicated, although he amplified certain points which had only been briefly mentioned before. Among other things he said in substance that he had been tempted to associate the name of George Washington with this gift

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

of his, but on reflection he had reached the conclusion that it would be unwise to do so. He also stated that the Carnegie Institution would not be such a national university as Washington thought possible in his day. Mr. Carnegie also gave emphasis to his repeated desire that the income of the fund should be largely devoted to extending human knowledge by original investigation and research. This would involve the selection of individual co-workers of exceptional powers. It would also lead to the publication of important memoirs. Beyond these fundamental restrictions the trustees are left free to proceed as they may think best from time to time. Accordingly, an executive committee of seven persons was authorized to formulate plans and to take such preliminary steps as might be important before the annual meeting of the trustees in November next. This committee consists of the president of the Carnegie Institution, Daniel C. Gilman, the four gentlemen with whom Mr. Carnegie has been advising during the last few weeks, namely: Hon. Abram S. Hewitt, Dr. John S. Billings, Hon. Carroll D. Wright and Hon. Charles D. Wolcott, and, in addition, Hon. Elihu Root and Dr. S. Weir Mitchell. The executive committee immediately after their appointment proceeded to discuss the next step to be taken and determined to begin by opening, temporarily, rooms in Washington at No. 1439 K Street, where conferences may be held. Next they propose to correspond with men in all parts of the country who are acknowledged leaders in science (using the word science in a very broad sense), and after their answers

are received to consider the suggestions they may make, preliminary to future action. They also propose to make a diligent inquiry respecting all the kindred agencies that are now promoting research under the auspices of the government or under the direction of universities and technical schools. The experience of foreign countries will also be carefully studied.

From this statement it will be obvious that the further development of this new institution will be slow and gradual. It is not expected that scholarships will be established at present, and all requests for assistance will be laid before the executive committee.

These points should be borne in mind. The great object of the foundation is the advancement of knowledge. The methods are left to the free action of the trustees, who will await the carefully matured suggestions of the executive committee. Nothing has been done in founding the new institution to further or to hinder the establishment of a national university which has been so many times proposed to Congress. Nothing is projected which will in any way interfere with the purpose of the George Washington Memorial Association to secure the funds requisite for the erection of a memorial building. Nor has there been any step taken which will prevent the Washington Memorial Institution, initiated early in the last summer, from developing plans for the introduction of students to the various scientific bureaus of Washington.

The Carnegie Institution is simply a new

force for the promotion of science, ready to cooperate with other institutions which are now or may be established in Washington or elsewhere. By its very foundation it is precluded from any thought of rivalry. If the founder's hopes are realized his wise and munificent bounty will benefit not only our own country but the interests of mankind.

D. C. G.

THE WRECK OF MT. MAZAMA.*

INTRODUCTION.

THE geological record of this country from the earliest epochs to the present time is replete in volcanic phenomena, but the climax in such matters appears to have been reached in the earlier portion of the Neocene, when one of the largest known volcanic fields of the world was vigorously active in our Northwestern States. It stretches from the Rocky Mountains to the Pacific, embracing a large part of Wyoming, Montana, Idaho, Washington, Oregon and California, and presents a great variety of volcanic phenomena concerning which, notwithstanding a copious literature, there has been as yet but a small amount of detailed investigation. The work of the Geological Survey has taken me across this field in various directions and afforded an extended opportunity at intervals during nearly a score of summers upon the Pacific coast to study the western portion of the field. Instead of attempting a summary of what has been done in this large field, as perhaps might be expected upon this occasion, I beg to call your attention more particularly to a special feature in the volcanology of the Cascade Range, which,

* Abstract of Presidential address delivered before the Geological Society of Washington, Dec. 18, 1901. The full address with geological map and illustrations will probably appear as a bulletin of the U. S. Geological Survey.

so far as I am aware, is not well represented in any other portion of the field nor in fact anywhere else within the United States. To set forth more clearly the wreck of Mt. Mazama, which is the central theme, it is necessary to consider briefly the general relations of the whole range.

LIMITS OF THE CASCADE RANGE.

The western limit of the great volcanic field is marked by the corresponding border of the Cascade Range, which is made up at least largely, if not wholly, of volcanic material erupted from a belt of vents extending from northern California to central Washington. Lassen Peak marks the southern end of the Cascade Range and Rainier is near the northern end. Beyond these peaks the older rocks rise from beneath the Cascade Range and form prominent mountains, the range itself occupying a depression in these older terranes.

FOUNDATION OF CASCADE RANGE.

A clearer conception of the development of the Cascade Range may be gained by considering the geography of the region during the later portion of the Cretaceous. At that time the coast of northern California, Oregon and Washington subsided, causing the sea to advance upon the land. In California it reached the western base of the Sierra Nevada and covered a large part, if not the whole, of the Klamath Mountains. In Washington it beat upon the western base of the range near the coast north of Mt. Rainier, but in Oregon it extended far into the interior. Marine deposits of this period occur along the base of the Blue Mountains in eastern Oregon. The Cascade Range of Oregon did not then exist to shut out the open sea from that region. East of the Klamath Mountains, as shown by the position and distribution of the Cretaceous strata and their fossils of marine origin, the open sea connected directly with that of the Sacramento Val-

ley. The Cascade Range throughout a large part of its extent rests upon Cretaceous rocks and is associated in Oregon and California with a depression in the older rocks between the Klamath Mountains on the one hand and the Blue Mountains and Sierra Nevada upon the other. This depressed area beneath the lavas of the Cascade Range must not be regarded primarily as a region of subsidence. Its chief movement since the Cretaceous has been upward. It has been raised above the sea. The Klamath and Blue Mountains, as well as the Sierra Nevada, however, have been elevated so much more that the region in question would appear on the surface as a depression were it not filled with lava. The depression is so deep where the Cascade Range is cut across by the Klamath and Columbia rivers that the bottom of the lavas forming the bulk of the range is not reached. However, at the ends of the range the older rocks rise to form a more or less elevated base for those parts of the range, and at Mt. Shasta as well as on the divide between the Rogue and Umpqua rivers, where an arch of the older rocks extends northeasterly from the Klamath Mountains towards the Blue Mountains of eastern Oregon, the Cascade Range gets so close to the western side of the depression that the lavas lap up over the arch of older rocks rising to the westward. At various points of the range granolitic rocks, such as gabbro and diorite, occur, but the deep erosion at these points may have reached the granolites corresponding to the lavas of the upper portion of the range.

CASCADE RANGE DURING THE EOCENE.

There can be no reasonable doubt that fossiliferous Cretaceous rocks of marine origin are widely distributed beneath the Cascade Range from Lassen Peak to the Columbia, and that during the Chico epoch the whole area was beneath the sea.

At the close of the Chico important changes occurred in the distribution of land and sea. Northern California, as well as southern Oregon, was raised above the sea and subjected to extensive erosion before the subsidence which admitted the sea during the early part of the Tertiary as far southeast as Roseburg, Oregon. The marine deposits of the Eocene epoch in the vicinity of Roseburg run under the Cascade Range, but have not yet been found upon the eastern side. The conglomerates of the Eocene, like those of the Cretaceous, contain many pebbles of igneous rocks, but they are of types common to the Klamath Mountains and rare or unknown among the lavas exposed in the Cascade Range. During the Eocene in the Coast Range of Oregon there was vigorous volcanic activity,* but the record of such activity, if such existed, has not yet been found in the Cascade Range. That volcanoes were active along the range during the Eocene is rendered more probable although not yet conclusive by Dr. J. C. Merriam's discovery of Eocene volcanic deposits in the John Day region.†

CASCADE RANGE DURING THE MIOCENE.

There can be no doubt, however, that during the Miocene‡ the volcanoes of the Cascade Range were most active and the greater portion of the range built up, although it is equally certain that volcanic activity continued in the same region at a number of points almost to the present time. While it may be presumed that the volcanoes of the Cascade Range are extinct, there are many solfataras, hot springs and fumeroles, showing that the volcanic energy of the range is not yet wholly dissipated.

* U. S. Geol. Survey, Seventeenth Annual Report, Part I., p. 456.

† *Bulletin Geol. Dept. of Univ. of Cal.*, Vol. 2, No. 9, p. 285.

‡ U. S. Geol. Survey, 20th Annual Report, 1898-9, Part III., p. 32.

All the peaks of the Cascade Range were once active volcanoes, and from them came most of the lava of the range. Each great volcano was surrounded within its province, at least during the later stages, by numerous smaller vents from which issued the lava that filled up the intervening spaces and built up the platform of the range.

All of the great volcanoes of the range probably had their beginning in the Miocene. Many of them, like Lassen Peak and Mount Shasta, continued their activity into the Glacial Period and have suffered much erosion since they became extinct. In this manner important structural differences have been brought to light among the peaks about the headwaters of the Umpqua, Rogue river and the Klamath, and these may be noted as throwing some light upon the history of Mt. Mazama, whose wreck we are to consider.

UNION PEAK.

Union Peak (7,881 feet) is on the summit of the Cascade Range in Oregon about 50 miles north of the California line, and 8 miles southwest of Mt. Mazama. It is a sharp conical peak rising about 1,400 feet above the general summit of the range. About the base upon the east and west sides, as well as upon its very summit, are remnants of the original tuff cone, but the mass of the peak exposed upon all sides is solid lava. The molten material did not sink away after the final eruption. The volcanic neck resulted from the cooling of lava within the cinder cone in the very top of the volcanic chimney, and Union Peak to-day shows us the neck stripped of its cinder cone.

MT. THIELSEN.

Mt. Thielsen (9,250 feet), the Matterhorn of the Cascade Range, is 12 miles north of Mt. Mazama and rises about 2,000 feet above the general summit of the range.

It is built up of brightly colored red, yellow and brown layers of tuff interbedded with thin sheets of lava, and the whole is cut by a most interesting network of dikes radiating from the center of the old volcano. No trace of a volcanic neck is present; the peak is but a remnant carved out of the lava and tuff cone surrounding the vent. After the final eruption the molten material withdrew from the cone before consolidation so as to leave no volcanic neck corresponding to that of Union Peak. The subsidence after eruption within the chimney of Mt. Thielsen must have been over 1,000 feet, for the sheets of lava effused from that vent reach more than 1,000 feet above the central portion of the peak.

MOVEMENT IN MT. MAZAMA.

To simplify matters it seems best at this point to anticipate some of the conclusions to be reached and state that upon what is known as the rim of Crater Lake there once stood a prominent peak to which the name Mt. Mazama has been given. The crowning event in the volcanic history of the Cascade Range was the wrecking of Mt. Mazama, which resulted from a movement similar to that just noted in Mt. Thielsen but vastly greater in its size and consequences. It culminated in the development of a great pit or caldera, which for grandeur and beauty rivals anything of its kind in the world.

Mt. Mazama is practically unknown to the people of Oregon, but they are familiar with Crater Lake, which occupies the depression within the wreck of the great peak. The destruction of the mountain resulted in the formation of the lake, and the remnant of Mt. Mazama is most readily identified when referred to as the 'rim of Crater Lake.'

CASCADE RANGE SUMMIT.

The Cascade Range in southern Oregon is a broad irregular platform, terminating

rather abruptly in places upon its borders, especially to the westward, where the underlying Cretaceous and Tertiary sediments come to the surface. It is surmounted by volcanic cones and coulees, which are generally smooth but sometimes rough and rugged. The cones vary greatly in size and are distributed without regularity. Each has been an active volcano. The fragments blown out by violent eruption have fallen about the volcanic orifice from which they issued, and built up cinder cones. From their bases have spread streams of lava, raising the general level of the country between the cones. From some vents by many eruptions, both explosive and effusive, large cones, like Pitt, Shasta and Hood, have been built up. Were we to examine their internal structure, exposed in the walls of the canyons carved in their slopes, we should find them composed of overlapping layers of lava and volcanic conglomerate, a structure which is well illustrated in the base of Mt. Mazama.

VIEW OF MT. MAZAMA FROM A DISTANCE.

Approaching Crater Lake from any side the rim by which it is encircled, Mt. Mazama, when seen at a distance, appears as a broad cluster of gentle peaks rising about a thousand feet above the general crest of the range on which it stands. The topographic prominence of Mt. Mazama can be more fully realized when it is considered as the head of Rogue River and sends large contributions to the Klamath River, besides being close to the head of the Umpqua. These are the only large streams breaking through the mountains to the sea between the Columbia and the Sacramento, and their watershed might be expected to be the principal peak of the Cascade Range.

GENERAL VIEW OF MT. MAZAMA AND ITS LAVAS.

Arriving by the road at the crest of Mt. Mazama, the lake in all its majestic beauty

appears suddenly in view and is profoundly impressive. The long gentle slope upon the outside at the crest is changed to a precipice. Nearly 20 miles of irregular cliffs ranging from 500 to nearly 2,000 feet in height encircle the deep blue lake and expose in sections many streams and sheets of lava and volcanic conglomerate which radiate from the lake as a center. Along the southern border the rim above the lake level has many superimposed flows, but upon the northeast where it is not so high it is composed largely of one great flow which coursed down a ravine of the ancient Mt. Mazama.

The rim is cut by a series of eleven dikes, one of which is prominent and reaches from below the lake level to the rim crest. Others rise only part way and spread into flows for which they afforded an outlet. Near the west border of the lake is Wizard Island with its lava field and cinder cone surmounted by a perfect crater.

Three kinds of lava occur in Mt. Mazama, andesite, dacite* and basalt. The andesites form nearly nine-tenths of the mass of the rim. Dacites, generally accompanied by pumice, form the surface flows upon the north and east crest of the rim and are everywhere underlain by andesites. Both came from the central vent of Mt. Mazama, which, however, furnished no basalt. It all came from a number of small volcanic cones upon the outer base of the mountain. The dacites are younger than the basalts, for showers of dacite pumice fell in the extinct craters of the basalt cones. As the oldest lavas of Mt. Mazama are andesites, so are the latest, for the lava of Wizard Island is andesite which was poured out upon the floor of the caldera after the destruction of Mt. Mazama. It marks the beginning of a second petrographic cycle from the same vent.

* My collections were studied by Dr. H. B. Patton, who now regards as dacites what I have heretofore called rhyolites.

ORIGINAL CONDITION OF MT. MAZAMA.

Thus far the existence of an original Mt. Mazama has been assumed. The evidence on which this assumption is based may be briefly stated as follows: The inner slope of the rim presents sections of the broken lava flows which radiate from the lake and were evidently effused from a source higher in each case than the respective flow in the rim. If the flows of the rim were to be restored to their original size by extending them inwards from the rim, as they once certainly did, they would converge to a common source and make a volcano which would occupy the place of the caldera and make a prominent peak, Mt. Mazama.

The peak must have had a crater similar in character to that of Wizard Island, for it was the source of much fragmental material spread in all directions upon the mountain slope.

The former existence of Mazama Peak is indicated also by the radial series of dikes which cut the rim. They evidently originated in the pressure of the column of molten material in the chimney of a volcanic peak rising some distance at least above the rim.

The most convincing evidence of the existence of Mt. Mazama on the site of Crater Lake is to be found in the glaciation and drainage of the rim. The radiating glaciers, which in their descent scored the crest of the rim, could have come only from a central peak. The records of the ice and water drainage from the peak in the topography of the rim are unmistakable.

There can be no reasonable doubt as to the former existence of Mt. Mazama, but its shape and size are more difficult to determine. Mt. Mazama is composed largely of lavas similar to those of Mt. Shasta, and from the slopes of that famous peak we may draw an inference as to those of Mt. Mazama. Mt. Shasta, unlike Mt. Mazama, does not stand on an elevated platform. It

rises with a majestic sweep of 11,000 feet from gentle slopes about its base, gradually growing steeper upwards to the bold peak. At the height of 8,000 feet it has about the same diameter as Mt. Mazama at an equal elevation in the rim of Crater Lake. Above this Mt. Shasta rises over 6,300 feet. The prominence of Mt. Mazama as a drainage center is quite equal to that of Mt. Shasta, but its slopes on the rim of Crater Lake, ranging from 10 to 15 degrees, are scarcely as great as those of Mt. Shasta at a corresponding elevation. On the other hand, the canyons of Sun and Sand creeks on Mt. Mazama are more profound and have been much more deeply glaciated than any of those on Mt. Shasta. It therefore appears reasonable to suppose that Mt. Mazama had an altitude at least as great and possibly greater than that of Mt. Shasta (14,380).

DEVELOPMENT OF MT. MAZAMA.

Mt. Scott is only a large adnate cone to Mt. Mazama. It belongs to the same center and holds essentially the same relation to it as Shastina does to Shasta. The slopes of Mt. Mazama reach to the plains at its eastern base, and it is one of the largest members in the composition of that range.

The beginnings of Mt. Mazama are now deeply buried beneath the lavas of the range, including those displayed on the lower slopes of the great caldera beneath the water of Crater Lake. The earliest lavas now visible are those of the southern and western lake border, and when they were erupted the volcano was normally active, sending out with its streams of lava large contributions of fragmental material to make the heavy conglomerates of the older portion of the rim. The many succeeding flows of andesite and layers of conglomerate built up the mountain slope to the crest of the rim upon the southern

and western side, and Mt. Scott, too, had attained its full development when the principal vents of basalt opened and by a series of eruptions built up the surrounding country with adnate cones upon the outer slope of the rim of the lake. Then followed the large eruptions of dacite forming Llao Rock and the northern crest of the rim to Cloud Cap. These flows occurred during the period of glaciation of Mt. Mazama, and streams of lava alternated with streams of ice, a combination which doubtless gave rise to extensive floods upon the slopes filling the valleys below with volcanic débris from the mountain. In connection with the eruption of these viscous lavas (dacites) there were great explosive eruptions of pumice, spreading it for 20 miles or more across the adjacent country. The explosive activity of Mt. Mazama culminated in the eruption of the peculiar dark pumice rich in hornblende which followed the outflow of the tuffaceous dacite.

DESTRUCTION OF MT. MAZAMA—ORIGIN OF THE CALDERA.

Then came the revolution which removed the upper 6,000 feet of Mt. Mazama, as well as a large core from its base, and gave rise to the caldera. How was this change produced?

There are only two ways in which it could have been effected: either by an explosion which blew it away, or a subsidence which engulfed it.

The occurrence of vast quantities of pumice spread for a distance of 20 miles in all directions about the base of Mt. Mazama is evidence of a most tremendous explosive eruption at that point, an eruption the equal of which, so far as known, has not yet been found anywhere else in the Cascade Range. Vast quantities of fine material were blown out at the same time and by drainage gathered into the sur-

rounding valleys, which it fills to an extent unknown, as far as I have observed, upon the slopes of any of the other great volcanoes of the range.* This impressive evidence shows conclusively that a late, if not the final, eruption of Mt. Mazama was explosive, and of such magnitude as to suggest that the removal of the mountain and the origin of the caldera may be counted among its effects. This suggestion, however, is not supported by the evidence resulting from a study of the ejected material and its relation to the lava flows of the rim. The fine material filling the valleys and the pumice throughout its great area is hornblende in character and belongs to the dacites of the rim. Andesitic material may be present locally, but its occurrence is exceptional. Practically the whole of the material ejected by the final explosion is dacite. The eruption therefore was of the usual type and not of the kind which removes mountains. As far as may be judged from the pumice deposits in the rim, the greatest eruption of that sort of material from Mt. Mazama occurred before the extrusion of the dacite of Llao Rock, and furnishes evidence that the greatest explosion occurred long before the destruction of Mt. Mazama.

There is another matter of importance bearing directly upon the explosive theory of the caldera which renders that theory wholly untenable and fully corroborates the conclusion derived from a study of the character and distribution of the pumice. The lava exposed upon the inner slope of the rim is chiefly andesite, and its relation is such as to indicate that solid sheets of andesitic lava formed by far the larger part of Mt. Mazama. If the caldera resulted from an explosion this mass of andesitic flows would be broken to frag-

* As far as my own observation goes, the above remarks apply to Lassen Peak, Mt. Shasta, Mt. Pit, Mt. Thielsen, Diamond Peak and Mt. Hood.

ments and blown out to fall around the caldera and form a rim of fragmental material. From the size of the lake and the remaining portion of Mt. Mazama it is possible to compute approximately what the size of the rim formed in this way would be. But before we can do this it is necessary to consider the size and shape of the caldera, especially that part which lies beneath the lake.

THE BOTTOM OF CRATER LAKE.

To determine the configuration of the bottom of Crater Lake a large number (168) of soundings were made under the direction of Major Dutton. His results were published by the U. S. Geological Survey upon a special map of the lake, scale 1: 62,500 with a contour interval of 100 feet. The principal lines of soundings are noted, including 96 of the 168 measured depths. From these data, together with information from Mr. W. G. Steel, who was present when the soundings were made, the bottom has been roughly contoured upon the large scale map with a vertical interval of 500 feet. The positions of the two sublacustrine cones were indicated, and it is clear from the soundings that a large mass of lava spread from the Wizard Island vent over the lake floor. The great deep toward the eastern margin of the lake may not have been filled up any after the caldera was formed, but it is evident that the depth of the western portion has been greatly reduced by the material erupted from the three small vents upon its floor. It appears well within the bound of reason to assume that 1,500 feet is not greater than the average depth of the original caldera below the present level of the lake.

ESTIMATED SIZE OF FRAGMENTAL RIM.

The area of the caldera, as marked out by the crest of the rim, is over 27 square miles, and its original volume, making

some allowance for the subsequent refilling from the craters on its floor, is about 12 cubic miles. If to this we add 5 cubic miles for the part of the mountain above the caldera, and this is a conservative estimate, we get 17 cubic miles of material for whose disappearance we have to account. If this material were blown out by a great explosion and fell equally distributed upon the outer slope of the rim, within three miles of the crest it would make a layer over 1,000 feet in thickness. This mass would be so conspicuous and composed of such fragmental material that its presence could not be a matter of doubt. There can be no question concerning its complete absence, for the surface of the outer slope of the rim exposes everywhere either glaciated rock, glacial moraine or pumice, all of which are features which belonged to Mt. Mazama before its destruction, and no trace of a fragmental rim, such as is referred to above, was found anywhere.

The evidence of the outer slope of the rim lends no support to the view that Mt. Mazama was blown away and the caldera produced by a great volcanic explosion. In fact, it completely negatives such a view, and we are practically driven to the opinion that Mt. Mazama has been engulfed. Major Dutton, who studied the rim of Crater Lake with a training gained from among the active volcanoes of the Hawaiian Islands, recognized the wide distribution of the pumice, but the absence of a well-defined fragmental rim kept him from attributing the origin of the caldera to an explosion. On the other hand, he fully appreciated the difficulty of proving that it originated in a subsidence.*

The present inner slope of the rim may not in all cases, or even generally, be the one formed at the time of the collapse. In some cases, however, the inner slope was

* U. S. Geological Survey, 8th Ann. Rept., Part I, p. 157.

formed at that time. Of this we have evidence in the behavior of the flow at Rugged Crest. It was one of the final flows from the slope of Mt. Mazama. Before the central portion of the flow where thickest had congealed within the solid crust, Mt. Mazama sank away and the yet viscous lava of the middle portion of the stream flowed down over the inner slope of the andesitic rim into the caldera. The liquid interior of the flow having withdrawn, the crust caved in and formed Rugged Crest with its peculiar chaotic valley of tumbled fragments, columns and bluffs. Other explanations of the peculiar reversed flow of Rugged Crest have been sought, but without avail. The facts are so simple and so direct that they appear to preclude any other hypothesis.

It would be apparent from the facts also that the collapse of the mountain was at least moderately sudden, for it is not at all probable that the Rugged Crest flow was long exposed before reaching the present level of the lake and beyond into the caldera.

We may be aided in understanding the origin of the caldera by picturing the condition that must have obtained during the eruption of the Rugged Crest dacite from the upper slope of Mt. Mazama. At that time a column of molten material rose in the interior of the mountain until it overflowed at the summit or burst open the sides of the mountain and escaped through the fissure. The rent of the mountain side is formed in such cases by the pressure of the column of molten material it encloses. The molten lavas being heavy, the pressure of the column within the mountain is very great, and increases rapidly with the height of the volcano. During the final activity of Mt. Mazama there must have been within it a column of lava over 8,000 feet in height above the base of the Cascade Range. It is possible that on ac-

count of this great pressure, aided possibly by some other forces, an opening was formed low down upon the mountain slope, allowing the lava to escape. The subsidence of the lava within the mountain left it unsupported and caused its collapse. Phenomena of this sort are well known in connection with the Hawaiian volcanoes. In 1840, according to Professor J. D. Dana, there was an eruption from the slopes of Kilauea, 27 miles distant and over 3,000 feet below the level of its summit. At Kilauea the summit of the lava column is well exposed in a lava lake. In connection with the eruption of 1840 the lava of the lake subsided to a depth of 385 feet, and the irregular walls surrounding it left without support broke off and fell into the molten material below. During the intervals between the eruptions of Kilauea the molten column rises towards the surface only to be lowered by subsequent eruptions. The subsidences, however, are not always accompanied by an outflow of lava upon the surface. At other times it may gush forth as a great fountain hundreds of feet or more in height, as if due directly to hydrostatic pressure.

That Mt. Mazama disappeared and the caldera originated through subsidence seems evident, but the corresponding effusion upon the surface, if such ever occurred, has not yet been found. It is hardly conceivable that 17 cubic miles of material, much of it solid lava, could collapse, be refused and sink away into the earth without a correlative effusion at some other point.

The bottom of the caldera is over 200 feet below the level of Klamath Marsh, which lies at the eastern base of the Cascade Range, and it is not to be expected that the point of escape would occur at any level above (4,200). This consideration would indicate that the effused mass should be sought on the western slope of

the range. The 4,200-foot contour, the level of the lowest portion of the lake bottom, occurs along Rogue River at a distance of less than 12 miles from the rim of the lake. The correlative lavas might perhaps be expected to be dacites closely related to the final flow of Mt. Mazama, but on Rogue River no such lavas were seen,—they are generally basalt; nor is there any suggestion of the escape of such an enormous mass of lava as recently as the time of the great collapse. Whether or not we are able to discover the corresponding effusion, there seems no reasonable doubt that Mt. Mazama was once a reality and that it was wrecked by engulfment.

J. S. DILLER.

U. S. GEOLOGICAL SURVEY.

*THE TEACHING OF ANTHROPOLOGY IN THE UNITED STATES.**

THERE is a feeling among students of anthropology that official instruction in that field has not kept pace with the growth of societies and museums of anthropology, as well as with the ever-increasing volume of literature pertaining to the subject. A science which is rapidly filling our museums and now occupies so much space in current publications should have an exponent at every important seat of learning.

The past decade has, however, witnessed such rapid strides in the progress of anthropological teaching that fears for the future of this particular field of activity may, after all, prove groundless.

Nearly three years ago I began to collect information on the extent of instruction in anthropology in Europe and the United States. The results were embodied in a paper† that was read before Section H at

the Columbus meeting, August, 1899, and which led to the appointing of a committee to consider ways and means of furthering instruction in anthropology in our own institutions of learning. The members of the original committee appointed by Vice-President Wilson were W J McGee, of Washington, chairman; Frank Russell, of Cambridge; and George Grant MacCurdy, of New Haven. Two additional members, Franz Boas, of New York, and W. H. Holmes, of Washington, were appointed later and, at the New York meeting in 1900, the committee of five was made a special committee of the Association, 'Committee on the teaching of anthropology in America.'

This committee is at present preparing a circular, the object of which is to set forth the aims, scope and importance of anthropology, as well as its place in higher education. At a recent committee meeting held in Washington it was decided that such a circular note, to be of the highest value, should be based on the latest and fullest information relative to the extent and trend of instruction in anthropology. Having already published one paper on the subject, I was appointed to bring that paper up to date so far as it related to the United States.

A circular note of inquiry was addressed to one hundred and twenty-one of our most important universities, colleges and medical schools. The number and character of the responses have been very gratifying. Of the one hundred and twenty-one institutions 31* offer instruction in anthropology, 36 do not, and 54 have not yet been heard from.

This is a vast improvement over the conditions which prevailed in 1899, so far as we had knowledge of them, as may be seen by comparison with the following table prepared two years ago:

*Read at Denver before Section H of the American Association for the Advancement of Science, August 29, 1901.

†SCIENCE, December 22, 1899, pp. 910-917.

* Including Phillips Academy, Andover, Mass.

The details furnished by officers of their respective institutions are as follows:

BELOIT COLLEGE, BELOIT, WISCONSIN.

"A slight reference is made to anthropology in a one-hour course in American archaeology throughout the sophomore year." This is elective and is offered by Dr. G. L. Collie, Professor of Biology and Curator of the Rust Museum.

BELLEVUE COLLEGE, BELLEVUE, NEBRASKA.

Anthropology is grouped with the history of civilization and sociology. Professor C. A. Mitchell gives a general sketch of anthropology in a three-hour course for one semester.

BOSTON UNIVERSITY, BOSTON, MASSACHUSETTS.

According to President Warren, while anthropology, in its newest developments and literature, receives incidental attention in a number of courses, no distinct course or courses are devoted to the subject exclusively.

BROWN UNIVERSITY, PROVIDENCE, RHODE ISLAND.

Anthropology is classed with zoology and geology and is taken as a senior elective. Professor A. S. Packard's general

course includes the principles of ethnology, ethnography and prehistoric archaeology.

The Museum of Anthropology in Rhode Island Hall contains a collection of 'articles of dress and rare implements from foreign countries, and valuable stone implements of the aboriginal races of America.'

CLARK UNIVERSITY, WORCESTER, MASSACHUSETTS.

Anthropology is grouped with psychology and may be taken as major or minor for the Ph.D. degree.

Alexander F. Chamberlain, Ph.D., Acting Assistant Professor of Anthropology, offers two courses, twice a week throughout the year, besides theses, conferences and laboratory work. The general course embraces history, scope and relations of the science of anthropology, physical anthropology, ethnography, linguistics, criminal and pathological anthropology, historical and archaeological. The special course is upon anthropological topics most akin to psychology and pedagogy.

During the month of July, Professor Chamberlain gave a course of twelve lectures on 'Education among Primitive Peoples' at the Summer School of Clark University.

COLLEGE OF PHYSICIANS AND SURGEONS, BOSTON, MASS.

Dr. John S. Flagg, Professor of Biology and Embryology and Lecturer on Anthropology, gives a series of 'optionally attended lectures, both general and special, on anthropology.' Besides, 'all matters of biology and embryology are treated from a more or less anthropological standpoint.'

COLUMBIA UNIVERSITY, NEW YORK CITY.

Anthropology is included in the Division of Philosophy and Psychology.

Franz Boas, Ph.D., Professor of Anthropology.

1. Ethnography. Lectures, essays and discussions.
2. Statistical study of variation, introductory course.
3. Physical anthropology. Lectures and laboratory work.
4. American languages.
5. Physical anthropology, ethnology, North American languages. Research work in conjunction with Professor Farrand.

Livingston Farrand, Ph.D., Adjunct Professor of Psychology.

1. Anthropology, general introductory course. Lectures, essays and discussions.
2. Ethnology—primitive culture.

COLUMBIAN UNIVERSITY, WASHINGTON, D. C.

There is a department of anthropology in the Corcoran Scientific School where students may choose the subject either as major or as minor for the degree of Ph.D. Professor Otis T. Mason, LL.D., of the U. S. National Museum, is the Director and offers the following courses:

1. Study of the races of man.
2. History of culture as embodied in the languages, industries, art, social life, philosophy and mythology of the various peoples of the earth.
3. Archæology and folk-lore.

Other professors whose courses bear more or less directly on anthropology are Daniel K. Shute, M.D., Anatomy; William P. Carr, M.D., Physiology; Mitchell Carroll, Ph.D., Classical Archæology; Andrew

F. Craven, Ph.D., Sociology; Theodore N. Gill, LL.D., Zoology; Edward B. Pollard, Ph.D., Semitic studies; J. McBride Sterritt, D.D., Political Economy.

CREIGHTON UNIVERSITY, OMAHA, NEBRASKA.

Anthropology is studied as a division of mental philosophy and 'considered as a branch of primary importance.' Seniors devote one hour a week to the subject, which is in charge of C. Coppens, S. J., Professor of Philosophy.

DARTMOUTH COLLEGE, HANOVER, NEW HAMPSHIRE.

David Collin Wells, Professor of Sociology.

1. Anthropology and ethnology, introductory course, 54 exercises.
2. Anthropological geography. Man in relation to his physical environment, as determining his dispersal over the face of the earth, his mode of life, and the density of population. Fifty-four exercises.
3. Social statistics and applied sociology. The biological side of social life. Fifty-four exercises.

GEORGETOWN UNIVERSITY, WASHINGTON, D. C.

Anthropology is officially classed with psychology and is treated in the senior year and in the Graduate School. The Rev. Edward I. Devitt, S.J., Professor of Psychology, and the Rev. Timothy O'Leary, S.J., Professor of Philosophy, have charge of the work.

HARVARD UNIVERSITY, CAMBRIDGE, MASS.

Division of American Archæology and Ethnology, Courses in Anthropology.

Frederick W. Putnam, A.M., S.D., Professor and Curator of the Peabody Museum of American Archæology and Ethnology.

1. Special course in American archæology and ethnology. Museum, laboratory and field work. Theses.

Frank Russell, Ph.D., Instructor in Anthropology.

1. General anthropology. Lectures and theses.

2. Somatology. Lectures and laboratory work.
3. American archæology and ethnology.
4. Advanced somatology. Laboratory work and theses.

James H. Woods, Ph.D., Instructor in Anthropology.

1. Primitive religions. Lectures, reading and reports.

NATIONAL UNIVERSITY, WASHINGTON, D. C.

Thomas Wilson, LL.D., of the U. S. National Museum. Professor of Prehistoric Anthropology.

NEW YORK UNIVERSITY, NEW YORK CITY.

J. J. Stevenson, Professor of Geology, offers a course in anthropology, one hour a week throughout the year. The course 'covers the natural history of man, deals very little with ethnology and not at all with sociology.'

NIAGARA UNIVERSITY, NIAGARA COUNTY, N. Y.

Anthropology is treated as a branch of philosophy. The philosophy course extends over two years, of which time anthropology occupies about one sixth, or sixty hours. The Rev. P. J. Conroy is the instructor.

PHILLIPS ACADEMY, ANDOVER, MASS.

A Department of Archæology was recently established with a fund of \$150,000. A museum is to be erected immediately. Dr. Charles Peabody, of Harvard, is honorary director and Mr. Warren K. Moorehead is curator. There are about 40,000 specimens with which to begin study. Dr. Peabody and Mr. Moorehead will give instruction after September, 1901.

OHIO STATE UNIVERSITY, COLUMBUS.

Mr. W. C. Mills, Curator, Ohio State Archæological and Historical Society, gives an approved course in anthropology which is open to all members of the University. More than 100 students have taken the course within the past two years.

UNIVERSITY OF CALIFORNIA, BERKELEY.

Professor W. E. Ritter, of the Department of Zoology, is preparing to give instruction in anthropology.

UNIVERSITY OF CHICAGO, CHICAGO, ILL.

Department of Sociology and Anthropology.

Frederick Starr, Ph.D., Associate Professor of Anthropology and Curator of the Anthropological Section of Walker Museum.

(a) Six courses for seniors, covering general anthropology, ethnology, prehistoric archæology and physical anthropology.

(b) Courses for graduates.

1. Mexico. Archæology, ethnology, physical anthropology.
2. New Mexico. Pueblo Indians.
3. Japan.
4. Laboratory courses in anthropology.

During summer quarters, two of the above courses are offered; in others, two courses in class work and laboratory work besides.

Merton L. Miller, Ph.D., Associate in Anthropology.

1. The races of Europe. Seniors.

William I. Thomas, Ph.D., Associate Professor of Sociology, gives a number of courses related to anthropology.

UNIVERSITY OF ILLINOIS, URBANA.

Dr. A. H. Daniels, Professor of Philosophy, gives a course in general anthropology, three hours per week for one semester.

Physical and psychical elements of ethnography. Origin of man. Races of mankind. Historical and comparative study of customs, ceremonies, rights beliefs and folk-lore of primitive peoples.

UNIVERSITY OF INDIANA, BLOOMINGTON.

Anthropology is officially classed with the Department of Economics and Social Science.

Olysses Grant Weatherly, Professor of Economics and Social Science, offers two

terms' work, two hours per week. Physical anthropology, anthropometric work, race classification, etc. The origins of civilization and of society, with some study of American antiquities.

UNIVERSITY OF KANSAS, LAWRENCE.

Frank W. Blackmar, Professor of Sociology.

1. General anthropology, twenty weeks, five hours a week.

2. General ethnology, twenty weeks, five hours a week.

UNIVERSITY OF MINNESOTA, MINNEAPOLIS.

Samuel G. Smith, Lecturer in Sociology, treats incidentally of anthropology in his courses.

UNIVERSITY OF MISSOURI, COLUMBIA.

Charles A. Ellwood, Professor of Sociology.

One course in ethnology, three hours a week, throughout the year.

There is no course given in anthropology in the narrow sense of the term. The work in ethnology 'necessarily covers the subject matter of anthropology in a general way.' The work now offered is only elementary. Professor Ellwood will offer advanced work as soon as an assistant in anthropology and ethnology is appointed.

UNIVERSITY OF NEBRASKA, LINCOLN.

The reply of Professor Charles E. Bessey, Dean of the University, is quoted in full:

"As a separate subject it has no place as yet in the departments of instruction. Indeed, the word, 'Anthropology' does not occur in our Annual Calendar. Yet we have for years offered instruction in some of the topics which enter into scientific anthropology. Thus we have several courses covering the greater part of the field of somatology (in the department of zoology), and psychology (in the department of philosophy), as well as something of an-

thropology proper (in the departments of sociology and history). If these were to be brought together in one greater department the amount of anthropological work offered and actually taken by students each year would be found to be quite considerable. I estimate that during the year just closed fully 1,200 of the 2,200 students in the University pursued anthropological studies. If we were to bring these together they would make a department second only to that of English, which has about 1,800 students."

The instructors are Drs. H. B. Ward (Zoology); R. H. Wolcott (Physiology); Dr. A. B. Hill (Psychology, Logic, Ethics); Dr. E. A. Ross (Sociology); and Dr. F. M. Fling and Professor H. W. Caldwell (History).

UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA.

Faculty of Philosophy. Courses in ethnology and American archæology.

Stewart Culin, Lecturer and Curator of the Section of Asia and General Ethnology.

1. Outlines of North American archæology.
2. Comparative ethnology.

In order to systematize the work offered in archæology, Dr. Hilprecht, Professor of Semitic Philology and Archæology; Dr. Clay, Lecturer in Assyrian, Hebrew, and Semitic Archæology; and Dr. Bates, Lecturer in Greek and Classical Archæology have been associated with Mr. Culin in the administrative group entitled Archæology and Ethnology. The work is to be developed in connection with the Free Museum of Science and Art.

Progress is reported in the movement to found a 'Brinton Memorial Chair' of Anthropology at the University of Pennsylvania.

UNIVERSITY OF VERMONT, BURLINGTON.

Anthropology is grouped with natural and social science.

G. H. Perkins, Professor of Geology.

1. General course. Senior elective. A survey of the ethnological, social, moral and intellectual characteristics of the principal races of the world, followed by a discussion of the origin and development of laws, government, arts, industries, language, literature and religious systems.

Professor Emerson.

1. Social institutions.

UNIVERSITY OF WISCONSIN, MADISON.

Joseph Jastrow, Ph.D., Professor of Psychology, offers one course bearing on anthropology. It is entitled, 'Mental Evolution' and is based on Tylor's Anthropology.

WESTERN RESERVE UNIVERSITY, CLEVELAND, OHIO.

M. M. Curtis, Professor of Philosophy, gives a course of lectures on the history of anthropology, its main problems and bearings.

WILLAMETTE UNIVERSITY, SALEM, OREGON.

President Willis C. Hawley, Professor of Sociology, offers a course in anthropology for juniors and seniors consisting of text, lectures and assigned readings. Two hours a week for the year.

YALE UNIVERSITY, NEW HAVEN, CONN.

William G. Sumner, LL.D., Professor of Political and Social Science.

What Professor Sumner offers is described by himself as follows: "Somatic anthropology has no independent place in the undergraduate curriculum. It is taught as an adjunct to the social sciences by text-books and lectures. Two hours per week. Special students in the Graduate School have lessons in the subject as presented in Ranke's 'Der Mensch,' with lectures, other literature and museum illustrations." The last named course has hitherto been given on alternate years.

E. Hershey Sneath, Ph.D., Professor of Philosophy.

1. Philosophical anthropology. An outline study of man, his body and mind in their rela-

tions, his relations to nature, to his fellows, and to God.

Of the thirty-one universities and colleges offering anthropology, it is found to be an adjunct of sociology in nine, of philosophy in five, of psychology in three, of geology and zoology in five, and of medicine in one; while in five instances it stands practically alone and in three it is unclassified.

The process of differentiation has already taken place in the larger institutions and is destined to reach all at an early date. If about four fifths of those who are teaching the subject are impelled to do so because of its important bearing on their chosen field of work and because there is, at present, no one else to do it, they have a right to depend on being relieved of this additional burden by their own students, some of whom will specialize in anthropology and hold professorships where none now exists.

This seems to be the normal line of development and would of itself, in time, suffice to carry instruction in anthropology to every growing college and university in America. But there is evidence of forces at work which will serve to accelerate the general forward movement. An instance of this is the founding of a 'Department of Archaeology' at Phillips Academy, Andover, Massachusetts, with two instructors, a collection of 40,000 specimens and funds to carry on the work.

No institution of higher learning, worthy of the name, can long afford to be without advantages which can be had at a first class preparatory school.

GEORGE GRANT MACCURDY.

NEW HAVEN, CONN.

ON THE MEASUREMENT OF TIME.

IN the period of the earth's rotation on its axis, called the sidereal day, Nature has provided a convenient, easily determined

and, for present purposes, practically invariable unit of time. For the subdivision of the day into the arbitrary units of time called hours, minutes and seconds, recourse is had to artificial mechanical devices known as clocks.

It may perhaps be stated in general, without serious danger of dispute, that the pendulum clock is the most accurate and reliable of all types of timekeeping mechanism. Chronometers have the advantage of portability and often run remarkably well for considerable periods of time, but they cannot compete with the pendulum clock in carrying an even rate during a series of months or years.

Yet a still higher degree of accuracy than that now prevalent in the performance of astronomical clocks is attainable, and is necessary in the present state of astronomy. There seems to be no reason why improvements in timekeeping should not take place along with the general progress in other directions, where scientific results depend on the perfection of mechanical appliances. The sidereal clock is one of the main features of an astronomical observatory, and if it is to continue to be used to measure the angular distance in right ascension between the fixed stars, greater uniformity in its rate than is now usual must be secured. It is also important in time service work to have clocks which will carry time with greater accuracy during long intervals of cloudy weather when observations of the stars cannot be made. The development of the pendulum clock dates from the time of Huyghens, the celebrated Dutch astronomer, who, in 1656, published his theory of the pendulum. From that time until the present the perfecting of the pendulum clock has received the attention of the best mechanical artists in Europe and America. Important improvements in clock-making were made early in the eighteenth century, when the

mercurial compensation and dead-beat escapement were invented by Graham, of England. The gridiron pendulum, previously suggested by Graham, was soon after constructed by an Englishman named Harrison.

Excellent practical work was done a century later by a German named Kessels, of Altona, who improved the dead-beat escapement by modifying the form of the 'anchor.' The mechanical work of Kessels is remarkably fine. He made a clock for the observatory at Pulcowa in Russia, and another for the celebrated astronomer, Bessel at Königsberg. Bessel investigated the running of the clock with his usual thoroughness and was much pleased with it. He writes of Kessels as 'der kenntnissreiche und vorsichtige Künstler.' Kessels also made a clock for the Naval Observatory in Washington, which, after running for half a century, is in perfect condition and is still giving good service.

Later Tiede, of Berlin, and Hohwü, of Amsterdam, attained great success in making astronomical clocks, and there are now two or three English and American makers who are doing work of great merit.

The Dennison gravity escapement, which has recently come into use, is supposed to be an improvement on the dead-beat escapement, because any small irregularity in the action of the train of wheels should theoretically have little or no effect on the pendulum. It should, for this reason, be better adapted for use in clocks provided with an electric contact, worked, as is usually the case, by a toothed wheel on the seconds arbor for transmitting signals for record on the chronograph. This is an important practical advantage, and to more certainly secure it, American clocks are usually made strong and heavy and are run with heavy weights. The relative merits as timekeepers of the best American and

German clocks is an interesting subject for investigation.

Within the last ten years a clock by Riefler, of Munich, having certain novel features, has come into notice. In the Riefler clock the pendulum rod is a tube filled with mercury by which the compensation is effected. The pendulum is perfectly free, except that it receives its impulse from the spring by which it is suspended. The Riefler clocks have given good results, and one of them has been adopted as the standard clock of the Pulcowa Observatory at Odessa in Russia.

Various devices have been used with success at Greenwich, Pulcowa and elsewhere for compensating clocks for variations of barometric pressure. A newly discovered alloy of 36 per cent. nickel with 64 per cent. steel, which has a remarkably small coefficient of expansion, makes it possible to compensate clocks more perfectly for changes of temperature.

The astronomical clock is a simple piece of mechanism and the perfection of design, excellence of workmanship and the efficiency of the various contrivances for compensating for variations of temperature and barometric pressure seem to have been developed to a point beyond which no great advance is to be expected along present lines. Even if the effects of change of temperature and air pressure on the pendulum could be perfectly eliminated by compensation, we should still have their effects on the clock train as well as the harmful influence of dust and moisture, unless the clock-case affords protection from the latter.

The most obvious chance for future progress seems to lie in securing the greatest possible uniformity of conditions. With a clock securely mounted, enclosed in an air-tight case and kept at an invariable temperature and barometric pressure, the only conceivable cause for variations in its rate

would be perhaps the imperfections in the mechanism of the clock itself. It is necessary for obvious reasons that the sides of the air-tight case should be rigid. A constant pressure cannot be maintained without constant temperature, as may be seen from the well-known formula connecting the pressure, volume and temperature of a body of gas,

$$pv=kt,$$

in which, for our present purpose, v may be regarded as constant. We may therefore write,

$$p=k't.$$

In an air-tight case filled with air the change of pressure due to a change of temperature of 1° Centigrade is between 2 and 3 millimeters for pressures of 650 to 750 millimeters.

The first successful attempt to mount a clock in an air-tight case seems to have been made by Tiede, of Berlin, who in 1865 installed for Professor Foerster in the basement of the Berlin Observatory an electric clock in an air-tight glass cylinder. This clock, the escapement of which is a very simple piece of mechanism, is described by Professor Foerster in the 'Astronomische Nachrichten,' Nr. 1636. The impulses given to the pendulum are independent of the strength of the current, since they are produced by the falling of weights which are lifted each second by an electromagnet. The reason for adopting the electric clock was that the winding of a clock run by weights is attended by difficulties when the clock is enclosed in an air-tight case. While this clock does not run under ideal conditions, being subject to a gradual change of temperature and a consequent slight variation of barometric pressure during the year, it is probably the best time-keeper in the world. It has frequently run for periods of two or three months with such accuracy

that the average deviation of the mean daily rates for the whole period is only $0^s.015$ and with a maximum deviation of $0^s.03$. The clock was dismantled for cleaning in 1894 after running continuously for eight years. The pressure of the air in the case has been kept below the normal atmospheric pressure, and mention is made of the pressure having been made at one time as low as 180 mm., about 7 inches. Little difficulty seems to have been found in keeping the cylinder air-tight. Indeed a slight progressive diminution of the pressure in the cylinder has been observed, and is attributed by Professor Foerster to oxidation of the metal parts of the clock and to absorption by the glass walls of the cylinder of particles of moisture from the air within. This clock has been for thirty-six years the normal clock of the Berlin Observatory.

Soon after, Tiede succeeded in mounting a clock run by weights in an air-tight glass cylinder, and it was exhibited at the Paris Exposition of 1867. In his report of the Pulcowa Observatory for 1867 Otto Struve, the director, announced, with enthusiasm, Tiede's success, and stated that a clock run by weights and enclosed in an air-tight case had been ordered for that observatory. It appears subsequently that much difficulty was experienced from various causes in getting the clock into working order. But it was finally set up, about the year 1880, in the basement of the Pulcowa Observatory, where the temperature changes only four or five degrees a year, and was found to run with a satisfactory rate. This was for many years, and presumably is still, used as the principal clock of that observatory, which is an institution widely known for the high quality of its work. The pendulums of these clocks at Berlin and Pulcowa were compensated, of course, for change of temperature.

The Riefler clocks mentioned above are

constructed so as to be easily mounted in air-tight cylinders, which together with the clock itself rest on a shelf bolted to the clock pier. There is one of these clocks mounted in the usual way at the Georgetown University Observatory at Washington. It is run by a weight which is wound up every few minutes by electricity. But it is not found practicable, under the conditions there, to keep the temperature strictly constant.

The standard clock of the Greenwich Observatory by Dent, of London, is mounted in the basement of the observatory, where the temperature changes are small and very gradual, and is fitted with an electrical device for barometric compensation.

The standard clock of the Paris Observatory, by Winnerl, enjoys the unique distinction of being mounted in a vault at a depth of 27 meters underground. The temperature changes at that depth are of course very small, being, according to Tisserand, not more than one or two hundredths of a degree during the year, but the effect of barometric changes on the rate of the clock has been found to be serious.

There seems to be no case where an attempt has been made to keep both temperature and barometric pressure strictly constant. There is, I think, no doubt that it is entirely feasible to maintain a suitably constructed vault at a practically constant temperature throughout the year by artificial means. Then, with an air-tight case, the barometric pressure could be kept practically uniform and the clock would be completely protected from dust and moisture. Even if it were not practicable to get the case perfectly air-tight, a practically uniform pressure could be maintained by exhausting the air from time to time, provided that the leakage is very small.

Accurate comparisons of clocks running

under such uniform conditions would be exceedingly valuable, not only in giving the highest order of results in timekeeping, but also in developing the peculiarities and comparative merits of the clocks themselves. The extreme accuracy with which two clocks, one keeping sidereal and the other mean time, can be compared by coincidences of the beats, which take place every six minutes, is familiar to every astronomer. Again, the more rapid minor variations in the rates of clocks could perhaps be detected and their periodicity determined by comparison with the vibrations of a pendulum swinging in vacuo.

Improvement in performance of astronomical clocks is of special importance in fundamental astronomy. An independent redetermination of the positions of the fundamental stars is necessary, and for this the most accurate possible timekeeping is needed because, in order to be of value in the present state of astronomy, such work must be of the highest degree of accuracy. All this has long been recognized by astronomers, and during the past forty years efforts in the direction of improved timekeeping have been made in all the principal observatories of Europe where fundamental work is attempted.

Commenting on the bad effect of variations in the rates of astronomical clocks due to the diurnal changes of temperature, Professor Foerster, the distinguished astronomer, who has been for 38 years director of the Royal Observatory at Berlin, wrote in 1867:

“How detrimental to accuracy such a large and changeable irregularity is, is evident since it operates like a variable division error.

“It is therefore necessary, in order that a clock may be of service in absolute determinations of star places, to have it protected from the daily temperature change, and also from all sudden changes of tempera-

ture. That is, it should be mounted in a place of nearly constant daily temperature so that it will remain for the compensation of the pendulum to effect only the last remaining fine adjustment.

“The air-tight confinement is safe in underground rooms or in heavy masonry against injury to the clock-work, because in the hermetically enclosed space any moisture present can be done away with by known means and the coming in of new moisture is impossible.”

MILTON UPDEGRAFF.

U. S. NAVAL OBSERVATORY,
WASHINGTON, D. C.

SCIENTIFIC BOOKS.

The Stars, A Study of the Universe. By SIMON NEWCOMB. Pp. v+333. New York, G. P. Putnam's Sons; London, John Murray.

This is professedly a book written to order, as a part of the science series now appearing under the editorial supervision of Professor Cattell, and its author states plainly in his preface that he has found the task, ‘to sketch in simple language for the lay as well as the scientific reader the wonderful advances of our generation in the knowledge of the fixed stars,’ much more onerous than he had anticipated, on account of ‘the extent and complexity of the subject and the impossibility of entering far into technical details in a work designed mainly for the general use.’

If one may judge the extent of systematized knowledge concerning the fixed stars by the space allotted to its presentation in the most approved text-books of general astronomy, from that of Arago to the present time, it appears that this branch of astronomy has grown during the century from about one eighth to one sixth part of the entire science. But the indexes to recent volumes of the principal astronomical periodicals show that about one-third of the articles there appearing relate to problems of stellar astronomy and thus mark an accelerated growth of interest in and knowledge of the remoter parts of the visible universe. The author who attempts to digest

this rapidly accumulating material and to present its substance in untechnical form merits the thanks of both professional and lay readers, even though occasional inaccuracies or omissions affect the text or the rapid advance of knowledge renders obsolete some passages before the ink is dry upon the pages. A double acknowledgment is due when, as in the present case, that author is the one astronomer marked out by long and distinguished service in important parts of this field as peculiarly adapted to the task. The title, Retired Professor U. S. Navy, that follows the author's name upon the title page, suggests thoughts far from complimentary to that fatuous governmental policy in accordance with which astronomers are retired from the public service upon reaching an age limit not far removed from the maximum of intellectual power.

In substance, though not in formal arrangement, the present work falls naturally into two parts; first, a description of methods of research and such elementary classification of stars as are the familiar province of the better text-books, *e. g.*, the grouping of stars into constellations, the explanation of stellar magnitudes, proper motions, parallaxes, stellar spectroscopy, the description of the phenomena presented by variable and double stars, nebulae, etc.; and second, a more original part devoted to the larger problems of stellar distribution, the significance of the milky way, the sun's motion, stellar evolution and similar matters which may be grouped, fairly enough, under the title, the structure of the heavens. We welcome here a presentation of some of Kapteyn's results not hitherto accessible, of Huggins's views of stellar evolution, and the author's own methods, inferences and conclusions from the new material collected and sifted in the preparation of this work. As types of these last-named categories it is interesting to note the simple statistical method (p. 300) by which certain results first obtained by Kapteyn through an elaborate and tedious mathematical process are independently derived. Of a very different order is the suggestion made with reference to Bailey's discovery of variable stars in clusters, that there is 'a strong presumption that the variations

in the light of these stars are in some way connected with the revolution of bodies round them, or of one star round another.' The distribution of the stars in space is treated with a fullness of detail that occasions some surprise at the almost complete neglect of a possible absorption of starlight in the interstellar spaces; a possible defect of transparency in the celestial void, that has been rendered a classic theme by Struve's speculations and more recently has been elaborated by Schiaparelli.

Taken as a whole the work contains in excellent form a large amount of material interesting to the professional astronomer and in even larger measure valuable to the popular expositor of astronomy, teacher, lecturer or writer. As it is sure to be largely drawn upon by this class it seems important to eliminate as rapidly as possible those errors and inaccuracies inseparable from a first edition, among which we note the following:

P. 158, line 10, for eleven read five and one-half.

P. 182, line 3, for Triphid read Trifid.

P. 194, insert a^2 in the numerator of the fraction.

P. 198, line 1, for $2m$ read 2^m .

The statement made on p. 179 with regard to the Orion nebula, 'This is plainly visible to the naked eye and can be seen without difficulty whenever the constellation is visible,' does not at all correspond to the experience of the present writer who has great difficulty in seeing the nebula with unaided vision, even under favorable circumstances, and whose experience is shared by a dozen young people, of both sexes, who at his request have looked for the nebula.

In the matter of nomenclature some objection may fairly be raised to the apparently needless introduction of new terms in place of the familiar old ones, such as the logically inappropriate, apocenter, pericenter, for apastron, periastron, in connection with double star orbits, and the rechristening of the Fraunhofer lines of the solar spectrum as Wollaston lines. But with all due allowance for such minor blemishes the book remains in its entirety a notable contribution to the literature

of astronomy. Its style is clear and attractive and the illustrations, some excellent, are in the main adequate although many of the diagrams are disagreeably crude. A familiar literary device, that of prefixing a brief metrical introduction to each chapter, has here been so felicitously applied as to deserve especial mention. An excellent table of contents and index greatly facilitate the use of the work as a book of reference. GEORGE C. COMSTOCK.

EARTH-CURRENT OBSERVATIONS IN THE GERMAN TELEGRAPH SYSTEM.*

The origin of these important observations dates back to 1881, when a committee was called together by Werner Siemens, to study the phenomena of earth-currents. Through their efforts, two underground cables were provided by the Imperial Telegraph System, one running in an easterly direction from Berlin to Thorn, 262 km., the other nearly due south from Berlin to Dresden, 120 km. The present work deals chiefly with the continuous observations of earth-currents from these two lines, from 1884 to 1888. The Prussian Academy of Sciences assisted, in part, in the maintenance of the observations.

The assumption is made at the start that the observed currents are due to potential differences between the ends of the lines; that is, they are derived from currents that flow in closed circuits within the earth, parallel to its surface. Of course *vertical* differences of potential have to be left out of consideration.

The attempt to express the intensities in the two lines by trigonometrical formulæ according to Gauss, using the latitude and longitude as variables, leads to equations whose constants are too difficult to be determined. Assuming the validity of Ohm's law, however, the intensity of the earth-current components in the two directions may be given by the equations

$$J = A \frac{W}{L} i, \quad J' = A \frac{W'}{L'} i',$$

* Die Erdströme im deutschen Reichstelegraphengebiet und ihr Zusammenhang mit den erdmagnetischen Erscheinungen, bearbeitet und herausgegeben von Dr. B. Weinstein. Braunschweig, Friedrich Vieweg & Sohn, 1900.

where A is a constant and W, W' are the resistances, L, L' the lengths and i, i' the observed current strengths in the two lines respectively.

We thus obtain for the total earth-current,

$$E = A \sqrt{\frac{W^2}{L^2} i^2 + \frac{W'^2}{L'^2} i'^2}.$$

The value of the constants was computed for each of the two lines. The results are only relative, however, as no reductions to absolute units were made.

The most characteristic feature of earth-current variations is their dependence upon the position and condition of the Sun. The diurnal and annual variations are especially marked. In view of this, the attempt is made to modify the trigonometrical representation in such a way as to use, instead of the latitude, the angle with the Sun's declination, and for the longitude, the local time or the right ascension of the Sun. The results indicate, however, as was to be expected, that this is not sufficient, but that other factors have to be considered. In general there can be distinguished a constant component of the current, due to terrestrial and local conditions, and a variable component, depending chiefly upon the Sun. The four years of observations were not enough to make the derivation of accurate formulæ possible. As approximations, however, expressions for the components in the two directions were derived, as functions of the local time and its multiples, from which the diurnal variation is made evident.

The self-recording instruments were of two different types. In the Berlin-Dresden line a Siemens 'Russschreiber' was used, in the other line a mirror-galvanometer reflected a beam of light on to photographic paper. The sensitiveness of both instruments was frequently determined, and though the results were not reduced to absolute measure, still it is always possible to get accurate relative values between the two lines.

The magnetic records, which, as the title indicates, formed an essential part of the work, were obtained chiefly from the observatories at Wilhelmshaven and Vienna, but to a lesser extent also from the observations during the

international polar year 1882-3 made at Kingua-Fjord, South Georgia and Fort Rae.

The discussion of the earth-currents is based upon the tabulated hourly ordinates from the curves. Instead of measuring a single ordinate for each hour, a planimeter was employed, covering a region on each side of the ordinate sought. A further reduction, by means of trigonometric series, was carried out, in order to get a still closer approximation to the true hourly values.

The diurnal variation of the earth-currents was well marked, showing two principal maxima, and two secondary. An examination of the equations for the mean diurnal variation for the different years shows a slight systematic change from year to year. The mean variation for each year is prettily shown in the excellent vector diagrams, which are a feature of the work. All of the curves show a motion in the direction of the hands of a watch, and in the details of configuration the agreement is also good. A number of interesting deductions are drawn, indicating the dependence of the phenomena upon the Sun's position.

This dependence is no less clearly shown by the annual change in the diurnal variation. A principal maximum of current intensity occurs at the time of the vernal equinox, a secondary one at the summer solstice. The principal minimum is at the winter solstice. The east-west and south-north components for the diurnal variation are very similar throughout the year. As the Sun moves north, the principal waves in the diurnal variation become more pronounced, the secondary waves less so. In winter the reverse is the case, making the winter curves the more complicated. Similar fluctuations are shown in the coefficients of the trigonometrical representation, as well as by a series of vector diagrams for the months and the seasons. The latter are particularly interesting, showing that the mean current in winter is only about half as strong as in summer. Changes of a few days' duration in the character of the curves also occur frequently, which the author attributes to the varying relative position of nonhomo-

geneous portions of the Sun, with reference to the earth.

A patient study was made of the diurnal variation, bringing to light the existence of 36 secondary waves in the course of a day. These occurred about 11 minutes later in the north and south than in the east and west line. The exact number of wavelets may be open to doubt, for the personal equation carries great weight in such investigations; but at least the existence of a system of regularly occurring secondary waves seems established.

The second part of the work is devoted to a discussion of the magnetic records from the stations already mentioned, and the connection between them and the earth-currents. The method of treatment is essentially the same as with the earth-currents, the three rectilinear components of the total intensity being considered. A study of the diurnal variation by means of vector diagrams reveals a more or less definite connection with the Sun's motion. In discussing the direction of the variation, two systems of coordinates are used: First, the 'geopolar,' given by the hour-angle and latitude of the point where the direction at any hour cuts the Earth's surface; and second, the 'heliopolar,' in terms of the angle with the Sun's direction (heliopolar distance), and the angle which the plane through the direction at any hour and the Sun makes with the equator. The track of the diurnal variation upon the Earth's surface is described in detail, and shows interesting similarities between the different stations. The vector diagram of the total variation is also resolved into components in the directions of the planes of the equator, the meridian, and a plane perpendicular to both; in each case the dependence upon the Sun's position is well marked. The vector diagram in heliopolar coordinates takes the form of a conical surface around the Sun. The variation vector sometimes makes an angle as great as 90° with the direction of the Sun, but never points directly toward it, from which the conclusion is drawn, that if the Sun is the cause of the variation, the influence can not be exerted along a straight line from the Sun to the Earth. We must pass over the many interest-

ing details in the results from the different stations, merely noting that the vectors for the diurnal variation at Fort Rae move in a direction opposite to that at all other stations.

The study of the course of the magnetic variation throughout the year makes it appear that all phenomena occurring in any one season in the southern hemisphere do not, as was formerly supposed, correspond to those of the opposite season in the northern; on the contrary, certain features in the yearly variation seem to indicate the presence of influences outside the Earth, affecting the Earth as a whole. The dependence of the variation upon the latitude of the station is brought out with great clearness.

The above results have an important bearing upon Schuster's theory of the diurnal variation. This theory, as von Bezold has pointed out, requires an *invariable* system of forces, in whose field the Earth rotates. Weinstein's deductions show that excessive deformations of the system would be needed to account for some of his observed phenomena, so excessive, in fact, as to lend strong evidence in favor of local influences. We must therefore assume at least two systems of forces, one external, possibly subject to variations, the other of local character.

This part of the work concludes with a discussion of secondary magnetic waves, of which, for Wilhelmshafen in 1884, a mean of 36 were detected in the course of a day, in the case both of declination and of horizontal intensity. The connection between waves in the two elements could not however be established with certainty. It is at least significant that the number of secondary waves here is the same as in the case of the earth-currents.

The work reaches its culmination in Part III., where the relation between terrestrial magnetism and earth-currents is discussed. We regret that space does not permit a more extended review of this interesting chapter. To test first the hypothesis that the earth-currents are simply inductive currents caused by changes in the Earth's magnetism, the author compares the mean diurnal variation in vertical intensity for Vienna in 1884, with that of the earth-currents for the same year. Instead

of maxima in increase of vertical intensity corresponding to maximal current, etc., we find almost the reverse to be the case. The author therefore confines himself to the question whether variations in magnetism are partly due to the earth-currents. If the *vertical* component of the current changes were known, the problem would be much simplified; in lieu of this, ingenious methods have to be resorted to in order to gain such circumstantial evidence as is possible. Even in a horizontal direction only the mean components for certain distances in two directions are known, while the true path of the current lies wholly in the dark. An increase in one or both of these components would not of necessity cause an increase in any one of the magnetic elements, since any such effect might be more than counterbalanced by changes in the direction of the earth-current.

A comparison of the mean absolute values of vertical magnetic intensity and earth-current intensity for the 24 hours tends to strengthen the theory. To explain certain peculiarities in the former, assumptions are made concerning the variation in direction of flow of the earth-currents, which in turn would require an increase in the magnetic horizontal intensity; and this increase is in fact found to take place. When the changes in azimuth of the horizontal components of earth-current and magnetic intensity are compared, the evidence is weaker, though still in the same direction. The comparison of changes from season to season is also favorable, certain minor variations agreeing remarkably well.

As concluding evidence, reference is made to the parallelism in the occurrence of sudden disturbances. By picking these out on the declination traces in Vienna and comparing them with corresponding disturbances on the Berlin earth-current records, the difference in longitude between the two cities could be quite accurately determined. A rigid comparison would of course be possible only if both direction and amount of the resultant disturbances were known, which is far from being the case in the present state of the science.

The author states his conviction that almost the whole of the variations observed by magnetometers are due to earth-currents which act upon the instruments as upon galvanometers. An immense amount of patience and skill has been devoted to the compilation of results, and it must be admitted that the evidence is favorable to this theory. As a working hypothesis it may be found of great value; but our knowledge of the phenomena, and particularly the mass of actual observations, must be vastly extended before we can finally accept the solution as a physical fact.

W. G. CADY.

U. S. COAST AND GEODETIC SURVEY,
MAGNETIC OBSERVATORY, CHELTENHAM, MD.,
December 21, 1901.

The Birds of North and Middle America: A Descriptive Catalogue of the Higher Groups, Genera, Species and Subspecies of Birds known to occur in North America, from the Arctic Lands to the Isthmus of Panama, the West Indies and other Islands of the Caribbean Sea, and the Galapagos Archipelago. By ROBERT RIDGWAY, Curator, Division of Birds, U. S. National Museum. Part I. Family Fringillidæ—The Finches. Washington, Government Printing Office. 1901. Bulletin of the United States National Museum, No. 50. 8vo. Pp. xxxii + 715, pls. 20.

The geographical scope and general character of this important work is well indicated by the above transcript of the title-page, which does not, however, give an adequate idea of the amount of labor involved in its preparation, which has largely engaged the author's attention for the last twenty years, and for the last six years has occupied the greater part of his time. The present volume is the first of the series of eight required to complete the work, averaging about 800 pages and some twenty plates to each volume. As much of the drudgery of collating references, and taking measurements, for the 3,000 species and subspecies comprised in the work, has been mostly completed, it is expected that the publication of the remaining volumes will proceed with little further delay.

The present volume treats only of the single family Fringillidæ, or Finches, which number 389 species and subspecies, of which about one-half occur in North America, the rest being exclusively birds of 'Middle' America. The introductory matter comprises an appropriate dedication to the late Professor Baird, followed by a preface of seven pages, stating the principles that have guided the author in his work, with other explanatory matter. The author has to regret the necessity of beginning his work with the highest instead of the lowest forms, owing to the lack of adequate facilities for arranging the collection of birds in the National Museum, the larger birds being inaccessible for study. This state of affairs has existed for some ten to fifteen years, greatly to the regret and inconvenience of many ornithologists besides the curator, and affords a striking commentary on the neglect by the government of our great but inadequately housed National Museum.

The first twenty-five pages of the main text are devoted to a critical consideration of the classification of the class Aves, with diagnoses and keys for all the higher groups, and for the families of the Oscines. His system is admittedly eclectic, but is on the whole a quite satisfactory compromise. The Fringillidæ, as defined by Mr. Ridgway, embrace several finch-like genera usually referred to the Tanagridæ, but which seem to fit better as members of the Fringillidæ; yet, with these transfers, there is still no hard and fast line of division between the two groups.

Mr. Ridgway's work is strictly systematic and technical. Aside from the descriptions of the forms, the elaborate keys, and the statements of range, a special feature is the very full bibliographical citations, which constitute a large part of the text, and include all references of any value, thus forming an index to the literature of each species. The locality to which a citation relates is stated whenever possible, thus greatly facilitating the labors of future workers. In compiling the references extreme exactness has been attempted in all matters of orthography and nomenclatural combinations—a feature often neglected, but of the highest importance. As Mr. Ridgway

observes: "Anyone who has had occasion to verify citations must know that the amount of inaccuracy and misrepresentation in current synonymics, even the most authoritative and elaborate, is simply astounding. They abound with names which do not even exist in the works cited, with those which do not correspond with the originals in orthography, with others that have no use or meaning whatever, being evidently culled from indices without reference to what their status may be on the pages indicated."

In matters of nomenclature the author has followed the American Ornithologists' Union 'Code of Nomenclature,' which has 'been strictly adhered to in all respects.' He has, however, reached different conclusions, in a few cases, regarding the status of certain forms, from those of the A. O. U. Committee. Considering the large amount of time he has been able to give to such points, aided by access to all of the available material, the benefit of the doubt may be safely permitted to rest with Mr. Ridgway, till some equally competent expert, with superior resources, reverses his conclusions.

The 20 plates give outline figures of the bill, feet, tail and wings of each genus treated, and are thus a valuable aid to the student. The work in all its details shows the author's characteristic and well-known thoroughness of treatment, and ornithologists the world over will wish him health and strength to complete the enormous undertaking involved in the preparation of the 'Birds of North and Middle America.'

J. A. A.

SCIENTIFIC JOURNALS AND ARTICLES.

The American Naturalist for January begins with an article on 'Prehistoric Hafted Flint Knives,' by Charles C. Willoughby, describing various forms of these implements; Douglas H. Campbell discusses 'The Affinities of Certain Anomalous Dicotyledons' and J. H. Comstock and Chujiro Kochi present a long and careful study of 'The Skeleton of the Head of Insects,' using the known facts of embryology to give a clearer idea of the structure of the head, attention being mainly given

to representatives of the more generalized orders of insects. The article is well illustrated and a long list of references is appended. R. W. Shufeldt contributes a paper 'On the Habits of the Kangaroo Rats in Captivity,' and under the title 'A Contribution to Museum Technique' S. E. Meek describes the method of mounting fishes for exhibition in flat jars, the specimens being hardened in alcohol, then painted with water-colors and then replaced in alcohol.

The Plant World for December, 1901, contains 'Farther Notes on Trees of Cuba,' by Valery Havard, with a fine plate of the silk cotton tree; 'Notes on the Pan-American Exposition,' by Pauline Kaufman, in which we are sorry to see an account of a 'petrified body'; 'The Flora of Snow Cañon, California,' by S. B. Parish, besides the customary Briefer Articles, Notes and Reviews. In the Supplement Charles L. Pollard continues the description of the families of the order Parietales.

The Museums Journal, of Great Britain, contains a brief biographical sketch of Dr. Henry Woodward, who has just retired from the keepership of the department of geology in the British Museum. J. G. Goodchild describes, under 'Astronomical Models in Museums,' a practical orrery on a rather large scale devised by him for the Edinburgh Museum of Science and Art, and D. P. H. discusses 'Hygiene as a Subject for Museum Illustration,' giving an outline of the method and objects of such an exhibit. There are a few short articles and numerous notes on Museums in various parts of the world.

The American Museum Journal for November-December continues L. P. Gratacap's paper on 'The Development of the American Museum of Natural History,' and deals with the department of vertebrate palæontology. Other articles deal with recent work of the Museum, and the number has a well-illustrated supplement on 'The Saginaw Valley Collection,' by Harlan I. Smith, which is to serve as a visitors' handbook.

FOLLOWING the death of Dr. Charles Henry Brown, the former proprietor of the *Journal*

of *Nervous and Mental Diseases*, Dr. Smith Ely Jelliffe of New York has become the responsible editor. Dr. William Osler, Dr. Frederick Peterson and Dr. Wharton Sinkler have joined the advisory board. Dr. William G. Spiller of Philadelphia will continue to be acting editor.

SOCIETIES AND ACADEMIES.

THE AMERICAN PHYSICAL SOCIETY.

THE Annual Meeting of the Physical Society was held at Columbia University on Dec. 27, 1901. From some points of view the date was an unfortunate one, coming as it did so soon after Christmas day. But in spite of this fact the attendance was unusually good, while the program included a larger list of papers than that of any previous meeting except the one held in connection with the New York meeting of the American Association in 1900.

Officers were elected for the year 1902 as follows:

President, Albert A. Michelson; *Vice-President*, Arthur G. Webster; *Secretary*, Ernest Merritt; *Treasurer*, William Hallock.

Messrs. Carl Barus, D. B. Brace and A. L. Kimball were elected members of the Council of the Society.

The following papers were read:

'A Suspected Case of the Production of Color by the Selective Electrical Resonance for Light Waves of Very Minute Metallic Spheres': R. W. WOOD.

'Report on Electrostriction': LOUIS T. MORE.

'Further Experiments on Electrostriction': J. S. SHEARER.

'The Transmission of Excited Radioactivity': E. RUTHERFORD.

'Excited Radioactivity and Ionization of Atmospheric Air': E. RUTHERFORD and S. J. ALLEN.

'Note on Drude's Elektronentheorie': E. H. HALL.

'The Disturbances of a Plumb-bob suspended on a Steel Wire': WM. HALLOCK.

'A Thermograph for Earth Temperatures': WM. HALLOCK.

'The Viscosity of Water determined by the Aid of Capillary Ripples': F. R. WATSON.

'Magnetization of Steel at Liquid Air Temperatures': C. C. TROWBRIDGE.

'The Pfandler Calorimeter': W. F. MAGIE.

'Standards of High Electrical Resistance': H. C. PARKER.

'Variation of Contact Resistances with Change of E. M. F.': H. C. PARKER.

'On a Ruling Engine for Diffraction Gratings': A. A. MICHELSON. (Read in abstract by the Secretary.)

The next meeting of the Society will be on Feb. 22, at 10:30 o'clock A. M., in Fayerweather Hall, Columbia University.

ERNEST MERRITT,
Secretary.

OHIO STATE ACADEMY OF SCIENCE.

THE eleventh annual meeting was held at Columbus, November 29 and 30. This was a month earlier than the usual time but the attendance was as good as usual, about thirty-five. The policy of holding a summer field meeting every year the Academy decided to abandon. Some of these meetings have proved very successful, but of late the attendance of members living at a distance has been small, except when held in connection with the meeting of some other organization. Hereafter the executive committee each year may or may not call a summer meeting.

The following resolution was passed: "That the Academy, through its secretary, respectfully represent to the postal authorities that the present provisions and rulings of the postal department regarding transmission of natural history specimens are inconsistent and a serious hindrance to exchange of scientific material and urge that better provisions be afforded."

The secretary read obituary notices of Edward W. Claypole, first president of the Academy, and of Mrs. Claypole, and a committee was appointed to draft a suitable memorial.

A letter was read from Emerson E. McMillin, again placing \$250 at the Academy's disposal. Eighteen persons were elected to membership.

The topographic survey of Ohio by the U. S. Geological Survey in cooperation with the State was begun in 1901 as a result of determined efforts put forth by the Academy of Science beginning in 1896, when Albert A.

Wright made the matter the subject of his presidential address. The progress of the topographic survey during the past season was described by C. N. Brown. The report of the Committee on Topographic Survey, prepared by Albert A. Wright, the chairman, was read by Lynds Jones. In conclusion it says: "It is very desirable that the members of the Academy and all other supporters of the survey, should make known, to their representatives in the legislature and to the governor and other officers of the State, their desire that this work, so well inaugurated, should be followed out to its completion, in the mapping of the entire area of every county of the State."

The following officers were elected for the ensuing year: President, W. R. Lazenby; Vice-Presidents, C. J. Herrick and C. S. Prosser; Secretary, E. L. Moseley; Treasurer, Herbert Osborn; Elective Members of Executive Committee, Wm. Werthner and John Uri Lloyd.

The program was as follows:

'New Fossils, including Sea-weeds, two new genera, Carboniferous, Marietta; Land Plants, two species, Carboniferous, one species, Corniferous; Corals, fifteen Cyathophylloids, Corniferous; Brachiopods, one, Corniferous; Cephalopods, six, Corniferous': H. HERZER.

'Notes on the timber of trees of Ohio': WILLIAM R. LAZENBY.

'The self-pruning of woody plants': JOHN H. SCHAFFNER.

'The Ohio species of *Phyllachora*': W. A. KELLERMAN and J. G. SANDERS.

President's Address—'The Future of Vegetable Pathology': A. D. SELBY (will be published in SCIENCE).

'A striking case of mimicry, with exhibition of specimens': HERBERT OSBORN.

'Smut infection experiments': W. A. KELLERMAN and O. E. JENNINGS.

'Further observations on the preglacial drainage of Wayne and adjacent counties': J. H. TODD.

'The weight, waste and composition of apples': WILLIAM R. LAZENBY.

'Plant ecology of Ohio; a general outline': JOHN H. SCHAFFNER and FRED. J. TYLER.

'Observations on the flora of the Gauley Mountains, West Virginia': W. A. KELLERMAN.

'Preliminary list of tamarack bogs in Ohio': A. D. SELBY.

'Report for 1901 on the State Herbarium with additions to the Ohio Plant List': W. A. KELLERMAN.

Joint Meeting of the Academy of Science and the Modern Language Association of Ohio. (Three titles.)

'Modern Languages and Science in High School Course': WILLIAM WERTHNER.

'Botanizing in the Colorado Mountains'—Illustrated: A. D. SELBY.

'Some notes on a trip to southeastern Siberia': GERARD FOWKE.

'Notes on Hemiptera with some records of species new to the Ohio list': HERBERT OSBORN.

'Observations on some South American Hemiptera, with exhibition of specimens': HERBERT OSBORN.

'A species of Diptera mining the leaves of wild rice at Sandusky': JAS. S. HINE.

'Experiments with chemicals to improve seed germination': W. A. KELLERMAN and F. M. SUBFACE.

'A possible cause of Osars': G. H. COLTON. Read by the secretary.

'The introduced species of *Lactuca* in Ohio': A. D. SELBY.

'Gradations between *Verbena stricta* and *Verbena angustifolia*': THOS. A. BONSER.

'New plants for the Ohio Catalogue': A. D. SELBY.

'Observations on the origin of forest belts in Clay County, Kansas': JOHN H. SCHAFFNER.

'A report on the Revised Catalogue of Ohio Birds': LYNDY JONES.

'The summer birds of Lake Erie's Islands': LYNDY JONES.

'Perverted Benevolence': GERARD FOWKE.

'Notes on *Anthurus borealis* and *Erysiphe graminis*': W. W. STOCKBEGER.

'Report on Ecology of Big Spring Prairie': T. A. BONSER.

'Some aspects of plant growth as illustrated by methods of watering': W. J. GREEN. Presented by the president.

Shall we continue the field meetings?

What places of interest to scientists or to the general public are in need of protection by the State?

In what manner may the Academy become more serviceable to the scientific interests of the State?

'An insect pest new to Ohio': F. M. WEBSTER. Read by title.

'The trend of insect migration in America':
F. M. WEBSTER. Read by title.

'A plasmodium found in the blood of a turtle
and related to the plasmodium of malaria': C. B.
MORREY. Presented by Herbert Osborne.

E. L. MOSELEY,
Secretary.

NEW YORK ACADEMY OF SCIENCES.
SECTION OF BIOLOGY.

A REGULAR meeting of the Section of Biology was held on January 13, Professor Charles L. Bristol occupying the chair. The following program was presented:

1. 'The Relation between the Variability of Cells and that of Organisms': FRANZ BOAS.

2. 'Degeneration in *Paramæcium* and so-called Rejuvenescence without Conjugation': GARY N. CALKINS.

3. 'Natural Selection in *Samia cecropia*': HENRY E. CRAMPTON.

Professor Boas, in his paper, which has been printed in full in SCIENCE for January 3, 1902, established the following conclusions: "(1) The elements of organisms are more variable than the organisms themselves. (2) The elements of organisms vary in correlated groups. (3) The characteristics of the variability of an organism depend upon the correlations of its constituent elements, so that a knowledge of these correlations will enable us to determine the characteristics of the variability of the organism." (4) It was also pointed out that skew distribution of variations does not necessarily indicate selection, or instability of type, but may occur in stable forms.

Dr. Calkins presented the history of two individuals, *A* and *B*, of *Paramæcium caudatum*, from different localities, which were isolated February 1, 1901. These were fed on twenty-four hour hay-infusion, and the number of divisions recorded at periods of from one to three days throughout the year, one individual being isolated each time. Conjugation occurred for the first time, among the extras, in May. This period was followed, in July, by well-marked degeneration of both *A* and *B*, which went so far that nearly all of the stock was lost. The survivors were stimu-

lated to renewed activity by treatment with extract of lean beef. After three months of normal and active divisions, another period of conjugation occurred. This again was followed by degeneration and again the cultures were saved by treatment with beef-extract. At the present date (January 13), *A* is in the 416th generation, and *B* in the 375th generation, and no conjugation has taken place in the direct line of the cultures. Thus far the experiments have yielded the following results: (1) *Paramæcium* unquestionably passes through more or less regular cycles of activity and weakness. (2) The period of weakness is preceded by one of greater dividing activity. (3) The period of weakness ends in death, provided the diet (hay-infusion) remains the same. (4) Beef-extract, without conjugation, restores the weakened functions of growth and division. (5) Exogamous conjugation of *A* and *B*, if followed by the same diet (hay-infusion), does not restore these weakened activities, but is soon followed by death. (6) Exogamous conjugation between wild gametes, and followed by hay-infusion diet, results in normal growth, division, and life. (7) Endogamous conjugation among gametes from the cultures does not differ from exogamous conjugation. The ex-conjugants live and divide normally if fed for a time with beef-extract, but die if fed directly with hay-infusion. (8) One intra-cellular effect of beef-extract upon weakened *Paramæcium* is the formation of 'excretory granules.' Another is the disintegration of the old macronucleus. (9) A few conclusions to be drawn are: (a) a change of diet is necessary for the continuance of vital activities; (b) the equivalent of parthenogenesis in higher animals may be induced by change in diet; (c) conjugation, by itself, does not 'rejuvenate'; (d) conjugation probably has some other significance than that usually accepted, though what this significance may be is not indicated, thus far, by the experiments.

Professor Crampton presented the results of a statistical study upon pupæ of *Samia cecropia*. Twenty-five characters were determined for a lot of 456 pupæ, the measurements were tabulated, and the usual constants of the curves of variation were ascertained, viz., the

range, mode, mean, standard deviation and coefficient of variability. It was found that only 349 of these pupæ produced perfect moths at the time of metamorphosis, the others being imperfect to a greater or less degree, and therefore presumably ruled out as far as reproduction is concerned. When, now, the former class was compared, sex by sex, with the whole group of pupæ, it was found to be a selected class of the less variable individuals, while the more variable ones were eliminated. Selection is therefore 'periodic' in the sense of Pearson. The fact of primary interest appears when this case is contrasted with that of *P. cynthia*. As reported last spring, selection in the latter species is similarly of the less variable individuals, but is 'secular' as well, that is, the perfectly metamorphosing pupæ form a class by themselves, with a type which differs from that of the whole group. It was pointed out that the real basis of selection was probably a correlative one, a physiological 'fitness' depending upon the proper coordination or correlation of the various parts of the organism.

HENRY E. CRAMPTON,
Secretary.

SECTION OF ASTRONOMY, PHYSICS AND CHEMISTRY.

THE Section met at the Chemists' Club on the evening of January 6. Mr. H. C. Parker gave the results of some experiments he had made on the 'Variation of Contact Resistance with Change of Electromotive Force.' The resistances used in the experiments consisted of oxide of manganese on cobalt glass, the new form of standard high resistance described in a previous paper given before the Academy. The electromotive forces employed consisted of 10, 50 and 100 dry cells, respectively. It was found in every case that the resistance decreased with increase of electromotive force. This decrease might be only a small percentage, or the resistance might be reduced to a small portion of the original value. Improving the contacts rendered this change in resistance much less marked. It was stated that the decrease in resistance when the electromotive force was increased might possibly be due to a kind of coherer action taking place

at the contacts. Very high resistances, measured by the electrometer method, were found to practically obey Ohm's law. It was pointed out that in such cases the contact resistance was probably only a small portion of the entire resistance.

Professor Hallock presented a paper on the 'Magnetic Deflection of Long Steel Wire Plumb-lines.' He stated that in the course of the work in the very deep shaft of the Tamarack Mining Co. on Lake Superior it had been found desirable to plumb down certain points from the surface. The plumb-lines used were of No. 24 piano wire and the weights were fifty pounds of iron. At first the lines were 16.33 feet apart at the top and they were later moved to 17.66 feet. The remarkable observation was made, that in the first case they were 0.08 ft., and in the second case 0.07 ft., further apart at the base than at the top. It was pointed out that a deflection of such an amount could not be explained as due to the gravitational attraction of the walls of the shaft for the nearer plumb-bob. Professor Hallock suggested that the effect was probably due to the magnetization of the wire and the consequent repulsion of the north poles at the bottom. In order to test the possible applicability of this theory a number of experiments were made in the research shaft at Columbia University which gave much corroborative evidence. Two plumb-lines about 85 ft. long were suspended in the shaft. One was of copper wire and the other of iron wire, about 0.03 in. in diameter. Lead weights were attached and it was found that the lines were about $\frac{1}{2}$ in. closer together, at the bottom, when the iron line was south of the copper than when it was north. Two lines of iron wire were also used and the distance apart at top and bottom measured. The deflections obtained were of the same order of magnitude as those produced by the earth's field. The deflections, thus obtained, give evidence of the action of magnetic forces of sufficient magnitude to explain the deviations observed in the plumb-lines in the Tamarack shaft.

Professor Hallock also described a form of recording thermometer which he had lately devised. It consists of a large copper bulb

which was connected by means of capillary copper tubing to a series of cells similar to those used in the construction of aneroid barometers. The bulb, tube and cells, were filled with oil and the recording mechanism attached to the aneroid cells.

F. L. TUFTS,
Secretary.

PHILOSOPHICAL SOCIETY OF WASHINGTON.

At the 545th meeting, held on January 18, 1902, Mr. L. P. Shidy, Chief of the Tidal Division, Coast and Geodetic Survey, gave a brief 'Explanation of the Currents in Unalga Pass, Aleutian Islands, Alaska.' Dr. Dall spoke of the difficulties of navigation in this pass when there is a strong current, and of the unaccountable dying away of the wind near the center of the pass.

He said that these currents seem to conform to Torricelli's theorem for the flow of liquids

If we extract the square root of $2g$, we have

$$V=8.0215 \sqrt{d} \text{ feet per second,}$$

or converting this into nautical miles per hour, it becomes

$$V=4.75 \sqrt{d} \text{ knots,}$$

in which d is expressed in feet, as before.

The tides at each end of Unalga Pass were tabulated in the accompanying table.

The computed velocities of the current in the given table were obtained by the application of Torricelli's theorem. It may be remarked that there is, in general, a satisfactory agreement between the observed and computed velocities. The times of changing direction of flow are correctly given by computation, and the interesting phenomenon which occurred at 16 hours on June 14, 1901, where the southerly current had decreased to 1 knot, and then increased again without reversing its direction, is reproduced by computation within small limits of error.

TIME.	TIDE.		CURRENTS.	
	South End of Pass.	North End of Pass.	Computed.	Observed.
12 = Noon.				
Hour.	Feet.	Feet.	Knots.	Knots.
June 14, 1901				
8	3.14	2.91	+ 2.3	+ 2.6
9	3.75	3.20	+ 3.5	+ 3.7
10	4.38	3.87	+ 3.4	+ 3.1
11	5.00	4.69	+ 2.6	+ 1.9
12	5.66	5.63	+ 0.8	+ 0.6
13	6.31	6.38	- 1.2	- 1.1
14	6.86	7.12	- 2.4	- 2.4
15	7.21	7.34	- 1.7	- 1.7
16	7.20	7.28	- 1.3	- 1.0
17	6.84	7.03	- 2.1	- 1.8
18	6.68	6.89	- 2.2	- 2.0
June 15, 1901				
8	2.86	3.17	- 2.6	- 2.4

10	3.78	3.22	+ 3.6	+ 3.8
11	5.22	3.75	+ 5.7	+ 5.8

due to a difference of head, which may be expressed thus:

$$V=\sqrt{2gd} \text{ feet per second,}$$

where $g=32.1722$ feet = the velocity of a falling body at end of first second, and d = the difference in feet between the elevation of the water surfaces at each end of the strait.

Professor J. H. Gore gave an account of the proposed 'Draining of the Zuider Sea,' illustrated by many lantern slides. The old plans have been found commercially impracticable, and the plan definitely recommended by a large Commission appointed in 1892 is the following: Only those portions are to be reclaimed that have a clay bottom; this leaves free

the mouths of the rivers and the present lines of water communication. First, a great sea dyke should be built at the north end with many locks, and with sluiceways to allow drainage at low tide; this will require some ten years and cost \$16,000,000. Then a tract of 52,000 acres in the N. W. part should be dyked and drained, requiring five years and \$5,000,000. Continuing the work, in all about a million and a quarter acres would be reclaimed in thirty-three years' time at a cost of \$69,000,000. Experience shows that such lands can be rendered arable in about three years; and it is estimated that they could be rented by the state at \$7 per acre per year. The report is a model of thoroughness for its consideration of every interest involved. The project now awaits the consideration of the legislative body.

CHARLES K. WEAD,
Secretary.

THE ELISHA MITCHELL SCIENTIFIC SOCIETY.

THE Society held its one hundred and thirty-eighth meeting on Jan. 21 at the University of North Carolina. The following papers were read:

'Recently Discovered Minerals in North Carolina': J. H. PRATT and COLLIER COBB.

'Arizona, Its Mineral Wealth': J. H. PRATT.

CHAS. BASKERVILLE,
Secretary.

DISCUSSION AND CORRESPONDENCE.

THE DAILY BAROMETRIC WAVE.

IN the *Monthly Weather Review* for Nov., 1901, Dr. O. L. Fassig has an interesting article on 'The Westward Movement of the Daily Barometric Wave.' The article is illustrated by charts showing the lines of equal pressure departure in the western hemisphere for each hour of the day for the month of July. Dr. Fassig's study was suggested by my own paper on the eclipse cyclone and the diurnal cyclones, but he was the first to complete charts of this kind and his charts add much to a knowledge of the behavior of the daily barometric wave and will no doubt aid materially in clearing up the cause of this wave.

The charts show very clearly that the diurnal areas of high and low pressure have distinct centers like the cyclones and anticyclones of the weather map, but unlike the latter move rapidly toward the west instead of toward the east. Moreover, the charts show very strikingly the effect of ocean and continent on the depth and position of the diurnal areas of high and low pressure, and one can scarcely doubt that surface heat and cold play a very important part in their formation.

Particularly instructive in this connection is the behavior of the early morning minimum of pressure. At 2 a. m., 75th meridian time, it is chiefly over the two Atlantic oceans, and is central over the North Atlantic, the cold ocean at this time of year when contrasted with the surrounding continents. Between 3 a. m. and 6 a. m. this barometric minimum passes over the land areas of North and South America and then the low pressure is found central over the cold southern continent where winter prevails, and the pressure scarcely falls below normal in the warmer northern continent. These facts appear to point very clearly to the dependence of this depression on a relatively low surface temperature, and are in line with the suggestions in my papers on the eclipse cyclone and the diurnal cyclones, namely that the morning minimum of pressure is the result of a cold air cyclone.

The afternoon barometric minimum moves from South America to North America during the afternoon following the place of highest temperature, thus indicating its dependence on surface heating.

Mr. Fassig does not state from what source his data are obtained. In drawing my own charts I have found a great scarcity of data from over the Pacific Ocean. The data for South America will be greatly added to when Professor Bailey's observations are published in the *Harvard Annals*. In constructing my own charts I scaled off the values at his stations from the curves published by him in the *American Meteorological Journal*, Vol. XII., p. 331.

H. H. CLAYTON.

NOTES ON INORGANIC CHEMISTRY.

NEW BORIDS.

AMONG the compounds which the high temperature of the electric furnace has rendered easy of preparation are the borids of the metals, few of which were known until within the last decade or so. Moissan has described the borids of the alkaline earths, of iron, nickel, and cobalt, and of carbon and silicon. In the last number of the *Journal of the Chemical Society* Tucker and Moody recount the preparation of the borids of chromium, molybdenum and tungsten, and of zirconium. All were made by heating the mixed elements in the electric furnace, and are crystalline bodies of great hardness; they are but slightly attacked by hot concentrated acids, except that the molybdenum and tungsten borids are vigorously acted on by hot aqua regia. The formulas obtained by analysis are, CrB , Mo_2B , WB_2 , and Zr_2B_3 . The authors suggest that as a consequence of their high fusing point, hardness, and good crystallization, it is quite possible that some of these and other borids may prove to have industrial uses.

ETHYLENE FROM INORGANIC SOURCES.

IN a recent *Journal of the Society of Chemical Industry* the same authors describe the production of ethylene from inorganic sources. Since calcium carbide when treated with water evolves acetylene, and aluminum carbide evolves methane, it was hoped that a mixture of these carbids would give ethylene, but this was found not to be the case; only acetylene and methane were obtained. When, however, a mixture of barium silicide, which evolves hydrogen, with calcium carbide is decomposed by water, ethylene is present in the evolved gases to the extent of two per cent. If barium carbide is substituted for the calcium carbide, the gases contain up to fifteen per cent. of ethylene.

ORGANIC ARAGONITE AND CALCITE.

A NEW reaction to distinguish between aragonite and calcite is given by W. Meigen in the *Centralblatt für Mineralogie*. The finely powdered substance is boiled for a few moments with a dilute solution of cobalt nitrate. In the presence of aragonite a lilac

red precipitate of basic cobalt carbonate is formed, while calcite remains uncolored even after prolonged boiling, or is occasionally colored yellow. Magnesium carbonate is also unchanged in color and calcium phosphate gives a blue precipitate. Using this diagnostic reaction upon shells, corals, and other animal remains, both recent and fossil, the author gives long lists of those consisting of aragonite and calcite respectively. No rule of distribution is apparent from his lists; most orders, recent and fossil, are represented in both classes. The larger number of corals are aragonite, but corallium and tubipora are calcite; the outer shell of trigona is calcite while the inner shell is aragonite; the argonauts are calcite but nautilus and sepia are aragonite; hens' eggs are calcite.

UTILIZATION OF FLUORIN FROM FERTILIZER PLANTS.

WHEN natural phosphates are decomposed by sulfuric acid in the manufacture of superphosphate fertilizers, there is a considerable quantity of hydrofluoric acid set free as such, or as fluoride of silicon. This is especially the case when apatite is used; indeed this fact detracts very materially from the value of the immense apatite deposits of Canada. In Germany manufacturers are compelled by law to prevent the escape of these deleterious gases into the atmosphere and efforts are being made to utilize the waste product. By leading the gases through water, fluosilicic acid is formed and from this solution sodium fluosilicate or magnesium and aluminum fluosilicates may be readily prepared. The last two have some use in hardening calcareous stone. More recently it has been discovered that fluosilicic acid has strong antiseptic properties and that as a preservative of manure it surpasses plaster, kainite or superphosphate of lime. The denitrifying action of bacteria is checked, preventing the loss of nitrogen. The greatest difficulty in the way of its adoption for this purpose is its preparation in suitable form. The aqueous acid in bottles would hardly be acceptable to the farmer and no satisfactory absorbent of the acid has been found. A patent for a new manure preservative has recently been taken out, in which the fluosilicic acid

is incorporated with clay, with the bases of which it for the most part combines. With this powder goes another consisting of a porous substance saturated with sulfuric acid. A small quantity of each powder is scattered over the manure pile and by the action of the sulfuric acid on the fluosilicates fluosilicic acid is generated which acts as an antiseptic. In describing this process in the *Chemiker Zeitung* C. Elschner suggests that it would be more economical to absorb the gases directly by lime and then dry the calcium fluosilicate formed, and that a powdered bisulfate could be more advantageously used than sulfuric acid. Should some practicable method be devised for utilizing these noxious gases it would give great value to many apatite deposits which contain too much fluor spar to be utilized at present.

A GYPSUM WEATHER-SCALE.

AROUND the 'Stone Gallery' at the base of St. Paul's Cathedral is a balustrade of Portland stone, surmounted by a heavy coping of the same material. All of the stone is greatly weathered and coated with a gray or black deposit, much resembling boiler scale. Under the coping this attains a thickness of three-quarters of an inch. An examination of this deposit is given by E. G. Clayton in the *Proceedings* of the Chemical Society. It contains no fungoid matter, and contrary to expectation no carbonates were found in it. It is essentially calcium sulfate, with a small amount of silica. Since there is no neighboring source of sulfates the conclusion is reached that it has been formed by two centuries' solvent and weathering action of rain, charged with sulfurous and sulfuric acids derived from the gases and smoke of innumerable surrounding chimneys. The rain water, running and dripping from the under side of the coping stone, has here left an especially thick deposit, which presents a curiously close resemblance to a deposit of calcareous tufa.

J. L. H.

CURRENT NOTES ON PHYSIOGRAPHY.

PHYSIOGRAPHY OF WISCONSIN.

COLLIE has contributed two articles on the physiography of his State. The first ('Physi-

ography of Wisconsin,' *Bull. Amer. Bureau Geogr.*, II., 1900, 270-287) is a general and elementary account, giving fuller statement of features due to glacial action than to those determined by the underlying rock. The second ('Wisconsin shore of Lake Superior,' *Bull. Geol. Soc. Amer.*, XII., 1901, 197-216) is the result of detailed local study, with special reference to shore features in the neighborhood of the Apostle Islands. These islands consist of horizontal sandstones, usually cliffed and caved along the waterline, but also modified by bars and spits, of which the largest encloses Chequamegon bay.

In both these papers the bluff by which descent is made from the northwest border of the uplands of disturbed Keweenawan rocks to the lower land of horizontal sandstones bordering Lake Superior is described as a fault scarp, 'formed by the movement of rocks one upon the other, * * * particularly noticeable because it is not formed, as most of the Wisconsin cliffs are, by erosion.' This interpretation of the recency of the fault is novel. The considerable erosion indicated by the truncation of the upturned edges of the sandstones near the fault line throws some doubt upon the accuracy of Collie's view; should it be proved correct the scarp would be an interesting addition to our physiographic types, for faults that are young enough to preserve something of their initial topographic expression are rare in the eastern half of our country.

GLACIAL EROSION IN SKYE.

THE laccolithic mass of the Island of Skye, west of Scotland, was deeply dissected in preglacial time. During the glacial period, its mountains bore local glaciers, whose eastern members stemmed the great ice sheet that came westward from the Scotch highlands, dividing it into two parts which flowed northwest and southwest out to sea. The effects of the Skye glaciers as agents of erosion have lately been studied by Harker ('Ice Erosion in the Cuillin Hills, Skye,' *Trans. Roy. Soc. Edinburgh*, XL., 1901, 221-252, map). He finds that the floors and walls of the ice-scoured valleys exhibit much less relation to rock structure than is usual in districts of

subaerial erosion only, and regards this as a natural consequence of the massiveness and relative rigidity of the ice streams. The valleys are comparatively straight, with broad floors and rather smooth and steep sides, heading in amphitheatres or corries that seem unduly large for their drainage areas. The valley floors frequently descend by abrupt slopes to lower and lower levels. Rock basins, excavated in the valley floors, and holding lakes, are justly regarded as subordinate and incidental to the general scouring of the shallower and narrower preglacial valleys to their present trough-like form. Short side glens open characteristically on the walls of the larger valleys to which they are tributary. The divides between the uppermost corries of the main valleys are sharply serrate, in consequence of the retrogressive erosion of the glaciers that headed in the corries, as has been pointed out by Richter for the Alps, and by Matthes for the Big Horn range of the Rocky mountains.

The comparison instituted by Harker between rivers and glaciers is not altogether satisfactory inasmuch as it fails to point out certain similarities between the two. It is stated that, 'the bed of a river which has attained a mature state maintains a steady gradient so long as the volume of water is unchanged'; but it is the surface, not the bed, of the river that should be thus described. The bed of a mature river, such as the Mississippi, has numerous hollows, whose dimensions are to those of the river in about the same proportion as the dimensions of rock basins are to those of the glaciers that scoured them out. When a mature river crosses a reef of resistant rocks, it habitually sweeps out a shallow basin-like depression in the weaker rocks next up stream; while another basin may be eroded by the plunge of the waters down stream from the reef. Rivers whose volume is greatly reduced in the dry season exhibit the hollows in their bed as a series of pools strung together by the diminished stream. It therefore seems wrong to say that 'ice erosion does not, like water erosion, work constantly towards the establishment of an even gradient along a valley.' Both tend to

establish even gradients in their surface; both produce inequalities in their beds; the inequalities of a river bed receive little attention; they are comparatively small and are usually out of sight; the inequalities in the beds of existing glaciers are even less open to observation, although it can hardly be doubted that they exist. The inequalities in the beds of extinct glaciers are often so large and so plainly visible that their analogy with the hollows in river beds is too commonly overlooked.

THE SEVERN BORE.

A SERIES of views of the Severn bore taken with a bioscope camera by Vaughan Cornish was thrown on the screen at a meeting of the Royal Geographical Society of London in November last, the first cinematographic illustration of this tidal phenomenon. Four of the views are reproduced in the *Geographical Journal* for January, 1902, and show the approach and passage of the bore with some distinctness. Cornish proposes to make similar studies of other tidal rivers. His well-known studies of rippled sands, under waves, tides and winds have been published in recent years.

W. M. DAVIS.

RETIREMENT OF MONSIEUR HATON.

THE report of the proceedings at a meeting of the faculty, alumni and friends of M. Haton de la Goupillière on the occasion of his retirement from the directorship of l'École nationale supérieure des Mines, accepting Vice-Presidency of the Conseil général des Mines is just distributed. This ceremony took place June 8, 1901, in the great auditorium of the Société d'Encouragement. The list of contributors numbered 580 and the farewell offerings were numerous and various, including a bust of M. Haton and bronzes by Dubois and others. The bust is reported to have proved a very accurate likeness of its distinguished original. The addresses were made by M. Carnot, Director of the Ecole des Mines, and M. Lemonnier, president of the Association.

M. Haton was 'élève ingénieur' in 1852, when about 20 years of age, was made professor in the preparatory course immediately on graduation as Ingénieur, taught general

chemistry in 1855 and mathematics pure and applied; in 1872 he became professor in the course then including machines and exploitation of mines, and became director of the School of Mines in 1887, where he remained until the end of the XIXth century, nearly a half-century of continuous service, substantially all at l'Ecole des Mines. His principal works had meantime been published, on 'Mines and Mining' and on 'Thermodynamics and Motor-Machines.' He had been called to serve on several international juries, and on various commissions, and had earned many honors, including that of Member of the Institute in 1884 and of 'grand-officier' of the Legion of Honor in 1900.

In replying to the cordial and eloquent addresses of MM. Carnot and Lemonnier, M. Haton stated that alumni of the school had supplied 39 members of the Institute and 8 'Correspondents':

"Hommes d'action, hardis explorateurs, chez de grandes industries, ingénieurs chargés de la conduite des travaux ou des affaires, ils soutiennent dans le monde entier le bon renom de l'École."

The *Compte Rendu*, as its frontispiece, has an excellent portrait of M. Haton de la Goupillière. It indicates that its original retains his youth and vigor wonderfully and we may hope for him many more years of active, fruitful and honorable life. His friends in this country will cordially unite with those about him in wishing for him 'many happy new years.'

R. H. THURSTON.

SCIENTIFIC NOTES AND NEWS.

PROFESSOR E. C. PICKERING has completed twenty-five years of service as director of the Harvard College Observatory, and in recognition of the fact the staff of the Observatory has presented him with a silver cup.

THE condition of Professor Rudolf Virchow, who recently suffered an injury from a fall, causes apprehension to his physicians.

DR. W. W. KEEN, who is at present in India, recently fell from his horse, fracturing one of his clavicles. The accident was not serious.

THE daily papers state that President Roose-

velt has overruled the decision of Secretary Long to send Capt. Charles H. Davis, superintendent of the Naval Observatory, to sea.

DR. HENRY B. KÜMMEL was appointed state geologist of New Jersey by the board of managers of the Geological Survey at their meeting on January 10. Mr. Kümmel has been connected with the Survey since 1892, and since 1899 has been assistant state geologist, being in charge of the work since Dr. Smock's resignation last July. He is a graduate of Beloit College, A.B. 1889, and did post-graduate work in geology at Harvard University, and the University of Chicago, from which he received the degrees of A.M. and Ph.D. respectively. He was elected a fellow of the Geological Society of America in 1895.

SAMUEL McCUNE LINDSAY, assistant professor of sociology in the University of Pennsylvania, has been nominated for Commissioner of Education in Porto Rico.

THE Paris Academy of Medicine has awarded its Hugo prize of \$200 for the best work on the history of medicine to Dr. Melanie Lapinska for her book on the history of women physicians.

DR. CHARLES H. BURNETT, a well-known writer on diseases of the ear, died at Bryn Mawr, Pa., on January 30, aged sixty-one years.

LIEUTENANT VON SIEGSFELD, after a balloon ascension from Potsdam to study artificial respiration, was killed in the descent.

THE American Philosophical Society, Philadelphia, has arranged for a general meeting on April 3 and 4, and a large number of scientific men from all parts of the country have signified their intention of being present. Members wishing to present papers are asked to communicate the titles to the secretaries without delay, so that they may be inserted in the preliminary program which will be issued as soon after February 15 as practicable. Members expecting to attend the meeting are requested to notify the secretaries at as early a date as possible so as to facilitate the arrangements for their entertainment.

THE 'Leopoldinisch-Carolinische Akademie deutscher Naturforscher,' now in Halle, cele-

brated the two hundred and fiftieth anniversary of its foundation on January 1. The academy, under the name, 'Academia Naturæ Curiosorum,' held its first meeting in Schweinfurt on January 1, 1652, and is thus the oldest academy of sciences north of Italy, the Royal Society having been established in 1662, and the French Academy in 1666. The academy began the publication of proceedings in 1670 and enjoyed extraordinary privileges, the president and secretary being elevated to the nobility, the former with the rank of count. At the present time the Academy has about nine hundred members and is planning for the erection of a new building.

THE Association of American Universities will hold its annual meeting at Chicago on February 25, 26 and 27.

PRESIDENT HADLEY, of Yale University, will give six Lowell lectures at Boston on 'The History of Academic Freedom.'

PROFESSOR B. E. FERNOW, of the College of Forestry, Cornell University, will lecture in Ottawa, Canada, on March 6, before the Canadian Forestry Association.

UNDER the auspices of Columbia University, Professor William D. Burr is giving at the Cooper Union the following lectures on mechanical engineering:

February 4, 'Ancient Civil Engineering Works.'

February 11, 'Bridges.' The latter portion of the lecture will include the treatment of masonry arches and suspension bridges, with examples of applications to the longest spans yet contemplated.

February 18, 'Water Works for Cities and Towns.'

February 25, 'Some Features of Railroad Engineering.'

March 4, 'Nicaragua Route for the Isthmian Ship Canal.'

March 11, 'The Panama Route for the Isthmian Ship Canal.'

The lectures will be issued in book form by the Columbia University Press.

THREE lectures, in German, by Max Uhle, Ph.D., Hearst lecturer in anthropology, and director of the excavations and explorations of the University of California in Peru, are being given as follows:

February 3 and 5, 'The Sources of Ancient Peruvian Civilization.'

February 10, 'Some Incasic Ruins of Central-Peru.'

ARTHUR CURTISS JAMES, Esq., has purchased the collection of Ainu objects made by Professor Bashford Dean last year and has presented it to the American Museum of Natural History. The Museum has also received from Mr. W. Jochelson, of the Jesup North Pacific Expedition, his Koryak collection from Siberia, consisting of about 1,200 pieces, among which there are many objects of prehistoric age.

PROFESSOR J. S. KINGSLEY, Tufts College, announces that the summer school of biology known as the Harpswell Laboratory, established at South Harpswell, Maine, in 1898, will be open from June 16 to September 13, 1902; the regular courses of instruction beginning July 2, and continuing for six weeks. The laboratory is a small wooden building directly on the shore and affords accommodations for fifteen or twenty students. South Harpswell is in Casco Bay, sixteen miles from Portland, from which place it is reached by steamer. Casco Bay has a rich fauna and flora and is not excelled as a collecting ground by any point between Eastport and North Carolina. Already 529 species of invertebrates have been reported from its waters and many novelties turn up each season. South Harpswell itself is well situated, being at the extremity of a narrow peninsula, ten miles in length, thus ensuring freedom from hot weather. In 1901 the thermometer did not reach 80° in the laboratory.

THE New York State Medical Society at its session in Albany on January 29 received recommendations of the legislative committee as follows:

That local Boards of Health be requested to follow the work of the Milk Committee of the New York City Medical Society in the efforts made to provide pure milk.

That the recommendation making toward the establishment of a National Health Board, with a representative in the President's cabinet, be indorsed.

That the questions involved in Dr. Koch's pa-

per at the London Tuberculosis Congress upon 'The Communicability of Bovine Tuberculosis' invite further experiments in this field before any conclusions can be drawn that would modify existing methods for dealing with the disease.

THE report of the library committee for 1901 of the College of Physicians of Philadelphia, as abstracted in the *Philadelphia Medical Journal*, shows 64,916 volumes in the library, including 1,070 duplicates. 4,079 volumes have accumulated since July, when all duplicates on hand were disposed of. In addition to the volumes, there are in the library 58,395 unbound pamphlets, reports and transactions. The library regularly receives 356 medical periodicals, 86 of which are American, and 270 foreign. 2,212 inaugural dissertations have been received during the year.

At a meeting of the Royal Institute of British Architects on January 21, a paper on 'The Recent Architectural Discoveries at Stonehenge' was read by Mr. Detmar Blow, who, with Dr. Gowland, superintended the excavations which were made in October last for Sir E. Antrobus. Mr. Blow, according to the report in the *London Times*, pointed out that the great monolith called the leaning-stone was the largest in England, Cleopatra's needle excepted. It was one of the pillars of the highest trilithon, and stood behind the altar-stone near which it leaned at an angle of 65 degrees. Half-way up it had a fracture one third across it; and the weight of stone above that fracture was a dangerous strain on it. It had now been brought to a vertical position. One Roman coin and one George III. penny were found quite near the surface. Numerous chippings of the sarsen and blue stone of which Stonehenge was built were discovered. The flints found were used for the softer sarsen and blue stones, and the hand-hammers and mauls for rough dressing. From this the deduction had been made that the building belonged to the Palæolithic period. All authorities agreed that it was the work of a highly civilized people. The construction was one of a stone development and the surface of the stone was finished much like that of granite. The design of the pillars was in his opinion evolved from the shapes of the flint instru-

ments used by the workman, to which his hand had grown accustomed. Each pillar had a bold entasis in its elevation, and in its plan foreshadowed the column. With the aid of the illustrations he described the method of raising the leaning stone and the sifting process, the articles found being afterwards shown to the audience. Stonehenge having been generally supposed to be of the bronze age, it was with great joy that he lighted upon the stone implements. It was, he believed, the only occasion on which the implements were found actually next to the stone building where they were used. Sir Norman Lockyer, in opening a discussion on the paper, said he believed archeologists had come to the conclusion that, from the evidence which had been obtained, they were justified in assuming that the sarsen stones were erected in the Palæolithic times—that was to say, before the age of bronze, or at all events before bronze had been used for any ordinary kind of work in that part of England. Before the excavations were commenced Mr. Penrose and himself had been occupying themselves with Stonehenge from a slightly different point of view. They were very anxious to determine its age, and it was found much easier to get certain astronomical data from Stonehenge owing to its position than from other ancient monuments. He gave a number of astronomical data in support of his assumption that Stonehenge was a solar temple and one used for observation in the height of summer. From their observations they came to the conclusion that the avenue which was associated with the sarsen stones was laid down about the year 1680 B. C. Such temples as Stonehenge were erected in the very first blush of civilization in order that the people should be able to fix the time for performing agricultural operations. He thought that Mr. Penrose and himself had been able to show beyond all doubt that we had in Stonehenge a temple for observing the length of the year by observing the rising of the sun on the longest day of the year, although in other parts of England there were temples for observing the sun not on June 21 but early in May and early in August.

THE *American Museum Journal* reports

that through the generosity of a friend of the Museum, who desires to have his name withheld from the public, six groups have recently been added to the very attractive and instructive series representing birds amid their natural surroundings which are to be seen in the halls of the Ornithological Department. The new groups represent the American dipper, or water-ousel, the osprey, the yellow-headed blackbird, the coot, Wilson's phalarope and the wild pigeon. The material for the first-named was gathered by Mr. Frank M. Chapman last summer on the banks of a rushing icy stream issuing from a glacier in the Selkirk mountains of British Columbia. The rocky bank of the stream, the nest in the cleft of the rock and the birds in and about the nest have been reproduced with lifelike fidelity in the Museum exhibition case. Mr. Chapman collected the specimens and accessories for the osprey group on Gardiner's Island, off the eastern end of Long Island, and those for the blackbird, coot and phalarope groups at Shoal Lake, Manitoba. The twelve specimens included in the wild-pigeon group were secured with much difficulty from collectors and dealers throughout the country, the surprising fact being incidentally developed that a species which, within the last fifty years, was one of the most abundant native birds of this country, is now so rare, not only in nature, but also in collections, that specimens of it are practically unobtainable. Each of these new groups is designed to illustrate not only the haunts and habits of a species of birds, but also some fact of general biological interest. This feature will be fully set forth in the labels accompanying the cases.

At the annual meeting of the Mathematical Association, London, Professor A. Lodge read a paper introducing for discussion the subject of improvements in the teaching of elementary mathematics. According to the report in the *London Times* he explained that the special object in bringing the whole question forward now was to enable the Association to cooperate with the British Association committee formed for the purpose at the Glasgow meeting last year. Many teachers had been for a long time

aware that the teaching of geometry in this country was suffering from its being based on a fixed ancient model which, however excellent, was not in many respects satisfactory as a text-book for beginners. The efforts hitherto made had been powerless to make any appreciable effect on the action of the great examining bodies in the country, and without their cooperation much progress was not possible. Now, however, with the powerful leverage of the British Association to assist them, the Association might confidently look for real and lasting progress. The best method of teaching geometry would, no doubt, be the question which would require most attention, as that was a matter in which all, teachers and examiners, must move together if at all. Men came up to engineering colleges who were slow and inaccurate in computation, who did not know the contracted methods of multiplication and division, who were as likely as not to put the decimal point in the wrong place. They wanted boys taught to be ready and rapid computers, to be able to make rough checks on their own work so as to avoid gross errors, to cultivate common sense in connection with problems, and to be in the habit of verifying answers. It had to be remembered that the pupil's mental equipment was chiefly arithmetic and algebra, and his geometry should be built on these notions as much as possible, instead of being carefully divorced from them, as was done in so many text-books. It would be advisable at the outset to adopt some French text-book as our model. The Americans had done so already, and the chief points in their books were: (1) The more orderly arrangement of propositions; (2) the entire separation of theorems from problems of construction, hypothetical constructions being used in proving a theorem; (3) the closer association of a proposition and its converse when both were true; (4) the adoption of arithmetical notions and algebraic processes; (5) the early introduction of simple *loci*; (6) insistence on accurate figures drawn by accurate and practical processes; (7) practice in exercises from the very beginning. It had been suggested that he should add, 'Attention paid to the various phases of a theorem as the figure

changes, and (as the student progresses) to the easier forms of generalization.' The greater part of these improvements could be adopted at once, provided that the sanction of the great examining bodies could be obtained. In conclusion he urged on all who were convinced that reform in geometrical teaching on some such lines as he had indicated was urgent and imperative that they should not rest content until some at least of the reforms were sanctioned by the great public examining bodies. The meeting ought not to conclude without appointing a strong committee to keep in touch with the British Association committee.

UNIVERSITY AND EDUCATIONAL NEWS.

MR. JOHN D. ROCKEFELLER has offered to give \$1,000,000 toward the construction, equipment and endowment of the new buildings of the Harvard Medical School, on condition that \$500,000 be secured from other sources.

ALLEGHENY COLLEGE has recently added two hundred thousand dollars to its endowment fund through the efforts of the president, Dr. Wm. H. Crawford.

DR. NICHOLAS MURRAY BUTLER will be installed as president of Columbia University on April 19. The ceremonies will be similar to those on the occasions of the installations of Presidents A. P. Barnard and Seth Low. The charter and keys of the University will be presented by Mr. William C. Schermerhorn, chairman of the board of trustees, to the president-elect, who will respond briefly, and who in turn will be succeeded by speakers representing faculty and alumni. Brief speeches of greeting will be made by Presidents Eliot and Hadley and by representatives of other universities, and the program will conclude with the president's inaugural address.

REV. DANIEL S. BRADLEY, of Grand Rapids, Mich., has been elected president of Iowa College, Grinnell, Iowa.

THE Supreme Court has dismissed the suit of the New York University against the Loomis Laboratory to gain possession of its property.

OWEN'S COLLEGE, Manchester, will celebrate

in March the fiftieth anniversary of its foundation.

PROFESSOR HUGO MÜNSTERBERG, as chairman of the philosophical department of Harvard University, is making special efforts to secure funds for the erection of a building for the department, to be known as Emerson Hall. Plans have been drawn by Mr. A. W. Longfellow, according to which the hall is to be a three-story structure, of red brick. On the first floor there will be small recitation rooms and one large lecture hall, seating 400 students. The rest of the floor will be taken up by a philosophical library, comprising an extensive collection of philosophical works. The second story will contain small recitation rooms and seminary rooms for advanced work. The entire third floor will be used for a psychological laboratory. There will be one large room, where work of a general character may be done. The rest of the laboratory will be divided into fifteen sections, each of which will be specially equipped for certain specific branches of the subject.

It appears that the elective courses of the junior year at Yale University have been selected by students, as follows: History 390, English 374, philosophy and psychology 336, social science 323, German 117, French 97, Latin 36, Greek 21, geology 112, chemistry 85. Philosophy and psychology were last year made elective for the first time and are doubtless more popular than when they were required. The classical languages appear to fare badly, for it is probable that only those who carry them into the junior year get an adequate return for required routine work of previous years.

THE reorganization of the faculty of the Imperial University at Peking, with the retirement of President Martin, is contemplated. He criticised the government severely after the siege of the legations, but his age is the principal reason for his removal.

R. J. PARANJPE, the Hindoo who was senior wrangler of Cambridge University three years ago, has returned to his native country, and has been given a professorship at Fergusson College, Poona.

WITH the first year of the new century new conditions have arisen which profoundly affect all problems of cooperation between the national scientific societies. The project which emanated from the American Association for the Advancement of Science to establish Convocation Week has made, as you all know, so great progress that we are now meeting for the first time in this week set apart by the action of numerous universities for the purpose. The Association also has sought to establish wider and more numerous affiliations, such as long existed between it and several important national societies. For many years it has been the rôle of the Society of Naturalists to act as the organ of affiliation for societies which are concerned with the various branches of natural history, and which have been accustomed to meet during the Christmas recess. But the Association is now intending to meet at this period and we may safely entrust the function of establishing affiliation between the representatives of the various sciences in America to this larger body which can include all the branches of science.

A few words as to the history of our

* Annual discussion before the Chicago meeting of the American Society of Naturalists and Affiliated Societies.

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

Society. It was founded in 1883 under the title of the Society of Naturalists of the Eastern United States. It owes its birth to the action of Professor Hyatt in formulating and proposing the plan, in accordance with which the Society was actually organized, and in interesting others in its establishment. The first secretary was Professor S. F. Clark, now of Williams College. The first meeting was a small gathering at Springfield, Mass., on the 10th of April, 1883. Unfortunately Professor Clark was obliged to resign his office as he was going abroad. For some time it seemed doubtful whether the Society would get beyond its first meeting. I was then asked by Professor Hyatt to act as secretary, and during the remainder of that year I carried on an extensive correspondence with the professional naturalists of the country and nearly all of those who were invited accepted membership.

It was then decided to hold a meeting in New York, December 27 and 28 of that same year. We started with 109 original members, of whom there still remain in the Society not less than 39. At the close of the first meeting the membership had risen to 133 and we have now nearly 250. The original scope of the Society was to have papers on methods of investigation, on technique, on museum administration and devices and on methods of instruction; and in fact at our early meetings many such papers, both of value and of interest, were presented. In 1886 the name was altered to '*The American Society of Naturalists.*' You are all familiar with the gradual change which has come about and know that at present our functions at our annual gatherings are confined to a discussion on some topic of general interest, to a social dinner and to the presidential address. Many of these addresses in the past have been of a noteworthy character, and we are anticipating an address from our president

this year which will well sustain the high standard set by even his most distinguished predecessors.

The most important achievements of the Society have been somewhat different from what was foreseen at the time of its organization. It has, of course, accomplished a great deal in the general promotion of natural science. Its meetings have done that. But perhaps more important than this somewhat general fact have been certain specific results which have been attained by the Society. It was, I think, the very first society of national scope which confined its membership strictly to professional scientific investigators, and the rule adopted by the Society for determining what constituted a professional naturalist was very strict and has been well enforced. Many other societies have this same quality of membership, having, in many different branches of science, been formed from our example. Collectively they represent the very best that there is at the present time in American productive scholarship. We may, therefore, claim as one of our most essential and significant achievements the generation of our affiliated daughter societies. They are all characterized by a seriousness of purpose and intensity of scientific work, which can not by any means be always matched by what one encounters in the meetings of foreign societies. Our American societies to which I have referred meet for earnest, scientific discussion. They take but little time for anything else. How striking a contrast there is between the meetings now being held, with each day filled by a long series of valuable papers before each society, and the gatherings, such as many of us have attended in Europe, where a few hours only are kept for the strictly scientific meeting, and many for excursions, picnics and balls. I remember attending an anniversary of one of the oldest scientific societies on the

Continent. The celebration occupied three entire days; the scientific meetings almost four hours. May we not claim it as a merit to thus maintain a higher standard for national scientific meetings than we find in other countries?

Another important contribution of our Society was the introduction of winter meetings. We were the first, I think, to use the Christmas vacation regularly for this purpose. Now many societies use it and experience has shown that it is the best time in the whole year, under American conditions, for the holding of national meetings. It is, therefore, from our example that the demand for the establishment of Convocation Week arose.

The fourth achievement is the introduction of discussions of broader scope in which topics of common interest to those in allied branches of science are debated by high authorities. Such discussions do much to broaden our views and increase our appreciation of the solidarity of all science.

Now as to our future. I have already expressed my conviction that we should resign our function as the central body of affiliation in favor of the American Association, which, being so much larger, and so much wider in its scope, can undertake this work of affiliation on a larger scale and therefore more efficiently. The Association has adopted our plan of meeting during the Christmas holidays so that the substitution will be easy. It seems to those of us who have been interested in these plans that it will be of great value to the science of the country to have from time to time a great gathering, so great that its mere magnitude will impress the public and impress our public authorities. Science has yet to make in this country enormous demands from the public for support before it will attain the proportions which are indispensable for the maintenance of the national welfare. It is a duty, therefore, both to science and

to the country, for every scientific man to contribute what he can to make known the needs of science. We depend wholly upon the dissemination of such knowledge for our resources, whether we get them from generous private individuals or by State or national legislation. But it must be remembered further that though affiliation is valuable, bringing together great numbers at one place is not always the wisest plan. Therefore it is necessary that every affiliated society should preserve absolute freedom and that it should be understood between the Society and the Association that the former may meet with the Association or not, as may be deemed expedient each time by the Society. There should be no compulsion from the Association, and I think it will often happen that one or several societies will find it advantageous to meet apart. The only absolute obligation which the affiliated societies ought to assume is the election of one or more delegates to represent the Society upon the Council of the American Association. It is hoped that by this means the Council will become, so to speak, a national senate representing the scientific interests of the country, and representing them very fully. Such a senate will have great influence and may exert its influence from time to time to the advantage of the country. It can speak with authority in regard to problems of legislation, of education and of scientific organization. It might make effective protests, as, for instance, against the outrageous system of duties upon scientific apparatus by which all our work is now impeded; or against the public clamor recently made in one of our States for the reduction of the income of the State University; or against the abuses of arbitrary and ignorant authority at some of our universities, of which we have heard during the last year.

If we resign this part of our work to the American Association, will there remain

enough for us to do to make the perpetuation of our Society desirable? I think clearly, Yes. Even if we could do only what we are now doing—viz., keep up our annual discussion, our dinner and our presidential address—I should say we had in these purposes justification for our continued life. But I believe that we can take up a new task of affiliation which will solve one of the problems which we must solve. It is not enough to have great national meetings. We need besides less formal and more local meetings. The great distances in our country render this important. I should like, therefore, to suggest for your consideration an entirely new plan, viz., that of forming a series of local organizations or branches of our Society. There might be one such organization for example for New England, another for New York, a third for the Middle Atlantic States, a fourth for the Central States and a fifth for the Pacific coast. Each one of these branches could hold meetings for the presentation of scientific papers and invite to the meetings all the local members of the societies now affiliated with us. These meetings might last one or two days and could be held at a time of year when they would not in any way compete with the larger national meetings during Convocation Week. In that way the freedom of the individual societies affiliated with ourselves will be in no wise affected. Competition between ourselves and the American Association will be entirely avoided and the demand, which is real, earnest and well founded, for local meetings, will be answered. It would, moreover, contribute usefully towards the general organization of science throughout the country. That organization I believe to be of the greatest importance. If we look back on the history of science in this country we should probably all agree that the most important step ever taken to promote it has been the estab-

lishment of what are commonly called post-graduate courses at our principal universities; because these courses offer varied and excellent opportunities to train young men seeking discipline in science in order to become scientific investigators. But may we not say that to form a wide-reaching organization of science, national in extent and power, is a yet more important step destined to rank among the great achievements of the century upon which we are just entering? We have learned from our political organizations that numerous independent states and a central government work harmoniously and increase by their cooperation and power the welfare of all. So in our organization of science let us profit by this political example, and though we favor the organization and the strengthening of the central power, let us never forget that every body of men which joins in the organization must also be free. If we make 'freedom and affiliation' our watchwords, we shall escape many perils and conquer success.*

CHARLES SEDGWICK MINOT.

I SHALL speak to the following motion: Resolved, that the American Society of Naturalists authorizes the naturalists of the Central and Western States to organize a branch of that Society to meet at Chicago. That a committee of three be appointed by the president to arrange the details of the relation of the Eastern and Chicago branches and to provide for a joint meeting of the two branches at intervals of two or three years alternately in eastern and central territory. I shall not take time to argue the importance of annual meetings

*The original address was delivered from brief notes, with no thought of publication. In writing the article I found it impossible to recall the original discourse accurately, but I think the substance of it is unchanged except that certain parts of momentary or local interest have been omitted. C. S. M.

of naturalists. I shall not try to show how they aid in the development of science. All of us are willing for the love of research to work ten to fifteen hours a day; but it is the coming meeting at which we have announced a paper that stimulates us to work all night. Furthermore, as scientific men have no longer time to read, if it were not for this annual treatment of fifty doses of papers taken in fifty quarter hours we should be more ignoramuses than savants. I assume, therefore, that it is agreed that naturalists should get together once a year.

The question is: How inclusive should these meetings be? Some naturalists, even of the Mississippi Valley, urge that all of the naturalists of the country should meet together every winter. That is not practicable. As evidence it is only necessary to point out that if it were possible it would have happened already. As a matter of fact, the proportion of naturalists from the Central States attending the meetings of the American Society has always been small. At the present meeting, despite the most cordial interest of the eastern naturalists, we are all regretting the absence of many of our eastern friends and colleagues. Again, the experience of the American Association for the Advancement of Science proves that the great majority of the naturalists of one section of the country will not exceed a certain limit of time and expense to attend meetings in another section. At the Boston meeting of the Association 666 members, or about 74 per cent. of those in attendance, were from the Middle and New England States. At Denver, with great attractions for a summer meeting, there were 82 such members in attendance, or 27 per cent. of all attending. From the nature of the case you can't draw definite limits of distance and expense for the regular attendance of naturalists on meetings. But experience indicates that most naturalists will not travel regularly more

than for about fifteen hours to attend a meeting, nor spend more than fifty dollars. In other words, an institution that will regularly send a majority of its naturalists to a meeting must be within 500 miles of the place of meeting. These facts teach that it is futile to hope that all naturalists of this country will meet regularly together; or even that those east of the Rocky mountains will do so.

A second proposition is that the Naturalists' meeting should be held in successive years in different sections of the country to meet the needs of the naturalists located in those sections. Thus, it might meet successively in New York, Chicago, Denver and San Francisco.

The objections to this plan are too obvious to require debate. It does away with the precious opportunity of an annual meeting of the naturalists of any one section of the country. Local societies would spring up to fill the need and the American Society would be sapped of its strength by them. The advancement of science demands that naturalists gather at least once a year.

A third proposition was made by a committee of the American Society of Naturalists at its last meeting. It is that the name 'American Society' should be abandoned. That the eastern society should reassume the name of 'Society of Naturalists of the Eastern United States,' with which it started. That the naturalists of the Central States might then form an independent and coordinate society. This plan would be a good one, perhaps, if the central and eastern sections were sharply marked off from each other or were politically distinct as, thank God, they are not. The Boston naturalist of this year will very likely be located in Chicago next year and the Michigan naturalist of a decade ago is a scientific leader in New York to-day. We change houses with facility, but we do not change

the flag to which we owe allegiance and we don't want to change more than possible our scientific comradeship. We of the Mississippi Valley, if called east at Christmas time, would like to be able to attend the eastern meeting of naturalists as rightful members; and if any eastern naturalist (pro tempore) were in Chicago or vicinity at the time of our meeting, it would give us pleasure to realize that it would be his meeting also. We don't want to have the naturalists of the country artificially separated by geographical boundaries.

The fourth proposition is based on the national political principle. It suggests the organization of local, self-governing branches bound together by a central organization. For the present two of these branches seem necessary—one meeting in the east; the other at Chicago. It is proposed, further, that the two branches should meet together every third year, that is, once in six years we in the west will go east, and once in six years the east will come to the west. We should all try to attend these joint meetings, thus to renew old acquaintances and to make new ones. It may, however, appear better to try to meet together every other year; I trust we shall have a discussion of that point.

I have assumed above that the central naturalists will meet in Chicago. This is a local matter, but I take this occasion to refer to the fact that if we draw a circle of 500 miles radius, having Chicago as a center, it includes 99 per cent. of the naturalists who have met here in the past and it is generally agreed, I think, that no other point in the Central States would be so convenient to so many.

The plan here proposed has been opposed on the ground that it means disunion and tends towards the breaking up of the American Society. Precisely the opposite will be the effect. By this plan some hundred or more naturalists of high rank in

the Central States will be added at once to the membership of the Central Society which will then become truly an *American Society of Naturalists*. At the same time that *continuity* of work that depends on a regular attendance of members will be gained.

C. B. DAVENPORT.

UNIVERSITY OF CHICAGO.

IN viewing the relations of American scientific societies in general, and of the American Society of Naturalists in particular, it is needful to occupy some platform; and since the limitations of time will permit no more than a hasty glance, a platform of two planks may suffice. The first of these has to do with the rate of progress of American science, and the second is connected with the trend of this progress; for it is not to be forgotten that while the maker of things moving begins with direction and proceeds toward rate, the interpreter of natural movement begins with rate and then proceeds to ascertain trend or direction—nor is it to be forgotten that the study of institutions is still in the interpretative stage. So the first plank may be defined as Advancement, while the second may be called Coordination.

To one in the thick of the turmoil it is not easy to keep note of the tremendous rate of scientific progress in America during recent years; for no adequate units of measure of intellectual activity and attainment have yet been devised. A suggestion may be found in the development of university facilities, since our universities partly lead and partly reflect our progress in science. Without tabulating the statistics in detail, it would seem safe to say that during the first half of the nineteenth century—*i. e.*, from 1800 to 1850—the university facilities of the United States were doubled; that during the next quarter-century, from 1850 to 1875 (despite the shock

of the Civil War—perhaps partly by reason of it) they were doubled again; that from 1875 to 1890 they were once more doubled; and that during the last decade of the old century the doubling was again repeated, so that the nineteenth century went out with at least sixteen times the university facilities (including endowments, etc.) of her incoming. Nor is this the end; for present indications are that our university wealth will double again within the first five years of the new century. Even this is not all; for the fin de siècle university is scientific—an institution for research into the unknown as well as for the preservation of the known—in far larger degree than was the university of 1800. So the university mete shows that American science is advancing in a geometric ratio, an increasing rate in which the rate of increase is still increasing with increasing rapidity. Any other measure gives similar results: Reckoning what may be called state science in terms of appropriations for its maintenance, the growth, from Olmsted's Geological Survey of North Carolina, beginning in 1823 at \$250 per year, to our present two-score of state surveys and related institutions, has been even more vigorous than that of our universities; while our direct federal appropriations for scientific work, beginning with a few hundreds in 1811, passing the million mark about 1870, and now rising above ten millions annually, give eloquent testimony of national advance in knowledge-making at an ever-increasing rate. A still more striking measure is afforded by the growth of our scientific societies—or will be when the statistics are tabulated. Yet all these measures, impressive though they be, are little more than symptoms attending the permeation of a healthful serum throughout the body of American citizens; for our average citizen, whose ancestors in 1800 planted potatoes in the dark of the moon and sniffed witch-

craft and black art afar, is now a devotee of the methods of science as well as of rational interpretations of nature, and looks to the Agricultural Department or the Smithsonian Institution or the neighboring university for standards of practical thought—even if he half complies against his will, and is half of old opinion still. It is a hopeful sign of the times that American science, measured by any standards, is advancing more rapidly than our fast-growing population or quick-increasing national wealth—that it is indeed drifting into its true place in the lead of our industrial development. Such is the Advancement of American science.

Turning now to Coordination: The advance of science is largely—indeed wholly, in the last analysis—dependent on social development; and the law of social development is integration. The ways along which integration proceeds are many: The growth of the family into the clan and of the clan into the tribe, and the union of tribes into confederacies, with the ultimate welding of these into nations, all represent a process of integration peculiarly instructive to students of institutions, scientific and other; the steady breaking down of racial barriers, the world-wide blending of blood and culture, the merging of laws and languages, and the diffusion of cults (whether of faith or of works) according to their fittingness for the several stages of intellectual development, all represent ways of social integration—ways whose name is legion, and whose ramifications and osculations it were needless now to follow. Yet he who would fairly view the growth and relations of our voluntary associations for scientific research can not afford to neglect the analogy of primitive society in its growth from clan to tribe, and thence on and upward along the noble course of intellectual strengthening and human betterment. Now the germ of the clan is a

family bound by ties of common interest; and its analogue in scientific organization is the group of kindred spirits working to a common end, like the half-dozen geologists who later formed the American Society of Geologists, the precursor of the American Association for the Advancement of Science. The clan itself is an enlarged family, comparable to the same half-dozen geologists and their fellows when the magnet of knowledge-making drew them into the closer union of definite organization; while the tribe may be likened to the permanent association defined and bound by articles and constitutions and by-laws. The likeness between the primitive tribe and the society of specialists is much more than a fanciful parallel—indeed the analogies are many and close, too many for counting and too close for discussing in brief space; it must suffice to accept the analogy and pass to the application. The significant point is that the tribe, after reaching a certain (*i. e.*, uncertain) magnitude, either multiplies by fission (breaks down beneath its own weight, in other words) and so forms subtribes which are eventually confederated on the basis of higher laws, or else passes directly into more or less definite confederation with alien tribes. It is no less significant that the confederated tribes long retain their integrity, just as do the component clans in many instances and the constituent families in all; so that the confederacy becomes a sort of hierarchy of interdependent groups, presaging the interdependent townships, counties, wards, municipalities, judicial districts, representative districts, States, and other collective units of enlightened society. Now accepting the analogy between the tribe and the voluntary scientific association, the application is simple; the association may either multiply itself by fission (*e. g.*, into sections), or in some other way prepare for reorganization

on a more comprehensive plan; yet the broader organization need not interfere with the original affinities and affiliations, any more than the Seneca Indian was made less a Seneca by the Iroquois confederation, or the citizen of Chicago is less a Chicagoan because he is a native of Illinois and a citizen of the United States—as well as a Mason, a Presbyterian, and a free-trade Republican. The plank of social integration is too broad and too long for easy trimming into a three-minute platform; but fortunately it tells half the story in itself.

Such are the great fact and the fundamental principle to be borne in mind in our search for the best way of future progress for the American Society of Naturalists—the fact of unparalleled Advancement, and the principle of institutional Coordination.

The Society of Naturalists is conspicuous among American scientific societies in many ways, notably for its habitual exaltation of the scientific spirit above the letter of organic law and hence for unprecedentedly rapid and vigorous growth—indeed this Society, more than any other, may be regarded as the type and expression of modern scientific activity in America. Founded primarily to meet the needs of serious students of science, incidentally as a foil if not an antidote for the peripatetic pleasuring and jocose junketing charged against an older organization, it has kept even pace with the tremendous scientific progress of the last two decades, and has become a leading power in guiding scientific thought and shaping scientific policy. Naturally, in view of its phenomenal growth, it reveals signs of that fission whereby all social institutions prepare for reintegration on a higher plane. True, the laxity of the law is such that the original organization is not unduly constrained; yet, as a nucleus for a group of affiliated societies, its vitality is diffused to the benefit of the group rather than concen-

trated in the sole interest of the unit. The career of the Society from 1883 up to the present seems to have been normal, fully in accord with the times, and beyond reproach; its present function as a nucleus for special societies—*i. e.*, subtribes, in the analogy with primitive socialry—would also seem to be ideal; yet the question arises, May not the naturalists assume a larger rôle on the stage of American science? And this in turn evokes another: If so, how?

In seeking answers to these queries, the mind turns at once to broader affiliations and stronger affinities than those already developed within the Society of Naturalists; and among the first of the possible affines, thought rests on the American Association for the Advancement of Science, that older organization of which the younger body is, in some measure, the reciprocal if not the antithesis. It is to be remembered that the Association, also, has reached the stage of fission, or of reintegration on a higher plane, the stage being marked partly by increasing autonomy of the component sections, partly by the affiliation of several special societies, each a power in its specialty and all an immeasurable force in shaping the science of a nation. Originally an agency of diffusion and direct advancement combined, the Association for a time was mainly devoted to the former function; of late, thanks largely to the influence of the affiliated societies, it seems to be resuming the original function of direct advancement through its own activity and through fostering kindred societies, so that its present aims are so nearly akin to those of the Naturalists that the two organizations might well cooperate, or even confederate, for mutual advantage and the common benefit of American science. The possible modes of cooperation, and the possible lines of confederation, are too many for present discussion; but it may be held, in the light of analogy with primi-

tive socialry as in that of current experience, that neither cooperation nor confederation need involve loss of autonomy, or efficiency, or dignity, on the part of either organization.

Out of the many possible lines of action leading to coalition between the two most vigorous and virile of our voluntary scientific societies, one or two may be urged: The American Association for the Advancement of Science has already decided to hold a winter meeting in Washington during the Convocation Week of 1902-3, and it has just been decided by this body to hold its annual meeting at the same time and place. Now it is suggested that the American Society of Naturalists take the requisite steps toward admitting representatives of the Association to its Council, and toward securing representation in the Council of the Association, preferably at this approaching meeting, and if not then, at the earliest possible occasion; it is also suggested that this Society take early steps toward enlarging and strengthening its Council in such manner that the administrative bodies of the two organizations may attain parity of power. It need hardly be said that the joint meeting would serve, and better serve, every purpose of separate meetings; and it need hardly be added that one effect of the joint meeting would be to increase common membership in the two organizations, and thus to strengthen the already strong bonds of common interest.

In another place* it was pointed out that a need of American science to-day is a delegate organization—a Senate of Science—in which our many and constantly multiplying local and special voluntary associations of scientific men might be equitably represented in a body not too large and unwieldy for effective work in coordinating lines of research and keeping in touch with national progress; and it was suggested

* SCIENCE, N. S., Vol. XIV., 1901, pp. 277-280.

that the Council of the American Association might well serve as the nucleus for such an organization. To-day a still more promising nucleus for a national scientific organization of unprecedented dignity and power may be glimpsed through eyes of hope; for it is within bounds to anticipate joint meetings of the Councils of America's two representative organizations of science, and joint action with all the strength of union, at no distant day.

W J MCGEE.

BUREAU OF AMERICAN ETHNOLOGY.

It is not long since a gathering as representative of American science as the present one would have been a very different kind of audience. It would have been much smaller, without men enough specially representative of any one branch of knowledge to warrant them in meeting together as a section, but composed of men practically all of whom would have heard with interest and discussed with intelligence any paper on the program.

Recent years have brought about a marked change in science as in other things. Material prosperity has made it possible for more men than formerly to devote themselves to the acquisition and diffusion of learning, and the means and appliances at their hand have increased to no less a degree. With this has come, as a means to the performance of the more difficult tasks of research, specialization and attendant division of labor, so that the scientific organizations are now commonly not only larger, but far more complex, and one often goes away from a meeting with something like an intellectual dyspepsia, induced by the many and extremely varied courses offered on the program.

In another important respect conditions have greatly changed. The time was when the great distances lay beyond the workers in science. To-day, because of the develop-

ment of the whole country, they lie between the workers, not equally, but in such a manner as to cause a concentrated eastern and a more scattered western population. Though distances are now traveled in hours that formerly required days, the expenditure of time and money involved in passing these great distances is so great as to seriously interfere with the holding of truly national meetings, and I desire to express my full appreciation of the action of this society in setting aside a geographic restriction of its constitution in order that this most successful meeting might be held in Chicago. Shortly before leaving home I received a letter from a friend, in which regret was expressed that the eastern botanists who commonly meet in conjunction with this Society had not felt it wise to set aside a like provision of their own constitution, so that they are now meeting in the east, and adding that, much as would be gained by meeting with the affiliated societies now in session here, it did not seem quite right to depart from their custom and so deprive the younger men, not blessed with a superabundance of this world's goods, of a meeting that they desired and were entitled to, but for which they could not travel far.

In our childhood we all learned the fable of the man who one day brought in an armful of twigs, and, handing them one after another to his son, asked him to break them, which was readily done; but when a like number were closely bound together into a bunch, they could not be broken nor even greatly bent. I believe it was the schoolmaster who first made practical use of this particular demonstration of the strength that lies in union, but before my own time he had abandoned it because of the greater flexibility of the unit. Business men have recently begun to make much and profitable application of the principle, and as, in manufacture and

traffic, material results are quickly available for the testing of changes in organization and management, they are rapidly securing both strength and economy and efficiency of administration, by combination. If the century just closed is likely to stand out prominently in history as that marked by specialization and differentiation, that on which we have just entered appears likely to take place as that in which rational union, coordination and centralized organization form prominent features; and this is likely to be as true of the machinery of instruction and of research as it is of business combinations.

Professor Minot has very thoughtfully and logically presented the bearing of this line of thought on this society and the affiliated organizations. Difficulties may be experienced at first in perfecting the details of the most useful and workable organization, but they are likely to be seen and overcome, and I have little doubt that the great Washington meeting that we are all hoping to attend next winter will initiate a federation of scientific interests that, without losing in productiveness, will gain an almost irresistible strength which will be productive of great good in many ways.

But in this centralization of interests those who can not travel great distances to attend the general meetings should not be forgotten. I feel that while none of us who can attend the great meetings can afford to miss them, those who can not go to them should be given every help and encouragement in holding meetings at places convenient to their homes. I have assumed that your committee, in inviting me to take part in this discussion, did so because they wished the point of view of the central botanists represented. On this assumption I have tried as far as possible to ascertain the feeling of those botanists, and I think I may say without impropriety that the botanists now meeting in connection with

this Society feel the need of a local organization, and have taken steps toward its formation, though, in view of the discussion to be held this afternoon, possible action by this Society this evening, and the announcement of a general meeting of the central naturalists called for to-morrow morning, for the consideration of the same question, they have deferred their final action until to-morrow. Whatever they may believe desirable for the furtherance of their more immediate interests, I am confident that their support may be counted on for all wise concentration, and that at all times, those who are able and free to attend the general meetings may be counted on to do so, while those who must stay nearer home will prove willing to act in unison with the central body on all matters of scientific importance where concerted action is needed, while they anticipate no refusal of the full power of the general organization in any matter concerning which it is proper for them to ask support.

WILLIAM TRELEASE.

MISSOURI BOTANICAL GARDENS.

THERE are evidently two subjects under consideration by the Society, and these are only indirectly related. One is the subject of cooperation, affiliation, or more organic union between the American Society of Naturalists and the American Association for the Advancement of Science; and the other is the organization of local branches of the Society of Naturalists, or sectional societies having a similar field and affiliated with that general organization.

Assuming that the time of meeting of the American Association is to be changed to Convocation Week, there seems to be a practically unanimous judgment favorable to a meeting of that society and the Society of Naturalists at the same time and place, and to a close coordination or affiliation of the work of these societies. I can see how

certain practical difficulties would arise from the meeting at the same time and place of two societies or groups of societies so largely similar in character and scope—meetings of the Botanical Section of the American Association, and of the Society of Plant Morphologists affiliated with the Naturalists' Society; meetings of the Zoological Section of the American Association, and of the Society of American Morphologists; and so on—but I presume that these matters have all been considered and that means of adjustment will readily be found. As to the soundness of the idea, I cannot see that there need be any doubt.

With respect to the formation of a local society in the central states, to be affiliated in some way with the group of societies in session here at this time, I think the only subject upon which difference of judgment might possibly arise is that of the method of the affiliation. It seems to me that in the nature of the case we shall finally be forced to form sectional societies in most of the branches of science represented by the existing organizations. As the scientific population of the country becomes more equally dispersed over its whole area, we find this area too large to permit general annual meetings of those most interested and most likely to profit by them. The distances are so great as practically to prohibit attendance upon the part of many members, and the number presenting papers in each society or subdivision is such as to crowd the programs unduly, diminishing the interest and value of the meetings. We need a satisfactory geographical unit of assemblage for scientific meetings, one not so large as to make attendance a burden upon those living on the outskirts, and yet large enough to permit a satisfactory subdivision of the programs of societies into sections corresponding to the subdivisions of the subject matter. From what we have seen during the

last two years and at the present meeting, it seems to me quite clear that the states of the Mississippi Valley—now coming to be known as the Central States of the Union—should form one such unit of assemblage. Indeed a society of naturalists has already been formed for this area, and has had two highly successful meetings, definite organization having been delayed merely with a view to the issues of this meeting. Probably other such sectional societies might be organized to advantage (if not now, before many years), all to be associated as divisions of a more general organization for the country as a whole.

On the supposition that such a society is now to be organized here, the subject of its relations to existing societies will come up for settlement. In this connection it is helpful to notice the difference in organization of the Society of Naturalists and that of the American Association for the Advancement of Science. In the former there is one general society which serves as a bond of union for special societies, each independent in organization and management, but associated by affiliation with the general body, the latter being scarcely more than an administrative convenience. In the American Society for the Advancement of Science, on the other hand, there is a more compact general society, with subdivisions, called sections, formed mainly for program purposes. In the American Society of Naturalists we have had, thus far, no sections in the latter sense, but only affiliated societies, and I am inclined to think that this method of organization should be continued as local societies spring up in response to local requirements. I would rather, in short, see the naturalists of the Central States organized under the form of an independent but affiliated body than in the form of a section of the national society.

I doubt also the advisability of attempt-

ing to fix in advance the place of meeting of the proposed new society or section or to determine unnecessarily any detail of its policy by a resolution passed by this body at this timé. If its members should prefer peripatetic meetings to those held at one fixed point, I think it should be possible for them so to determine, especially as that is now the policy of the whole group of societies associated in this organization.

I am obliged to you, Mr. Chairman, for the opportunity to participate in this discussion, which I owe to your courtesy only; and I have spoken merely on a few points which have occurred to me as I listened to those who have preceded me.

S. A. FORBES.

UNIVERSITY OF ILLINOIS.

‘A HAND apart from the rest of the body is not a hand,’ said Aristotle, and modern psychology shows that each of us exists only in his relations to others. Writing and the printing-press have made science possible by permitting intercourse between those separated in time and space, but they have not done away with the necessity for personal contact. Correspondence schools can not replace universities, nor do journals and books make needless the coming together of scientific men. The organization of academies and societies has been an essential factor in the development of modern science. Two or three hundred years ago the men of a neighborhood began to meet to discuss scientific questions. Fifty to a hundred years ago, when railways made it possible, national associations were established. As the sciences became differentiated, the academies and associations met in sections, and special societies were established in each country for different sciences. These societies or their members now meet occasionally in international congresses.

We have indeed at present a somewhat

bewildering array of scientific societies which have arisen in answer to special needs. It is time that the methods of science should be applied to their proper coordination. The two closest bonds of union are common interest in a subject and local proximity. We have, as a matter of fact, national societies for nearly every science, and local academies in nearly all our larger centers. When there are enough students of the same subject in the same place we have the natural unit; these groups should unite on the one hand to form the local academy, and on the other hand to form the national society. The national societies should be parts of a great national association. The presentation and discussion of research belong to the special societies; the coordination of the work of different sciences, legislation on behalf of science as a whole, and the representation of science before the intelligent public, belong to the national association. For the transaction of business, this association can no longer be a plebiscite, but must be a house of delegates representing the scientific interests of the country.

The American Society of Naturalists, with which we are at present more especially concerned, represents certain sciences and a certain region; it does not form an integral part of what appears to be the trend of scientific organization. Historically our society has performed a service of immense value. In the limitation of participation in its work to scientific men, in delegating special papers to special societies affiliated with it, in its discussions of questions of general scientific interest, and in its choice of midwinter as a time of meeting, it has set an example to the American Association. In recent years, however, the American Association has maintained the same scientific standard, and we have practically one group of scientific societies meeting in midsummer and an-

other in midwinter. The greater power of a general association is indicated by the fact that all the societies meet in summer under the auspices of the American Association, whereas at present the national societies are meeting not only here in Chicago, but also in New York, Philadelphia, Rochester and Washington. The greater influence of a national association is again shown by the fact that it has been able to secure from our universities and colleges a special convocation week in midwinter. This could not have been accomplished by our Society representing only certain sciences and a certain region.

Hereafter the chief meeting of the American Association will probably be held in convocation week, and the national societies devoted to special sciences will probably meet with it. Our views as to the future functions of the Society of Naturalists depend on how we answer two questions. Should our special scientific societies be national or sectional? Should they meet at the same time and place? To me it seems that the special societies should surely be national, or American, with local sections. A national society for each science will ultimately be essential for purposes of publication and for legislative functions. An annual or occasional meeting of those engaged in the same kind of work is of the utmost importance—scientifically, professionally and socially—and should be maintained in spite of the sacrifices of time and money imposed by the large area of our country. It seems to me further that our national societies should meet together. It is economical to make local, railway and other arrangements, once for all. Most of us belong to more than one society and like to meet friends following different lines of scientific work. Indeed, sharp lines can not be drawn between the sciences; we have astrophysicists, electrochemists, general biologists, physio-

logical psychologists, and the like, who would be divided by separate meetings. There are judicial, legislative and executive functions, in which all men of science should unite, and for their accomplishment a general meeting is essential. Then, lastly, the weight of science is impressed on the general public only by a meeting of sufficient magnitude.

The limits of a thousand words do not permit an attempt to emphasize the importance of national scientific societies and of a general congress of scientific men, and after all the logic of events is the strongest argument. We *have* national scientific societies, and they *do* meet in groups—nearly all the sciences in the summer, with the American Association, and the biological sciences in the winter, with the Society of Naturalists. The meetings of the American Association have, it is true, been interfered with by summer holidays, summer heat and the winter meetings; and the winter meetings of the American Society of Naturalists are threatened with a local division. It seems reasonable, however, to assume that next year, at least, all our societies will meet together at Washington in convocation week.

Supposing there to be a general annual meeting, say once in three years at Washington, once in the eastern states and once in the central or western states, what should be the function of the Society of Naturalists? It seems that the general arrangements should be left with the American Association, covering all the sciences and the whole country, and having permanent and salaried officers. Our society might hold separate meetings in the east when the national societies meet in the west. I myself, however, regard this as undesirable. Should the Society of Naturalists then be disbanded, having accomplished its work? I think not. There is place for a compact organization within

the American Association representing certain sciences and a certain region. The original objects of the Society—the organization of scientific work, the teaching of science, the conduct of museums and the like—still need an organization. Our discussion, our public lecture and our dinner with a presidential address should not lightly be abandoned. Within the Royal Society and the British Association there have been clubs, primarily social, but exerting great influence on the policy of the larger organizations. The National Academy performs valuable functions as a select association composed of some of our more eminent scientific men, and the Society of Naturalists, composed of some of our more efficient and public-spirited students of the natural sciences in the eastern states can accomplish much, in the future as in the past, for the advancement of science.

J. McKEEN CATTELL.

COLUMBIA UNIVERSITY.

THE ASTRONOMICAL AND ASTROPHYSICAL
SOCIETY OF AMERICA.

I.

THE first winter meeting of this Society was held at the Cosmos Club, Washington, D. C., Monday, Tuesday and Wednesday of Convocation Week. Sessions for the reading of papers were held both morning and afternoon, on Monday and Tuesday, and on Wednesday morning. The maximum attendance of about fifty was reached on Tuesday.

Twenty-eight new members were elected, and it was decided to hold the next meeting of the Society at Washington during Convocation Week, 1902-3.

A number of the members lunched together both on Monday and Tuesday at Barton's, and on Monday evening attended a dinner at the same place. The president of the Society presided, and among the most delightful features were the after-dinner

speeches of Professor W. W. Campbell, Professor George E. Hale and Professor S. I. Bailey. If a similar function is held at the next meeting it is hoped that the ladies of the Society will more generally follow the example of the two present at this time.

On Tuesday evening President and Mrs. Newcomb received the members of the Society and numerous invited guests at a conversation held at the Arlington Hotel. During the evening papers illustrated by stereopticon were read by Mr. Percival Lowell on Mars, by Professor S. P. Langley on personal equation and the infra-red spectrum, by Professor George E. Hale on a comparison of the results obtained by photography from the forty-inch refractor and the two-foot reflector of the Yerkes Observatory, and by Professor W. W. Campbell on the work of the Lick Observatory eclipse party in Sumatra and the nebula surrounding Nova Persei.

After the reading of these papers the guests were invited into an adjoining room to partake of still another astronomical treat and refreshments. Here the room was fitted up with numerous transparencies, and photographs from the Harvard College Observatory, from the Yerkes Observatory, from the Lick Observatory and from the United States Naval Observatory.

On Tuesday a number of the members visited the Astrophysical Observatory of the Smithsonian Institution upon a special invitation to the Society from Secretary Langley.

At the adjournment of the Wednesday morning session the members formed in line, marched to the White House and paid their respects to President Roosevelt, special arrangements having been made for their reception.

OFFICERS ELECTED.

For 1902: *President*, Simon Newcomb; *1st Vice-President*, George E. Hale; *2d Vice-Presi-*

dent, W. W. Campbell; *Treasurer*, C. L. Doolittle.

For 1902-3: *Councilor*, E. C. Pickering; *Councilor*, R. S. Woodward.

Holdovers: *Secretary*, George C. Comstock; *Councilor*, S. J. Brown; *Councilor*, Ormond Stone.

RESOLUTIONS ADOPTED.

Resolved, That the members of the Astronomical and Astrophysical Society in attendance at this meeting hereby tender their cordial thanks to the Board of Management of and to the members of the Cosmos Club for the use of the Club, Assembly and Council rooms, for the excellent facilities afforded for the illustration and exposition of the papers presented at this meeting, and for the kindly social courtesies extended to all members of our Society.

Resolved, That the thanks of this Society be tendered to Professor S. P. Langley for the special opportunity afforded by him to visit the Astrophysical Observatory of the Smithsonian Institution.

Resolved, That the thanks of the Astronomical and Astrophysical Society be tendered to the Philosophical Society and to its treasurer, Mr. Bernard R. Green, for the use of apparatus and courtesies shown during the present meeting of the Astronomical and Astrophysical Society.

Resolved, That the Secretary of the Society be requested to transmit the substance of these resolutions to the Board of Management of the Cosmos Club, to Professor S. P. Langley and to the officers of the Philosophical Society respectively.

Resolved, That the members of the Society in attendance hereby express their cordial appreciation of the active services of the President in perfecting all arrangements for this meeting and in providing so amply for social as well as for astronomical and astrophysical entertainment.

PAPERS PRESENTED.

ABSTRACTS OF PAPERS.

The Flash Spectrum, Sumatra Eclipse, May 18, 1901: S. A. MITCHELL.

The writer, through the courtesy of the director of the Naval Observatory, became a member of the expedition to view the Sumatra eclipse on May 18, 1901, and was stationed at Sawah Loento. Two instruments were employed, a camera of 104 inches focus to be used in connection with a cœlostát; and a spectroscope consisting of a Rowland flat grating of 15,000 lines having a ruled space of $3\frac{1}{2} \times 5$ inches, and a quartz lens of $3 \frac{23}{64}$ inches aperture and 72 inches focal length. Light from the sun reflected by the cœlostát mirror in a horizontal direction, fell on the grating where it was diffracted, and was brought to a focus on the photographic plate by means of the quartz lens. If grating and photographic plate are each perpendicular to the diffracted beam, the spectrum is 'normal.'

It was arranged to photograph the first order spectrum from λ 3,000 to λ 6,000.

The weather on the day of the eclipse was extremely disappointing. First contact was observed in a perfectly clear sky, but clouds soon began to gather and were so dense at second contact that the first flash was not observed at all. Toward the middle of totality conditions became a trifle better, so that it was possible to see, through clouds, the corona extending for about half a diameter from the sun. During no time of the 5 min. 41 sec. of totality was an unclouded view of the corona obtained, but nevertheless, the second flash was seen beautifully. Altogether eight exposures were made, one before and one just after totality for the cusp spectrum, one at first and one at second flash, and four with different lengths of exposure during the total phase. The second flash seemed fully exposed, and it is to a discussion of this photograph that this paper is devoted.

The peculiarities of this photograph are:

1. Normal spectrum.
2. Great dispersion.

On the plate the distance from F to H is 95.4 mm., and as the spectrum is normal, 1 mm., therefore, corresponds to a difference of wave-length of 9.37 tenth-meters, or 1 tenth-meter corresponds to a dispersion of about 0.1 mm. For some reason, the spectra were not in perfect focus, but in spite of this fact, in view of the great dispersion of the spectrum, measures were made and wave-lengths determined with a high degree of accuracy. The spectrum extends from λ 4,924 to λ 3,320, but the focus becomes poor beyond K, and measures were discontinued at λ 3,835. For the purposes of the present comparison, the region from F to H only was regarded. In this part of the spectrum 363 lines were measured in the flash. An arbitrary scale of intensities was assumed whereby 0 represents the faintest line seen with certainty,

10 the strongest line. Wave-lengths were compared with Rowland's measures of the solar spectrum. Of the 363 flash lines, 269 were identified with lines on Rowland's map. Although we cannot directly compare the intensities of the bright lines of the flash (scale 0-10), with those of the dark lines given in Rowland's tables (scale 1-1,000), we can arrive at certain theoretical considerations if we compare the average intensities for the different elements, *i. e.*, Flash intensities, and also the ratios of the Solar intensities, and also the ratios of the number of lines of each element identified to the whole number of solar lines for that metal. Forming these ratios and arranging them, we are at once struck with the systematic variations, not only in the ratio of intensities, but also in the per cent. of lines identified. The meaning of these systematic differences will be understood if we consider these ratios in combination with the atomic weights of the various elements, as in the following table, where also

is put down the number of the lines in the flash due to each metal.

These lines naturally fall into three groups, as given in the table below.

To these may also be added the following lines:

La, atomic weight, 138.5.....	3 lines
Ba, " " 137	1 line
Ln, " " 65	1 line

In Group I. would also fall Al if we consider the relative intensities of the two lines λ 3,944.160 and λ 3,961.674; and undoubtedly Na if our plate took in the D lines. The remarkable variation of the relative intensities in the flash and Fraunhofer spectra, as Evershed has pointed out, is undoubtedly due to the *heights* to which the vapors of the different metals ascend in the chromosphere. A gas with an intrinsic brightness 1 and a layer 100 miles in thickness, would give a photographic line in the flash spectrum just as bright as a gas of intrinsic brightness 100 and only 1 mile

Group I.—Lines Strong in Flash and in Solar Spectrum.

Element.	Atomic Weight.	Number of Lines.	Intensity Flash.	Lines Identified.
			Intensity Solar Lines.	Total Number of Lines.

thick, if the sun and moon were relatively at rest during the period of the 'flash'; but considering the gradual advance of the moon in covering successive layers of the sun's atmosphere, we see that in the emission spectrum the flash line of the fainter gas would be many times more intense than that of the brighter. The absorption lines of the two gases would be very nearly the same. The extent of the metallic vapors of the sun's surface probably varies inversely proportional to their atomic weights.

In consideration of these facts, it seems altogether likely that the gases of the metals of Group II. extend very high, and are nowhere very much condensed. The flash lines are to be regarded as true reversals of the corresponding solar lines. The metals of Groups I. and III. are somewhat denser near the sun's surface and do not extend so high as those of Group II., but as it is the upper portions that contribute most to the formation of the emission lines, the flash lines are to be regarded as only partial reversals of the Fraunhofer lines, the solar intensities being greater than the flash intensities. Most of the strongest lines in the solar spectrum have been found in the flash; and this, taken in connection with the meaning of the differences of intensities, leads us to further renew our faith in the existence of the 'reversing layer.'

The Total Solar Eclipse of May 18, 1901:

C. D. PERRINE.

The expenses of an expedition to Padang, Sumatra, from the Lick Observatory, to secure observations of this eclipse, were defrayed by Mr. William H. Crocker, of San Francisco. Eclipse day dawned with light clouds covering the sky. But little change occurred during the morning. At the time of first contact, the sun shone through a rift in the clouds. At the beginning of

totality all parts of the sky near the sun were covered with light cirrus clouds and haze. The inner corona only and Mercury and Venus could be seen during the early part of totality. The clouds became very much heavier towards the end of totality. The time of beginning and ending of totality was 3 or 4 seconds later than the time of these phases computed from data given in the *American Ephemeris*, but the uncertainty of longitudes in Sumatra may account for nearly if not all of this. Twelve photographs of varying exposures were secured with a camera of 40 feet focal length. These show the inner corona and prominences as well, probably, as if the sky had been free from clouds. The longest exposure, one of 150 seconds, shows the streamers to a distance of one and one-third diameters from the limb—more than could be seen with the unaided eye. A number of small prominences are visible on the east limb of the sun. One of these at position-angle 115° is covered with a series of coronal hoods or envelopes. Attention is called to a remarkable disturbance in the corona in the northeast quadrant. At a position-angle of about 65° there is a small compact prominence, over which there is a disturbed area resembling roughly an inverted cone. From the apparent apex of this area a number of irregular streamers and masses of matter radiate as if thrown out by an explosion. I am not aware that a disturbance of this kind has been observed before in the corona proper. Eight photographs were secured with the Floyd telescope of 70 inches focal length. These negatives show the same extensions of corona as those taken with the 40-foot camera. Twelve negatives were secured of six regions on either side of the sun in the direction of his equator for the purpose of detecting any planets existing there. These negatives were obtained with lenses of 3 inches aperture and 11 feet 4

inches focal length.* A preliminary examination of these negatives was made at the station and 92 stars of magnitude 8.6 to 8.8 were found in three of the regions. The plates taken during the latter part of totality show no star images, owing to the increased cloudiness. A negative with long exposure was secured with each of two spectrographs, one having the slit tangential, the other radial. The principal Fraunhofer lines are shown in the outer corona in both, none, however, being observable in the extreme inner corona. Ten negatives were secured with a camera of 21 inches focal length, having a double-image prism placed in front of the objective. The two images given by such a prism and camera furnish a means of detecting by differential methods any considerable polarization in the corona. The axis of the prism was set at several different position angles between the sun's equator and his poles. In this way all parts of the corona were tested. The negatives secured show a large percentage of polarization in the outer corona and a slight amount in the inner corona. The two spectrographs and the polarigraph were designed and prepared for use by Director Campbell and Assistant Astronomer W. H. Wright. The great southern comet was a conspicuous object in the evening sky for several days and was visible without aid for more than a week. Photographs of it with a portrait lens were secured on May 6. The exposures were necessarily short, but show 3° or 4° tail. A faint streamer is also shown to the south, making an angle of about 35° with the principal tail. A number of large copies, on glass, of the eclipse photographs, as well as lantern slides, were shown at the meeting.

* Two of the four lenses used in Sumatra were kindly loaned for the purpose by Professor E. C. Pickering, Director of the Harvard College Observatory.

A Martian Cloud: PERCIVAL LOWELL.

This paper gave an account of two projections seen upon the terminator of Mars by Mr. A. E. Douglass at the Lowell Observatory on December 7 and 8, 1900; the observations which gave rise to the popular impression last year of signals from Mars. Calculation showed them to belong to different parts of the planet and to have moved during the time they were under observation. Furthermore, the motion in each case was approximately the same—nearly due west in each case. Neither of them reappeared on any succeeding night. They thus showed themselves to be not illuminated mountain tops, but sunset clouds floating in the planet's atmosphere.

Preliminary Statement of Results of International Magnetic Observations made during the Total Solar Eclipse of May 17-18, 1901: L. A. BAUER.

To further test the results obtained by the United States Coast and Geodetic Survey magnetic parties during the total solar eclipse of May 28, 1900, regarding a slight magnetic effect that may be attributable directly to some change produced in the electrification of the upper atmospheric strata by the abstraction of the sun's rays, due to the interposition of the moon between the sun and the earth, an appeal was made for international cooperation in magnetic and allied observations during the recent total solar eclipse. The repetition of the observations was doubly interesting owing to the fact that the present eclipse occurred in the opposite magnetic hemisphere to that of last year, and hence the opportunity was afforded for ascertaining whether the magnetic effect was reversed in its general character to that of last year, as is, for example, the case with the diurnal variation in passing from one magnetic hemisphere to the other. The conditions, however, for obtaining observa-

tions at a number of stations distributed along the belt of totality, as was done last year, and thus testing whether the magnetic effect again followed directly in the wake of the shadow cone, were not favorable owing to the present location of the belt of totality. In response to the appeal, simultaneous magnetic observations were made on May 17 from 14 to 21 o'clock, Greenwich mean astronomical time—an interval amply covering the time of the eclipse—at a number of stations encircling the entire globe, three of which were in the belt of totality. The prime purpose of making the observations so as to cover the entire globe was to furnish the possibility of separating a possible eclipse magnetic effect from a contemporaneous magnetic storm of the usual type. The eclipse effect, for instance, doubtless would be confined to a very small belt, whereas a customary magnetic storm, in conformity with the usual experience, would manifest itself at practically the same moment of time over a very large area, and thus be felt at stations far from the totality belt. At none of the outside stations has a disturbance of any appreciable size been thus far reported to me, the general consensus of opinion of observers at these stations being that 'nothing unusual occurred.' At the three stations within the belt of totality the majority of the opinions is that something unusual did occur during the time of the eclipse. Thus at Karang Sago, where was situated the Dutch eclipse party, Dr. W. van Bernelen, assistant director of the Batavia Magnetic Observatory, observed the change in the magnetic declination and horizontal intensity, and he reports the occurrence of 'an extremely interesting magnetic effect.' He has courteously sent me an extract of his observations made during several days before and on the day of the eclipse, and there certainly appears evidence of a magnetic effect in both elements different from that

observed on the days prior to the eclipse. At Sawah Loento, the site of the Massachusetts Institute of Technology party, of Boston, the variations in magnetic declination were observed by Mr. G. L. Hosmer on May 17 and 18. Comparing the two days' results for the interval of the eclipse, there is indisputable proof that something different occurred on the day of the eclipse than on the day before. Namely, at this station, situated so close to the magnetic equator the range of the diurnal variation of the magnetic declination is about one minute of arc. The magnetic effect during the time of the eclipse was of about the same amount, so that a steady *decrease* of east declination resulted during the time of day when normally there is a steady *increase*. There was but one magnetic observatory directly within the belt, viz., the one at Mauritius and this was situated not far from the place of beginning of the eclipse. No special magnetic observations were made at this place; however, the regular photographic curves giving the variations in the magnetic elements were obtained. The declination and the vertical intensity curves apparently do not show any disturbance that could easily be picked out and referred to the eclipse. Regarding the horizontal intensity curve—the more sensitive one—Mr. Claxton states 'that the original curve shows slight tremors between 7.15 and 7.50 and occasionally between 8.5 and 9.0 A. M.' I have plotted this intensity curve on a large scale and find that the curve shows no very marked disturbance that might be readily referred to the eclipse, with the exception of one producing an easily perceptible bulge in the curve amounting to about 3–4 units in the fifth decimal e.g.s. units and lasting about 30 minutes. Any way the effect, if there be one, is very minute, and will not be so readily separated from the usual diurnal variation as in the case of the two previous stations. Whether

this is due to the fact that owing to the vicinity of Mauritius to the beginning of the eclipse, the minute eclipse magnetic storm did not have time to develop itself or was just in the embryonic state, cannot be said. The magnetic effect observed at Karang Sago and at Sawah Loento does not appear to have extended very far outside of the belt of totality, it being scarcely appreciable at the Batavia Magnetic Observatory. My grateful and appreciative acknowledgments are due to all who have participated in this interesting investigation—one to my mind of fundamental importance to the theory of the diurnal variation of the earth's magnetism as elaborated by Schuster and von Bezold.

Meridian Circle Positions of Nova Persei:

R. H. TUCKER.

Meridian circle positions were obtained on eight evenings in February and March, and on four evenings in November. The difference in the right ascensions resulting from the two series of observations is 0.05 seconds. The star was more than four magnitudes brighter at the time of the first series than at the second. Making allowance for the magnetic equation, the difference between the right ascensions for the two series reduces to 0.01 seconds. The declinations in the two series differ by 0.05". It is therefore evident that these observations indicate a very small parallax and proper motion. The large proper motion recently reported by a European astronomer is not confirmed.

On the Parallax of Nova Persei: F. L. CHASE.

This paper was based upon observations made with the Yale heliometer, the first set in February and March, the second in July and August and a third in December. The result derived for the parallax confirmed the value found from the first two sets alone, in which the proper motion

could not be taken into account, which value was published in a paper presented at the Denver meeting of the A. A. A. S. last August. This value was practically zero relative to the mean parallax of the two comparison stars employed, stars of about the eighth magnitude. In conclusion the author remarked that, considering its probable error, the value found was not incompatible with that required by the hypothesis advanced by Wolf and others, viz., that the apparent displacements in the nebula surrounding the Nova represent a velocity corresponding with that of an electric wave.

Note on the Parallax of Nova Persei:

R. G. AITKEN.

An attempt was made to determine the parallax of Nova Persei from the micrometric measures of six faint stars near it. The first set of measures was obtained, under very unfavorable conditions, shortly after the appearance of the Nova, and a second set on two nights in the latter part of July. The resulting values of the relative parallax were all negative, so that no conclusion can be drawn, unless, possibly, that the parallax of Nova Persei is very small. No account was or could be taken of possible proper motion.

The Energy of Condensation of Stellar Bodies: By R. S. WOODWARD.

This paper considers the density, pressure and energy of condensation from a state of infinite diffusion, of a spherical stellar body in which Laplace's law of density holds. Denoting the potential, density, and pressure at a distance r from the center of such a mass by V , ρ and p , respectively, the problem is stated in three equations, namely:

$$\frac{d^2(rV)}{dr^2} + 4\pi krp = 0,$$

$$dp = cpdp = \rho dV,$$

wherein k is the gravitation constant and

c is the constant connecting density and pressure in Laplace's celebrated hypothesis. Assuming the density to vanish at a distance r_0 from the center of such a body, it turns out that V , ρ and p are given by the following formulas, in which ρ_c and p_c are the central density and pressure, respectively, and M is the mass of the star:

$$\begin{aligned} a &= \pi/r_0, & q &= \sin ar/(ar), \\ \rho_c &= M\pi/(4r_0^3), & p_c &= M^2k\pi/(8r_0^4), \\ V &= \frac{Mk}{r_0}(1+q), & \rho &= \rho_c q, & p &= p_c q^2. \end{aligned}$$

The energy of condensation of such a mass is found to be

$$\frac{3}{4} \frac{m^2 k}{r_0} = \frac{3}{4} F r_0,$$

where F is the force of attraction between M and an equal mass of infinitesimal volume situated at a distance r_0 from the center of M . It will be observed that the results here given require no hypothesis as to the temperature of such bodies.

Optical Distortion of Photographic Telescopes: HAROLD JACOBY.

The observations discussed in the present paper form part of a more extended series undertaken in the year 1895, having for its principal object a study of the optical distortion of astronomical photographic objectives. A question had been raised as to the fidelity with which photographic telescopes reproduce upon the negative exact relative positions of the stars as they appear on the sky. This matter is fundamental to the art of astronomical photography throughout the entire range of its more important applications to stellar parallax, interstellar motion within the close clusters, and star charting in general; so that the large amount of labor involved even in its partial elucidation does not appear to be superfluous. Valuable cooperation in the work has been granted with ready kindness by several astronomers; and with their aid the special problem under

investigation has been solved in a fairly satisfactory manner.

This special problem may be thus stated: Is the scale-value of an astronomical photograph absolutely independent of the direction of measurement on the negative? In other words, if we determine the coordinates of star-images on the plate in millimeters with reference to a pair of rectangular axes, the question is: Will a distance of one millimeter measured from the center of the plate along the X-axis correspond to precisely the same number of seconds of arc on the sky as a distance of one millimeter measured from the same center along the Y-axis? The matter may be put in still another way. Suppose there were upon the sky a number of stars so situated as to form a small but perfectly exact circle. Would a photograph show these stars situated upon a similar exact circle on the negative, or would defects of the object glass distort their position into an ellipse-like oval, after the manner of atmospheric refraction? If this is the case, equal diameters of the circle on the sky will become unequal diameters of the oval on the plate; and, in general, equal distances upon the sky expressed in seconds of arc will become unequal distances upon the plate expressed in millimeters, even after correction for all known sources of difference, such as refraction, aberration, etc.

Various investigations of optical distortion have been published by Donner, Turner and others; but they were all made by methods necessitating a knowledge of relative star positions based on measures other than photographic. To avoid this inherent difficulty, the writer suggested in 1893 a process in which it is not essential to have a precise previous knowledge of relative star positions. It is thus rendered entirely unnecessary either to make a laborious and time-consuming heliometer trian-

gulation, or resort to comparatively inaccurate star-places, such as those obtained with meridian instruments. Proper motion, also, which necessitates new heliometric triangulations made very near the date of the photographic observations, is altogether eliminated in the use of this method.

It is merely necessary to arrange the telescope so that it can be rotated around its optical axis, or some other axis parallel to its optical axis. Suppose two photographs of a group of stars have been made with such a telescope, rotated 90° between the two exposures. If, then, the object glass possesses the peculiarity of making all the Y-coordinates too large in the first exposure, the same peculiarity will show itself in the second exposure by making all the X-coordinates correspondingly too large. Thus it is sufficient to make a series of negatives of the same star-group, rotating the instrument through various angles between the exposures, when a simple comparison will surely bring to light any form of optical distortion depending on the direction of measurement upon the plate.

The process is a purely differential one, and requires only a roughly approximate knowledge of the absolute star-positions, sufficient for the computation of refraction corrections, etc. It can be applied to an equatorial telescope of the ordinary form if we photograph the region immediately surrounding the pole of the heavens. In that case, the polar axis of the equatorial becomes a suitable axis for rotating the telescope, since the polar axis is parallel to the optical axis, when the tube is pointed at the pole. It is obvious that a trial of this method will furnish not only a determination of optical distortion, but will yield also, as a sort of by-product, a photographic catalogue of the close polar stars. For this reason it seemed desirable to include in the work a set of plates of the south pole as well as the north. In this way

we should obtain very precise catalogues of both sets of close polar stars, all reduced and computed according to a uniform method.

In 1895 the writer was visting at the Cape of Good Hope Observatory, and discussed the matter with Sir David Gill. The plan met with his approval, and he consented gladly to make the necessary south polar plates. With equal readiness, Dr. Anders Donner, of the Helsingfors Observatory, offered to make the north polar plates. These latter negatives were measured at Columbia University by Mrs. Herman S. Davis and Mrs. Annie Maclear Jacoby; the measures were reduced at Vassar College by Miss C. E. Furness; and they were published by the Vassar College Observatory. The south polar plates were similarly measured and reduced at Columbia by Misses F. E. Harpham, Mary Tarbox, Eudora Magill and H. L. Davis, and the results will soon be published by the Observatory of Columbia University. The researches for both poles agree in showing that the optical distortion depending on direction of measurement is too small to be detected with certainty even by the delicate differential method here described.

W. S. EICHELBERGER,

For the Council.

(To be concluded.)

THE U. S. COAST AND GEODETIC SURVEY.

THE last annual report* of the Superintendent of the United States Coast and Geodetic Survey to Congress is fully illustrated with maps and diagrams and presents in detail the work accomplished by this bureau for the fiscal year ending June 30, 1901.

Throughout the report there is frequent evidence of the increased scope of the Survey's operations within the last few years, as well as proof of the flexibility of the

* Now in the hands of the printer.

organization, which appears to have readily adapted its methods to the diverse conditions of our widely distributed possessions.

Appendix 4 in a manner indicates the continuous growth of the area to be charted by the Survey, which has followed upon the territorial expansion of our country. It consists of tables used in the computation of geographical positions. The first publication of this character was limited to the United States, between 23° and 50° of latitude. Two extensions carried the tables to the Arctic Ocean and the present one extends them to the equator.

The physical and social conditions of Alaska and of the Philippines make a strong contrast, and the methods employed in charting the two regions must on that account, to a certain extent, differ. But it appears from the report that there are other conditions common to both which require similar treatment. It is the general belief that both Alaska and the Philippine Islands are on the threshold of a commercial awakening. The rich mineral resources of the former promise steady development, while the many valuable products of the latter only await organized effort to be the source of a boundless traffic. For the safety of the vessels and cargoes engaged in this commerce accurate charts are most important. Those of a large portion of the coast of Alaska and adjacent waters are still constructed from the information obtained by early explorers and navigators, whose facilities for obtaining accurate locations were meager. In the Philippines the charts are truly oriental in their untruthfulness.

It is the policy of the Survey to first attack those portions most urgently needed and the doubtful areas in Alaska are being gradually reduced in size. Thus during the year surveys were extended along the coast of Seward Peninsula where Nome, the focus of the latest and most promising gold fields,

is situated. It faces the open sea and at present the transfer of persons and property to and from the vessels is subject to the risks of sudden storms and heavy surf. In the future development of this region a harbor for ocean-going vessels will be a necessity, and with this in view the two nearest, Port Clarence to the north and Golofnin Bay to the east, were included in the Survey. Later in the year the principal passes through the Aleutian Islands into Bering Sea, as well as Icy Straits and Cross Sound, were taken up with every prospect of completion.

In the Philippines, Manila, as the seat of the government, is the central point from which the telegraph lines diverge in all directions. A suboffice and astronomical station were established there, and from the latter as the initial point the longitudes of 14 stations were determined by telegraph and also at the same time latitude and azimuth observations were made. Three charts and notices to mariners were issued and six additional charts were ready for publication on July 1. A steamer was purchased by the Philippine Commission for the use of the Coast and Geodetic Survey, and money was appropriated by the Commission to repair and equip this vessel.

In Porto Rico, hydrographic work was continued in the harbors and bays and offshore. The triangulation around the island and topographic surveys of the shore line were continued. The topographic survey of Vieques Island was completed.

Our home interests were not neglected as may be seen from the fact that hydrographic and topographic surveys were made in localities in 19 States for the purpose of bringing the charts up to date in consequence of natural or artificial changes which have occurred since the original surveys.

Speed trial courses for the use of ships and torpedo boats were established in Dela-

ware and Chesapeake bays, and the Santa Barbara channel course was extended.

In addition to other field and office work, continuous tidal stations were maintained in this country at 6 stations and at 1 in the Philippines, and tide tables for 1902 were published, giving predictions for 70 principal and about 3,000 subordinate stations throughout the world.

During the year the Coast Pilot relating to southeast Alaska was thoroughly revised in the field and prepared for the printer. The field revision of the Coast Pilot between San Diego and San Francisco was completed and new editions of sections relating to the Atlantic coast were published, and the revision and issue of other numbers are in progress.

Strict business methods are not often associated with the measurement of the bases of a great trigonometrical survey. From the literature on the subject it appears that in the endeavor to attain a high degree of accuracy financial considerations have been subordinated to the scientific and experimental. The conduct of the measure of the nine bases along the ninety-eighth meridian was an exception to this rule, and Appendix No. 3, which describes the methods and results has an added interest of novelty. This was the first campaign of a party organized solely for the measurement of bases. A great gain in economy and time was accomplished by taking advantage of the skill acquired by the party by the frequent repetition of the same operations. After a thorough study of former measures a standard of accuracy was determined upon, and the operations so planned, by strengthening some points in the methods, that the number of measures could be reduced and certain refinements omitted. These bases form part of the chain of triangulation which it is proposed to extend along the ninety-eighth meridian, in both a north and south direc-

tion from the transcontinental chain, to the boundaries of the United States. It will include an arc of 23° , and together with the transcontinental triangulation as the backbone will form one of the ribs of the main framework for the control of all the triangulation in the United States. The Mexican Government has already in progress a system along the same meridian which, it is expected, will extend the arc 9° in latitude, and it is also possible for the Canadian Government to extend the arc far to the northward. Appendix No. 6 treats of the completed portion of the work in Kansas and Nebraska.

In connection with the general magnetic survey which supplies the data for constructing the compass diagrams on the charts, and furnishes the land surveyor the information for correctly running his traverse lines, observations were made at 374 stations in 30 States and Territories, including Alaska, Porto Rico, Hawaii and the Philippine Islands. In southeastern Alaska places have been examined where local magnetic disturbances affect the compasses of passing ships to such an extent as to endanger navigation.

A magnetic observatory has been established in Maryland, and sites for others have been selected in Alaska and Hawaii. In addition to their regular work, these will cooperate, at the formal request of the German Government, with the international magnetic work to be carried out during the time of the various antarctic expeditions which have been sent out from Germany and Great Britain.

Another piece of work of international interest was executed by the Survey in 1900. Observations were then made with the half second pendulum apparatus, devised by the Survey, at several of the more important European base stations, for the purpose of connecting Washington, which is used as the base for the American pendu-

lum observations. Appendix No. 5 gives the details of the results secured.

A special report on 'The Eastern Oblique Arc of the United States was completed and is being printed as a special publication. It is an important contribution to the subject of geodesy.

Satisfactory results have been obtained at the astronomical observatories maintained under the direction of the Survey at international expense, at Gaithersburg, Md., and Ukiah, Cal., for the purpose of determining the variation of latitude.

The Survey has been represented by its officers on commissions charged with the marking of one international and two state boundaries.

The report refers to the reorganization of the Office of Standard Weights and Measures and its establishment as the National Bureau of Standards by act of Congress March 3, 1901. The principal reasons for the change in order to meet the present requirements of scientific and commercial interests are summarized, and a description of the functions of the new bureau and the proposed buildings and accessories is given in detail.

SCIENTIFIC BOOKS.

A Treatise on Zoology. Edited by E. RAY LANKESTER. Part IV. *The Platyhelminia, Mesozoa, and Nemertini.* By W. BLAXLAND BENHAM, D.Sc., M.A. London, Adam and Charles Black, Publishers; New York, Macmillan & Company. Pp. 204. 114 figs. in text. Price \$5.25.

Volume IV. of Lankester's valuable series well maintains the standard set by the parts previously issued, and the lower divisions of the old group 'Vermes' are here treated in a broad and suggestive manner by a well-known helminthologist. The author deserves the gratitude of all zoologists for bringing together in a concise but comprehensive form the many facts that have been accumulated in connection with these lower forms of Invertebrata.

From the nature of the subjects treated the text is necessarily disconnected, but each division is accurately set forth in respect of the structural modifications and types, and each is complete in itself. The divisions which are thus separately treated are: Turbellaria, Temnocephaloidea, Trematoda, Cestoidea, Nemertini, and appendices to the Platyhelminia, including Rhombozoa (*Dicyema*, etc.), Orthonectida, Trichoplax, Salinella, etc. The author adopts Lang's classification of the Turbellaria into Rhabdocelida, Tricladida and Polycladida; Monticelli's orders of the Trematoda, and Bürger's divisions of the Nemertini. The greatest changes are to be found in the Cestoidea. Here Lang's 'orders' *Cestoda monozoa* and *Cestoda polyzoa* are changed to the 'grades' *Cestoda monozoa* and *Cestoda merozoa*, while each is further divided into sections and orders. Among the *monozoa* we find the orders *Amphilinacea*, *Gyrodactylacea* and *Caryophyllacea* based upon the characters of the genera similarly named. The *merozoa* are further subdivided into sections *Dibothridiata* and *Tetrabothridiata* according to the number of sucking cups or 'bothria.' In the former there is one order, *Pseudophyllidia* of van Beneden, while in the latter the number of orders is raised to four: *Tetraphyllidia*, *Diphyllidia*, *Tetrarhyncha* of van Beneden and *Tetracotylea* of Diesing. (*Tæniidæ* auct.)

We are particularly pleased with the substitution of the term 'merozoa' for Polyzoa in the classification of Cestoidea and it should do away with the confusion of terms among English-speaking zoologists who adhere to Thompson's term Polyzoa for an order of the Molluscoidea. The use of the term 'Mesozoa' in the title of the book is less satisfactory for it perpetuates the probable error of regarding a small group of parasitic and degenerate forms of Platyhelminia (?) as 'intermediate' or primitive types, notwithstanding that this view is strongly attacked in the text, where the word appears only in an historical sense.

An innovation of great value is the introduction of a concise historical statement, in which are given the names and dates of the men who have added to our knowledge of each of the classes considered; and still another

feature which adds interest and value to the book, is the frequent allusion to general zoological theories. For example, the relations of the Nemertini to the theories of the origin of metamerism are considered in sufficient detail to make the matter clear. On this particular question the author takes no positive stand one way or the other, but is inclined, on the whole, to follow Hatschek and Mayer. These additions greatly enhance the general interest of technical works like the one under consideration and materially lessen the burden of the load of detail which the student must struggle under.

The style of writing, although somewhat heavy, is clear and definite, and awkward phrases like 'a pair of groups,' and 'than which,' or careless statements, such as 'the very close relationship of these two groups (Turbellaria and Nudibranch molluses) with the Cœlenterata' (p. 12), are rarely encountered. The author puts himself in the way of a great temptation by describing at the outset what he considers to be an 'ideal' Platyhelminth, and throughout the book we find him, consciously or unconsciously, setting up this ideal as a phylogenetic fetish. Such a method of presentation may or may not be subject to criticism, according as the book is to be used as a text-book or as a reference book. The 'type' method is very handy for teaching purposes, but as a basis for phylogenetic deductions it appears somewhat out of place and becomes a source of possible error. These are but minor criticisms, however, and may be easily overlooked when we consider the many merits and interesting suggestions which the author has embodied in this volume.

GARY N. CALKINS.

COLUMBIA UNIVERSITY.

Yale Bi-Centennial Publications. Contributions to Mineralogy and Petrography from the Laboratories of the Sheffield Scientific School of Yale University: Edited by S. L. PENFIELD and L. V. PIRSSON. 1901. With three plates and several figures.

The volume comprises 'a series of reprints from some of the most important of the papers containing the results of the researches made

in the chemical, mineralogical and petrographical laboratories at Yale in the lines of mineralogy and petrography.' Part I. by Professor Penfield includes a history of the mineralogical department and of the development of mineralogy at Yale, which goes back to the first years of the last century and continues since then to represent American mineralogical research. A bibliography of mineralogical papers and summary of new mineral species determined, or of formulas established, is added. Forty-three papers on mineralogical subjects are reprinted, mainly from the *American Journal of Science* between 1850 and 1901; the authors are S. L. Penfield, Geo. J. Brush, E. S. Dana, H. L. Wells and others. Part II. by Professor Pirsson gives a similar history and bibliography for the petrographical department, which, notwithstanding its comparatively recent organization, makes a valiant exhibit even compared with its older companion. Eight petrographic papers, several of classic interest to American petrographers, are reprinted. The volume is a valuable collection of important papers, and a striking record of original research in the departments included.

JOHN E. WOLFF.

HARVARD UNIVERSITY.

Velocity Diagrams. By CHAS. W. MACCORD, A.M., Sc.D. New York, J. Wiley & Sons; London, Chapman & Hall. 1901. 8vo. Pp. 113. Figs. 83. \$1.50.

Professor MacCord has published in this form an abstract of lectures forming a part of his course of instruction, illustrating his methods of treatment of problems in kinematics involving the construction of 'velocity diagrams' and supplementing the work embodied in his larger treatise on 'Kinematics of Practical Mechanism.' He has, for many years, found this class of graphical construction peculiarly interesting as bearing upon the work of the designing engineer planning combinations of mechanical movements, and he has developed this feature of his work with rare skill, ingenuity and practicality. The occasional appearance of an article by the same hand in the technical journals, notably in the *Scientific American Supplement*, has been al-

most the only evidence since the time of Willis that any master-hand has been working in this important field. The present publication places on record, in a convenient form, a considerable collection of such work and one likely to prove valuable to all mechanical engineers and draughtsmen.

The points here discussed and graphically treated are the general principles of the science, angular velocities, instantaneous axes, contact motions, including cams, rolling contacts, eccentric and related motions, linkwork, including 'slow advance and quick return' compositions, which are extensively treated, and, finally, the accelerative motions.

These discussions are concise, accurate, direct and clear. The theory of each case is developed as the construction progresses, in an admirable manner, and the graphical work is always equally clear, exact and legible. The author is an expert in this field and his skilful hand is recognized in the graphical constructions and their beautiful lines quite as well as in the text.

The book is printed on fine paper—which is, in fact, essential to the proper production of the illustrations—and the type and finish are alike appropriate to the artistic work of the writer of the treatise.

R. H. T.

GENERAL.

ON behalf of the Committee on Historical Documents of the American Historical Society, Supreme Court Justice Mitchell reported at the last meeting that arrangements had been made for the publication in full of the original journals of Lewis and Clark. These notebooks were deposited with the Society nearly a century ago by Governor Clark at the request of President Jefferson, under whose direction was sent out the expedition which gave the country the first knowledge of the newly acquired northwestern possessions.

THE Berlin and Copenhagen Academies of Sciences have commenced the task of collecting all the manuscript left by Galen and compiling a new and complete edition of his works.

THE preliminary work upon the preparation of a revised catalogue of the birds of Ohio has resulted in the addition of twenty species to the list since Dr. Wheaton's catalogue was published. Nearly 150 preliminary lists have been sent out for additions and corrections, but hardly a third of them have been returned to date. From those returned annotated much valuable information has been gained, particularly of an ecological nature, furnishing a basis for comparisons with conditions in Dr. Wheaton's time. Considerable field work must still be done in the extreme western, the eastern and the southern fifth of the State before the ideals upon which the work of revision was founded can be even approximately realized. As an aid to the furtherance of this work the compiler solicits information from all who are familiar with Ohio birds, who have not already examined a preliminary list. Communicate with Lynds Jones, Oberlin, Ohio.

SOCIETIES AND ACADEMIES.

BIOLOGICAL SOCIETY OF WASHINGTON.

THE 348th meeting was held on Saturday evening, January 25.

Under the heading of notes W. H. Dall called attention to the practice indulged in by some writers of rejecting names in biology which differ only by terminations indicating gender, as *Cyprina* from *Cyprinus*. He reprobated the practice as, if carried out strictly, likely to overthrow many names which have been in universal use for a century or so, and with absolutely no gain to science. As a particularly glaring instance of this he cited a recent experience with the work of Duméril, 'Zoologie Analytique,' issued in 1806. Duméril gave names to the animals of mollusca, distinct from those applied to the shells, by adding to the latter the termination *arius*. Thus we have the animal of the shell called *Nassa* by Lamarck, referred to a genus *Nassarius* by Duméril. On the ground that this name existed, though, like all Duméril's names an absolute synonym, the later genus *Nassaria* of Adams and Reeve has been rejected by a recent writer. On looking up the facts in the

case and making a list of Duméril's names for future reference, it was found that among them was one called *Pleurotomarius*, founded on the animal of *Pleurotoma* Lamarck. This, if the above obnoxious custom were adopted, would oblige us to reject *Pleurotomaria* J. Sowerby, and its equivalent *Pleurotomarius* Blainville, for the well-known archaic genus of mollusks which has been accepted by everybody since 1821. The type of *Pleurotomarius* Duméril, furnished by Froriep in his translation of 1806, is *Pleurotoma babylonia* Lamarck, which is the type of Lamarck's genus *Pleurotoma*, 1799.

David Griffiths described, under the title 'A Seed Planter,' the peculiar method by which the seeds of *Plantago fastigata* are enabled to obtain a foothold on the baked plains of the southwest. The seeds of this plant are very abundant and are scattered far and wide, accumulating in every little depression. After the slightest shower these seeds are surrounded by a thick mucilaginous layer which, as it dries and shrinks, creates a minute pit under each seed, into which it sinks and is covered with dust and buried ready to germinate and send down a rootlet after the next shower.

F. A. Lucas presented 'A Phase of the Blue Fox Question,' referring to a paper read before the Society two years ago, in which he described the methods of trapping blue foxes devised by Mr. James Judge and employed on St. George Island of the Pribilof group. He recalled that males only were kept in the endeavor to make the foxes polygamous and his remark that the results of the experiment would be awaited with interest. The present communication gave the observations of Mr. Walter I. Lembkey, Treasury Agent, showing that after four years of trapping there was no evident increase either in the total number of foxes, or in the number of females. The entire paper will be given later in SCIENCE.

Rodney H. True discussed at some length 'The Physiology of Sea Water' and a synopsis of the paper will be found in the account of the meeting of the Society of Plant Morphology and Physiology given in SCIENCE.

F. A. LUCAS.

NATIONAL GEOGRAPHIC SOCIETY.

THE meeting of January 10 was devoted almost wholly to business affairs. The following named gentlemen were elected to serve as managers for the ensuing three years: Alexander Graham Bell, Henry Gannett, A. W. Greely, Angelo Heilprin, Russell Hinman, W. J. McGee, Gifford Pinchot and Otto H. Tittmann. The secretary's report showed an increase in membership, the total being over 2,600.

At the meeting of January 24 Dr. L. A. Bauer, in charge of the Division of Terrestrial Magnetism, U. S. Coast and Geodetic Survey, gave an account of the magnetic survey of the United States now being prosecuted. The importance of an accurate knowledge of the variation of the magnetic compass was dwelt on at some length.

The present survey involves a determination of the compass variation throughout the United States and the publication of the results in such form as shall be most useful to those interested. Stations about 25 miles apart have been established for the purpose of ascertaining the compass variation, while four magnetic observatories have been installed at the following named places: Cheltenham, Md.; Baldwin, Kans.; Sitka, Alaska, and Honolulu, Hawaii. At these observatories complete records of all the magnetic elements will be obtained.

The second paper of the evening was by Mr. James Page of the Hydrographic Office, Navy Department, on Ocean Currents. Mr. Page showed that an intimate relation existed between the general atmospheric circulation and the system of ocean currents, and that the latter were due directly or indirectly to the frictional action of the wind. The rate of drift of ocean currents varies greatly; in extreme cases it might be as much as 75 to 100 miles in 24 hours, but generally it is very much less, not more than 20 to 30 miles in 24 hours.

A. J. HENRY,
Secretary.

SCIENCE CLUB, UNIVERSITY OF WISCONSIN.

At the December meeting of the Science Club of the University of Wisconsin, Decem-

ber 17, Professor T. C. Chamberlin, of the University of Chicago, gave an address entitled, 'Some Further Studies as to the Early States of the Earth.' The nebular hypothesis of the origin of the earth, as stated by Laplace, was discussed, and a brief summary made of certain tests to which the theory had been put by Professor Chamberlin and others, as described by Professor Chamberlin in various publications. It was concluded that the Laplacean hypothesis will not stand fundamental tests and that some modification of the hypothesis or some new hypothesis is necessary.

Professor Chamberlin's researches have furnished criteria for a new hypothesis of the origin of the earth. The parent body out of which the solar system was evolved must have been one which possessed limited matter; a very small proportion of matter near the exterior with very high energy of movement; in the central portion very low energy of movement, and with the conditions in the central portion permitting the development of a spherical body as the controlling center.

The earth in its early history may be conceived to have been a small body, growing gradually by the infall of material from without, without, in the early stages, an atmosphere, because of its incompetency to hold one. The atmosphere, instead of being the dominant phenomenon at the beginning of the earth, was practically absent from the exterior of the earth until it was $\frac{1}{5}$ or more grown. Gradually the accretion of the atmosphere permitted the gathering of water vapor, and this by condensation at length formed the oceans. These thenceforth protected the infalling matter of that portion of the earth, for matter falling into water does not undergo as ready decomposition as that which falls upon the surface. This process going on from age to age gave to certain areas a higher specific gravity than other portions. We therefore have an explanation of the superior gravity of the portion of the earth lying under these beds of water as compared with the land, and thus, perhaps, of the great depth of ocean basins.

It is obvious that from a very early stage volcanic action must have arisen from the ex-

cessive heat generated in the interior through self-compression of the mass, as may be shown by mathematical calculation. The volcanic action would affect certain substances before others, and the selection thus made from the time of its inauguration, when the earth was perhaps not more than $\frac{1}{80}$ or $\frac{1}{100}$ grown, is sufficient to explain the present distribution of volcanic matter.

Another phase of the history of the earth may be traced in this way: If the temperature of the interior is sufficiently accounted for by compression, the temperature developed by the infall of matter may have been made available for the sustenance of life at a very early period. Therefore we escape the objections raised by geologists against the prolonged era of evolution insisted upon by biologists.

C. K. LEITH.

THE ACADEMY OF SCIENCE OF ST. LOUIS.

At the meeting of the Academy of Science of St. Louis on the evening of January 20, Dr. George Richter delivered an address on the physical and chemical properties of gelatin, which he described as a spongy substance differing materially from other solids. The manner of manufacture of gelatin and its chemical and physical characters were described in detail, and considerable attention was given to the rate of absorption and evaporation of water by gelatin, and the phenomenon of its apparent solution in water. A new hygrometer was exhibited and described, the action of which was based upon the water absorption of gelatin.

At the meeting on February 3, Mr. Trelease presented, with the aid of lantern illustrations, some of the principal results of his recent studies of Yuccas and their allies.

WILLIAM TRELEASE,
Recording Secretary.

DISCUSSION AND CORRESPONDENCE.

WIRELESS TELEGRAPHY.

TO THE EDITOR OF SCIENCE: I wish to enter formal protest against the statement concerning Wireless Telegraphy, on page 112, etc., of the issue of SCIENCE for January 17.

In anything that I may say let it be understood that I am not personal to Professor Franklin, who brings the editorial from London *Electrician* to our attention. The readers of SCIENCE need no statement from me as to Professor Franklin's qualifications.

It is too much the habit of scientists to be conservative about the application of scientific theory to commercial use. It seems to be an attitude which it is impossible to avoid; and the limitations of the individual are usually regarded as those of the science. For this reason I protest against the conclusions so hastily drawn in the present immature stage of the art of Wireless Telegraphy, viz., that it is practically incapable of any substantial extension. In this connection I quote from the *Scientific American* Supplement, the issue of August 5, 1882, page 5490, from an article called 'Electro-Mania' by W. M. Williams.

I well remember making this journey to Boxmoor (upon one of the early steam railway carriages on the London and Northwestern Railway), and four or five years later travelling on a circular electro-magnetic railway. Comparing that electric railway with those now exhibiting, and comparing the Boxmoor trip with the present work of the London and Northwestern Railway, I have no hesitation in affirming that the rate of progress in electro-locomotion during the last forty years has been far smaller than that of steam. The leading fallacy which is urging the electro-maniacs of the present time to their ruinous investments is the idea that electro-motors are novelties, and that electric lighting is in its infancy; while gas lighting is regarded as an old, or mature middle-aged business, and, therefore, we are to expect a marvelous growth of the infant and no further progress of the adult.

This quotation is a type. Further, application of scientific theory to the affairs of man has from time immemorial been met by the scoffs not only of the ignorant (which may be borne with equanimity), but of those who ought to know better. The article by Mr. Williams was written after the birth of the dynamo, and he was doubtless incapable of distinguishing then between the old galvanic battery electric railways and those which followed the development of mechanical electric contrivances. We now know that the electric

railway, so lightly characterized then, is an every-day matter involving the use of more capital than all other electric contrivances combined. The capital liabilities of the electric railways in the United States alone amount to \$2,000,000,000; the telegraphs of the United States amount to \$175,000,000, and the telephone systems of all kinds to a little less than \$250,000,000.

Further, I protest that the entire article in the London *Electrician* is of the most unscientific character, utterly unworthy the attention of any one who tries to preserve fair-mindedness; and again that it misrepresents facts in the baldest manner; take such an example as this:

The wireless channel of transmission will be rigorously avoided by business men, to whom a guarantee of secrecy and the certainty of a recorded message are absolutely indispensable. Wireless signals in the ether can never be secret; it must always be possible to intercept them. And messages received in no more permanent form than by sounds in a telephone are too evanescent and uncertain to commend themselves to the purposes of commerce.

And this in spite of the fact that the most enormous transactions are undertaken and consummated by telephone!

Ipse dixit predictions of this kind are unscientific. The scientist who has learned to distinguish between 'It can't be done' and 'I can't do it' has learned something which the evanescent gentleman who penned the article brought to our attention has certainly neglected. A caution against undue haste or boldness of prediction is all right; but predictions of what cannot be done are all wrong, and very much further wrong, because they neglect all the teachings of the past, and instead of adopting a Baconian philosophy would render it impossible for scientific men to obtain the means of pursuing investigations.

T. J. JOHNSTON.

SHORTER ARTICLES.

THE DISCOVERY OF TORREJON MAMMALS IN MONTANA.

LAST spring (1901), after it was decided that an expedition should be sent from Princeton

University to the region of the Musselshell river in Montana, the writer suggested to Professor W. B. Scott the possibility of finding fossil mammals in the Fort Union beds which are so well developed in the Crazy Mountains and vicinity. It was his idea that in a country where the Laramie, Livingston and Fort Union beds occur and attain a considerable thickness, the long-sought ancestors of the placental mammals of the Puerco might be found.

In the region where the camp was established, near Fish Creek, to the eastward of the Crazy Mountains, the writer had found, during the previous year, near the top of the series of rocks so beautifully exposed in this region, many fossil deciduous leaves. Many of these were in a hard, fine-grained sandstone and were excellently preserved. Below the layers of sandstone containing the best leaves were dark or gray shales in which were carbonaceous matter, plant impressions and distorted gasteropod shells, interstratified with layers of quite hard gray sandstone, which were often ripple marked. Still lower were dark gray shales with concretions, and bands or lenses of limestone containing fresh-water Bivalves and Gasteropods. The concretions are brown (ironstones) and break in angular fragments. The shales are partly soft and fine-grained and in part sandy.

During the greater part of last summer the writer was collecting for the Princeton Museum and was with the Princeton party during their stay in this region. In August, while ascending the butte from which leaves had been procured the previous year, and examining the dark shale beneath the sandstone cap, he found fragments of a tooth, which, when put together looked like the canine tooth of a mammal. Near it a premolar was found that at once settled the matter. It appears to belong to a small species of *Pantolambda*. This level was followed and carefully searched. Several teeth of *Euprotogonia* were found and fragmentary remains of one or two more mammals, besides teeth and fragments of jaws of crocodiles. This exposure was small. Afterward on another side of the butte, ravines which exposed the shales at

about the same level were examined, and other bones and teeth were found.

These mammalian remains, which are now in the Princeton Museum, have been examined by W. B. Scott, M. S. Farr, and W. D. Matthew, as well as by the writer. One or two have been specifically determined and all agree that the beds belong to the Torrejon horizon. The fossils determined are:

Mioclanus acolytus (Cope),
Anisonchus close to *A. sectorius*,
Euprotogonia,
Pantolambda (?),
Psittacotherium (?).

This is a very interesting discovery, as heretofore Torrejon mammals have been found only in a limited area in New Mexico, and the beds have been searched with the greatest care, 'on hands and knees,' with a scientific zeal to know more of the peculiar mammals of this age.

The importance and interest of the discovery are doubled by the fact that everything seems to indicate that these are the Fort Union beds, the exact position of which has been uncertain. The collection of fossil leaves that was made in the summer of 1900 has been sent for with a view to the accurate determination of the species. As the Fort Union flora is a characteristic one it is confidently believed that the plants together with the mammals will settle the position of the Fort Union formation beyond controversy.

EARL DOUGLASS.

PRINCETON, N. J.

ENGINEERING NOTES.

ECCLES, a small town in England, has introduced the automobile fire-engine. It carries five men, three hundred feet of hose and standpipes, ladders, jumping sheet, etc. It is driven by an electric motor at a speed, on a smooth and level pavement, of about fifteen miles an hour. It climbs heavy gradients and is reported to be preeminently satisfactory. The self-propelled steam fire-engine has often been built, in the United States and abroad, and has sometimes proved satisfactory, though usually too heavy. The electric machine has at least one peculiar advantage in its instant

readiness for work. No delay is compelled as in starting fires and getting up steam or in waiting for horses, and immediately the alarm is heard, the attendant can jump upon his engine and start for the fire. In large cities, with their paid fire departments where the steam fire-engines always stand with water hot and steam making, and the horses and crews ready to move out of the house in intervals measured by seconds, this is a matter of less consequence; the engine will seldom fail to start promptly and to have steam ready before reaching its position at the fire. With small places, the case is very different. There, the engine is cold, no crew at hand, the horses often in a detached stable, or even at some distance, and in many cases hand-power only available. In such places, should a source of supply be at hand for charging batteries, the electric automobile fire-engine would prove ideal.

THE advance made to date in the production of locomotives for heavy work is illustrated by the completion, recently, for the Atchison road, by the Schenectady Locomotive Works, of a ten-wheel engine weighing 275,000 pounds; while the progress of the business of locomotive construction is evidenced by the acceptance of orders by the Baldwin Works to an aggregate of seven hundred engines of all styles for the year 1902.

The *Providence Journal* owns an electric automobile, which has been working since the early autumn. It has traversed 1,000 miles and is expected to make the record 1,500 or 1,800 before its batteries will require replacement. The normal output is 22 amperes; but it has risen to 80 when ascending the hill to Brown University from Market Square. It has shown the practicability of rising a 10 per cent. gradient, although at serious cost in life of battery. It is estimated by the *Journal* that the cost is about that of keeping a single horse and carriage.

R. H. T.

BOTANICAL NOTES.

THE 'BROWN DISEASE' OF POTATOES.

FOR several years the potato crop of Nebraska has been seriously damaged by a disease

which causes the fibro-vascular bundles to turn brown. This disease appears to be widely distributed in both America and Europe, but as yet nothing satisfactory has been published in this country concerning the cause of the trouble. About the first of March, 1901, Mr. J. A. Warren, now of the Santee Normal Training School, began a series of experiments in the botanical laboratories of the University of Nebraska in order to determine if possible what produced the disease. He now reports as follows: "My first cultures soon showed tufts of mould filaments projecting from the diseased bundles, and in a few days there were many ripe fruits of *Stysanus stemonites* (Pers.) Corda. I repeated the experiment many times, using both affected and unaffected tubers from different fields. In nearly every case the cultures containing brown bundles produced *Stysanus*, while those containing no brown bundles produced no *Stysanus*. Tubers grown at Lincoln, Harvard, Humboldt and Santee, Nebraska, and Cedar, Minnesota, were used, always with the same results. These experiments have now been continued for about eight months, and I hope to follow them the coming season. The results seem to show that *Stysanus stemonites* is the cause of the disease."

The importance of this discovery lies in the fact that this appears to be the first record which connects *Stysanus stemonites* with this disease in this country, as well as the first record of its occurrence.

MORE ON THE PHILIPPINE FLORA.

THE Forestry Bureau of the Philippine Islands has issued a sixteen page pamphlet on the 'Tree Species,' giving the scientific and common names, the families and a little information in regard to the usefulness of the trees in the industries. No less than sixty-one families are represented, and the whole number of species enumerated is six hundred and twenty-two. The larger families are Urticaceae, with 45 species; Leguminosae, 42; Euphorbiaceae, 30; Myrtaceae, 28; Rubiaceae, 28; Sapotaceae, 24; and Lauraceae, 22. Of the Cupuliferae there are 13 species, two of which are species of *Castanopsis*, the remainder being

species of *Quercus*. There are 18 species of Palms (*Palmaceae*), and 5 of *Coniferae*. A solitary species (*Vernonia arborea vestita*) represents the arboreous *Compositae* of the islands.

A second publication of the same bureau, 'The Spanish Public Land Laws of the Philippine Islands,' is worthy of notice here. This consists of translations and compilations of the principal laws which governed the sale of the public lands in the islands under Spanish rule. It is worthy of mention that the Spanish laws made provision for the reservation of those tracts of land which are denominated 'forest zones,' and of which it is declared that 'the state desires to hold for the commonwealth.' It is further declared in regard to these forest zones that 'no private ownership can be claimed in them by any process of law, unless they are explicitly declared to be salable by competent authority.' One may wish that such wise counsels had prevailed when our forefathers took possession of the forest wealth of this country. Had this been done we should not now be trying to save the last of our forests by the reservation of such mere fragments as have escaped destruction because scarcely worthy of notice by the lumbermen.

ANOTHER TEXT-BOOK OF BOTANY.

A LITTLE book entitled, 'Outlines of Botany,' prepared by R. G. Leavitt, of the Ames Botanical Laboratory at North Easton, Mass., 'at the request of the Botanical Department of Harvard University' is very suggestive of the change which has taken place in our notions as to the proper study of plants in the high schools. Here is a book 'based on Gray's Lessons in Botany,' which is as different from the book of which it is supposed to be a modification as can well be imagined. In fact the preface indicates as much, when it speaks of many schools 'having outgrown certain now antiquated methods of teaching botany.' Instead of a book of lessons to be memorized, we have here a book to be worked through in the laboratory, with the proper material and appliances at hand. Only one feature of the new book has a familiar look, viz., the illustrations, over which some of us bent thirty-five years ago.

All else is new, and to these old-time friends are added many new ones in order to illustrate the new topics and new treatment.

The treatment of the subject may be made out from the headings of the chapters, some of which are as follows: 'Laboratory Studies of Seeds and Seedlings,' 'Laboratory Studies of Buds,' 'Laboratory Studies of the Root,' and so on for the stem, the leaf, the flower, the fruit and the 'Cryptogams.' After each laboratory chapter there follows one of general discussion on the same subject. The closing chapters are devoted to the 'Minute Anatomy of Flowering Plants' and a 'Brief Outline of Vegetable Physiology.' The book is thus an introduction to modern botany, and since it is to be presumed that it has had the oversight of the eminent men in the Department of Botany in Harvard University, we need not be surprised at its excellence, although its author is yet a comparative stranger in botanical circles. We are glad to welcome the book as a valuable addition to the text-books for use in high schools.

INDIAN USES OF PLANTS.

IN a recent bulletin of the Division of Botany of the United States Department of Agriculture, Mr. V. K. Chesnut tells of the uses which the Indians of Mendocino County, California, make of a large number of plants, ranging from red seaweeds, fungi, lichens, ferns and conifers to flowering plants. Fibers, medicines and food constitute the principal uses which the Indians make of the wild plants of the region studied. One is astonished at the large number of fiber plants used by these people, and the question arises after reading this account whether the whites are not allowing valuable native fibers to go to waste. We have probably little to learn from the Indians in regard to the medicinal values of plants, but when we come to the food plants we are again inclined to wonder whether these primitive people may not be able to teach us to make better use of the products of the soil. The number of plants whose seeds yield wholesome food is very much larger than we had supposed possible. One curious feature in the food habits of these Indians is brought to

light, viz., that they eat clover (species of *Trifolium*), not the flower-heads, as white children do sometimes, but the leaves and stems, quite after the manner of other herbivorous animals! "From the beginning of April along into July it is no uncommon sight to see small groups of Indians wallowing in the clover and eating it by handfuls, or to see an Indian squaw emerging from a patch of clover and carrying a red bandana handkerchief full of the crisp stems."

CHARLES E. BESSEY.

THE UNIVERSITY OF NEBRASKA.

ELIZABETH THOMPSON SCIENCE FUND.

This fund, which was established by Mrs. Elizabeth Thompson, of Stamford, Connecticut, 'for the advancement and prosecution of scientific research in its broadest sense,' now amounts to \$26,000. As accumulated income will be available November next, the trustees desire to receive applications for appropriations in aid of scientific work. This endowment is not for the benefit of any one department of science, but it is the intention of the trustees to give the preference to those investigations which cannot otherwise be provided for, which have for their object the advancement of human knowledge or the benefit of mankind in general, rather than to researches directed to the solution of questions of merely local importance.

Applications for assistance from this fund, in order to receive consideration, must be accompanied by full information, especially in regard to the following points:

1. Precise amount required. Applicants are reminded that one dollar (\$1.00 or \$1) is approximately equivalent to four English shillings, four German Marks, five French francs, or five Italian lire.
2. Exact nature of the investigation proposed.
3. Conditions under which the research is to be prosecuted.
4. Manner in which the appropriation asked for is to be expended.

All applications should reach, before April 1, 1902, the Secretary of the Board of Trus-

tees, Dr. C. S. Minot, Harvard Medical School, Boston, Mass., U. S. A.

It is intended to make new grants in April, 1902.

The trustees are disinclined, for the present, to make any grant to meet ordinary expenses of living or to purchase instruments, such as are found commonly in laboratories. Decided preference will be given to applications for small amounts, and grants exceeding \$300 will be made only under very exceptional circumstances.

A list of the grants recently made is given below.

(Signed.)

HENRY P. BOWDITCH, *President.*

CHARLES S. RACKEMANN, *Treasurer.*

JAMES M. CRAFTS.

EDWARD C. PICKERING.

CHARLES-SEDCWICK MINOT, *Secretary.*

1900.

\$200, to Dr. H. H. Field, Zürich, Switzerland, to aid in the publication of a card catalogue of biological literature.

\$500, to S. H. Scudder, Esq., Cambridge, Mass., for the preparation of an index to North American Orthoptera.

\$300, to Professor P. Bachmetjew, Sofia, Bulgaria, for researches on the temperature of insects.

\$250, to Dr. E. S. Faust, Strassburg, Germany, for an investigation of the poisonous secretion of the skin of Amphibia.

\$250, to Professor Jacques Loeb, Chicago, Ill., for experiments on artificial parthenogenesis.

\$650, to the National Academy of Sciences, Washington, D. C., towards the expenses of three delegates to attend the conference of academies at Wiesbaden in October, 1899, to consider the formation of an International Association of Academies.

1901.

\$150, to Professor E. W. Scripture, New Haven, Conn., for work in experimental phonetics.

\$300, to Professor W. Valentiner, Heidelberg, Germany, for observations on variable stars.

\$50, to A. M. Reese, Esq., Baltimore, Md., for investigation of the embryology of the alligator.

1902.

\$125, to F. T. Lewis, M.D., Cambridge, Mass., for investigation of the development of the vena cava inferior.

SCIENTIFIC NOTES AND NEWS.

THE American Philosophical Society has elected Dr. Samuel P. Langley, secretary of the Smithsonian Institution, to be vice-president of the Society, and Dr. Ira Remsen, president of the Johns Hopkins University, to be one of the councilors.

'THE Races of Europe,' by Professor W. Z. Ripley, of the Massachusetts Institute of Technology, and professor-elect of economics at Harvard University, has been 'crowned' by the award of the prix Bertillon of the Société d' Anthropologie of Paris.

PROFESSOR J. W. GREGORY has been appointed acting head of the Geological Survey of Victoria, with a view to its reorganization.

M. MICHEL LEVY, inspector of the French mines, has been appointed a member of the council of the Conservatory of Arts and Measures.

THE foreign papers report that Professor Virehow, who has been confined to the house as the result of a fall, is making good progress towards recovery.

THE Medical Advisory Board of the Health Department of New York City has organized by electing Dr. Edward G. Janeway chairman and Dr. T. Mitchell Prudden secretary.

DR. F. W. PAVY, F.R.S., has been chosen president of the National Committee for Great Britain and Ireland at the Fourteenth International Congress of Medicine to be held at Madrid in April, 1903.

DR. JOHN D. JONES, formerly assistant chief of the bureau of forestry, and more recently a representative of the Department of Agriculture for the purpose of investigating the condition of agriculture in Asia, Hawaii and the West Indies, was appointed in June, 1899, as technical adviser to the Japanese department of agriculture and commerce. In recognition of his services the Emperor has recently conferred on him a high order.

DR. SAMUEL G. DIXON, president of the Philadelphia Academy of Natural Sciences, has been formally notified of election to honorary membership in the National Society of Natural Science and Mathematics, Cherbourg.

DR. J. W. LOWBER, of Austin, Tex., has been elected a fellow of the Royal Astronomical Society of London.

DR. T. H. MACBRIDE, professor of botany in the State University of Iowa, has been invited to deliver the address at the opening of the new library building at Muscatine. The address is to be given under the auspices of the Fortnightly Club of that city.

IN a course of lectures at Trinity College, Professor H. S. Graves, of Yale Forest School, will give 'Problems of American Forestry' March 11, and Rev. Henry C. McCook, D.D., 'The Homes and Habits of American Ants.' In addition Dr. McCook will address the students of the department of natural history upon spiders.

THE Navy Department has extended for six months the leave of absence granted to civil engineer Robert E. Peary, now in the Arctic regions.

DR. EDWARD PALMER, the veteran explorer of Mexico, left Washington on January 15 for a collecting expedition in the province of Santiago, Cuba. He will obtain the usual number of sets, which will be offered for sale upon his return. Dr. Palmer will be accompanied by Mr. Charles Louis Pollard and Mr. William Palmer, both of the United States National Museum, who will collect plants, mammals, birds and reptiles for that institution. As the party will pay especial attention to the unexplored mountains in the southern portion of the province, it is expected that the scientific results will be valuable.

PROFESSOR RALPH S. TARR, of Cornell University, is spending the winter in geological study in Italy and will spend the spring and summer in the study of the glacial deposits of Germany and the British Isles.

Nature states that an expedition to Lake Eyre, the great depression in Central Australia sinking below sea-level, has recently left Melbourne. The party consists of Professor J. W. Gregory, his assistant, Mr. H. J. Grayson, and five students of the geological department of the Melbourne University. The main objects of the expedition are the study of the

physical history of the Lake Eyre basin and the collection of fossils, especially the extinct giant vertebrates. The camel caravan starts from Hergott Springs, a station 440 miles north of Adelaide. It is hoped that the collections will throw light on some unexplained native traditions as to former giant animals that inhabited the Lake Eyre basin.

A BUST of Sir Frederick Bramwell has been presented to the Royal Institution, of which he was formerly honorary secretary.

At the celebration of University Day at the University of Pennsylvania on February 22, a portrait of Benjamin Franklin, by Gainsborough, will be presented by the class of 1852.

DR. PAUL F. MUNDÉ, the well-known New York gynecologist, at one time professor at Dartmouth College, died on February 7, aged fifty-five years.

ALFRED BRASHEAR MILLER, D.D., LL.D., president emeritus of Waynesburg College, Waynesburg, Pa., died on January 30, aged 72 years. He had been identified with the college from its foundation in 1851, having been president for 40 years and president emeritus three years.

COMMISSARY-GENERAL G. D. LARDNER, an Englishman who contributed to the advancement and popularization of astronomy, has died at the age of eighty-four years.

THE British National Physical Laboratory at Bushy House will be officially opened on March 19.

At the annual meeting of the Association of American Universities which opens at Chicago on February 24, the following four main questions will form the basis for discussion:

(1) 'The scope and character of the dissertation required for the degree of Doctor of Philosophy'; (2) 'The membership and policy of the Association of American Universities: Should it be enlarged, and, if so, under what principle of selection? Should the Association devote its attention to questions of graduate work in the arts and sciences exclusively, or shall it also consider and include law, medicine, theology, and political science?'; (3) 'What is research in a university sense, and how is it best promoted?' and (4) 'The degree of Master of Arts: Shall the granting of

this degree be encouraged, and, if so, what should it mean, and under what conditions shall it be given?'

These four topics have been assigned respectively to the University of Chicago, the University of California, Clark University, and Cornell University.

THE annual congress of the British Sanitary Institute will be held in Manchester on September 9-13. The section of sanitary science and preventive medicine will be presided over by Sir J. Crichton Browne; that of engineering and architecture by Sir Alexander Binnie; and that of physics, chemistry and biology by Professor A. Sheridan Delpéine.

THE board of directors of the American Academy of Political and Social Science, at its annual meeting in Philadelphia, elected the following officers: Professor Leo S. Rowe, *President*; Samuel McCune Lindsay, Franklin H. Giddings and Woodrow Wilson, *Vice-Presidents*; James T. Young, *Secretary*.

At the annual meeting of the Peary Arctic Club, the present officers were reelected: M. K. Jesup, *President*; H. W. Cannon, *Treasurer*; and H. L. Bridgman, *Secretary*. Resolutions were adopted congratulating Lieutenant Peary on rounding in 1901 the northern end of the Greenland Archipelago.

A CIVIL service examination will be held on March 25 to fill the position of computer in the Bureau of Forestry, at a salary of \$1,000 a year. On the same day an examination will be held for the position of piece-work computer in the Naval Observatory and also for a similar position in the Nautical Almanac Office. On March 4 there will be an examination for the position of seed laboratory assistant in the Bureau of Plant Industry, at a salary of \$720.

THE feasibility and advisability of adopting the metric system of weights and measures in the United States will be the subject of discussion at a stated meeting of the Franklin Institute of Philadelphia on February 19. The basis of the discussion will be the report of a special committee, which is as follows:

WHEREAS, It is desirable to obtain an international Standard of Weights and Measures, also

to simplify and regulate some of our existing standards; and,

WHEREAS, The Metric System is commendable not only as a suitable International Standard, but also for facility of computation, convenience in memorizing and simplicity of enumeration;

Resolved, That the Franklin Institute approves of any movement which will promote the universal introduction of the Metric System with the least confusion and expense.

Resolved, That the National Government should enact such laws as will ensure the adoption of the Metric System of Weights and Measures as the sole standard in its various departments as rapidly as may be consistent with the public service.

At a recent meeting of the convocation of the University of London the following resolution was passed: "That this House is of opinion that, in the interests of commerce, science and education, legislation should be promptly undertaken to make compulsory in this kingdom, after a proper interval, the use of the metric system of weights and measures for all purposes."

We take the following items from the current issue of *The Botanical Gazette*: Dr. E. B. Copeland, formerly of the University of West Virginia, is engaged in research work at the University of Chicago.—Dr. Bradley M. Davis, of the University of Chicago, has returned to his work from a stay in Paris.—Miss Josephine E. Tilden, of the University of Minnesota, has returned from an exploring trip on the Vancouver coast.—Dr. John M. Coulter, formerly of Syracuse University, has been appointed professor of botany in the Manila Normal School, Philippine Islands.

MR. S. HARBERT HAMILTON has started on a scientific exploring and collecting trip in the vicinity of Santiago, Cuba. Collections will be made in all branches of natural history, the bulk of which will go to The New York Botanical Gardens, The American Museum of Natural History and The Academy of Natural Sciences of Philadelphia. Specialists or institutions desiring material direct from the locality are invited to correspond with Mr. Hamilton at Santiago, Cuba.

At a meeting of the Zoological Society of London on December 3, a series of papers on the collections made during the 'Skeat Expe-

dition' to the Malay Peninsula in 1899-1900 was read. Mr. F. G. Sinclair reported on the Myriapoda, and enumerated the forty species of which specimens had been obtained. Of these, nine were described as new to science. Mr. W. F. Lanchester contributed an account of a part of the Crustacea, viz., the Brachyura, Stomatopoda and Macrura, collected during the Expedition, and described six new forms. Mr. F. F. Laidlaw enumerated the Snakes, Crocodiles and Chelonians which had been obtained, and described two new species based on specimens in the collection. An appendix to these papers, drawn up by Mr. W. W. Skeat, contained a list of names of the places visited by the members of the 'Skeat Expedition.'

OUR consul general at St. Petersburg writes to the Department of State that the gradual deforestation of Russia is attracting increased attention throughout the Empire, and the Forestry Society, as well as the forestry department of the Ministry of Agriculture and Domains, are discussing means for regulating the consumption of timber and for propagation. 'Wooden Russia,' as it is familiarly called, does not appear to be in any immediate danger, as a recent official report states that forests in this country now cover a gross area of 188,000,000 hectares (464,548,000 acres). Among European countries, Sweden comes next, with 18,000,000 hectares (44,478,000 acres) of forest. In Russia, the forests cover 36 per cent. of the whole imperial area. The Swedish forests occupy 44 per cent. of the total area, and the Austro-Hungarian 32 per cent. of the territory of the Dual Monarchy. Reckoned by the population, there are 2 hectares (4.9 acres) of forest to each inhabitant in Russia, 3.85 hectares (9.5 acres) in Sweden, 4.22 hectares (10.4 acres) in Norway, and 0.28 hectare (0.69 acre) per head in Germany. The forests have a greater importance for Russians than for people of West European countries, as villages and country houses are largely built of wood, stone and brick houses being almost unknown, and the forests furnish the main sources of fuel supply. While the imperial committee complains that it is private owners who are recklessly devastating the forests and urges that adequate laws and regulations be

enacted to prevent this, the Forestry Society calls attention to the fact that, according to the official report of the forestry department of the Ministry of Agriculture and Domains, the Crown forests furnished a revenue of 17,600,000 rubles (\$9,064,000) in 1890 and 48,000,000 rubles (\$24,720,000) in 1899. It is claimed that this advance in nine years could not be due to the natural increase of timber growth, and it is urged that the Government set an example in moderation.

UNIVERSITY AND EDUCATIONAL NEWS.

THE Laboratory of Engineering, presented to the Stevens Institute of Technology by Mr. Andrew Carnegie, at a cost of \$55,000, was dedicated on February 6. Mr. Carnegie made a speech and was presented by President Morton with a silver box containing a piece of the first 'T' rail ever made, the rail that was invented by Robert L. Stevens and was made in 1830 by Sir John Guest at his works in Wales, under the personal supervision of Mr. Stevens.

THE new Hall of Liberal Arts of the State University of Iowa, erected and equipped at a cost of about \$200,000, was dedicated on January 23.

WAYNESBURG COLLEGE celebrated its semi-centennial anniversary in November last at which time gifts to the endowment amounting to \$36,000 were announced. Col. J. M. Guffey, of Pittsburg; J. V. Thompson, Esq., of Uniontown, and Timothy Ross, John Rose and T. J. Wisecarver, of Waynesburg, contributed \$5,000 each. The enrolment of students last year was 391.

MR. WARREN A. WILBUR, of South Bethlehem, Pa., has given an additional \$5,000 for the equipment of the new mechanical laboratory at Lehigh University.

THE midwinter edition of the Cornell University *Register*, just published, gives the first official and precise census for the current year. The figures are the following: Trustees, 39; teachers, 387; students, graduate department, 183; graduate students in undergraduate departments, 185; academic department, 817; law school, 197; medical college, 415; college

of agriculture, 86; veterinary college, 51; college of forestry, 38; college of architecture, 50; college of civil engineering, 212; Sibley college (mechanical, including railway, electrical, marine, etc.), 784. The total of all classes and courses is 2,792 in the regular lists and about 500 in the summer schools. Of the total 1,679 come from New York State, the remainder from every State in the Union and from all parts of America and of the British Empire, from China, Japan, Russia, Switzerland, Austria, Turkey and Korea. Of the 784 students in the undergraduate courses of Sibley College, 62 are graduate students; there are also 14 candidates for the Master's degree and 2 graduate students not candidates for a degree. There are 4 candidates for Ph.D., taking their major work in M.E., and one D.Sc., making a total for 1901-2 of 805 students in all classes and courses.

THE Wesleyan University Summer School of Chemistry and Biology will be organized in July, 1902, and will be open for a period of four weeks. It will be in charge of Professors W. O. Atwater, W. P. Bradley and H. W. Conn, aided by a number of assistants.

PROFESSOR WILLIAM L. ROBB, of Trinity College, has been appointed head of the new department of electrical science in the Rensselaer Polytechnic Institute, Troy, N. Y.

DR. GEORGE E. DE SCHWEINITZ, of Jefferson Medical College, has been appointed professor of ophthalmology in the University of Pennsylvania to succeed the late Dr. W. F. Norris.

MISS SUSAN M. HALLOWELL has resigned the professorship of botany at Wellesley College, and has been made professor emeritus. Miss Hallowell was appointed professor of natural history on the opening of the College in 1875.

AT Cambridge University Professor T. H. Middleton has been elected professor of agriculture in the place of Dr. Somerville.

DR. DAVID WELSH, the senior assistant to the professor of pathology in the University of Edinburgh, has been elected the first professor of pathology in Sydney.

THE Senior Mathematical Scholarship at Oxford has been awarded to Arthur W. Conway, B.A., Corpus Christi College.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE passage of a bill, during the closing days of the last session of Congress, providing for the establishment of a National Bureau of Standards, came as a surprise to many. As the work of this bureau ought in the future to have a large bearing upon science and industry it may not be without interest to record the circumstances under which this legislation was effected, and to bring to the attention of those who in the future may be interested in the matter the names of a few men who, though not men of science, gave their time and labor heartily in the interest of this work. It has so happened that, although my own part in this has been very small, the circumstances have been known to me.

The National Bureau of Standards, as the new title reads, grew out of what has been called for many years the Office of Weights and Measures. In the early thirties large discrepancies were discovered in the weights and measures of the United States in the various custom-houses, and Congress authorized the Secretary of the Treasury to establish a shop for the manufacture of uniform standards. In 1836 provision was made for similar standards for the different states, and the 'Office of Standard Weights and Measures' was established.

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

The Office of Weights and Measures while in law a separate bureau of the Treasury Department, has been practically a part of the United States Coast and Geodetic Survey, and has been, since its organization, under the direction of the superintendent of that bureau. During its existence standards of weights and measures have been furnished to most of the states, and a great impetus has been given to the adoption by international agreement of the metric system. In its custody are kept the international kilogram and meter, and it has for years done a valuable work in the standardizing of steel tapes, thermometers and similar measuring instruments; while more recently it has begun the standardizing of electrical instruments.

On coming to the Coast Survey in 1897 I found the Office of Weights and Measures engaged in the work which I have just mentioned. In its service were two scientific assistants, an instrument maker and a messenger, and a small appropriation was made for office expenses. The work was under the charge of a field officer of the Coast Survey. The arrangement by which a field officer was in this way detailed temporarily for this duty did not seem to me good administration; it deprived the Coast Survey of the service of a much-needed officer, and in addition there was required for this duty not a surveyor but a physicist. I therefore asked Congress to appropriate a salary sufficiently large to induce a physicist of high standing to take charge of the office, under direction of the superintendent. An appropriation of \$3,000 was made. With this sum some difficulty was found in inducing any physicist of standing and reputation to accept the place, and only after many interviews and considerable correspondence I succeeded in persuading Professor S. W. Stratton, of the University of Chicago,

to become a candidate. The appointment to the position was made after competitive examination.

Mr. Stratton, after coming to the bureau, was instructed to make a report upon the work and efficiency of the office as then constituted, and to recommend, if it seemed advisable, a plan for its enlargement into a more efficient bureau of standards, which might perform in some measure for this country the work carried on by the Reichsanstalt in Germany.

Mr. Stratton entered heartily into this work, and the outcome of his examination was the preparation of a scheme for a National Bureau of Standards. This plan, after being discussed in the office of the Coast Survey, and receiving the criticism of Assistant Superintendent Tittmann and others acquainted with the history of such work abroad, was submitted to a number of physicists, chemists and manufacturers of the country. After their criticisms had been digested a final plan for the bureau was drawn, which is practically that submitted to Congress. In all of this work Mr. Stratton endeavored to avail himself not only of the criticism of those at home, but also of the work which has been done abroad; and the bureau as finally planned is not intended to be simply a copy of the Reichsanstalt, but a standardizing bureau adapted to American science and to American manufacture.

When the final plan had in this way been agreed upon, it was incorporated into a bill and placed before Secretary Gage and Assistant Secretary Vanderlip, of the Treasury Department. The idea at once commended itself to their judgment, and Secretary Gage entered most heartily into a study of the purpose of the proposed bureau, and of the relations which it might have with industry, with commerce and with science. Supported by his hearty advocacy the bill went to the house and was

referred to the committee on Coinage, Weights and Measures. The measure was before this committee two sessions, and received from its members long and serious consideration. There appeared before the committee at one time and another, not only men of science, but manufacturers and engineers who were competent to speak on such matters. Amongst all those who appeared in favor of the bill, both before the committee of the House and the committee of the Senate, there was none whose opinion had more weight than that of the Secretary of the Treasury, Mr. Gage. The following extract from his testimony before the Senate committee is worth remembering in the history of this matter as the suggestion of a high officer of the government who appreciated not only the direct commercial results of the measure, but also its indirect moral effect:

There is another side to this which occurs to me. It may appear to many to have a more sentimental than practical value, but it gives the proposition, to my mind, great force, and that is what might be called the moral aspect of this question; that recognition by the government of an absolute standard, to which fidelity in all the relations of life affected by that standard is required. We are the victims of looseness in our methods; of too much looseness in our ideas; of too much of that sort of spirit, horn out of our rapid development, perhaps, of a disregard or a lack of comprehension of the binding sanction of accuracy in every relation of life.

Now, the establishment of a bureau like this, where the government is the custodian and the originator of these standards of weights and measures as applied to all the higher scientific aspects of life which we are so rapidly developing in, has, to my mind, a value far and above the mere physical considerations which affect it, although those physical considerations are fundamental and most important. Nothing can dignify this government more than to be the patron of and the establisher of absolutely correct scientific standards and such legislation as will hold our people to faithfully regard and absolutely obey the requirements of law in adhesion to those true and correct standards.

The bill for the establishment of the bureau received at the hands of the Committee on Coinage, Weights and Measures a consideration seldom given to such a measure, and when it was finally reported it received from that committee on the floor of the House a support which indicated their appreciation of its importance and value. In particular the names of the chairman of the committee, Hon. James H. Southard, of Ohio; and Hon. John F. Shafroth, of Colorado, deserve special mention. In the closing days of the fifty-sixth congress, when it was doubtful whether the speaker could permit consideration of the measure, Mr. Southard kept his seat day after day, and even night after night, in order that no opportunity might slip by when the speaker might be able to recognize him for the passage of the bill. In the splendid new building which Congress has provided for the housing of this bureau, and which is to become in the future the home of the great influence which it will exert on science and on industry, two names of those who had to do with its successful inception, so far as legislation is concerned, may well be placed high on its walls; and these are the names of Lyman J. Gage, Secretary of the Treasury, and James H. Southard, Chairman of the Committee on Coinage, Weights and Measures.

In the Senate, also, the bill received friendly consideration at the hands of the Committee on Commerce.

Looking back over the history of this legislation, which was effected without the help of any lobby, at the recommendation of a few men qualified to speak on such matters, it is evident that it has been the result, in the first place, of the work of those who founded the Office of Weights and Measures; of the influence of the scientific recommendations of the last twenty years looking toward the enlarge-

ment of that bureau, and of the intelligent interest of the Secretary of the Treasury and of the Chairman of the Committee on Coinage, Weights and Measures. And finally, but by no means least in importance, the successful outcome is due to the intelligent way in which this bill was placed by Mr. Stratton before the committees in the House and in the Senate. The enactment of such a measure ought to reassure scientific men in their judgment of the relation of Congress to legislation in such matters, since it shows that such legislation can be had without the help of any lobby, without the stimulus of personal interest on the part of Congress, if there is presented a clear and satisfactory reason for such legislation by those in whom Congressmen themselves have confidence.

Another feature of this bureau, which is unique, will also be watched by scientific men, as time goes on, with great interest, and that is the provision under which a visiting committee of five men, not connected with government service, report each year on the efficiency and needs of the bureau. I shall be greatly disappointed if this does not have a wholesome effect on the bureau itself, and on the relations of the bureau with Congress and with the department. It is scarcely possible that a Secretary of the Treasury will dismiss from office a competent head of the bureau who is supported courageously by this committee, nor will he appoint to the office of director a man whom they consider incompetent and unsuitable. If out of this relation there comes a wholesome criticism and a quickening of the scientific spirit, one may well hope that this feature may find a place in other departments of government scientific work.

HENRY S. PRITCHETT.

THE ASTRONOMICAL AND ASTROPHYSICAL
SOCIETY OF AMERICA.

II.

The Constant of Aberration: C. L. DOOLITTLE.

For some time a revision of the latitude work carried on at the Sayre Observatory, Bethlehem, Pa., from 1876 to 1895, has been in progress with the view to its publication in a complete and final form. The first fasciculus of this publication appeared in the spring of 1901 and it is hoped that the remainder may be in form for the printer in the course of two or three months.

The present communication deals primarily with the value of the constant of aberration resulting from the series of observations extending from October 10, 1892, to December 27, 1893. A preliminary solution of the problem was published in the *Ast. Journal*, No. 406, 1897, which may be consulted for a fuller statement as to the method employed. The micrometer screw had become much worn by constant use for several years and the value was not constant throughout the series. Also the progressive errors which had been previously determined by means of Harkness' measuring engine were no longer applicable. It seemed very desirable that the screw value should be derived from the latitude observations themselves, but at the time spoken of the star declinations were not known with the requisite precision. For these reasons there was some hesitation as to the desirability of publishing the preliminary result, as it was thought possible that a considerable error might be involved. Recently a very careful discussion of the declinations has furnished the required data, and a result obtained which seems entirely free from the above named objections.

From the method of observing it is not possible to separate the correction to the aberration constant from the latitude vari-

ation without introducing an assumption with respect to one or the other. It has accordingly been assumed that the latitude variation can be represented by two periodic terms of 14 and 12 months, respectively. Each observed latitude, therefore, gives an equation of this form

$$z \sin N + y \cos N + z \sin \odot + u \cos \odot + E_p + T_\mu + \Delta\phi + \phi_0 = \phi$$

where N is the 14-month term, E_p the correction to the aberration and T_μ secular change in the latitude.

The evening and morning observations furnish 1,744 and 1,052 equations of this form, respectively. These were solved retaining all terms. Then another solution was made excluding the annual term, as it is obvious that this can not be separated from the 14-month term in a series embracing a period of less than 16 months. The resulting value of the constant of aberration from both the preliminary and revised solution is as follows:

	Preliminary.	Revised Solution.
1st solution,	20".552 ± .0095	20".551 ± .0092
2d " "	20 .555 ± .0093	20 .552 ± .0090

It thus appears that the suspected error in the preliminary reduction was a vanishing quantity.

Two other series of observations made at the Sayre Observatory have been employed for a similar investigation. The first, from December 1, 1889, to December 13, 1890, embracing 1,344 latitude determinations, was treated in a manner similar to that above described except that only one solution was made involving periodic term of 14 months. The resulting aberration constant is 20".448 ± .014. It is doubtful whether this result is entitled to much confidence, the most serious objection being that the series does not cover a full term of 14 months, which is assumed for the period of latitude variation. The other series referred to extends from January 19,

1894, to August 19, 1895, the arrangement being that sometimes called the polygon method by which the aberration is obtained independently of the latitude variation. The result is 20".537. Other recent determinations are given for comparison:

Flower Observatory.

1896-98	20".580
1898-99	20 .542

The Period of Delta Equulei: W. J. HUSSEY.

Delta Equulei enjoys the distinction of having a period shorter by nearly half than that of any other visual double star and in being at the same time a spectroscopic binary. The latter characteristic is due to the visible components. It therefore forms a connection between the visual and spectroscopic double stars. This pair was discovered in 1852 by Otto Struve and observed by him occasionally for thirty years. Burnham's observations from 1880 to 1883, inclusive, appeared to indicate a period of 10.8 years; the elements subsequently derived by Wroublewsky and by See gave nearly 11.5 years. Between 1899.85 and 1900.65 the components rapidly approached each other and the apparent distance was extremely small at the latter date. This rapid change in distance is not explainable on the hypothesis that the period is nearly 11.5 years, but is entirely in accord with one of about half this length. The elements derived by the writer a year ago have a period of 5.7 years. From these elements he predicted that the components should separate to a measurable distance

this year and again close in. Observations show that this has happened. In July, 1901, the distance was approximately $0''.15$. It has now decreased to less than $0''.05$, or approximately the same as in the autumn of 1900. The data at present available appear to show that the period of 5.7 years is substantially correct.

The Duration of Twilight within the Tropics: S. I. BAILEY.

The atmosphere renders many services to man. Not the least of these, perhaps, is the twilight. If there were no atmosphere, there would be no twilight, and the brightness of midday would be succeeded, the moment after sunset, by the darkness of midnight. Such a condition of affairs would cause considerable inconvenience. Twilight may be said to last until the last bit of illuminated sky disappears from the western horizon. In general it has been found that this occurs when the sun has sunk about 18° below the horizon. The duration of time which the sun takes in reaching this position is very different at different latitudes. At the North Pole one would have about six months of daylight, followed by nearly two months of decreasing twilight, followed in turn by more than two months of night. In summer, at latitudes greater than 50° , twilight lasts from sunset to sunrise. There is no night there, during this season. In the temperate zones the duration of twilight ranges from an hour and a half to more than two hours. Within the tropics the sun descends nearly or quite vertically; but even here the time required for the sun to reach a point 18° below the horizon is more than an hour. There seems to be no reason, therefore, in the general theory, for the widespread belief that the duration of the tropical twilight is extremely brief. This idea is found not only in current popular literature, but also in some of the best text-books on gen-

eral astronomy. Young's 'General Astronomy,' p. 69, says: "At Quito and Lima it (the twilight) is said to last not more than twenty minutes." Why Quito should be classed with Lima I do not know, except that both are within the tropics. 'The Heavens Above,' by Gilbert and Rolfe, remarks: "Within the tropics, where the air is pure and dry, twilight sometimes lasts only fifteen minutes." Since Arequipa, Peru, lies within the tropics and has an elevation of 8,000 feet, and the air is especially pure and dry, the conditions appear to be exceptionally favorable for an extremely short twilight. On Sunday, June 25, 1899, the following observations were made at the Harvard Astronomical Station, which is situated there: The sun disappeared at 5:30 P.M., local mean time. At 6:00 P.M., 30 m. after sunset, I could read ordinary print with perfect ease. At 6:30 P.M. I could see the time readily by an ordinary watch. At 6:40 P.M., 70 m. after sunset, the illuminated western sky was still bright enough to cast a faint shadow of an opaque body on a white surface. At 6:50 P.M. the illumination was faint, and at 6:55 P.M., 1 h. and 25 m. after sunset, it had disappeared. On August 27, 1899, the following observations were made at Vincocaya. The latitude of this place is about 16° south, and the altitude 14,360 feet. Here it was possible to read coarse print 47 m. after sunset, and twilight could be seen for an hour and twelve minutes after the sun's disappearance. It appears, therefore, that while the tropical twilight is somewhat shorter than occurs elsewhere, and is still further lessened by favorable conditions, such as great altitude, and a specially pure air, it is never less, and generally much longer, than an hour.

The Determination of Double Star Orbits:

GEORGE C. COMSTOCK.

The usual data for the determination of

a double star orbit consist of a series of observed position angles and distances with the corresponding times of observation. From this data it is customary to derive the apparent orbit of the star by plotting the observed coordinates and drawing through the resulting points the best ellipse that can be fitted to them, subject to the condition that in this ellipse the radius vector must sweep over equal areas in equal times. The author knows no published statement showing how this condition is applied in the actual construction of the ellipse and it is not apparent how it can be applied in any satisfactory manner in this purely graphical process. Moreover, the process is open to the additional objection that it takes small account of the circumstance that of the three elements entering into a complete double star observation, position angle, distance and epoch, the time of observation is determined with a precision incomparably superior to that of the measured coordinates, and should therefore play a prominent part in the determination of the orbit instead of the subordinate rôle commonly assigned it. The method proposed for improving the current practice in these respects reverts to the practice introduced by Sir John Herschel, of plotting the observed position angles with the corresponding times as abscissæ, and extends the same practice to the observed distances. From the resulting curves data are derived for assumed epochs, and through a least square adjustment supplemented by mechanical quadratures are transformed into normal places that satisfy rigorously the condition of constant areal velocity. A partial control upon the character of the data and the treatment to which they have been subjected is furnished by the quasi rigorous condition that the adjusted normal places shall all lie upon some ellipse. In the adjustment of the data there is incidentally determined the

areal velocity of the radius vector and this in connection with the apparent orbit, plotted from the normal places, leads immediately to a determination of the periodic time and to the independent determination of the dates of periastron and apastron passage. The agreement of the double interval between these dates with the periodic time first determined furnishes a partial check upon the work. The transition from the apparent to the real orbit may be made by any of the standard methods, but that of Klinkerfues when simplified by the introduction of the elements above derived is especially convenient. There was presented an application of the method above outlined to the determination of the orbit of Struve 2,107, showing that the labor involved does not greatly exceed that of the ordinary methods and is fully compensated by the checks furnished *en route* as well as by the increased precision of the results.

A Cosmic Cycle: FRANK W. VERY.

An application of a new doctrine of an explosive condition of matter (limited by composition, pressure and temperature) to various phenomena of the heavenly bodies, and to stellar evolution. *Novæ* are regarded as the culmination of long-enduring antecedent stages of stellar preparation, and as indicating (along with the helium stars) a condition of instability and active modification which is incompatible with planetary growth, but which is followed by other relatively quiescent stages favorable to the production of planets and to their orderly development. An extension of the doctrine of the conservation of energy is involved, and the problem of the sustentation of solar heat is approached from a new standpoint which admits of a great extension in the duration of the solar system, thus satisfying the demands of the geologist for a prolonged terrestrial

duration. (The paper will appear in full in the *American Journal of Science*.)

A Comparison of Printing and Recording Chronographs: C. S. HOWE.

A printing chronograph, to be of any value to astronomers, should be easily set and regulated; it should run several hours without any attention; it should have a small probable error; its results should agree, or differ by a constant amount each night, with the results from the recording chronograph. Several months' experience with the Hough printing chronograph at the Case Observatory shows that the instrument can be easily set and adjusted and that it runs several hours without any attention. The probable error of one record was found to be $\pm .011$ seconds, and the probable error of the mean of nine wires $\pm .004$ seconds. Similar tests with the recording chronograph give respectively $\pm .006$ and $\pm .002$ seconds. These errors are so small that they can be neglected. A direct comparison of the two chronographs showed an average difference between them of .025 seconds, the printing chronograph making the record first.

The Clock Room at the Case Observatory:

C. S. HOWE and E. H. BROWN.

The clock room is a room built of tile within one of the rooms of the basement of the Physical Laboratory. The basement is warmed in the daytime, but not at night. The space outside the clock room is warmed by two gas stoves, the gas being turned on or off by an automatic burner which is regulated by a thermostat made of steel and hard rubber. This controls the temperature outside the clock room within one degree centigrade and inside the clock room within about one half degree. The inside temperature is further controlled by another thermostat, which by means of a relay throws in or out one or more electric lamps, the heat of which changes

the temperature. This arrangement keeps the temperature within one tenth of a degree. The hourly rates of a Riefler clock, enclosed in a glass case from which the air is partially exhausted, were also given.

The Almucantar as an Instrument for the Determination of Time: C. S. HOWE.

In 1885 Dr. Chandler compared the clock corrections determined with a small almucantar with those determined with the large Transit Circle of the Harvard Observatory. The Case Almucantar is a large instrument with a six-inch object glass. It was not possible to compare it with a large transit and so its value for the determination of time could only be determined by the consistency of the several results obtained on any one night and by the excellent and nearly uniform clock rates determined by it. The differences between the several values of the clock corrections on any one night were usually not more than two or three hundredths of a second and the greatest difference since June, 1901, was 0.13 of a second.

A Description of the Second (Chile) Mills Spectrograph: W. W. CAMPBELL.

The mechanical features of the instrument and its method of support are radically different from those of the conventional spectrographs. The entire framework is composed of a single steel casting with webs and flanges bracing it thoroughly in every direction and with especial reference to the supports near its two ends. The slit, the prism box, the camera and the collimator and camera lenses are all fixed directly to the casting. A reflecting slit is used, curved to make the spectrum lines straight. The weight of the entire spectrograph is about 75 pounds. The instrument is mounted in a supporting cradle composed of tee and channel steel bars in such a way that it will rest on two points (a plate and a ring) near the two ends of

the instrument, respectively. Strains in the supporting cradle cannot induce strains in the spectrograph. The old method of supporting spectrographs entirely from one end, allowing the other end to project unsupported out into space, invites flexure effects, and it is hoped that the new method of support will prove to be a radical improvement. The whole spectrograph will be moved to bring the slit into the focus of the Cassegrain telescope. A temperature case similar to the one used for the past three years on the original Mills spectrograph will enclose the instrument.

On the Capture of Comets by Jupiter:

PERCIVAL LOWELL.

This paper gave in diagrams a part of the author's memoir on the subject, not yet published, in which he explained the action of Jupiter upon a comet entering the planet's sphere of activity, and the relation borne by the direction and the speed of approach to the comet's subsequent behavior. The paper showed that Jupiter was not only capable of transforming at one encounter a parabolic comet into an elliptic one of about half his own major axis, but could actually cause a comet to make the planet instead of the sun the goal of its visit, and send it back again into space without circumnavigating the sun at all. The argument then developed a critical angle differentiating those comets which Jupiter's action might render retrograde from such as it could not. A table here showed that the angle of approach of each of the comets composing Jupiter's comet family not only at the present moment fell within the critical angle for each, but must do so for all time, abstraction made of perturbations by other bodies and the approximation being of the first order. In other words, that under these conditions the present direct motion of all

the members of Jupiter's comet family was such in perpetuity. The planet might drive them off into space but could never render any of them retrograde.

The Latitude-Variation Observatory of the International Geodetic Association:

HERMAN S. DAVIS.

A brief statement of the plan of the International Association in the establishment of the four stations at Gaithersburg, Maryland, Ukiah, California, and in Japan and Sardinia for a systematic and continuous series of observations for the study of variations of latitude. Particular attention was given to the two stations in the United States under the general direction of the Coast and Geodetic Survey, the one in charge of Dr. Schlesinger, at Ukiah, and the other in charge of the speaker, at Gaithersburg. Illustrations with the lantern were shown of both these stations with plans of the buildings and views of the telescope at Gaithersburg. Attention was called to the admirable quality of the observations made by Mr. Edwin Smith, who was in charge of the station at Gaithersburg prior to January, 1901, and entire credit given him for the erection of the buildings and installation of the instruments at this station, and to the active and enthusiastic support of the superintendent of the Coast Survey from the very inception of the plan to establish these stations in the United States.

Some Vices and Devices in Astronomical Computations: HERMAN S. DAVIS.

Owing to the briefness of the time requested for the presentation of this paper and the fact that a considerable portion of that time was devoted to the preceding paper which was presented by request—not being regularly on the program—the speaker gave only a meager description of some of the methods which he is now using in the new reduction of the 160,000 star-

observations made by Piazzì at Palermo between 1792 and 1813. Particular attention was directed to only one of the many devices which have been applied for shortening the computations whereby already the work is two years ahead of the schedule outlined at the beginning of the undertaking, that device being the use of specially constructed table of limiting-values instead of such logarithm or anti-logarithm or other tables as appear in print. Illustrations of these special tables and their application and data as to the percentage of time saved by their use were also given. Another one of the devices has already been published in *Astronomical Journal*, No. 498 (XXI.:143-4), and a number of others, of which mention was omitted for lack of time and the lantern slides which had been designed (but unexpectedly delayed) for their proper exposition will be put into print at some future date.

Observations of Meteors, November 13-16, 1901: J. K. REES.

As in previous years, I observed with Mr. Charles A. Post from his observatory at Bayport, Long Island. We arranged (1) to photograph meteor trails with four cameras mounted on the equatorial which was driven by an excellent clock, (2) to count the meteors and (3) to record individual meteors which exhibited striking peculiarities.

1. The equatorial and cameras employed are shown in Plate II., *Popular Astronomy* (No. 82), February, 1901.

The apertures and focal lengths are given in the following table:

Instrument.	Aperture.	Focal length
Equatorial telescope.	6 inches.	90 inches.
Willard photographic doublet.	5½ "	23 "
Darlot portrait.	1½ "	6½ "
Anthony portrait.	3 "	13½ "
Goerz wide angle double anastigmatic.	1½ "	9½ "

PHOTOGRAPHIC EXPOSURES.

Nov. 13. 12:00 to 18:00 (Eastern Standard time). A number of experimental plates were taken but no effort was made to photograph meteors, as so few were seen.

Nov. 14. 11:20 to 12:24. Exposed the Goerz lens pointed at the belt of Orion. 13:15 to 14:05. Exposed all the cameras pointed as follows: Willard and Anthony lenses at Procyon, Goerz lens at belt of Orion, and Darlot lens at μ and ϵ Leonis. At 15:00 the sky clouded but cleared again at 15:30. 15:42 to 16:30 all cameras were exposed. The Willard and Anthony on ϵ Leonis, the Goerz on ζ , ϵ , δ Hydræ, and the Darlot on Ursa Major.

The clouds began to spread over the sky again, and in a short time it was impossible to see a star, later it cleared. Observers then confined their attention to counting and observing the meteors.

Nov. 15. 11:45 to 13:00. Exposed all cameras. Willard and Anthony lenses on Pollux, Goerz lens on Procyon, and Darlot lens on γ Geminorum. 14:35 to 15:45. Exposed all cameras. Willard and Anthony on ζ Leonis, Goerz on Regulus, and Darlot on λ and μ Leonis Minoris. Clock did not work as well as usual. 16:01 to 17:00. Willard lens was omitted. The other cameras were pointed as in the preceding exposure.

Mr. Post developed all the plates. The plates taken on November 14 show a number of trails. Quite a remarkable meteor trail is shown on the plates taken with the Willard and the Anthony lenses between 15:42 and 16:30. The notes given under 'Record of Individual Meteors' seem to show that this meteor appeared at 15:58.

2. Count of Meteors.

Only during the night of November 14 was any careful attempt made to count. Miss Edith Post and Miss Greenough observed the eastern sky looking toward the radiant. At first both observed the same part of the sky, but after 38 had been counted Miss Greenough observed the southeastern sky from the line from the radiant to the zenith, and Miss Post ob-

served the northeastern sky from the same line. The count was as follows:

Nov. 14. 12:15 to 13:40. Miss Post and Miss Greenough, 38; Miss Post—northeastern sky, 31; Miss Greenough—southeastern sky, 31. 13:40 to 14:20. Messrs. Post and Rees looking out of the opening in the roof of the Observatory toward the radiant, 20. 14:20 to 15:00. Miss Post—northeastern sky, 10; Miss Greenough, southeastern sky, 15. 15:50 to 17:55. The Misses Post and Greenough counted being assisted from 16:30 to 17:55 by Post and Rees. The total count of the four observers was 273. Total for the evening, 418.

Nov. 15. Post and Rees assisted by Mr. Post's 'handy man' counted, while engaged on the photographic work and looking out of the observatory opening, as follows: 11:45 to 13:00. 25, several of which were non-Leonids. 14:35 to 15:45. 3 of which 1 non-Leonid. 16:01 to 17:00. 23, several non-Leonids.

Nov. 16. 12:00 to 17:00. Looked out frequently but saw so few that no record was kept.

3. Individual Meteors.

Nov. 14. 11:30. Two bright Leonids—trails yellow-red 10° long—width very distinct. 11:51. Leonid from Procyon to θ Orionis—blue streak. 12:07. From star above Procyon to 'yardstick'—trail 25° long—lasted several seconds—yellow—Leonid. 12:10. Leonid through Ursa Major—bright trail. 12:15. Leonid through Ursa Major. 12:17. Leonid through Auriga. 13:18. Brilliant Leonid, near radiant—very small trail—orange color—bright as Mars at best. 13:27. Fine Leonid from Leo to zenith—trail 30° long—yellow-red. 13:30. Leonid through Ursa Major—fine. 13:40. Meteor near Procyon—from zenith down—short trail. 13:44. Fine Leonid through bowl of dipper—trail 5° . 13:51. Leonid under Procyon— 8° trail—yellow-red. 15:58. Brilliant Leonid—trail 5° —lasted twenty seconds—blue-white—1st magnitude. 16:04. Leonid under Procyon—blue-white— 10° trail. 17:28. Two brilliant meteors visible at same time—trails crossed—bright heads. One came from radiant and passed near α and β Can. Ven.—trail 30° long and lasted several seconds. The second seemed to come from below β Leonis and cut the trail of the first under Canes Venatici—trail 30° . Magnitude of each—2.

Nov. 15. 14:52. Bright Leonid under Leo Minor. 15:37. Leonid bright as Jupiter—in sickle—blue and red trail. About 15:55. Fire

ball below Leo came from Orion. 16:10. From zenith through Leo Minor (λ and μ)—long train 40° . About 17:00. The zodiacal light showed itself in a grandly beautiful manner.

A Theorem concerning the Method of Least Squares: HAROLD JACOBY.

The following theorem and conclusion are doubtless well known to many astronomers, but the writer has not found an explicit statement of them in print. Let there be given two series of observation equations as follows:

$$\left. \begin{aligned} a_1x + b_1y + c_1z + \dots + n_1 &= 0 \\ a_2x + b_2y + c_2z + \dots + n_2 &= 0 \\ &\vdots \\ &\vdots \end{aligned} \right\} (1)$$

$$\left. \begin{aligned} a_1x + b_1y + c_1z + \dots + p_1w + \dots + n_1 &= 0 \\ a_2x + b_2y + c_2z + \dots + p_2w + \dots + n_2 &= 0 \\ &\vdots \\ &\vdots \end{aligned} \right\} (2)$$

the equations being identical in the two series except for the addition of one or more new unknowns, w, \dots in (2). Let each series of equations be solved by the method of least squares, and let $[vv]_1$ be the sum of the squares of the residuals resulting from the solution of equations (1), $[vv]_2$ be the sum of the squares of the residuals resulting from the solution of equations (2); then, no matter what may be the law of the coefficients p_1, p_2, \dots , and even if these coefficients are assigned at random, $[vv]_1$ is always larger than $[vv]_2$.

Corollary.—The theorem can be extended easily to an additional case of equal importance. Instead of introducing the new unknowns w, \dots , by adding them to those already occurring in equations (1), we may select out certain equations from the series (1), and simply substitute new unknowns, like w , for old ones, like z , leaving the coefficients unchanged.

Conclusion.—The method of least squares is used ordinarily to adjust series of observation equations so as to obtain the most probable values of the unknowns. But

there is a subtler and perhaps more important use of the method; when it is employed to decide which of two hypothetical theories has the greater probability of really being a law of nature; or to decide between two methods of reducing observations. Cases abound in astronomy where the method of least squares is used for this purpose. It has been so employed, for instance, to decide whether stellar parallax observations should be reduced with equations involving terms depending on atmospheric dispersion, and terms depending on the hour-angle, to ascertain whether portable transit observations should be reduced on the supposition of a change of azimuth on reversal of the instrument (an application of the corollary), etc.

In such cases, astronomers not infrequently give preference to the solution which brings out the smallest value of $[vv]$, the sum of the squared residuals. But in the light of the above theorem, it becomes clear that the mere diminution of $[vv]$, alone is insufficient to decide between two solutions, when one involves more unknowns than the other. To give preference to the second solution it is necessary that the diminution of $[vv]$ be quite large, and that the additional unknowns possess a decided *a priori* probability of having a real existence.

The Nebula about Nova Persei, 1901:

FRANK W. VERY.

The rapidly shifting and fast fading nebulosity around the new star is regarded as an evanescent phenomenon comparable to the tail of a comet. Velocities of propagation of different orders are surmised, but as there is no known motion of material particles, even when of the dimensions of negative ions, swifter than that of light, the latter may be taken as a limiting value of velocity, from which it is deduced that the distance of the nova can not exceed

750,000,000,000,000 miles, an estimate which gives us a first approximation to the distance of the Milky Way, since the novæ all belong to the galactic stream. An explanation of the meaning of the complex structure of the hydrogen bands in the spectrum of the nova is given, and a further cometary analogy is shown through the existence of concentric spherical envelopes near the star, resembling comæ, which are inferred from the structure of the spectral bands. From the spectral variations attending the formation and motion of these envelopes, the mass of the star is concluded to be about 1,150 times that of the sun; and as this mass does not appear to have been appreciably changed in the first month, in spite of the enormous outpourings of hot gases, it follows that the luminosity of the star is not conditioned by the mass or by the state of the star's internal activity; and it is suggested that the brightness of the star's continuous spectrum depends upon the formation or dissolution of clouds of cosmic dust in the spaces immediately surrounding the nova.

A Short and General Method of Determining Orbits from Three Observations: A. O. LEUSCHNER.

The method is principally intended to aid in the rapid determination of an orbit from three observations, made at short intervals. It is essentially an improvement on Harzer's modification of Laplace's method contained in *Méc. céleste*, T. I., première partie, livre II., Chap. IV. The first part of the paper deals with the discussion of Harzer's method. The modifications introduced by the author consist in: (1) The restriction of the number of observations to three, the minimum number necessary for the solution of the problem. (2) The reduction of the number of fundamental data to be approximated. In Harzer's method the fundamental data to be ap-

proximated are the heliocentric coordinates and their velocities, while in the present method they are the geocentric distance and the velocities of the heliocentric coordinates, all for the zero date. (3) A short method of obtaining preliminary values of the geocentric velocities and accelerations at the zero date. (4) A direct solution of the fundamental equation of the seventh degree in ρ_0 , on the basis of von Oppolzer's table XIIIa ('Bahnbestimmung,' Vol. I.). (5) Differential formulæ for the determination of the final values of the heliocentric coordinates and velocities from which the elements are computed by Encke's formulæ. Chief among the advantages of the method here outlined are the ease with which such corrections to ρ_0, x'_0, y'_0, z'_0 maybe determined as will cause the residuals due to the original values of these quantities to disappear, and the possibility of determining these corrections directly from the residuals. On that account, it is of no great consequence if the originally adopted velocities and accelerations in α and δ are only approximate.

Elements of Asteroid 1900 GA and its Ephemeris for the Opposition of 1901-1902: A. O. LEUSCHNER and ADELAIDE M. HOBE.

This asteroid was discovered June 28, 1900, by the late director, James E. Keeler, of Lick Observatory, while photographing the region of the sky near Saturn with the Crossley Reflector. Trails were photographed on four days and point-images on two of these days. The problem of determining the orbit of the asteroid presents many points of interest and has led to the derivation of the 'Short and General Method of Determining Orbits from Three Observations.' The existing methods for determining orbits could not be used to advantage in this case, but the solution was successfully accomplished by means of the

'Short and General Method of Determining Orbits from Three Observations' outlined above. The magnitude of the asteroid at the present opposition (1902, Jan. 4) is $19.5 \pm .75$. The asteroid is, therefore, the faintest so far observed. The paper concludes with the discussion of the residuals of the measured positions of the termini of the trails relatively to the middle of the trails.

Discovery of Motion in the Faint Nebula Surrounding Nova Persei: C. D. PERINE.

Early in the apparition of the new star in Perseus, short exposure photographs of it were secured with the Crossley Reflector by Messrs. H. K. Palmer and C. G. Dall. The first long exposure was secured on the nights of November 7 and 8. This negative had a total exposure of 7 h. 19 m. It was developed on the 9th, but owing to stormy weather was not dry and was not carefully examined until the morning of the 10th, when it was compared with the reproduction of a negative taken at the Yerkes Observatory on September 20 by Mr. Ritchey and published in the October number of the *Astrophysical Journal*, and the discovery at once made that several of the principal condensations in the nebula had moved to the southeast over a minute of arc in the interval. The main facts were embodied in a telegram which was sent to the Harvard College Observatory, for distribution to all observatories, at noon of November 10. A negative was obtained on the nights of November 12 and 13 with a total exposure of ten hours. A more rapid plate was used than on November 7 and 8 and with the longer exposure considerably more detail is shown. An exposure of 5 h. 28 m. was obtained on the night of December 4. As a storm came on, this plate was developed the following day. Considerable detail was shown on the negative and three

of the condensations were seen to have moved appreciably, while the strong one nearest the Nova showed but little if any change. An exposure of ten hours was secured on the nights of December 8 and 11, the 9th and 10th being cloudy. The motion of the nebula is so rapid that even in this interval of three days, blurring in the best-marked condensation is noticeable. A comparison of the last negative with that of November 12 and 13 reveals a number of changes. Condensations *A*, *B* and *C* (Lick Observatory Bulletin No. 10) have each continued their motions to the south-east full $\frac{1}{2}'$. Condensation *D* shows little or no change. Perhaps it is moving nearly in the line of sight. The negatives of December 4 and 8-11 show two new wisps of nebulosity southwest of the Nova at distances of $13'$ and $14'$, respectively. They are approximately arcs of circles of which Nova is the center and are about $2'$ in length. They have been carefully looked for on the November negatives, but no traces are there found of them. Throughout the entire southeast quadrant faint nebulosity is shown to a distance of $18'$ on the negative of December 8-11. There is but little appearance of structure in this outlying nebulosity. Several wisps of nebulosity $6'$ to the north of Nova are sufficiently strong to show that motions outward of $\frac{1}{4}'$ to $\frac{1}{2}'$ have taken place in the interval of 27 days. A wisp $9'$ to the north has also moved outward full $\frac{1}{2}'$. $6'$ to the northwest of Nova is a wisp which has moved outward $\frac{1}{4}'$. None of these wisps to the north and northwest are well enough defined lengthwise to make the other component of motion certain in the interval. Directly to the west is an arrow-shaped mass of nebulosity resembling somewhat the structure of condensation *A*. It has certainly moved outward and there appears to have been a motion to the northwest. Many changes of form and intensity of

masses of nebulosity have been noticed other than those referred to above, but which can not well be described. A longer series of photographs is necessary to deduce the character and amount of motion of these fainter masses. Lantern slides of the various photographs secured with the Crossley reflector were exhibited.

A Determination of the Wave Lengths of the Brighter Nebular Lines: W. H. WRIGHT.

In the progress of our investigations upon the spectrum of Nova Persei (see Lick Observatory Bulletin No. 8) there arose the necessity for a more accurate knowledge than then existed of the wave lengths of the Brighter Nebular lines. The spectra of the Orion Nebula and of three of the brighter planetary nebulae have been photographed in some cases with one prism, and in other cases with three prisms, and the resulting plates have been measured and reduced. The wave lengths of 16 bright lines have been determined with considerable accuracy, the fifth significant figure being determined definitely for the principal ones, and the uncertainty in the sixth place for the brighter lines being comparatively small. A slight correction appears to be needed in the values at present accepted for the positions of the two chief nebular lines determined by visual means. In the course of the work three new nebular lines have been discovered. The well-known lines usually described as H_{ϵ} and λ 3,727 have been found to be double.

A Determination of the Cause of the Discrepancy between Measures of Spectrograms made with Violet to Left and with Violet to Right: H. M. REESE.

In this paper three possible causes of the effect in question are investigated: (1) The curvature of the spectral lines; (2) the position of the star-spectrum in the

middle of the plate, enclosed by the comparison-spectrum; (3) a mere subjective tendency to set the cross-hair relatively farther to the right on a dark line in a white field than on a bright line in a dark field. The conclusion is reached that the third cause alone really operates, or at least that neither the curvature of the lines nor the relative position of star-spectrum and comparison affect the case.

Four New Spectroscopic Binaries: W. W. CAMPBELL.

Four stars have recently been observed with the Mills spectrograph to have variable velocities in the line of sight. These are φ Persei, ξ Herculis, α Equulei and ν Andromedæ. The first of these is an interesting bright-line star. The second has a large radial velocity, and is moreover an interesting visual double star whose period is about 33 years. This therefore affords another connection between visual and spectroscopic binaries. In the case of the third star, a composite spectrum was observed a few years ago by Miss Maury at Harvard College Observatory. Thirty-two spectroscopic binaries discovered with the Mills spectrograph in the past three years had previously been announced, thus bringing the number up to 36. On the list of suspected binaries are 14 stars, awaiting confirmation. Before the discovery of these binaries, 3 had been found in the same list of stars by Belopolsky, making about 40 spectroscopic binaries in 325 stars observed. The proportion is therefore one spectroscopic binary for every eight stars observed. The variable velocity of our sun, due to its revolving planets, has a double amplitude of only a few hundredths of a kilometer. As the work progresses and the degree of accuracy attainable increases, we shall probably find that there is a regular gradation of double amplitudes from that of our sun up to those of the spectroscopic

binaries already discovered, and it is possible that the star that is not a spectroscopic binary will prove to be the rare exception. This field of investigation is one of extreme richness.

Discovery of Five Hundred New Double Stars: W. J. HUSSEY.

While observing the Otto Struve double stars the writer discovered new companions to five of them and also picked up several new pairs in the vicinity of others. This led to the notion of making an extended search for new pairs, which was begun as soon as it was possible to do so without interfering with the work in progress. In the spring of 1899 search was commenced in a tentative way and in July of the same year it was taken up regularly, and since then has been conducted in a systematic manner. While only a part of the writer's time has been devoted to the consideration of new double stars, he has now discovered and measured five hundred new pairs having distances under five seconds. The work has been done with both the twelve- and thirty-six-inch telescopes of the Lick Observatory. Many close and difficult pairs, some of them having distances less than a quarter of a second, have been found with the smaller instrument, but nearly all the measures have been made with the great telescope. The classification of the new pairs with respect to the distances between their components is as follows:

0".25 or less,	37 pairs,
0 .26 to 0".50,	96 pairs,
0 .51 to 1 .00,	112 pairs,
1 .01 to 2 .00,	112 pairs,
2 .01 to 5 .00,	143 pairs.

Seventy-one per cent. of the total number have distances under two seconds; 49 per cent. under one second; 27 per cent. under half a second; and seven and one-half per cent. under quarter of a second.

On the Discovery of 300 Double Stars: R. G. AITKEN.

The writer's experience in observing double stars led him to conclude that it was desirable to make a systematic search for new pairs. As a contribution toward such a piece of work, 10,917 stars brighter than 9.1 magnitude have been examined by him since April, 1899, with the result that 301 new double stars have been found. These all have distances between their components of less than 5".00, 217 or 72 per cent. being closer than 2".00, and 19 closer than 0".25. The search has been made mainly with the 12-inch telescope. The zones examined also contain 530 stars previously catalogued as double, but only 308 of these pairs are comparable with the new pairs with respect to the angular separation of their components. A new double star has been found for every 36 stars examined and one star in every 18 examined is double within the adopted limit. On this basis it is estimated that more than 3,000 close double stars, within the reach of the telescopes of the Lick Observatory, still await discovery.

A Kinematic Study of Hansen's Ideal Coordinates: KURT LAVES.

In the 'Auseinandersetzung' of Hansen the ideal coordinates are defined by the equations

$$\begin{aligned} X \frac{da}{dt} + Y \frac{d\beta}{dt} + Z \frac{d\gamma}{dt} &= 0 \\ X \frac{d\alpha'}{dt} + Y \frac{d\beta'}{dt} + Z \frac{d\gamma'}{dt} &= 0 \\ X \frac{d\alpha''}{dt} + Y \frac{d\beta''}{dt} + Z \frac{d\gamma''}{dt} &= 0 \end{aligned} \quad (1)$$

$\alpha, \beta, \gamma, \dots \gamma''$ are functions of the time, the fixed coordinates xyz are connected with the movable coordinates X, Y, Z by means of the equations

$$\begin{aligned} x &= \alpha X + \beta Y + \gamma Z \\ y &= \alpha' X + \beta' Y + \gamma' Z \\ z &= \alpha'' X + \beta'' Y + \gamma'' Z. \end{aligned} \quad (2)$$

Hansen joins to the conditions (1) the condition:

$$Z = 0 \quad (3)$$

and obtains a well-defined system of ideal coordinates. Hansen has shown that the three homogeneous equations (1) lead to the following theorem: "In every ideal system of coordinates, referred to movable axes, the instantaneous axis of rotation coincides with the radius vector, drawn to the point." It is the intention of this paper to show that the last condition (3) will give rise to a kinematic theorem of similar import. Indeed, when we consider the three vectors, (1) the vector A of absolute acceleration of the point, (2) the vector of $A^{(r)}$ of relative acceleration of the point and (3) the vector $A^{(e)}$ of the acceleration of the movable system, we obtain for their components along the fixed axis three equations, of which only one is written down:

$$A_x = A_x^{(r)} + 2 \left(\frac{dX}{dt} \cdot \frac{da}{dt} + \frac{dY}{dt} \cdot \frac{d\beta}{dt} + \frac{dZ}{dt} \cdot \frac{d\gamma}{dt} \right) + A_x^{(e)} \quad (4)$$

Calling the middle terms on the right sides

$$R_x, R_y, R_z$$

respectively, and projecting them upon the movable axis, we obtain

$$\begin{aligned} R_x &= -\frac{dY}{dt} \cdot r + \frac{dZ}{dt} \cdot q \\ R_y &= -\frac{dZ}{dt} \cdot p + \frac{dX}{dt} \cdot r \\ R_z &= -\frac{dX}{dt} \cdot q + \frac{dY}{dt} \cdot p \end{aligned} \quad (5)$$

p, q, r having their usual meaning.

$$R = \sqrt{R_x^2 + R_y^2 + R_z^2}$$

will therefore be the moment of

$$\omega = \sqrt{p^2 + q^2 + r^2}$$

with respect to the point, which has for coordinates the quantities

$$\frac{dX}{dt}, \frac{dY}{dt}, \frac{dZ}{dt}$$

Selecting the position of the XY plane to be that which coincides with the plane of this moment, we have two homogeneous equations of condition, namely,

$$\begin{aligned} -\frac{dY}{dt} r + \frac{dZ}{dt} \cdot q &= 0 \\ -\frac{dZ}{dt} p + \frac{dX}{dt} \cdot r &= 0 \end{aligned} \quad (6)$$

it can be shown that these are equivalent to the one equation $Z=0$. We derive therefore the following: *Theorem.* The condition $Z=0$, which Hansen imposes upon his ideal coordinates, means that he selects for the XY plane the plane of the moment of the vector of instantaneous rotation with respect to the point of coordinates

$$\frac{dX}{dt}, \frac{dY}{dt}.$$

The Computation of Laplace's Coefficients by Means of Gylden's γ -coefficients:
KURT LAVES.

In this paper it is shown, how the quantities $b^{(6)}$ and $c^{(6)}$ can be determined by means of the definite integrals β^2 tabulated by Gylden in his Hülfsstafeln (after multiplication with functions of the argument α). A comparison is made with the table of Runkle, formerly used for this purpose.

Astronomical Photography with the 40-inch Refractor and the Two-foot Reflector of the Yerkes Observatory (Illustrated with lantern slides): G. W. RITCHEY.

The 40-inch refractor, which was designed for visual observations, has been made available for photography through the use of a color screen and isochromatic plates. The greenish-yellow screen, placed in contact with a plate sensitized for light of this color, permits only those rays to pass for which the object glass is corrected. For all but the briefest exposures a double-slide plate-holder is employed. By means

of two screws, which move the plate and guiding eye-piece, a star just outside the field being photographed is kept at the intersection of two spider lines throughout the exposure. In this way irregularities in the driving of the telescope, changes in refraction, etc., are corrected. The resulting photographs of the moon, Orion nebula, star clusters, etc., are exceedingly sharp, and are well adapted for measurement on account of their great scale. The two-foot reflector, on account of its short focal length (8 feet) and its freedom from chromatic aberration and absorption, is adapted for a different class of work, in which it admirably supplements the 40-inch refractor. All parts of this reflector were constructed at the Yerkes Observatory. On account of the perfect driving of the clock, permanence of collimation of the large mirror and freedom from flexure in the mounting, photographs of excellent definition are easily obtained. Among those exhibited were the Andromeda nebula, the Orion nebula, nebulae in the Pleiades, and the expanding nebula surrounding *Nova Persei*.

A Remarkable Disturbance of the Sun's Reversing Layer: GEORGE E. HALE.

A series of photographs of the solar spectrum, taken at the Kenwood Observatory in February, 1894, shows that the reversing layer surrounding a sun-spot was the scene of a great disturbance, which lasted only a few minutes. The diameter of the disturbed area was not less than one-sixth that of the sun. Over this entire region the dark lines of the solar spectrum were for a short time so changed in appearance as to be wholly unrecognizable. Measurements of the photograph show that nearly all of these lines occur in the normal solar spectrum, and that the changed appearance is due to great changes of relative intensity. Thus numerous lines barely visible on Row-

land's map were for a short time very intense, while others, such as the aluminium line of intensity 20 at λ 3,961.674, disappeared entirely. Two sharp bright lines appeared at λ 3,884.67 and λ 3,896.21. These were strongest in the spot, and did not extend to the limits of the disturbed area. Full details will be published in the *Astrophysical Journal*.

The Bruce Spectrograph of the Yerkes Observatory: EDWIN B. FROST.

The equipment of the Yerkes Observatory has been recently enlarged by the completion of a spectrograph designed for the special purpose of the determination of the motion of the stars in the line of sight. The addition of this instrument to the accessories of the forty-inch telescope was made possible by the liberal gift of \$2,300 from Miss Catharine W. Bruce and \$500 from the Rumford Fund of the American Academy of Arts and Sciences. The spectrograph is very rigidly constructed, chiefly of iron and steel, and the prisms are maintained in a fixed, invariable position. The whole instrument is inclosed in a large aluminium case with double walls, for protection against changes of temperature. Coils of wire inside this case can be heated by the 110-volt current of the observatory mains, and it has been found not difficult to keep the temperature of the air in the prism-box within $0^{\circ}.1$ C. during exposures of an hour or more. A correcting lens placed one meter in front of the slit makes the visual forty-inch object-glass efficient for the violet light (λ 4,500) which passes through the prism-train at minimum deviation. The collimator is of 2 in. aperture and 38 in. focus; and two cameras are provided, one of 3 in. aperture and 24 in. focus and another, a Zeiss anastigmat, of about 2.8 in. aperture and 18 in. focus. The first three lenses are of triple construction, designed by Professor C. S. Hastings and

made by Brashear. It has proved to be a matter of great difficulty to obtain prisms of the large size necessary to transmit a two-inch beam which are sufficiently homogeneous. (The face of the largest prism is 133 mm. long and 57 mm. high.) After an unsuccessful experience with a set of prisms of what appeared to be excellent glass from Mantois, a quantity of glass was ordered from Schott & Co., of Jena, which should be finely annealed and of the quality of telescope objectives, a requirement which, strangely enough, does not appear to be customary in respect to glass for prisms. This new set of prisms shows considerable improvement over the first ones, but the definition is still not the same over the whole surface of the faces. This is now assumed to be due to the moulding of the prisms in triangular shape at Jena instead of melting disks, as we had desired, from which the prisms would be cut by Brashear. Although the spectrograph does not fully realize the resolution which the length of the faces of the prisms would imply, the instrument has nevertheless been shown to be capable of furnishing results of a very high degree of accuracy, as illustrated in the paper by an example of a plate of *a Arietis*. The comparison spectra so far employed have been the spark of titanium and of iron and the helium tube. During the exposure on a star the observer guides the telescope by light reflected from the speculum slit jaws, which are not in the same plane, but symmetrically inclined away from the line of collimation, each making with it an angle of $92^{\circ} 55'$. It is also possible, by merely turning a mirror, to observe in the same guiding telescope the light that has gone through the slit and has been reflected at the first surface of the first prism. The method of measuring and reducing the plates briefly described by the writer at the meeting of the Society in 1899 is still in regular use. Plates are measured

both with violet to right and with violet to left under the measuring microscope, as an observer may have a large systematic difference in his mode of making a setting on the dark lines of the comparison spectrum and the white lines of the stellar spectrum (on the negative). The writer has a large systematic error of this kind, which is reversed in sign but of the same size when the measures are made on a positive copy of the negative. By measuring the plate in both directions this systematic difference appears to be wholly eliminated. Each plate is reduced by itself, independently of any standard plate of a solar or metallic spectrum, with the aid of the Cornu-Hartmann formula in its simple form, the 'fit' of which can be checked up at the position of each comparison line and the wavelengths corrected accordingly. The first star found by the Bruce spectrograph to be a spectroscopic binary is γ Orionis. Four of the first plates, taken by Mr. W. S. Adams and the writer, yield the following velocities:

1901, Nov. 27,—68 km. per second.			
Dec. 6, +13	"	"	"
Dec. 18, +54	"	"	"
Dec. 19,—56	"	"	"

The period is not yet determinate. In concluding the paper the proposal was made that the six or seven observatories, which now include in their work the determination of stellar velocities in the line of sight, should cooperate in regularly observing a short list of fundamental velocity stars. The comparison of the results obtained for the same stars with the different spectrographs and different observers, using different sources of comparison spectrum and different lines of the stellar spectra, could hardly fail to be of great value both in indicating causes of error in the separate instruments and in establishing with a high degree of accuracy the velocities of these fundamental

stars. (To be published in *The Astrophysical Journal*.)

W. S. EICHELBERGER,
For the Council.

THE RELATION OF THE AMERICAN SOCIETY OF NATURALISTS TO OTHER SCIENTIFIC SOCIETIES.*

I AGREE in general with all that has been said, and find myself in especially close accord with the remarks of Professor Trelease—so much so, indeed, that I might well refrain from saying more. Yet there are two points in the discussion to which I should like briefly to call attention.

We are all agreed that the object of our meetings is to spread the method and temper of science among the people—to inoculate the community with the spirit of science. Now, while the great central scientific meetings, so well described by Professor Minot, attract the attention of the whole country for a brief time, they do very little and can do very little in extending the influence or the real temper of science. This must be done, if at all, by the teaching, example and lives of those who are devoted to science, scattered through the country and making their influence felt daily throughout the year. It is, therefore, of the utmost importance that the local centers of science, and especially the smaller centers, remain vigorous. By these small centers I do not mean the great universities, or even the smaller colleges. The life of science in institutions of this character does not need the stimulus of meetings. Even at the present time men thoroughly trained in the methods of science are teaching in the normal schools and in the larger high schools throughout our country and the number of such teachers is rapidly increasing. One most im-

* Part of the discussion before the American Society of Naturalists received after the report had been published in the issue of SCIENCE for February 7.—Ed.

portant object of scientific meetings is to furnish to these men, most of whom are working singly in their schools and communities, a stimulus to continue the scientific work for which they have been trained, and an opportunity of bringing the results of their study before a sympathetic audience. This opportunity, however, can be afforded only by a local meeting, and any arrangement of meetings which sacrifices the local gathering to the national meeting will have a disastrous effect on the spread of the scientific temper in the country, because it will necessarily weaken these local scientific centers which, from their number, are quite as important as the more conspicuous and stronger centers of science in our great institutions.

I may perhaps be permitted to call attention to a second matter suggested by the discussion, although it is one in which I am not in any way officially interested. I must own that I look with some concern on the change of the American Association for the Advancement of Science from a general gathering to one composed of professional scientists. It has always seemed to me that a most important part of the work of this Association has been in serving as a common ground of meeting for the professional scientists and those who, without professional knowledge, were interested in science. Its meetings have served as an important means of communication between the professional scientific world and the community, reaching the community in the best of all ways—through those individuals who, though without special knowledge of science, have yet a personal interest in it. This function certainly ought to be performed by some organization and it will be of no small concern to science if the American Association decides to abandon this function.

E. A. BIRGE.

UNIVERSITY OF WISCONSIN.

ALPHEUS HYATT.

ALPHEUS HYATT died suddenly of heart disease at Cambridge, Mass., January 15, 1902, a few months before the completion of his sixty-fourth year.

He was born at Washington, D. C., April 5, 1838; prepared for college at the Maryland Military Academy and passed a single year at Yale College. After a year's travel in Europe, he entered the Lawrence Scientific School at Harvard in 1858, graduating with the degree of Bachelor of Science in 1862.

He enlisted in the volunteer militia in 1862, served for nine months, and at the close of the Civil War was mustered out in 1863, as Captain of the 47th Massachusetts Infantry.

Returning to Cambridge, he resumed his studies under the guidance of Professor Louis Agassiz, the greater part of his time being directed to work upon the fossil Cephalopoda. In 1867 Mr. Hyatt went to Salem, Mass., and was associated with Messrs. Putnam, Packard, and Morse in the care of the natural history collections of the Essex Institute, and of the Peabody Academy of Science, and in the editorial management of the *American Naturalist*. He remained in Salem until 1870, when, on May 4, he was elected custodian of the Boston Society of Natural History. By yearly choice Mr. Hyatt remained the scientific head of the Society until his untimely death.

He held professional chairs in Boston University and in the Massachusetts Institute of Technology, and was at one time or another officially connected with the Museum of Comparative Zoology, and the United States Geological Survey.

Professor Hyatt was a member of the National Academy of Sciences (1875), the American Philosophical Society (1895), the American Academy of Arts and Sciences (1869), and of other leading scientific so-

cieties both in this country and abroad. In 1898 Brown University conferred upon him the degree of Doctor of Laws.

Professor Hyatt's private life, though uneventful, was attended with many blessings; he had vigorous health, congenial work and many friends. He enjoyed scientific meetings and general society; his welcome to his own home, where he was the most charming of hosts, can never be forgotten. His death, though premature, came as he would have wished, in the fulness of his power and without attendant suffering. As a man of true science he was ready, yet loath, to die.

Professor Hyatt possessed traits of character the worth of which cannot be exaggerated; his kindness towards those working with him was very marked, as was also the purity of his thought and speech; his friendship was sincere and hearty, for while he had, as every man has, his moments of excitement, caused by misunderstandings and differences, one could disagree with him on any or on every vital question with full confidence that such clashes would not weaken his regard. Such an entire absence of all personal feeling must be regarded as a very rare and remarkable trait.

From the outline as given, the life work of Alpheus Hyatt may be grouped in three sections: First, as the head of a museum of natural history; secondly, as a teacher of science; and, thirdly, as an investigator. A few salient features of these phases of work may be noted.

For the head of a museum of natural history, Professor Hyatt had many and marked qualifications; his knowledge of zoology, of paleozoology and of geology was extensive; he was skilful in manipulation, suggestive in council, enthusiastic and approachable.

His plan that a natural history museum should be arranged so that a visitor on entering should pass from the simpler groups

to those more specialized, and that the specimens in each case should be similarly classified, though opposed as impractical, is both sound and feasible. Somewhat disposed in late years to a too great use of diagrams and models in place of actual material, his recognition of the value of these, of descriptive labels and of a personal guide was early, important, and helpful. His invention of the 'Hyatt bracket' gave an accessory at once simple, effective, and inexpensive, and applicable for greater use than that for which it was planned. It is true that the full realization of much of his best museum work and thought is left for appreciative successors, as Professor Hyatt was too apt to be content with an initiative, the result of which he clearly apprehended, and did not always give attention to the actual carrying out of details, details that in many cases required continuous interest through successive years.

Professor Hyatt's reputation as a teacher will rest largely on the work he did for the Teachers' School of Science. His management of this school was very skilful, and his lectures, of which he gave many courses, were uniformly successful. It was here that he enforced the value of direct observation and comparison, and transmitted the spirit instilled into him by Agassiz to another generation of teachers, many of whom to-day attribute a large share of their success to his methods. His direct influence upon the work of other lecturers in this school may also be mentioned. His early maintenance of a seaside laboratory at Annisquam, Mass., the resources of which were open to teachers so far as space and means would allow, was also an important educational mode.

In the pursuit of his investigations, Professor Hyatt not only studied the accumulations preserved in museums in this country and abroad, but he partook in active field work; he dredged off the east coast at

various points from Labrador to Noank, Conn., and explored many geological horizons in Canada, the Maritime provinces, New England, New York and the far west. His published writings, though less numerous than those of some of his contemporaries, are many and important; they cover a wide field in the Invertebrata, both fossil and recent, and in some cases represent pioneer work in the group studied.

The titles of a few of the more important of his publications may be noted: Observations on Polyzoa (1866-68); On the parallelism between the different stages of life in the individual and those of the entire group of the molluscan order Tetrabranchiata (1867); Fossil cephalopods of the Museum of Comparative Zoology. Embryology (1867); Revision of the North American Porifera (1875-77); The genesis of the Tertiary species of *Planorbis* at Steinheim (1880); Genera of fossil cephalopods (1883-84); Larval theory of the origin of cellular tissue (1884-85); Genesis of the Arietidæ (1889); Bioplastology and the related branches of biologic research (1893); Phylogeny of an acquired characteristic (1894); Cephalopoda (1900).

From the beginning Professor Hyatt's researches were very largely devoted to evolutionary questions, and to the special study of fossil cephalopods; at the time of his death he was one of the foremost authorities upon the fossil Cephalopoda. The true value of his work upon this group must be left for the future; memoirs such as the Genera of fossil cephalopods (1883-84), and the chapter on the Cephalopoda (1900) contributed to the English issue of Zittel's 'Palaentology' cannot be properly estimated by the present generation; they require prolonged and detailed study founded upon large series of specimens. His theory of parallelism based on acceleration and retardation, and his discoveries concerning the laws of development,

growth and decline were advocated with persistence and vigor; and while his treatment is not always lucid, he is to be credited as the originator of a distinct school, a school devoted to exact methods of research. The growth of this so-called Hyatt school, never of greater importance than at the time of his death, was a source of sincere gratification to him.

SAMUEL HENSHAW.

SCIENTIFIC BOOKS.

Dictionary of Philosophy and Psychology.

Written by many hands and edited by JAMES MARK BALDWIN, Ph.D., with the cooperation and assistance of an international board of consulting editors. In three volumes, with illustrations and extensive bibliographies. Vol. I. New York, The Macmillan Company. 1901.

In considering an enterprise of such magnitude as this dictionary offered by Professor Baldwin, the reviewer should keep in mind several important points. He should remember the purpose which guided the editor in his work, its value to those for whom it is especially intended, and the great difficulties of the undertaking. He should not measure it by ideals which the editor never aimed to realize and which it was not necessary for him to realize under the circumstances. Two purposes are combined in the work, Professor Baldwin tells us—'first, that of doing something for the thinking of the time in the way of definition, statement and terminology; and second, that of serving the cause of education in the subjects treated.' The task, therefore, is 'to understand the meanings which our terms have, and to render them by clear definitions; and to interpret the movements of thought through which the meanings thus determined have arisen, with a view to discovering what is really vital in the development of thought and term in one.' The other part of the problem is pedagogical and carries with it the duty 'to state formulated and well-defined results rather than to present discussions.' The reader, therefore, who expects to find nothing but original articles written for experts

and by experts, a work, for example, like Schönberg's 'Handbuch der politischen Oekonomie' or Conrad's 'Handwörterbuch der Staatswissenschaften,' will be disappointed. There are, indeed, 'special' articles on certain topics, and these are of 'encyclopedic character,' but they are in the minority. The Dictionary is meant primarily for the student, not for 'the practised man of research'—a fact which should be kept constantly in view. This will also help to explain the great scope of the enterprise, as set forth in the subtitle: 'including many of the principal conceptions of ethics, logic, æsthetics, philosophy of religion, mental pathology, anthropology, biology, neurology, physiology, economics, political and social philosophy, philology, physical science and education.' The editor justifies himself for attempting to cover such an enormous field with the statement that 'the introduction to a large subject—philosophy, indeed, is the largest subject—must needs include various details of knowledge of other branches of science and information, and of methods, preliminary to its proper task.' The wide inclusion of science receives further justification from the editor's conception of philosophy and of its relation to science. Philosophy is for him 'the attempt to reach statements, in whatever form, about mind and nature, about the universe of things, most widely conceived, which serve to supplement and unify the results of science and criticism.' "It is," he says, "one of the safest sayings of philosophy, at the close of the outgoing century, that whatever we may become to end with, we must be naturalists to begin with—men furnished with the breastplate of natural knowledge. We must know the methods as well as the results of science; we must know the limitations of experiment, the theory of probability, the scientific modes of weighing evidence and treating cases. Lack of these things is the weakness of many a contemporary writer on philosophy. Such a one criticises a science which he does not understand, and fails to see the significance of the inroads science is making into the territory which has so long seemed to be exempt. Note the application of biological principles, in however modified form, to

psychological facts; the treatment of moral phenomena by statistical methods; and the gradual retreat of the notion of purpose before the naturalist, with the revised conception of teleology which this makes necessary." The prominent place given to psychology is another necessary consequence of the editor's standpoint, and will receive the approval of all who agree with him as to the fundamental importance of this discipline for science on the one hand, and philosophy on the other. "In biology, in sociology, in anthropology, in ethics, in economics, in law, even in physics," he declares, "the demand is for sound psychology; and the criticism that is making itself felt is psychological criticism. How could it be otherwise when once it is recognized that science is the work of mind, and that the explaining principles by which any science advances beyond the mere cataloguing of facts are abstract conceptions made by processes of thought?" All this is very good, and most modern thinkers will have no difficulty in accepting it. The philosopher cannot ignore science, nor can either he or the scientist do without psychology.

Taking the Dictionary, or rather the first volume of it, as a whole, and judging it by what it sets out to do, we cannot withhold from it our full measure of praise. It is beyond question the best production of its kind in the field, and will doubtless prove a valuable aid to those for whom it was made; indeed, there are few, if any, interested in the general philosophical branches who will not find it a useful *vade mecum*. Professor Baldwin and his collaborators certainly deserve the gratitude of all students and teachers of philosophy and psychology in the English-speaking world for the arduous task which they have so successfully performed.

And now a word or two with respect to particular points. One of the objects of the Dictionary is to do something in the way of definition and terminology. This is, of course, a highly commendable aim. But there seems to us to be some danger of *overdoing* the thing, of attempting to define what cannot be defined, or at any rate cannot be defined satisfactorily within the narrow limits of a sentence

or two. Some of the older American philosophical text-books were in the habit of defining or at least trying to define concepts like consciousness, mind, feeling, etc., and many persons who have used these books still remember the thought-destroying effect produced by their study. Perhaps these experiences have made us too sceptical with regard to certain definitions, but it does not seem that we are helped very much by statements like the following: "Activity (mental). If and in so far as the intrinsic nature of conscious process involves tendency towards a Terminus (q. v.), it is active process, and is said to have activity." "Admiration. Feeling as going out in active approval." "Attention. The mind at work or beginning to work upon its object." "Being. The most general predicate possible and to be affirmed of anything whatever." "Consciousness. The distinctive character of whatever may be called mental life. It is the point of division between mind and not mind." "Determination. The cooperation of all the factors which adequately condition and issue in a mental End-state (q. v.)." "Feeling. Consciousness as experiencing modifications abstracted from (1) the determination of objects, and (2) the determination of action." Perhaps the best thing we can do in many cases is to confess our inability to give satisfactory definitions, as the German professor did, who, when told by one of his students in an examination that he did not know what an animal was, frankly declared that neither did he. So far as the terminology is concerned it is to be hoped that the Dictionary will bring about some uniformity of usage. Its recommendations are, as a rule, very sensible, and there is no reason why they should not be adopted.

With respect to the value of the different articles there will, of course, be difference of opinion. Most of them, however, serve their purpose well. Among those pertaining to philosophy and closely allied subjects the following do not seem to receive the treatment which their importance demands: Analogies of Experience; Association of Ideas; Conscience; Cause Theory (perhaps the article on Parallelism will supply the deficiency); Deism; Dia-

lectic; Dogmatism (Kant's meaning of the term is not clearly brought out); Education; Empirio-criticism; Free Will (and determinism); Innate Ideas (Leibniz's view should be mentioned here); Instruction. The following are among the most helpful and suggestive: Cause; Cause and Effect; Change; Epistemology; Experience; Greek Terminology; Hegel's Terminology; Kant's Terminology (unfortunately this does not include Kant's ethical and aesthetic terminology); Judgment; Latin and Scholastic Terminology. The articles on psychology and aesthetics are generally very good.

The number of subjects discussed in the first volume is quite large, and the Dictionary seems to be very complete in this respect. It would, of course, be impossible to give each possible topic a separate place in the book; many things will have to be considered together under general heads, and the index to the entire work, which is to appear at the end of the second volume, will most likely help the student in his search for certain terms. Perhaps some of the following subjects, which I have tried to find, may turn up in this way: Animal Spirits; Astrology; Corpuscular Theory; Duty (and inclination); Dynamism; Dysteleology (a term coined by Hæckel); Eduction (a term used by some English logicians); Egoism (in the sense of solipsism); Energetik (the term used by Ostwald); Ethelism; Ethical Culture Movement; Euhemerism; Evaluation; Idiopathic (as contrasted with sympathetic, a term frequently used by the Germans—*e. g.*, by Paulsen); Illusionism; Individualism (ethical. Reference might here be made to the article on Anarchism); Intelligible and Empirical Character. There are two articles which might easily be brought under the same head: *Ætiology* and *Etiology*. In the article on Determinism we are referred to an article on Free Will Controversies. There is no such article. There ought to be a reference under Empirio-criticism to the article on Introjection, which gives one a much better idea of Avenarius's system than the first article.

The biographical part of the work is, in my opinion, capable of great improvement. Many important names are left out, many unimpor-

tant ones given. Every one cannot be mentioned, of course, but it would be a distinct gain if names like Alanus ad Insulis, Antisthenes, Aristarchus of Samos (he is, it is true, mentioned under the Copernican Theory), Beda Venerabilis, Bolingbroke, Buridan, Calderwood, Cardanus, Digby, Euler, Fiske, Galileo, Gaunilo, Gerbert, Gizycki, Glogau, Guyau, Hamann, Hegesias, Herschel, Wilhelm von Humboldt, Kepler, Laas, Lamennais, Lanfranc, Laplace, to call attention to but a few prominent omissions, could take the place of: Abbadie, Abdalatif, Achenwall, Johann Alanus, some of the Alexanders, Allamand, Arnott, Atwater, Beaseley, the two Hodges and others comparatively unimportant. It is a pity, too, that no biographies are given of living thinkers, say of men like Baumann, Brentano, Dühring, Eucken, Kuno Fischer, Fouillée, Hartmann, Höfding, Jodl, to say nothing of English and American writers of note; but perhaps that would have increased the size of the work beyond all reasonable expectations.

The bibliographies are unequal in value. The psychological bibliographies are usually excellent, including, as they do, the best monographs in the field. The literature on æsthetics is also good. The philosophical, logical, ethical, epistemological and educational lists of references, cannot as a rule compare with the others; some of them are quite meager, often ignoring the best recent literature. It is one of the most valuable functions of a work like the Dictionary to guide the student in his reading and to put him in touch with the best work done everywhere. It would be an advantage if the third volume of the Dictionary could give not only the names of books, but critical comments on some of them.

In conclusion I should like to call attention to a few minor details. There should be some uniformity (1) in German spelling, (2) in the use of the English possessive, and (3) in French titles. Sometimes the old style of German spelling is used, sometimes the new. We get *Urteil* and *Urtheil*, *Funktion* and *Function*, *Defekt* and *Defect*, *Produkt* and *Product*, etc., etc. Sometimes the Dictionary uses the apostrophe followed by *s* in English

possessives ending in *s*, sometimes it uses the apostrophe only. Thus we find St. Vitus's, Cornelius's, James's, St. Thomas's, Leibnitz's, and Descartes', Averroës', Leibnitz', and so on. In the French titles capitals are sometimes used and sometimes not. There are a few other cases in which we get differences in spelling. The Dictionary writes *Kratylus* and *Kritias*, but *Crates*, *Carneades*, *Cleantes*. *Quesnai* and *Quesnay* occur, *Frankfurt* and *Frankfort*, *Clement* and *Clemens*, *Renaissance* and *Renascence*, *spatial* and *spacial*, and if I am not mistaken *Occam* and *Okham*.

The terms *adoptionism* and *Adoptionismus* are used instead of *adoptionism* and *Adoptianismus*, which are the more common forms. *Clanberg* should be *Clauberg*. Instead of *Agent* the Germans use the term *Agens* in the sense employed on page 25. The usual German equivalent for common sense in the meaning given on page 200 is *gesunder* or *gemeiner Menschenverstand*. *Askese* is more common than *Asceticismus*. The counter-reformation is *Gegen-reformation* in German. On page 92 Höfding is referred to as an authority on mediæval philosophy. Schmidt's 'Ethik der alten Griechen' is spoken of as a history of ethics on page 344; it is a history of Greek morality and ideals rather than of Greek systems. The title of Ziegler's book is: 'Die Ethik der Griechen und Römer.' On page 67 the term *patristic fathers* is used. On page 500 a passage from Munro's translation of Lucretius is given without credit. On page 5 a translator's name is given as *Filkin*, on page 189 as *Falkin*, on page 557 as *Felkin*. *Homousios* (p. 67) should be *homoi-ousios*. On page 596, first column, eighth line from the bottom, the word *to* should be placed between *that* and *phenomena*.

Typographical errors are: *Nature* for *Natur* (p. 5); 1794 for 794 (18); *peripheral* for *peripheral* (28); *Gaston* for *Galton* (46); *base* for *bare* (61); *Bohme* for *Böhme* (124); *idiot-motor* for *ideo-motor* (217); *Adeckes* for *Adickes* (246); *Elsenhaus* for *Elsenhans* (216); *Seipsis* for *Scepsis* (320); *Raumvorstellungen* for *Raumvorstellung* (364); 21 for 214 (521); *Frauenstadt* for *Frauenstädt* (537); *instinct* for *institut* (579); *Mansell* for *Man-*

sel (347); Micklejohn for Meiklejohn (285); Laud for Land (21); and a few others even more insignificant than the above.

Volume II. will contain the remainder of the text, from Le to Z, Addenda, full indices of Greek, Latin, German, French, and Italian terms, while volume III. will be devoted exclusively to the general bibliographies.

The Macmillan Company deserve great credit for making such a publication possible and for the manner in which they have performed their part of the work. FRANK THILLY.

UNIVERSITY OF MISSOURI.

Report on a Botanical Survey of the Dismal Swamp Region. By THOMAS H. KEARNEY.

Contributions from the U. S. National Herbarium, VI.: 6. Washington, 1901. 8vo. Pp. 263, 12 plates, 39 figures and 2 maps.

The account of the Dismal Swamp vegetation here presented is both a valuable and a thoroughly readable one. The subject is handled from a number of viewpoints in such a way that the reader obtains a well-rounded conception of this particular vegetative covering and of the interrelations of its constituents. The author is especially to be commended for his careful inquiry into the causes which produce the characteristic modifications of the various vegetation forms, and for the histological investigation of certain species, a study which is altogether too rare as yet in ecological research.

Under 'Climate' the author discusses the usual physical factors, temperature, sunshine, humidity, precipitation and wind, though the data unfortunately could not be secured for the Swamp itself, but only for the neighboring meteorological stations, Norfolk and Cape Henry. The prominent physiographic features of the region, to which correspond, of course, certain plant formations, are (1) the beach and the dunes, (2) the salt marsh, (3) the plain and (4) the swamps. A very important discussion of the soils of these areas is contributed to this portion by Mr. F. D. Gardner, of the Division of Soils.

In the treatment of the vegetative covering of the region, the author recognizes a maritime and an inland group of formations.

The former comprises the saltmarsh formation and the sand-strand formations. Under the first are arranged a number of associations, *Spartina stricta* association, *Typha* association, *Juncus* association, which are, in fact, alternating areas of the formation, in which a certain facies or principal species is controlling. Little attention is given to the relative importance of the species constituting the formation, or to their sequence in time. The most important physical conditions which cause modification in saltmarsh plants are partial submersion at high tide, a soft yielding substratum and an excess of sodium chloride in soil and water. The resulting modifications are largely concerned with the reduction of the water loss, as is typical of halophytes, by thickening the cuticle and the epidermal walls, by the development of a dense hairy covering, the sinking of the stomata, the conduplication of the leaf, or its partial or complete reduction, the development of succulency, the presence of a considerable quantity of salts in the cell sap, and the development of palisade tissue. The value of the sheathing bases of the old leaves in preventing the access of salt water must be regarded as somewhat doubtful. The consideration of the sand-strand vegetation is clear and interesting. The beach and outer dunes are characterized chiefly by *Ammophila arenaria*, *Uniola paniculata*, *Iva imbricata*, *Panicum amarum minus*, *Cakile edentula* and *Salsola kali*. The vegetation of the middle dunes is much less open in nature. The most characteristic feature is, perhaps, the dense, often pure, thickets of *Myrica carolinensis*. Other thickets are constituted by *Prunus angustifolia*, *P. serotina*, *Salix fluviatilis* and *Cephalanthus occidentalis*. The inner dunes are wooded for the most part with *Pinus taeda*, but a number of deciduous trees and shrubs, *Quercus*, *Diospyrus*, *Sassafras* and *Juniperus*, occur here also. An excellent analysis of the effect of the mechanical action of the wind, and of the effect of excessive transpiration follows the floristic discussion.

The non-hygrophile inland formations are (1) forest formations, embracing the mixed forest and the pine barrens, (2) cleared-land formations, non-cultural and cultural, (3)

fresh-water formations, comprising the hygrophile forest, with its two types, the black gum swamp and the juniper swamp, and the fresh-water marsh formation, with the reed marsh and the low-marsh types. The phytogeographical affinities of the flora are discussed at some length, touching upon the position of the species in the various vegetation zones. The northern limit of Dismal Swamp species is tabulated in an exhaustive manner. The broader relationship of the flora receives some attention also, a number of interesting comparisons being made. The agricultural products of the region are touched upon briefly, special consideration being given to the influence of drainage and soil composition upon the native and cultural vegetation.

Anatomical notes upon the leaf structure of a number of the most interesting species ecologically constitute a very important feature of the work. The notes treat chiefly of the adapted structures of the leaf, embracing a brief description of the leaf, the epidermis, mesophyll, mesotome and stereome. Much is to be said in commendation of thorough histological work of this sort, a field of investigation which must come to play an increasingly important part in all comprehensive ecological work. The text closes with a list of the plants of the region, a bibliography of the books and papers consulted, and a full index.

FREDERIC E. CLEMENTS.

UNIVERSITY OF NEBRASKA.

Monographie der Termiten Afrikas. By Yngve Sjöstedt. Köngl. Svenska Vetenskaps-Akademiens Handlingar, Vol. xxxiv., No. 4, 1900 (received late in 1901). Pp. 236. Plates IX.

Africa, the classic land of Termites, has, in recent years had its termitid fauna quite thoroughly explored. New species have been coming thick and fast from the pens of Sjöstedt, Wasmann, and Haviland; and now the work is capped by an excellent monograph from the hands of the Swedish student.

The author has had at his disposal practically all of the available material, and with great care has produced a work that will always be the basis for the future study of

African white ants. Descriptions are given of 82 species, arranged in six genera; and tables are given for the determination of the species. One of the notable features of the work is the attention paid to biology. The habits of each species, when known, are detailed at considerable length, and four of the plates represent nests or parts of them. We are accustomed to think of Termite nests as being pyramidal in shape, but this applies only to certain species of *Termites*; the nests of *Eutermes aurivilli* and *E. fungifaber*, which are illustrated, are larger at the top than at the base, and have the appearance of some gigantic mushroom. The tree-nests of *E. arborum* and *E. arboricola* are also figured, the former attached to the twigs, the latter to the trunk of a tree. Accounts are given of how the natives collect certain species for eating, and of how other species collect grass and leaves, and conduct their mushroom gardens. Two bibliographies are appended: One, a list of papers on African termites; the other, a list of termitid literature published since Hagen's 'Monograph of the Termites' in 1855.

NATHAN BANKS.

SCIENTIFIC JOURNALS AND ARTICLES.

The January number of the *Botanical Gazette* (the first of Volume XXXIII.) opens with an article on 'Binucleate Cells in Certain Hymenomycetes,' by R. A. Harper, of the University of Wisconsin. Dr. Harper confirms and extends the results of Maire, finding the young cells of numerous Hymenomycetes to be binucleate. On the basis of these and other observations he then discusses the relationship of the Basidiomycetes with the Ascomycetes, controverting the conclusions of Masee, and holding that "the widespread occurrence of regularly binucleated cells in the Basidiomycetes, with the additional evidence that these cells reproduce by conjugate division and constitute the reproductive series in each individual through at least a considerable part of its life-history, leading up to the formation of basidia, while no such binucleated cells are found in Ascomycetes, in either vegetative or ascogenous hyphæ, shows that the two groups are widely separated phylogenetically. * * *

On the other hand, it is quite clear that the binucleated condition in the hyphæ of both groups still further strengthens the evidence for the relationship between the rusts and Basidiomycetes."

Judson F. Clark, of Cornell University, discusses the 'Toxic properties of some copper compounds, with special reference to Bordeaux mixture.' Clark shows that solution of such of the $\text{Cu}(\text{OH})_2$ in Bordeaux mixture as is of fungicidal value, is chiefly accomplished by the solvent action of the fungus spores themselves, the total amount of copper necessary being probably not more than one part in 80,000. The amount of injury done to the host, which also has the power of absorbing the copper hydroxid deposited on its leaves, depends on the specific susceptibility of the protoplasm, the solvent properties of the cell sap, the permeability of the epidermis, and the weather conditions following spraying.

G. P. Clinton, of the University of Illinois, announces the discovery of *Cladochytrium Alismatis* Büsg. on *Alisma Plantago*, near Cambridge, Massachusetts. This is the first time this fungus has been found in America. He describes also a peculiar temporary sporangial stage which it had not been previously known to possess. He was also successful in germinating the resting sporangia, which had not been accomplished before.

J. C. Arthur, of Purdue University, discusses briefly 'Clues to Relationships among heterœcious Plant Rusts,' and Leslie N. Gooding describes six new species of plants from the Rocky mountain region.

Fifteen pages of reviews of current literature and four pages of news complete the number.

THE December number of the *American Geologist* contains a portrait and a short biographical sketch of the late Ralph D. Lacey of Pittsburg, Pa., by the Rev. H. F. Hayden. Also the scientific work of the late W. H. Barris of Davenport, Iowa, is described briefly by C. H. Preston and the article accompanied by a portrait. Neither of these men were professional scientists but their contributions to paleontology are valuable and lasting. 'The Loess

of Iowa City and Vicinity' is discussed by B. Shimek. He describes the fossils found in the loess and compares them with the forms now living in the vicinity and other loess deposits. E. R. Cummings discusses 'A Section of the Upper Ordovician at Vevay, Indiana,' accompanying the article with two plates of fossils. 'The Cleveland Water Supply Tunnel,' by S. J. Pierce. From the evidence furnished by this tunnel and other work done in the vicinity the author describes a deep V-shaped preglacial valley emptying into Lake Erie, about nine miles long and at its greatest depth 450 feet below the lake level.

The Journal of Physical Chemistry. November. 'Equilibrium between Carbonates and Bicarbonates in Aqueous Solution,' by Frank J. Cameron and Lyman J. Briggs; 'Solubility of Gypsum in Aqueous Solutions by Sodium Chlorid,' by Frank K. Cameron. These papers are communications from the Bureau of Soils of the United States Department of Agriculture. 'Mathematical Expression of the Periodic Law,' by S. H. Harris; 'The Optical Rotatory Power of Cane Sugar when Dissolved in Pyridin,' by Guy Maurice Wilcox.

December. 'Oxidation of Ferrous Solutions by Free Oxygen,' by J. W. McBain. It is found that the oxidation of ferrous solutions by free oxygen is unexpectedly slow and that it increases with the concentration of the ferrous salt. 'Some Applications to Chemistry of J. J. Thomson's Work on the Structure of the Atom,' by Felix Lengfeld; 'Solubility of Gypsum in Aqueous Solutions of Certain Electrolytes,' by Frank K. Cameron and Atherton Seidell. A further study from the Bureau of Soils. In dilute solutions the solubility curves follow the direction indicated by the application of the mass law to the hypothesis of electrolytic dissociation. For high concentrations this is not generally the case, but in such solutions ionic complexes seem to be formed.

SOCIETIES AND ACADEMIES.

THE NORTHEASTERN SECTION OF THE AMERICAN CHEMICAL SOCIETY.

THE regular monthly meeting of the Section

was held in the rooms of the German Turnverein on Tuesday evening, January 28. Dr. James Locke, of Yale University, addressed the Society on 'Some Recent Problems in the Systematization of Inorganic Compounds.' The paper was a résumé of some work on the solubility of various alums, and of certain double sulphates, which has been in progress for several years in the laboratories of the Sheffield Scientific School. It was shown that when the solubility of the alums of aluminium, vanadium, chromium, and iron with ammonium, sodium, potassium, caesium, rubidium, and thallium is expressed in gram-molecules per liter of water as a function of the atomic weight of the trivalent metal, a figure is obtained in which the straight lines connecting the solubility of any two trivalent metals with successive univalent metals meet in a point, if prolonged. It was assumed that the points of solubility stand in fixed mathematical ratio to one another, and it was shown that if the difference of the solubility of the alums of a trivalent metal with two alkali metals is called the increment of solubility of the latter, then the ratio between the increments of solubility of the corresponding alums of two trivalent metals for any two alkali metals is a constant. This general law was amply confirmed by the experimental results, and it was shown that the solubility of new alums could be predicted with considerable accuracy.

Dr. B. S. Merigold, of the Worcester Polytechnic Institute, read a paper on 'Some Recent Work on Uranium,' in which he described the method and apparatus for obtaining pure anhydrous uranous bromide and the use of this substance for the determination of the atomic weight of uranium. The mean value of two sets of experiments was 238.52, about one unit lower than the recent values of Zimmerman.

HENRY FAY,
Secretary.

SECTION OF ANTHROPOLOGY AND PSYCHOLOGY OF
THE NEW YORK ACADEMY OF SCIENCES.

A MEETING was held on January 27. The chairman, Professor Farrand, after opening the meeting, called on General James Grant Wilson to preside.

Mr. F. S. Dellenbaugh explained his understanding of the location of the historic towns and 'nations' of the Rio Grande valley in New Mexico prior to 1630. This differs radically and entirely from the present accepted arrangement. He maintains that the location of Tiguex, rather than Cibola, is the key to the correct solution of this problem, and from strong evidence derived from Benavides, Espejo, Castañeda and others, he locates Tiguex near San Antonio station. The site at Bernalillo, for this central town, so long advocated by Bandelier and his followers, he declares is impossible. With Tiguex at San Antonio station, the famous 'Seven Cities of Cibola,' which Bandelier placed on the site of modern Zuñi, are thrown instead into southwestern New Mexico, either on the Gila near Old Camp Vincent, or Old Fort West, or between these and the Florida Mountains, with the balance in favor of a site on the Gila. Cicuyé, instead of being at Pecos, was apparently a Tompiras town, either what has been erroneously called *Gran Quivira* or some village of that locality. The Braba of Coronado would fall in the vicinity of the present Cochiti, instead of at Taos, and Tusayan instead of being at the Moki Towns, would fall in its position 20 leagues (50 or 60 miles) northwest of the position of Cibola.

Mr. Harlan I. Smith presented a paper on the 'Hauptman Earthwork,' in Ogemaw County, Michigan. The discovery of this earthwork was first announced by him in SCIENCE, June 21, 1901 (p. 991). Personal observation in July enabled him to correct its location somewhat. It is on Section 33 or 34, or both, T. 22, N. (instead of 21), R. 1, E. It was found to lie in a lumbered pine area, and, unlike most such earthworks, far from any watercourse. It is covered by dense undergrowth and fallen timber. It is composed of a rounded embankment of earth, about 2 feet high and 12 feet wide, encircling an area about 197 by 177 feet; outside this is a ditch, 2 feet deep, 6 feet wide at the top, but narrowing towards the bottom. Signs of another embankment were seen outside the ditch, and within the enclosed area were several hummocks which may prove to be mounds or sim-

ilar works. There are three openings in the embankment. The antiquity of the work is indicated by the presence of large pine stumps on the embankment and in the ditch; the largest stump measured 13 feet 4 inches in circumference.

An effort is being made to have this ancient work enclosed in a state, county or township park. The land, now worth perhaps less than \$10 an acre, can easily be secured. If neglected, the road to be built on the line between sections 33 and 34 will probably destroy the work.

Dr. John R. Swanton reported some results of his investigations into the mythology and origin of the Haida Indians of northern British Columbia. The whole Haida people is divided into two clans, Raven and Eagle, each of which is strictly exogamic with descent in the female line, and has its own crests, its own names, its independent traditional centers of origin. Each is subdivided into a number of families. The Raven clan traces its origin from a single legendary ancestress, who is reputed to have emerged from the waters with the Haida island. Some families of that clan, however, trace their descent from other sources. The Eagle clan has much less traditional unity of origin, and there are certain indications in the tradition that this clan is of foreign origin or at least has received considerable admixture of foreign blood. One important fact that seems to point to the Raven clan as the indigenous element is the great preponderance of Ravens among the supernatural beings of the island.

R. S. WOODWORTH,
Secretary.

SECTION OF ASTRONOMY, PHYSICS AND CHEMISTRY.

The Section of Astronomy, Physics and Chemistry met at the Chemists' Club on February 3. Mr. G. B. Pegram addressed the Section on the subject of 'Experimental Methods of Studying Radio-Activity.' Mr. Pegram described the principal methods which have been used in the study of radio-active substances and also gave a brief summary of the more important results so far obtained.

The address was followed by a very interesting discussion of the subject.

F. L. TUFTS,
Secretary.

ZOOLOGICAL CLUB, UNIVERSITY OF CHICAGO.

At the meeting of October 23, 1901, the following paper was presented:

'The Origin and Development of the Wings of Coleoptera': W. L. TOWER.

The embryonic origin of the wings was studied in *Lepitinotharsa decemlineata*, where the hind wings were found to be derived from the rudiment of the metathoracic spiracle. The elytra are also probably derived from the remains of the mesothoracic spiracular disk, which are left in the segment after the anterior migration of the spiracle of the mesothorax.

In the larvæ of several species of beetles the wings were found to develop in one of three ways: (1) Directly beneath the cuticula—Carabidæ, Cerambycidæ, Buprestidæ and others; (2) in a shallow peripodal sac, which is broadly open against the cuticula—Scarabæidæ; (3) in a closed peripodal sac which is removed to a greater or less distance from the surface—Coccinellidæ, Chrysomelidæ.

In the wings there is a larval temporary tracheal system which develops from the cells of the hypotracheal membrane of the tracheal trunks. This system is functional in the late larva, prepupa and early pupa, but is destroyed during the pupal stage, probably by ferments in the hæmolymp and not by phagocytes.

The elytra and hind wings were found to have an essentially similar structure, both gross and microscopic, and are therefore homodynamous organs. The development of scales and glands, the development and finer structure of the cuticula, and the behavior of the hypoderm were followed in detail, and have given interesting results.

The conclusion reached is that the wings of beetles are homologous to those of other insects, but are specialized by reduction. They are not divergent organs specialized for a new function, as was stated by Krüger.

MEETING OF NOVEMBER 6, 1901.

'Spermatid Transformations in *Gryllus*

assimilis with Special Reference to the Nebenkern: W. J. BAUMGARTNER.

After the anaphase of the second spermatocyte division, the chromosomes separate and break up as has been described in other forms. But as the nucleus elongates to form the head of the spermatozoon, it forms a tube instead of a solid mass as described for other forms. The head has a darkly-staining outer wall of chromatin, and a hollow clear space probably filled with nuclear sap.

The remaining fibers, after they are cut by the division-plane, become fewer and thicker; their ends bend together and they form a 'striated' nebenkern, a condition not previously described. This striated nebenkern looks like an egg with dark drawn-out ends, and several (frequently five) dark cross striæ parallel with the long axis of the cell.

In a relatively short time the fibers break up, and soon the dark-staining substance appears as a round ball, which, with the immediately surrounding clear space, is enclosed by a surrounding membrane. In cross-section this appears as a dark circle, a ring of clear space and another dark ring.

As the axial filament grows out it passes over the surface of the bounding membrane, and not through the nebenkern. Soon after this the nebenkern elongates, loses the ring, and the dark ball passes back (away from the nucleus) along the tail, sometimes breaking up into several small drops. The substance is thus distributed over the tail and forms a covering for it.

A second body in the cytoplasm is smaller and always lies in the angle between the nucleus and the nebenkern. As the nebenkern passes backward and disappears, it moves up against the nuclear membrane, passes to the front end of the elongating head and forms the point. Its origin could not be determined, but from its destiny it corresponds to an acrosome.

C. M. CHILD,
Secretary.

THE TEXAS ACADEMY OF SCIENCE.

THE formal midwinter meeting of the Texas Academy of Science was held in the rooms

of the Business Men's Club, at Waco, on Thursday evening, December 26, and Friday morning, December 27, 1901.

The speaker at the evening session was Dr. Frederic W. Simonds, Professor of Geology in the State University. He was introduced by the president, Professor J. C. Nagle, of the Agricultural and Mechanical College of Texas.

The subject as announced was 'Petroleum.' The speaker opened with a brief statement concerning the oil development in the State of Texas—a comparison having been made with the fields in the North and in California. He then entered upon a discussion of the nature of petroleum, showing its position in the hydro-carbon compounds and commented at some length upon its physical properties. The theories of the origin of petroleum received special attention, references having been made to the early work of the late Dr. T. Sterry Hunt and the more recent work of the late Professor Orton as well as to the investigations of many other distinguished students. The evolution of the oil well from that which was hand drilled to the modern steam drilled well was discussed and the latest statistics of the oil industry both in the United States and in Texas announced. With the generous assistance of Dr. A. F. Sontagg thirty excellent illustrations of the present condition of the oil development in Texas, including several Beaumont gushers, were thrown upon the screen.

At the morning session the following papers were presented: 'The Petroleum of Jefferson County, Texas,' by Professor H. H. Harrington, of the Agricultural and Mechanical College of Texas. Of this oil he says: "It makes an excellent fuel oil; but this is not to my mind its most promising feature. The sulphur which it contains (about 2 per cent.) is larger than that found in any other known petroleum; and is a menace to it as a source of illuminating oil or kerosene. Unlike most other oils in the United States, it has asphalt for a base * * *. This, it seems to me, is the key to its usefulness. Distilled it furnishes a good quantity of kerosene fraction, but with a high boiling-point and leaves a residue of fine asphalt, not excelled perhaps by that of

Trinidad. A protective tariff on asphalt is all that is needed to increase the value of the Beamont residue.

* * * * *

The following is a detailed analysis of the oil: Sp. Gr.—.912—very heavy. Begins to distill at 70°C. and boil at 150°C.:

70°—150°C.—	3.337 %	comes	over.
150°—260°C.—	41.00	"	"
260°—300°C.—	19.00	"	"
300°—350°C.—	20.00	"	"
Above 350°C.—	16.67	"	"

"The first distillate below 150°C. is what is ordinarily known as the 'Benzine Fraction,' and as noted is 3.33% of the crude oil; it boils at 70°C. 150° to 260°C. is the illuminating oil fraction; 260° to 300°C. are the light lubricating oils; and 300° to 350°C., heavy lubricating oils, mixed with asphalt. The remaining 16½% is asphalt. As before mentioned, the amount of sulphur in the oil is the greatest obstacle in the way of refining it. When the illuminating fraction is refined, it requires the use of a much larger percentage of sulphuric acid, and the loss on refining from treatment with this acid is much greater * * than takes place with oils having a paraffine base and very little sulphur."

Professor Frederick W. Malley, of the Agricultural and Mechanical College, presented a paper on 'Factors of Progress in Insect Warfare,' in which he indicated the lines of effort and research among economic entomologists at the present time and made a comparison with similar work attempted twenty years ago. He grouped the warfare roughly into four great divisions: Insecticides, Cultural Methods, Parasites and Natural Enemies, and Climatic Conditions. The whole discussion was from the standpoint of *applied* entomology and a plea was made for elementary instruction along these lines in the public schools of the State.

Professor D. W. Spence, of the Agricultural and Mechanical College, discussed the 'Effects of Prolonged Exposure to X-rays on the Human Body,' showing their extraordinary effects, in some instances, in producing a disintegration and diseased condition of the skin. He himself had his hand in bandages covering

a 'burn' of some months duration and not yet healed.

'A Preliminary Report on the Austin Chalk Underlying Waco and the Adjacent Territory' is the title of a paper presented by Mr. J. K. Prather. The rocks of this formation within the area mentioned were described minutely and their position in the great Upper Cretaceous Series, pointed out. Reference was made to the early work of Dr. Ferdinand v. Roemer and a list of fifteen characteristic fossils given. Examples were also given of the vertebrate remains found in this formation and attention called to the fruitfulness of this field for investigation in that direction.

Professor T. U. Taylor, of the Engineering Department of the University of Texas, gave an account of the 'Big Springs of the Edwards Plateau'—the region bounded by the Colorado River, the International and Great Northern and the Southern Pacific railroads—showing their fluctuation in discharge and offering an explanation therefor.

Mr. John K. Strecker, Jr., made a 'Preliminary Report on Reptiles and Batrachians of McLennan County.' In this paper are recorded many interesting and valuable observations extending over a period of years concerning the life and habits of these little-known species of animals.

The closing paper, on 'Dr. Ferdinand von Roemer, Father of the Geology of Texas: His Life and Work,' was presented by Dr. F. W. Simonds of the State University. Dr. Roemer was born at Hildesheim, Hanover, in 1818, and died in Breslau in 1891. In 1845 he visited Texas and wrote the first account of the physical geography and geology of the State. His monograph upon the Cretaceous of Texas—'Die Kreidebildungen von Texas'—appeared just fifty years ago.

FREDERIC W. SIMONDS,
Secretary.

UNIVERSITY OF TEXAS.

THE ELISHA MITCHELL SCIENTIFIC SOCIETY.

THE 139th meeting of the Society was held on February 11, at the University of North Carolina. The following papers were read:

'The Pressure of Light': J. E. LATTI.

'A Nineteenth Century Geometry': ARCHIBALD HENDERSON.

'The Absolute Properties of Molecules': J. E. MILLS.

CHAS. BASKERVILLE,
Secretary.

DISCUSSION AND CORRESPONDENCE.

A GEOGRAPHICAL SOCIETY OF NORTH AMERICA.

If a general American Geographical Society, equivalent in rank to the Geological Society of America, could be developed by following Professor Russell's plan (*SCIENCE*, Jan. 31), there is no question that great good would come from it; but I do not believe that his plan would lead to the desired end. After stating some of its difficulties, I will present an alternative.

Centralization that weakens local activity is of doubtful value. It is perfectly true that the publications of the existing geographical societies are not always of a high order, but they are the best that the local societies can produce; they serve a very useful purpose in providing opportunity for beginners to publish their early efforts; they are the necessary steps toward something better. Furthermore, several of the local journals, being largely concerned with personal narratives of outings and excursions, are of greater interest to their local readers than any general and scientific geographical journal could be. It would more likely kill than kindle geographical interest to replace such local journals by a high-grade scientific central journal. The sufficient reason for this is that the great majority of the local readers are not geographers. This leads to the next difficulty.

No equivalent of the Geological Society of America could be made by uniting the existing geographical societies of the country. Candidates for membership in the Geological Society are carefully scrutinized. They must have had good scientific training and they must have actually accomplished something in the way of geological work, either in the field or in the lecture room, before they are recommended by the Council of the Society for election. The standard of training and accomplishment is not by any means discouragingly high, but it is set at such a level

that membership in the Society really means something regarding a member's geological attainments. There is not a single geographical society in the country in which there is any corresponding requirement for membership. Any reputable person who is willing to pay the necessary fee may be elected. The societies are all glad to add his name to the count of members, and his fee to the treasury. In some of the societies it may perhaps be assumed that a considerable number of members feel a certain interest in the general subject of geography, an interest that is passive rather than active; but in nearly all the societies there is a large number of members whose interest is excited chiefly by the meetings, outings and excursions that the societies promote. Even in this respect, only one society, the Mazamas, exacts any performance as a measure of interest, and the performance that it demands—the ascent of a mountain some thousands of feet in height—is no more a test of geographical training and accomplishment than is the test that might be exacted by a yachting or a hunting club. By all means let the meetings, outings, excursions and mountain ascents continue; let the societies that conduct them flourish; let the publication committees secure the best narratives that the members can produce; but do not let us imagine that the members of these societies are all geographers.

Turning now to constructive suggestions: Let the proposed society be satisfied with the northern part of the New World for its field; let its name be the Geographical Society of North America, in order not to imply that America is all north of the Isthmus, and not to infringe upon the name already occupied by the society long established in New York city. Let the various geographical societies of North America be invited to send delegates, one for every five hundred members, to Pittsburgh next summer at the time of the meeting of the American Association; and let these delegates invite fifty or a hundred persons of real geographical attainments to become 'original members' of the new society. Let those who accept this invitation meet at Washington in Convocation Week, 1903, and

proceed with the more formal organization of the society. Let them at the beginning imitate the Geological Society of America and other societies of similar grade by requiring that all approved candidates for membership shall be well-trained and productive students of geography, or of some phase of that broad subject. Let the membership fee be set at such a figure that the society may be self-supporting, able to conduct its own publications. Let essays for publication be carefully scrutinized by the council, and let it be recognized that a merely personal narrative of travel no more constitutes a geographical essay because it mentions a harbor or a hill than it constitutes a botanical essay because it mentions a swamp or a forest. Let it be understood that all communications must present an objective account of some element of inorganic environment, or of some organisms in their environment, or an account of the relationship of the two. Let such treatment of the subject be required as shall indicate that the contributor has had sound training in preparation for his work of observation, description, generalization, inference and so on; let the work of apprentices and amateurs be referred to local societies for further development before acceptance in the general society. In a word, let the beginning be marked by careful attention to quality rather than to quantity. Let growth be sound even if slow. Let membership be accessible not to the mere traveller, the lover of outdoor nature or the reader, but only to the investigator, whether he stays at home or roams abroad. Let a standard be set that will demand training and accomplishment on the part of those who reach it, in contrast to the dilettanteism that suffices for membership in all the present geographical societies.

The manifest difficulty in the way of establishing and maintaining such a society is the great diversity of interests among those who should be considered as trained geographers. The subject is a natural unit for schools in its elementary reaches; but the paths of its maturer scholars are divergent. The geodesist, the meteorologist, the hydrographer, the geomorphologist, the ethnologist, the economist, might perhaps repel rather than attract

one another, so unlike are their lines of thought and their methods of work. Their association with other sciences might be stronger than with geography; the geodesist with astronomy, the meteorologist with physics, the hydrographer with engineering, the geomorphologist with geology, the ethnologist and the economist with ethnology and economics. But diversity of specialization characterizes all learned societies. In the Geological Society, the paleontologist does not always listen attentively to the glacialist, nor the petrographer to the physiographer, and all these sometimes fail to follow the local stratigrapher. Diversity of interest does not, therefore, prohibit the effective union of experts; and such a union along geographical lines would be well worth trying. I hope that others who may be interested in any aspect of this scheme will send a statement of their opinions either to SCIENCE or to Professor Russell direct. If a considerable measure of interest is thus indicated, let us beg Professor Russell to proceed in the direction indicated by the majority of his correspondents and take the necessary steps for a preliminary meeting at Pittsburgh, so that an effective organization may be made at Washington a year hence.

W. M. DAVIS.

HARVARD UNIVERSITY,

Feb. 6, 1902.

THE RISE OF ALKALI SALTS TO THE SOIL SURFACE.

THE explanation given by Means (SCIENCE, of January 3) of the accumulation of soluble salts on the surface of soils by the differential action of capillary and gravitational pores, seems also to offer a correct explanation of the length of time and large amount of water required for an effectual leaching-out of alkali salts by flooding. The fact shown in the investigations of the California Station, that in coarsely sandy lands the maximum of the salts is found not *at*, but at some distance *below*, the surface, offers a correlative corroboration.

But this explanation certainly does not apply to the case referred to by Means, viz.,

the Fresno region, where the ground water originally stood forty feet below the surface, while now it is at a few feet, and sometimes *at* and above the soil surface. It is historically certain that the rise of the ground water came about there, as at many other points, not from direct over-irrigation, but by the enormous leakage of water from ditches with porous, sandy bottoms and banks. From these I have frequently traced the water slope sideways until the auger reached a depth of ten or more feet; and the gradual rise of the water level in neighboring wells, whose sides remained dry save within reach of the capillary rise of the water, proved plainly that the water was ascending from the original level by hydrostatic adjustment, not by penetration from above; where as a matter of fact irrigation often had not even begun.

The extraordinary accumulation of alkali salts at the surface that has occurred in the Fresno and some other regions of the San Joaquin valley, are clearly due originally to the leaching upward of the entire mass of alkali in the sub-strata. The investigations of the California Station have shown that in the arid region few uplands normally contain less than from 2,000 to 2,500 pounds of soluble salts per acre in four feet depth; and much more has been found in the silty sub-strata of the Salton basin in southern California, even to 22 feet depth. When all the salts thus contained in 40 feet of material are leached to the surface in addition to the accumulation already existing there, the overwhelming invasion we find where these leaky ditches exist cannot surprise us.

E. W. HILGARD.

REPRINTS OF SCIENTIFIC PAPERS.

TO THE EDITOR OF SCIENCE: Will you allow me space for a word concerning a point of professional courtesy? It arose in connection with a personal experience. The incident is wholly trivial, namely, the failure of the publishers, or editor, of the *New York Teachers' Monographs* to furnish the reprints promised of an article which appeared in the October number.

It is the custom of writers on technical science to exchange copies of their published

monographs. The brochure is sent frequently with an explicit—and always with at least the implied—request for a similar courtesy in return, upon the appearance of anything of the receiver's own in print. The relation thus becomes one of simple duty, which may not be considered or disregarded at will. To each of his correspondents one owes a debt which is discharged only when copies of his own published work have been sent in exchange.

But the matter goes deeper. The contributor to technical scientific periodicals is rarely, if ever, paid for his writings. These publications, in many instances founded and supported by associations of scientific students, are not primarily commercial enterprises, but vehicles of communication among scholars having common interests and aims. They are means by which is made possible the publication of monographic literature, the printing of which, in the majority of cases, would be too heavy a burden for the individual writer. It is part of the meaning of these technical journals' existence that the process of thus communicating scientific thought shall be facilitated as greatly as possible.

This function has been very widely and generously recognized by the publishers of our reputable scientific periodicals in America. It is expressed in the custom of presenting to each substantial contributor a larger or smaller number of separately bound reprints of his article for distribution. Upon the free exchange of monographs which thus becomes possible the scholar depends in no small degree for the equipment of his working library; for this literature, which represents the points of immediate growth in special lines of thought, finds its way only slowly and incompletely into permanent print. It is, therefore, a matter of serious and general importance that these relations between contributor and publisher should be cordially maintained, and the flagrant infraction of them should not remain unknown.

ROBERT MACDOUGALL.

NEW YORK UNIVERSITY.

THE SACRAMENTO FORESTS OF NEW MEXICO.

TO THE EDITOR OF SCIENCE: In a communication to your paper dated November 8, 1901,

upon the Sacramento forests of New Mexico, the typist made me say that trees 25 feet in diameter were quite common. It was my intention to say 'trees from two to five feet,' etc.

ROBERT T. HILL.

SHORTER ARTICLES.

NOTE ON THE EMBRYO OF NYMPHÆA.

ALTHOUGH the mature embryo of *Nymphaea* Sm. has been frequently figured and described during the last half century as typically dicotyledonous, the interesting paper of Mr. Lyon on *Nelumbo* (*Minnesota Bot. Studies*, Ser. II., Part 5, p. 645-55, Pl. 48-50) made a further investigation desirable. Having already considerable material in hand with a view to a careful study of the genus (which is approaching completion), I have examined the mature and germinating embryos of several species, and studied the development in three members of widely differing sub-genera, viz., *N. odorata* Ait., *N. cœrulea* Sav., and *N. Lotus* L. The course of events seems identical in all of these. A suspensor of three to five cells in linear series is formed, upon which a 'spherical embryo' of some hundreds of cells develops as described by Mr. Lyon for *Nelumbo*. This is embedded in a soft mass of endosperm at the micropylar end of the ovule; three fourths of the length of the seed is occupied with perisperm. The spherical embryo, however, unlike that of *Nelumbo*, gives rise to two opposite and symmetrical outgrowths near its lower end. These become the two equal cotyledons. The intervening apical portion of the sphere becomes the plumule, with the rudiments of two unequally developed leaves. The basal portion of the sphere becomes the radicle. At maturity the embryo exhibits two thick, concave, hemispherical cotyledons, applied against each other all round by their edges; while the central concavity is occupied by the plumule. The endosperm is now reduced to a single layer of cells and a line of thin crushed walls between these and the cotyledons. A large amount of oil is stored in the embryo and endosperm, with a little starch and some proteid. The perisperm is densely packed with starch.

It seems necessary, in view of these facts, to modify Mr. Lyon's classification of Nymphaeaceæ among the Helobie. If we are to consider the development of *Nelumbo* as strictly monocotyledonous, then it must be separated as a distinct order, as some writers have already placed it. However, we would prefer to interpret the peculiar embryogeny of *Nelumbo* as a modified form of dicotyledony. The symmetry of the early embryonic vascular system supports this view; and the decurrence of the cotyledons around the radicle is paralleled in *Tropæolum*. Further, a complete fusion of the cotyledons along one edge has been noted in *Nuphar lutea* by Hegelmaier, as quoted by Henslow, and a much more pronounced 'pseudo-mocotyledony' is seen in *Trapa natans*, *Ranunculus ficaria*, etc. A number of striking examples and suggestions in this connection are followed up by Henslow in his paper on 'A Theoretical Origin of Endogens from Exogens' in *Journ. Linn. Soc.*, London, 29; 485-528, and in his 'Origin of Plant Structures,' pp. 136-79. Mr. Lyon's observations have numerous interesting bearings on Henslow's theory.

HENRY S. CONARD.

UNIVERSITY OF PENNSYLVANIA.

WILLIAM LE ROY BROUN.

DR. WILLIAM LE ROY BROUN (M.A., LL.D.), president of the Alabama Polytechnic Institute, died suddenly on January 23. He was one of the foremost educators of the country, and, from time to time, had been prominently associated with the leading educational institutions in the South.

In recent years he was conspicuous for the great work he accomplished as a pioneer in the field of technical education. Since 1884 he had been president of the Alabama Polytechnic Institute, and under his wise and progressive guidance this institution had been developed into a highly successful and widely known college of applied science. His death will be an immense loss to the cause of Southern, indeed of national, education.

He was a native of Virginia, born in Lou-

don county, 1827, and a distinguished Master of Arts of the University of Virginia, where he was a fellow student and an intimate friend of a group of prominent Southerners, including Dr. J. A. Broadus, William Wirt Henry, Professor Frank Smith of the University of Virginia, and others. Dr. Broun was graduated in 1850. He was elected to the professorship in the college of Mississippi in 1852 and stayed there two years, then to the chair of mathematics in the University of Georgia.

In 1856 Dr. Broun founded Bloomfield Academy near the University of Virginia, which he conducted successfully until the outbreak of the war between the States. In 1859 he married Miss Sallie J. Fleming, daughter of a prominent Virginia family. She has been dead a number of years.

Dr. Broun enlisted in the Confederate army as a lieutenant of artillery. He rose to the rank of lieutenant colonel in the Ordnance Department, and on account of his high mathematical and scientific attainments was made Commandant of the Arsenal in Richmond. He, perhaps, gave the last order in that city directing the blowing up of the Confederate Arsenal.

After the close of the war Dr. Broun was elected to the chair of physics in the University of Georgia, and in 1872 he became president of the Agricultural and Mechanical College of that University. From 1875 to 1882 he was professor of mathematics in Vanderbilt University, Nashville, Tenn., and in 1882 was elected president of the Agricultural and Mechanical College of Alabama, now known as the Polytechnic Institute. He remained in Auburn one year and went to the University of Texas as professor of mathematics, where he was made chairman of the faculty. In 1884 Dr. Broun was reelected president of the Alabama Polytechnic Institute at Auburn. He had served continuously as president of the institution since 1884.

Dr. Broun was a man of varied and accurate scholarship and of rare wisdom in the control of a great institution. Broadly founded in the principles of educational science, he always planned wisely, and was the first to

establish and to develop several new branches of scientific education in the South, such as manual training, electrical engineering and biology.

SCIENTIFIC NOTES AND NEWS.

PLANS have been formed for the erection of a memorial tower and meteorological station in honor of Dr. J. P. Joule, F.R.S., at Sale, Cheshire, where he lived from 1872 to the time of his death in 1880.

DR. ED. SUSS, professor of geology at Vienna, has been made an honorary member of the Academy of Sciences at St. Petersburg.

M. ALFRED PICARD has been elected a member of the Paris Academy of Sciences.

THE Prince of Wales has been admitted as a fellow of the Royal Society.

DR. J. R. GREEN, the well-known botanist, has been elected a fellow of Downing College, Cambridge.

DR. WILHELM HITTORF, professor of physics at Münster, celebrated the fiftieth anniversary of his professorship on January 12. He was on the occasion made an honorary doctor of engineering of the Technical School at Charlottenburg.

THE twenty-fifth anniversary of the professorship of Augusto Tamburini, professor of psychiatry at the University of Modena, was celebrated on December 25, by the presentation of a medal and other ceremonies.

PROFESSOR ERNST VON LEYDEN, the eminent pathologist at the University of Berlin, will celebrate his eightieth birthday on April 20.

DR. KARL PIESKE, engineer in the hydrological bureau in Berlin, has been given the title of 'professor.'

DR. C. H. HERTY, of the University of Georgia, will shortly resign to accept a position in the bureau of forestry.

PROFESSOR A. C. HADDON, of Cambridge University, has been appointed advising curator of the Horniman Museum at Forest Hill, now under the charge of the London County Council.

DR. ADOLF MEYER, the new head of the Pathological Institute of the New York State

Hospitals, has recommended the reappointment of Dr. P. H. Levine as head of the chemical department and of Dr. Brooks as associate in bacteriology.

It is stated in *Nature* that Professor E. Millosevich has succeeded Professor P. Tacchini as director of the Astronomical Observatory of the Roman College and of the astronomical museum connected with it. Professor Tacchini has resigned his office of administrator in the Reale Accademia dei Lincei, and Professor Volterra has been appointed as his successor. Professor P. Villari having been unable to accept the office as president, an election to the presidential chair will be made early in June.

MR. W. S. BRUCE, the leader of the Scottish Antarctic expedition, has secured the services of Captain Thomas Robertson, who for the last twenty years has sailed regularly every spring to the Arctic regions and once to the Antarctic.

SIR W. E. GARSTIN has started for the Sudan to examine the upper reaches of the Blue Nile and the Atbara. He expects also to visit Lake Tzana, in Abyssinia.

M. HUGUES LE ROUX, the French explorer and civil engineer, is in the United States for the purpose of delivering lectures. His first lecture in New York will be given on March 18, before the Geographical Society.

THE Royal College of Physicians of London has appointed Dr. D. Ferrier, F.R.S., to be Harveian orator, Dr. Cullingworth to be Bradshaw lecturer, and Dr. H. T. Bulstrode to be Milroy lecturer.

PROFESSOR WILLIS L. MOORE, chief of the Weather Bureau, lectured at Wesleyan University on February 18, his subject being 'Storm Phenomena.'

THE British Association of Technical Institutions held its annual meeting on January 31, when Lord Avebury was elected president for the ensuing year, and delivered an address, in which he dwelt on the neglect of modern languages and science in the system of education.

DR. H. A. GILES, professor of Chinese at the

University of Cambridge, will give a series of lectures at Columbia University, beginning on March 5. They inaugurate the new department of Chinese, established at the University by General Charpentier with an endowment of over \$200,000.

THE death is announced of Dr. Robert Adamson, professor of logic and rhetoric at Glasgow University and the author of numerous contributions to philosophy, including works on 'Roger Bacon' and on the 'Philosophy of Science in the Middle Ages.'

DR. C. M. GULDBERG, professor of mathematics at Christiania, died on January 14, aged sixty-five years.

MME. CLÉMENCE ROYER has died at Paris at the age of seventy-two years. She first became known as the translator of Darwin's 'Origin of Species,' to which she prefixed an important introduction. She was the author of numerous works and articles on philosophy, ethics and natural science.

DR. THOMAS NEALL PENROSE, medical director, United States Navy, retired, died on February 13, aged sixty-seven years.

CAPTAIN CHEYNE, R. N., who was present as an officer with the three Arctic expeditions that went in search of Sir John Franklin, has died in Halifax, N. S., on February 9, in his seventy-fifth year.

MR. ALFRED WILLIAM BENNETT, a well-known English botanist, died on January 23. According to a notice in the London *Times* he was born at Clapham, in 1833, and was educated at University College, London. The first of his more important contributions to scientific literature was editing, with Mr. Thistelton Dyer, the English edition of Sachs's 'Text-book of Botany,' 1875; in 1889 he published, in conjunction with Mr. G. Murray, a 'Handbook of Cryptogamic Botany'; his most popular work was the 'Flora of the Alps,' which appeared about seven years ago. He was a fellow of the Linnean Society and of the Royal Microscopical Society, the *Journal* of which society was edited by him.

IN a recent number of SCIENCE it was stated that the collection of Aino objects made by

Professor Bashford Deau in Japan was 'purchased' for the American Museum of Natural History. It should have been said that the museum reimbursed Professor Deau for the sum which he advanced in making the purchases, and that he contributes as his share in the collection his field expenses and services.

A BILL appropriating \$50,000 to enable Professor John B. Smith of Rutgers College to make experiments for the eradication of mosquitoes has been reported favorably in the New Jersey legislature.

THE position of assistant in pathology with a salary of \$840 and of assistant in physiology at a salary of \$1,000 in the Bureau of Plant Industry, Department of Agriculture, will be filled by civil service examination on February 26.

A TELEGRAM has been received at the Harvard College Observatory from Professor W. W. Campbell at Lick Observatory stating that Professor Perrine finds that the remarkable coronal disturbance in the Sumatra eclipse was immediately above the prominent and only sunspot visible during eleven days.

At the meeting of the Connecticut Academy of Sciences on February 12, Professor A. E. Verrill exhibited several remarkable photographs in natural colors, made direct from nature by a new autochromatic process, invented by Mr. A. Hyatt Verrill of New Haven. One of these photographs was a Bermuda landscape in which the beautiful tints of the water, etc., were well brought out. Three other plates were copies of water-color drawings of brilliantly colored Bermuda fishes. The photographic reproduction of these showed accurately all the delicate shades of green, blue, pink, purple, yellow and orange. The intense red colors appear to be the most difficult to render by this process at present, but no doubt this will soon be remedied by further experiments now in progress.

THE third annual Charter Day meeting of the Sigma Xi Society at the University of Nebraska was held on February 14. Professor Samuel Calvin, of the University of Iowa and director of the Iowa Geological Survey, was the guest of the Society at the annual banquet

and delivered the annual address on 'Records of the Great Ice Age in the Upper Mississippi Valley.' The lecture, which was illustrated by lantern slides, presented the important discoveries of the speaker on the precise limits and characteristics of the various ice sheets which have been demonstrated as present during the ice age in Iowa and the adjacent States.

Nature reports that at the recent annual general meeting of the Royal Scottish Arboricultural Society, Lord Mansfield said he was authorized to state that it was Mr. Hanbury's intention to appoint a departmental committee to inquire into and report upon the present position and future prospects of forestry and the planting and management of woodlands in the United Kingdom, and to consider whether any further measures might be taken with advantage, either by the provision of further educational facilities or otherwise, for their promotion and encouragement. Mr. Munro-Ferguson, M.P., has been invited and has consented to act as chairman of the committee.

THE London *Times* states that the recent acquisitions to the zoological department of the British Museum of Natural History include the interesting collections made by Sir Harry Johnston in Uganda. The great interest attaching to the discovery of the now celebrated okapi has overshadowed the rest of the collection forwarded to the museum by Sir Harry. It contained, nevertheless, many specimens of considerable scientific interest. Mr. Oldfield Thomas, the mammalogist of the department, has been unable to separate specifically the five-horned giraffe obtained near Mount Elgon from the ordinary North African form. The specimen has unusually developed horns, and on that account is of special interest. The collection of birds, though small in number, was particularly welcome, since it was made up chiefly of big birds, such as vultures, storks and herons. Travelers, as a rule, will not take the trouble to skin and bring home birds of this description. The fishes also proved to be very valuable, as they were the first specimens received from Lakes Victoria and Baringo. They included two specimens new to science, described by Mr. Boulenger.

UNIVERSITY AND EDUCATIONAL NEWS.

It will be remembered that several citizens offered to give the Johns Hopkins University a new site in the northern suburbs, consisting of 176 acres, on condition that a million dollars be raised for the erection of buildings. It is understood that the condition has been withdrawn and that the land will be presented to the University at the celebration on Feb. 22.

COOPER UNION, New York City, has received an anonymous gift of \$250,000 to be added to the endowment.

The sum of £5,000 has been bequeathed to the Aberdeen University, to be applied to the purposes of the University at the discretion of the senate, by the late Surgeon-General Robert Harvey.

IMPROVEMENTS have been completed in the Rotch Building at Harvard University during the last few months which add largely to its facilities for the study of mining engineering. A gift from J. J. Storow, '85, has made possible the entire refitting of the laboratory of metallurgical chemistry. A new laboratory, to be known as the 'Simpkins Assay Laboratory,' has been fitted up in a large room in the addition on the east side, and another, the 'Simpkins Metallurgical Laboratory,' which is now being equipped, will occupy the remainder of this section. A large room in the northwest corner of the building is to be used for the study of steel; and a complete set of machinery is being installed for this purpose. The laboratory of metallography has been moved to the old Infirmary Building.

A FIRE in the anatomical laboratory of the University of Minnesota on January 25, caused a loss of \$10,000. The students saved the valuable libraries of Professors Erdman and Reed, but some collections were destroyed.

PROFESSOR VICTOR VAUGHAN, dean of the Medical College of the University of Michigan, is chairman of a committee composed of representatives from the leading schools of the United States, whose object is to make it possible for a system of credits to be standardized in all these schools, so that a student in any one of them may transfer to any other without loss of standing. The colleges represented

on the committee are Michigan, Harvard, Pennsylvania, Johns Hopkins, Columbia and Western Reserve.

It is officially announced that law students in Germany need no longer hold a certificate from a classical gymnasium, but may be graduates of the Realgymnasien or higher Realschulen.

THE Dowager-Empress of China has issued an edict which, after pointing out that many Chinese have studied abroad formerly, but that no Manchus have done so, orders the Manchu clan at Court and the generals of eight banners to nominate Manchus of between 15 and 25 to go abroad to study foreign branches of knowledge.

LORD CURZON, the viceroy of India, has appointed a commission to visit the university centers and colleges of India to inquire into their prospects, report on their working, and recommend measures for the improvement of the teaching and the standard of learning. The commission is composed as follows: Mr. T. Raleigh, president; Syad Hossain Bilgrami Nawab; Mr. J. P. Hewett, Secretary to the Home Department; Mr. A. Pedler, Director of Public Instruction in Bengal; Professor A. Bourne, Principal of Madras College; and the Rev. Mr. Mackichan, Principal of Wilson College, Bombay.

DR. R. W. HALL, at present instructor in biology at Yale University and at the Marine Biological Laboratory at Wood's Holl, has been engaged as instructor in biology at Lehigh University. Mr. E. A. Regestein (Massachusetts Institute, '99) has been appointed instructor in electrical engineering at Lehigh University.

PROFESSOR VON KRAFFT-EBBING is about to retire from the chair of psychiatry at Vienna and will be succeeded by Professor W. von Jauregg.

MR. W. E. JOHNSON, of King's College, Cambridge, has been appointed Sidgwick lecturer in moral science.

DR. PIERRE JANET has been elected to the chair of psychology in the Collège de France vacant by the resignation of Professor Th. Ribot.

This is not the time, although it is a birthday, to review the infancy of this University. Reminiscences of the cradle and the nursery are profoundly interesting to a very small number of the near and dear, but according to a formula, which may be stated with mathematical precision, the interest varies inversely as the square of the distance.

It is meet and right and our bounden duty to commemorate the munificence of the founder, who in his grove at Clifton, and at his residence in town, spent the close of his life in perfecting a plan by which his fortune might be made to benefit humanity. Two noble purposes, the education of youth and the relief of suffering,—the Johns Hopkins University and the Johns Hopkins Hospital, became the objects of his thought and bounty. It would be pleasant to dwell upon the personalities of his early advisers,—three of whom may now witness our fervent congratulations. We might journey with them to Cambridge, New Haven, Ithaca, Ann Arbor, and Charlottesville, as they engaged in enquiries respecting the nature and offices of those leading universities, an example of

* By Daniel C. Gilman, President of the Johns Hopkins University from 1875 to 1901, on the occasion of the celebration of the twenty-fifth anniversary of the founding of the university.

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

original research, praiseworthy and beneficial. We might sit with them in a little room on North Charles Street, and listen to Presidents Eliot, Angell, and White as they were subjected to 'interviews,' recorded by the swift strokes of the stenographic pen, and now preserved in our archives. We might wonder by what process the Trustees selected a president, and be willing to learn what he said to them in his earliest conversation. It would gratify some curiosity to review the correspondence carried on with those who afterward became members of the faculty,—and with those who did not. It would be an extraordinary pleasure to the speaker on this occasion, to awaken the memories of those early days of unbounded enthusiasm and unfettered ideality, well described in a periodical by one who was here at the outset,—days which surprised and delighted intelligent observers.

These temptations must be avoided. The occasion is too important, the audience too varied, the visitors too many and too distinguished, to warrant the employment of this brief hour in personal reminiscences and local congratulations. We are rather bound to consider some of the grave problems of education which have engaged, during a quarter of a century, the study of able and learned men, and have led to the development, in this country, of the idea of the University. This period has seen marvellous improvements in higher education, and although, in the history of intellectual development, the nineteenth century may not be as significant as the thirteenth, when modern universities came into being at Bologna, Paris, and Oxford, yet we have lived at a time when forces have been set to work of the highest significance. Libraries, seminaries and laboratories have been enlarged and established in every part of the land.

Let us go back to the year 1876, that

year of jubilee, when the centennial celebration in Philadelphia brought together, in open concord, states and peoples separated by dissension and war. Representatives from every part of the land assembled, in the City of Brotherly Love, to commemorate the growth of a century. The triumph of liberal and industrial arts, the progress of architecture, sculpture, and painting, were interpreted by the music of our Sidney Lanier. The year was certainly propitious. So was the place. Maryland was a central state, and Baltimore a midway station between the North and the South. The people had been divided by the war, but there were no battle fields in our neighborhood to keep in mind the strife of brethren. The State of Maryland had been devoted to the idea of higher education ever since an enthusiast in the earliest colonial days projected the establishment of a university on an island in the Susquehanna. Liberal charters had been granted to colleges, of which St. John's, the successor of the first free school, must have honorable mention, a college likely to be increasingly useful during the twentieth century. The University of Maryland, with scanty resources, encouraged professional training in law, medicine, and the liberal arts (nominally also, in theology), but its efforts were restricted by the lack of funds. Nathan R. Smith, David Hoffman and other men of eminence were in the faculty. The Catholic Church had established within the borders of the state a large number of important schools of learning. One of them, St. Mary's College, under the cultivated fathers of St. Sulpice, had been the training place of some of the original promoters of the Johns Hopkins University. Yet there was nothing within the region between Philadelphia and Charlottesville, between the Chesapeake and the Ohio, which embodied, in 1876, the idea of a true university. Thus it appears that

the time, the place and the circumstances, were favorable to an endowment which seemed to be extraordinarily large, for the munificence of Rockefeller, Stanford and Carnegie could not be foreseen.

The founder made no effort to unfold a plan. He simply used one word,—UNIVERSITY,—and he left it to his successors to declare its meaning in the light of the past, in the hope of the future. There is no indication that he was interested in one branch of knowledge more than in another. He had no educational ‘fad.’ There is no evidence that he had read the writings of Cardinal Newman or of Mark Pattison, and none that the great parliamentary reports had come under his eye. He was a large minded man, who knew that the success of the foundation would depend upon the wisdom of those to whom its development was entrusted; and the Trustees were large minded men who knew that their efforts must be guided by the learning, the experience, and the devotion of the Faculty. There was a natural desire, in this locality, that the principal positions should be filled by men with whom the community was acquainted, but the Trustees were not governed by an aspiration so provincial. They sought the best men that could be found, without regard to the places where they were born, or the colleges where they had been educated. So, on Washington’s birthday, in 1876, after words of benediction from the President of Harvard University, our early counsellor and our constant friend, the plans of this University were publicly announced in the President’s inaugural speech.

As I cast my thoughts backward, memories of the good and great who have been members of our society rise vividly before us,—benefactors who have aided us by generous gifts, in emergencies and in prosperity; faithful guardians of the trust; illustrious teachers; and brilliant scholars who

have proceeded to posts of usefulness and honor, now and then in Japan, in India, in Canada, but most of them in our own land, from Harvard to the Golden Gate.

I must not linger, but lead you on to broader themes. May I venture to assume that we are an assembly of idealists. As such I speak; as such you listen. We are also practical men. As such, we apply ourselves to useful purposes, and to our actions we apply the test of common sense. Are our aims high enough? are they too high? are our methods justified by experience? are they approved by the judgment of our peers? can we see any results from the labors of five and twenty years? can we justify a vigorous appeal for enlargement? These and kindred questions press themselves for consideration on this memorial day. But in trying to answer them, let us never lose sight of the ideal,—let us care infinitely more for the future than we do for the past. Let us compare our work with what is done elsewhere and with what might be done in Baltimore. In place of pride and satisfaction, or of regret that our plans have been impeded, let us rejoice that the prospects are so encouraging, that the opportunities of yesterday will be surpassed to-morrow.

If it be true that ‘the uses of Adversity’ are sweet,—Adversity that ‘wears yet a precious jewel in his head,’ let us look forward to leaving our restricted site for a permanent home where our academic life will be ‘exempt from public haunt,’ where we shall ‘find tongues in trees, books in the running brooks, sermons in stones, and good in every thing.’ In faith and hope and gratitude, I have a vision of Homewood, where one person and another will build the structures of which we stand in so much need,—where scholarship will have its quiet retreat, where experimental science will be removed from the jar of the city street, where health and vigor will be

promoted by athletic sports in the groves of Aedemus. The promised land which Moses sees from Pisgah, our Joshua will possess.

Some curious parallels, familiar to the readers of history, may here be brought to mind. Thrice, in three centuries, great universities have arisen with their healing influence at the close of long wars. In familiar language, Motley tells us how the university of Leyden was established by the Dutch Republic, after the fearful siege which that brave city had endured. On the 5th of February, 1575, three hundred years before our natal day, the city of Leyden crowned itself with flowers, and 'with harmless pedantry, interposed between the acts of the longest and dreariest tragedy of modern times,' celebrated the new foundation. Allegorical figures moving in procession escorted the orator of the day, the newly appointed professors and other dignitaries, to the cloister of Saint Barbara where with speech and banquet they celebrated the day. Ever since, Leyden has been a noble seat of learning, and many of our own countrymen in early days resorted to it. The university of Berlin was established after the humiliation of Prussia by the Napoleonic wars. William von Humboldt has many titles to fame,—but none of his laurels are so fresh as the wreaths which crown his brow as the founder of that great university to which so many of the foremost scholars of Europe have been called, from F. A. Wolf to Van't Hoff. Within the memory of most of us, the university of Strasburg sprang into life at the close of the Franco-Prussian war. The German Emperor could see no better way of giving peace and prosperity to the captured province, than by making it the seat of a great university.

At the close of our civil war came the opportunity of Baltimore. It led to an extraordinary and undesigned fulfilment of an

aspiration of George Washington. As his exact language is not often quoted, I venture to give it here. In his last will and testament, after expressing his ardent desire that local attachments and State prejudices should disappear, he uses the following words.

"Looking anxiously forward to the accomplishment of so desirable an object as this is (in my estimation), my mind has not been able to contemplate any plan more likely to effect the measure, than the establishment of a University in a central part of the United States, to which the youths of fortune and talents from all parts thereof may be sent for the completion of their education, in all the branches of polite literature, in arts and sciences, in acquiring knowledge in the principles of politics and good government, and, as a matter of infinite importance in my judgment, by associating with each other, and forming friendships in juvenile years, be enabled to free themselves in a proper degree from those local prejudices and habitual jealousies which have just been mentioned, and which, when carried to excess, are never-failing sources of disquietude to the public mind, and pregnant of mischievous consequences to this country."

You will please to notice that he did not speak of a university in Washington, but of a university 'in the central part of the United States.' What is now the central part of the United States? Is it Chicago or is it Baltimore?

Let me now proceed to indicate the conditions which existed in this country when our work was projected. You will see that extraordinary advances have been made. The munificent endowments of Mr. John D. Rockefeller and of Mr. and Mrs. Leland Stanford,—the splendid generosity of the State legislatures in Michigan, Wisconsin, Minnesota, California, and other Western States, the enlarged resources of Harvard, Yale, Columbia, Princeton, Pennsylvania and other well established universities, and now the unique and unsurpassed generosity of Mr. Carnegie have entirely changed the aspects of liberal education and of scientific investigation.

As religion, the relation of finite man to the Infinite, is the most important of all human concerns, I begin by a brief reference to the attitude of universities toward Faith and Knowledge. The earliest universities of Europe were either founded by the Church or by the State. Whatever their origin, they were under the control, to a large extent, of ecclesiastical authorities. These traditions came to our country, and the original colleges were founded by learned and Godly men, most of them, if not all, the ministers of the gospel. Later, came the State universities and later still, the private foundations like that in which we are concerned. Gradually, among the Protestants, laymen have come to hold the chief positions of authority formerly held by the clergy. The official control, however, is less interesting at this moment than the attitude of universities toward the advancement of knowledge. To-day, happily, apprehensions are not felt, to any great extent, respecting the advancement of science. It is more and more clearly seen that the interpretation of the laws by which the universe is governed extending from the invisible rays of the celestial world to the most minute manifestations of organic life reveal one plan, one purpose, one supreme sovereignty—far transcending the highest conceptions to which the human mind can attain respecting this sovereign and infinite Power. Sectarian supremacy and theological differences have dwindled therefore to insignificance, in institutions where the supreme desire is to understand the world in which we are placed, and to develop the ablest intellects of each generation, subservient to the primeval injunction 'replenish the earth and subdue it; and have dominion over the fish of the sea, and over the fowl of the air, and over every living thing that moveth upon the earth.' Notwithstanding these words, the new Biology, that is the study of living creatures, en-

countered peculiar prejudices and opposition. It was the old story over again. Geology, early in the century, had been violently attacked; astronomy, in previous centuries, met its bitter opponents; higher criticism is now dreaded. Yet quickly and patiently the investigator has prosecuted and will continue his search for the truth, —heedless of consequences, assured by the Master's words,—'the Truth shall make you free.'

Still the work goes on. Science is recognized as the handmaid of religion. Evolution is regarded by many theologians as confirming the strictest doctrines of predestination. The propositions which were so objectionable thirty years ago are now received with as little alarm as the propositions of Euclid. There are mathematicians who do not regard the Euclidean geometry as the best mode of presenting certain mathematical truths, and there are also naturalists who will not accept the doctrines of Darwin, without limitation or modification, but nobody thinks of fighting over the utterances of either of these philosophers. In fact, I think it one of the most encouraging signs of our times that devout men, devoted to scientific study, see no conflict between their religious faith and their scientific knowledge. Is it not true that as the realm of Knowledge extends the region of Faith though restricted remains? Is it not true that Science to-day is as far from demonstrating certain great propositions, which in the depths of our souls we all believe, as it was in the days of the Greek philosophers? This university, at the outset, assumed the position of a fearless and determined investigator of nature. It carried on its work with quiet, reverent, and unobtrusive recognition of the immanence of divine power,—of the Majesty, Dominion, and Might, known to men by many names, revered by us in the words that we learned from our mothers'

lips, Almighty God, the Father everlasting.

Another danger, thirty years ago, was that of conflict between the advocates of classical and scientific study. For many centuries Greek and Latin were supreme in the faculty of liberal arts, enforced and strengthened by metaphysics and mathematics. During the last half century, physical and natural sciences have claimed an equal rank. The promotion has not been yielded without a struggle, but it is pleasant to remember that in this place, no conflict has arisen. Among us, one degree, that of Bachelor of Arts, is given alike to the students of the Humanities and the students of Nature and the degree of Doctor of Philosophy may be won by advanced work in the most remote languages of the past or in the most recent developments of biology and physics. Two illustrious teachers were the oldest members of the original faculty;—one of them universally recognized as among the foremost geometers of the world,—the other, renowned for his acquaintance with the masters of thought in many tongues, and especially for his appreciation of the writers of ancient Greece, upon whose example all modern literature is based.

Our fathers spoke of 'Church and State,' and we but repeat their ideas when we say that universities are the promoters of pure religion and wise government. This university has not been identified with political partisanship,—though, its members, like all patriots, have held and expressed their opinions upon current questions, local and national. Never have the political views of any teacher helped or hindered his preferment; nor have I any idea what would be the result of the party classification of our staff. This, however, may be claimed. The study of politics, in the sense of Freeman, 'History is past politics, and politics present history,' has

been diligently promoted. The principles of Roman law, international arbitration, jurisprudence, economics, and institutional history have here been set forth and inculcated,—so that in every part of the land, we can point to our graduates as the wise interpreters of political history, the strong promoters of democratic institutions, the firm believers in the merit system of appointments, and in local self-government.

A phrase which has lately been in vogue is original research. Like all other new terms, it is often misapplied, often misunderstood. It may be the highest occupation of the human mind. It may be the most insignificant. A few words may therefore be requisite to explain our acceptance of this word. When this university began, it was a common complaint, still uttered in many places, that the ablest teachers were absorbed in routine and were forced to spend their strength in the discipline of tyros, so that they had no time for carrying forward their studies or for adding to human knowledge. Here the position was taken at the outset that the chief professors should have ample time to carry on the higher work for which they had shown themselves qualified, and also that younger men, as they have evidence of uncommon qualities, should likewise be encouraged to devote themselves to study. Even those who were candidates for degrees were taught what was meant by profitable investigation. They were shown how to discover the limits of the known; how to extend, even by minute accretions, the realm of knowledge; how to cooperate with other men in the prosecution of enquiry; and how to record in exact language, and on the printed page, the results attained. Investigation has thus been among us the duty of every leading professor, and he has been the guide and inspirer of fellows and pupils, whose work

may not bear his name, but whose results are truly products of the inspiration and guidance which he has truly bestowed.

The complaint was often heard, in the early seventies, that no provision was made in this country for post-graduate work except in the three professional schools. Accordingly, a system of fellowships, of scholarships, and of other provisions for advanced study was established here, so well adapted to the wants of the country at that time that its provisions have been widely copied in other places. It now seems as if there was danger of rivalry in the solicitation of students, which is certainly unworthy, and there is danger also that too many men will receive stipendiary encouragement to prepare themselves for positions they can never attain. In the early days of the French Academy when a seat in that body was a very great prize, a certain young man was told to wait until he was older, and the remark was added that in order to secure good speed from horses, a basket of oats should always be tied to the front of the carriage pole as a constant incitement. It would indeed be a misfortune if a system of fellowships should be open to this objection. Nevertheless, whoever scans our register of Fellows will discover that many of the ablest men in the country, of the younger generation, have here received encouragement and aid.

When this university began the opportunities for scientific publication in this country were very meager. The *American Journal of Science* was the chief repository for short and current papers. The memoirs of a few learned societies came out at slow intervals and could not be freely opened to investigators. This university in the face of obvious objection determined to establish certain journals which might be the means of communication between the scholars of this country and those abroad. Three journals were soon commenced: The

American Journal of Mathematics; the *American Journal of Philology*; the *American Chemical Journal*. Remember that these were 'American' journals, in fact as well as in name, open to all the scholars of the country. Other periodicals came afterwards, devoted to History and Politics, to Biology, to Modern Languages, to Experimental Medicine and to Anatomy. Moderate appropriations were made to foreign journals, of great importance, which lacked support, the *English Journal of Physiology* and the German *Journal of Assyriology*. Nor were the appropriations of the Trustees restricted to periodical literature. Generous encouragement was given to the publication of important treatises, like the researches of Dr. Brooks upon *Salpa*; to the physiological papers of Dr. Martin; to the studies in logic of Mr. Peirce and his followers; to Professor Rowland's magnificent photographs of the solar spectrum; to the printing of a facsimile of the earliest Christian document after the times of the Apostles; and recently, with the cooperation of the University of Tübingen, to the exact reproduction by Dr. Bloomfield of a unique manuscript which has an important bearing upon comparative philology.

I am not without apprehensions that our example to the country has been infelicitous, not less than thirty institutions being known to me, which are now engaged in the work of publication. The consequence is that it is almost impossible for scholars to find out and make use of many important memoirs, which are thus hidden away. One of the problems for the next generation to solve is the proper mode of encouraging the publication of scientific treatises.

I cannot enumerate the works of scholarship which have been published without the aid of the university by those connected with it,—studies in Greek syntax, in mathematics, in history, in chemistry, in medicine and surgery, in economics, in pathol-

ogy and in many other branches. The administration now closing can have no monument more enduring than the great mass of contributions to knowledge, which are gathered (like the cairn of boulders and pebbles which commemorates in Cracow, the burial place of Kosciusko), a bibliothecal cairn, in the office of the Trustees, to remind every officer and every visitor of our productivity in science and letters.

There are many who believe that the noblest work in which we have engaged is the advancement of medical education and science. Several agencies have been favorable. The munificence of the founder established a hospital, which was recognized as soon as it was opened, as the foremost of its kind in Christendom. He directed that when completed it should be a part of the University and, accordingly, when the time came for organizing a medical and surgical staff, the principal professors were simultaneously appointed to the chairs of one institution, to the clinics of the other. They were to be constantly exercised in the relief of suffering and in the education of youth. For the lack of the requisite funds, the University at first provided only for instruction in those scientific branches which underlie the science of medicine. At length, the organization of the school of medicine was made possible by a very large gift of money, received from a lady of Baltimore, who was familiar with the requirements of medical science, and eager to see that they were met. By her munificence the University was enabled to organize and maintain that great department, which now reflects so much honor upon this city and which does so much by example, by publication, by systematic instruction, and by investigation to carry forward those varied sciences, anatomy, physiology, physiological chemistry, pharmacy, pathology, and the various branches of medicine and surgery. In accordance with the plans of the

University, the generous donor made it a condition of her gift that candidates for the degree of Doctor of Medicine should be those only who had taken a baccalaureate degree based upon a prolonged study of science and the modern languages. A four years' course of study was also prescribed and women were admitted to the classes upon the same terms as men. The liberal and antecedent aid of women throughout the country in the promotion of these plans is commemorated by a building inscribed 'the women's fund memorial building.' The excellent laboratory facilities, the clinical opportunities, the organization of a training school for nurses, and especially the ability of the physicians and surgeons have excited abundant emulation and imitation in other parts of the country,—a wonderful gain to humanity. It is more and more apparent among us that a medical school should be a part of a university and closely affiliated with a hospital. It is also obvious that the right kind of preliminary training should be antecedent to medical studies.

I must ask the indulgence of our friends from a distance as I now dwell, for a moment, on the efforts which have been made to identify the Johns Hopkins University with the welfare of the city of Baltimore and the State of Maryland. Such a hospital and such medical advisers as I have referred to are not the only benefits of our foundation. The journals, which carry the name of Baltimore to every learned society in the world are a minor but serviceable advantage. The promotion of sanitary reform is noteworthy, the study of taxation and in general of municipal conditions, the purification of the local supply of water, the advancement of public education by courses of instruction offered to teachers, diligent attention to the duties of charity and philanthropy, these are among the services which the faculty have rendered to

the city of their homes. Their efforts are not restricted to the city. A prolonged scientific study of the oyster, its life history, and the influences which help or hinder its production, is a valuable contribution. The establishment of a meteorological service throughout the State in connection with the Weather Bureau of the United States is also important. Not less so is the Geological Survey of Maryland, organized with the cooperation of the United States Geological Survey, to promote a knowledge of the physical resources of the State, exact maps, the improvement of highways, and the study of water supplies, of conditions favorable to agriculture, and of deposits of mineral wealth, within this region. To the efficiency of these agencies it is no doubt due that the State of Maryland has twice contributed to the general fund of the university.

Nor have our studies been merely local. The biological laboratory, the first establishment of its kind in this country, has carried forward for many years the study of marine life at various points on the Atlantic and has published many important memoirs, while it has trained many able investigators now at work in every part of the land. Experimental psychology was here introduced. Bacteriology early found a home among us. The contributions to chemistry have been numerous and important. Here was the cradle of Saccharine, that wisely diffused and invaluable concentration of sweetness, whose manufacturers unfortunately do not acknowledge the source to which it is due. In the physical laboratory, light has been thrown upon three fundamental subjects:—the mechanical equivalent of heat, the exact value of the standard ohm, and the elucidation of the nature of the solar spectrum. For many years this place was the chief seat in this country for pure and advanced mathematics. The study of languages and liter-

ature, oriental, classical, and modern, has been assiduously promoted. Where has the Bible received more attention than is given to it in our Semitic department? where the study of ancient civilization in Mesopotamia, Egypt, and Palestine? where did the Romance languages, in their philological aspect first receive attention? To American and institutional history, persistent study has been given. Of noteworthy significance also are the theses required of those who are admitted to the degree of Doctor of Philosophy, which must be printed before the candidate is entitled to all the honors of the degree.

I might enlarge this category, but I will refrain. The time allotted to me is gone. Yet I cannot sit down without bringing to your minds the memories of those who have been with us and have gone out from us to be seen no more: Sylvester, that profound thinker devoted to abstractions, the illustrious geometer whose seven prolific years were spent among us and who gave an impulse to mathematical researches in every part of this country; Morris, the Oxford graduate, the well trained classicist, devout, learned, enthusiastic, and helpful, most of all in the education of the young; accomplished Martin, who brought to this country new methods of physiological enquiry, led the way in the elucidation of many problems of profound importance, and trained up those who have carried his methods to every part of the land; Adams, suggestive, industrious, inspiring, versatile, beneficent, who promoted, as none had done before, systematic studies of the civil, ecclesiastical, and educational resources of this country; and Rowland, cut down like Adams in his prime, honored in every land, peer of the greatest physicists of our day, never to be forgotten in the history of physical science. I remind you also of the early student of mathematics, Thomas Craig, and of George Huntington Wil-

liams, the geologist, whose memory is cherished with admiration and love. Nor do I forget those who have here been trained to become leaders in their various departments throughout the country. One must be named, who has gone from their number, Keeler, the gifted astronomer, who died as the chief of the Lick Observatory in California, whose contributions to astronomical science place him among the foremost investigators of our day; and another, the martyr Lazear, who, in order that the pestilence of yellow fever might be subdued, gave up his life for humanity.

Like clouds that rake the mountain summit,
Or waves that own no curbing hand,
How fast has brother followed brother
From sunshine to the sunless land.

It is sad to recall these interrupted careers. It is delightful to remember the elevated character of those I have named, and delightful to think of hundreds who have been with us, carriers to distant parts of our country and to other lands of the seeds which they gathered in our gardens of science. It is delightful to live in this age of bounty; it is delightful to know that the citizens of Baltimore who in former years have supplemented the gifts of the founder by more than a million of dollars have come forward to support a new administration with the gift of a site of unsurpassed beauty and fitness. A new day dawns. "It is always sunrise somewhere in the world."

INAUGURAL ADDRESS.*

It has been said that 'old men tell of what they have seen and heard, children of what they are doing, and fools of what they are going to do.' Your speaker, fearing to furnish data that may suggest to you his place in this system of classification, prefers this morning to deal with

* By President Renssen, on the occasion of his inauguration as President of the Johns Hopkins University.

matters that are largely independent of time.

The American University as distinguished from the College is a comparatively recent product of evolution—or of creation. Being young, its character is not fully developed, and we can only speculate in regard to its future. On an occasion of this kind, when one of the young universities of the country is celebrating in a quiet way the twenty-fifth anniversary of its foundation, and when a new presiding officer makes his first appearance before a large assembly, it seems fitting that he upon whom has been placed the responsibility of guiding, for the present, the affairs of the University, should take the opportunity thus afforded of giving expression to a few thoughts that suggest themselves when one begins to reflect upon the significance of the University movement in this country. Everyone at all acquainted with educational matters knows that the differentiation of the University from the College is the most characteristic fact in the history of higher education during the past quarter century. It is well that we should ask ourselves, What does this tendency mean? Whither is the movement likely to carry us?

While, from the beginning, the authorities of the Johns Hopkins University have maintained a collegiate department as well as a graduate or university department, and have endeavored to make this as efficient as possible under existing circumstances, the subjects that present themselves in connection with this branch of our work are so familiar and have been so much discussed that I can pass over them now without danger of giving the impression that we consider these subjects of less importance than those more directly connected with the work of the University. At all events, in what I shall have to say, I propose to confine myself to the latter.

The idea that a student who has completed a college course has something yet to learn, if he chooses the career of a teacher or scholar, does not appear until quite recently to have taken strong hold of the minds of those who had charge of the educational interests of our country. Perhaps it would be better to put it in this way: They do not appear to have thought it worth while to make provision in the system for those who wanted more than the college gave. The college has for its object the important work of training students for the duties of citizenship, not primarily the duties of scholarship, and no one doubts that, in the main, they have done their work well. Nor does any one doubt that, whatever may come, the college has a leading part to play in this country. Collegiate work by its very nature necessarily appeals to a much larger number than university work. But college work requires no apologist nor defender. It appeals strongly to the American people, and it is well that this is so. The college is in no danger of annihilation, though the indications are that it will undergo important modifications in the future as it has in the past. Upon this subject much might be said, and I feel strongly tempted to enlarge upon it, notwithstanding the intention already expressed of confining myself to problems more directly connected with the university proper.

There is, however, one phase of the college problem that is so closely connected with that of the university that I cannot avoid some reference to it. There is a marked and rapidly growing tendency to make college work the basis of the work in professional schools. As is well known, some of our medical schools now require a college degree for admission. The average age of graduation from our leading colleges is so high that the students cannot begin their professional courses until they

are from twenty-two to twenty-three years of age on the average. Then, too, the length of the professional courses is greater than it formerly was, so that some of the best years of life are taken up in preparatory work. One thing seems to admit of no denial, and that is that, in so far as it prevents students from beginning their professional studies or their work in business life until they have attained the age of twenty-two or twenty-three, our present system is seriously defective. The defect is one that must be remedied. Various efforts are now being made looking to improvement, but it is not yet clear how this problem will be solved.

In this country the name university in the new sense is frequently applied to one department, and that is the philosophical department. This has to deal with philology, philosophy, history, economics, mathematics, physics, geology, chemistry, etc.; in short, it comprises all branches that do not form an essential part of the work of the departments of medicine, law and theology. A fully developed university, to be sure, includes at least four departments—the medical, the legal, the theological, and the philosophical; or, in other words, the university faculty comprises faculties of medicine, of law, of theology and of philosophy.

The new thing in educational work in this country is the philosophical faculty of our universities.

This meets the needs of those students who, having completed the college course, and having, therefore, had a good general training that fits them for more advanced study, wish to go forward in the paths of learning, and, so far as this may be possible, to become masters of some special branch. Most of these students are preparing to teach in colleges and elsewhere, so that the philosophical department of the University is to-day a professional school just as much as the medical or the legal de-

partment. On the completion of the college course, the student holds the same relation to the philosophical department of the university as to the other departments, or to the professional schools, and the age question is fully as important in the case of the student in the philosophical faculty as in the case of those who are to enter the professional schools. Now, if it be conceded that the training of specialists—not necessarily narrow specialists, but necessarily those who are thoroughly grounded in some one subject—I say, if it be conceded that the training of specialists is essential to the growth of the highest scholarship, then by advancing the age of graduation from our colleges, we are interfering with the development of scholarship in the highest sense, because the greater the age of graduation from the colleges the less will these graduates be inclined, or be able, to take up the advanced work that is essential to convert them into scholars. But let me close what I have to say on this subject by the safe prediction that the time will come when the work of our colleges will be adjusted to the work of the various faculties of the university so that the passage from the one to the other will not involve something unnatural—either hardship to the student or a telescoping of college and university which now on the whole furnishes the best way out of the existing difficulty.

I have said that the new thing in educational work in this country is the philosophical faculty of our universities. The growth of the work of the philosophical faculty has, however, undoubtedly influenced that of the other faculties—more particularly the medical. Gradually the medical schools, those connected with the universities at least, are adopting university standards. The same is true to some extent of schools of law and of theology, so that, I think, it is safe to assert that the great activity that has characterized the

work of the philosophical faculties of our universities has tended in no small measure to the improvement of the work of our professional schools. It has lifted them to a higher level, and that is a result that the world at large may congratulate itself upon.

One of the most remarkable facts in connection with what we may call the development of the university idea in this country, is the surprisingly rapid increase in the attendance upon the courses offered by our philosophical faculties during the last few years. In what I shall have to say I shall for the present use the term graduate student in the restricted sense which it has come to have, meaning a college graduate who is following courses offered by the philosophical faculty of some university, and excluding, therefore, those who are studying medicine, or law, or theology in universities.

I have recently asked the United States Commissioner of Education to help me answer the following questions:

1. How many graduate students were in the United States in the year 1850?
2. How many in 1875, and
3. How many in 1900?

The answers are these:

1. In 1850 there were 8 graduate students in all the colleges of the country. Of these 3 were enrolled at Harvard, 3 at Yale, 1 at the University of Virginia and 1 at Trinity College.

2. In 1875 the number had increased to 399.

3. In 1900 the number was 5,668.

At present the number cannot be far from 6,000.

In order that these facts may be properly interpreted we should know how many Americans are studying in foreign universities. The records show that in 1835 there were 4 American students in the philosophical faculties of German universities; in

1860 there were 77; in 1880, 173; in 1891, 446; in 1892, 383; in 1895, 422, and in 1898, 397.

These figures show clearly that the increase in the attendance at American universities is not accounted for by a falling off in attendance at German universities. On the other hand, they do show that for the last ten years at least there has been no increase in the attendance at German universities, but rather a slight decrease.

Six thousand students are, then, to-day pursuing advanced courses in our American universities, while not longer ago than 1875 the number was only about 400. In this connection it must further be borne in mind that during this period the colleges have not relaxed in their requirements. The tendency has been in the opposite direction. So that it means to-day more rather than less than it did in 1875 to be a graduate student. That there is an increasing demand for university work is clear and it seems to be destined to play a more and more important part in the development of our educational methods.

Now, what is the cause of the rapid increase in the demand for university work, or the rapid increase in the attendance upon university courses? No simple answer would be correct. Probably the principal direct cause is the increased demand on the part of the colleges, and to some extent of the high schools, for teachers who have had university training. The degree of Doctor of Philosophy being the outward and visible sign of such training, many colleges have virtually taken the ground that none but Ph.D.'s need apply. This would, of course, tend directly to increase the attendance at the universities. Operating in the same way is the multiplication of chairs in the colleges. While not long ago one man often taught a number of subjects, sometimes related, sometimes not, the college authorities are coming more and more

to entrust a single subject to a single man. The old-fashioned professor who could teach any subject in the curriculum with equal success is a thing of the past except in a few remote regions. The university-trained man has largely taken his place, and the universities are spreading their influence into the nooks and corners of the country through these men.

I need not discuss this phase of the subject further. It will, I am sure, be acknowledged without argument that it is desirable that our college faculties should be made up of men who have enjoyed the best educational advantages. In supplying such men the universities are doing a work of the highest value for the country. If nothing else were accomplished by our universities they would be worthy of all the support they get. The results of their work in this direction are not as tangible as that of the work of the colleges, for the latter reach much larger numbers and in ways that can be more easily followed. But if we keep in mind the fact that the college is dependent upon the university for its faculty and that the character of the college is in turn dependent upon the character of its faculty, it will be seen that whatever good may come from the college is to be traced directly to work done by the universities. In order to keep our colleges up to a high standard it is absolutely necessary that our universities should be maintained on a high plane. This university work is not something apart, independent of other kinds of educational work. It is a necessary part of the whole system. It affects not only our colleges, but our schools of all grades, and must, therefore, have a profound influence upon the intellectual condition of the whole country. It is difficult, perhaps, to prove this, but it seems to me that the statements just made are almost self-evident truths.

But the universities are also doing another kind of work of importance to the

country. Through their specially prepared men they are doing something to enlarge the bounds of knowledge. To be sure, such work is also being done to some extent in our colleges and elsewhere, but the true home of the investigator is the university. This work of investigation is as important as the work of training men: What does it mean? All persons with healthy minds appear to agree that the world is advancing and improving. We see evidences of this on every side. Those results that appeal most strongly to mankind are, perhaps, the practical discoveries that contribute so much to the health and comfort of mankind. These are so familiar that they need not be recounted here. If great advances are being made in the field of electricity, in the field of medicine, in the field of applied chemistry, it is well to remember that the work that lies at the foundation of these advances has been done almost exclusively in the universities. It would be interesting to trace the history of some of these advances. We should find that in nearly every case the beginning can be found in some university workshop where an enthusiastic professor has spent his time prying into the secrets of nature. Rarely does the discoverer reap the tangible reward of his work—that is to say, he does not get rich—but what of it? He has his reward, and it is at least a fair question whether his reward is not higher than any that could be computed in dollars and cents.

The material value to the world of the work carried on in the university laboratories cannot be over-estimated. New industries are constantly springing up on the basis of such work. A direct connection has been shown to exist between the industrial condition of a country and the attitude of the country towards university work. It is generally accepted that the principal reason why Germany occupies such a high position in certain branches of

industry, especially those founded upon chemistry, is that the universities of Germany have fostered the work of investigation more than those of any other country. That great thinker and investigator, Liebig, succeeded during the last century in impressing upon the minds of his countrymen the importance of encouraging investigations in the universities, and since that time the German laboratories of chemistry have been the leaders of the world. In Germany the chemical industries have grown to immense, almost inconceivable, proportions. Meanwhile the corresponding industries of Great Britain have steadily declined. This subject has recently been discussed by Arthur C. Green in an address read before the British Association at its meeting at Glasgow last summer. The address has been republished in *SCIENCE*, volume 2, page 7, of 1902. I call the attention especially of our business men to this address. I think it will show them that university work in some lines at least is directly and closely connected with the industrial position of a country. Speaking of the coal-tar industry, the author of the paper referred to says: "In no other industry have such extraordinarily rapid changes and gigantic developments taken place in so short a period—developments in which the scientific elucidation of abstract problems has gone hand in hand with inventive capacity, manufacturing skill, and commercial enterprise; in no other industry has the close and intimate interrelation of science and practice been more clearly demonstrated." And further on: "Again, besides the loss of material wealth which the neglect of the coal-tar trade has involved to this country, there is yet another aspect of the question which is even of more importance than the commercial one. There can be no doubt that the growth in Germany of a highly scientific industry of large and far-reaching proportion has re-

acted with beneficial effect upon the universities, and has tended to promote scientific thought throughout the land. By its demonstration of the practical importance of purely theoretic conceptions it has had a far-reaching effect on the intellectual life of the nation. How much such a scientific revival is wanted in our country the social and economical history of the past ten years abundantly testifies. For in the struggle for existence between nations the battle is no longer to the strong in arm, but to those who are the strongest in knowledge to turn the resources of nature to the best account."

What I want to make clear by these quotations and references is that universities are not luxuries, to be enjoyed or not, as we may please. They are necessities. Their work lies at the very foundation of national well-being.

But there is another aspect of university work of greater importance than that of which I have spoken. I mean the intellectual aspect in the highest sense. The world is advancing in other ways than along material lines. While as I have pointed out, the material interests of the world are connected with the intellectual condition, there are thoughts, there are ideas, that are above material considerations, ideas pertaining to the history of mankind, to the origin and development of the universe, to the phenomena of life, to the development of thought, to the significance of religions. All these are of importance, and the character of a nation is determined by the extent to which these ideas are cultivated. There is call for investigation in every subject—in the various branches of philology, in history, in economics, in archaeology, as well as in the natural sciences, and here again the universities furnish the workers and the workshops.

There are, then, deep-seated reasons for

encouraging the work of our universities in every possible way. We cannot afford to let them languish. The interests involved are too great. The more clearly this is recognized the better for us.

The rapid advances that have been made in university work in this country have brought us somewhat suddenly face to face with new educational problems, and we have not yet had time to adjust ourselves to the new situation thus created. We are in the experimental stage. We are trying to determine how we ought to deal with our graduate students in order to get the best results; how, in general to make the work as efficient as possible.

As one who, with others, has been engaged for twenty-five years in studying the new problems and in attempting to solve them, I may be permitted to say a few words in regard to one of the most important problems that the universities have to deal with at present. I refer to the problem of the professors. Having been a professor for about thirty years, and having during that time known intimately many of those who belong to this class and worked with them, I feel that I may speak of the professor problem with some confidence.

The university is what the professors make it, and the president has no more important duty to perform than that of seeing that the various chairs are filled by the right kind of men. He should not take the full responsibility of selection. He should take all the good advice he can get. He is sure to have some that is bad. He should, however, not only take advice, but he should endeavor to determine for himself by every available means whether or not the persons recommended to him are worthy of appointment. He should not shirk this responsibility. A mistake in this line is almost as difficult to rectify as a mistake in the matrimonial line—perhaps

more difficult. It is, therefore, doubly important that an appointment should be made with great deliberation and with a full realization of the gravity of the act. It is not, however, the process of appointing that I wish especially to speak of, though much that is interesting to university circles might be said on this subject. It is rather the principles that are involved. What constitutes a good professor? What kind of men are the universities looking for? Is the supply of this kind of men equal to the demand? These are some of the questions that suggest themselves in this connection. Let me attempt to answer them briefly.

The development of universities in this country has created a demand for a kind of professor somewhat different from that demanded by the college. It would not be difficult to describe the ideal university professor, but we should gain little in this way. I shall assume that he has the personal traits that are of such importance in those who are called upon to teach. A man of bad or questionable character, or of weak character, is no more fit to be a university professor than to be a college professor or a teacher in a school. That is self-evident. At least it seems so to me. Leaving these personal matters out of consideration, the first thing that is essential in a university professor is a thorough knowledge of the subject he teaches and of the methods of investigation applicable to that subject; the second is the ability to apply these methods to the enlargement of the field of knowledge; and the third is the ability to train others in the use of these methods. But a knowledge of the methods, the ability to apply them, and the ability to train others in their use, will not suffice. The professor, if he is to do his duty, must actually be engaged in carrying on investigations both on his own account and with the cooperation of his most advanced students. This is

fundamental. It may be said, and this cannot be denied, that there is much research work done that is of little value to the world, that, in fact, much of that which is done by our graduate students is trivial judged by high standards. It would be better, no doubt, if every professor and every advanced student were engaged upon some problem of great importance to the world. But this is out of the question in any country. Few men possess that clearness of vision and that skill in devising methods, combined with the patience and power of persistent application that enable them to give the world great results. If only those who can do great things were permitted to work, the advancement of knowledge would be slow indeed. The great is built upon the little. The modest toiler prepares the way for the great discoverer. A general without his officers and men would be helpless. So would the great thinker and skillful experimenter without the patient worker, 'the hewer of wood and drawer of water.'

Of so-called research work there are all grades. A man may reveal his intellectual power as well as his mental defects by his investigations. But it remains true that the university professor must be carrying on research work or he is failing to do what he ought to do. It is part of his stock in trade. He cannot properly train his students without doing such work and without helping his students to do such work. One of the best results of carrying on this research work is the necessary adoption of world standards. A man may teach his classes year after year and gradually lose touch with others working in the same branch. Nothing is better calculated to keep him alive than the carrying on of a piece of work and the publication of the results in some well-known journal. This stimulates him to his best efforts, and it subjects him to the criticism of those who

know. He may deceive his students and himself—no doubt he often does—but he cannot deceive the world very long. The professor who does not show what he can do in the way of adding to the knowledge of the world, is almost sure to become provincial when he gets away from the influence of his leaders.

Other things being equal, the professor who does the best work in his special branch is the best professor. The universities want leaders. Unfortunately, the number of these is quite limited, and it is not surprising that there are not enough to go round. It is becoming very difficult to find properly qualified men to fill vacant university professorships. Given sufficient inducements and it would be quite possible to 'corner the market.' There are at least half a dozen, probably more, universities in this country on the lookout for young men of unusual ability. They are snapped up with an avidity that is a clear sign of the state of the market. One of the greatest obstacles in the way of the advancement of our American universities to-day is a lack of enough good professorial material. Fortunately, the universities are themselves providing the means by which this obstacle may be overcome, though not as rapidly as we should like. That is, however, not the fault of the universities. Some deeper cause is operating. Nature does not seem to supply enough raw material. It is often raw enough, to be sure, but its possibilities are limited.

This, too, suggests another question of deep import for the intellectual development of our country. Do our ablest men enter universities and engage in advanced work? This is a question which it is very difficult, if not quite impossible, to answer. I think it is not uncommonly assumed that they do not; that our ablest men, our best thinkers, are not in the universities. It is often said that they are in the law or in

business. It may be. Certainly the great jurists and the great business men seem to be relatively more numerous than the great university teachers. I should not think it worth while to touch upon this subject were it not for the fact that recently the suggestion has been made that some of the men who become great in other lines might be induced to enter the academic career if only sufficient inducements were offered. The proposition is that a marked increase in the emoluments of professors would tend to attract some of the best material from other fields. I do not feel sure of this. In any case, the subject is hardly worth discussing. Whatever improvement is to come will come slowly, and this is fortunate. A sudden increase of the salaries of the leading professors of this country to, say, \$10,000 or more, would not suddenly change the status of these professors among their fellow men, and, while the professors might be pleased, and probably would be, the main question is, Would this change have any effect in the desired direction? Speculation on this subject seems to me of no value. If it be true that the men of the best intellects do not find their way into university circles, it is safe to assume that this is due to a great many conditions, and that the conditions are improving. The intellectual standards of our colleges and universities are gradually being raised. We cannot force matters.

The best thing we can do for our students is to give them good professors. Sumptuous laboratories, large collections of books and apparatus, extensive museums are well enough. They are necessary, no doubt. But I fear they are too much emphasized before the public. A university is, or ought to be, a body of well-trained, intelligent, industrious, productive teachers of high character provided with the means of doing their best work for their students, and therefore for the world.

The Johns Hopkins University cannot live on its past, however praiseworthy that past may have been. If the contemplation of the past has the effect of stimulating us to our best efforts, it is a profitable occupation. If it lulls us into inactivity, it is fatal. We should not, nor can we, escape criticism for present misdeeds by referring to a glorious past. We have, to be sure, inherited certain ideals that we should cherish. So, also, we have probably done things that we ought not to have done, and the study of our past may help us to see where we have made mistakes and to show us how to avoid them in the future. There is only one way to make a university what it ought to be, and that is by doing good work according to the highest standards. Professors and students must cooperate in this. With the right professors we shall have this cooperation. Students have the power of collective judgment that is probably fairer than the judgment of any individual. They will work well if their masters work well. The professor is teaching all the time. His duty to his students is not done when he dismisses them from the lecture room or the laboratory. His influence for good or evil is continuous and lasting.

Will you allow me a few personal words? Those of you who know most of the occurrences of last year know best that the office, the duties of which I formally assume to-day, came to me unexpectedly and against my wishes. My life up to the present has been spent as a teacher. I ask no higher occupation. There is none more rewarding. It would have been agreeable to me to continue in this occupation to the end. Indeed, even as matters now stand, I hope it will not be necessary for me to withdraw entirely from the work to which my life has thus far been devoted. On the other hand, I recognize to the full the importance of the new work to which I have been called, and I accept the new duties with the inten-

tion of using every effort to further the interests of this University. Having taken the step, I accept the responsibility. I cannot permit anything to interfere with the work of the presidency. I believe, however, that I shall not be obliged to give up that which is dear to me in the science of chemistry.

In conclusion, I wish to express my hearty thanks to my distinguished predecessor, to my colleagues, to the students of the University, and to this community for the kindness with which they have accepted my election. I could not ask for better treatment. In return, I can only promise to do all that in me lies to make this University worthy of its history, to make it as helpful as possible, not only to this community, of which I am proud to be a member, but to the State and to the country. It is my earnest wish, as I am sure it is yours, that the period upon which the University now enters may be at least as useful as that which now ends.

We have passed through a time of great anxiety. Causes have been in operation that have of late seriously interfered with our development. It is not strange that the world at large should have received the impression that the Johns Hopkins University has seen its best days. The fact is that the doleful stories that have been going the rounds have a slight basis. It is this: The growth of the University has been temporarily checked. It has not gone backward, but, for a time at least, it has stood still. I believe that a new day has at last dawned and that the onward march will soon be taken up. Our difficulties have by no means been overcome, but a magnificent beginning has been made. The public spirit and generosity of William Wyman, of William Keyser, of Samuel Keyser, of Francis M. Jencks, of William H. Buckler and Julian Le Roy White, are worthy of the highest commendation. These high-

minded men have started the new era. They have shown their confidence in the work of the University and set an example to their fellow men. I would not detract in the least from the praise due to every one of these gentlemen, but I am sure the others whom I have named will pardon me if in conclusion I exclaim, Long live William Wyman and William Keyser!

PRESENTATION OF CANDIDATES FOR
HONORARY DEGREES.*

To the Assembly:

From time immemorial, it has been the custom of universities at festive celebrations, to bestow upon men of learning, personal tokens of admiration and gratitude. In conformity with this usage, our university desires to place upon its honor list the names of scholars who have been engaged with us in the promotion of literature, science and education. In accordance with the request of the Academic Council and in their name, I have the honor and the privilege of presenting to the President of the Johns Hopkins University those whose names I shall now pronounce, asking their enrolment as members of this 'Societas magistrorum et discipulorum.'

To the President:

MR. PRESIDENT: In the name of the Academic Council, I ask that several scholars, who pursued advanced studies under our guidance, without proceeding to degrees, be now admitted to the degree of Master of Arts, *honoris causâ*, and assured of our hearty welcome to this fraternity.

WILLIAM THOMAS COUNCILMAN,
BENJAMIN IVES GILMAN,
JOHN MARK GLENN,
CLAYTON COLMAN HALL,
THEODORE MARBURG,
WILLIAM L. MARBURY,

* On behalf of the University, by Dr. D. C. Gilman, President Emeritus, on the occasion of the celebration of the twenty-fifth anniversary of the founding of the University.

ROBERT LEE RANDOLPH,
LAWRASON RIGGS,
HENRY M. THOMAS,
JULIAN LE ROY WHITE.

MR. PRESIDENT: I have now the honor of presenting to you, one by one, a number of eminent men, recommended by a committee of the professors, and of asking you to admit them to the degree of Doctor of Laws, *honoris causâ*, in the Johns Hopkins University.

Three of these scholars were friends and counsellors of the Trustees before any member of this Faculty was chosen. They pointed out the dangers to be avoided, the charts to be followed, and during seven and twenty years they have been honored friends, by whose experience we have been guided, by whose example we have been inspired.

CHARLES WILLIAM ELIOT, President of Harvard University, oldest and most comprehensive of American institutions,—the Chief, whose wisdom, vigor, and devotion to education have brought him honors which we gladly acknowledge, which we cannot augment.

JAMES BURRELL ANGELL, teacher, writer, diplomatist, scholar, excellent in every calling, whose crowning distinction is his service in developing the University of Michigan, a signal example of the alliance between a vigorous state and a vigorous university.

ANDREW DICKSON WHITE, honored Ambassador of the United States in Germany, the organizer of Cornell University, whose diplomatic success increases the distinction he had won as an able professor, a learned historian, and a liberal promoter of science, literature and art.

With these early friends, I now present to you several men who have been associated with us in carrying on the work of this University:—

JOHN SHAW BILLINGS, able adviser of the Trustees of the Johns Hopkins Hospital respecting its construction, an authority on the history of medicine, a promoter of public hygiene, a famous bibliographer and the wise administrator of public libraries in the City of New York.

GRANVILLE STANLEY HALL, who planned and directed the first laboratory of experimental psy-

chology in the United States, and who left a professorship among us to become first President of Clark University in Worcester,—a learned and inspiring philosopher, devoted to the education of teachers in schools of every grade from the lowest to the highest.

JAMES SCHOULER, successful lecturer and writer on law and history, a lover of truth, a diligent explorer of the historical archives of this country, author of a history of the United States, comprehensive and trustworthy.

JOHN WILLIAM MALLET, of the University of Virginia, one of that brilliant band of lecturers to whom we listened in the winter of 1876-77, an ornament of the University founded by Jefferson, where scholars of every birthplace are made to feel at home; where two of our earliest colleagues had been professors. He is a chemist of international renown, whose researches are an enduring contribution to the science that he professes.

CHARLES DOOLITTLE WALCOTT, Superintendent of the United States Geological Survey, a government bureau of the highest standing, that extends its investigations to every part of the land, securing for other States, as it does for Maryland, an accurate knowledge of the structure and resources of the earth. The chief of this survey is a geologist whose administrative duties have not prevented his personal devotion to scientific research in which he maintains acknowledged eminence.

SIMON NEWCOMB, professor of mathematics in the United States Navy, once professor here, who has carried forward the researches initiated by Copernicus. His astronomical memoirs, above the ken of ordinary minds, have caused his name to be enrolled in the learned academies of Europe among the great investigators of celestial laws.

I have now the honor to present to you two scholars from a neighboring commonwealth, the Dominion of Canada, the representative of the University of Toronto, and the representative of McGill University in Montreal, who came to rejoice with us in this our festival,—JAMES LOUDON and WILLIAM PETERSON. We welcome them in the brotherhood of scholarship which knows of no political bounds, appreciating what they have done to uphold the highest standards of education in two great universities, with which we are closely affiliated.

It is not easy to discriminate among our own alumni, so many of whom we honor and admire, but on this occasion I have been asked to present four candidates, all of whom are widely known as scholars.

JOSIAH ROYCE, a graduate of the University of California, one of the first to be called to a fellowship among us, and one of the first four Doctors of Philosophy in this University, Doctor Subtilis, now Professor in Harvard University, Gifford lecturer in two of the Scotch universities, historian, man of letters, and philosopher.

JOHN FRANKLIN JAMESON, of the University of Chicago, one of the most accurate and serviceable students of the Constitutional History of this country, an editor of historical papers, whose rare erudition is always placed at the command of others in a spirit of generous cooperation.

EDMUND B. WILSON, of Columbia University, a profound investigator and an acknowledged authority in biological science,—one of the men not seen by the outer world, who look deeply into the fundamental laws of organic life.

WOODROW WILSON, of Princeton University, writer and speaker of grace and force, whose vision is so broad that it includes both north and south, a master of the principles which underlie a free government, whom we would gladly enrol among us a Professor of Historical and Political Science.

I now present to you nine men, the number of the muses, each of whom, like others already presented to you, is a leader of higher education,—two from New England, two from the Central States, two from the far South, one from the Northwest, and two from the Pacific coast. These are all our collaborators,—sentinels on the watch towers, heralds of the dawn.

FRANCIS LANDEY PATTON, under whose presidency 'old Nassau Hall,' the College of New Jersey, has become the University of Princeton, revered as a preacher of righteousness, admired as an Abelard in dialectics, beloved as an inspiring teacher of theology and philosophy.

WILLIAM RAINEY HARPER, interpreter of the Sacred Scriptures, a fearless leader, a skillful organizer, who has brought into the front rank the University of Chicago.

CHARLES WILLIAM DABNEY, of the University of Tennessee, a man of science, and EDWARD A.

ALDERMAN, of Tulane University in New Orleans, a man of letters,—two leaders in the advancement of education in the South, advocates of schools and colleges of every grade, and their zealous promoters.

NICHOLAS MURRAY BUTLER, whose enthusiasm, energy, and knowledge of the principles and methods of Education have given him distinction throughout the land and have led to his promotion to the presidency of Columbia University in the city of New York.

HENRY SMITH PRITCHETT, astronomer and geodesist, who went from his home in Missouri to distant lands, now to observe an eclipse, now a transit, who has been the distinguished head of the United States Coast Survey, and is now the head of a vigorous foundation in Boston, the Massachusetts Institute of Technology.

I present to you the two representatives of learning and scholarship in 'the new world beyond the new world,' a Grecian and a student of Natural History, BENJAMIN IDE WHEELER, President of the University of California,—an idealist worthy to represent the aspirations of Berkeley, and DAVID STARR JORDAN, the naturalist, who has led in the organization of the Stanford University, chiefs of two harmonious institutions, one of which was founded by private bounty, the other by the munificence of a prosperous State.

As this roll began with Harvard it ends with Yale. I present to you finally one of the strongest and most brilliant of this strong and brilliant company,—ARTHUR TWINING HADLEY, a writer and thinker of acknowledged authority on the principles of finance and administration, the honorable successor of Timothy Dwight as President of Yale University.

THE CHICAGO MEETING OF THE AMERICAN PHYSIOLOGICAL SOCIETY.

THE American Physiological Society held its fourteenth annual meeting at the University of Chicago, December 30 and 31, 1901. Notwithstanding the fact that the Society had hitherto met only in the East, there was a large attendance of members,

and great interest was shown in the proceedings. The following new members were elected, making the total membership ninety-seven: Harvey B. Cushing, A.M., M.D., Associate in Surgery, Johns Hopkins University; Joseph Erlanger, M.D., Instructor in Physiology, Johns Hopkins University; Martin H. Fischer, M.D., Associate in Physiology, University of Chicago; Arthur W. Greeley, A.M., Assistant in Physiology, University of Chicago; E. Mark Houghton, Ph.C., M.D., Lecturer on Experimental Pharmacology in the Detroit College of Medicine; H. S. Jennings, Ph.D., Assistant Professor of Zoology, University of Michigan; Waldemar Koch, Ph.D., Assistant in Pharmacology, University of Chicago; David J. Lingle, Ph.D., Instructor in Physiology, University of Chicago; Elias P. Lyon, Ph.D., Assistant Professor of Physiology, University of Chicago; E. Lindon Mellus, M.D., Baltimore; George B. Wallace, M.D., Instructor in Pharmacology, University and Bellevue Hospital Medical College, New York. The Council for the past year was reelected, viz., Professors R. H. Chittenden, W. H. Howell, Frederic S. Lee, W. P. Lombard and W. T. Porter. The Council subsequently reelected as president Professor Chittenden, and as secretary and treasurer Professor Lee.

The scientific program was an unusually full one, thirty-two papers being presented. A considerable number of demonstrations, especially of new apparatus, were also made. Only a very brief outline of the program can be indicated here.

The Relation of Blood-plates to the Increase in the Number of Red Corpuscles at High Altitudes: Professor G. T. KEMP, University of Illinois.

The red corpuscles and the blood-plates were counted at Paris, and found to number, respectively, 4,800,000 and 457,000 per cubic millimeter. Seventy-two hours later,

the final twenty-four hours of which were spent at Görner Grat, Switzerland, the respective numbers were 7,000,000 and 1,206,900. The plates had thus increased much more than the red corpuscles. The predominance of plates of large size was very striking; the number of small red corpuscles was much greater than is seen in normal blood. The whole appearance suggested the *crise hématoblastique* of Hayem. The most careful search, however, failed to reveal plates colored by hæmoglobin.

Some New Observations on Blood-plates:

Professor G. T. KEMP and O. O. STANLEY.

The experiments of Dutjen have been repeated, and his statement corroborated, viz., that the plates exhibit amœboid movements when examined in proper media. From preparations made from the blood of animals, into whose circulation methylene blue had been injected, and examined by Dutjen's method, and from others studied by Macallum's method for the detection of phosphorus, the authors conclude that the plates consist of nucleo-proteid existing as granules scattered through the clear mass (of protoplasm?), which is capable of exhibiting amœboid movements.

Notes on the Physiology of the Circulatory System in the Hagfish, Polistotrema slouti: Professor C. W. GREENE, University of Missouri.

The California hagfish possesses three well-developed hearts, the systemic heart, the portal heart and the caudal heart. The systemic heart is different from that in all craniate vertebrates so far examined, in that it possesses no regulative nervous system. The portal heart also is devoid of such a system. The caudal heart propels blood from the great lateral subcutaneous sinuses into the caudal vein. It was proved that these sinuses normally contain blood, and not lymph alone. The blood of the

hagfish has a concentration very close to that of the sea water in which the animal lives. The lowering of the freezing point of hagfish serum is 1.934° C.—1.992° C., while that of sea water in Monterey Bay is 1.945° C.

The Mechanism of Fibrillar Contraction of the Heart: Professor W. T. PORTER, Harvard.

On Further Experiments on the Importance of Sodium for the Heart-Beat: Dr. D. J. LINGLE, University of Chicago.

Heart stimulants like caffein can not make strips of muscle from the ventricle contract, unless sodium chloride is present. A recovery from the standstill induced by sodium chloride alone occurs in oxygen gas and in solutions containing hydrogen peroxide, as well as in various salt solutions. Heart strips placed first in a solution of sodium chloride, and then transferred to oxygen gas contract as long and as well as they do in a solution of calcium or other salts.

On the Prolongation of the Life of Unfertilized Eggs of the Sea-urchin by Potassium Cyanide: Professor JACQUES LOEB, University of Chicago, and Mr. LEWIS.

Death is an active process due to enzyme action. Fertilization greatly retards it. In the eggs of the sea-urchin brief treatment with certain salts, such as potassium cyanide, acts like fertilization to retard the mortiferous processes.

The Action of Alcohol on Muscle: Professor FREDERIC S. LEE, Columbia, and Dr. WILLIAM SALANT.

A frog's muscle which has absorbed a moderate quantity of ethyl alcohol will contract more quickly, relax more quickly, perform a greater number of contractions in a given time, and do more work than a muscle without alcohol, while the onset of fatigue is at the same time delayed. In

larger quantities alcohol is detrimental, diminishing the whole number of contractions, inducing early fatigue and diminishing the amount of work that the muscle is capable of doing, even to the extent of doing away entirely with contractile power. In moderate quantities the alcohol is, at least temporarily, beneficial; in larger quantities poisonous. After-effects have not yet been studied.

The Excretion of Lithium: Mr. C. A. GOOD. (Presented by Professor A. R. CUSHNY, University of Michigan.)

Lithium chloride injected hypodermically in poisonous doses is excreted in large quantities by the alimentary tract. It is here that the chief symptoms of poisoning arise.

On the Question whether Dextrose is Produced from Cellulose in Digestion: Professor GRAHAM LUSK, New York University.

The feeding of cellulose in the form of paper to diabetic goats does not cause an increase of sugar in the urine; therefore, dextrose is not a product of the digestion of cellulose.

Experiments on the Relation Between the Spleen and the Pancreas: Professor L. B. MENDEL, Yale, and L. F. RETTGER.

These experiments were performed on dogs, and show that the extract of the spleen aids the transformation of the zymogen of the pancreas into trypsin. Similar results were obtained both within the living body and outside. The observations support the Schiff-Herzen hypothesis.

The Role of the Cell Nucleus in Oxidation and Synthesis: R. S. LILLIE. (Presented by Professor W. T. PORTER, Harvard.)

New Experiments on Allantoin Excretion: Professor L. B. MENDEL, Yale.

Rectal injections of thymus gland substance in dogs were followed by character-

istic excretion of allantoin in the urine. The diet was free from constituents yielding purin. Vegetable nucleic acids and nucleates from wheat germs experience transformations in metabolism comparable with those obtained from nucleins of animal origin. Allantoin and uric acid are excreted in noticeable quantity. Other physiological actions were studied after the introduction of nucleic acid into the circulation.

Studies on Diuresis: Dr. J. T. HALSEY, McGill.

Nussbaum's experiments on the circulation in and the function of the frog's kidney have been repeated, and it has been found that in the kidney in which the renal arteries have been tied some glomeruli are still supplied by the blood. In such cases the blood supply is so small that such glomeruli may be considered as physiologically negligible quantities. It seems a necessary conclusion that the substances which are excreted by the kidney under these conditions are excreted by the epithelium of the uriniferous tubules.

An Unrecognized Feature of Diuresis: Professor A. R. CUSHNY, University of Michigan.

The author's experiments had led to a conclusion somewhat the opposite of that of the preceding paper. Excretion occurs in the uriniferous tubules, but chlorides and water are excreted there much more readily than sulphates, phosphorus or urea.

The Physiological Effects of the Electrical Charge of Ions, and the Electrical Character of Life Phenomena: Professor JACQUES LOEB, University of Chicago.

The author has found that the stimulating power of chemical substances varies directly with the valence of the substance. The paper reviewed also some of the

author's previous work in the light of recent discoveries, and maintained that vital phenomena, in general, are caused by the electrical charges of ions.

The Nature of Nerve Stimulation, and Alterations of Irritability: Professor ALBERT P. MATHEWS, University of Chicago.

The irritability of nerve protoplasm varies inversely with the stability of the hydrosol state of its colloids. Stimulation is gelation, and is brought about by negative electrical charges. Chemical stimulation is really an electrical stimulation due to the charges which the ions bear. Negative charges stimulate, positive charges prevent stimulation. The nerve impulse is due to a progressive precipitation of colloids by negative charges, the negative charges being regenerated by the precipitation of each succeeding mass of colloids. The negative variation, in other words, stimulates each successive segment of the nerve, and is regenerated by the change it produces in the colloids. Anæsthetics prevent precipitation. It is not the valence, in ultimate analysis, which produces stimulation, but the movement of the charge, chemical stimulation being thus identical with stimulation by light.

The Effect of Potassium Cyanide and Lack of Oxygen on the Fertilized Eggs of the Sea-urchin, Arbacia: Professor E. P. LYON, University of Chicago.

During each cleavage of the egg (tested to the third), there is a period of slight resistance to potassium cyanide and to lack of oxygen, followed by a period of much greater resistance. The period of least resistance comes about ten minutes after fertilization, and almost immediately after each succeeding cleavage.

Experiments with Zygadenus venenosus:

Professor REID HUNT, Johns Hopkins.

The author has made a chemical and

physiological study of this poisonous plant. He has isolated an alkaloid or a mixture of alkaloids having most of the chemical and physiological characteristics of veratrine.

Demonstration of the Glands in the Oviduct of the Fowl: Professor A. R. CUSHNY, University of Michigan.

Four varieties of glands have been found, secreting, respectively, albumen, the soft membrane, the hard shell, and, apparently, mucus. The last variety has been hitherto undescribed. They are interposed between those secreting albumen and those secreting the soft membrane.

An Attempt to Obtain Regeneration of the Spinal Cord: Dr. PERCY M. DAWSON and EDWIN N. RIGGINS, Johns Hopkins.

The animal, a young bitch, was nursed with the greatest care for one hundred and twelve days after the operation. Although the healing was *per primum*, with very little formation of scar-tissue, there was never any conclusive clinical evidence of conscious sensation, or of voluntary motion in the parts of the body supplied by the cord posterior to the section.

The Formula for Determining the Weight of the Central Nervous System in Frogs of Different Sizes: Professor H. H. DONALDSON, University of Chicago.

It was shown that in the case of the bull-frog and leopard frog, the weight of the central nervous system (brain and spinal cord) was a function of the body-weight and length of the frog, combined.

If the weight of the central nervous system (in milligrams) = N ;
length of the entire frog (in millimeters) = L ;
weight of the body (in grams) = W ;
and the constant coefficient = C ;
then:

$$N = 1 (\sqrt[3]{L \log W}) C.$$

In the case of the bull-frog $C = 30$.

In the case of the leopard-frog $C = 27.5$.

The Chemical Analysis of the Brain: Dr. W. KOCH, University of Chicago.

This paper was a preliminary report on the chemical analysis of nervous tissues, including methods for preparing cerebrin, cephalin and lecithin, in sufficient quantity for subsequent work.

The Study of Metabolism in a Case of Lymphatic Leukæmia: Dr. YANDELL HENDERSON, Yale.

In a typical case of lymphatic leukemia, with the white corpuscles at 300,000 and the red corpuscles only 2,500,000, there was no increase in the excretion of nuclein decomposition products (uric acid and P_2O_5). The pathological condition, therefore, seems to be due, not to an increased nuclein metabolism, in general, but to a diminished katabolism. As nearly all the leukocytes are lymphocytes, this seems to be due to an arrest in their development—i. e., they are not transformed, as normally, into other forms of white cells.

The Mode of Action of Certain Substances on the Colored Blood Corpuscles, with Special Reference to the Relation between So-called Vital Processes and the Physico-Chemical Structure of the Cells: Professor G. N. STEWART, Western Reserve University.

On the Surface Action of Metals: Professor F. G. NOVY, University of Michigan.

The author has studied with Professor Freer the conditions favoring the formation of organic peroxides. In Nef's method of preparing benzoyl acetyl peroxide, the reagents, benzaldehyde and acetic anhydride, are mixed with sand and exposed in a thin layer to the action of air, with the result that auto-oxidation takes place, and the peroxide is formed. That this change is one of surface action was demonstrated in various ways. If a strip of paper is introduced into the mixture, the yield of peroxide is increased by more than 200 per

cent. Strips of cloth and various metals were tested in like manner, and gave similar results, showing that the rate of formation of this peroxide depends on surface action, and varies within wide limits with the kind of surface employed.

Demonstrations of apparatus for teaching and for research were made by Professors W. P. Lombard, University of Michigan; W. T. Porter, Harvard; W. S. Hall, Northwestern University; Graham Lusk, New York University and Bellevue Hospital Medical School; and G. P. Dreyer, University of Illinois.

FREDERIC S. LEE.

SCIENTIFIC BOOKS.

TWO NEW WORKS ON MOSQUITOES.

A Monograph of the Culicidæ, or Mosquitoes, mainly compiled from the collections at the British Museum from various parts of the world, in connection with the investigation into the cause of malaria conducted by the Colonial Office and the Royal Society. By FRED V. THEOBALD, M.A., F.E.S., London. Printed by order of the Trustees of the British Museum. 1901. 3 vols. Pp. 424, 391, pl. 37+5, text figures 318.

Mosquito Brigades and How to Organize Them. By RONALD ROSS, F.R.C.S., D.P.H., F.R.S. London, Geo. Philip & Son. 1902.

The literature of mosquitoes is becoming enormous. The number of scientific papers published about these insects in the last three years has been very great and is increasing almost daily. It is safe to say, however, that two books which will be greeted with the greatest pleasure by thousands of people who have become interested in the mosquito question are those the titles of which have just been given.

When the Royal Society, at the request of the Right Honorable Joseph Chamberlain, appointed a committee to cooperate with the officials of the Colonial Office in the investigation of the causes of malaria and the possibility of controlling that scourge of tropical lands, one of the first steps of the committee was to secure the services of Mr. F. V. Theo-

bald to prepare an illustrated monograph of the family Culicidæ, based upon the collections of the British Museum and upon the collections sent in by private individuals and collectors throughout the world. The date when this work was placed in Mr. Theobald's hands is not mentioned, but his work has certainly been done in little more than two years, and the results are displayed in the three volumes mentioned. The material at his disposal has been larger than has ever been brought together elsewhere and he has described in detail, with synoptical tables of subfamilies, genera and species, 340 species of Culicidæ, distributed in twenty-three genera, 108 of the species and 10 of the genera being new to science. Of the species, 131 belong to the old genus *Culex*, and of these 51 are new to science. Of the malaria-bearing genus *Anopheles*, 39 species are described, of which 12 are new to science. For North America 37 species are described, of which 5 are new, but the author calls especial attention to the fact that but little collecting of mosquitoes has been done upon the Pacific coast.

The end is by no means reached, since Ray Lankester, in his preface, states that collections are still arriving at the Museum, and it is to be hoped that this will continue for years to come; so that a supplementary volume will be necessary at no distant date to record additional species and correct present conclusions.

Mr. Theobald has given the world a remarkable monograph in a remarkably short space of time. His work is original in a high degree. In his preliminary matter, covering nearly a hundred pages, he enters extensively into the morphology of the group and its biology. He arrives at the interesting conclusion that the scale structure of these insects is one of the most important characters for both generic and specific distinction. This conclusion is of great importance, but is in a measure unfortunate for workers since it necessitates the use of a compound microscope in addition to the high-power hand lens for the proper separation of species. He establishes five new subfamilies of Culicidæ, namely, the Anophelina, the Culicina, *Ædeomyia*, *Trichoprosoponina*

and *Corethrina*. It is unfortunate that these groups were not given the uniform subfamily *inæ* termination required by modern rules of zoological nomenclature, but after all this is a small point.

Especial care has been taken with the important subject of geographic distribution, and many interesting points have been brought out. As with other Diptera, these insects have apparently no great faunistic value, and many species, such as *Anopheles maculipennis*, *Culex pipiens*, *C. fatigans* and *Stegomyia fasciata*, are widespread.

The character and great number of the illustrations are worthy of especial commendation, and Mr. Theobald is heartily to be congratulated upon his great work; and the joint committee is to be congratulated as well upon the fact that it is able to secure a man who was able to perform this enormous task so successfully and in so short a space of time. The work is provided with a bibliography, defective in some respects, and with an index which might to advantage have been made somewhat more complete.

Realizing the necessity for concise and practical directions to communities, municipal and health organizations and individuals who wish to start a mosquito crusade, Major Ross, the distinguished investigator who first established the transfer of malarial parasites by mosquitoes and who has since directed the practical work which England has attempted to carry on in certain of her tropical colonies, has filled the want most excellently in his 'Mosquito Brigades.' The book is written by a man of highest scientific rank who is at the same time a practical man. His book is divided into sections, entitled, 'Things to be Learnt,' 'Things to be Done,' 'Summary,' 'Miscellaneous Remarks,' 'Appendix,' 'Books.' It is a handy little book of only 98 pages, but covers the ground in an admirable manner.

Taking the headings of his section, entitled 'Things to be Done,' for example, they are as follows: Appointment of Superintendent, The First Step, How to Raise Funds, Small Beginnings, Organization of the Brigade, Organization and Duties of the *Culex* Gang, Organization and Duties of the *Anopheles* Gang,

Destruction of Larvæ, Destruction of Adults, Last Stages of the Campaign. This is followed by a summary of the objects and a summary of the methods, to which is appended a motto, which Dr. Ross thinks will shortly become the first law of tropical sanitation, namely 'No Stagnant Water.' Major Ross's book is based upon experience gained during many years' study of mosquitoes in many parts of the world, and more especially upon the actual results of the operations now being carried on under the Liverpool School of Tropical Medicine, in West Africa. A great deal is said which applies chiefly to tropical regions, yet the book as a whole should be in the hands of every one in this country who is interested in the fight against mosquitoes.

In his section on sanitary anarchy Dr. Ross complains bitterly of the inertia of the sanitary and medical branches of the Imperial Service, and points out by contrast the energetic measures adopted by our government in Cuba. The British authorities, he says, "love to ponder things. They will go on pondering for twenty years."

L. O. HOWARD.

The World and the Individual. Gifford Lectures Delivered before the University of Aberdeen. Second Series: *Nature, Man and the Moral Order.* By JOSIAH ROYCE, Ph.D., LL.D. (Aberdeen), Professor of the History of Philosophy in Harvard University. New York, The Macmillan Co. 1901. 8vo. Pp. xvii + 480. Price, \$2.25, net.

Although it contains what may be called a philosophy of nature, this new series of Gifford Lectures presents less of direct interest to readers of SCIENCE than its predecessor. Accordingly, as a detailed philosophical criticism would be out of place here, it may suffice to give a general account of the work, and some indication of the author's standpoint.

The lectures, ten in number, fall roughly into three main parts and an epilogue. (1) Lectures I.-III. furnish what Mr. Royce himself calls 'a sketch of an idealistic Theory of Human Knowledge' (Preface, vi). Lecture IV., on 'Physical and Social Reality,' mediates

between this Theory and the outline of a Philosophy of Nature, which follows. (2) Lecture V. supplies this outline, and an inkling of its purport may be obtained from the following passage. "Any hypothesis about Nature, which is just to the demands of a sound metaphysic, must, like ours, conceive the natural world as directly bound up with the experiences of actually conscious beings. That, in addition to all these considerations, we should be led to reject Berkeley's cosmological hypothesis, is due, in part, to our own special form of Idealism; but, in part, also to the fact that our theory about nature ought to be just to the empirical inductions which have now been summed up in the modern Doctrine of Evolution. The essence of this Doctrine of Evolution lies in the fact that it recognizes the continuity of man's life with that of an extrahuman realm whose existence is hinted to us by our experience of Nature. Accepting, as we are obliged to do, the objective significance of this modern doctrine, we find ourselves forced to interpret Nature, not as an arbitrarily determined realm of valid experiences founded only in God's creative will and man's sensory life, but as an orderly realm of genuine conscious life, one of whose products, expressions, and examples we find in the mind of man" (241-2). (3) Lectures VI.-IX. discuss the self and the problems which occur in considering the relation of the self to a universe of physical and social reality, where it is at once a factor and the feature. Lecture X. contains the epilogue. Here, gathering up all the conclusions reached hitherto, Mr. Royce attempts to estimate the significance of the individual life in relation to the cosmic whole, and to that ultimate unity which natural religion terms God. Of course such an inquiry touches the conclusions of modern science at every point. But, for this very reason, it is difficult in any case, and impossible in a short review, to show what the point of contact is. Rather, each one who is interested must find out for himself by perusal of the entire argument.

Apart altogether from its considerable weight as a contribution to original metaphysical thought, the work has great significance

as an indication of prevalent philosophical tendencies in English-speaking lands. Save for the sporadic efforts of Coleridge and Carlyle in Britain, of Emerson and his group in this country, the English mind remained in long isolation from the transitive speculation of Europe, originated by Kant and Herder, cast abroad by Goethe, and systematized by Hegel. At length, in the sixties of the nineteenth century, thanks to Dr. Stirling, Wallace, the brothers Caird, Mr. W. T. Harris and the St. Louis circle, Hegel burst upon the Anglo-Saxon world, and threatened to carry all before him by the seventies. During the same years, the hypothesis of evolution, together with certain discoveries in physiology and physics, brought scientific men into contact with metaphysical problems which had been stilled awhile. Huxley's speculations, significant in their changes, Clifford's 'mind-stuff,' and similar so-called 'monistic' theories, were the result—a belated product being Haeckel's recent 'Riddle of the Universe.' While the immanent tendencies and animating problems happened to be much the same in both cases, it may be declared that the Hegelian and the Clifford-Huxley explanations could not be true together. As a matter of fact, each emphasized elements incident to the problem which the other minimized. A few of the younger men trained, like Mr. Royce, in the idealistic school, have come to clear consciousness of this situation; and, retaining the essential principle for which Hegel stands, have striven to rid themselves of his formalistic baggage, so affording opportunity for a fuller recognition of the scientific standpoint and—more important—of the scientific conscience. On the whole, then, these lectures are essentially mediating. This constitutes their strength now, and will prove their weakness twenty years hence. They cleave to the idealistic as opposed to the 'monistic' solution. On this ground I have no fault to find with them.

At the same time, I am by no means satisfied that the implications of 'monism' have been threshed out thoroughly, even if the discussion differ widely, as it does, from such cavalier treatment as that accorded, say, by

Professor Pringle Pattison in the new 'Dictionary of Philosophy.' Moreover, I have very serious misgivings about the evident reversion to Fichte manifested by Mr. Royce. Nevertheless, his lectures constitute a thoroughly characteristic contribution—one that cannot be overlooked—to the very meaningful development within the English sub-Hegelian school. And if Mr. Royce appear to look back more than Mr. F. H. Bradley or Mr. Ellis McTaggart, one must perhaps hold the lecture-form of his work partly responsible. I am still haunted by the idea, to which I have given expression more than once, that it is a real misfortune that Mr. Royce should have produced so extended a series of books dominated by this method. For, as he himself says, 'In the public lecture-room the hearer has no time to meditate, and the speaker too little opportunity to be either concise or exhaustive.' We await the 'system' therefore. Like little girls, we believe in the man in the moon, but, like older girls, we would believe more in the man in the honeymoon.

R. M. WENLEY.

UNIVERSITY OF MICHIGAN.

SCIENTIFIC JOURNALS AND ARTICLES.

Popular Science Monthly for February is of more than usual interest for the general reader. The first article, on 'Stellar Evolution in the Light of Recent Research,' by George E. Hale, shows how much knowledge has been gained by the use of the camera and spectroscope. In 'Winged Reptiles' S. W. Williston tells of the pterodactyls, and particularly of the great American toothless species of the genus *Ornithostema*, which includes the largest flying animals. Appropriately following this is 'The Journeys of Birds,' by F. H. Knowlton, which gives an excellent résumé of the subject of bird migration, and Otis T. Mason discusses 'Environment in Relation to Sex in Human Culture'; and R. H. Thurston, in 'The College Man as Leader in the World's Work,' expresses his belief that the educated man will in the future be even more in the front than now. Charles B. Dyke treats of 'Theology versus Thrift in the Black Belt,' believing that the religious teaching received

by the average negro is apt to make him care little for the things of this world, and is thus a drawback to him, while Lindley M. Keasbey intimates, in 'The Descent of Man,' that his physical inferiority to beasts of prey acted as a stimulus to his brain.

The Osprey for January begins a new series in a new garb, with new type. It contains 'The California Jay,' by D. A. Cohen; 'Random and Reminiscent Maine Bird Notes,' by W. C. Kendall; 'August Birds of Stony Man Mountain, Virginia,' by William Palmer; and a review of the 'Life and Ornithological Labors of Sir John Richardson,' by Theodore Gill. A review of 'Animals of the Past' includes reproductions of the restorations of *Phorochacos*, *Archæopteryx* and *Hesperornis*. Also, in the form of a supplement we have the first part of a 'General History of Birds,' starting with an interesting history of the etymology of bird.

The Museums Journal of Great Britain, for January, under the title 'The Man as Museum-Curator,' has an appreciative notice of Dr. G. Brown Goode in a review by F. A. Bather of the memorial volume published by the Smithsonian Institution. There is also a good article, 'On the Arrangement of Mineralogical Collections,' by J. G. Goodchild, and notes on 'New Zealand Museums' and 'Oxford Museums,' besides a long list of General Notes, which as a rule constitute a most, if not *the* most, interesting portion of scientific periodicals.

SOCIETIES AND ACADEMIES.

THE CHICAGO SECTION OF THE AMERICAN MATHEMATICAL SOCIETY.

THE tenth regular meeting of the Section was held at Northwestern University, Evanston, Illinois, on January 2 and 3, 1902. Four sessions were devoted to the reading and discussion of the following papers:

- (1) Professor M. W. HASKELL: 'A fundamental theorem in the geometry of the tetrahedron.'
- (2) Professor M. W. HASKELL: 'A theorem for the twisted cubic analogous to Pascal's theorem.'
- (3) Professor M. W. HASKELL: 'A special cubic transformation in space.'

(4) Professor H. S. WHITE: 'Note on a twisted curve connected with an involution of pairs of points in a plane.'

(5) Dr. J. W. GLOVER: 'On the derivation of the asymptotes of an algebraic curve from the definition' (preliminary communication).

(6) Professor ARNOLD EMCH: 'Algebraic transformations of a complex variable realized by linkages.'

(7) Professor L. W. DOWLING: 'On the conformational representation of the isosceles triangle containing an angle of 120 degrees.'

(8) Professor E. H. MOORE: 'On Hilbert's plane desarguesian geometry.'

(9) Dr. F. R. MOULTON: 'A simple non-desarguesian geometry.'

(10) Dr. JACOB WESTLUND: 'Note on multiplying perfect numbers.'

(11) Dr. JACOB WESTLUND: 'On the class number of a particular cyclotomic number-field.'

(12) Dr. CHARLES L. BOUTON: 'The equivalence of linear differential equations for a transformation of the independent variable.'

(13) Dr. T. P. HALL: 'An algebra of space.'

(14) Professor J. B. SHAW: 'Commutivity of matrices and application to the theory of linear associative algebra.'

(15) Dr. H. G. KEPPEL: 'A cubic three-way locus in four-fold space.'

(16) Dr. J. C. FIELDS: 'An equivalent of Plücker's formulæ.'

(17) Professor H. B. NEWSON: 'On the product of linear substitutions.'

(18) Professor G. A. MILLER: 'On the groups of order p^m which contain operators of order p^{m-2} .'

(19) Professor L. E. DICKSON: 'Some simplifications in the theory of linear groups.'

A topic of a more distinctly pedagogical character was introduced by Professor Townsend, namely, the question of uniformity in the requirements for the Master's degree where mathematics is the major subject, and the allied question of equivalent credits for students migrating from one institution to another. After some discussion the matter was referred to a committee for report at the next meeting of the Section. An enjoyable feature of the meeting was the dinner served in one of the University buildings to the members present, and followed by an exhibition by Dr. Keppel of about fifty portraits of eminent mathematicians.

At the business session the secretary was re-elected for the ensuing year and associated with him on the program committee were Professors Townsend and Dowling.

THOMAS F. HOLGATE,
Secretary of the Section.

THE TORREY BOTANICAL CLUB.

At the annual meeting of the Club, held on January 14, the Secretary reported 15 meetings held with an attendance averaging 20; 28 active members elected, total present active membership 238. Alternate meetings have been held at the Botanical Garden at Bronx Park and at the College of Pharmacy. The number of scientific papers has been 26, besides about 34 informal notes.

The editor in chief, Professor Underwood, reported issue of the largest volume of the *Bulletin* in its history, 706 pages and 48 plates. It is the intention to make the *Bulletin* a necessity to botanists the world over. The monthly index of recent literature has been reprinted as usual in card form and includes 983 titles for 1901, an increase of 127. Volume 10 of the *Memoirs*, including the first part of E. S. Burgess' 'Aster Studies' is nearly through the press. No. 1 of Vol. 11, Mr. Griffiths' memoir on North American Sordariaceae, has been printed. The principle adopted with the issue of Vol. 7 to make the memoirs pay for their own publication has been eminently successful. An increased sale of recent volumes and of sets was reported. The following forthcoming publications were announced: In Vol. 8, the conclusion of Professor Lloyd's studies on the embryology of the Rubiaceae; by Dr. A. W. Evans, 'A Monograph of the Lejeuneae of the United States and Canada'; by Mrs. E. G. Britton and Miss Alexandrina Taylor, 'The Life History of *Vittaria lineata*'; in Vol. 11, 'The Ulothricaceae and Chetophoraceae of the United States,' by Mr. T. B. Hazen; Vol. 12, the second part of E. S. Burgess' 'Aster Studies.'

Dr. M. A. Howe, the editor, reported an encouraging first year for *Torreyia*, the monthly started by the club with January, 1901, for

briefier notes and botanical matter of a more popular nature.

Dr. J. K. Small reported on the recent installation of the club's herbarium at the Botanical Garden, where it is now to form the nucleus of a representative local collection to cover the flora of New York and vicinity within the 100-mile limit.

The annual election followed, the officers elected including Hon. Addison Brown, *President*; Dr. T. F. Allen and Dr. H. H. Rusby, *Vice-Presidents*; Professor F. E. Lloyd, *Treasurer*; Edward S. Burgess, *Recording Secretary*; Dr. L. M. Underwood, *Editor of the Bulletin*; Dr. M. A. Howe, *Editor of Torreyia*.

E. S. BURGESS,
Secretary.

GEOLOGICAL SOCIETY OF WASHINGTON.

THE 123d meeting was held January 22. The first paper, 'The Development of Septa in Paleozoic Corals,' by Dr. J. E. Duerden, gave an account of some of his recent results on the mesenterial and septal development of modern and fossil corals. After referring to the difference in this respect between *Porites* and *Madrepora* as compared with most other recent corals, the author proceeded to show how closely the septal development in the Palaeozoic Rugose corals conforms with the mesenterial sequence in living Zoanthid polyps. Serial sections of the Carboniferous *Lophophyllum proliferum* (McChesney) demonstrate that the primary stage in the growth of this coral is six-rayed, and that in the subsequent development new septa are added successively within only four of the six primary interseptal chambers. The relationships can also be confirmed by means of the external ridges and grooves on the corallum.

The facts prove that while in their primary stage the Rugosa are hexamerous, yet they can not be brought into close relationship with modern corals, but are undoubtedly allied to the Zoanthids which flourish to-day mainly in tropical seas. In the past the Zoanthids probably bore much the same relationship to the Rugose corals which living Actinians hold to recent corals.

The second paper, entitled 'The Mesabi Iron Range,' was presented by Mr. C. K. Leith.

Mr. Leith discussed certain new developments in the geology of the Mesabi iron range of Minnesota. He showed that the Keewatin series of the Minnesota Survey comprises two distinct series—an igneous 'basement complex' and a sedimentary series. The former is classed as Archean and the latter as Lower Huronian by the United States Geological Survey. The district therefore shows a complete succession from the Archean through the Lower Huronian into the Keewenawan, and in the fullness of the succession and in the clear-cut unconformities the Mesabi may be regarded as the type of Pre-Cambrian district of the Lake Superior region.

The iron ores result from the alteration of certain peculiar rocks composed of aggregates of minute green granules. The granules were called *glauconite* by Spurr, and were supposed to be of organic origin. The present investigation, however, shows them not to be glauconite. They are composed essentially of ferrous iron and silica, and lack potash, a constituent essential to glauconite. The granules, it is believed, were developed in much the same manner as the iron carbonates, which are the original iron-bearing rocks of the older iron districts. The iron (derived from the disintegration of older basic rocks) was carried in a ferrous form into the ocean, which was depositing iron formation material, and was there precipitated as hematite or limonite, and at the bottom of the ocean was again reduced by organic matter to a ferrous form, and then combined with silica, giving the substance we now find. The occurrence of the substance in granules is due to the same causes as the oolitic structure in limestone. After the iron formation, thus formed, emerged from the sea, weathering and the concentration of the ore began. The ferrous silicate was broken up and the iron oxidized. As the work was done through the agency of percolating underground waters, the position of the ore deposits was determined by the laws of flowage of such waters. The deposits are now found in gently pitching troughs formed by the gentle folding of the iron formations and bottomed by slaty layers,

or their altered equivalents, the paint rock, in the iron formation.

Dr. Whitman Cross then made some comments on an article by Mr. Bailey Willis dealing with stratigraphic classification. Dr. Cross expressed the belief that a geologic map should express as much of geologic development as practicable; that a map whose cartographic units were discriminated solely on the lithologic characters of the so-called 'lithologic individuals' was not entitled to be called a geologic map. It was really a lithologic map. He contended that in order to express geologic development the units of cartography must be established with due regard to all classes of available facts, and that restrictions were both undesirable and unnecessary.

ALFRED H. BROOKS,
Secretary.

DISCUSSION AND CORRESPONDENCE.

THE ENDOWMENT OF RESEARCH.

TO THE EDITOR OF SCIENCE: IN SCIENCE OF February 8, 1901, N. S., Vol. XIII, p. 201, there is an article by Professor E. C. Pickering remarking on and requesting suggestions in regard to the reasons why there is so little demand for grants from various funds which are available for research. I had hoped that some one with wide experience would have some suggestions to offer on this subject. But since no one, so far as I am aware, has published a reply, I am moved to offer a few thoughts of my own. I feel inclined to do so at this time because Mr. Carnegie has just endowed research on a magnificent scale, and, as some of the difficulties which have confronted Professor Pickering will doubtless confront the trustees of this fund, a discussion of the matter seems particularly desirable.

The lack of requests for research funds is not because there is lack of desire to do research work. There are plenty of students eager to investigate questions in which they are interested. More than a dozen have mentioned such a desire to me within the last ten years. Two or three of these were Harvard or Technology graduates, amply prepared by training to carry on such researches. I have

told all of them of the different research endowments with which I was acquainted and mentioned especially the two funds in which I knew Professor Pickering is interested as a trustee. However, I think not one of these persons applied for an appropriation from these funds.

I have sought the reasons for this, and I believe the chief one is that each person feels that in case such funds are granted he will be expected to give in return some tangible result or discovery, and who can tell when entering an unknown country whether anything will be discovered worthy of the name? The student may be compared to De Soto entering a new country in search of gold. He may find nothing but seemingly interminable forests, passage through which is beset by pain and even danger, and he may return discouraged without the expected gold, his work being regarded by himself and by the friends who helped him as an absolute failure. And yet, as De Soto discovered a land the great forests of which returned more value in gold than the wildest dream of the explorer, and where fertile valleys now support a population whose total wealth must be counted by millions of dollars, so a student seemingly finding nothing may really have discovered facts which a succeeding generation will consider of inestimable value. Even negative results are frequently of great value in pointing out the true road to the subsequent explorer. In my opinion, then, research funds should be administered in the broad spirit that all results are valuable, and while the funds should be made to feel that all that is required of him is an earnest effort in quest of truth and a guarantee that such an effort has been made.

The feeling that the trustees of these funds expect definite results has, I know, in my own case, except in one instance, deterred me from asking for grants. Many lines of investigation suggest themselves to me, and some of them I feel might be approved by the trustees, but I cannot be sure that the results will be what I had hoped or even worthy of publication; so I refrain from asking for grants, preferring to spend my own

money, however inadequate, in order that I may be free to publish results when I have any worthy of publication, and refrain when I have none.

Another reason why students do not apply for research endowments is because they are usually granted in sums so small as to be entirely inadequate for the work. No one can estimate exactly, and usually not even approximately, how much money it will take to penetrate an unknown region or attain an unknown result. He may find that if he accepts a small amount it will prove only adequate to allow him to learn the difficulties of the situation, and yet insufficient to allow him to obtain any results whatever. A remedy would be to give larger and less numerous amounts, or assure the student of more if the preliminary study is promising.

A third reason why many students do not apply is that most of the grants stipulate that no money must be spent for personal expenses. If a student is not wealthy this requirement means that he must give his best thought and spend the main part of his energy in earning a living, a duty which he cannot shirk, and give to research only the remaining fragments of his time, and perhaps a weary brain. Few care to undertake it. This aspect of the case, from the teacher's standpoint, is given by Professor E. L. Nichols in the article in *SCIENCE* which immediately follows that of Professor Pickering (Vol. XIII., p. 203). He says, "The tax upon the nervous system of the proper teaching of science is very great, and it is more often the want of surplus energy with which to carry on an investigation, than lack of actual time or of the necessary equipment that defeats us."

If the student has wealth he does not need endowments and usually does not ask for them, but prefers instead to give them. If all men with equal opportunities were equally capable of research, as is frequently, but erroneously, assumed, this restriction of research funds would not matter since the work of research could be left to the classes having wealth and leisure, while the others could do the necessary daily work of the world. But the talents of men are diverse. The military

genius of a Grant may be associated with an inability to acquire or even retain wealth. Inventions which have added enormously to the wealth of the nation have been made by men so poor that they were obliged to borrow money for living expenses. A prominent patent attorney with much experience recently said to me that he thought inventors as a class were without business ability, that is, without the ability to turn advantageously the product of their brains into money by means of which they could have leisure to do other work. No one can say how much the world has lost by the inability of the properly qualified men to give their best thought to discovery and invention. Had such a fund as that given for research by Mr. Carnegie been available in the past and been properly administered, the human race would in my opinion have been transformed into something immensely better than we have at present.

Hence, I believe that research funds, instead of prohibiting the payment of the personal expenses of the investigator, should be mainly devoted to the payment of such expenses, so that the investigator might be allowed to devote his whole time and his best thought to the investigation, even if for only a short time.

The funds thus administered would have plenty of applicants, and much work would be thrown on the trustees in seeing that the appropriations were made to the proper persons and properly used, but this is a task I think the trustees ought to assume.

A RARE 'WHALE SHARK.'

TO THE EDITOR OF SCIENCE: The National Museum has obtained a skin of a rare 'whale-shark,' *Rhinodon*, from an eighteen-foot specimen found on the beach three miles north of Ormond, Florida, January 25, 1902, this being the first record of the occurrence of the genus on the Atlantic coast of America. The Museum is indebted to Messrs. Anderson and Price, managers of the Hotel Ormond, who

telegraphed the discovery to the Smithsonian Institution and later had the skin removed and shipped to Washington under instructions from Dr. F. W. True, Head Curator, Department of Biology.

Rhinodon typicus was first figured and described by Dr. Andrew Smith in his illustrations of the zoology of South Africa, in 1841, the type being a sixteen-foot example found at the Cape of Good Hope.* Another one of this species taken at the Seychelle Ids. is known from the teeth only.†

A genus related to *Rhinodon* was described by Dr. Theodore Gill in the proceedings of the Academy of Natural Sciences of Philadelphia, 1865, p. 177, under the name *Micristodus*, from jaws, vertebrae and notes, received by the Smithsonian Institution in 1858, from Captain Stone, and taken from a twenty-foot shark captured in the Gulf of California, where it was known as the '*Tiburón ballenas*,' or 'Whale Shark.'

RECENT PROGRESS IN GLACIOLOGY.

OUR knowledge concerning glaciers past and present is gradually being extended by local studies in various parts of the earth. For several years, systematic effort has been made to record observations on the movements of existing glaciers for the sake of determining the conditions and laws governing their advance and retreat. Harry Fielding Reid has published a number of articles bearing on this general topic in recent years. The last of these articles‡ presents a summary of existing knowledge on the present phases of glacier movement in various parts of the world, with reference to advance and retreat.

Most of the glaciers of the Swiss Alps are retreating. In the eastern Alps about one half are retreating, while about one fourth are stationary, and nearly as many advancing. In

* Preserved in the Museum of the Jardin des Plantes, Paris.

† British Museum.

‡ 'Variations of Glaciers,' *Journal of Geology*, Vol. IX., pp. 250-254.

other parts of the Alps retreat is the rule. The meager records from Scandinavia indicate general retreat for the glaciers which have been under observation. The few available records from the United States (including Alaska), Canada, Greenland and Russian Asia indicate the same phase of glacier movement. In the Himalayas there has been little change observed in recent years. More extensive observations, carried on through long periods of time, are much to be desired.

A significant conclusion has been reached by Myron L. Fuller* in his studies of the glacial drift of eastern Massachusetts. He finds evidence of two distinct sheets of till, the lower being differentiated from the upper, both physically and lithologically. The physical difference is such as to indicate that the underlying sheet of till was subjected to extensive decay before the overlying sheet was deposited. This conclusion is in harmony with the recent interpretations put upon the drift in other parts of the State by other geologists, and with the interpretations which have long been given to the drift of the Mississippi basin.

Glaciation has been determined† in Siberia between the parallels of 35° and 36°, and near the 93d meridian there is evidence of glaciation in an area about one hundred square miles in extent. Among the glacial features are drumlins and cirques. Elsewhere cirques occur in the high Altai, and glaciers are now found in the same mountains about the sources of the Irtysh River, near the Mongolian border, at elevations of about 10,000 feet.

Several points of interest in connection with the Pleistocene glaciers in the western part of the United States have been determined during the past year.‡

Mr. Wallace W. Atwood has been studying the glacial drift of the Wasatch mountains, and has determined the positions of 50 Pleistocene glaciers exceeding a mile in length. Of

these, ten exceeded five miles in length; fourteen descended to an altitude of less than 6,000 feet, and seven to an altitude of 5,000 feet. Seven of these glaciers reached the shore-line of Lake Bonneville. The elevation necessary to give rise to a glacier was about 9,000 feet. Mr. Atwood and his party also found that the drift of the Wasatch mountains is referable to two distinct epochs of glaciation. In the valley of the North Fork of the American Fork, the two sheets of drift, produced by glaciation from nearly opposite directions, are separated by a soil thicker than that which covers the surface of the upper sheet of drift. Other evidences of the duality of the glacial period in this region are found in the unequal weathering to which different parts of the drift have been subjected, and in the unequal amount of erosion which the drift of different localities has suffered.

Pleistocene glaciation has been determined in the mountains of New Mexico near Santa Fe. The glaciation, so far as determined, was between the parallels 35° 45', and 36°, and between the meridians of 105° 35' and 105° 50'. Within this area, the positions of something like 50 Pleistocene glaciers have been determined, chiefly by Messrs. John Webb and William A. Averill. Study was carried far enough to indicate that local glaciation was the rule, in the vicinity of altitudes reaching or exceeding 12,000 feet. Some of the glaciers reached a length of several miles. The glacial features found in this region are such as are developed by small mountain glaciers.

Pleistocene glaciers were found to have existed on the north slopes of the Spanish Peaks of Colorado. The glaciers here were less extensive than might have been anticipated from the elevation of the mountains, but their small size is probably the result of the small extent of the areas attaining the requisite height.

In northwestern Montana, east of the Rocky mountains, Mr. F. H. H. Calhoun has studied the relations of the drift deposited by the Kewatin ice sheet to that deposited by the glaciers coming out to the eastward from the mountains. It appears from his work that the Wisconsin drift extended somewhat farther to the westward than has been supposed, reach-

* 'Probable Representatives of Pre-Wisconsin Till in Southeastern Massachusetts,' *Jour. of Geol.*, Vol. IX., pp. 311-329, 1901.

† 'A Single Occurrence of Glaciation in Siberia,' *Am. Geol.*, Vol. XXVII., pp. 45-47, 1901.

‡ 'Glacial Work in the Western Mountains in 1901,' by Rollin D. Salisbury. *Jour. of Geol.*, Vol. IV., pp. 718-731.

ing nearly to the Rockies in the region mentioned. The drift of the northeastern ice sheet overlapped that coming from the mountains, just south of the 49th parallel. This relation of the two bodies of drift shows that the continental ice sheet reached its most advanced position after the valley glaciers from the west had retreated. There is no evidence, however, that the interval between the deposition of the two bodies of drift was considerable. The Sweet Grass Hills, just south of the 49th parallel, and thirty miles back from the edge of the ice sheet, were nunataks. The slope of the surface of the continental ice sheet between its edge and the Sweet Grass Hills is estimated to have been about 50 feet per mile. A long narrow lake existed in front of the Keewatin ice sheet, the standing water resulting from the obstruction of drainage by the ice. The present drainage of the region is in many respects notably different from that which obtained in pre-glacial times.

Messrs. George Garrey and Eliot Blackwelder, partly in company with the writer and partly alone, made a number of determinations with reference to Pleistocene glaciation west of the Rockies and east of the Cascades. The boundaries of the Okanogan or Coulee City (Wash.) ice lobe, south and east of the Columbia River, were traced out. This ice lobe had previously been made known by Russell, and its general limits indicated. Messrs. Garrey and Blackwelder also determined the existence of a great glacier down the valley of the Columbia just west of the 118th meridian. This glacier descended the valley of the Columbia to the point where the Spokane River comes in. The eastern margin of this glacier looped northward around Huckleberry Mountain (Tp. 32, R. 38 E.), and to the east of this point another glacier descended the valley of the Colville River. These two glaciers were, therefore, separated only at their southern ends, becoming continuous to the north. The eastern margin of the Colville glacier, which descended to Springdale, probably connects around Old Dominion Mountain with the ice which descended the Pend d'Oreille valley. The ice of this valley descended southward to a point three miles southwest of

Davis Lake. A few data were also gathered concerning glaciation at points farther east.

Extensive deposits of loess were found in eastern Washington and northeastern Oregon. In geographic distribution, the loess corresponds, in a general way, with the wheat-growing areas of these States. Beds of volcanic ash are sometimes interbedded with the loess. Some of the loess, how much was not determined, had an æolian origin.

ROLLIN D. SALISBURY.

RECENT ZOOPLAEOLOGY.

A FOSSIL CAMEL FROM SOUTHERN RUSSIA.

PROFESSOR NEHRING,* of Berlin, describes the skull of a Pleistocene camel from beds along the Volga, in the same state of preservation as the mammoth, wild horse, reindeer and *Elasmotherium*. From the distribution of this and other Pleistocene camels in Roumania and Algiers, the author agrees with the view expressed by Lehmann (1891) that the dromedary and Bactrian camel originated in two distinct regions, the former being a *sub-tropical* steppe and desert animal, the latter belonging to the *subarctic* steppes and deserts.

FOSSIL REMAINS OF LAKE CALLABONA.

E. C. STIRLING,† director of the South Australian Museum, opens a series of memoirs on the large deposit of fossil bones discovered in the bed of Lake Callabona, South Australia, first reported in *Nature* in 1894. The present memoir is devoted to the manus and pes of *Diprotodon*, the largest and most abundant marsupial in this remarkable deposit. The salt clay in which the bones were embedded was always wet, the necessary excavations soon filling with water. Nevertheless fourteen feet were removed *en masse* within large balls of the matrix clay. Besides the great difficulties of removal the fossils had to be carried two hundred miles to a railway station, by camel

* 'Ein fossiles Kamel aus Südrussland, nebst Bemerkungen über die Heimat der Kamele,' *Sonderabdr. aus dem Globus*, Bd. LXXX., Nr. 12, pp. 188-189.

† 'Fossil Remains of Lake Callabona,' Part I. *Mem. Roy. Soc. S. Australia*, Vol. I., Part I., pp. 1-40, Pl. I.-XVIII, 4to. Adelaide, 1899.

transport. The limbs evidently rested chiefly on the carpals and tarsals, the phalanges and metapodials being extraordinarily reduced with the exception of the metatarsal of the fifth digit. The feet as a whole are comparable to those of the wombats, there being evidences of syndactylism and reduction in the second and third digits. A limb of *Genyornis*, the great struthious bird from this deposit, has recently been sent to the American Museum.

TRANSFERENCE OF SECONDARY SEXUAL CHARACTERS FROM MALES TO FEMALES.

IN this brief but important paper, Dr. C. I. Forsyth-Major* reviews Darwin's statement in the 'Descent of Man,' as to the probability that horns of all kinds, and canine tusks even when they are equally developed in the two sexes, were *primarily* acquired by the male in order to conquer other males and have been transferred more or less completely to the female. Darwin's inference did not rest upon paleontological evidence, and Dr. Major therefore reviews the evolution of the families of Cervidæ, Giraffidæ, Bovidæ and Suidæ, with the general conclusion that Darwin's inference was correct. He concludes with the remark, "In our own species the modern aspirations of women are to all appearances incipient signs of the same natural law. Physical and mental characters of man, originally acquired in the struggles of the males, are apparently being slowly transferred to women. They only require time for their full evolution."

HOMO NEANDERTHALENSIS A DISTINCT SPECIES.

PROFESSOR G. SCHWALBE† publishes in the proceedings of the *Anatomische Gesellschaft* an exhaustive study of the famous Neanderthal skull, which he concludes as follows:‡ "I believe I have shown that the Neanderthal skull is distinguished by no small number of characters which in many respects bring it much nearer that of the anthropoid apes

* *Geol. Mag.*, Dec. IV., Vol. VIII., 1901, pp. 241-245.

† 'Ueber die spezifischen Merkmale des Neanderthalschädels,' *Verh. der Anat. Ges.*, XV. versamm. in Bonn., 26-29 Mai, 1901, pp. 44-61, Svo. Jena.

‡ Translation and abstract.

than that of man. I therefore regard the position of King and of Cope in designating this as a type of a distinct species as entirely justified. I follow in this respect the modern practice of zoologists and paleontologists. This species is by no means to be included with the Paleolithic or Quaternary man; it is an older form, which is to be compared only with the skull of Spy, and the lower jaw found at Naulette. Very probably these skulls belong to the lowest diluvium, lying near the limits of the Tertiary, although the possibility must be admitted that *H. Neanderthalensis* may represent a persistent lower race contemporary with the newer Pleistocene *Homo sapiens*."

DISTINCTIONS BETWEEN THE SKULLS OF LEMURS AND MONKEYS.

DR. C. I. FORSYTH-MAJOR,* of the British Museum, has recently been comparing in a most exhaustive and critical manner the facial region of the lemurs and monkeys, and has especially shown that the commonly accepted view of the exposure of the lachrymal bone upon the face as a primitive character is probably erroneous. This has been one of the most frequently employed distinctions between lemurs and monkeys. He proves that, on the contrary, even in the supposedly ancestral Insectivora an exposed lachrymal and lachrymal canal are not a common character. In the fossil lemurs, *Adapis* shows the lachrymal bone and duct within the orbit. Among existing types the lachrymal is scarcely more frequent in the lemurs than in the higher groups, and the greatest known reduction of this bone occurs within the lemurs. The author's conclusion is that a great facial expansion of the lachrymal, and particularly its extension beyond the fossa lachrymalis is, in the lemurs, as well as in the monkeys, not a primitive condition, but an extreme specialization; it can always be traced back to an elongation of the facial cranium necessitated by a more powerful dentition. In the reviewer's opinions each elongation is not secondary but primitive.

* 'On some Characters of the Skull in the Lemurs and Monkeys,' *Proc. Zool. Soc.*, Feb. 19, 1901, pp. 129-153, Pl. XI-XIII.

DISTINCT PHYLA OF RHINOCEROSSES.

In 1900 Osborn attempted to demonstrate that the rhinoceroses, so far from being included in a single genus, should be separated into at least six lines of descent, which have been distinct for so long a period that they are almost entitled to subfamily value, extending back to the Lower Miocene and even probably into the Oligocene. Oldfield Thomas and R. Lydekker, of the British Museum, have recently accepted this conclusion in the main, and the former* proposes to divide the living types into three genera, namely, *Rhinoceros*, the Indian forms (*R. unicornis*, *R. sondaicus*), *Dicerorhinus* Gloger, the two-horned Sumatran types (Thomas points out that this name has the priority over *Ceratorhinus* Gray), and *Diceros* Gray for the African two-horned species (this name taking precedence over *Atelodus* Pomel). It is pointed out that Osborn was in error in describing the smaller African rhinoceros (*D. bicornis*) as dolichocephalic since its head is much shorter than that of *D. simus*, the white rhinoceros. Professor A. Nehring, of Berlin, also dwells in a recent paper upon the extraordinary dolichocephaly of the white rhinoceros, showing that the skull surpasses in length even the longest recorded skull of the woolly rhinoceros (*D. tichorhinus*).

H. F. O.

THE BOTANICAL SECTION OF THE CONCILIIUM BIBLIOGRAPHICUM IN ZÜRICH.

For some years past the increasing success of the Concilium Bibliographicum in the zoological part of its work induced a number of botanists to urge this institute to undertake a botanical bibliography on similar lines to those followed in zoology. Such a course was also recommended by the chief of the Swiss 'Department of Interior' in awarding the government subsidy to the work. Such wishes have always found a sympathetic echo with the committee in charge of the Concilium, as well as with the founder of the Institution. It seemed, however, unwise to extend the enter-

* 'Notes on the Type Specimen of *Rhinoceros lasiots* Scalter; with Remarks on the Generic Position of the Living Species of Rhinoceros.' *Proc. Zool. Soc.*, June 4, 1901, pp. 154-158.

prise to other branches, until the finances had become quite satisfactory. For this reason, no public statement of our intention in this regard has been made, save such general allusions as are to be found, for example, in the presidential address to the Botanical Section of the American Association meeting in 1900.

Recently, however, the committee of the new 'Association Internationale des Botanistes' has offered us means for organizing such a section of the Concilium without involving the latter in financial liabilities greater than it could with safety assume. The negotiations which were begun by telegraph late in January have been carried on with great rapidity, and we are now able to announce the organization of a botanical section comprising two energetic Zürich botanists, Dr. Stephan Bruneis and Mr. Emil Schoch-Etzensperger. For the year 1902 it is of course out of the question to issue a card catalogue. The year will be spent in preparation, so that the difficulties encountered in the first two years of the zoological card bibliography may be entirely avoided. Also no attempt will yet be made to record new species and genera, as is done in zoology. For the present merely the well-known bibliography of the *Centralblatt* will be continued, with certain minor improvements. The main object of this announcement is to make a direct personal appeal to all those who publish botanical papers, urging them to send copies to the *Concilium Bibliographicum*, Zürich-Neumünster, Switzerland. It is particularly important that this appeal should be brought home to editors and publishers of periodicals containing botanical notices; for the journals are far easier to excerpt than authors' reprints. Journals already reaching a Zürich library need not be sent; but we hope that all botanists will assure themselves of this fact before assuming that their collaboration in the matter of securing a given publication is unnecessary. The response that zoologists in America have given to our former appeals justifies the hope that their botanical brethren will show similar public spirit.

HERBERT HAVILAND FIELD.

ZÜRICH.

SCIENTIFIC NOTES AND NEWS.

THE twenty-fifth anniversary of the founding of the Johns Hopkins University and the inauguration of Dr. Remsen as president of the university were celebrated at Baltimore on February 21 and 22. The commemorative address of Dr. D. C. Gilman, for twenty-five years president of the university, and now president emeritus and president of the Carnegie Institution, and the inaugural address of President Remsen are published above, as is also the list of those on whom honorary degrees were conferred. The assembly of eminent educators, scientific men and others at the exercises was one of the most notable that has gathered in America. One of the most interesting events was the presentation to Dr. Gilman of an address signed by over 1,000 alumni and others who are or have been connected with the university.

THE University of Pennsylvania has conferred the Doctorate of Laws on Professor Wolcott Gibbs.

AT the annual general meeting of the Royal Astronomical Society on February 14, the Society's gold medal was presented to Professor J. C. Kapteyn, of Gröningen, Holland, for his work in connection with the Cape Photographic Durchmusterung, and his researches on stellar distribution and parallax. The Jackson-Gwilt (bronze) medal and gift was presented to the Rev. Thomas D. Anderson, of Edinburgh, for his discovery of Nova Aurigæ and Nova Persei.

DR. T. J. J. SEE, U. S. Naval Observatory, has been elected to membership in the Deutsche Mathematiker-Vereinigung, and to the Société Mathématique de France.

DR. ERNST VON BERGMANN, professor of surgery at Berlin, was given the title of privy councillor on the Emperor's birthday.

PROFESSOR MAX GRUBER, of the University of Vienna, gave the Harben Lectures before the Royal Institute of Public Health in January, the subject being 'Bacteriolysis and Hemolysis.'

MR. WILLIAM MARCONI sailed for Canada on February 22 to continue his trans-atlantic experiments in wireless telegraphy.

MR. C. E. BORCHGREVINK, the antarctic explorer, is at present lecturing in the United States.

PROFESSOR DUCLAUX, director of the Pasteur Institute, Paris, suffered recently an attack of hemiplegia. After lying in a critical condition for a number of days, he is now improving.

THE papers note that a marble statue of Professor Ernst Haeckel is being made by the sculptor Harro Magnussen.

MR. JOHN ACKHURST, a taxidermist residing in Brooklyn, died on February 15 at the age of eighty-six years.

DR. E. SELENKA, professor of zoology at Munich, died on January 20, at the age of sixty years.

THERE will be a civil service examination on April 2 for the positions of plant pathologist, chemist, physiological chemist and analytical chemist in the Philippine service. The salaries of these positions are from \$1,500 to \$2,000. There will also be filled by civil service examination on the same day the position of agrostological clerk in the Bureau of Plant Industry at a salary of \$720.

MRS. GEORGE WHITFIELD COLLETT has contributed \$5,000 to the endowment fund of the New York Botanical Garden, in memory of the late Josiah M. Fiske.

THE laboratory for the investigation of cancer in Buffalo has been removed into the building donated through the generosity of Mrs. Gratwick.

PROFESSOR B. TIRUSCH has bequeathed to the Museum of Natural History at Prague his library and estate, valued at \$25,000. He had previously given numerous specimens to the zoological, botanical and geological sections of the Museum.

MR. DEBOE, of Kentucky, has introduced a bill in the Senate to establish a university of the United States. It provides that the grounds set aside by Washington for a university, lately occupied by the U. S. Naval Observatory, are to be used as the site.

THE Minnesota Seaside Station party of 1902 plans to leave Minneapolis on July 12, at the close of the meeting of the National Educational Association. It will proceed via the Canadian Pacific Railway to Vancouver, thence by steamer to Victoria and finally to Port Renfrew by coasting vessel. The party will return to Minneapolis about September 1, giving a month or more by the sea and ample time for stops in the Rockies and Selkirks, arrangements for which have been made with the railway. The following staff is expected to organize the work of instruction and, as far as necessary, research, during the term of station activity: Professor Conway MacMillan, M.A., director-in-chief and lecturer on algology (Phæophyceæ); Professor Raymond Osburn, M.S., professor of zoology; Professor K. Yendo (Rigakushi), professor of algology (Rhodophyceæ); Miss Josephine E. Tilden, M.S., professor of algology (Chlorophyceæ and Cyanophyceæ).

THE annual report of Will. C. Ferrill, curator, State Historical and Natural History Society, Denver, Colorado, shows the following record for the past year. The additions to the library and historical collections were 1,159, and to the scientific collections, 3,425 specimens, making a total for the year of 4,584. This Society, which is both historical and scientific in its scope, now occupies fourteen rooms in the state house, and its museum was visited during the past year by 156,148 people. A valuable addition to the museum during the year was the Horace G. Smith Arapahoe County collection of about 650 birds, obtained in the vicinity of Denver. These, together with Colorado specimens obtained by Curator Ferrill in field work, added to an older collection, now give the department of ornithology about 2,500 specimens of Colorado birds.

It should have been stated in the issue of SCIENCE for February 14, page 269, that the original journals of Lewis and Clark will be published under the auspices of the American Philosophical Society.

A WRITER in the New York *Sun* states that the strange giant cactus, *Cereus giganteus*, is being exterminated by irrigation, and that

many years will not elapse before extinction has taken place. This is probably an extreme view of the case, for there must be many localities, comprising vast areas of land, where irrigation will not only not be attempted, but be impossible, and here the weird-looking plant may hold its own. The species attains a height of sixty feet and, contrary to popular belief, is short lived. Moisture is fatal to it and as soon as it receives a constant supply rapid decay sets in and destroys the plant.

AFTER being cut off from communication with the outside world for two and a half years in hitherto unexplored parts of mid-Asia, Dr. Sven Hedin, the Swedish explorer, reached India towards the close of December. In an outline of his expedition the London *Times* says that reaching Andijan by the Trans-caspian Railway in the middle of 1899, he traveled to Kashgar on horseback, and from thence sailed down the river Tarim, or Yarkunddarja, to Lob Nor, in the heart of Eastern, or Chinese, Turkestan. Making this place on the shores of the lake of the same name his headquarters, he took excursions of varying length through the Gobi Desert and over the great range of the Shian Shan mountains. Out of the 6,000 miles thus traveled only some 500 miles were along the tracks of earlier wanderers, all the rest having been unexplored. He discovered a series of ruined cities of Chinese and Mongolian origin, about 800 years old, and found in them some extraordinary sculptures and some ancient manuscripts of an extremely rare description. These cities would, he said, throw an altogether new light on questions affecting the distribution of the various human races and the migratory movements of Asiatic peoples. He went through the whole of the northern and central parts and a portion of Eastern Tibet, and through the great Gobi Desert in Western China. His last and most prolonged journey was right across Tibet, first from north to south and then from south to west. He proposed to publish three 'rather ponderous tomes of a scientific nature,' but he would first compile a large book for popular reading giving a description of his travels. He had taken over 4,000 photographs and numerous sketches. In scientific results this

was far and away the most important journey he had ever made, and he expressed his gratitude to King Oscar, and to some friends interested in scientific research for placing the means at his disposal for the journey.

The *Geographical Journal* states that it has lately been announced that an expedition, under the command of Lieutenant Héron, and including several other officers on its staff, was to leave Marseilles for Indo-China on January 12. Its object is to complete our knowledge of the coasts of Indo-China by accurate surveys, and to study the distribution of terrestrial magnetism in that region, besides carrying out general investigations in matters relating to hydrography and navigation. It sails under the orders of the Minister of Marine.

UNIVERSITY AND EDUCATIONAL NEWS.

THE gift of Mr. John D. Rockefeller to the Harvard Medical School of \$1,000,000 was conditional on \$765,000 being collected to meet the sum required for the removal and rebuilding of the school. Of this sum about \$600,000 has been subscribed in two weeks.

THE executors of the will of the late Jonas D. Clark have agreed to transfer \$800,000 to Clark University for the establishment of a collegiate department.

BUCHTEL COLLEGE at Akron, Ohio, has received an unconditional gift of \$20,000.

THE directors of the Pennsylvania Railroad have given \$5,000 to the fund for the rebuilding of the University of Wooster, destroyed by fire on December 11.

A BILL is now before the New York Legislature, appropriating \$200,000 for new buildings for the College of Agriculture at Cornell University.

THE State Department has notified President Butler, of Columbia University, of the receipt of a despatch from Minister Conger at Peking, which gives full information regarding the gift of books and other material to illustrate the instruction in Chinese subjects to be undertaken under the new Dean Lung or Charpentier foundation at the

University. The collection selected by the Foreign Office of China for presentation to Columbia is known as the T'u Shu Chi Ch'eng, a standard collection of ancient and modern works. It is the most comprehensive ever made in China and consists of more than 6,000 volumes, divided into thirty-two classes in which all facts regarding China are recorded and classified, all sources of information and all authorities cited and discussed.

IT is announced that hereafter students of the medical school of Yale University may complete the course in three years if they elect the necessary preliminary studies in the academic department.

DR. CHAS. H. JUDD, professor of psychology in the University of Cincinnati, has received a call to Yale University.

DR. J. W. MOORE, professor of physics, has been appointed dean of the Pardee Scientific Department of Lafayette College, succeeding the late Dr. T. C. Porter.

DR. W. F. SNOW has been made acting-head of the department of hygiene at Stanford University.

MR. S. E. BRASEFIELD has been appointed instructor in civil engineering in Lafayette College.

THE Universities of St. Petersburg, Kieff and Kharkoff have been closed, owing to the difficulties between the students and the authorities.

THE Government has dismissed all the European professors at the Imperial University of Peking, and Dr. Martin, the president, has been offered a subordinate position.

MR. F. T. TRONTON, M.A., F.R.S., has been appointed to the Quain chair of physics in University College, London.

MR. FREDERICK PURSER, fellow of the College, has been elected to the chair of natural philosophy in Trinity College, Dublin, lately vacated by Dr. Tarleton.

MR. GEORGE REYNOLDS, M.A., F.R.S., professor of engineering in the Owens College, Manchester, has been appointed to the office of Rede Lecturer at Cambridge University for the present year.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

AMERICAN SOCIETY OF BACTERIOLOGISTS.

The third annual meeting of the Society was held at Chicago University on December 31, 1901, and January 1, 1902. The President of the Society was Professor W. H. Welch, of Johns Hopkins University. The following are abstracts of the papers presented at the three sessions of the Society:

Conditions affecting the Thermal Death-point of Bacteria in Milk: H. L. RUSSELL and E. G. HASTINGS, State University, Madison, Wis.

The authors have tested the resistance of bacteria in the surface pellicle ('scalded layer') that forms on milk when it is heated to temperatures of 60°C. and above. They confirmed under commercial conditions the fact demonstrated by Theobald Smith under laboratory conditions that the resistance of the tubercle organism is materially increased when milk is heated in contact with the air. In order to demonstrate this increased resistance more clearly they further experimented with a peculiarly resistant coccus that they had found in milk, which had, in a vegetative stage, a thermal death-point of 75°C. when exposed for ten minutes in sealed tubes. In open tubes the organism retained its vitality as high as 82°C. When surface membranes were removed and plated on agar, colonies developed from them, but not from samples

of the milk below. The increased resistance is not due to lowered temperature at surface, as was shown by removing membrane and placing same in water, when it sunk to the bottom. The protection therefore afforded the bacteria is due to the nature of the membrane itself, preventing the heat from exercising the usual effect.

The Comparative Growth of Bacteria in Milk: H. W. CONN, Wesleyan University, Middletown, Ct.

This paper described a series of experiments, the design of which was to determine what species of bacteria develop in milk during the first twenty-four hours and what species disappear. The general purpose of the experiments was to determine as far as possible the relation of milk bacteria to the healthfulness of milk. The conclusions presented by the paper were as follows: (1) Milk freshly drawn from the cow contains a large variety of bacteria. (2) For the first six hours and sometimes more, there is no increase in the number of bacteria, even when the milk is kept at 70°. On the contrary, there is commonly a decrease due to what has been called the 'germicide power' of milk. (3) In the fresh milk the largest number of bacteria are streptococci, which come, in most cases, directly from the udder of the cow. (4) During the first forty-eight hours there is a very great increase in the number of bacteria, but the number present after one or two days' growth is quite independent of the number present at the start. In many cases milk, which when fresh contained a small number of bacteria, at the end of forty-eight hours contained a number far greater than other samples of milk which at the outset had a larger number of bacteria present. (5) During the first forty-eight hours there is a considerable increase in the number of streptococci, followed by their decrease and final

disappearance. (6) At the outset the number of lactic bacteria is extremely small, so small as, at times, quite to escape observation. (7) These lactic bacteria are, at least in the series of experiments described, derived from sources external to the cow and never, or rarely, from the milk ducts. (8) The lactic bacteria, though very few in number at the outset, increase far more rapidly than any other types, so that within twenty-four hours they are commonly in the majority, and by the end of forty-eight hours they commonly comprise considerably over ninety per cent. of all the bacteria present.

Rusty Spot in Cheddar Cheese: H. A. HARDING and L. A. ROGERS, N. Y. Agricultural Experiment Station, Geneva, N. Y.

Rusty spot is a bacterial trouble of cheddar cheese characterized by reddish-yellow discolorations scattered in points or blotches throughout the mass. The cheese does not become poisonous and the flavor is not affected, but the market price is reduced on account of the unusual appearance. This trouble is confined to a few factories, but a considerable part of their output is affected. A short, plump, causal bacillus was isolated by Cornell in 1898 and called *Bacillus rudensis*. By the addition of pure cultures to vats of milk he was able to reproduce the discoloration in the resulting cheese. In practice, the main source of trouble is the bacterial growth upon the factory utensils. However, there are often outside foci in connection with the dairies, capable of reseeding the factory after it has been once freed from the infection by a careful cleaning and disinfection. The direct application of steam to all the factory utensils on three days each week was tried in three infected factories during the past season. This is most easily accomplished by placing all

the small utensils in the large vat, drawing a canvas cover over the same and forcing steam into the vat for twenty minutes. This treatment was highly successful in two factories and fairly so in a third where the outside influences were quite unfavorable.

On the Apparent Identity of the Cultural Reactions of B. coli communis and Certain Lactic Bacteria: S. C. PRESCOTT, Massachusetts Institute of Technology, Boston, Mass.

While engaged in an examination of certain lactic bacteria, the author was impressed with the similarity presented by some of the cultures to *B. coli communis*, and has carried on investigations with a large number of lactic-acid-producing organisms, comparing their cultural reactions to those of *B. coli*. He defines the colon bacillus as a short, motile rod of intestinal origin, which forms thin, irregular films upon the surface of gelatin; produces no liquefaction; gives nail growth in stick cultures; a whitish translucent layer upon agar; a more or less abundant, moist, yellowish growth upon potatoes; produces turbidity and some sediment in broth; ferments dextrose and lactose with the formation of gas; reduces nitrates to nitrites; coagulates milk; reduces litmus with subsequent slow return of the color, and produces indol.

The lactic acid group is broadly defined as consisting of those bacteria in which the ability to bring about the fermentation of sugars to lactic acid is strongly developed. Forty-seven cultures were isolated from the following sources: bran (7), fresh meat (3), sour milk (4), flour (2), cornmeal (6), buckwheat (7), barley (4), butter culture (3), an acid-producing organism in technical use (5), and a breakfast food (2). All these were tested in the following particulars: growth on lit-

mus, lactose agar, gelatin agar, milk, dextrose broth, nitrate solution, Dunham's solution, bouillon and potato; and were further compared morphologically with relation to motility and spore formation, and with relation to air. Of the forty-seven cultures examined, twenty-five gave the typical colon reactions; six gave the tests weakly or failed in one test only, while the others failed in a greater degree. Some of the bacteria from most of the sources gave typical colon reactions.

The author points out two views that may be entertained regarding these bacilli: (1) They may be true colon bacilli from sources which can only be conjectured, or (2) they may be lactic acid organisms, not absolutely identical with the colon bacilli, but yet almost impossible to differentiate from them. The latter view the author regarded as more probable. Of great importance is the fact that had they been isolated from water they would have been undoubtedly regarded as colon bacilli. Hence the work has a very practical sanitary bearing and indicates that too much reliance must not be placed upon the so-called colon test of potable waters.

Oysters and Sewage in Narragansett Bay:

CALEB A. FULLER, Brown University, Providence, R. I.

The city of Providence discharges, daily, about 14,000,000 gallons of sewage into upper Narragansett Bay, chiefly through a single main. This sewage is carried down the bay by tide and comes into more or less direct contact with some of the oyster beds. Samples of water and oysters were collected from different localities in the bay, and analyses made before the material was six hours old. The ordinary tests for sewage contaminations were used, the fermentation tube, carbol broth and litmus lactose agar.

The results showed: (1) That water,

oysters, mussels and clams from a point one quarter of a mile distant from the sewer opening contained *B. coli*, *B. cloacæ* and *Bact. lactis aërogenes*. (2) That water and oysters from a bed two miles below the sewer contained the same organisms. (3) That thirty per cent. of the oysters and about sixty per cent. of the water samples from a bed situated in a strong tidal current, about five miles from the sewer, contained *B. coli*. (4) That forty per cent. of the oysters and seventy per cent. of the water samples from a bed in sluggish water, five and a quarter miles from the sewer, contained *B. coli*. (5) That oysters from a bed six miles below the sewer contained *B. coli*. (7) That oysters from a bed six miles and one half below the sewer contained no colon bacilli; the water contained *B. coli* only occasionally and then on a falling tide. (7) That beds still farther down the bay were entirely free from contamination.

Toxicity of Water toward Pathogenic Bacteria and the Possible Significance of the same in the Spontaneous Purification of Polluted Waters: H. L. RUSSELL, Madison, Wis.

The preliminary data here reported have to do with the action of natural water on the vitality of various bacteria, particularly pathogenic organisms. When typhoid and colon organisms (several cultures of each) were inoculated in boiled waters (surface, deep well, spring) growth generally occurred. This was more marked with the colon than with the typhoid, and was more pronounced where the seeding was light. When the same cultures were exposed to the action of water filtered through a Chamberland or Berkefeld filter, or to etherized waters in which the anæsthetic had been removed by aspiration, growth not only did not take place, but the numerical content was greatly re-

duced, so that the cultures were often sterile in twenty-four hours. Further test showed that this toxicity of filtered water was lost when heated to about 60°C. for ten minutes. The origin of these toxic substances is ascribed to the development of water bacteria, as shown by taking boiled lake water and seeding the same with water bacteria. After incubation for thirty-three days, this water was again filtered and found toxic for typhoid and colon, which toxicity was again lost by reheating. Some bacterial species develop luxuriantly in standing water and, in some of the cases, it was found that these grew quite rapidly in filtered water, indicating their ability to tolerate the toxins. The relation of this toxicity to the destruction of pathogenic and faecal organisms in water was suggested.

The Bacteria of the Ames Sewage-disposal Plant: L. H. PAMMEL, Agricultural College, Ames, Iowa.

The Ames sewage disposal plant has been in operation since 1898. During this time bacteriological, chemical and temperature records have been kept; account also has been taken of the flow of raw sewage and the effluent. These records indicate that this form of sewage disposal is a most efficient one, and is adapted for many inland towns. The average number of bacteria per c.c. in the effluent from January to December, 1899, inclusive, was 5,127. For the year 1900 the record is somewhat incomplete, arising from an unavoidable loss by fire; but from January, 1900, to September, 1900, inclusive, it was 5,414, having been as efficient as the previous season, the smallest number having been found during August, when there were 546. In January the average was 830; in September, 850. The average number of bacteria in the manhole, from August, 1899 to September, 1900, inclusive, was 639,720.

The average number of bacteria in tank during the same period was 446,611. The records during 1901 are as follows: Average number of bacteria per c.c. in effluent, 14,785; average number of bacteria per c.c. in manhole, 1,318,328; the average number of bacteria per c.c. in tank, 1,667,522.

No effort has been made to study a large number of different forms found in the effluent. *B. cloaca*, *B. coli communis*, *B. liquefaciens fluorescens* and *Sarcina aurantica* have been found. *Bacillus prodigiosus* has also been found. This was introduced from the Manhattan sewage in 1900. That season it was found three times in the tank on June 19, in the east effluent on June 22, and in the west effluent on June 27. It was not found again till August, 1901, when it appeared in the effluent and continued to appear until the first of September. Various media were used. The Nüsterstoff Heyden did not prove better than either pepton agar-agar or pepton gelatin. The blue litmus-agar and gelatin are excellent for differentiation.

On the Germicidal Action of the Organic Peroxides: Drs. F. G. Novy and P. C. FREER, University of Michigan, Ann Arbor, Mich.

The investigation of the authors was begun with the object in view of finding the correct explanation of the action of metals and of sunlight upon bacteria. As is well known, certain metals, such as gold and copper, exert a marked inhibiting and even germicidal effect upon some bacteria. The studies of Miller, Behring and Bolton, Thiele and Wolf, have fully established the above-mentioned fact, but the interpretation of the results has not been wholly satisfactory. The fact that various surfaces, such as metals and fabrics, exert a marked effect upon the formation of benzoyl acetyl peroxide was established by the authors and served as a basis for the view that met-

als act upon bacteria by giving rise to energetic peroxides, which, of necessity, must be more active than ordinary peroxides. The action of sunlight has been ascribed by different workers to hydrogen peroxide, but the destructive action observed is greater than that which can be credited to this body. In order to substantiate the theory of the authors regarding the action of metals and of sunlight, it was deemed necessary to investigate the action of a number of known organic peroxides. The results show that some of these bodies, such as acetone peroxide and dibenzoyl peroxide, are wholly inert.

On the other hand, solutions of diacetyl, benzoyl acetyl, and of benzoyl hydrogen peroxides, and of phthalmonoperacid, exert pronounced and even remarkable germicidal properties. With reference to diacetyl peroxides and benzoyl acetyl peroxide, it was shown that the bodies themselves are chemically and bacterially inert, but on contact with water they undergo hydrolysis and give rise to the extremely energetic acetyl hydrogen and benzoyl hydrogen peroxides.

A solution of these peroxides (1:3,000) is capable of destroying all pathogenic bacteria, and even such resisting spores as those of the potato bacillus, within one minute. Cholera and typhoid germs added to tap water are promptly destroyed by the addition of one part of peroxide to 100,000 parts of water. The authors point out the probable value of these peroxides in the prevention and cure of these and allied diseases. The destruction of bacteria in the mouth and saliva takes place with extraordinary rapidity and the reagents have shown themselves useful in diseases of the mouth.

The powerful effects of the organic peroxides is not explainable as due to nascent oxygen, since a solution of hydrogen peroxide, which will produce equal germicidal

action, contains one or even two hundred times as much nascent oxygen. The authors incline to the belief that the acetyl and benzoyl ions are the active agents.

Full papers upon this subject will appear in the *Journal of Experimental Medicine* and in the *American Journal of Chemistry*.

The Etiology of Yellow Fever: WALTER REED, M.D., Surgeon U. S. Army, and JAMES CARROLL, M.D., Contract Surgeon, U. S. Army.

In former contributions to this subject the authors have shown by observations made on human beings that yellow fever may be produced in the non-immune individual either by the bite of the mosquito (genus *Stegomyia*) or by the subcutaneous injection of a small quantity of blood (0.5 to 2 c.c.) drawn from the general circulation of a patient suffering with this disease. Thus far, however, microscopic examination of the blood, as well as of the bodies of infected mosquitoes, has proved negative. Cultures taken from the blood during the active stages of the disease also have yielded equally negative results. Leaving out of consideration, therefore, for the present the further microscopical search for the specific agent, both in the blood of the sick and in the bodies of infected mosquitoes, the authors presented some additional observations bearing on the etiology of the disease. In conducting these experiments they have been guided by the observations of Loeffler and Frosch on the foot and mouth disease of cattle, wherein it was conclusively demonstrated that the specific agent of this disease was so small as to readily pass through the pores of a porcelain filter.

Adopting the same line of procedure, it was ascertained that in yellow fever the blood serum which has been filtered through a Berkefeld laboratory filter is

still capable of producing this disease when subcutaneously injected in small quantity (1.5 c.c.) into non-immune human beings. The authors reported an attack of yellow fever after the usual period of incubation in two out of three individuals thus treated, and further stated that the blood drawn from one of the cases produced by the injection of the filtered serum was capable of producing an attack in a third individual, when injected in small quantity; thus proving that the specific agent had really passed through the filter. They were also able to show that the blood in yellow fever, when heated to a temperature of 55°C. for ten minutes is quite innocuous if injected into susceptible individuals. The specific agent of yellow fever therefore is destroyed or markedly attenuated by this degree of heat.

Brain Abscess in Typhoid Fever due to Bacillus typhosus: R. W. McCLINTOCK, Rush Medical College, Chicago, Ill.

There are mentioned in the literature up to August, 1901, nineteen cases of meningitis and five of abscess of the brain in connection with typhoid fever, *Bacillus typhosus* having been present in all the cases of meningitis, but not found in any case of abscess of the brain.

Clinical History.—Temp. 101° A.M. to 104° P.M. In second week, rose spots appearing on 8th day, nausea on taking food; diazo-reaction questionable. Third week, agglutination test probably positive. Fifth week, 33d day, three epileptiform convulsions at intervals of forty minutes, followed by clonic spasms lasting five minutes, very much more marked on the right side than on the left; pupils equal. Much mental confusion in following two weeks, with marked amnesic aphasia. During eighth week, much better. In ninth week spasms returned, with coma, terminating in death on the 66th day.

Autopsy.—Suppurative basilar meningitis; abscess of left temporal lobe; purulent exudate in lateral ventricles; healing typhoid ulcers in ileum; acute splenic tumor; cloudy swelling of solid viscera; moderate diffuse arteriosclerosis; chronic interstitial nephritis.

Histology.—The organs show the usual typhoid appearances. The wall of the brain abscess shows a capsule, with purulent exudate inside, and regenerative changes outside; and with groups of short blunt bacilli with rounded ends, both inside and outside the capsule.

Bacteriology.—The cerebellar exudate and the cerebral abscess both contain in pure cultures an actively motile bacillus of typhoid-like morphology, which from its growth on differential culture media and from its reactions with typhoid serum, and the action of its specific serum on typhoid and allied bacilli, is evidently *Bacillus typhosus*. The same organism, together with *Bacillus coli communis*, is also present, in the liver and kidney; the lung contains *Staphylococcus pyogenes citreus*; the blood from the heart and the kidney is sterile.

The Diplococcus scarlatinae: W. J. CLASS, M.D., Chicago, Ill.

The author gives a brief description of a germ which he considers the etiologic factor of scarlet fever. This germ is a polymorphic coccus, usually occurring as a large diplococcus. It stains with any of the ordinary aniline stains, has no capsule and no independent motion. It forms small grayish-white colonies upon a special medium devised by the author, consisting of glycerine agar to which five per cent. of garden earth has been added. It also grows to some extent upon blood serum and in bouillon. It is found in the throat secretions, blood scales and urine of patients suffering from scarlet fever. It is also found in certain cases of angina which

are probably scarlatina sine eruption. Control experiments have been made showing that the germ is found practically only in cases where contact with scarlet fever patients can be traced. Swine, guinea-pigs and mice are susceptible to the diplococcus. In swine a disease characterized by fever, a red rash and subsequent scaling has been produced by Gradwohl Jaques and the author. Organs from these animals examined histologically by Le Count showed the changes usually found in fatal cases of scarlatina. Experiments were made regarding immunity. These showed that blood from a scarlet fever patient conferred immunity against the *Diplococcus scarlatinae*. Guinea-pigs were also immunized by means of blood serum from a pig that had been injected with gradually increased doses of the toxin. The author gave the following reasons why he considers this diplococcus to be the causative factor of scarlet fever. (1) Because the germ is invariably present in cases of scarlatina. (2) Because it is a decidedly pathogenic microorganism. (3) Because with it a disease can be reproduced in swine which closely resembles scarlet fever. (4) Because blood serum from a scarlet fever convalescent exerts an inhibitory effect upon the germ, whether in the body or in culture. (5) Because the germ grows in milk without producing any change in the medium. (6) Because the disease produced in mice and swine is contagious. (7) Because the authors' findings have been corroborated by reliable observers so often that errors of observation can be excluded. In closing, the author makes a plea that the germ be given a thorough investigation, as he feels certain that unprejudiced work will show the truth of his statements.

A Contribution to the Physiological Differentiation of Pneumococcus and Strepto-

coccus, and to *Methods of Staining Capsules*: P. H. HISS, M.D., College of Physicians and Surgeons, New York.

The author believes that up to the present time it has not been demonstrated that pneumococci and streptococci can at all times be clearly differentiated from each other. Well-marked capsules have been found by various observers to occur on organisms more reasonably classified as streptococci than as pneumococci. On the other hand, capsules may not be demonstrable by the usual methods on pneumococci, especially when these organisms are growing on artificial media. Pneumococcus cultures may also show a predominance of chains, while streptococci may occur in pairs. The usual cultural characters and reactions of these organisms are at the best not diagnostic, and are subject to variations.

Experiments by the author, with cultures of pneumococci and streptococci from many different sources indicate well-marked, constant differences between the metabolic activities of pneumococci and those of streptococci. These differences in metabolism become apparent when the organisms are cultivated in the following media: (1) A medium composed of ox serum, one part; distilled water, two parts; normal sodium hydroxid, 0.1 per cent. (2) A medium composed of ox serum, one part; distilled water, two parts, and inulin, 1 per cent. These serum media are not coagulated by boiling and are sterilized at 100°C. Acid is formed in each of these media by pneumococci when grown at 37°C., and a solid yellowish-white coagulum results. The coagulation is rapid in the inulin medium, slower in the alkaline. Streptococci do not form acid in these media, and no coagulation occurs. These media have, therefore, in all instances, served to differentiate pneumococci from streptococci.

Other mono-, di- and poly-saccharids were tested in media made in the same manner as the inulin medium, but were fermented and the media coagulated, by various members of the streptococcus group, as well as by pneumococci. Hence, these carbohydrates are not of use in differential tests. Special methods were devised for demonstrating capsules on pneumococci and streptococci. Chief among these was to grow the organisms on ascitic serum agar, preferably plus one per cent. glucose. Spread the organisms on the cover-glass by mixing with a drop of serum, or a drop of one of the fluid serum media. Dry in the air and fix by heat. Then stain for a few seconds in a one half saturated aqueous solution of gentian violet. Wash off with a 0.25 per cent. solution of potassium carbonate, mount and study in this solution. This is a good stain for capsules of pneumococci in blood or serum of infected animals. Pneumococcus capsules may also be stained by the following method and be mounted in balsam without injury. A five per cent. or ten per cent. solution of gentian violet or fuchsin (500 sat. alcoholic sol. gentian violet plus 95 e.c. distilled water) is used. This is placed on the dried and fixed cover-glass preparation and gently heated until steam arises. The dye is washed off with a twenty per cent. solution of copper sulphate (CuSO₄ cryst.). The preparation is then dried and mounted in balsam. By these methods most streptococci were found to have capsules.

Well-marked examples of encapsulated organisms, such probably as those which have been described by some investigators, and separated by them into new species distinct from *Streptococcus pyogenes*, or with no certainty differentiated from pneumococci, have been examined and have been found to correspond to *Streptococcus pyogenes* in the media mentioned in this paper.

The conclusion from these facts is that such encapsulated organisms should with hesitation be separated from *Streptococcus pyogenes*, unless well-marked cultural differences can be shown to exist.

Branching in Bacteria, with Special Reference to B. diphtheriæ: HIBBERT W. HILL, M.D., Boston Board of Health Bacteriological Laboratory.

The chief problems considered divide themselves into morphological and physiological or developmental problems. The general subject is one of fundamental importance, theoretical and, in its relation to diagnostic work, practical.

The principal hypotheses to be considered as offered to explain branching may be briefly stated: (1) Accidental opposition. (2) Budding from single-celled rods. (3) The turning aside of a medial cell in a chain of closely connected cells, supposed to compose the larger bacterial rods, and the subsequent 'chaining out' of such a cell (Nakanisch's view). (4) The development of a medial melochromatic granule of a new rod. (5) Involuntary changes.

The writer describes the results of the examination of individual bacilli developing in a moist warm chamber under the microscope and concludes: (1) That degenerative (involuntary) changes do at times give rise to distortions distantly simulating branches. (2 and 3) That active branching, by apparent budding resulting in multiplication, does occur in young (five to ten hours old) cultures on agar. (4) That various modifications of the process exist. (5) That such branching may be reversionary or evolutionary in character, but involuntary only in the case noted above (1).

A review of the literature and consideration of nomenclature follow, and a number of drawings are given in the full article.

'Hanging Block' Preparation for Microscopic Observation of Developing Bacteria: HIBBERT W. HILL, M.D., Boston Board of Health Bacteriological Laboratory.

The writer cuts a cube of nutrient agar from a Petri dish full of solidified jelly. The organism to be examined, as an emulsion in water from a solid culture, or as a drop of broth from a liquid culture, is spread upon the upper surface of the agar, as in making an ordinary smear preparation on glass. After drying the cube at 37°C. for ten minutes, a clean cover-slip is applied to the inoculated surface and sealed in place by running a little melted agar round the edges of this surface. The cover-slip is then placed over the opening in the moist chamber, the agar block lowermost, and the microscope focused upon the bacteria. For organisms growing best at 37°C. some form of warm chamber is necessary. The writer describes two such warm stages, devised by himself, and a very simple method of securing a circulation of warm water through them.

A System of Recording Cultures of Bacteria Genealogically for Laboratory Purposes: BURT RANSOM RICKARDS, S.B., Boston Board of Health Bacteriological Laboratory.

The writer applies to the recording of all individual tube cultures of bacteria and the data relating to them a modification of the Dewey Decimal System under card catalogue entries to correspond. Each species is known by some whole number in the hundreds (or thousands if a great many cultures of one species are to be dealt with). Thus:

<i>B. coli</i> =100,	<i>B. diphtheriæ</i> =300,
<i>B. typhi</i> =200,	<i>B. mallei</i> =400.

Individual specimens of any one species are numbered in the order of their isola-

tion, 1 to 49 (or 1 to 499 if the species are numbered in the thousands). Thus:

B. mallei from one horse=401,

B. mallei from a second horse=402,

B. mallei from a different lesion in the second horse=403.

The first culture isolated pure is given a number in the first place of decimals—thus the pure culture of glanders bacilli from the first horse mentioned would be 401.1.

Subcultures are expressed by the number of the original culture with the figure 1 placed in the next right place of decimals. If further subcultures (sister cultures) are made from the same mother culture, they are differentiated by increasing this last new figure in arithmetical order. The system is very simple, very accurate, very elastic, and, construed under the card catalogues described, saves an enormous amount of work, and ensures a complete record of every tube used.

Variety of the Hog Cholera Bacillus which closely resembles Bacillus typhosus:
M. DORSET, Biochemic Laboratory,
Washington, D. C. (By title.)

The author described a variety of the hog cholera bacillus which was isolated from a virulent outbreak of hog cholera in Page County, Iowa. This variety corresponds in every way with the hog cholera bacillus as usually seen, except in its action upon glucose, which it ferments without the evolution of gas. The failure to produce a gaseous fermentation of glucose places this variety of the hog cholera bacillus culturally closer to *Bacillus typhosus* than to the hog cholera group of bacteria. A comparison with several cultures of *Bacillus typhosus* has shown that culturally this variety of hog cholera bacillus cannot be distinguished from some of them; but the author concludes that when the source and pathogenic properties of this variety

are considered, it should be classed among the hog cholera bacteria.

The Morphology of Bacillus Diphtheriæ:

FREDERIC P. GORHAM, Brown University,
Providence, R. I.

The experiments described were made for the purpose of proving that the long, granular form of the diphtheriæ bacillus, type C of Westbrook, can be changed into the short, thick, solid-staining, sometimes double-headed bacillus, type D² of Westbrook. A pure culture of type C was made from a clinical case of diphtheria. After several platings a culture was obtained that showed only long granular forms, careful search and the use of Neisser's stain failing to demonstrate a single bacillus of any other type. Plates were made from this culture and some thirteen colonies examined. The colony that showed the largest number of shorter forms was selected, and plates made from it. This process of selection and plating was continued for some fifteen generations.

The colony of the fourth generation was composed of forms distinctly smaller than those of the original culture; all were still granular, however, and stained by Neisser's method. In the fifth generation, some of the bacilli failed to show granules by Neisser's method, were barred, and of the type C of Westbrook's. In the eighth generation many of the bacilli failed to react to Neisser's stain, and a large number of barred and solid staining forms were present. Some of these approached the double-headed type D². On continuing the selection until the fifteenth generation all the granular forms were eliminated and the colony became a pure culture of the type D²; the majority of forms were of the double-headed variety.

The experiment is being continued by testing the various types for virulence. From the results already obtained it ap-

pears that the different forms of the *Bacillus diphtheria* can be produced by the variations of a single type.

An objection to the validity of these results, of course, can be made by the claim that pure cultures of the various types were not used. The objection seems to me not well taken, on account of the large number of platings and the fact that several generations were passed before any change appeared. These experiments are directly in line with the results already obtained by the author in the study of the changes of form observed in the diphtheria bacillus in the noses and throats of persons immune or becoming so.

A Note on Branched Forms of Tubercle Bacilli Found in Cultures: M. DORSET, Biochemic Laboratory, Washington, D. C.

The author describes branched tubercle bacilli found in a six weeks' old bouillon culture of human tuberculosis which had become contaminated with a streptothrix. The branches were always Y-shaped and, from various stages in the branching found in cover preparations, the author concludes that the branching has probably taken place in the following manner: The end of a rod first enlarges and then probably separates into two small knobs, which forms have been seen in the cover preparations. These separate knobs grow out and constitute the branches.

An Undescribed Pathogenic Diplococcus:

H. GIDEON WELLS, Chicago University.

This was obtained first in cultures from a subcutaneous abscess on the thigh of a woman, aged twenty-two, with the following history: When sixteen years of age her hand was badly cut by a piece of window glass. The wound became infected and it was nearly a year before it entirely healed. During this time she developed a number

of subcutaneous abscesses on other parts of the body, which healed slowly. During the six years that have followed she has had, at varying intervals, seldom more than three months, recurrences of the subcutaneous abscesses, which have appeared at one time and another, over almost the entire body. They appear independent of any injury or other known exciting cause, and produce only slight constitutional symptoms. The patient is in fair health otherwise, and is able to work except when an abscess is developing. Physical examination gives no information. Blood count shows 3,862,000 red and 7,100 white corpuscles two hours after dinner. Cultures from a vein gave the *Diplococcus* in pure culture at a time when the patient was free from abscesses. Inoculated into animals, the *Diplococcus* sometimes fails to cause any change. Sometimes it produces a slow emaciation which does not terminate fatally, but more often it causes local abscesses. The most characteristic fact is that it can be obtained from the heart's blood of these animals long after subcutaneous or intraperitoneal inoculation, even when there have been no local lesions, and when the animal seems well. It often produces abscesses at the sites of injuries several weeks or months after inoculation; in one case, after four months.

Morphologically, it resembles the *Gonococcus* in fresh cultures, sometimes later, becoming more a double sphere. It seldom forms chains or tetrads, does not destain by Gram's method, possesses a capsule that is difficult of demonstration in culture, grows well on all ordinary media, liquefies gelatin after three or four days at 24°C., with production of a funnel-shaped excavation filled with fluid. It produces no gas nor indol; slowly acidifies milk; produces no pigment; its growth is slimy and rather tenacious both in solid and liquid media.

The Distribution of B. coli communis in Natural Waters: C. E. A. WINSLOW, Massachusetts Institute of Technology, Boston, Mass.

The work of certain observers has shown that organisms apparently identical with *B. coli communis* are found widely distributed in nature. The problem for the bacteriologists, and especially for the sanitarian, becomes, then, a quantitative one. Even if this organism does occur in various places in the outside world, may it not still be true that it thrives only, or at least most abundantly, in the intestine of the higher vertebrates, and that an overwhelming proportion of the individual representatives of the species occurs in that habitat? May it not be true then that while the *Bacillus coli* is found at times in unpolluted waters, its presence, constantly, or in numbers, is still characteristic of sewage pollution? As a preliminary contribution to this question a number of presumably unpolluted waters in the neighborhood of Boston have been examined for the *Bacillus coli*. In each case one centimeter of the water was incubated in dextrose broth and one hundred cubic centimeters were incubated with the addition of phenol-glucose broth. From the one hundred cubic centimeter bottles, after incubation, dextrose broth was inoculated, and from all dextrose tubes showing gas, litmus-lactose-agar plates were made. Three characteristic colonies were fished from each reddened litmus-lactose-agar plate, and subcultures inoculated. Only those which gave the following reactions were considered as *B. coli*: The fermentation of dextrose broth with the production of gas in twenty-four hours; the fermentation of lactose in the litmus-lactose-agar plate, with distinct reddening in twenty-four hours; the coagulation of milk in twenty-four hours; the production of nitrite from nitrates in twenty-four hours; the production of indol in pep-

tone solution in three days; the formation of an abundant growth covering nearly the whole surface of the agar streak in twenty-four hours, later becoming whitish and cheesy, but not stringy to the needle; the formation of round or oval white colonies in the gelatin shake culture, often with gas bubbles, with no liquefaction of the gelatin in seven days. The use of one hundred cubic centimeters appears in these experiments to have increased the proportion of dextrose and lactose fermenting organisms, but not of colon bacilli. The investigation included the study of seventy-nine samples of water. The results lead to the conclusion that the colon bacillus is so rare in normal unpolluted waters as to be found infrequently when single centimeters of the water are examined. The presence of this organism, constantly, or in a majority of cases, in one cubic centimeter, may still be assumed to be due to the entrance of some polluting substance.

Preliminary Observations on B. coli communis from Certain Species of Animals:
VERANUS A. MOORE and FLOYD R. WRIGHT, Cornell University, Ithaca, N. Y.

A study has been made of *B. coli communis* found in a single place in each of the large and small intestines of nine horses, eleven cattle, eight sheep, four swine, eight dogs and six chickens. This organism was not found in the intestines of six frogs, two young and one old rabbit. It had previously been found in several rabbits. These animals were all supposedly healthy and, excepting the frogs and rabbits, were for the greater part killed for dissection or food. Cultures in bouillon from six colonies from the gelatin plate cultures from each of the large and small intestines were made; these were replated, and from the colonies which developed on them subcultures were made and studied on gelatin, agar and potato; in milk,

bouillon, and in bouillon containing one per cent. dextrose, lactose and saccharose. The degree of motility and the indol reaction were also considered.

The purpose of these examinations was to find the extent to which varieties of this bacillus exist normally in the intestines of both different individuals of the same species and of different species of animals. This was to determine if the many varieties of the colon bacillus which have been described from polluted water, soil and from lesions of various kinds in man and animals, have their natural existence in the generally supposed normal habitat of this species of bacteria. The results showed no pronounced variation in the morphology or the cultural characters of these bacilli from different sources on gelatin, agar, potato and bouillon. The action on the sugars, milk and the indol production differed somewhat. The two varieties, A and B, described by Smith in 1896 were found. The A variety, *i. e.*, those that ferment, with gas production, dextrose, lactose and saccharose, and the B variety, *i. e.*, those that do not ferment saccharose, were found in about equal numbers in each species of animals. Other varieties did not appear, although there were slight variations in the quantity of gas, the gas formula, and the time required for the milk to coagulate. The cultures from different colonies from the same plates did not show any appreciable difference except in one instance, from a dog. The plate cultures made from one dog did not develop colonies resembling those of *B. coli communis*. The cultures from dogs were more virulent for guinea-pigs than those from the other species of animals. The action on the sugars was considered of the most differential importance.

Color Standards for Recording the Results of the Nitrite and Indol Tests: C. E. A.

WINSLOW, Massachusetts Institute of Technology, Boston, Mass.

In studying the effect of certain external conditions on the reactions of the *Bacillus coli communis*, need was felt of some definite standard by which to measure somewhat quantitatively the capacity for nitrite and indol production. It is true that even when the conditions of the experiment—the composition of the medium, the amount and character of the culture used for inoculation, and the time allowed for the development of the reaction—are rigidly controlled, striking variations sometimes appear. The laws of such variations can, however, only be properly studied when their sequence is made manifest by definite comparable standards.

The use of a color standard for measuring the reduction of nitrate and the formation of indol obviously suggests itself as simpler and more practical than any other method. Up to the point at which a precipitate forms in the nitrite reaction, the depth of color in both cases may be considered as roughly proportional to the amount of the end product formed by the bacteria in a given time. The problem for the bacteriologist is then to select from the numerous schemes of color values, prepared for artistic and educational purposes, that one best suited for the matching of the reaction in question.

The most rational system of color standards is that prepared by Milton Bradley, of Springfield, Mass., based on pure spectral colors of known wave-length. It is issued in the form of a small booklet, and by cutting out and pasting to a card the colors between red and yellow, orange and their tints, a chart is obtained on which the color of the indol reaction produced by *B. coli communis* can be readily matched. The hue is read by holding the tube parallel to a white surface and looking through it at right angles, while the matching color on the

card is isolated by a small card with a window cut in it. The tube and card are viewed in strong diffuse daylight. The Milton Bradley color scheme has not, however, proved satisfactory for measuring the reduction of nitrates. A large majority of the tubes tested lay somewhere between the reds and the violet reds of the scale, and could not be well matched with either. Some other standards were therefore sought and more suitable ones found in the book of standard colors published by Louis Prang, Boston, Mass. This system has no definite scientific basis. The hues are less pure and the tints less bright and clear than in the Bradley system; the gradations, however, are more numerous. Of the seven plates in the Prang book the last five, including the darker shades, are not needed. On the 'pure color' plate and the 'first shade' plate the colors produced by both the indol and the nitrate test can be quickly and easily matched. As far as this standard has been used it has been found to be a satisfactory system of record and an important aid in forming definite ideas as to the behavior of microorganisms under various conditions.

Observations upon the Morphological Variation of Certain Pathogenic Bacteria:

A. P. OHLMACHER, M.D., Northwestern University Medical School, Chicago, Ill.

Three observations are here recorded. The first was upon experimentally-induced morphological variation in *B. diphtheriae*. Here a race, presenting the long, granular or barred type, was transformed to the short, solid type by a forty-eight-hour sojourn in the subcutaneous tissue of a white rat. Two originally short, solid organisms were converted into long, granular ones by a single passage through the organs of a guinea-pig. In the second observation a race of *Streptococcus pyogenes* from a case of follicular tonsillitis was observed to as-

sume the form of a large polymorphous bacillus each of the seven times it was transferred to Loeffler's medium, each time resuming the morphology of the ordinary *S. pyogenes longus* when grown in bouillon. A race of *B. coli communis* recovered from a case of gangrenous cholecystitis and cholangitis is concerned in the third observation, in which the organism showed a remarkable polymorphism in the original smears and early generations of cultures, taking on a diversity of forms from long, quite coarse filaments to excessively minute coccoid or diplococcoid organisms.

Special Laboratory Apparatus: WM. R. COPELAND, Spring Garden Water Works, Philadelphia, Pa.

The bacteriological laboratory at the Testing Station of the Bureau for Improvement, Extension and Filtration of the Water Supply in Philadelphia, has been equipped with the special object of making examinations of water. Therefore a thermostat was designed and built under special directions. The interior chamber is divided by perforated partitions into four sections. The glass doors, which hang directly in front of these sections, are divided in such a way that the door in front of one section may be opened without exposing the interior of the other sections to the temperature of the laboratory. Between the walls of the interior chamber and the surrounding jacket, strips of copper are soldered, so that water pumped into the open space between the walls must circulate round all four sides of the interior, before it can escape through the drain.

The apparatus employed at the Testing Station for filling test-tubes consists of a copper funnel screwed on to a brass pipe, which, in turn, is screwed on to the top of a brass cylinder. Inside of the cylinder is a brass plug containing two holes, one holding ten, and the other five, cubic centi-

meters. The plug fits snugly inside of the cylinder, but may be turned from right to left easily by a lever attached to a post on top of the plug. This post passes through a hole in the cap. A delivery tube is screwed on to the bottom of the cylinder, and is attached at a point 90° from the opening in the top cap to the funnel. Directly over the delivery tube a little hole is drilled through the cap to serve as an air vent.

When one of the chambers in the plug has been filled with the medium, the lever is reversed and, as the chamber passes over the delivery tube, the medium is discharged into a test-tube below.

An Unusual Bacterial Grouping: MARY HEFFERAN, University of Chicago, Chicago, Ill.

An organism presenting peculiar morphological characteristics, obtained from Kral's Laboratory Collection, Prague, was sent under the name of *B. rosaceus metalloides*. This organism produces an orange-red pigment, but differs from the original description of the above-named form in three important cultural features, viz., lack of metallic luster, for which *B. rosaceus metalloides* is peculiarly known, non-liquefaction of gelatin to any active degree, and possession of the power of motion. A hanging drop preparation from a bouillon culture of seventy-two hours, room temperature, shows the characteristic grouping to best advantage. Short small bacilli, about the size of *B. acidi lactici*, are seen grouped together in aster-like clusters varying in composition from but three or four bacilli up to fairly compact spherical burrs of rodlets radiating from a center. The number of these asters increases in a culture for several days, especially at the surface, where they are loosely packed to form a reddish surface scum. There seems to be nothing like a capsule or a gelat-

inous zooglea massing. Below the surface a greater number of free motile bacilli are present. In old cultures the asters are irregular and fewer in number, free bacilli predominating. On solid media the aster formation has been observed only on agar cultures. The bacilli are longer and more slender than in bouillon, and, when stained, show the *Volvox*-like grouping very beautifully. On potato the bacilli are short and thick, and may show well-defined capsules enclosing two rods.

Observations on the important question as to whether the asters are formed by cell division as a process of growth, or by a method akin to agglutination, are as yet incomplete. The regularity of the formation, the occurrence on solid as well as in liquid media, and the final disappearance of the asters, point, however, to the conclusion that this phenomenon is a growth phase in the life-history of the organism.

An Improved Method of making Collodion Sacks: C. S. GORSLINE, M.D., University of Michigan, Ann Arbor, Mich.

Apparatus.—A long test-tube or other tube, closed at one end except for a perforation 2-4 mm. in diameter, and having a caliber corresponding to the diameter of the desired sack; a wide-mouthed 6-8 oz. bottle one-third full of colorless collodion of U. S. P. strength, and a few ounces of distilled water.

Manipulation.—Touch the perforated end of the tube to the surface of the collodion, thereby obtaining a film of collodion over the opening, but none inside. Allow this to dry a few moments. Incline the bottle containing the collodion as much as possible without spilling, and insert the tube, rotating slowly, allowing only the lower one-fourth to be immersed in the collodion. Withdraw from time to time to allow partial drying to take place, repeat-

ing the operation until the desired thickness is reached. As soon as the collodion has set, the tube may be repeatedly immersed in water at about 25°C. to hasten the drying of the sack. When this is accomplished pour distilled water into the open end of the tube, and applying the mouth, force the water, which carries the collodion ahead of it, through the perforation in the tube. The water now creeps in between the sack and the tube and this process is aided and made to progress evenly on all sides by slightly twisting back and forth on the free end of the sack. When the water has traversed the entire length of the sack, the latter slips off easily into the hand. The water, by its pressure, not only releases the sack, but tests it for weak places or perforations at the same time. Tubes may be made from one sixteenth inch to two inches in diameter and twenty inches long. 200 c.c. of saturated magnesium sulphate were dialyzed out through such a sack against running water in four hours and twenty minutes. Parchment requires seven to eight days to accomplish the same.

Neutral Red in the Examination of Water:

ERNEST E. IRONS, University of Chicago.

In 1898 Rothberger found that *B. coli communis* will reduce neutral red in a culture medium, changing the color from red to a canary yellow, with an accompanying green fluorescence. Schleffler tested a number of races of *B. coli* and found that all gave the neutral red reaction. In 1901 Savage employed neutral red for the detection of *B. coli communis* in water. He concluded that a positive reaction, obtained with neutral red, while not certainly diagnostic of *B. coli*, yet in the vast majority of cases, points to the presence of that organism, and that in the case of the fifty waters examined, the margin of error in assuming that *B. coli* was present where

a positive neutral red reaction was obtained, was less than five per cent.

The object of the present experiments was to determine further the value of neutral red in the routine examination of water. Following the suggestion of Savage, ordinary bouillon was used, to which was added one-half per cent. of dextrose and one per cent. of a one-half per cent. aqueous solution of neutral red. All cultures were kept at 37°C. Determinations were made by the dextrose fermentation tube and neutral red methods in exact parallel. Samples of forty-five waters were employed with a number of dilutions of each, such that in the case of each water *B. coli* was almost always found in the lowest, and rarely in the highest dilution. In this series 285 determinations were made by either method, with thirty-five per cent. positive results for the fermentation tubes and forty-seven per cent. positive with neutral red. Of the neutral red tubes showing positive results when the corresponding fermentation tubes were negative, 31 were examined for *B. coli*. From five of the 31 typical *B. coli* were isolated, and from 25 organisms were isolated which differed more or less from *B. coli*, but which gave the neutral red reaction. Of these 25, 18 gave no gas in dextrose bouillon. In all, 122 cultures were examined. Of 17 conforming culturally to *B. coli*, 15 gave a positive and two only a very slight reaction with neutral red. Of eleven gas-producing organisms, differing slightly from *B. coli*, four gave positive and seven negative reactions. Four organisms conforming culturally to *B. cloacæ* gave complete reactions. Of 65 non-gas-producers three gave decided, and 24 partial, reactions with neutral red.

The results show that the neutral red reaction is produced, under the conditions of the test, by a number of water bacteria,

which no classification, however liberal, would place in the colon group.

A Graphical Tabulation of the Morphological, Cultural and Biochemical Characters of Certain Bacteria, together with References to Authorities, Synonyms, Literature, Etc.: ARTHUR I. KENDALL, S.B., Massachusetts Institute of Technology, Boston, Mass.

Great difficulty is experienced by bacteriologists in establishing the identity of a given bacterium whose morphological, cultural and biochemical characters have been worked out. This is due, as has already been shown, to the following facts: (a) Inaccessibility of the literature, (b) incompleteness of descriptions and indefiniteness of terms used, and (c) lack of uniformity, in both the choice and composition of media. The object of this paper is to collect in one set of tables the descriptions of as many bacteria as possible, tabulated after each individual characteristic, has been verified by comparison with the leading authorities, using (a) terms that admit of one and only one interpretation, and (b) terms that will exclude as far as possible the *personal factor*. The graphical method of tabulation first proposed by Fischer ('Vorlesungen über Bakterien'), and first used as a means of classification by Fuller and Johnson (*Journal of the American Health Association*, Vol. XXV., p. 580 et seq.), has been adopted because the definiteness of characteristics attained with this method of representation cannot be equalled by any other known method. Tables were shown, including those micrococci, which do not liquefy gelatin and do not produce pigment—these being the first of a set of tables and references in which the author hopes to include the more common forms of bacteria.

As a result, even a cursory glance at the tables show the great similarity between

certain bacteria that are supposed to be different species. For example, nine species of micrococci were referred to table 2. These bacteria were isolated and described by the same authority, were obtained from different varieties of cheese, were supposed to be separate species, and yet the characteristics shown by this method are identical, and even the written descriptions point strongly to the fact that these 'species' are, at best, only varieties of the same form.

Some Experiments with Synthesized Media: M. X. SULLIVAN, Brown University, Providence, R. I.

Pasteur, Cohn and others recognized that some bacteria can secure their carbon, hydrogen, oxygen and nitrogen from simple compounds. This is to be expected from the close relationship of the bacteria to other plants. Recently the question of simple synthesized media has received some attention from Kuntz, Jordan and de Schweinitz. Since Pasteur, however, little use has been made of media other than those made of meat infusion and peptone, with agar or gelatin as a base. Meat infusion and commercial peptone vary so widely in their chemical composition and in their nutrient value, that media composed of these substances are practically of no use in the study of pigment or anti-toxin production or in the study of bacterial metabolism. Analysis of standard bouillon shows such small amounts of albumoses and peptones that it appears as if we might neglect the meat infusion entirely, or at least replace the peptone by a non-nitrogenous, non-albuminous body.

On medium (A) consisting of water 100 grams, Witte's peptone 5 gms., NaCl 3 gms., agar 1 gm., 17 different kinds of bacteria, including *Microspora comma*, *B. anthracis*, *B. typhosus* and *B. coli*, grew more slowly than on the standard media.

Chromogenic bacteria, as *B. pyocyaneus* and *M. pyogenes citreus*, however, failed to produce pigment. On medium (B), made of water 100 gms., peptone 6 gms., NaCl 2 gms., $MgSO_4$ 0.3 gm., K_2HPO_4 0.5 gm., agar 2 gms., 15 varieties grew quickly with the production of pigment and, in one case, of phosphorescence. Then the peptone was replaced by a non-albuminous compound, such as ammonium salts or asparagin. On medium (C) containing water 100 gms., glycerin 50 gms., $(NH_4)PO_4$ 10 gms., Na_2HPO_4 1 gm., $MgSO_4$ 0.2 gm., agar 1 gm., 19 varieties grew rather slowly. On medium (D) consisting of water 100 gms., asparagin 1 gm., NaCl 0.5 gm., $MgSO_4$ 0.3 gm., agar 1 gm., 9 varieties grew with no formation of pigment. On medium (E) consisting of water 100 gms., asparagin 1 gm., Na_2PO_4 0.1 gm., NaCl 0.2 gm., agar 1 gm., 20 different kinds of bacteria, mostly pathogenic, grew as quickly as on the standard media.

Further experiments are now being carried on and, in view of the fact that so many bacteria can grow on this non-albuminous medium, it is probable that some combination of simple chemicals can be found that will replace the ordinary meat infusion. A medium consisting of such compounds, qualitatively and quantitatively known, would be of great value in the study of bacterial metabolism.

A Tank for the Growth of Germs in Large Numbers: VICTOR C. VAUGHAN, Ann Arbor, Mich.

Professor Vaughan, of the University of Michigan, described an apparatus, devised by himself, for the purpose of obtaining bacterial cells in large quantity. A copper tank ten feet long, two feet wide, and four inches deep, with a trough around the edge one inch deep, is covered by a top of the same material. This tank is supported by an iron frame with legs ten inches high,

and the whole is placed on a table covered with galvanized iron. A similar tank, two inches shorter and two inches narrower, also provided with a trough around the edge and a cover, sets in the larger one, and is separated two inches from the bottom of the larger one by iron bars extending from side to side. The bottom of the outer trough is filled with water, and the seal trough of the outer tank is also filled with water, while the seal trough of the inner tank is filled with glycerin. Both lids are raised and lowered by wire ropes passing through pulleys in the ceiling. It is necessary that the tanks should be set perfectly level. Twenty liters of two per cent. agar are placed in the inner tank; both lids are lowered, and with large burners underneath the apparatus becomes a sterilizer. After repeated sterilizations, the upper lid of the outer tank is raised and the agar inoculated by pouring through tubular openings, in the top of the inner tank, a liter of a beef-tea culture of the germ. These openings are then sealed with wax and the outer lid lowered. With gentle heat underneath the apparatus becomes an incubator.

After the germ has grown for fourteen days or longer in this tank, the germ substance can, by the addition of a little water, be scraped from the agar, and from each tank there may be obtained forty or more grams of dried, pulverized germ substance.

With the colon bacillus the following facts have been learned concerning its toxin: (1) The toxin is contained within the cell from which it does not, at least under ordinary conditions, diffuse into the culture medium. (2) The toxin is not extracted from the cell by alcohol or ether. (3) Very diluted alkalis do not extract the toxin from the cell. (4) The germs may be heated in sealed tubes with water to 184° for thirty minutes, without loss of

toxicity. (5) Boiling with a .2 per cent. aqueous solution of hydrochloric acid has but little, if any, effect upon the germ cell or its contained toxin. (6) Heating the germ substance for an hour at the temperature of the water-bath with water containing from one to five per cent. of hydrochloric acid lessens but does not destroy the toxicity of the cell. (7) The toxin may be partially separated from the cell wall by digestion of the whole with hydrochloric acid and pepsin. (8) With the dried bacterial cells rabbits may be immunized to the colon bacillus. (9) Rabbits thus immunized furnish an antitoxic serum. This antitoxic serum agglutinates the colon bacillus and precipitates the toxin from suspensions in water.

H. W. CONN.

WESLEYAN UNIVERSITY.

THE NEW VAPOR-ENGINES.

THE recent announcement from Berlin of the successful construction of a new 'binary-vapor,' or, as the writer has been accustomed to designate it, 'series-vapor engine,' and the almost simultaneous account in the Paris technical and scientific journals of a 'newly invented' ether-vapor engine, are reviving an old-time error. The distinction between the latter of the two systems and the former, between a fallacy and known truth, as fundamental elements of the revival of these classes of heat-engine, is once more a subject of misconception with the technical and even, often, with the scientific writers describing them.

Professor Josse, at the great Charlottenburg technical school, and his co-workers among the steam-engine builders of Berlin, have been for some time at work determining the practicability of utilizing the binary-vapor system of heat-engine, supplementing the steam-engine by a 'waste-heat engine' in which a more volatile vapor

is employed to transform into useful mechanical energy the large fraction of heat rejected from the former.* The system is old, well-known and entirely correct, thermodynamically.

The real question of the moment which is sought to be solved is the practical one: With our refined systems of design, construction and manipulation, to-day, is it possible to practically, safely and conveniently and, above all, economically employ this system, often previously tried and found wanting, and to thus secure, for the user, a larger return of power for the unit of expenditure and for the life of the 'plant' than by use of the steam-engine alone? Can dividends be increased through an unquestionably greatly improved thermodynamic transformation of energy?

There is here no question of thermodynamics or of a possibility of dynamic gain; the experiment has often been tried and this possibility exhibited beyond question. It is now a matter of choice of secondary fluid, of safety, permanence of construction, convenience, reliability, ultimate gain in returns on the investment and operative costs. It is now thought, by those most familiar with the facts of this new case, that this problem has at last been solved and that the 'series-vapor engine' will find a permanent place in the arts. Time and experience will confirm or refute their conclusions.

Susini, in Paris, on the other hand, has introduced a 'new' vapor-engine in which he substitutes ether for steam, maintaining that the machine is advantageous as a primary rather than as a secondary or waste-heat engine, and, if his reporters are correct, basing his claim to this superiority upon the assertion that ether, with its volatility and low latent heat of vaporiza-

* Mittheilungen aus dem Maschinen-Laboratorium der Kgl. Techn. Hochschule zu Berlin, 1901.

tion has thus great intrinsic advantage over the vapor of water as a working fluid in the heat-engine. This is a well-known and oft-repeated fallacy, and it has been almost as common among inventors or would-be inventors as was formerly, according to Dircks, that of a '*perpetuum mobile*.'

The thermodynamic efficiency of any heat-engine is determined, at best, by the range of temperature worked through and without regard to the nature of its working substance. It is true that the practicability of employment of one or another fluid in the heat-engine varies with the temperature- and pressure-ranges and that there is as yet no known fluid which precisely adapts itself to the demand of the engineer within the practical limits of pressure and of temperature, coincidentally, which he now safely, conveniently and economically handles. He finds one fluid suited to the pressure, the other to the temperature-range, one to the upper, another to the lower, portion of either scale; but he knows of none which meets his needs on both scales.

The proposition regarding 'latent' heats is easily verified by reference to the well-known expression of Rankine for the work, U_1 , of the common vapor-engine cycle with complete, adiabatic, expansion between T_1 and T_2 , and without compression:*

$$U_1 = \int_{p_2}^{p_1} v dp = \int_{T_2}^{T_1} (JC \log_e T_1/T_2 + v_1 \dot{d}p_1/dT_1) dT;$$

$$= JC[T_1 - T_2(1 + \log_e T_1/T_2)] + H_1(T_1 - T_2)/T_1;$$

where H_1 is the 'latent' heat of vaporization at T_1 in dynamic units.

The work of compression in the Carnot cycle, to which this cycle is reduced by its introduction, is found by making $H_1=0$, the compression reducing the fluid to the

liquid state at the close of the compression period, when we shall have

$$U_2 = \int_{p_2}^{p_1} v dp = JC[T_1 - T_2(1 + \log_e T_1/T_2)].$$

Deducting this quantity, the first expression reduces to that for the work of the Carnot cycle for vapors,

$$U_1 - U_2 = H_1(T_1 - T_2)/T_1;$$

which is identical with that for gases when, for H_1 , the latent heat of vaporization, is substituted the latent heat of isothermal expansion at T^* .

In other words, in the 'perfect-engine cycle' of Carnot, whether for one or another working fluid, or even for solids serving as working substances, the work is all performed by 'latent' heat; while, in the common steam-engine or other vapor-engine cycle, it is obtained from 'latent' heat more and more completely as the cycle approximates more and more closely to the conditions of maximum efficiency.

It is further evident from the above that efficiency is independent of the magnitude of the value of H , in the Carnot cycle, as well as of the measure of J or of C , the specific heat. As Carnot himself announced in 1824, maximum efficiency is not dependent upon the nature of the working fluid, and one vapor is as good as another in this respect. The magnitude of H determines how much heat shall be stored in the working substance in each cycle and how many units of weight of that fluid will be required per unit of work performed. Thus, with steam, a smaller number of pounds per horse-power-hour are required, other things equal, than with ether, or, in fact, with any other known substance; although the number of thermal units per unit of work developed in the

* 'Manual of the Steam-Engine,' p. 387.

* Thurston's 'Manual of the Steam-Engine,' Vol. I., p. 796.

unit of time will be the same for all. Efficiency remains the same while the quantity of working fluid circulating will vary inversely as the quantity of its 'latent' heat of vaporization.

In the actual engine, conditions external to the cycle determine the relative desirability of available fluids and extra-thermodynamic circumstances control. Since the machine has weight and is subject to friction; since the material of which it is composed is always a good conductor of heat; since the cost of production of power and that of purchase of machinery is a controlling factor; these and other, minor, conditions affecting the problem of the real engine compel the engineer to seek a working fluid that shall best combine minimum cost of fluid and of mechanism, maximum heat-storing power, maximum 'mean effective pressures' and minimum liability to heat-wastes other than thermodynamic. He is limited by pressures difficult to control safely and permanently in the steam-engine, by temperatures beyond his range of satisfactory operation in the gas-engine and by costs and risks, often very serious, with other fluids; while he finds it impracticable to utilize the lower portion of the temperature-range in the steam-engine and, in vastly greater degree, finds a similar limitation in the standard gas-engine.

No known fluid, up to this time, at least, has been found to satisfactorily combine the manageable range of temperature with the safe range of pressure in the heat-engines so as to serve as the ideal working substance. On the whole, steam has proved thus far best.

By combining fluids in series, however, it is at least ideally possible to secure this coincidence of available pressure- and temperature-ranges. Thus, it has often been proposed to utilize the rejected heat of the gas-engine in an accessory steam-engine, to thermodynamically transform the waste-

heat of the latter by a secondary apparatus employing one of the more volatile liquids in a cycle of low temperature-range. Wellington attempted to find a *series* of fluids, to be worked in a number of engines in series in this manner, years ago, and every aspect of the case has been carefully studied, and usually more or less thoroughly investigated experimentally by engineers, physicists and inventors.

Nothing new in this branch of the subject has been discovered recently. It is, however, usually the fact that the earlier inventors have commonly reported a measurable gain by the substitution of the more volatile substance for steam in heat-engines. It has seldom been large; but has been sufficient to make it evident to engineers that the problem involved is not to be absolutely ignored. It seems probable that most of these available fluids possess some advantage in one if not both of two ways—higher mean effective pressures at low ranges of cycle temperatures and less freedom of heat-exchange with the metal of the cylinder.* As the former permits expansion to a lower limit of temperature, as the gain by extending the range downward is comparatively large and as wastes by internal heat-exchanges are usually serious, in the common forms of engine, the engineer is interested in watching developments in the use of other fluids than steam, though not as yet expecting much progress through their use in the simple engine.

With the 'waste-heat engine' of the 'binary-vapor system' the case is different. There exists a very large defect in the standard steam-engine in its inability to utilize the temperature-range of its cycle below about 50° C. (122° F.), while it is usually true that at least one half, and often much more than one half, of the heat-

* Thurston's 'Manual,' Vol. I, pp. 172-704, 911-921.

energy which should be transformed into work escapes transformation simply because of the low terminal pressures of the engine at the lowest temperatures of its range. It is this loss which is sought to be reduced by the series-fluid engines and which, so far as the thermodynamic and the dynamic questions are concerned, may be actually saved in large degree. The uncertainty remaining is that regarding costs, safety and convenience.

Du Trembley, about two generations ago, built binary-vapor engines, with ether as the secondary fluid, for a line of trans-oceanic steamers and 'broke the world's records' for his time in economy of power-production; but the compound engine came in and his secondary fluid proved dangerously inflammable. He lost one of his ships, Randolph & Elder bettered his record and the matter dropped out of sight. Later, many inventors have gone through the same experience in one way or another. Ether, chloroform, alcohol, ammonia, carbon-disulphide and sulphur-dioxide, among other volatile substances, have been tried, usually with some apparent gain but never yet with permanent success.

Recently, however, Professor Josse, at Berlin, has again 'broken the world's record' in heat-engine operation by producing the horse-power with an expenditure of less than eight and a half pounds of moderately superheated steam per hour. The experiment has been made with the utmost care and repeated under varying conditions, until there can remain no doubt of the fact. He further states that the steam and sulphur-dioxide, binary-vapor system adopted by him can be constructed at no greater cost than the standard triple-expansion engine which it rivals, that, properly cared for, it is not subject to injury by corrosion as had been anticipated by engineers generally, and that it can be safely insured against loss or accident

through leakage. If experience confirms this claim, this means that the long-sought utilization of the waste heat of the steam-engine may be practically accomplished.

Time and experience will confirm or refute these expectations and it is for time and experience to settle the ultimate questions of the engineer relative to cost, reliability, safety and *net* gain or loss by the substitution of the series-vapor engine for the compound, the single-fluid, series-engine.

R. H. THURSTON.

WHAT ARE THE REQUIREMENTS OF A
COURSE TO TRAIN MEN FOR WORK
IN TECHNICAL CHEMISTRY.*

THE subject before us may be discussed in two parts; first, what sort of instruction in chemistry should be given to men who are to become technical chemists, and, second, what work in other subjects should be required? Our consideration of the question will perhaps be more definite if we have before us a list of the occupations followed by a number of young men who have received training of this sort.

During the past twelve years twenty-three men have graduated from the chemical course of the Rose Polytechnic Institute. These have been employed as follows: One is inspector of coke for a large steel company, three are chemists in iron or steel laboratories, two are assayers, two are teachers, three chemists in soap factories, two employed by a firm manufacturing liquid carbon dioxide, two are draftsmen, one is superintendent of a gas company, one chemist for a firm manufacturing photographic supplies, one chemist for a paint oil company, one chemist for an electrical company, one manager of the paint department for a wholesale

* Read at the meeting of the Indiana College Association, December 27, 1901, and also at the Philadelphia meeting of the American Chemical Society.

house, one chemist for a packing company, one chemist in a testing laboratory, and one in charge of the technical science department in a large library.

No doubt the list of graduates from other technical schools would show a similar, or even greater, variety of occupations. It is at once evident that it would have been impossible to fit these men for the specific occupations which they now follow. Only in very rare instances could the occupation be predicted before graduation. Work spent upon the details of technical processes would, in the large majority of cases, have had no direct practical value. When we consider the ever-broadening scope of the chemical knowledge of our time, and the time limits which are practically set for the student's work, we cannot doubt that time spent in laying broad and solid foundations will be much more useful than any great amount of time given to the details of industrial chemistry.

At the basis of all must come a thorough training in analytical chemistry, and especially in quantitative analysis. While I think that the laboratory work should begin with work in general chemistry and that should be followed by qualitative analysis, no very large amount of time should be given to either by students who are to become chemists. Fifteen hours a week for one half to two thirds of a school year should be sufficient. The work given in general chemistry should be directed toward the illustration of fundamental principles and instruction in accurate manipulation with varied forms of apparatus, rather than to a large amount of detailed demonstration of the properties of elements and compounds. Beyond a very limited amount of the latter kind of study, the attention of the student will weary and he will acquire the fatal habit of performing experiments as directed, writing descrip-

tions in his note-book and straightway forgetting all about them. The same is even more true of some kinds of work often given in qualitative analysis. The greater length of time required for quantitative operations, and the comparative simplicity of the processes involved, are better suited for training the beginner in the accurate memory of detail which is so useful for the chemist.

In the selection of topics in quantitative analysis I heartily believe in beginning with pure salts, which give a rigorous test of the student's accuracy. After a limited number of such determinations, however, the student's work is best directed to the analysis of various commercial products, the object being to give as varied a training as possible and a knowledge of the most practical methods. In general, a reasonable economy of the student's time should be considered and long and tedious methods should not be used, especially when shorter methods give as good or better results. The determination of the principal constituents of iron and steel, determination of iron, copper, zinc and lead in ores, assaying for gold and silver, the determinations of sanitary water analysis, coal analysis, and gas analysis should be included for every student. One or more complex analyses, as a clay analysis or an analysis of a mineral water are also very desirable, and beyond this many special topics may be assigned to individual students. No hard and fast course should be laid down to be followed by all alike. At some point the quantitative work should be broken off and a few weeks given to inorganic preparations, and a few weeks, at some other point, to organic preparations. There should, of course, be lecture courses in general and organic chemistry and in the history and theories of chemistry. The lecture work in physical chemistry should be supplemented by laboratory work.

It is the custom, at all of our best technical schools, to require a thesis for graduation. This thesis should always be based on careful experimental work continued for some months. It should, if possible, contain some real addition to the world's knowledge. The student cannot be expected to select, independently, a suitable topic. Indeed, where the higher degree of Doctor of Philosophy is concerned, students rarely select their own subjects. The wish of the students as to the nature of the topic should, however, be consulted. Subjects pertaining to industrial chemistry are especially appropriate, but topics pertaining to the pure science are not to be excluded, and indeed are often to be preferred because of the broader and deeper insight which they give to the student. Every technical school should hold before itself not only the purpose of giving to its students a sound preparation for industrial pursuits, but it should also contribute constantly to the increase of knowledge in those fields with which it has to deal. The reflex influence of such ideals on the instruction given is of the greatest possible importance.

The second phase of our question pertains to the accessory studies which the chemist should have. There seems to be a very prevalent notion that a chemist needs very little mathematics. With the rapid development of physical chemistry and the application of that branch of chemistry to technical problems which is soon to come, if not already here, such a view is no longer tenable. Every chemist, and indeed every one dealing with physical science, should have, at least, a knowledge of the calculus. In physics, a thorough knowledge of fundamental principles should be given and especial attention should be devoted to the subject of electricity. The methods used by engineers in testing structural materials should be acquired by ac-

tual use of the instruments employed for the purpose. Free-hand and mechanical drawing are almost necessary and some work in machine design is very desirable. In language, a reading knowledge of German and French should be acquired and the knowledge should be practically used in connection with current chemical journals. Except for lack of time I should advocate some work in biology. But, while there are fields in industrial chemistry where some knowledge of biology is absolutely essential, and while all chemists should know something in a general way about bacteriology, room can scarcely be found for these subjects without displacing something of more vital importance. In conclusion, I would say that the accessory subjects, especially, should not be slighted by the student. If he becomes a chemist he will certainly learn a very great deal about chemistry after he leaves school, but much of this other knowledge he is far less likely to acquire afterwards, and very much of it he will find practically useful if it is at his command.

ROSE POLYTECHNIC INSTITUTE.

SCIENTIFIC BOOKS.

Plane and Solid Geometry. By ARTHUR SCHULTZE, Ph.D., and F. L. SEVENOAK, A.M., M.D. The Macmillan Company, New York.

The results of geometrical teaching in England are rather disappointing, if we are to judge by the reports and criticisms that have appeared in educational journals and scientific reviews. The blame is laid entirely on the system adopted, which is Euclidean pure and simple, and from which the universities and other examining bodies are unwilling to depart. It is good to be conservative; but it is also easy to overdo it. "Surtout pas trop de zèle" was Talleyrand's famous injunction. It applies as well to conservatism in pedagogics as it does to conservatism in politics. Euclid's text was excellent in his

day and for his purposes, and continued so for many a century.

The educational wants of our age are far more numerous, pressing and diverse than when the Greek geometer taught in the schools of Alexandria 2,300 years ago. We must remember, too, that it was before admiring throngs of men that he unfolded book after book of his 'Elements,' men who were attracted round his cathedra more by the knowledge that he had to impart than by the mental training to be derived from his teaching. The geometrical truths that Euclid discussed before his mature scholars have to be placed to-day before the undeveloped minds of mere tyros and placed before them as only one of the many elements of their daily pabulum.*

The necessities of our times call for less verbosity, prolixity and iteration than we find in Simson's rendering of Euclid, which is the orthodox text in English schools modified somewhat by Todhunter, Hamblin Smith, Mrs. Sophia Bryant and others. The whole presentation of the subject is decidedly hard and

* Here are the latest from *Nature* of January 16, 1902: "Mr. W. C. Fletcher, headmaster of Liverpool Institute, says that 'six years' experience in teaching geometry has led him to believe that Euclid is a great hindrance to ninety-nine boys out of every hundred in training and knowledge. A great deal of damage is done by insistence, not only upon the particular method, but on the particular order of Euclid" (p. 262).

A letter signed by mathematical teachers in the great public schools of England such as Eton, Harrow, Rugby and Winchester contains the following momentous acknowledgments: "It may be felt convenient to retain Euclid; but perhaps the amount to be memorized might be curtailed by omitting all propositions except such as may serve for landmarks. We can well dispense with many propositions in the first book. The second book, or whatever part of it we may think essential, should be postponed till it is needed for Book III., 35. The third book is easy and interesting; but Euclid proves several propositions whose truth is obvious to all but the most unintellectual. The fourth book is a collection of pleasant problems for geometrical drawing; and in many cases, the proofs are tedious and uninteresting. No one teaches Book V." (p. 258).

deterrent. Think of Book II. and especially Book V., also Books XI and XII., and try to realize the hardship, the worry and vexation of spirit they have caused! A different sequence of propositions is needed, as well as shorter demonstrations and modern methods. When we want to cross a stream, we do not go up one bank to its source and down the other; but avail ourselves of a bridge, a ferry or an electric launch if handy.

Nor is prolixity the only salient fault of Euclid's 'Elements'; it lacks suggestiveness and fails to adequately stimulate the inventive faculty of the student. It leaves him but too often unable to think out a simple matter for himself, to originate a plan of attack or even to act on a hint. He can appreciate a neat solution to a rider; he is receptive, but not creative enough; a good consumer but poor producer.

On the other hand, we have found boys very different who had worked out their Davies or Robinson or other simplifier or improver of Legendre's great work. They had a clearer apprehension of the meaning of geometrical truths and firmer grasp of them. They usually showed marked readiness in applying their knowledge, in extending conclusions, detecting flaws and attacking problems. There was a resourcefulness and a vigor about their ways that bespoke the benefit which they derived from the subject. It was less a task imposed upon them than a congenial study. Here, then, we have the full realization of the twofold end of all undergraduate study, viz., culture and utility; or, to put it otherwise, the awakening of the faculties and the acquisition of knowledge.

Euclid might well say to Ptolemy that there was no royal road to geometry; but all the same, such a work as the 'Plane and Solid Geometry' of Dr. Sevenoak and Dr. Schultze will go far toward smoothing the way for the young geometer and inspiring him with a liking for the subject. The letterpress and figures leave nothing to be desired; the demonstrations are well spaced, short and suggestive. The arrangement of the propositions follows a logical and pedagogical order, and the exercises, which form an integral part of

the work, bear evidence of having been selected for the purpose of gradually and systematically leading the student to do some independent thinking and original work. From every point of view this elementary work on 'Plane and Solid Geometry' is a commendable text-book.

M. F. O'REILLY.

MANHATTAN COLLEGE,
NEW YORK CITY.

Zoology: An Elementary Text-book. By A. E. SHIPLEY, M.A., and E. W. MACBRIDE, M.A. (Cantab.), D.Sc. (Lond.). New York, The Macmillan Company. 1901.

This is a neatly gotten up general zoology of xxii and 632 pages, with 349 text figures. The text is divided into 23 chapters, of which the first is an introduction of 12 pages briefly reviewing the properties of living things and defining a number of general terms and phrases. The remaining pages are apportioned in order as follows: Protozoa 27, Cœlenterata 29, Porifera 7, Introduction to the Cœlomata 6, Annelida 28, Arthropoda 87, Mollusca 39, Echinodermata 40, Brachiopoda 6, Polyzoa 5, Chætognatha 4, Hemichordata (*Balanoglossus*) 5, Cephalochordata (*Amphioxus*) 14, Urochordata (Tunicates) 9, Craniata 259, Platyhelminthes 21, Nemertinea 5, Rotifera 8, Nematoda 6, Index 16.

Putting aside likes and dislikes, one must admit that this is a pretty fair distribution. We cannot, however, see what is gained by considering the Cœlenterata before the Porifera, and the Flatworms, Roundworms, Nemerteans and Rotifers after the Mammals. Logical and natural sequence of generalizations is not without distinct value and interest, and from this point of view such an apparently insignificant matter of detail as intervening the Cœlenterata, or any other group, between the Protozoa and Porifera becomes important.

On the whole, the treatment of the phyla is good. In each group of animals some more or less representative form is described in considerable detail, and other forms of interesting habits or having a bearing upon some principle or generalization are noted. The systematic tables avoid the shoals of details and briefly characterize only the phyla, classes,

subclasses, orders and suborders. Under the final division of the group considered one to three genera are named as examples. The book being an English one, we are not surprised to see American forms somewhat slighted. The nomenclature is not always the most modern, but that is a matter of such minor importance in an elementary text that it may be overlooked. In some respects the authors have not always lived up to the excellent principles laid down in the preface. With them we believe technical terms and phrases should, so far as practicable, be elucidated in connection with the first presentation of forms illustrating them. We naturally expect to find radial symmetry noted in connection with the Cœlenterata, but it is first mentioned on page 80 in the introduction to the Cœlomata. As a rule the principle is lived up to in good shape. The very limited space given to embryology and physiology is in our opinion a real defect. It would have been better to make room for more of this by cutting out portions of the general accounts. We also believe that taking up a phylum by beginning with a consecutive account of some form as a type is the proper plan for an elementary text-book. In this respect the treatment of the Arthropoda, which is comparative, is inferior to that of the Annelida and other phyla.

To write a good text-book on zoology is no easy task, and to write one acceptable to every one is an impossibility. The most that should be expected of a text-book is positive and continuous assistance to teacher and pupil. Successful teaching lies with the teacher and not in the text-book.

The book before us is well gotten up. The typographical work is good, the figures as a rule are clear and the page is clean and inviting. While in some respects it still leaves room for improvement, we consider it one of the best and most worthy of recent elementary text-books on zoology.

HENRY F. NACHTRIEB.

Gustav Theodor Fechner. Rede zur Feier seines hundertjährigen Geburtstages gehalten von Wilhelm Wundt. Leipzig, Engelmann. 1901.

In his address delivered at the centenary of Fechner's birth, Professor Wundt does not attempt to give a full outline of the philosophical and scientific views of this last of the great German philosophers of the nineteenth century. He states at the outset that his object is to speak of the relation between Fechner the philosopher and Fechner the scientist, and he succeeds admirably in showing the fundamental connection between the religious mysticism of Fechner and those rigorously exact investigations which led to the establishment of the science of psycho-physics. He shows with a delicate touch, a keen insight and in masterly form, how originally purely metaphysical ideas resulted in the establishment of principles which lifted this new science for all future times above the danger of any subjective views. Professor Wundt defends Fechner the scientist against Fechner the philosopher and Fechner the poet, and apparently does not believe that the metaphysical speculations of the '*Innere Psychophysik*' will have many adherents in the future; he compares these aptly with Kepler's mystic '*world-harmony*' now forgotten, but valued by its author more than his immortal third law. The lasting service of Fechner, according to Wundt, consists in the fact that he for the first time introduced 'exact methods, exact principles of measurement and experimental observation into the investigation of mental life' and that, in consequence, he was the first to make a scientific psychology possible.

Wundt's pamphlet contains, besides, several interesting '*Addenda*': Personal Reminiscences, an essay on Fechner's relation to the natural philosophy of Oken and Schelling, on his philosophical method, his psychology, his attitude towards spiritism and a list of his principal works. Wundt's essay will serve as an excellent introduction to the world of thought contained in the works of Fechner, which are far too little known in this country, and which even in Germany are only beginning to take the rank which is due to them in the study of the history of philosophy.

If a further guide to the study of Fechner should be desired, we would suggest to take

up after Wundt's essay, R. Seydel's paper on *Religion und Wissenschaft* (Breslau, 1887), W. Bölsche's *Charakterbild (Deutsche Rundschau*, Sept., 1897), and K. Lasswitz' critical Biography (1896), which last is still unsurpassed and far preferable to the biography compiled by Kuntze, written from the one-sided standpoint of an orthodox theologian.

EWALD FLÜGEL.

STANFORD UNIVERSITY, CAL.

SCIENTIFIC JOURNALS AND ARTICLES.

The Plant World for January contains an illustrated article on 'The Missouri Botanical Garden,' by the Director, William Trelease; 'A Visit to the Royal Palm Hammocks, Florida,' by Charles T. Simpson; 'Plant Agencies in the Formation of the Florida Keys,' by Charles L. Pollard, besides the usual briefer articles. The Supplement, devoted to the families of flowering plants, contains the first portion of the Orders Opuntiales and Myrtifloræ.

Bird Lore for January-February opens with 'Recollections of Elliott Coues,' by D. G. Elliot and C. A. Curtis, in which we are told something of his youth and of his first army detail. 'The Western Evening Grosbeak' is described by Wm. Rogers Lord, and in 'Bird Clubs in America' Francis H. Allen tells of the Nuttall Club, the article being accompanied by a capital plate showing the President, Mr. William Brewster, and a number of the members. Frank M. Chapman contributes the second of the papers on 'How to Name the Birds,' which runs through the *Corvidæ*, and then follows 'The Christmas Bird Census' taken in many parts of the country, while Fred T. Morison contributes 'The Prize Crow Story.' In 'A Midwinter Meditation,' M. O. W. intimates that nature study may be so misdirected as to be decidedly harmful to the birds.

Popular Astronomy for March includes a paper entitled 'A Laboratory for General Astronomy,' by Miss Mary E. Byrd, of Smith College, and an illustrated article by Percival Lowell on the north polar rifts and the arctic canals on Mars. Other articles are

by W. F. Denning on 'Real Paths of Brilliant Meteors'; by J. C. Kapteyn, J. K. Rees and W. H. Pickering, 'On the Motion of the Nebulae in the Vicinity of the Nova Persei.' The Rev. Q. A. Wheat concludes his series of papers upon the 'Eclipse Aid to Chronology,' and Dr. Wilson contributes further observations of the 'Light Curve of the New Star in Perseus.'

THE first number of a botanical monthly, called *The New Phytologist* has appeared in England. Professor A. G. Tansley, of the University College, London, is its editor and the subscription price is 10 shillings a year. This journal will seek to satisfy an apparent need in Great Britain for a botanical journal with educational aims uppermost. Accordingly especial attention will be given to discussions of scientific questions, methods of teaching and research, notices of important books and papers and preliminary notes. Realizing the labor and sacrifice which such an undertaking involves, we wish Professor Tansley every success and trust that he will obtain cordial support from this side of the water.

SOCIETIES AND ACADEMIES.

THE IOWA ACADEMY OF SCIENCES.

THE sixteenth annual meeting of the Iowa Academy of Sciences was held in Des Moines on December 26 and 27, Professor A. A. Veblen presiding. The meetings were well attended and much interest was taken in the program. Thirty papers were presented, many of the more technical being read by title.

The address of the retiring president, Professor A. A. Veblen, was on 'The Relation of Physics to the other Material Sciences.' Physics was the first of the material sciences to develop the modern methods of research. The other branches are greatly indebted to physics for the aids it furnished them, and they in turn are under obligation to physics for the help it has rendered them. Professor Veblen also described several models; one to show the transmission of a wave by transverse vibration; another to illustrate the longitudinal or sound wave; and a third for compound simple harmonic motions.

'Preliminary Notes on the Flora of Western Iowa, especially from the Physiographical Ecological Standpoint,' was the subject of a paper read by Professor L. H. Pammel. The effects of the soil, climate, altitude, temperature and rainfall on the flora of the region were considered. The flora of the different physiographic regions was given, including the plants of the Missouri floodplain, the bluffs and the upland.

Professor Herbert Osborn presented a paper on the 'Factors of Extinction.' More attention has been devoted to the factors concerned in the production of new types than to the factors of extinction. It is worth while to attempt to formulate those factors which are especially concerned in the elimination of life forms. They were summarized as follows:

- (1) That extinction which comes from modification or progressive evolution, a relegation to the past as a result of the transmutation into more advanced forms.
- (2) Extinction from changes of physical environment which outrun the powers of adaptation.
- (3) The extinction which results from competition.
- (4) The extinction from extreme specialization and limitation to special conditions the loss of which means extinction.
- (5) Extinction as a result of exhaustion.

Professor Maurice Ricker described a 'Large Red Hydra,' found in large numbers in Echo Lake, Flathead County, Montana. The animals are bright coral red in color and the larger ones measure when feeding five eighths of an inch from mouth to proximal end. None of the tentacles was less than two and one-half inches long. So far as known, no other hydra has ever been collected in the State.

The following officers were elected for 1902: *President*, H. E. Summers, of Iowa State College, Ames, Iowa; *First Vice-President*, J. L. Tilton, of Simpson College, Indianola, Iowa; *Second Vice-President*, S. W. Beyer, of Iowa State College, Ames, Iowa; *Secretary*, A. G. Leonard, of the Iowa Geological Survey, Des Moines, Iowa, and *Treasurer*, B. Shimek, of the State University, Iowa City, Iowa.

A. G. LEONARD,
Secretary.

THE GEOLOGICAL SOCIETY OF WASHINGTON.

At the meeting of the Society on February 12 the first paper was by Mr. G. P. Merrill and was entitled, 'Rutile Mining in Virginia.' Mr. Merrill called attention to the fact that recent experiments in the making of cast iron and steel had called for titaniferous alloys. As a result of this, a rutile deposit, situated on the Tye River, near Roseland post-office, Nelson County, Va., had been opened up. The country rock is a strongly foliated gneiss traversed by dikes of hypersthene diabase. The rutile occurs associated with a coarsely crystalline quartz feldspar rock, the exact nature of which has not yet been made out, but which, from the size of the deposit and its crystalline nature, is judged to be eruptive. The rock is a coarsely crystalline aggregate of potash and soda-lime feldspar, of a light gray color, through which are disseminated small rutiles. With it is associated bluish, opalescent quartz, which occurs under such conditions as to suggest that it is not the result of primary crystallization.

In a brief paper entitled, 'Notes on the Geology of the Klondike,' Mr. W. C. Mendenhall sketched the general relations of the rocks in the mining district tributary to Dawson, so far as they are known, and outlined the relations borne by the gold-producing creeks to the geology. A brief account of the occurrence of the gold in the present stream gravels and on the terraces which mark older stream courses was given, and the probability that the gold was derived from stringers or lenses in the schists which are cut by the streams and has not been transported for any distance was brought out.

Mr. Arthur C. Spencer presented a paper on 'The Manganese Ores of Santiago Province, Cuba.' All the manganese produced in Cuba has been shipped from Santiago, the chief city of the easternmost province. The deposits are found back from the coast and are distributed over an extended region. In their mode of occurrence they are replacements of limestone and of calcareous green-sands in localities that have suffered disturbance and folding. From the association of jasper, also replacing calcareous rocks, it is believed that hot circulat-

ing water has been active in the formation of these valuable deposits.

Mr. Whitman Cross spoke of the evolution of ideas on systematic petrography in America, referring to the conservative attitude of geologists, presented in text-books, as represented by J. D. Dana; to the propositions for the classification of volcanic rocks presented by Clarence King, regarding them as the only true igneous rocks; and to the proposition made by M. E. Wadsworth. Concerning the part played by petrographers of this country in shaping existing systems, it was pointed out that while but few original proposals of note had been made, the results of the many investigations had almost unconsciously caused a gradual evolution of opinion, even without the influence of any American system.

Mr. R. H. Chapman exhibited some interesting photographs showing stratification in mine dumps.

ALFRED H. BROOKS,
Secretary.

BIOLOGICAL SOCIETY OF WASHINGTON.

THE 349th meeting was held on Saturday evening, February 8.

Dr. C. A. White gave a review of 'The Mutation Theory of Professor de Vries,' giving an outline of his experiments with various plants which had led to his conclusion that evolution was not always a slow process, but that under certain conditions might take place rapidly, and that there was a period in the growth of a race of plants or animals when it was particularly susceptible to external influences.

The paper will appear in the next 'Report' of the Smithsonian Institution.

Henry W. Olds presented 'Some Deductions from the Study of Bird Songs,' prefacing his remarks with the statement that the conclusions he was about to present were merely tentative, but, if corroborated by subsequent investigations, of much importance from their bearing on the question of the evolution of music. Music, he stated, seems to be popularly regarded as artificial and musicians apparently consider it largely, if not entirely, governed by fixed laws, while certain students

of the philosophy of the art, such as Helmholtz, Hanslick, Pole and others, believe that the truth lies between these two extremes—that the fundamental rules are governed by physical laws, while more complex questions of form are mainly, at least, arbitrary. The history of music appears to sustain the last view. The evolution of the diatonic scale, the comparatively recent rejection of all modes but the modern so-called major and minor, the absence of rhythm, as we know it, until about the eleventh or twelfth centuries, and of tonality, or reference in melody to a tonic or keynote, until the seventeenth century, all seem to support the theory that many present æsthetical rules of music are temporary and fortuitous and probably of no greater validity than those they have superseded. The octave, fifth and fourth of the modern scale are excepted, by those who hold this view, as resting upon a physical basis; but the other intervals are held to be arbitrary; and the necessity to the modern ear of a definite key, and all the requirements comprised under the term 'form,' are regarded as mainly casual, not necessarily indicating any advance toward a fixed ideal.

But if we find bird music undergoing an evolution that parallels our own progress—if advance in each independently follows the same lines, we have excellent evidence that there is an ideal standard toward which all progress must tend, a law which determines the direction of development of our æsthetical rules. A study of the songs of the birds seems to support this idea. Many birds, as for example the Carolina wren, wood thrush, chickadee and chewink, use the intervals of the modern scale. Birds songs are often rhythmical and may be divided into regular measures properly accented; and several of the formal rules of human music may be found governing the music of the birds.

Mr. Olds gave examples illustrating this statement. These included bits of melody satisfying to the human musical taste, phrases repeated on the same or a different pitch, antiphonal phrases coupled together by a single bird, or by two, with evident intention, and one instance of a song (by the wood pewee) in which the rules of construction governing

many ballads were followed. These Mr. Olds said were a few of the instances he had noted indicating a parallel and independent musical evolution and so leading to the conclusion suggested, but he wished to investigate further before positively announcing a principle opposed to the weight of authority and apparently in conflict with previous evidence.

F. A. LUCAS.

PHILOSOPHICAL SOCIETY OF WASHINGTON.

THE 546th meeting was held February 1, 1902, Vice-President Marvin in the chair.

Professor Simon Newcomb spoke on 'Recent Views of the Universe.' He called attention to the probability that the density of most stars is much less than that of the sun and the temperature higher; if the sun were removed to the same distance as the stars some of them would appear only 1/100 as bright as it, while *Canopus* and *Rigel* would be more than 1,000 times, probably 10,000 times, as bright. The probability is that most stars have dark bodies revolving around them. Our system is, so far as we know, very unusual in having circular orbits; the stellar orbits are generally quite eccentric, and life such as we know could not probably exist under the extremes of temperature prevailing near any star. The distribution of the stars appears to be remarkably symmetrical around the axis and plane of the Milky Way. The thinning out is slight up to a parallax of .01 second, and the stars extend to at least 1,200 times the distance of *α Centauri*. It is possible that the apparent limit may be due to absorption of light, caused for example by cosmic dust. Reference was made to Lord Kelvin's and J. J. Thomson's recent papers and the fact pointed out that all the new stars are in the Milky Way and therefore probably have a very small parallax, perhaps .001 second, more or less.

Professor F. H. Bigelow, of the Weather Bureau, spoke on 'Aristotle's Physics and Modern Physics.' Aristotle's profound work on the fundamental principles of nature ought to be better known to modern students. He defended the theory of nature which avoids both the extreme idealist view and the extreme material view, and developed the theory of

evolution from an inner potential which we now call life. He denied that atoms exist in a vacuum, but held that they possess mutual forces in a plenum. The recent views advanced by Lord Kelvin that the ether is imponderable or non-gravitational matter, and that action at a distance is the law of atoms, seem like a close return to the theory held by Democritus and Aristotle, and in this respect there is agreement between ancient and recent theories. But the startling theory advanced by Lord Kelvin that atoms and ether can occupy the same space identically is of course not in agreement with Aristotle. It is very well worth noting that many points of modern physics were anticipated by Aristotle.

Mr. A. L. Day, physicist of the Geological Survey, began a paper, 'On the Measurement of High Temperature.' An abstract will be deferred till the paper is concluded.

CHARLES K. WEAD,
Secretary.

ANTHROPOLOGICAL SOCIETY OF WASHINGTON.

THE 326th regular meeting was held January 28. Dr. J. Walter Fewkes exhibited a stone idol from Casas Grandes, Chihuahua, and, commenting on the resemblances of the ruins of northwestern Chihuahua and those of the Gila Valley, said that relief design characterizes the pottery of Casas Grandes, and that while this feature does not prevail in the Gila Valley, the ware is similar to that in the ruins of northwestern Mexico.

President W. H. Holmes, in discussing this paper, traced the distribution of relief work or life form in the United States and Mexico.

Major J. W. Powell's paper, 'An American View of Totemism,' was read by Mr. J. D. McGuire and was discussed by Mrs. M. C. Stevenson, Dr. J. W. Fewkes, and Professor W J McGee.

'Orenda and a Definition of Religion,' by Mr. J. N. B. Hewett, provoked much discussion and the subject was continued for consideration at the next meeting. Orenda is an Iroquoian word meaning mystic potency or magic, and is advanced to supplant the word animism, which seems not adequate to express this elusive belief. Messrs. McGee, Fewkes

and Pierce spoke in favor of adopting this word, but Miss Alice Fletcher thinks the word will not cover all forms of belief among our tribes.

WALTER HOUGH.

THE NEW YORK ACADEMY OF SCIENCES.

THE annual meeting of the New York Academy of Sciences was held at 108 West 55th Street on Monday, February 24, at 8:15 P. M., President R. S. Woodward presiding.

The reports of the officers for the last year showed that the affairs of the Academy were in a much more favorable condition than the year previous. The recording secretary reported that the Academy had 298 resident members, of which 92 were fellows, and that the principal work of the council during the year had been that of bringing about a revision of the constitution which would enable the Academy to carry on its work in accordance with the needs of science in New York City. A bill has just been passed by both houses of the State legislature, allowing a revision of the charter, which will enable the Academy to revise its constitution and by-laws, which will very shortly be done.

The publications of the Academy during the year have been small, owing to restricted appropriations; but through economy the finances have been straightened out, and the Academy opens the new year auspiciously. The principal paper besides short ones published in the *Annals*, Volume 14, has been that of Dr. Bashford Dean, entitled 'Paleontological Notes,' and printed as a Memoir, Volume 2, Part 3.

The library of the Academy continues to be housed in Schermerhorn Hall, Columbia University, and is rich in scientific serials, which are kept up to date largely through exchange.

The following honorary members, selected because of their eminent scientific services, were unanimously elected: James Dewar, M.A., LL.D., F.R.S., Jacksonian professor of experimental philosophy, University of Cambridge, England, 21 Albemarle St., London, England; William James, M.D., LL.D., Ph.D., Litt.D., professor of philosophy, Harvard University, Cambridge, Mass.; Wilhelm Wundt,

Ph.D., M.D., professor of philosophy, Leipzig, Germany. The number of honorary members is restricted to fifty.

The following resident members, because of their 'scientific attainments or services' to the Academy, were promoted to fellows, in accordance with the by-laws and constitution: Maurice A. Bigelow, Ph.D., Teachers' College, Columbia University; Professor Hermon C. Bumpus, American Museum of Natural History; O. P. Hay, Ph.D., American Museum of Natural History; E. O. Hovey, Ph.D., American Museum of Natural History; W. D. Matthew, American Museum of Natural History; S. J. Meltzer, M.D., 166 West 126th Street.

Ballots were then distributed, and votes counted, and the following officers were elected for the ensuing year:

President, J. McKeen Cattell; *First Vice-President*, Nathaniel L. Britton; *Second Vice-President*, Richard E. Dodge; *Corresponding Secretary*, Bashford Dean; *Recording Secretary*, Henry E. Crampton; *Treasurer*, Charles F. Cox; *Librarian*, Livingston Farrand; *Councilors*, Franz Boas, Hermon C. Bumpus, D. W. Hering, Frederic S. Lee, Chas. Lane Poor, L. M. Underwood; *Curators*, Harrison G. Dyar, Alexis A. Julien, George F. Kunz, Louis H. Laudy, E. G. Love; *Finance Committee*, John H. Hinton, John H. Caswell, C. A. Post.

The president and recording secretary-elect then assumed charge of the meeting, and the retiring president delivered his annual address, entitled 'Measurement and Calculation.' At the close of the address a vote of thanks to the president was carried on motion of Professor Henry F. Osborn, and the academy adjourned.

RICHARD E. DODGE,
Recording Secretary.

DISCUSSION AND CORRESPONDENCE.

THE UNION AND RIVERSDALE FORMATIONS IN NOVA SCOTIA.

TO THE EDITOR OF SCIENCE: In your issue of January 17, 1902, Vol. 15, No. 368, on page 90, the title and abstract of my second paper read before the Geological Society of America, held in Rochester, are given, which require a

slight emendation. The following exact title and brief abstract are herewith submitted:

TITLE: 'The Meso-Carboniferous Age of the Union and Riversdale formations in Nova Scotia.'

ABSTRACT: From internal paleontological evidence the Union and Riversdale formations are clearly Middle or Meso-Carboniferous. The insect, reptilian, lamellibranchiate, crustacean and other associated faunas, as well as the floras entombed in the Riversdale shales and sandstones, according to R. Kidston, of Stirling, Scotland; David White, of the U. S. National Museum, Washington; Dr. Wheelton-Hind, of Stoke-upon-Trent, Eng.; S. H. Scudder, of Cambridge; Henry Woodward, of the British Museum, London, Eng., indicate a typical Carboniferous horizon, which, when compared with similar faunas and floras elsewhere, lead one to state that a Meso-Carboniferous age is here represented.

In Cumberland County, Upper Carboniferous limestone beds, formerly classed as Lower Carboniferous, are thrust over siliceous shales and sandstones, etc., presumably of Meso-Carboniferous age, formerly classed as Devonian and referred to the 'rocks of Union' or Union formation. In Pictou and Antigonish Counties, Lower Carboniferous strata rest unconformably upon the upturned Eo-Devonian, with which the Union and Riversdale formations were formerly correlated by stratigraphers.

H. M. AMI.

OTTAWA, January 28, 1902.

HIGH WATER IN THE LAKES OF NICARAGUA.

THE numerous heavy flooding rains in Western Nicaragua and consequent rapid rise to unusual height of the water in Lakes Nicaragua and Managua (connected with each other by Rio Tapitapa) in November of last year, indicated that in February, 1902, the water in those lakes would be higher by several feet than the usual annual high water mark, or than since 1859 to 1861, when the height was about 12 feet above the average, and, consequently, that earthquakes and volcanic activity would occur.

The continuous rapid dry current of atmos-

phere passing over those lakes since the 20th of December, 1901, and the warm temperature has caused unusually great evaporation so that the water in those lakes is only about four feet higher at this date—February 9, 1902—than usual at this time of the year. There is also but slight increase of volcanic activity, indicated by an increased flow of gases and vapor from volcanic peaks. Only seven earthquakes in Western Nicaragua have occurred since November 15, each slight, from II. to IV. of the Rossi-Forel scale.

There are no indications of higher water in the Lakes this year. J. CRAWFORDS.

MANAGUA, NICARAGUA,
February 9, 1902.

UNIO CONDONI IN THE JOHN DAY BEDS.

PROFESSOR J. C. MERRIAM informs me that he 'found great quantities of that species at the original locality.' As this form was not among the material sent to me for determination, I erroneously inferred that it had not been detected. The original locality, as stated by Dr. White, is the North Fork of John Day River, Oregon, at the angle of the big bend, longitude 119° 40', latitude 44° 50'. My paper in SCIENCE January 24 last, pages 153-154, is hereby corrected in this particular.

ROBT. E. C. STEARNS.

NOTES ON INORGANIC CHEMISTRY.

THE NEW SULFURIC ACID MANUFACTURE.

ATTENTION has often been called within the last few years to the new process of making sulfuric acid from the pyrites-burner gases without the intervention of lead chambers, but the first authoritative description of the process, with the history of its development, was given in a lecture last fall by Dr. R. Knietzsch before the German Chemical Society. This lecture has now been published in the *Berichte* of the Society and deserves notice, not only on account of the intrinsic importance of the subject, but also as being a conspicuous example of how the persistent investigations of trained chemists have succeeded in overcoming what seemed to be insuperable obstacles.

The catalytic action of platinum upon mixtures of gases was discovered by Sir Hum-

phrey Davy in 1817, and in 1831 Peregrine Phillips, of Bristol, England, took out a patent for the manufacture of sulfuric acid by the action of finely divided platinum upon a mixture of sulfur dioxide and oxygen. This process, though exploited from time to time, and worked at by many chemists, came to nothing. In 1875 Clemens Winkler took up the study of this reaction, finding that the most favorable condition for this reaction is when the gases are present in the proportion of two volumes of sulfur dioxide to one of oxygen, and that the presence of other gases or even of an excess of either of those involved in the reaction is detrimental. Since, by decomposition, ordinary sulfuric acid yields a mixture of sulfur dioxide, oxygen and water, it was possible to utilize these gases in the manufacture of sulfur trioxide or of fuming sulfuric acid, by drying them to remove the water, and then leading them over platinum sponge. This was put into practical application with some success. This can, however, hardly be considered more than a very slight step toward the manufacture of ordinary oil of vitriol from the pyrites-burner gases.

The rapidly increasing development of the color-industry of Germany has occasioned a demand for enormous quantities of both concentrated and fuming sulfuric acid, and for the past decade the energies of the chemists of the great color corporations have been directed toward the problem of the manufacture of these acids without the intervention of the lead chambers and the platinum concentration stills. In these investigations Dr. Knietzsch, of the Badische Anilin- und Soda-Fabrik, was a most important factor, and to him belongs a great share of the credit of having rendered the new process a commercial success.

The gases from the pyrites-burners consist of sulfur dioxide, nitrogen and an excess of oxygen from the air. When these gases were thoroughly purified and carried to the laboratory it was found that on passing over a 'contact mass' containing finely divided platinum, the sulfur dioxide was completely oxidized to the trioxide, or to sulfuric acid if water was present. When, however, an attempt was

made to carry out the operation on a large scale, the contact mass quickly became inert. This was the case even when the gases had been purified by passing through long pipes, repeated washing with sulfuric acid, and further passage through coke and asbestos filters. In following up the cause of the difficulty, it was found that extraordinarily small quantities of arsenic were capable of inhibiting the action of the platinum in the contact mass. The same is true of a few other substances such as mercury and perhaps phosphorus. These substances seem to have what may be considered a poisonous action upon the platinum. Investigation showed that the arsenic was contained in the fine white fume which is formed in all cases where sulfur is burned. This fume consists of finely divided sulfuric acid, and its complete condensation has been one of the unsolvable problems of technical industry, especially in connection with smelting plants. Eventually the problem was solved by the thorough washing and wet filtration of the slowly cooled gases, with water or dilute sulfuric acid.

After this purification from every trace of mechanical impurity, as was shown optically, it was found that the contact mass still lost its activity after a time, and here again patient investigation revealed the fact of arsenic poisoning. This was finally shown to be due to the action of the condensed sulfuric acid from the burners upon the iron condensers, whereby traces of arseniuretted hydrogen (arsin) were generated. This difficulty was easily overcome, but when the process was attempted on a large scale, it was still unsuccessful. When the pyrites burners were used to their full capacity, there was formed a fume which resisted every attempt at condensation. This was unconsumed sulfur, which, of itself harmless, contained minute quantities of arsenic, thus again poisoning the contact mass. The formation of this fume was prevented by the injection of steam into the burners, which has other advantages, in preventing the action of the condensed acid on the iron pipes, and in hindering the formation of hard dust scales in the cooling pipes and chambers. Other difficulties appeared in the

cooling of the contact mass and in connection with the absorption of the sulfur trioxid, which is attended by a great development of heat, but they were slight in comparison with those which had attended the purification of the gases. At last the process was established on a commercial basis, as is shown by the fact that in the year 1900 the production of sulfur trioxid reached the amount of 116,000 tons.

The first interest of the process is of course for the manufacture of the concentrated and fuming acids, used largely in the color industry, but when it is considered that it is the concentrated acids which are most economically made in this manner, it is not difficult to foresee that in the near future the chamber process must be superseded for all acids which would require concentration in platinum stills. It is quite possible that the chamber process will continue to be used for many years to come, for the more dilute acids which require no concentration, but even so, the perfection of the contact process can be looked upon as little short of a revolution in this most important of the chemical industries.

J. L. H.

RELIEF SHIP FOR THE BRITISH ANTARCTIC EXPEDITION.

SIR CLEMENTS MARKHAM, president of the Royal Geographical Society, has issued the following appeal to the Society's fellows:

It is with some reluctance that I appeal again to the fellows of the Society on behalf of the relief ship, which must leave England not later than July next to obtain news of, and render what assistance may be necessary to, the expedition on board the *Discovery*. I make this further appeal in the belief that the fellows as a body do not realize the situation, and entertain an erroneous impression as to how much is expected of each individually. I am assured that many, if not most, of the fellows of the Society feel that, unless they can each contribute a very considerable sum, it would be useless to do anything.

I am particularly anxious to disabuse the fellows of this impression; I assure them that we shall be glad to receive any contribution,

however small. If each fellow of the Society made himself responsible for £2, we should be in a position to send off the relief ship fully furnished with all requirements. It is not necessary that each fellow should contribute £2 out of his own pocket; if he gives what he himself can afford, he would probably have no difficulty in obtaining the balance in small contributions from his friends.

Out of the 4,000 or more fellows of the Society, only 150 have contributed to the funds for the relief ship. I cannot help thinking that when those fellows who have not contributed realize this they will come to the help of the council, without hesitation, in the manner I have suggested, or in some way equally effective. The council has made itself responsible for the relief ship. The vessel, the *Morning*, has been purchased, and is now in the Thames undergoing the necessary alterations. When these are completed, the balance of the sum subscribed will be quite insufficient to furnish her with the necessary stores and to provide an adequate equipment of officers and crew.

In the hope of enabling the fellows to realize the situation and the Society's responsibility, I give the following extract from the last despatch from Captain Scott, written just before the *Discovery* left New Zealand to make her way through the ice to her destination:

It is with great satisfaction that I learn that it is intended to send a relief ship. I had contemplated writing most urgently to you on this subject, knowing how absolutely our retreat would otherwise be cut off should any accident result in the loss of the *Discovery*. The conditions which surround the Antarctic lands with a belt of tempestuous ocean have always impressed me with the difference to those existing in high northern lands, and I have felt that, since our retreat by boats to any civilized spot is a practical impossibility, our movements, and the risks we could rightfully take, must be greatly limited, if the loss of the ship of necessity implied the loss of all on board.

I see that every effort will be made to despatch the vessel which you have already purchased for the purpose. It will, therefore, be a great relief and satisfaction to me to leave Lyttelton, confident that such efforts will be successful and that a line of retreat is practically secured to us.

I feel sure that after this statement the fellows of the Society may be relied on to support the council in an undertaking absolutely essential to the complete success of the National Antarctic Expedition.

THE U. S. GEOLOGICAL SURVEY.

IN the U. S. Geological Survey the Geologic Branch is reorganized by the appointment of Mr. C. Willard Hayes to the position of geologist in charge of Geology to take effect March 1, 1902. Mr. Hayes has been connected with the survey since 1887 and has served with ability in various relations as assistant geologist, geologist, and since 1900 as geologist in charge of investigations of non-metalliferous economic deposits. He is now placed in administrative control of the geologic branch in order that the director may be relieved of executive details and the organization may be strengthened by the undivided attention of its head to carrying out the director's general policy. By this appointment Mr. Willis, who since 1897 as assistant in geology to the director has performed the administrative work of geology, is freed from that duty and will be at liberty to give more attention to the division of areal and stratigraphic geology, of which he has charge. In announcing these changes at a meeting of geologists in the office of the survey on February 20, the director called attention to the plan of organization of the geologic branch set forth in the Twenty-first Annual Report, pages 20 and 21, and more fully elaborated in the forthcoming Twenty-second Annual Report. The fundamental idea of the organization is that scientific direction and supervision may be and in most cases should be separated from administrative control. Specialists are placed in charge each one of investigations in a particular subject, Messrs. Becker, Chamberlin, Day, Emmons, Hayes, Stanton, Van Hise and Willis having been thus appointed, but their authority is in general limited to consideration and approval of the scientific aspects of the work. Administrative authority remained immediately with the director, and is now in a degree transferred to the geologist in charge of geology, Mr. Hayes.

SCIENTIFIC NOTES AND NEWS.

At the last meeting of the Rumford Committee of the American Academy of Arts and Sciences it was voted to appropriate the sum of \$300 to Professor E. F. Nichols, of Dartmouth College, for the purchase of a spectrometer in furtherance of his research on resonance in connection with heat radiations.

DR. FRANZ BOAS, professor of anthropology in Columbia University and curator of anthropology in the American Museum of Natural History, has been elected an honorary member of the Anthropological Institute of Great Britain and Ireland.

PROFESSOR W. O. ATWATER, of Wesleyan University, has gone to Havana for a conference on the dietary standards for the public institutions.

PROFESSOR EMILE BOUTROUX, of the Sorbonne, has been elected Gifford lecturer in the University of Glasgow, in succession to the Master of Balliol, whose term has expired.

PRINCIPAL E. H. GRIFFITHS, of Cardiff University College, has been given the degree of Doctor of Science by Cambridge University.

DR. M. E. WADSWORTH, head of the department of mines and mining in Pennsylvania State College, has been elected geologist for the Pennsylvania State Board of Agriculture.

MR. HENRY L. WARD, one of the managers and vice-president of Ward's Natural Science Establishment, Rochester, N. Y., has been elected to the position of custodian and secretary of the Public Museum of Milwaukee, which position he will assume the latter part of March.

PROFESSOR E. MILLOSEVICH has been appointed director of the Astronomical Observatory at Rome as successor to Professor Tacchini, who retired recently.

THE trustees of the Ohio State Academy of Science have made the following grants from the Emerson McMillin research fund: Professor Lynds Jones, Oberlin, Ohio, to enable him to complete his 'Catalogue of the Birds of Ohio,' \$75; Professor J. S. Hine, Columbus, Ohio, to enable him to complete his work on the Tabanidae, \$50; Professor J. H. Schaffner and Fred. Tyler, to study and report

on the ecology of Brush Lake, Champaign County, \$50. No. 5 of the Special Papers of the Academy will soon be printed. It contains the results of investigations made with the aid of this fund.

DR. CHARLES H. GILBERT, head of the department of zoology of Stanford University, will sail soon on the U. S. steamer *Albatross* on a six-months' scientific expedition to Hawaii, to continue the work conducted last year by Dr. David Starr Jordan and Dr. Oliver P. Jenkins. Dr. Gilbert will be accompanied by Professor C. C. Nutting, of the University of Iowa; Dr. John C. Snyder, instructor in zoology at Stanford, and Mr. Walter F. Fisher, a Stanford graduate from the same department.

THE British Government appointed some time since a committee of experts, consisting of Lord Rayleigh, Sir J. Wolfe Barry and Professor Ewing, to ascertain how, if possible, the vibration of the Central London 'tube,' which is causing serious injury to property overhead, can be prevented. The committee recommends substituting carriages with motors underneath for the locomotives now used.

DR. ADOLF MEYER, director of the pathological Institute for the New York State Hospitals, gave an address entitled 'Conditions for Psychiatric Research,' before the Philadelphia Neurological Society on February 25. After the address a reception was tendered Dr. Meyer at the University Club.

DR. L. O. HOWARD, entomologist of the U. S. Department of Agriculture, gave the annual public lecture before the Brown Chapter of the Society of the Sigma Xi on Wednesday evening, February 26, his subject being 'The Practical Applications of Entomological Science, with special reference to Shade Tree Insects.'

THE death is announced of Mr. William Martindale, a prominent British pharmacist at the age of sixty-one years. He had been president of the Pharmaceutical Society and was for many years one of its board of examiners.

THE death is also announced of Dr. Charles Stuart, a well-known English naturalist.

CIVIL service examinations will be held in New York City on March 15, for the following positions in the reorganized Pathological Institute: Associate in chemistry (\$1,800); associate in clinical psychiatry (\$1,200); associate in neuropathology (\$1,800).

THE Prussian *Budget* for 1902 appropriates 20,000 Marks for further study of means of prevention and early diagnosis of typhoid fever; 10,000 Marks to the Committee for Cancer Research, and 53,000 Marks to be applied to the erection and maintenance of a cancer ward and laboratory in connection with the Charité Hospital at Berlin.

THE newly-organized American Electro-Chemical Society, which now numbers 294 members, will hold its first meeting at Philadelphia on April 3, 4 and 5.

THE general meeting of the American Philosophical Society, to which we have already called attention, will be held in the hall of the Society in Independent Square on April 3, 4 and 5. The morning sessions begin at 10:30 A. M. and the afternoon sessions at 2 P. M. Members intending to be present who have not yet notified the Committee on Arrangements to that effect are particularly requested to do so without delay. Luncheon will be served in the rooms of the Society. A reception will be given to the members by the president and managers of the department of archeology of the University of Pennsylvania at the Free Museum of Science and Art, Thirty-fourth and Spruce Streets, on Thursday evening, April 3, at 9 o'clock. The visiting members will be the guests of the resident members of the Society at dinner on Friday evening, April 4. A considerable number of important papers have been promised, a list of which will be published later in this journal.

UNDER the auspices of the department of zoology of Columbia University Dr. Jacques Loeb, professor of physiology and experimental biology at the University of Chicago, will give in March a course of lectures on 'The Dynamics of Living Matter.' The subjects are:

March 18, 'The General Chemical Character of Life Phenomena'; March 19, 'The General Phys-

ical Constitution of Living Matter'; March 20, 'Protoplasmic Motion, Muscular Contraction and Cell Division'; March 21, 'The Effects of the Galvanic Current upon Life Phenomena'; March 24, 'The Effects of Ions upon Various Life Phenomena'; March 25, 'The Effects of Light and Heliotropism'; March 26, 'Artificial Parthenogenesis and the Problem of Fertilization'; March 27, 'Regeneration and the Reversibility of the Process of Development.'

DR. ALEXANDER MACFARLANE will give at Lehigh University during March a course of lectures on British mathematicians of the nineteenth century, the dates and subjects being as follows:

March 14, 5 P.M., 'James Clerk Maxwell'; March 15, 11:30 A.M., 'Henry John Stephen Smith'; March 18, 5 P.M., 'William John Macquorn Rankin'; March 21, 5 P.M., 'James Joseph Sylvester'; March 22, 11:30 A.M., 'Peter Guthrie Tait'; March 25, 5 P.M., 'William Thomson, first Lord Kelvin.'

A COURSE of nine lectures upon 'Science and Travel' has been arranged by the Field Columbian Museum, Chicago, for Saturday afternoons in March and April at 3 o'clock. The lectures will be illustrated by stereopticon views. The subjects, dates and lectures are:

March 1.—'Texas Petroleum': Dr. WILLIAM B. PHILLIPS, professor of field and economic geology, University of Texas, and director of the university mineral survey.

March 8.—'The Sun Dance of the Cheyenne and the Arapaho': Dr. GEORGE A. DORSEY, curator of anthropology, Field Columbian Museum.

March 15.—'The Northern Rocky Mountains': Dr. STUART WELLES, assistant professor of paleontologic geology, University of Chicago.

March 22.—'Geological Field Work in the Iron and Copper Districts of the Lake Superior Region': Professor U. S. GRANT, Northwestern University, Evanston, Illinois.

March 29.—'Birds and their Nests': Dr. JAMES ROLLIN SLONAKER, University of Chicago.

April 5.—'Insects of Southern Peru and Bolivia': Mr. WILLIAM J. GERHARD, assistant curator, Division of Entomology, Field Columbian Museum.

April 12.—'Interpretation of Some Features of Landscape': Professor CONWAY MACMILLAN, University of Minnesota, Minneapolis.

April 19.—'Recent Explorations in Prehistoric Hopi Ruins, Arizona' (Stanley McCormick Expedition): Mr. C. L. OWEN, assistant curator,

Division of Archeology, Field Columbian Museum.

April 26.—'The Crow Indians of Montana, A Western Plains Tribe': Mr. S. C. SIMS, assistant curator, Division of Ethnology, Field Columbian Museum.

WE learn from the London *Times* that the Government of India, which some time since selected an officer of the Forest Department to study the insects injurious to forests, more recently appointed an inspector-general of agriculture. It is reported now to be considering a further important step in the same direction, in the shape of the establishment of a scientific board to cooperate with the inspector-general. Probably it would consist of an economic botanist, entomologist, geologist and chemist. Agriculture is by far the greatest of Indian industries. The institution of a staff of trained inquirers to bring the light of Western science to battle with the legion of its chief enemies—drought, insect pests, and obstinate human ignorance—would be in entire accordance with the enlightened spirit of Lord Curzon's administration.

PROFESSOR M. FOSTER, secretary of the Royal Society, has addressed a letter to the London *Times* explaining the relation of the Royal Society to the proposed British Academy. He says: A committee of the Society was appointed to consider various suggestions which had been made to the Society as to the representation of philosophico-historical studies in an 'academy,' and to state 'the various reasons which may be urged for and against' the several suggestions. It is quite incorrect to speak of the eminent persons in question as 'applicants' for membership, or of the committee as appointed to consider whether the Society could recognize their claims, or should extend their charters in order so to do, though the committee did incidentally inquire into the powers given to the Society by the charters, and came to the conclusion that the above-mentioned studies could be included in the work of the Society. The suggestions were four in number—one proposing the creation of an independent organization and three proposing the promotion of these studies within the Royal Society itself in three different ways. The committee in its

report made no recommendations; it simply 'stated the reasons for and against.' The council consulted the whole body of fellows at a special meeting, and subsequently passed a resolution, the meaning of which was that it approved of the first suggestion.

THE British Meteorological Council has presented a report to the Royal Society which has been issued as a government blue book. The work of the office is summarized under the following heads: (1) Ocean Meteorology—the collection, tabulation and discussion of meteorological *data* for all parts of the ocean traversed by British ships. The preparation and issue of charts or other publications exhibiting the results obtained from the discussion of the observations. The issue of meteorological instruments for use on board the ships of the Royal Navy, and for observers belonging to the merchant service, with which is associated the supply of instruments to the telegraphic reporting stations, etc. (2) Weather Telegraphy—the collection of observations transmitted by telegraph three times in each day from selected stations in the British Isles (chiefly on the coasts) and on the continent of Europe, the preparation of a daily report embodying the observations and of forecasts of weather based upon them, and the issue of warnings to ports on the coasts of the United Kingdom whenever there are indications of the approach of severe storms. (3) Climatology—the collection of information of various kinds from observatories and other land stations in the British Isles and from a few stations in British possessions or in foreign countries with the view of extending the accurate knowledge of the meteorological conditions obtaining in the various districts in which the observations are made, and of the changes to which they are subject. (4) Library—for the collection and preservation of weather maps and other publications issued by the colonies and dependencies of the British Empire and by foreign countries, so that they may be available for consultation by those requiring information as to the weather in various parts of the globe. (5) Miscellaneous investigations. (6) Publications. (7) Finance.

Nature states that an astronomical observatory has been erected and equipped by the Bengal Government at the Presidency College, Calcutta, and was recently opened. The idea of providing means for the instruction of Indian youths in practical astronomy was conceived about five years ago, when the Maharaja of Tipperah presented to the Presidency College an equatorial telescope by Grubb, $4\frac{1}{2}$ -inch aperture. On Dr. J. C. Bose's representation, the Government of Bengal agreed to provide a building suitable for observations. But it was not done until after the eclipse of January, 1898, when the professional and amateur astronomers who visited India caused active interest to be taken in building the observatory. From an article in the *Pioneer Mail* it appears that the chief instrument of the observatory is a 7-inch equatorial by Sir Howard Grubb, with an electrically controlled driving clock and with electric lights for all the graduated circles. The telescope will generally be used for eye observations, but the object-glass may be adapted to photography, and the mounting of the telescope is of a strength that will admit of its being used for spectroscopic examination of the sun or the brighter stars.

At a meeting of the members of the Royal Institution on February 3 thanks were returned to Sir Frederick Bramwell, for his donation of £100, and to Mr. Frank McClean, for his donation of £50 to the fund for the promotion of experimental research at low temperatures. It was announced that the following valuable relics of Michael Faraday, bequeathed to the institution by the late Mr. Thomas J. F. Deacon, had been received: Medals of silver and bronze (numbering 20 in all), and including the Fuller medal of 1828, two Copley medals of 1832 and 1838, two Newton medals of the Royal Society, 1833 and 1838, and the Rumford medal of 1846; and two foreign Orders, contained in a small mahogany box; a book of portraits and autographs, including original letters from the Prince of Wales and Prince Alfred, Louis Napoleon, Humphry Davy, Thomas Young, Humboldt, John Dalton, Whewell, Mary Somerville and many others; a daguerrotype of a consultation of

Faraday with Professor Daniell; a drawing in colors of the laboratory of the Royal Institution, and a manuscript book entitled 'A Class Book for the Reception of Mental Exercises instituted July, 1818,' containing contributions by Faraday.

THE following sets of scientific books were recently sold at auction in London: *The Alpine Journal*, from the commencement in 1863 to November, 1901, £29 10s.; M. C. Cooke, 'Illustrations of British Fungi,' and supplement, 1881-91, with upwards of 700 colored plates, £23; the *Quarterly Journal of the Geological Society of London*, from the commencement in 1845 to August, 1901, £16; Sowerby's 'British Botany,' 1863, etc., £33; the publications of the Palæontographical Society, 1848-97, £17 15s.; H. G. L. Reichenbach, 'Icones Floræ Germanicæ et Helveticæ,' etc., 1850-99, 23 volumes with upwards of 2,000 colored plates, £63 10s.

WE learn from the *London Times* that under the presidency of Dr. Morris, the Imperial Commissioner of Agriculture, the fourth West Indian Agricultural Conference was held at Barbados on January 4 and 6 last, there being a large gathering of the representatives of the botanical, chemical, and educational departments, and of the chief agricultural societies in the West Indies. The proceedings were opened by Sir Frederic Hodgson, the governor of Barbados, in an address of welcome. In his presidential address Dr. Morris passed in review the various industries of the islands, from sugar to bee-keeping and onion-growing. With regard to the question of central factories he expressed the hope that in some of the smaller sugar islands it had approached a stage when the details may be submitted to the consideration of the planting community. In Barbados the opinion is not unanimous that central factories would materially improve the condition of all classes of the community. It is only proposed to introduce factories gradually, but so long as nothing is done it is difficult to look forward with any degree of comfort to the future of the sugar industry of the island. Papers on various subjects were read and discussed, sugar, naturally, taking the

foremost place. There were communications on sugar-cane experiments in Barbados, Antigua, St. Kitts, Trinidad and British Guiana. In Guiana an important feature has been the trials of canes on an estate scale, in addition to the necessary small plots. It is fully realized by the officials of the Imperial Agricultural Department that a strenuous attempt must be made to raise the general standard of intelligence amongst all classes; and it is in contemplation shortly to commence the publication of a fortnightly paper, the *Agricultural News*, containing hints and advice in regard to all points of interest in the islands.

UNIVERSITY AND EDUCATIONAL NEWS.

It is announced that Mr. James Stillman, of New York, has given \$100,000 for the establishment of a chair of anatomy in the Harvard Medical School.

THE University of Wooster, Wooster, O., successfully completed on February 21 a campaign to raise \$140,000 in order to secure two large conditional gifts, \$100,000 by Mr. Andrew Carnegie and \$50,000 by Mr. L. H. Severance, of Cleveland. In place of the building which was destroyed by fire on December 11, there will be erected a main building containing lecture rooms, a building for chemistry and physics, a building for biology and geology, an academy building and a heating plant.

It is proposed to establish in New York City a branch of the Catholic University of America, to be known as the Department of Pedagogy.

MR. JOHN D. ROCKEFELLER has given \$5,000 to Washington and Lee University, thus completing the fund of \$100,000 for a memorial to the late President William L. Wilson, in the form of an endowment for the chair of economics and political science.

THE trustees of the University of Pennsylvania have awarded the contract for the construction of the new Medical Laboratories. In the extent of the plan and in the cost of this addition to the facilities of the University, it is the most important agreement ever entered into by the corporation. Since the study of the subject was first begun, the scope of the

purposes to be attained has so widened that from the original projected cost of two hundred thousand dollars, three years ago, the cost of the completed undertaking now entered upon will be about six hundred thousand dollars. The study of the plans has covered all the scientific medical laboratories both in Europe and in this country; and the faculty of medicine feel, and the members of the medical committee of the trustees feel, that the result as submitted by the architects, Messrs. Cope & Stewardson, will repay all the attention and study and pains which have been taken. The building will be wholly fire-proof, and its extent may be understood when it is known that its front on Hamilton Walk is three hundred and forty feet, and the depth of its western wing, one hundred and ninety feet. Provision in respect of north light and of quiet and of freedom from dust has been made for original work in all three of the laboratories included in the building.

PROFESSOR JOSIAH ROYCE, professor of philosophy at Harvard University, and Professor J. Mark Baldwin, professor of psychology at Princeton University, will lecture before the summer school of the University of California during July.

At Cambridge University Professor Tilden, F.R.S., has been appointed an elector to the chair of chemistry; Lord Rayleigh, F.R.S., an elector to the chairs of chemistry and of mechanism; Dr. Hill, to the anatomy chair; Mr. F. Darwin, F.R.S., to the botany chair; Dr. Hinde, F.R.S., to the geology chair (Woodwardian); Sir G. G. Stokes, F.R.S., to the Jacksonian and Cavendish chairs; Dr. D. MacAlister, to the Downing chair of medicine; Dr. Hugo Müller, F.R.S., to the chair of mineralogy; Professor E. Ray Lankester, F.R.S., to the chair of zoology and comparative anatomy; Professor McKendrick, F.R.S., to the chair of physiology; Lord Lister, F.R.S., to the chair of pathology; and Professor Marshall Ward, F.R.S., to the chair of agriculture.

DR. FRANZ WILHELM NEGER, curator in the Botanical Museum at Munich, has been called to a professorship in the School of Forestry at Eisenach.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE
OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION
FOR THE ADVANCEMENT OF SCIENCE.

EDITORIAL COMMITTEE: S. NEWCOMB, Mathematics; R. S. WOODWARD, Mechanics; E. C. PICKERING, Astronomy; T. C. MENDENHALL, Physics; R. H. THURSTON, Engineering; IRA REMSEN, Chemistry; CHARLES D. The fifth regular annual meeting of this Society was held at Columbia University, New York City, December 31, 1901, and January 1, 1902, under the presidency of Dr. Erwin F. Smith. There was a good attendance of members, and the meeting was in all ways successful. Friendly greetings were exchanged by telegraph with the botanists in session at Chicago. Some business of general interest was transacted, of which a full account will be found below. This included action upon the report on the *Botanisches Centralblatt* and the Association Internationale des Botanistes, the nomination of American members of the executive committee of the Association Internationale, and the report on the College Entrance Option in Botany. The following new members were elected: Miss Margaret Ferguson, Wellesley; Messrs. Ernst A. Bessey, Washington; T. E. Hazen, St. Johnsbury, Vt.; A. S. Hitchcock, Washington; C. F. Hottes, Urbana, Ill.; E. C. Jeffrey, Toronto; and R. H. True, Washington. The following officers were elected for the ensuing year: President, Professor Volney M. Spalding, University of Michigan; Vice-President, Professor Byron D. Halsted, Rutgers College; Secretary-Treasurer, Professor W. F. Ganong, Smith College. The Society will meet next year with the other societies at Washington.

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

On the afternoon of January 1 the Society adjourned to the New York Botanical Garden at Bronx Park, where the museums, laboratories and collections of living plants were shown by members of the Garden staff, and Professor MacDougal exhibited some new appliances developed in connection with his physiological work.

Among the enjoyable social features of the meeting were the luncheon given to the Society and its guests at the Teachers College by Professor Lloyd, and the very pleasant informal dinner of the botanists on Wednesday evening. The hospitality of the New York botanists to the members of the Society and their guests was most cordial, and contributed greatly to the pleasure and profit of the meeting. A group photograph of the Society was taken, resulting in an excellent picture, concerning the cost and other particulars of which information will be furnished by the secretary.

The address of the retiring president, Dr. Erwin F. Smith, was delivered at the dinner. It dealt with 'Plant Pathology, a Retrospect and Prospect.' It will soon appear in full in SCIENCE.

The following papers and reports were presented and discussed. Owing to the crowded condition of the program at the preceding meetings, papers were accepted this year from members and nominees to membership only. The abstracts are prepared by the authors.

Artificial Changes affecting the Vegetation of the Huron River: Professor V. M. SPALDING, University of Michigan.

In the course of a botanical survey of the Huron river and valley it has been found that artificial changes induced by the erection and breaking down of dams have been followed by rapid and extensive readjustment and adaptation. Changes of water level and rapidity of current are respon-

sible for some of the most striking phenomena. Several species, among them *Polygonum emersum* and *Solanum Dulcamara*, exhibit remarkable plasticity, and their structural changes are such as enable them to play the part of aquatics or of land plants as the raising or lowering of the water level may require. Charts are being constructed to show the present distribution of the various plant societies of the river and valley in the vicinity of Ann Arbor.

A Floating Tropical Botanical Laboratory:

Dr. JOHN W. HARSHBERGER, University of Pennsylvania. (Illustrated.)

The West Indies, lying in close proximity to the United States, are easily accessible to American botanists. By means of lantern slides, a few of the possible lines of research work, suggested on a visit to the Bahamas, Haiti and Jamaica during the summer of 1901, were illustrated. It was suggested that an investigation of the mature bending of the trunk of the coco-nut palm, of the pollination of the West Indian grown figs (*Ficus*), of the ecologic relationship of the plants of the strand, of the xerophytic and mesophytic forests, might be undertaken with profit. As many of the islands have an irregular coast line, are somewhat inaccessible, and as the inhabitants of Haiti look with suspicion upon strangers, it was thought advisable in investigating the flora of the various islands to visit them by means of a steamer fitted up as a tropical research laboratory. The steamers, Norwegian built (such as the *Belvernon* and *Mt. Vernon* of the Cameron Line), cut away fore and aft, were thought best adapted for the purpose.

The Physiology of Sea Water: Dr. RODNEY H. TRUE, Department of Agriculture.

The studies reported were made at

Wood's Holl, Mass., during portions of the last three summers. The plant most used was *Cladophora gracilis*. This alga was able to survive temporarily in a cane-sugar solution containing 1.2 gram molecules per liter of solution without apparent injury, and carried on its functions with seeming regularity. A greater or less proportion of the cells lived in concentrations between 0.3 gm. mol. and 1.6 gm. mol., but at the extremes unbalanced osmotic forces wrought injury to the younger cells. The plants were fatally affected within an hour by solutions of sodium chlorid in all concentrations, and in a solution isotonic with sea water were unable to respond to plasmolytic tests after about one-half hour. A progressive synthesis of artificial sea water, containing those substances present in a quantity equal to five thousandths of one per cent., was made. Death in a solution containing the proper amount of sodium chlorid took place in about a half-hour. When to this magnesium salts were added, no marked change in the period of survival was seen. The addition of the trace of calcium sulfate required extended the time of survival to about two hours. On the further addition of the potassium compounds, the plants lived for about twenty-four hours. Although isotonic with natural sea water, this artificial mixture was less saline to the taste than the former. On adding further sodium chlorid (about three-fourths per cent.) until equal salinity to the taste was obtained, the artificial solution was found to be capable of supporting an apparently normal existence in the alga for eight days. Evidence that cannot be summarized here was presented in support of the view that not only the actual amount of substances dissolved is concerned in the physiological behavior of sea water, but that the form in which these things there exist is important. Further work is in progress.

On the Teaching of Plant Physiology to Large Elementary Classes: Professor W. F. GANONG, Smith College.

The author called attention to the fact that the advance of science depends not only upon the acquisition of new knowledge and its correct interpretation, but also upon its utilization, of which one phase is its application in education. Plant physiology is rapidly rising in educational favor, but a chief obstacle to its more rapid advance is the difficulty of teaching it to large classes by proper laboratory methods. It was pointed out that many of the practical difficulties are disappearing with the improvement in methods and appliances, and ultimately the subject will be taught through individual experimentation. This is not yet practicable in large elementary classes, and at present students must be taught *en masse*. After trial of various plans the author had attained fair success by selecting the ten or twelve most fundamental experiments and setting them up, with full explanations, before the class, requiring the students individually to make records and finally to present reports upon them. The details of the management of the plan on which its success largely depends can not be repeated here, but the paper is soon to be published in *School Science*.

Discussion on the Most Profitable Relation of the American Botanical Societies to one another.

The opinions brought out by this discussion agreed very closely with those expressed by the speakers before the American Society of Naturalists at Chicago on January 1, as reported in this journal for February 14. One speaker urged a closer union of the various societies with the American Association, while another advocated the merits of a double system, in which regional societies, meeting regularly

in the principal centers within natural geographical districts, would combine with the American Association whenever the latter meets within their territory, the American Association thus forming a bond between the various regional societies.

Report of the Committee on the Botanisches Centralblatt, presented by the Chairman, Professor W. G. FARLOW, Harvard University.

Printed copies of the report were distributed to those present. It showed a completely successful result of the committee's work. A full account of this report and its bearings will be given elsewhere in this journal, so that for the present it is enough to say that it describes the continuance of the correspondence with the proprietors of the *Botanisches Centralblatt* authorized by the Society last year, the purchase of the *Centralblatt* by the Association Internationale des Botanistes, and the selection of the seven American editors of the journal. The committee having completed its work was discharged with the thanks of the Society. Professor Farlow explained further the present status of the *Centralblatt* as the organ of the Association Internationale, and the business features of the arrangement. Membership in the Association is open to any one interested in botany, on payment of the annual subscription of 25 shillings, and all members will receive the *Centralblatt* free. To meet the purchase price of the *Centralblatt* one hundred bonds have been issued of the value of 250 florins each (\$100.68), subscription to one or more of which makes one a foundation member of the Association. These bonds bear interest at the rate of $2\frac{1}{2}$ per cent. and are to be redeemed from the profits of the *Centralblatt*. Very few have yet been taken in this country, and it is desirable, in order that this country may do its share in this important matter, that more

should be taken here. The *Centralblatt* promises to be a strong journal of reviews, indispensable to every botanist, and it now has the support of the leading botanists of the world. In the discussion which followed, it was pointed out that American members of the Association Internationale would soon be called upon to vote for two American members of the general executive committee of the Association. There appears to be no body of botanists with authority to make nominations of such members, although in the absence of nominations the votes are likely to be very scattering or even not cast at all. It was then suggested that, in view of the fact that this Society had managed the correspondence with the proprietors of the *Centralblatt* and had aided the Association Internationale to choose American editors, etc., it might not be inappropriate for the Society also to suggest nominations of American members of the executive committee. Accordingly the Society voted to thus suggest the nomination of Professors W. G. Farlow and C. E. Bessey. Professor Farlow stated that he would be unable to serve on the committee, and accordingly Professor W. F. Ganong was nominated instead. It was announced that any further information about the subject, copies of the report of the committee, or of the blank forms of application for membership in the Association or for subscription to bonds, could be obtained from Professor Trelease, Missouri Botanical Garden, St. Louis, Mo., chairman of the American Board, or from the secretary of the Society.

On the Teaching of Vegetable Pathology:
Dr. HERMANN VON SCHRENK, Shaw School of Botany.

The speaker discussed the scope of vegetable pathology and urged the necessity of recognizing the plant as a living organism. For a course of vegetable pathology, a

thorough knowledge of physiology, general chemistry (preferably also organic chemistry), physics, general morphology of higher plants, French and German ought to be required. He outlined a course in pathology beginning with the study of the influence of environmental conditions on the plant cell, followed by actual experimental work with bacterial and fungous diseases. Emphasis was laid upon the fact that the plant should be considered first and foremost, and that the student should work with this himself.

The Destruction of Cell Walls by Bacteria:
Dr. ERWIN F. SMITH, Department of
Agriculture.

Lantern slides were exhibited showing all stages in the destruction of the inner tissues of the turnip due to the parasitism of *Pseudomonas campestris*. All were made from one plant which was inoculated on the blades of the leaves by means of needle pricks, using a pure culture of this bacterium. The disease appeared on the leaves only after a number of days. There was a progressive downward movement of the disease. The plant was removed from the soil on the fifty-second day after inoculation, at which time most of the leaves were shriveled, but the root was white and entirely sound externally. Sections of the root showed the bacteria to be very abundant in the inner parts. A careful microscopic examination made at the time did not reveal the presence of any fungi or animal parasites in the tissue. Cultures made from the interior of this root yielded only *Pseudomonas campestris*. Portions of the root were fixed in strong alcohol and subsequently infiltrated with paraffin, cut on the microtome with a very sharp knife, and fastened to slides with water containing one-half per cent. gelatin, freshly prepared. The paraffin was subsequently dissolved out with turpentine, the sections stained in

carbol-fuchsin, washed in water containing 50 per cent. alcohol, passed through graded alcohols, dehydrated in absolute alcohol, passed into xylol and finally mounted in Canada balsam. A study of serial sections with the best microscopic appliances has failed to reveal the presence of any fungi in the sections. The parts which are attacked are only the inner parts of the root (vessels and parenchyma). Many of the bundles are filled with the short bacterium, and cavities in the parenchyma are found around some of these bundles. The fixing and subsequent treatment of the sections allow the study of the organism *in situ*. The bacterial masses are not torn or displaced by the knife, and an examination of these slides shows all stages in the solution of the cell walls, from single cells or vessels occupied by the bacteria, to cavities occupying the place formerly occupied by hundreds of cells and filled with the bacteria and the remnants of the cell walls. The cells are crowded apart by the growth of the bacteria, and the middle lamella first disappears, but the cell walls proper also become vague in outline and finally disappear.

Observations on the Bacterial Rot of the Calla Lily: Dr. C. O. TOWNSEND, Department of Agriculture.

This is a soft brown rot, with offensive odor, that usually attacks the bulbs but may appear on the roots or leaves. It has been observed to destroy the calla plants in entire houses in the vicinity of Washington. As a rule, the bulb shows the disease most frequently near the top, but it often happens that the attack is made below the surface of the ground, in which case the bulb is commonly almost entirely destroyed before the leaves indicate that the plant is diseased. If proper conditions prevail, the disease progresses rapidly and the diseased tissue is broken down. Agar

plate cultures, made with care from the advancing margin of the diseased area, give only bacteria and generally pure cultures of a rod-shaped motile Schizomycete. Neither fungi nor burrowing insects are present. The colonies appear in the agar plates in from twenty-four to thirty-six hours. The surface colonies grow rapidly, are nearly round, slightly convex, having a milky color, shining surface and entire margin. The imbedded colonies remain much smaller, are mostly spindle-shaped and have a brownish tinge. The organism grows rapidly on nutrient, slant agar, and on steamed potato, carrot, parsnip, salsify, beet and onion. It does not discolor the medium upon which it grows; it develops slowly in alkaline gelatin; the stab cultures are beaded in form, and the gelatin is not liquified. Milk is coagulated rather rapidly; blue litmus milk is changed to red and eventually faded to white. Nitrates are reduced to nitrites. The organism grows in the closed end of fermentation tubes containing peptonized beef bouillon with 5 per cent. grape sugar, but without formation of gas. Diseased plants have been treated with lime, sulfur and dilute formaline, with some success in controlling the disease, but the best treatment found thus far consists in changing the soil in the calla bed or in growing the plants in pots, and in the proper management of the greenhouses.

A Disease of the American Ash: Dr. HERMANN VON SCHRENK, Shaw School of Botany.

A disease of *Fraxinus Americana* caused by *Polyporus fraxineus* was described. Attention was called to the large per cent. of living trees affected with this disease in localities where the ash is present in large numbers.

Vegetative Reproduction in Leptolejeunea:
Professor A. W. EVANS, Yale University.
Certain species of the epiphyllous genus

Leptolejeunea reproduce themselves largely by means of leafy propagula, which represent modified branches. This type of vegetative reproduction, although known in several mosses, has not before been recorded for the hepatics. The first leaves and under leaves of the propagula show curious modifications, and the most remarkable of these are found in the underleaves, which develop disc-shaped suckers instead of the usual clusters of rhizoids. By means of these suckers, the propagula are able to attach themselves quickly to the smooth leaf-surface upon which they grow.

Observations on Pterygophora: Professor CONWAY MACMILLAN, University of Minnesota. This paper will be published in full in *Minnesota Botanical Studies*.

Pterygophora grows much larger in the Straits of Fuca than reported in systematic works upon the kelps. It has been found with stipe three meters in length and a decimeter in thickness. Secondary thickening, in *Lessonia* apparently limited to the stipe, takes place in *Pterygophora* in both hapteres and stipe, producing rings of growth in each of these organs. Secondary thickening in the haptere differs from that in the stipe. In the former the ringed appearance is principally due to succession of cell layers differing in contents; in the latter the ringed appearance is due to succession of cell layers in which the elements are of different size and shape. A cross section through the growth-ring in the stipe of *Pterygophora* recalls similar sections through the stem of Gymnosperms. The substance which by its varying abundance in successive cell layers gives rise to the ringed appearance in cross sections of old hapteres is related to that which has been called fucosan and appears to be polysaccharid in character. Pits, in the strengthening tissue and tissue of growth-rings of the stipe, are abundant upon the

concentric faces of the tracheid-like elements, but are generally absent from the radial faces. Mucilage canals announced for this plant by Ruprecht are wanting. An abundant formation of polysaccharids goes on in old pinnae and hapteres. *Pterygophora* differs strongly in its anatomical structure from *Lessonia*. The secondary thickening differs anatomically from that of other kelps studied. A series of young plants, from 2 cm. in length, shows that the midrib is basally developed in the principal lamina and that it is not present in the younger stages. In this respect *Pterygophora* strongly differs from *Alaria*. The classification of *Pterygophora* in the vicinity of *Alaria* is of somewhat doubtful value. It appears rather to be a genus of Laminariaceae and may be related with such a form as *Laminaria radicata* Kjellman.

Germination of Basidiomycetous Spores:

DR. MARGARET E. FERGUSON, Wellesley College.

This investigation was undertaken to determine, more definitely than is known at present, the conditions of germination in the Basidiomycetes, particularly in *Agaricus campestris*. Twelve species out of the twenty-six studied in preliminary tests yielded high percentages of germination in various media, and four species gave fifty per cent. germination or less. The spores of eleven species germinated in distilled water, but the percentages of germination were invariably lower than when an external food supply was present. The effect, on the germination of the spores of *Agaricus campestris*, of extremes of temperature, alkalies, acids, and organic substances was tested. The spores were also subjected to the action of an artificial digestive fluid. The percentages of germination obtained in these experiments with *Agaricus campestris* varied from 0 to 25. Almost perfect germination of the spores of this species

was, however, obtained in a large number of cultures and in various media; but a high percentage of germination never occurred except in cultures containing the growing mycelium of *Agaricus campestris*. The germinated spores were frequently transferred to test-tubes containing bean stems and other solid substrata, and in many instances abundant mycelium was produced. A full report of these studies, which were undertaken at the suggestion of Professor B. M. Duggar, is now in the hands of the publishers and will appear shortly.

Behavior of Mutilated Seedlings: Professor
BYRON D. HALSTED, Rutgers College.
(By title.)

The particular form of mutilation of seedlings here considered is that of the removing of the plumule. In radish seedlings the first change noticed was the deeper green of the cotyledons, followed by a remarkable elongation of the petioles. The cotyledons became thicker than in those of the normal plants, due to increase in size of cells, and filled with starch, while the roots grew to considerable size. In the morning glory a similar behavior of the cotyledons was observed, while the hypocotyls became enlarged and served as a repository for the large accumulation of starch. In the Hubbard squash the cotyledons of the deplumuled plants remained close to the earth and grew to four or more inches in length, and held green for over four months. The egg-plant as a type of a slow-growing seedling produced rigid upright cotyledons that became quite fleshy and remained alive for many months. The sunflower illustrates a type in which the hypocotyl elongates greatly until it is sometimes over nine inches in length, with the primitive structure retained. In other words, the ring of wood is not developed as in the normal plants. These experiments illustrate how

an organ normally designed to store food for the developing seedling may persist in an emergency and take on a greatly increased size for that purpose. The petiole may assume a direction in connection with its enlargement that will aid the blade in its work of photosynthesis. Along with these changes in the seed leaves there may be others in surrounding parts, particularly the hypocotyl which becomes thickened remarkably and green in the morning glory, and greatly elongated but slender in the sunflower. In the radish a place for any surplus growth still remains, for the root is naturally destined to be fleshy and the hypocotyl is not modified.

Notes on New Species of Lichens collected by the Harriman Expedition: Professor CLARA E. CUMMINGS, Wellesley College.

The list, soon to be published, contains an enumeration not merely of the species collected by the members of the Harriman expedition, but also of various other collections, notably that made by Professor Setchell in Alaska the same year. The total number of species and varieties listed is 219. Of these 97 species are new to Alaska, three of which are new to America and three others new to science. The three new species were referred provisionally to the genera *Verrucaria*, *Endocarpon* and *Pertusaria*. The *Verrucaria* was said to be characterized by an unusual development of the thallus. Three points of difference from the typical *Endocarpon* were noted, namely the distribution of the gonidia throughout the tissue of the thallus, the numerous perforations in the mature prothallus and the projection of the apothecia beyond both surfaces of the thallus. In further discussion the possibility was suggested that new genera might perhaps be established for the so-called *Verrucaria* and *Endocarpon*.

What is the Archesporium? Professor F. E. LLOYD, Columbia University.

It is proposed to limit the use of the term 'archesporium' to the mass of cells which, by tetrad divisions, gives rise to spores. The cells heretofore so designated have diverse origins and no peculiar morphological features, and are distinguishable only by their denser cytoplasmic contents. They are vegetative cells which are set aside when an extensive archesporium is necessary. It is only when the constituent cells enter the heterotypic mitoses that their peculiar character is without doubt evident. In parthenogenetically reproduced plants where true tetrad division in this sense lapses, the archesporium is determined on comparative grounds.

The Continuity of Protoplasm: Dr. HENRY KRAEMER, Philadelphia College of Pharmacy. (By title.)

The earlier studies of the author upon the structure of starch grains showed under certain conditions the presence of radiating feather-like clefts, which he concluded represented channels through which liquids are distributed throughout the grain. Studies with similar reagents upon cell walls seem to imply a similar nature for many markings which have commonly been explained as passages for permitting the continuity of protoplasm from cell to cell. He calls attention to references to the use of sulphuric acid in the study of continuity of protoplasm, and the objections to its employment for this purpose. The studies are being continued.

The Embryology and Germination of the Genus Peperomia: Professor DUNCAN S. JOHNSON, Johns Hopkins University.

The ripe seed of this genus is about .5 mm. long; the globular, fifteen-celled embryo only .04 mm. and the surrounding endosperm .1 mm. in diameter. In germination the endosperm bursts out of the

seedcoat at the tip but continues, as a jacket two cells in thickness, to enclose the embryo till the latter, after reaching a size of .15 mm. as a globular, undifferentiated mass of cells, at length develops two cotyledons and a root, and the latter bursts through the endosperm and bends down to anchor in the soil. From the beginning of its development to the time when it drops, with the exhausted seed, from the tips of the highly elevated cotyledons the endosperm seems never to serve for the storage of food material, but always as a digesting and absorbing organ for dissolving and passing on to the embryo the starch with which the abundant perisperm is filled. This seems to be the sole function of the endosperm also in many other genera, especially those with abundant perisperm, *e. g.*, *Saururus*, *Heckeria*, *Dianthus* and *Cerastium*.

Report of the Committee on the Standard College Entrance Option in Botany:
Presented by the Chairman, Professor
W. F. GANONG, Smith College.

The report stated that the option had been formulated by the committee, had been printed and distributed to members in April and had been widely circulated among prominent teachers. Notes calling attention to it had been inserted in *SCIENCE* and in *School Science* and had caused a demand which exhausted the edition of 200 copies. Taking into consideration the criticisms and suggestions received, the Committee (reduced to the chairman and Professor Lloyd by the withdrawal of Professor Atkinson) prepared a revised edition which was printed in June and distributed in October. As a whole, the replies to the request of the Committee for suggestions, etc., indicated a surprisingly wide approval of the features of the option recommended by the Committee. The adverse criticisms were practically only

three. First, it was thought by some too difficult for a year of high school study. In answer to this it was stated that it was the intention to make it fully as hard as a year of any other subject whatsoever taught in the high schools. The time is past when botany should be content to occupy a humble corner in the high school curriculum. It may be offered or not offered, but if offered at all it must be upon a plane equal to that of any other subject whatever. Second, it was objected, though not widely, that it laid too much stress upon ecology, which was thought not to be a proper high school study. The general consensus of opinion, however, seems to favor some ecology in the high school course, though it should be only of the most concrete and definite sort, and it is this kind of ecology the Committee has endeavored to emphasize. Third, it has been held that the part dealing with the types of plants and groups should not proceed primarily, as the Committee recommends, from the point of view of natural history but from that of morphology. In answer to this the Committee points out that the one does not exclude the other, and that in order that the course may be equally available for the education of those who go no farther and for those who continue into higher courses, it seems best to approach the subject from that point of view which will have the most meaning for the average high school student, and which will yield him the knowledge of most pleasure and profit to him in after life. In the opinion of the Committee such a point of view is rather that of natural history than of comparative morphology, and the special comparative morphology of the groups can best be taken up in second courses by those who go on. It was reported that the option had been formally adopted by the College Entrance Examination Board, and would shortly be pub-

lished in one of their documents. This, together with the widely favorable criticism it has received, indicates that it will probably be widely adopted. The Committee recommended that a standing committee of two be appointed to take the further interests of the option in charge, to keep it in touch with educational progress, and readjust it to changing conditions; and that a new edition be prepared for distribution. The report was adopted, and as the committee, the former committee, Professors Ganong and Lloyd, was reappointed.

W. F. GANONG,
Secretary.

THIRD ANNUAL MEETING OF THE CORDILLERAN SECTION OF THE GEOLOGICAL SOCIETY OF AMERICA.

THE Cordilleran Section of the Geological Society of America held its third annual meeting in the Academy of Sciences, San Francisco, on December 30 and 31, 1901. In the absence of the chairman, Professor W. C. Knight, of Wyoming, Mr. H. W. Turner was elected temporary chairman. The secretary reported the following rules as having been adopted by the Council of the Society at Denver, August 26, 1901:

1. *Officers.*—The officers of the Cordilleran Section shall be a Chairman and a Secretary. The latter shall also perform the duties of an accounting officer with reference to the expenses of meetings.

The officers of the Section shall be resident within the geographical limits of the Section. A President or Vice-President of the Society shall be, *ex officio*, Chairman of the Section whenever present at a meeting.

2. *Geographical Limits.*—For purposes of scientific fellowship and discussion the limits of the Section shall correspond with the limits of the general Society, and the meetings of the Section shall be open to all

Fellows of the Society for presentation of papers, either in person or by proxy. For purposes of administration the membership of the Section shall be limited to those Fellows residing west of the 104th meridian.

3. *Membership.*—No person not a member of the Society may become a member of the Section. Members may invite contributions to the discussions at their meetings under the same rules as those applied to meetings of the Society.

4. *Date of Meetings.*—The meetings of the Section may be held at any time, subject to approval by the Council of the Society (Article 4 of Constitution). All notices and programs of meetings shall be sent to all Fellows of the Society.

5. *Expenses.*—The expenses of the Section, so far as they shall be paid from the general fund of the Society, shall be limited to the ordinary economical expenses of the meetings.

6. *Publications.*—All papers presented to the Section shall be available for publication in the *Bulletin* of the Geological Society of America under the rules governing publication by the Society.

The officers elected for the ensuing year were: H. W. Turner, of San Francisco, Chairman, and Andrew C. Lawson, of Berkeley, Secretary. An executive committee consisting of the chairman, secretary and Professor J. C. Merriam was appointed.

Resolutions were adopted expressive of the sense of loss sustained by the Section in the deaths of Professors Joseph Le Conte and E. W. Claypole.

The following papers were read and discussed partly in the Academy of Sciences and partly at the University of California, where the Section met after the opening session, for the purpose of viewing illustrative specimens and lantern slides:

*An Instance of Variability in a Rock
Magma:* II. W. TURNER, San Francisco,
Cal.

The instance referred to is the granolite area east of Sonora in Tuolumne County, California. This area is enclosed on three sides by the sedimentary rocks of the Calaveras formation, and on the east by a granite and gneiss series of older age, so that it is practically an enclosed area. The rock is designated, on the Sonora geological map of the United States Geological Survey, granodiorite, but it is not a typical example of that rock. It contains at most points some orthorhombic pyroxene. The rock varies from a granodiorite containing nearly 63 per cent. of silica to olivine gabbro containing about 43 per cent. of silica, there being all gradations between these extremes. The mass is intrusive in the Calaveras formation. The gabbro forms a hill in the interior of the area. The variation in mineral and chemical composition is not regarded as being due to absorption of material from the surrounding rocks, but to a differentiation during crystallization. On the west and south the Calaveras rocks contain much limestone, but the most basic facies of the rock, the olivine gabbro, is not near their contact. Moreover the limestone is not a magnesian limestone, and if we seek to explain the high lime content of the gabbro (14.27 per cent.) by an absorption of lime from the adjoining calcareous rocks, we are also brought to account for the high magnesia content (7.65 per cent.) of the gabbro from a similar source, and there are no magnesian rocks in the neighborhood outside of the granodiorite-gabbro mass, except small amounts of perknite or amphibole-pyroxene rock, and these are not, except at one point, in juxtaposition to the granodiorite-gabbro area. There perknites may indeed be themselves the extreme result of differentiation of the granodiorite. There are

abundant dikes of diorite in the granodiorite, and pegmatite and quartz-tourmaline dikes or veins.

Triassic Reptilia from Northern California: JOHN C. MERRIAM, Berkeley, Cal.

Reptilian remains were first discovered in northern California in 1893, when Professor James Perrin Smith obtained two short series of vertebræ and two arch bones in the Triassic limestones. These specimens were described by the writer in 1895, under the name of *Shastasaurus*, and were thought to belong to a form closely related to the Ichthyosauria, though they did not appear to find a place in any known genus. During the summer season of 1901 a quantity of new material was obtained from the original locality. The collection includes considerable parts of five skeletons, also numerous loose limb-bones, vertebræ, ribs, etc. Nearly all of the specimens belong to the genus *Shastasaurus*, of which there are several well-characterized species. Two nearly complete series of dorsal and cervical vertebræ show *Shastasaurus* to be characterized by possessing single-headed ribs on all of the vertebræ in this region excepting the anterior 8-9. In the cervicals the parapophysis is relatively small and in the anterior dorsal region it disappears entirely. As far back as the middle dorsals the articular surface of the diapophysis is confluent with that for the reception of the upper arches. The anterior and posterior limbs have not been found together, but are known from species having the same type of vertebræ and ribs. The anterior limb is ichthyosaurian in type, but the transverse diameter of the humerus is much greater than the longitudinal. The radius and ulna are very short and are separated by a considerable space. In the posterior limb the femur resembles that of *Ichthyo-*

saurus. The tibia and fibula are longer than in that genus and are separated by a wide cleft. The anterior arch is ichthyosaurian excepting the scapula which is very broad. The posterior arch is very different from that of *Ichthyosaurus*. The skull is not well known. The dentition resembles that of *Mixosaurus*. The forms of this genus represent a distinct group of the Ichthyosauria. In some respects they are generalized and resemble *Mixosaurus*, in the other characters they show specializations which separate them from the other members of the family.

Ore Deposits of Shasta County: F. M. ANDERSON, Berkeley, Cal.

The copper belt of Shasta County, California, embraces, geologically, a series of old sedimentary rocks, Devonian, Carboniferous and Triassic, which extend in somewhat parallel bands northeasterly and southeasterly across the course of its longer axis. These strata have been penetrated and disturbed by intrusions of acid granite, generally of the character of granite porphyry, though variable, which have been accompanied by flows of rhyolite and lavas resembling trachyte. In the vicinity of these intrusions and generally enclosed in the metamorphosed sedimentary rocks occur the deposits of sulphide ore which forms the subject of this paper. There are three or more types of ore represented among these deposits. The first class includes deposits found to the south of Pitt river near the mouth of the McCloud. They consist essentially of lenticular bodies of pyrrhotite carrying pyrite and chalcopyrite, but on the whole a low percentage of copper. These pyrrhotite bodies sometimes reach a thickness of 8 or 10 feet and a length of 50 or 60 feet, and are apparently connected with intrusions of dioritic rock. The second class of deposits is represented in all of the large ore bodies west of the Sacramento

river, including the properties of the Shasta King, Balaklala, Iron Mountain and Mammoth mines. They are immense bodies of sulphide ore, consisting almost entirely of pyrite and chalcopyrite, with comparatively little zinc blende, but carrying both silver and gold. They appear to be replacement deposits, and have preserved in a measure the banded or stratified form of the original rocks. The largest of these deposits approximates 2,000,000 tons in extent. The grade of the ore varies from 1 to 20 per cent. in copper, averaging generally between 3 and 7 per cent., and carrying silver and gold to the value of \$2.50 per ton. The ores of the Pittsburg and Afterthought districts, which constitute the third class, are similar to each other in character and probably in the mode of their occurrence. They are comparatively poor in iron and contain a larger percentage of zinc blende than any of the others. The ore includes little pyrite, consisting largely of chalcocite, bornite, chalcopyrite and other rich sulphides, with a gangue of silica and barite. The average grade of the ore at Bully Hill is nearly 10 per cent. copper with a relatively high value in silver and gold. The surface alteration in these deposits has resulted in the removal of the copper contents from the upper levels in which there is considerable concentration of gold and silver. In many cases the copper has found secondary lodgment in lower portions of the deposit, forming what is sometimes designated the 'copper level.' This secondary enrichment of the ore bodies is the rule throughout the whole extent of the copper belt. The grade and magnitude of these sulphide deposits entitle them to rank among the most important in the United States.

Lake Chelan, Washington: H. W. FAIRBANKS, Berkeley, Cal.

Lake Chelan is one of the most remark-

able and interesting bodies of fresh water in the west. It is situated in an ancient valley upon the eastern slope of the Cascade range in northern Washington. The lake has a length of about 60 miles and a width of one to two miles. It has an elevation of 950 feet above the sea level and a depth of about 1,400 feet. The country surrounding the lower end of the lake is quite open and contains numerous settlers, but through the greater portion of its length it is inclosed by mountains which rise quite precipitously 3,000 to 5,000 feet. The valley in which the lake lies has had an interesting history. It was occupied in quite recent times by one of the largest glaciers upon the eastern slope of the Cascade range. Previous to that there was another lake here, but at a somewhat lower level. The earlier lake was probably raised but slightly above the level of the Columbia river, into which it must have emptied. In the opinion of the author the great depth of the lake is due not to the erosion of the glacier, but to the fact that it was the bed of a stream, and was cut out chiefly by stream erosion. The glacier undoubtedly enlarged the valley somewhat and may have deepened it a little. If this view is the correct one the valley in which the lake lies must have been eroded at a time when the level of the land with respect to the ocean stood many hundreds of feet higher. The Columbia lava plateau would interfere with the drainage of such a valley, so that it must have been excavated prior to the formation of the plateau. The lake is held at its present level of 325 feet above the Columbia river, from which it is distant only three miles, by a morainal dam. The lower end of the lake is shallow, but as far as known to the author there is no reason to suspect that bedrock would be encountered at about the level of the Columbia river, which would be the case if the bed of the lake had been dug out by the glacier.

Lake Quiberis, an Ancient Pliocene Lake in Arizona: WM. P. BLAKE, Tucson, Arizona.

The San Pedro river of Arizona drains a considerable area, and is bordered throughout its course by mountain ranges forming a valley from ten to twenty miles in width and nearly one hundred and fifty miles in length. The valley is in general parallel with that of the Santa Cruz, the next great valley to the westward. A lake-like sheet of water of which we have good evidence filled the greater portion of this valley in late Tertiary or Quaternary time. This evidence is chiefly the presence on both sides of the valley of unconsolidated red clays and sediments in horizontal beds of great thickness, often terraced by the river erosion, and extending high up on the sides of the bordering mountains. One of the best cross-sections is found on the line of the Southern Pacific railway which crosses the valley nearly at right angles to its course at Benson. Benson, in the bottom of the valley, has an altitude of 3,576 feet above the sea. The river is about fifty feet lower. The lacustrine clays rise from this point on each side to the height of about 3,800 feet. The exact limit of clay deposition is not easily determined. It appears most probable that the height of the water was about 4,000 feet above tide. The sediments are similar to those around Benson, bordering the valley northwards, towards the Gila Valley. We there find also, in addition, the thick beds of diatomite mingled with fine volcanic ash. These diatoms are mostly marine species, according to Dr. D. B. Ward, of Poughkeepsie. But some fresh water forms are present. The Quiberis Valley thus appears to have been occupied by sea-water. It was open on the north to the great open valley of the Gila and Salt rivers and would appear to have existed as a partly landlocked estuary, at least in the upper portion between the

Dragoon Mountains and the Whetstones and Huachuacas. The phenomena bear testimony also to the great epeirogenic uplift since the Miocene. A depression of four thousand feet would submerge the greater part of southern and southeastern Arizona, including the great valleys of the Gila river, Salt river and of the Santa Cruz, leaving only a few widely separated islands above the Pliocene Sea.

The Debris Fans of the Arid Region in their Relation to the Water Supply: E.

W. HILGARD, Berkeley, Cal.

The debris fans or cones of the torrential periodic streams that enter the broad and deep valleys of the Cordilleran region are wholly different in their genesis and structure from the alluvial fans of the streams that enter lakes, as described by Gilbert (Monograph No. 1, U. S. Geol. Survey). Immediately in front of the cañon mouth we always find an accumulation of cobbles and boulders, the latter sometimes of enormous size; these grade off into smaller cobbles and gravel as the distance increases, but there is always an irregularly semi-elliptical area, of an extent proportioned to the size of the stream, on which the water is partly or wholly absorbed unless the discharge exceeds a certain amount, when a portion of it passes over the gravel area, carrying with it the finer materials, which are deposited beyond. As the valley is filled up and the slope decreases, it takes exceptional floods to carry the coarse materials to any great distance from the cañon mouth. Yet while the slope was steep and the valley channel relatively narrow, the cobbles were often carried to considerable distances. The water so absorbed in the coarse materials forms a pressure column behind the main body of the fan, which when large becomes a prolific source of artesian water, as is prominently exemplified in the upper San Bernardino valley

and elsewhere in California. The extreme irregularity of structure within the fan, and the variations in the quantity and course of the main discharge of the stream, cause corresponding irregularity in the flows and static pressures of wells; high pressure being frequently coincident with small flows, and vice versa. Spontaneous outflows also frequently occur in times of high floods, or as the result of erosion on the fan slope. 'Artesian' springs and streams thus formed are important sources of irrigation water in southern California; they respond to the variations of the seasonal rainfall in from three to six months. Hence these debris fans form natural storage and regulating reservoirs of great importance. A striking example of the effect of these conditions upon the topography and hydrography of the valleys is afforded by the debris fan of San Antonio creek, a snow-fed torrent descending from the Sierra Madre northward of Pomona, Los Angeles County. Its typically regular fan has extended clear across the valley (nine miles) to the foot of the hills opposite, thus forming a water-divide between the Santa Ana and San Gabriel rivers. The creek itself has in the past evidently discharged alternately into the two drainage basins, which originally were probably a single one draining through the Los Angeles plain into the sea. This is an easily verifiable illustration of the manner in which the broad Cordilleran valleys have been filled in, as lately discussed by Shaler. Similar though less obvious examples exist in the Great Valley of California, as well as in the Santa Clara valley on San Francisco Bay.

A Post-Tertiary Elevation of the Sierra Nevada shown by a Comparison of the Grades of the Neocene and Present Tuolumne Rivers: H. W. TURNER, San Francisco.

The Neocene Tuolumne occupied the

same drainage basin and followed approximately the same course as the modern stream. The most western point where the gravels of the Neocene Tuolumne have been preserved is east of the head of Big Humbug Creek in the Sonora quadrangle, and the most eastern Piute Canyon in the Yosemite quadrangle. If we now calculate the average grade of the Tertiary stream between these two points, and the average grade of the present river between the same points, we can compare the grades of the two streams. The altitude of the Neocene Tuolumne gravels at Big Humbug Creek is about 2,800 feet, and at Piute Canyon 7,500 feet, giving a difference of 4,700 feet. The altitude of the present Tuolumne north of Big Humbug Creek is 1,500 feet, and at Pate Valley, at the mouth of Piute Creek, 4,550 feet, giving a difference of 3,050 feet. The horizontal distance between the two points is about 33 miles. Assuming that both the Neocene and the present streams took a direct course, we have a grade of 142 feet to the mile for the Neocene channel, and a grade of 92 feet to the mile for the present channel. While the Neocene river occupied a rugged canyon, nevertheless this canyon was much less deep and rugged than that of the present Tuolumne, which implies, other things being equal, a higher grade for the present than for the Neocene channel, while, as we have seen, the reverse is the case. The broad channels and large sand and gravel deposits of the Neocene streams of the Sierra further north can scarcely be explained on any other hypothesis than of comparatively gentle grades, indicating an old age for the streams, and this must have been likewise true of the Neocene Tuolumne, although in less degree. Assuming that the Neocene Tuolumne had originally a grade at least as low as that of the modern stream, which is evidently yet a young stream, it is clear that the present grade of the Neocene chan-

nel must have been brought about by a differential uplift on the east, resulting in a tilting of the range westward.

On an Orbicular Gabbro from San Diego County, California: ANDREW C. LAWSON, Berkeley, Cal.

The rock described in this paper is a very basic gabbro in the form of an aggregation of spheroids having both radial and concentric structure. The spheroids have an average diameter of about 6 centimeters, but are mostly somewhat deformed in shape. The core of these spheroids is a granular gabbro and the space between the spheroids is of a similar character. An analysis of the rock is given.

A Geological Section of the Middle Coast Ranges of California: ANDREW C. LAWSON.

The paper is an attempt to summarize recently acquired information as to the sequence of formations and their respective volumes of sediments in the Middle Coast Ranges of California. The results given for the thickness are approximations sufficiently close to afford a general idea of the section. Other features of the paper are the subdivision of the Franciscan into seven stratigraphic subdivisions by the recognition of a persistent horizon of foraminiferal limestone and two important horizons of radiolarian chert; a similar subdivision of the Monterey into seven stages and a summary announcement of the character and history of the post-Monterey Tertiary. The essential features of the paper are given in the following tabulation.

The Pleistocene Ecology of Southern California: RALPH ARNOLD, Stanford University, California.

A summary statement of the marine Pleistocene of San Pedro and other localities of southern California with a subdivision of the Pleistocene formations partly on the basis of structural unconformities

and partly on the basis of their fossil fauna.

A Contribution to the Petrography of the John Day Basin: F. C. CALKINS, Berkeley, Cal.

The paper is based on a study of specimens gathered during the last three summers, by the University paleontological expeditions conducted by Dr. J. C. Merriam. It may be considered as a supplement to Dr. Merriam's 'Contribution to the

Geology of the John Day Basin.' The igneous rocks of pre-Eocene age comprise quartz-mica diorite, serpentines and pyroxenite. The Tertiary series, including the fossil-beds, is almost entirely composed of volcanic materials. The Clarno Eocene began with the eruption of andesitic lavas and tuffs, followed by quartz-basalt and rhyolite. The John Day Miocene beds are mainly tuffs of trachytic and andesitic character. Upon them lie the great basalt series, which is in turn overlain by the Mascall beds, similar in general composition to the John Day. The Pliocene Rattlesnake formation comprises rhyolitic lava and tuffs. The most recent evidence of volcanic activity consists in ash-beds interstratified with the terrace gravels.

Colemanite: ARTHUR S. EAKLE, Berkeley, Cal.

The paper contains the results of a crystallographic study of a large number of colemanite crystals from the Calico district, San Bernardino, Cal. The crystals are exceptionally rich in forms and in the number of well-developed faces. Although only showing terminations on one end of the vertical axis owing to their attachment to the matrix, seldom less than twenty faces are present, and some of the combinations if completed would show upwards of one hundred faces. About fifty forms occur, of which one third are new. Four quite distinct habits are noticeable, governed by the absence or predominance of certain of the terminal forms. The measurements were made with the two-circle goniometer designed by Goldschmidt, and since this important method is comparatively new to the mineralogists of this country, a detailed description of the work is given, in order to make clear the method of calculating and projecting the forms. The figures accompanying the paper are a gnomonic projection of the forms, an orthographic projec-

tion on the base and several clinographic projections illustrating the varied habits and combinations observed.

Eocene and Earlier Beds of the Huerfano Basin, Colorado, and their Relation to the Cretaceous: R. C. HILLS, Denver, Colo.

The paper discusses the stratigraphical and structural features of the Huerfano Eocene, and associated Upper Cretaceous beds, for the purpose of correcting certain errors that appeared in earlier papers on the subject. The uppermost beds previously assigned to the Eocene have been shown to contain a Wind River and Bridger fauna, but there is a much greater thickness of conformable beds of similar character, the age of which has not been definitely established, which it is thought should be provisionally correlated with the Lower Eocene of the Uinta and San Juan basins. The Lower or Poison Canyon formation is found to be unconformable with the true Eocene and with the underlying Cretaceous, and to present a strong contrast with the latter lithologically. It is suggested that the Poison Canyon beds are nearly related to, if not identical with, the post-Laramie formation of the Denver Basin.

ANDREW C. LAWSON,
Secretary.

A NEW BAROMETRY FOR THE UNITED STATES, CANADA AND THE WEST INDIES.

A NEW system of reducing the barometric observations of pressure at the stations of the Government Services of the United States and Canada was put in operation on January 1, 1902. The Weather Bureau has received all the data necessary for carrying on the Canadian computations simultaneously with its own, through the courteous cooperation of Professor R. F. Stupart, Director of the Canadian Meteorological Office. The reduction of pres-

tures observed on the Rocky Mountain plateau to sea level is a problem of great scientific difficulty for two reasons: (1) Because it is not evident what the exact effect of the plateau is as modifying the ordinary Laplacean free air reduction, even when the mean temperature of the air column θ is assumed; and (2) because the vertical temperature gradient between the observed surface temperature t and the sea-level temperature t_0 is difficult to determine, or in other words because the connection between $\frac{1}{2}(t+t_0)$ and the true θ is hard to find. The solution of this problem has been forced upon the Washington Office ever since the opening of the service in 1870, inasmuch as the results of such reductions are used to form the daily weather maps, and the errors of reduction result in inaccurate systems of isobars, and consequently incorrect deductions regarding the existing weather conditions, especially west of the Mississippi Valley. The perplexity of the problem may be inferred from the fact that the present system constitutes the sixth effort to solve it. The indications are that the new isobars conform very closely to the true weather, and that the practical working of the system will prove to be satisfactory to the Bureau.

A brief summary of the earlier methods of reduction is as follows:

1. For the years 1870-81 all the low stations were reduced by an elementary application of tables given in Loomis' 'Meteorology' (the same as Guyot's table D, XVI., edition of 1859), using the temperatures observed at the moment of observation. 1872-1880. The higher stations were not reduced except by the application of a constant appropriate to the mean annual temperature and pressure; the lower stations continued with the elementary method, but this included an erroneous use of the observed pressure.

2. 1881-85. The Abbe-Upton system of monthly constants for each station, based on the mean monthly temperatures and pressures.

3. 1886-1887. Ferrel's system was in operation but found to be in a form which was too complicated for practical station work. However, some correct principles were introduced by him, namely, the mean temperature of twenty-four hours as the argument instead of the temperature at the time of observation; a separate correction for the plateau effect; the variation of the reduction with the local pressure; and a correction of the surface temperature t to the mean θ by an approximate vertical gradient.

4. 1888-1890. A mixed system, partly Ferrel's and partly Hazen's. 1891-1901. Hazen's empirical system alone, in which numerous changes were made in the wrong direction. The plateau correction was omitted, the pressure argument was abandoned, and the surface temperature not corrected to θ became the only argument. In constructing the empirical tables it was assumed that Mt. Washington is a correct type for the plateau effect, which is not true; the pressure on the sea level was taken as exactly 30.00 inches in working out the reductions, which does not conform to the facts; the check upon the reduction was limited to the criterion that the isobars could be smoothly drawn, and reductions for many stations received arbitrary modifications for that purpose. The result of this system was to give too high sea-level pressures at low temperatures, especially in cold waves, and too low pressures in warm weather.

5. In 1896 Professor Morrill computed tables which have been used somewhat in the office, but never published, in which the mean temperature θ and the pressure arguments were restored, and the treatment of the humidity put on an improved

basis, though the plateau effect was omitted and the correction between t and θ only roughly determined.

The following statement will indicate the most important changes which have been recently adopted. The principles introduced by Ferrel have been more closely followed than any of the others, but decided improvements have become possible by reason of the gradual accumulation of accurate observations on the plateau. It was first necessary to construct exact normals of station pressure. There have been numerous changes in the location of the offices during the past thirty years, involving variations in the elevation; there has been a gradual improvement in the general national surveys for elevation by which the local bases can be referred to the sea level; the instrumental errors were neglected during certain years when less than ± 0.007 inch; the observations have been made at different sets of selected hours; and the gravitation correction was not regularly applied. To reduce the entire set of observations from 1873 to 1900, inclusive, to a homogeneous system, they have been corrected to the elevation adopted for January 1, 1900, or the one occupied nearest that date, also to the mean of twenty-four hourly observations, and the corrections for instrumental errors and gravity have been added systematically. The monthly and annual means give the normals, and from these the variations in the year and from year to year are computed, the latter becoming the basis for the further discussion of climatic and seasonal problems.

The process of determining the sea-level temperature beneath the plateau was conducted as follows: The normal mean monthly temperatures of all stations between the Pacific coast and the Mississippi river were collected by groups according to their elevations, and reduced to selected

planes through short distances. Thus all temperatures observed between 0 and 1,000 feet were corrected to the 500-foot plane, between 1,000 and 2,000 to the 1,500-foot plane and so on up to 7,000 feet. Temperature gradients in latitude and longitude were worked out by discussing these data, and then all the data on the selected planes were further corrected to values on the centers of reduction, that is the points where the five-degree meridians and the five-degree parallels intersect. The several stations were carried in various directions to different centers, so that purely local conditions might neutralize themselves. Over these centers we have thus formed from the observations different temperatures in a vertical direction, and they were then plotted as points on diagrams through the average of which vertical temperature curves were drawn, and prolonged to sea level without much error. These sea-level temperatures were now transferred to charts of the United States and Canada, and in connection with all the stations available from the Atlantic to the Pacific coasts, sea-level isotherms were readily drawn, by which all the minor discrepancies occurring in the plateau district were removed. By interpolation we then found the true terminals of the vertical temperatures at sea level on the centers of reduction. This entire work was performed two or three times in succession by a series of approximations, and the interlocking of the vertical and horizontal lines on the sea-level plane were made to conform to the observed conditions. Thence the sea-level temperatures for the respective stations were found by interpolation from the isotherms to tenths of a degree, so that we have thus accurately obtained t_0 as well as t .

The plateau effect was determined on the theory that the wide swing of the temperatures in the annual period, amounting

to 0.400 inch, should be reduced to that which is observed at the low-level stations, about 0.150, by a correction of the form $C \Delta \theta . H.$, where $C=0.00100$, $\Delta \theta$ is the departure of the temperature from the annual mean, and H is the elevation in units of a thousand feet. This is readily computed for each station, and it is to be added to the free air correction computed by the Laplacean formula with modern constants.

The monthly station pressures B were now reduced to sea level, giving B_0 , and isobars were drawn as well as possible through the resulting values. Many of the old stations had their elevations determined only by barometers and were quite erroneous; in many cases the temperature argument used $\frac{1}{2} (t + t_0)$ was not exact enough to give very accurate results; not a few stations had only a short series of years to use in constructing their normals; from these causes considerable irregularities were found on the first system of sea-level maps. The pressures for each station were now interpolated from the map, B_m , and the differences, $B_0 - B_m$, computed. For certain stations these differences were about constant, indicating an error in the adopted elevation, or in the mean temperature from which the plateau effect was reckoned; in other cases the differences had a variation in an annual period, showing that the true value of θ differs from $\frac{1}{2} (t + t_0)$. By readjusting our data to allow for all these considerations, the sea-level pressures were computed a second time. The differences, $B_0 - B_m$, were now quite small for stations of long record, usually less than 0.010 inch. Assuming that the normal values of the short record stations should be reduced to the long record series, that is, 20 to 27 years, these last residuals were added to the original station pressures B to give the station homogeneous normals B_n . There still remain a

few stations, some of them at low level, so that any adopted method of reduction cannot be a possible source of error, wherein a nearly constant residual reduction is yet required to reduce them to the homogeneous system, marked $J.A.$ This is probably due to some local peculiarity of the wind circulation, or the exposure of the barometer, and it may properly be considered as a topic for further investigation.

We next proceeded to make reductions for all the stations now in operation to the 3,500-foot plane and the 10,000-foot plane, both of which are useful in the studies of cyclones and anticyclones, but instead of directly from B to B_1 and B_2 , by a roundabout circuit. The sea-level values B_m, t_0, e_0 , pressure, temperature, vapor tension, were interpolated on the centers of reduction from the sea-level charts. The temperatures t_1, t_2 and the vapor tensions e_1, e_2 , on the two upper planes, respectively, were computed by gradients derived from the cloud computations of 1896-97, and balloon and kite ascensions. With this data charts of t_1, t_2, e_1, e_2 were formed, the pressures B_1, B_2 , on these planes were computed by means of our new logarithmic general tables, and the corresponding pressure charts drawn. Thence the station data B_1, t_1, e_1 , for the 3,500-foot plane and B_2, t_2, e_2 , for the 10,000-foot plane were interpolated for each month and for the annual mean. As a check, station data B_n, t, e were reduced so as to give corresponding to B_n the values of B_1 and B_2 . We have thus derived B_1, B_2 , by two separate methods, and they generally agree to about 0.01 inch on the average. This check includes the construction of the general tables and the special station tables, also the drawing of the different sets of charts. We have therefore obtained the same results by means of two paths of reduction, the first to sea level from the station, and thence through the

centers of reduction to the two higher planes, and thence by interpolation to points over the station; the second, from the station pressure to the pressures on the two other planes directly. This agreement, therefore, unites the entire data in a homogeneous system, and it becomes the basis for future substantial scientific discussions in many meteorological problems. We can now deal quite confidently with hundredths of an inch of pressure.

A full report on this subject will appear in the Annual Report, Chief of Weather Bureau, Vol. II., 1900-1901, and will contain the following sets of charts for each month and for the year, $B_m . t_o . e_o$. and the relative humidity on the sea level plane, $B_1 . t_1 . e_1$ on the 3,500-foot plane, $B_2 . t_2 . e_2$ on the 10,000-foot plane, 130 in all; also charts of gradients in latitude, in longitude and in altitude, as well as charts for reducing selected hours of observation to the mean of twenty-four hourly observations. With these data a newly opened station can by a little computation be put on a better basis regarding its normals than would be given by at least ten years of regular observations. A summary table contains the above list of normals for 265 stations besides the original data for the station $B_n . t . e$., and will be a valuable source of reference for numerous questions in meteorology.

The reduction tables for pressure consist of three different sets: (1) The general logarithmic tables computed for every 100 feet up to 10,000 and for every 10 degrees from -40° to $+100^\circ$; (2) the station tables for publication, containing the following corrections for each of our three planes of reference, sea-level, 3,500-foot and 10,000-foot, namely, the Laplacean free dry air correction, the humidity correction, the correction for the plateau effect and the occasional residual correction, also the two arguments t surface tem-

perature and θ the mean column temperature. Diagrams have been constructed to show the relations between t and θ , and they form a most instructive analysis of the plateau temperature problem, showing that each district has local characteristics of its own; (3) the station tables are compiled from the forms (2), and they are expanded for the arguments surface t and surface B , so that there shall be no interpolation along the temperature argument in order to obtain the nearest hundredth of an inch, 0.010. The body of the table gives the reduced pressure on its plane, and not the correction to the actual pressure, which must be added to it to produce the reduced pressure, as is customary in such tables. There remains only a very simple interpolation for the intervals of a tenth of an inch of pressure to the required hundredth of an inch. It is thus an easy matter to enter the three tables in succession with the same arguments, surface ($B . t$), and find $B_o . B_1 . B_2$. These data will enable us to construct three sets of isobars at each hour of observation, showing three plane sections through the atmosphere, and these will probably prove to be of value in the forecasts of the weather conditions. The sea-level reductions went into operation on January 1, 1902, as stated, but some more work is required to furnish the stations the necessary tables of group (3), the two preceding groups being completed.

WEATHER BUREAU.

SCIENTIFIC BOOKS.

Memorial Lectures delivered before the Chemical Society of London, 1893-1900. London, Gurney and Jackson, Paternoster Row. 1901. Svo.

This volume contains the lectures commemorating deceased honorary and foreign members of the Chemical Society of London, delivered during the eight years designated in

the title, and if we take into consideration the historic eminence of the subjects of the lectures, as well as the fitness of the lecturers for their biographical tasks and their success in preparing them, it is safe to say that no more important or fascinating contribution to the history of chemistry has been issued within the decade. In each case care was taken to select as the lecturer one who had been personally intimate with the deceased chemist, or who was especially well qualified to write of his researches with the sympathy born of studies analogous to his; the result forms an illustration of the international character of science, for the native of Belgium is portrayed as to his life and labors by an American, the native of Switzerland by a Swede, the Germans by Englishmen, a Frenchman by another American, and only one lecture, on a Swede, is by a compatriot.

The methods followed by the lecturers in dealing with the individuals assigned them vary considerably, but the majority depict the personality of the chemist, his domestic life, his official duties, his positions of honor, and after these his labors and discoveries in the field of chemistry; in several instances the biographer introduces valuable disquisitions bearing on the theories which the person portrayed founded or helped to establish. Professor J. W. Mallet, of the University of Virginia, writing of Jean Servais Stas, precedes his account of the life-work of the Belgian in the determination of atomic weights, with a careful summary of the fundamental ideas that gradually led up to the question, 'What is the mass (or weight) of an atom of a particular element?'; and he presents a clear statement of investigations as to the atomic weight of the elements from the time of Berzelius to that of Stas. At the beginning of his painstaking researches Stas had an almost absolute confidence in the accuracy of Prout's hypothesis, but at their conclusion he said, 'The theory of Prout must be considered as a pure illusion.' Mallet himself, however, seems inclined to believe that there may be still something in it.

In passing, let me say that the biographer of Stas falls into the error of assigning to

Wenzel a share in the discovery of the law of neutrality, an error originating with Berzelius, and often repeated, but corrected by J. S. C. Schweigger, Angus Smith, Ladenburg and by others.

In his lecture on Marignac, the Upsala professor, Cleve, introduces a skilful survey of the complicated history of the rare earths, including a table giving the characters of the elements of the yttrium-cerium groups that was highly esteemed at the date of its publication (1895).

Dr. W. H. Perkin, in his sketch of the labors of Hofmann, introduces an authoritative account of the origin of the coal-tar color industry, and both Drs. Japp and Thorpe in their lectures on Kekulé and on Victor Meyer, respectively, insert most praiseworthy contributions to the history of those branches of organic chemistry in which each was laboring so successfully.

These disquisitions do not partake of padding, but are among the most valuable features of this very valuable volume.

One of the most difficult men to treat, on account of his gigantic intellectual position, Helmholtz, is presented in a masterful way, notable for its vigor and brevity, by Dr. Geo. F. Fitzgerald.

Dr. Percy Frankland's biography of Pasteur is very readable and appreciative; he points out that the French chemist long ago 'completely foreshadowed and grasped that important branch of our science which we now call stereo-chemistry' as shown by the philosophical reflections made by Pasteur after his discoveries in connection with racemic acid. Some bold experiments conducted by Pasteur were designed to accomplish 'the task of turning the Creator's world upside down'; one of these was carried on at Lille in 1854. He had a clock arranged with heliostat and reflector, to reverse the natural movement of the solar rays striking a plant from its origin to its death, so as to ascertain whether in such an artificial world, in which the sun rose in the west and set in the east, the optically active bodies could be obtained in enantiomorphic forms. Dr. Frankland reviews Pasteur's studies on fermentation, his researches on

spontaneous generation, on the vinegar process, on the diseases of wine, of silkworms, and the beneficent results of his success in combating disease in man himself. Of the 20,000 persons who have taken antirabic treatment, the mortality has been less than five per thousand.

The four lectures on August Wilhelm von Hofmann occupy the most space given to any individual in the volume; Lord Playfair writes of his personal reminiscences of Hofmann and of the conditions which led to the establishment of the Royal College of Chemistry; Sir F. A. Abel narrates the history of the same College and of Hofmann's professional work therein; Dr. W. H. Perkin chronicles the contributions of Hofmann and his distinguished pupils to coal-tar color manufactures; and Professor Henry E. Armstrong contributes a very full and careful analysis of the scientific work of this great master in research.

Professor O. Petterson, of Stockholm, writes of Nilson; Sir Henry E. Roscoe in a delightful sketch of Bunsen, his intimate friend and teacher, mentions many amusing episodes of the absent-minded, genial, big-framed man who has been loved by all who came into contact with him; Dr. P. P. Bedson portrays Lothar Meyer; Professor J. M. Crafts, of Boston, writes of his warm friend, Friedel; and Dr. Thorpe, of London, writes of the brilliant Victor Meyer as well as of Hermann Kopp. With each of the twelve lectures there is an excellent portrait of the person sketched, and most of the lectures contain valuable bibliographies. A copy of this memorable volume (of which the edition is limited to 500) should be found in every good library.

HENRY CARRINGTON BOLTON.

Allgemeine Physiologie. Ein Grundriss der Lehre vom Leben. By MAX VERWORN. Third edition, revised. Jena, G. Fischer. 1900. Pp. 631; illustrations 295.

The facts that Professor Verworn's book has reached its third German edition, and that it has been translated into English, French, Russian and Italian, are evidence of its worth. That it has exerted an influence on the de-

velopment of physiology during the six years of its existence is indicated by the frequency of references to it in physiological literature. The book improves with each successive edition. In its present revision it is unchanged in its fundamentals, but from the first to the last page it gives evidence of having been thoughtfully worked over. Apart from the alterations obligated by the newer researches, portions of the previous editions have been omitted, portions have been rewritten, and the language has constantly been made more precise. The quantitative result is an addition of twenty-five pages and ten figures, while qualitatively there is a betterment throughout. A few of the special features of the new edition may be here mentioned.

The use of the word *Eiweisskörper* has largely given place to that of *Eiweissverbindungen*, and stress is laid on the fact that the life process consists in the metabolism of the compounds of proteids rather than of proteids alone. The section on ferments is largely rewritten. As Emil Fischer has shown, it is now recognized that each ferment acts on one specific chemical body only, and not even on the isomers of that body. In many cases of ferment action by organisms, but not necessarily in all, the efficient substance is not the organism itself, but something secreted by the organism. Buchner proved this for alcoholic fermentation by the yeast-cell, and gave the name *zymase* to the enzyme. Another fact of interest is that no synthetic ferments have yet been discovered. Attention is called to the well-known results of Loeb and others in artificial parthenogenesis. Peter's observations that in ciliated cells the basal bodies are the place of origin of the impulse to movement are quoted. Peter's idea is supported by the work of Gurwitsch on the development of cilia.

The paragraphs on the origin of the current in a voltaic cell are rewritten and Sohneke's theory is replaced by that of Nernst. According to Nernst, metals have a great tendency to give off their molecules as cations in solutions of certain salts, the amount of loss depending on the relation of the osmotic pressure of the solution to the solution pressure

of the metal; the less the former and the greater the latter, the more cations are given off, and *vice versa*. The result of the loss is a charging of the metal with negative and of the solution with positive electricity. A second metal introduced into the solution, with a different relation of osmotic pressure and solution pressure, becomes charged positively, and the result is a difference of potential between the two metals.

In discussing the action of the galvanic current on protoplasm, the question is raised as to how the well-known effects are brought about. A possible factor is the electrolysis of the medium surrounding the living substance, in which case galvanic stimuli should be regarded as chemical stimuli. Verworn regards this possibility as doubtful, and if it occurs at all, it must be altogether subordinate. Much more important, doubtless, is the direct electrolysis of the living substance itself. A possible factor in the galvanic action is the movement of the liquids in the porous cell substance. This is suggested by the work of Carlgren, who, by the action of strong galvanic currents on dead cells, was able to obtain phenomena closely analogous to those occurring in living substance. The relative shares taken by these various factors in galvanic action must be decided by future investigation.

Molisch's work on the death of plants by freezing is noted, the general conclusion being that in such cases death is due to the abstraction of water from the protoplasm and the resulting profound alteration in the chemical structure of the compounds of the protoplasm. Regarding the action of chemical stimuli, the author takes the conservative position that in many cases, but not in all, osmotic action is associated with purely chemical action. The two factors have been only rarely distinguished sufficiently, and in most cases it remains to be decided to what extent the stimulating power of the chemical substance is due to its chemical, and to what extent to its osmotic properties.

The observations of Weil and Frank, which tend to disprove the hypothesis of the contractility of the dendrites of nerve cells, are

quoted approvingly. So also is the work of Myer and of Overton, who found that the solubility of narcotics in fats and oils is a great factor in their narcotizing power. Narcosis is accomplished through the agency of the undivided molecule of the narcotic, not through its decomposition products. Narcosis appears to be a contact effect.

The author devotes a page to the discussion of the effect of the Roentgen rays on organisms, but the facts so far discovered are too few to allow conclusions of value to be drawn.

In discussing the origin of life the theory of F. J. Allen is added to those heretofore given. This author believes the beginnings of life to date, not as Pflüger assumes, from the time of the earth's incandescence, but from the period when water first appeared on the earth's surface. The powerful shocks of lightning which must have occurred continually in the damp, warm atmosphere then existing, led to the production of ammonia and the oxides of nitrogen, as happens to-day. These substances were carried down in solution by the rains, and on the surface of the earth met solutions of carbonic acid and the chlorides, sulphates and phosphates of the alkalies and metals. Thus the opportunity was given for the most varied nitrogenous combinations, and the first living substance then came into being.

The chapter on the mechanism of life is not greatly altered. The 'biogen hypothesis,' as the author now terms it, is considered somewhat more fully than before, in the light of the work of Detmer, Loew and F. J. Allen, but it is not essentially changed. Attention is called to Jennings's careful work on the mechanism of tactic movements, and to Rhumbler's interesting physical analyses of cell phenomena.

In the preface Professor Verworn speaks of the present great activity of investigators in all fields of general physiology, and laments the fact that within the narrow confines of one book so many of the important contributions must be mentioned without discussion or be omitted altogether. Notwithstanding this fact, his book still remains by far the best

existing treatise on the varied subjects included under its comprehensive title.

FREDERIC S. LEE.

COLUMBIA UNIVERSITY.

SCIENTIFIC JOURNALS AND ARTICLES.

THE February number (Vol. VIII, No. 5) of the *Bulletin of the American Mathematical Society* contains a report of the eighth annual meeting of the Society, by the secretary; a report of the January meeting of the Chicago Section, by T. F. Holgate; a review of Wilson's Vector Analysis, by Alexander Ziwet; a review of books by M. Simon and J. M. Hill on Euclid, by J. S. Coolidge; 'Notes' and 'New Publications.' The March number of the *Bulletin* contains the following articles: 'The Application of the Fundamental Laws of Algebra to the Multiplication of Infinite Series,' by Florian Cajori; 'Concerning the Class of a Group of Order p^m that Contains an Operator of Order p^{m-2} or p^{m-3} , p being a Prime,' by W. B. Fite; 'Proof that the Group of an Irreducible Linear Differential Equation is Transitive,' by Saul Epstein; 'Lines of Length Zero on Surfaces,' by L. P. Eisenhart; 'Some Properties of Potential Surfaces,' by Edward Kasner; a review of Gibson's Calculus, by W. F. Osgood; 'Shorter Notices' of Cohen's Theory of Numbers and Beman's translation of Dedekind's Essay on the Theory of Numbers, by L. E. Dickson, and of the *Annuaire des Bureau des Longitudes*, by E. W. Brown; 'Notes' and 'New Publications.'

The *American Naturalist* for February opens with an article by W. M. Wheeler on 'A New Agricultural Ant from Texas, with remarks on the known North American Species,' the new ant being *Pogonomyrmex imberbiculus*, while the notes include a key for the identification of the species. Under the caption 'Phyllospadix as a Beach-builder,' R. E. Gibbs presents some new information regarding its life-history and shows how its spreading tufts hold the sand and produce sand-bars. G. H. Shull gives 'A Quantitative Study of Variation in the Bracts, Rays, and Disk Florets of *Aster Shortii* Hook., *A. Novæangliæ* L., *A. puniceus* L. and *A. prenanthoides*

Muhl., from Yellow Springs, Ohio.' The number contains the 'Quarterly Record of Gifts, Appointments, Retirements and Deaths,' and it is noted that hereafter these will appear in the numbers for February, May, August and November. The gifts for the past year to schools, colleges, libraries and museums amounted to \$43,233,635, and this does not include Mrs. Stanford's transfer of securities to Stanford University nor any appropriations made by national, state or local governments.

The *Popular Science Monthly* for March contains a long and well-illustrated article by J. C. Branner on 'The Palm Trees of Brazil,' describing the appearance and uses of many species. Alexander F. Chamberlain treats of 'Work and Rest: Genius and Stupidity,' drawing the inference that brief periods of intense work and long periods of rest produce better results than long periods of steady application. 'Science in 1901' is a résumé of progress along various lines from wireless telegraphy to the better understanding of yellow fever, reprinted from the *London Times*. Ellis P. Oberholtzer describes 'Franklin's Philosophical Society,' the oldest scientific society in the country, and W. H. Dall contributes an appreciative biographical sketch, with portrait, of the late Alpheus Hyatt. W. G. Sumner tells of the comparatively recent extraordinary outbreak of 'Suicidal Fanaticism in Russia,' and Lindley M. Keasbey discusses 'The Differentiation of the Human Species,' believing that mankind was homogeneous prior to the glacial period. E. B. Titchener, after considering the problem 'Were the Earliest Organic Movements Conscious or Unconscious,' decides in favor of the necessity of mind at the first appearance of life. Finally we have the full text of the 'Trust Deed by Andrew Carnegie creating a Trust for the benefit of the Carnegie Institution.'

SOCIETIES AND ACADEMIES.

AMERICAN PHYSICAL SOCIETY.

THE regular bimonthly meeting of the Physical Society was held at Columbia

University on Saturday, February 22. The severe storm in the region near New York at that time delayed the arrival of many of those present, and doubtless prevented others from coming. But the attendance was satisfactory in spite of the storm, and the meeting an enjoyable one.

A paper on the 'Velocity of Light,' by President Michelson, took the place of the president's annual address, which could not be delivered at the holiday meeting of the Society on account of Professor Michelson's unavoidable absence. The paper contained a brief discussion of the various determinations of the velocity of light, together with the determinations of the ratio of the electrostatic and electromagnetic units, and of the velocity of electric waves. The conclusion was reached that the great theoretical importance of demonstrating, or disproving, the absolute equality of these three quantities made a re-determination of the velocity of light desirable. Certain criticisms, from the theoretical standpoint, of the revolving mirror method, which up to the present time has given the most consistent results for V , were also mentioned. A method was proposed which combined the advantages of both the method of Cornu, in which a toothed wheel was used, and the method of the revolving mirror, as used by Michelson and by Newcomb. While free from the objections that have been suggested in connection with the latter method, the method proposed promises a higher accuracy than has ever heretofore been reached.

In a paper on 'Magnetostriction in Bismuth,' by A. P. Wills, experiments were described which were intended to detect any change in length in bismuth produced by longitudinal magnetization. Similar tests by Bidwell had shown an appreciable elongation for a magnetic field of less than 2,000 c. g. s. units. The experiments of Professor Wills were made with a stronger field and with an arrangement of levers of sufficient sensitiveness to show a much smaller elongation than that reported by Bidwell; but no effect could be observed.

In a paper entitled, 'The Transmission of Sound Through Solid Walls,' Mr. F. L. Tufts

gave the results of determinations of the transmitting power for sound of various non-porous walls. The results were in many respects different from what would probably be anticipated from a hurried consideration of the case. For example, a wall of sheet lead, in spite of its great density and its lack of elasticity, was found to transmit much more sound than a glass wall of equal thickness. Two walls separated by an air space were no more effective in cutting off sound than the same two walls in contact. The results indicate that the sound is transmitted in such cases by the forced vibration of the wall as a whole, not by the elastic waves carried through the wall. Other things being equal, that medium which yields most to pressure steadily applied will transmit best.

Professor A. G. Webster, in a paper on the 'Spherical Pendulum,' showed some very pretty traces illustrating the vibrations of a pendulum whose motion is not restricted to one plane and whose amplitude is large. The traces were made by photographing the path of a small incandescent lamp attached to the pendulum bob. The theory of such a pendulum was briefly discussed, and it was shown that the traces actually observed were in close agreement with those predicted by theory.

Certain distorted coronas, produced by a medium containing drops of moisture of different sizes, were described by Carl Barus in a paper entitled 'The Flower-like Distortion of Coronas Due to Graded Cloudy Condensation.' The author developed the theory of such coronas and showed that it was in agreement with observation.

A second paper by Professor Barus dealt with 'Persistent Nuclei Produced by Shaking Solutions of Solids, Liquids or Gases.' The author stated that whereas the nuclei produced by pure water were very fleeting, nuclei produced by solutions persisted until removed by gravity. It follows that small droplets of solutions do not evaporate below a certain dimension, very large compared with molecular dimensions.

The results of measurements of the current between a cold metal and an incandescent carbon kathode were presented in a paper by

Ernest Merritt and O. M. Stewart. Curves were shown giving the observed relation between current and potential difference for different degrees of incandescence and for different air pressures. At low pressures (0.05 mm. or less) these curves were similar to the 'saturation' curves observed in the case of conduction due to Röntgen rays, etc. With increasing potential difference the current at first increased, reached a maximum at about six volts, and then remained practically unaltered for higher potentials, even up to 120 volts. At pressures in the neighborhood of one millimeter the curves were of the same character at low potentials; but instead of remaining constant throughout the whole range from six volts to 120 volts, the current remained unaltered until a potential difference of about thirty volts was reached, and then increased rapidly for higher voltages. The authors suggest that the result may be explained by the ionization of the residual gases by the negative ions from the incandescent carbon.

The Society voted to request the Council to arrange for a summer meeting of the Society in connection with Section B of the American Association for the Advancement of Science.

ERNEST MERRITT.

AMERICAN MATHEMATICAL SOCIETY.

A REGULAR meeting of the American Mathematical Society was held at Columbia University on Saturday, February 22. Vice-President Maxime Bôcher occupied the chair. Thirty members were in attendance at the two sessions. The Council announced the election of the following persons to membership in the Society: Professor Edward Brand, Howard College, Ala.; Mr. D. R. Curtiss, Harvard University; Miss Alice B. Gould, Boston, Mass.; Dr. Carl Gundersen, Columbia University; Mr. A. F. van der Heyden, Middlesbrough, Eng.; Rev. Jean de Seguiet, S. J., Paris, France; Mr. J. W. Young, Cornell University. Fourteen applications for membership were received.

The term of Professor T. S. Fiske as member of the editorial board of the *Transactions* having expired, he was reelected for a term of

three years. Dr. Edward Kasner was reelected assistant secretary. It was decided to hold the next summer meeting of the Society at Evanston, Ill., about the end of August.

The organization of a Pacific Section of the Society is now under consideration. The activity and number of members on the Pacific slope would appear to justify the Council in granting the desired authorization. The Chicago Section, founded in 1898, has proved a gratifying precedent.

The Annual Register of the Society has recently appeared, containing the list of officers and members, annual reports, constitution and by-laws, and a complete list of all periodicals now in the Society's library. The total membership of the Society is now 379, of whom 18 are life members. The treasurer's report shows a credit balance of over \$2,000, in the face of a considerable expenditure for the *Transactions* and the *Bulletin*.

The following papers were read at the February meeting:

Dr. E. V. HUNTINGTON: 'A complete set of postulates for the theory of absolute continuous magnitude,' 'Complete sets of postulates for the theories of positive integral and positive rational numbers,' and 'A simplified definition of a group.'

Dr. M. B. PORTER: 'On the arithmetic nature of the zeros of Bessel functions.'

Dr. W. B. FITE: 'On a property of groups of order p^m .'

Professor L. E. DICKSON: 'The groups of Steiner in problems of contact.'

Dr. VIRGIL SNYDER: 'On the forms of quintic scrolls.'

Mr. PERCIVAL LOWELL: 'On the capture of comets by Jupiter.'

Mr. H. L. RIETZ: 'On primitive groups of odd order.'

Professor MAXIME BÔCHER: 'On systems of linear differential equations of the first order.'

Dr. E. J. WILCZYNSKI: 'Covariants of systems of linear differential equations.'

Professor JAMES MACLAY: 'On some associated surfaces of negative curvature.'

Professor E. W. BROWN: 'On the small divisors in the lunar theory.'

Mr. OTTO DUNKEL: 'Some applications of Green's theorem in one dimension.'

Mr. J. W. YOUNG: 'On a certain group of isomorphisms.'

Dr. A. S. GALE: 'On the rank, order and class of algebraic minimum curves.'

Mr. W. H. ROEVER: 'Brilliant points and loci of brilliant points.'

At the close of the regular program Professor A. G. Webster gave a résumé of a paper, also read before the American Physical Society, on 'The Motion of a Spherical Pendulum,' illustrating it with photographs and stereopticon views.

The next meeting of the Society will be held on Saturday, April 26. The Chicago Section will meet at the University of Chicago on Saturday, March 29.

F. N. COLE,
Secretary.

MEETING OF THE NEBRASKA ACADEMY OF
SCIENCE.

The twelfth annual meeting of the Nebraska Academy of Science was held the 24th and 25th of January, 1902, at the University of Nebraska, Lincoln, Nebraska.

The President's address, given by Professor E. W. DAVIS, was upon the subject, 'The Numerical Basis of Induction'; the remainder of the program being composed of the following papers:

'A Method of Instruction in Crystallography,' by Professor E. H. BARBOUR, in which he described an original method of instruction by the use of paper models to illustrate the extension of the faces; and plaster of Paris models, to allow of cutting in various planes, in which may be imbedded strings to show the position of the axes. He also showed apparatus for casting the latter.

'Preliminary Notice of a Bacterium Associated with Apple Rot,' by Mr. P. J. O'GARA, a review of experiments tending to show that rotting of apples is due to bacilli hitherto undescribed.

'Some New Properties of Conics,' by Dr. CARL C. ENGBERG, in which he illustrated some new facts bearing upon the transformation of well-known curves into other curves in accordance with certain assumed conditions.

'Report of Progress of the Nebraska Geological Survey': Professor E. H. BARBOUR.

'The Quadrat Method in Phytogeography,'

by Dr. F. E. CLEMENTS, in which the author described the way in which this method was applied and gave some curious results of an attempt to estimate plant population under certain conditions.

'A New Bat Parasite,' by J. C. CRAWFORD, Jr., being a description of a new genus and species belonging to the family Hippoboscidae which has hitherto only been reported in North America from New Mexico.

'The Fossil Bryozoa of Nebraska,' by Professor G. E. CONDRA, in which he stated that the total number of species known for the State was 51, of which a score were hitherto undescribed.

'On a New Form of Psychrometer,' by Mr. JOHN FOSSLER, in which he described a form of psychrometer in which the thermometers were rotated about a vertical plane with such a small radius that the apparatus could be used in a very limited space without at the same time any loss in accuracy.

'New Bird Lice from Nebraska': M. A. CARRIKER, Jr.

'Notes on North American Bees': J. C. CRAWFORD, Jr.

'Nebraska Water Mites': Dr. R. H. WOLCOTT.

The last three papers were entirely systematic, containing descriptions of new species, together with records of occurrence, and in the case of the last paper also a table for the separation of species and such biological data as would present a complete view of what is known of the hydrachnid fauna of the State.

'Some Observations on the Buried Rock Surface of Eastern Michigan': Dr. C. H. GORDON.

'On the Use of Closed Aquaria in School-rooms,' by Professor HAVEN METCALF, in which the author also gave hints on what could be grown, where and how to gather it and the best methods of cultivating the same.

'Some Remarkable Fossil Shark's Teeth from Nebraska,' by Professor E. H. BARBOUR and CARRIE BARBOUR, in which the authors called attention to some teeth of *Campodus* and other sharks much more perfectly preserved than any hitherto found.

'The Strength of Nebraska-grown Catalpa and Osage Orange,' by Professor G. R. CHATBURN, a paper of considerable practical importance for the suggestions made as to the properties of the woods named for various economic purposes.

'Progress of the State Botanical Survey': Dr. ROSCOE POUND.

'The Present Knowledge of the Distribution of *Daimonelix*,' by Professor E. H. BARBOUR, detailing the great extension in range of this curious fossil which has resulted from the work of the State and national geological surveys, together with researches carried on by private individuals in Nebraska and adjoining States.

'Some Recent Changes in the Nomenclature of Nebraska Plants,' by Professor C. E. BESSEY, these changes being rendered necessary by the modifications of nomenclature introduced in recent botanical text-books.

'Relative Humidity in Dwelling Houses,' by Professor G. A. LOVELAND, giving the results of experiments upon the humidity of houses heated by various means, and the results of experiments with various expedients to increase the degree of moisture.

'A New Form of Sunshine Recorder,' by Professor G. D. SWEZEY, describing an instrument capable of registering not only the total amount and hours of sunshine during the day, but also varying intensity.

'Suggestions for a Revision of *Alysidium*': Dr. ROSCOE POUND.

'Preliminary Table of the Described Species of *Andrena*': Professor L. BRUNER.

'Some Observations on the Leeches of Nebraska': Professor HENRY B. WARD.

The last three papers were largely systematic.

'Plant Formations of Colorado': Dr. F. E. CLEMENTS.

'Some Experiments on the Paving Bricks of Nebraska': Mr. C. A. FISHER.

'Discovery of the Laramie Cretaceous in Nebraska,' by Mr. C. A. FISHER, in which he called attention to observations which extended the formation over the Wyoming line into Nebraska.

'Notice of certain fine Selenite Crystals

from Cedar County, Nebraska': Professor G. E. CONDRA.

Forty-five members of the Academy were in attendance and an unusual amount of interest manifested. The secretary reported on the publication of Vol. VII. of the Proceedings, being a volume of 170 pages and 15 plates, which had recently come from the press, and also upon the plans for the immediate publication, as Vol. VIII., of the proceedings of the present meeting.

Forty-four new members were elected and the following officers decided upon for the ensuing year:

President, Professor J. H. Powers, Doane College, Crete; *Vice-President*, Professor H. B. Duncanson, State Normal, Peru; *Secretary*, Dr. R. H. Wolcott, State University, Lincoln; *Treasurer*, Professor G. A. Loveland, United States Weather Bureau, Lincoln; *Directors*, Mr. William Cleburne, Omaha; Dr. C. H. Gordon, Lincoln; Professor A. A. Tyler, Bellevue College, Bellevue; Dr. A. S. Von Mansfelde, Ashland.

The Academy passed resolutions commendatory of the United States Hydrographic Survey, and also resolutions endorsing the proposal to establish tree-planting reserves in Cherry County, Thomas County and in Grant and Arthur Counties in the sand-hill region of the State.

After the transaction of other minor business the Society adjourned for one year.

ROBT. H. WOLCOTT,
Secretary.

PHILOSOPHICAL SOCIETY OF WASHINGTON.

At the 547th meeting, held February 15, 1902, Dr. A. L. Day continued his paper begun at the previous meeting. He reviewed briefly the history of high temperature measurement from the Wedgewood clay pyrometer (1782) down to the most modern mechanical, electrical and optical methods. The interesting development of gas thermometry was treated in some detail; the remarkable early measurements of Prinsep, Pouillet and Becquerel with the more perfect gases and metallic bulbs; the hardly less remarkable, but unfortunate, experiments of Sainte-Claire Deville and Troost with iodine vapor in porcelain bulbs, which led pyrometric measurement in

the wrong direction for so many years; the extensive and nearly simultaneous researches of Dr. Barus in the Geological Survey and Holborn and Wien in the German Reichsanstalt; and finally the successful return to first principles at the Reichsanstalt, with the help of the electric oven and the experience of the long line of distinguished predecessors, in which the speaker himself had a part.

The various methods for carrying pyrometric measurement beyond the range of the gas thermometer by making direct comparisons with it as far as it is available, and extrapolating the empirical relation thus obtained, were then taken up; Violle's calorimetric method, by which he obtained the results generally accepted for twenty-five years or more; the electrical resistance method (Siemens, Callendar and others), depending upon the variation in the resistance of a platinum wire with the temperature; the thermoelectric method (Barus, Holborn and Wien, and others), depending upon the electromotive force developed in a pair of wires (*pt 90 rh 10—pt 10* usually) whose junctions are maintained at different temperatures; and several others. In closing, some recently published optical methods were reviewed (Berthelot, Lummer, Holborn and Kurlbaum) which promise to extend the upper limit of measurable temperatures almost indefinitely though with what accuracy, in view of the extent of the extrapolation necessary, it is hardly possible yet to say.

Dr. Day gave as the approximate limit of accuracy of the best methods now available $\pm 1^\circ$ up to 1000° , $\pm 10^\circ$ to perhaps 1600° , $\pm 100^\circ$ to 3000° or more. He did not consider that the limit had been reached either in the accuracy or range of pyrometric measurement or even of gas thermometry and expressed regret that no more attention was being paid to so promising a field in this country.

Dr. L. A. Bauer presented a paper on 'Energy and Entropy: Their Rôle in Thermodynamics and Thermochemistry.' As suggested by the title, the respective rôles played by the two fundamental principles of thermodynamics, the principle of the conservation of energy and the principle of the increase of entropy, were set forth and elucidated by

examples. It was shown that as much is known about the physical properties of entropy as of energy, and that in the phenomena of heat the entropy principle first comes into play, prescribing the direction or method in which stable equilibrium can take place. After the state of equilibrium has been reached then the principle of energy can be applied. It was shown that it would be a gain, now that the entropy function has been found, to discard the historical method of establishing the entropy principle and instead adopt a method similar to that followed by Hertz with regard to the fundamental equations of electromagnetism—*i. e.*, begin with an equation expressing a relation between the specific heats at constant pressure and at constant volume which admits of experimental proof and which prescribes that the entropy function has the same essential property as energy, *viz.*, of being independent of the path or process used in going from one state to another.

A relationship between entropy and the term introduced by Helmholtz—*wärmegehalt*, changed by von Bezold to *potential temperature* and used by him extensively in his paper on the 'thermodynamics of the atmosphere,' was established and the name *entropic temperature* in place of *potential temperature* suggested.

CHARLES K. WEAD,

Secretary.

DISCUSSION AND CORRESPONDENCE.

AGRICULTURE AND THE EXPERIMENT STATIONS.

THE agricultural experiment stations of the United States, which the Federal Government has established in the several States, have now themselves passed the experimental stage and have to a remarkable degree won the respect and confidence of the farming and allied interests which it is their function to serve. There are at present fifty-nine experiment stations more or less completely maintained by Federal funds, two of which are colonial, and one of which is in Alaska. The organization and location of the continental stations affords an interesting example of the effect of the application of political conceptions to scientific investigation.

Agriculture is simply the business of growing plants and selling their products, either directly in the form of crops or indirectly in the form of the animal body into which they have been converted.

Affecting this are soil and climatic conditions, the market, the farmer's knowledge of the plants he grows and of the best methods for marketing their products.

None of these factors has anything to do with state boundaries. The fact that wheat is grown in a certain state is of no more, nor indeed of as much, significance as the fact that it is grown along a certain line of railway. A State boundary is a fiction of some political, but of absolutely no scientific importance whatever. A range of mountains or a river, on the other hand, is of tremendous significance so far as its effect on plant life is concerned. The northern and southern boundaries for a state like Kansas, two hundred miles wide, may be of some importance scientifically, as representing whatever differences in fauna or flora may be found resulting from the rather slight difference in the mean annual temperature of the two regions. But from the standpoint of scientific agriculture there is not a tittle of the significance in such a difference north or south from the center of this State as in the two hundred miles east or west of that point. Still more strikingly is the same fact exemplified in the states of Oregon and Washington.

The significant thing to know is not whether a given crop can be raised in the state of Oregon or in the state of Washington, but whether it can be raised in the region east of the Cascades, where there is a small annual precipitation and great evaporation, or west of the mountains where the reverse is true.

What does it convey to a scientific mind to say that such and such varieties of wheat are best for Ohio or Nebraska, when regional or climatic conditions within these states may furnish areas which demand wheat varieties of the most diverse character? Politically a state is a plane surface, holding a certain number of inhabitants subject to exactly the same civil laws.

Scientifically regarded, a state is an arbi-

trary block of territory chopped out at random, sometimes consisting of some vast physiographic domain of mountain, forest or prairie, sometimes comprising portions of all these within its imaginary boundaries.

One would naturally suppose that in the location of agricultural experiment stations, the points alone considered would be physiographic and meteorological ones. For scientific purposes, for example, one station in the western fourth of any one of those portions of the earth's surface called North Dakota, South Dakota, Nebraska or Kansas could more efficiently solve the problems of that whole vast region than can the present four stations, each of which is located outside of the high plains area, and in the eastern part of its geographic fiction, the state, which represents in each case in the eastern and western portions, such opposing facts of climate and topography.

One would naturally suppose that a geographical area of 62,000 square miles, of such very similar conditions as regards soil, climate and physiography as are found in the New England states, would scarcely need be provided with as many stations for experiment in agriculture as the region of 262,000 square miles which we call Texas, and which contains such diverse climates as are found in the humid tropical region of Brownsville, the desert tropical of El Paso, and the high, cool, semi-arid area of the Staked Plains. Yet we find six stations in the former and one in the latter geographic area.

The inconsistency involved in the absurdly unscientific location and distribution of our experiment stations is seen at a glance on a map of the United States having the stations prominently marked. Two stations dominating similar areas so far as agriculture is concerned, and of necessity dealing with precisely the same problems are found located ten miles from each other. But because they are in the separate 'states' of Idaho and Washington, it occurs to nobody to be an economic waste, as it certainly would if the neighboring boundary line were moved ten miles east or west, thereby throwing them into the same 'State.'

The location of stations within seventy miles of each other and in the midst of sim-

ilar areas impresses no one as useless, so long as it is known that one is in Wyoming and the other in Colorado.

This fundamental error involved in the establishing of one of the United States experiment stations in each state, regardless of the facts of climate, soil or physiographic aspect, which may make a unit of several states for the purposes of agricultural experiment or may subdivide one state into several wholly distinct areas so far as plant life is concerned, must necessarily be responsible for a lesser efficiency to the country in proportion to the number of stations established than would exist if locations had been settled upon by a committee of scientific experts, without any regard whatever to state boundaries.

In other words, the quasi-dual nature of the experiment stations, receiving as they do their support from the Federal Government while their allotment is to the states as such, to which are also left the direction and control of the experimental work, together with the appointment of their staffs, results in a regrettable lack of coordinated and economically directed work. It would seem that experiments in agriculture in the various agricultural areas of the country would be conducted to much better advantage, if all the operations of the Federal experiment stations were planned, directed and controlled directly by the Department of Agriculture at Washington. This, in fact, is the only way in which the faults of indirection and of duplication of work could well be avoided. Under the control of the Federal Government, the problems of each agricultural area could be assigned to such stations as were best fitted to deal with them, instead of their energies being distributed vaguely over a variety of subjects, more or less intermittently and at haphazard, as local influences or the curiosity of the individual investigators dictate.

One of the great difficulties with experiment station workers at present is the isolation in which they labor, and the limitations of their outlook upon agricultural problems in general, due to the intense localization of their work and thought. This cannot well be otherwise, as lack of funds precludes them from

the travel necessary to gain a knowledge of the work of other experiment stations, and the conditions of other agricultural regions.

If the experiment station staffs were filled by civil service appointment from Washington, and a system of transfers from station to station and back to Washington were made possible, it would seem that the resultant increased breadth of view, and more comprehensive grasp of the problems of scientific agriculture would inure greatly to the benefit of the whole country. By such a system of transfers the right man to attack any given problem could be detailed, at any time, to any experiment station in the United States, while by a civil service system of appointments a constantly higher standard of efficiency than now prevails could be insured everywhere.

At the present time a tendency seems to exist, if one station makes a reputation for itself in any one line of experiment, for others in the neighborhood to be stimulated to emulate, and if possible to excel, its efforts, due to the influence of state pride or rivalry. A duplication of work here occurs which is often wasteful and useless.

Under a Federal system of control a given problem might oftentimes be divided and assigned in part to three or four stations working coordinately. The advantage of such an assignment in the case of many experiments is sufficiently obvious.

One of the difficulties in the way of the highest efficiency on the part of experiment station workers lies in the association of the experiment stations with the state educational institutions, and the combination of the duties of a teacher in one of these with those of an investigator in the experiment station. As a matter of fact, the work of the teacher and the investigator cannot be wholly divorced, but oftentimes by far the greater part of the time of the experiment station men is swallowed up in the details of college duties, to the serious detriment, of course, of the work of the station. The absolute separation of the federal station workers and the state agricultural college workers, so far as their duties are concerned, need not prevent the chemist

of the station from doing some teaching in soil chemistry for example, or the professor of botany of the college from taking advantage of the work and, so far as possible, sharing the interests of the botanist of the experiment station.

The main necessities then for the increased efficiency of our agricultural experiment stations would seem to be:

1. A centralized management, with the direction and distribution of all experimental work left to a single board of control, preferably to be connected with the United States Department of Agriculture.

2. A system of civil service appointments to positions in all Federal stations, and an elasticity in the organization of the different staffs, making possible the transfer of scientific workers from one station to another according to the judgment of the governing board.

3. The complete separation of the experimental research work, of the station investigators and the pedagogical work of the college teachers of science in localities where the experiment station is located on the grounds of a state institution. This would necessitate an increased salary roll in both the college and station, but would increase the working efficiency of both in a far greater ratio.

H. F. ROBERTS.

KANSAS STATE AGRICULTURAL COLLEGE.

INJURIES TO THE EYE, CAUSED BY INTENSE LIGHT.

MR. FRANK ALLEN's observations in these columns (January 17, 1902, p. 109) suggests an experience of my own which is worth recording in some detail.

Last April I ran the projection lantern one evening for a friend, the exercise lasting nearly two hours. The lantern is an arc lamp, hand feed, and the current was giving some trouble. The arc had to be kept rather short, and it was necessary to look in at the arc very often. To guard my eyes from the glare, I had three thicknesses of blue glass in front of the arc. Yet I noticed that my eyes were being injured. At the close of the lecture there was a distinct dimness in the center of my field

of vision. This has often happened after looking at a bright light, and I thought nothing of it. Next morning, however, my neighbor at breakfast wore a bright yellow rose, and I noticed a distinct spot of pink on it, yet on examining it closely there was no pink, or at least only a trace of pink in the center of vision. At a distance of six feet the whole rose was pink.

On the street that morning, an orange peel on the walk at a distance of twelve feet was bright red; on a nearer view only a central spot was red. And every yellow house had a pink spot, and every orange surface a red one from that time on. Then I saw that in reading there was a gray area on the page in the center of vision.

It was plain that focusing so long on the arc through the blue glass had paralyzed or killed the cones in the *fovea centralis* and its immediate vicinity—that is, such cones as normally respond to the short waves at the blue end of the spectrum. So my eyes in that area of the retina responded only to the longer or red waves from the rose or the orange, and in ordinary vision I was deprived of just that much illumination.

This condition persisted in a very striking way all summer, but gradually disappeared in the autumn, and now, at the end of ten months, I can discover no trace of the dimness in the center of vision, nor can I see any trace of pink in a yellow surface. So whatever the disability was, it has been overcome. If the cones were destroyed, they have been replaced; and if only paralyzed, they have resumed their normal function.

J. PAUL GOODE.

THE UNIVERSITY OF PENNSYLVANIA.

A GEOGRAPHICAL SOCIETY OF NORTH AMERICA.

TO THE EDITOR OF SCIENCE: Referring to the very interesting letter from Professor W. M. Davis (SCIENCE, XV., No. 373, p. 313, February 21, 1902), there seems to be no reason why the aims of the professional geographer should exclude any non-professional who is anxious to keep in touch with the latest advances in geographical knowledge.

Their need is apparently mutual. The pro-

fessional should be glad of all the support, moral and financial, which he can secure throughout the community, while there are many students who wish to keep advised of all progress as it is made.

Let the 'professionals' constitute the 'members' of the Society and let the test for 'membership' be as rigid as may be found necessary, so that being a member shall constitute *prima facie* evidence to the world of established professional ability and experience.

Let there also be a class of 'associates,' who shall include any respectable person of legal age (duly elected) who desires to join and is willing to pay the established dues.

All members should be elected as associates and any associate should have at all times the privilege of applying to a 'board of examiners' for election to full membership.

This course of procedure has been found satisfactory in the American Institute of Electrical Engineers and in other engineering bodies. It preserves to the professional all the honor and exclusiveness which he can desire, yet serves to draw into a compact and powerful organization all who for any reason wish to keep in touch with the most recent advances.

Such an inclusive policy would seem to be the wise course for all of our scientific societies, each of which is supposed to exist for the purpose of educating the public at large and of arousing a widespread interest in its specialty as well as for the benefit of its professional members.

J. STANFORD BROWN.

NEW YORK CITY.

THE PHYSIOLOGICAL EFFECTS OF THE ELECTRICAL CHARGE OF IONS.

IN No. 374 of SCIENCE Professor Lee gives a review of the Chicago meeting of the American Physiological Society in which he says that I 'maintained that vital phenomena, in general, are caused by the electrical charges of ions.' I wish to state that I have never held nor expressed such an opinion.

JACQUES LOEB.

THE UNIVERSITY OF CHICAGO,
March 3, 1902.

NOTES ON INORGANIC CHEMISTRY.

IN proposing the toast, 'The Houses of Parliament,' at the annual dinner of the fellows and associates of the Institute of Chemistry held in London last December, Professor Ramsay referred to the recent jubilee of Professor Berthelot in Paris and the cooperation of the French government with the scientific societies in honoring the distinguished chemist. He then said that while the British government often has occasion to take the advice of scientific experts, it does not as a rule honor science generally in the persons of those who have most distinguished themselves, as is done in many other countries. He called attention to the work of the chemists of the United States Geological Survey, and regretted that this example is not followed by the Geological Survey of Great Britain. Touching upon the question of water supplies, he gave it as his opinion that, valuable as the bacteriological examination of water is, it must be looked upon as merely confirmatory of the examination of the chemist. In responding to this toast for the House of Commons, Mr. Hanbury remarked incidentally that science would be of incomparably more practical value if its 'hideous terminology' could be done away with.

THE question of the existence of the ammonium radical, NH_2 , has been very exhaustively studied by Moissan, whose results are published in the *Comptes Rendus* and in the *Archives Néerlandaises*. His methods included the electrolysis of ammonium chlorid and ammonium iodid in solution in liquid ammonia, the examination of ammonium amalgam at a temperature as low as -90° , where the amalgam is perfectly stable, and the action of liquid hydrogen sulfid on lithium-ammonium and calcium-ammonium at -75° . In none of the experiments was any evidence of free ammonium found, incidentally confirming the recent results of Ruff. Moissan believes, however, that under some circumstances a hydrid of ammonium, NH_2H , is capable of existence.

The passivity of iron has been studied from the standpoint of physical chemistry by Finkelnstein. Determinations of its polarization

capacity and resistance indicate that there can be no coating of badly conducting oxid on the iron, as has been assumed by some observers. The conclusion is drawn that the surface of passive iron consists solely of trivalent iron, the formation of passive iron by oxidizing agents and by electrolysis being due to the replacement of bivalent by trivalent iron.

The subject of the action of water upon metallic lead is one that has been much studied, and the results of different observers have been by no means concordant. A recent extended investigation by Stanislaw Růzička furnishes results which are not wholly in accordance with the generally received ideas. His method was to place bright lead in cylinders containing various solutions, insert a stopper and leave the whole for twenty-four hours. The amount of lead in the solution was then estimated. Care was taken to ensure the absence of air. Nitrates, chlorids, sulfates and carbonates of alkalis and alkaline earths were studied, and also various organic substances. Among his conclusions are the following: The action of salts is wholly independent of the base, and is proportionate to the solubility of the lead salt of the acid of the salt used. Thus nitrates have the most action, chlorids next, sulfates next and carbonates least. The action of the first-mentioned salts is diminished by the presence of carbonates in the water, while the addition of a nitrate increases the action of other salts. If the same piece of lead is exposed to fresh solutions of the carbonate, the action is much diminished, and the same diminution occurs even in the presence of nitrates and free oxygen. Free carbon dioxide greatly diminishes the action of water or salt solutions on lead, while air in all cases increases it. Infusions of grass leaves diminish the action of water, while it is greatly increased by infusion of peat.

A RECENT number of the *Mineralogical Magazine* contains a paper by J. W. Evans on the action of ground-water on pyrites, a study called forth by the building of a reservoir in northern Mysore. It was feared that the large quantity of pyrites in the underlying rock would act harmfully on the water. It was

found that when the water was free from carbonates the pyrites are very slowly acted on with the formation of iron sulfate. On the other hand, when carbonates are present iron carbonate, hydroxids and oxids are to be expected, the hydrates being first formed. Free carbon dioxide in the water seems to be without effect. In the presence of pure water, metallic arsenids are changed into arsenates, which are generally insoluble, and the presence of carbonates has merely the effect of retarding the change.

IN an examination of Oriental medicines, P. Guigues had occasion to test a sample of 'Zerquoun minium,' which is used as a rather expensive substitute for the red oxid of mercury. The specimen resembled red lead, but had a lower specific gravity. On treatment with water a white sediment and a red solution were obtained. The former proved to be a magnesium silicate and the red substance a coal-tar dye, revealing the fact that adulterations are not peculiar to the Occident.

The above recalls the fact that the writer came into the possession some years ago of a specimen of Chinese medicine held in high esteem, which, it was supposed, was prepared from urine by some intricate method. Examination showed it to be ordinary salt, and of so pure a quality that it was hardly conceivable that it had been prepared from its reputed source.

J. L. H.

CURRENT NOTES ON METEOROLOGY.

MAURITIUS METEOROLOGICAL SOCIETY.

IT is a pleasure to note that the Meteorological Society of Mauritius has taken a new lease on life. This Society, with which the late Dr. Charles Meldrum was so closely associated, has in the past been active in promoting a study of the cyclones of the South Indian Ocean, to which study Meldrum devoted a large share of his time for about forty years. The successor of Dr. Meldrum as director of the Royal Alfred Observatory and also as secretary of the Meteorological Society of Mauritius, is Mr. T. F. Claxton, F.R.A.S., who is evidently doing much to arouse inter-

est in a society which the honored traditions of the past should most certainly keep alive and active. In the *Proceedings of the Meteorological Society of Mauritius* for 1901, Mr. Claxton has some 'Remarks on the Objects for which the Meteorological Society of Mauritius was Established.' In this paper it is shown that the work already accomplished has been most important, and the hope is expressed that the number of observing stations cooperating with the Royal Alfred Observatory may be increased. An unforeseen decrease in the number of vessels which call at the island of Mauritius has resulted in a corresponding decrease in the number of marine meteorological observations received by the Mauritius Observatory. The annual number of vessels has decreased from 787 in 1878 to 283 in 1900. The material for the daily weather maps is now so scanty that these charts have been discontinued except during cyclone weather, when they are useful for determining the tracks of cyclones. For giving a correct representation of the atmospheric conditions over the Indian Ocean, with a view to studying the sequence of weather changes, the charts are now well-nigh useless.

Vol. I. of a new series of the *Proceedings and Transactions of the Meteorological Society of Mauritius, 1896-1900*, has come to hand recently, and is welcome as a continuation of the older series, which was discontinued in 1864 for lack of funds and other reasons. This volume contains a number of interesting papers, chiefly on the cyclones of the South Indian Ocean from 1896 to 1900. A cyclone in February, 1896, passed centrally over Mauritius, this being the second case of this kind on record since the commencement of systematic observations in 1848. The diameter of the 'eye' was about twenty miles. Meteorologists will be glad to have in their hands these further contributions to the study of the Mauritius cyclones, and will not be slow to express their thanks to Mr. Claxton for his energy in continuing Meldrum's great work.

BRITISH RAINFALL.

THE annual volume on 'British Rainfall' comes this year in its familiar blue cloth

binding, but with a new name, that of Dr. Hugh Robert Mill, on its title page. As has already been reported in these 'Notes,' Mr. H. Sowerby Wallis succeeded to the editorship of this important publication after the death of Mr. George J. Symons in 1900. Mr. Wallis was associated with Mr. Symons for over thirty years, and from 1890 on his name appeared with that of Mr. Symons on the title-page of 'British Rainfall.' Dr. Mill, as already noted in these columns, has assumed the editorship of *Symons's Monthly Meteorological Magazine*, and is now associated with Mr. Wallis in carrying on the work of the British Rainfall Organization. The present volume is a particularly interesting one. Dr. Mill has a paper on 'The Ilkley Flood of July 12,' which was caused by an unusually heavy rainfall amounting to 5.40 in. at Ilkley itself (the maximum fall for the year in the British Isles); and another paper, of historic value, on 'The Development of Rainfall Measurement in the last Forty Years,' in which the material, size, form, exposure and elevation of rain gauges used in England are considered. It is a satisfaction to know that 'British Rainfall' is to be continued in such excellent hands.

CLIMATIC CONDITIONS OF PANAMA AND NICARAGUA.

In a recent paper on 'The Present Condition of the Panama Canal' (*Engineering Mag.*, January, 1902), Gen. H. L. Abbot considers briefly the climatic conditions of the Panama and Nicaragua canal routes. Throughout the entire region the temperature varies but little during the year from the annual mean of 79°. The high temperatures and high relative humidity forbid hard manual labor on the part of white men. The hospital records of the Panama Railroad and of the Canal Company during the past twenty years show that there is no reason for apprehending serious trouble from sickness in the future. At Colon the annual precipitation is about 129 inches, in the interior, about 94 inches, and on the Pacific coast, about 57 inches. There is a clearly defined dry season of about four months everywhere along the

route of the Panama canal. This season can be used for especially difficult engineering operations. Furthermore, the heaviest work is in the interior, where the rainfall is not excessive. The conditions are less favorable in Nicaragua. Near the Gulf coast, where the heaviest excavations are required, the rainfall appears to be about 250 inches and there is no dry season. On the Pacific coast and in the interior there is less rainfall, and there is also a dry season. Even here, however, the rainfall seems to be somewhat greater than in the corresponding portions of the Panama district.

DAY DARKNESS IN LONDON.

A SHORT article of some interest in *Symons's Monthly Meteorological Magazine* for January concerns the number of hours during which artificial light was necessary in a London office (J. E. Clark, 'Day Darkness in the City'). The record has been kept since September, 1897, and runs through 1901. Office hours were from 9 to 5, and to 1 P. M. on Saturdays. A curve illustrates the diurnal distribution of dark quarter hours. There is a rapid rise from 9 to 10.15; then a marked fall to just before noon; then a slight rise; a fall after 12:30 until just before 1; a rise till after 1 and a steady and marked rise from about 2 on. The first rise is believed to be associated with the lighting of office fires. The noon rise seems to follow luncheon preparations in the restaurants, and that an hour later is thought to be due to the fact that lunching is then in full swing. The results of these observations are not without interest, but the explanation of the facts discovered on the basis of so few records cannot be accepted as at all convincing.

R. DEC. WARD.

SCIENTIFIC NOTES AND NEWS.

THE National Observatory question has assumed a new phase through the action of the secretary of the navy, in sending to Congress through the secretary of the treasury an estimate for the salary of a director of the naval (or national) observatory. The committees of Congress thus have the matter before them in a form in which it was never before pre-

sented, and it lies with Congress to decide whether it will accede to the recommendation.

PROFESSOR HERMON C. BUMPUS, formerly of Brown University, who has held during the past year the position of assistant to the president in the American Museum of Natural History, New York, was appointed director of the museum at the annual meeting of the board of trustees. This places the museum in the same position as regards administration as the Zoological Park and the Botanical Garden of New York. Morris K. Jesup was reelected president, William E. Dodge first vice-president, and Henry F. Osborn second vice-president.

PROFESSOR W. H. BREWER, for thirty-seven years professor of agriculture in the Sheffield Scientific School of Yale University, will retire from the active duties of the professorship at the end of the present academic year.

DR. J. KINYOUN, who has for fifteen years been connected with the U. S. Hospital Service and is at present commanding officer and chief surgeon of the hospital at Detroit, has resigned from the service.

MR. ALEXANDER AGASSIZ has had a portrait of himself painted by M. Jules Lefevre. The painting in which he is shown in the robe of members of the Paris Academy will be presented to Harvard University.

M. ANDRÉ, of Lyons, has been elected a correspondent of the Paris Academy of Sciences in the Section of Astronomy in the room of the late B. A. Gould.

THE Zoological Society of London will confer its gold medal on Sir Harry Johnston, whose remarkable discovery of the okapi has recently attracted so much attention, and its silver medal on Mr. E. W. Harper, of Calcutta, who has given many rare Indian birds to the society's collections.

SIR JOHN S. BURDON-SANDERSON, professor of physiology at Oxford University, has been given the degree of Doctor of Science by Owen's College, Manchester.

THE University of Jena has awarded and conferred an honorary doctorate on Herr Wilhelm Winckler, in recognition of his astronomical researches.

DR. C. S. BELL, of Turin, has been appointed director of the Botanical Gardens at Cagliari.

DR. A. A. IVANOV, assistant astronomer at Pulkova Observatory, has been appointed inspector in the St. Petersburg Institute of Weights and Measures and at the same time has been made docent in astronomy and geodesy at the University.

At the anniversary meeting of the Geological Society of London officers were elected as follows: President, Professor C. Lapworth, F.R.S.; Vice-Presidents, Sir Archibald Geikie, F.R.S., Mr. J. E. Marr, F.R.S., Professor H. A. Miers, F.R.S., and Professor H. G. Seeley, F.R.S.; Secretaries, Mr. R. S. Herries and Professor W. W. Watts; Foreign Secretary, Sir John Evans, F.R.S.; Treasurer, Dr. W. T. Blanford, F.R.S. The medals and funds were awarded in accordance with the announcement that we have already made.

M. BERTHELOT has been elected honorary president, and M. Moissan, president, of the council of the Chemical Society of Paris.

M. TEISSERENC DE BORT has made a visit to Denmark to establish a meteorological station in which kites and captive balloons will be used.

PROFESSOR BESSEY, of the University of Nebraska, is to give a course of twenty lectures on botany in the Colorado Springs Summer School, which is to be held in Colorado Springs, Colo., in July and August.

PROFESSOR VOLNEY M. SPALDING, of the University of Michigan, is at present on a botanical expedition to Florida.

MAJOR RONALD ROSS, of the Liverpool School of Tropical Medicine, left Liverpool on February 22 for Sierra Leone to make an examination of the drainage scheme being carried out there, and to study the health of the natives.

THE committee of the Medical School of the Johns Hopkins University, appointed to erect a memorial to the late Jesse William Lazear, who lost his life as the result of an experiment on the transmission of yellow fever by mosquitoes, reports that sufficient money has been subscribed to erect a memorial tablet and to

establish a library fund for the purchase of works relating to tropical diseases. The committee now hope that a sufficient sum may be subscribed to establish a permanent scholarship for the study of tropical diseases. Subscriptions for this purpose may be sent to Dr. Stewart Paton, treasurer, 213 West Monument Street, Baltimore, Md.

PROFESSOR LEO KÖNIGSBERGER, of Heidelberg, is preparing an extended biography of Hermann von Helmholtz, which will be published by Friedrich Vieweg and Son.

THE students of the University of California held memorial exercises in honor of the late Professor Joseph Le Conte on February 26, the anniversary of his birth. An address was made by Professor Thomas R. Bacon. The students of the university are collecting funds to assist in the erection of a granite lodge which the Sierra Club proposes to construct in the Yosemite Valley as a memorial to Dr. Le Conte.

DR. CHRISTIAN PENGER, professor of clinical surgery in the Rush Medical College of the University of Chicago, died on March 7, at the age of fifty-two years.

WE regret to record the following deaths among foreign men of science: Dr. Emil Holub, a distinguished African traveler, in Vienna on February 21, aged fifty-four years; Professor Moriz Kaposi, of the University of Vienna, well-known for his publications on diseases of the skin, on March 6, at the age of sixty-four years; Dr. Carlos Berg, director of the National Museum at Buenos Ayres, at the age of fifty-nine years; Dr. Johannis Pernet, professor of physics in the Polytechnic School at Zurich, at the age of fifty-seven years, and Captain Gaetano Casati, an Italian explorer who spent ten years in Africa, at the age of sixty-three years.

At the annual meeting of the Board of Managers of the New York Zoological Society it was reported that the society has contributed \$250,000 towards the Zoological Park and has \$18,000 in the treasury yet to expend, in addition to \$17,000 which has been expended upon the plans and designs for the buildings. The City of New York has expended \$425,000

in the general development of the park, and in the erection of a monkey house and lion house. The latter building will be open to the public in September next. During the past year a medical staff has been established in order to secure scientific treatment of the animals and to study the causes and prevention of diseases. This consists of Dr. Frank H. Miller, a veterinarian of European training; Dr. Howard Brooks, a well-known pathologist, and a laboratory assistant. A number of interesting facts have already been secured by this staff which will be reported later in SCIENCE. The Society has applied to the Board of Estimate and Apportionment for an additional sum of \$500,000, to be expended in the development of the physical features of the park, in forestry, and also in the construction of additional buildings, especially the antelope house, ostrich house and a larger bird house.

As we have already announced, the seventy-second annual meeting of the British Association for the Advancement of Science will be held at Belfast, beginning on September 10. Professor James Dewar is the president-elect, and the presidents of the sections are as follows: Mathematical and Physical Science, Professor John Purser; Chemistry, Professor Edward Divers; Geology, Lieutenant-General C. A. McMahon; Zoology, Professor G. B. Howes; Geography, Col. Sir T. H. Holdich; Economic Science and Statistics, Mr. E. Cannan; Engineering, Professor John Perry; Anthropology, Professor A. C. Haddon; Physiology, Professor W. D. Halliburton; Botany, Professor J. Reynolds Green; Educational Science, Professor Henry E. Armstrong. Professor Dewar's presidential address will be given on the evening of September 10; on September 11 there will be a soirée; on the evening of September 13 a discourse on 'Becquerel Rays and Radio-Activity' will be delivered by Professor J. J. Thomson; a lecture will be given to the operative classes on September 14 by Professor L. C. Miall; on Monday evening, September 16, a discourse on inheritance will be delivered by Professor W. F. R. Weldon, M.A., F.R.S.; on Tuesday evening there will be a soirée; on Wednesday,

September 18, the concluding general meeting will be held at 2:30 P.M.

LETTERS dated from Franz Josef Land, August 17, have been received at Copenhagen from members of the Baldwin-Ziegler Arctic expedition which left Tromsøe, Norway, on July 16, last year, on the steamers *America* and *Belgica*. The vessels arrived at Franz Josef Land, after trying experiences, with all on board well. The *America* intended to winter at Franz Josef Land, and then proceed northward until stopped by the ice, when the party on board of her was to start towards the North Pole. Mr. Baldwin hoped that the *America* would reach 83 degrees north.

At a meeting of the Royal Geographical Society, on February 24, Sir Clements Markham, president, described the progress of the British Antarctic expedition and laid special stress on the need of securing sufficient money for the relief ship which is to be sent out in June. Subscriptions for this purpose include: The Royal Society, £500; the Goldsmiths' Company, £200; Mr. L. W. Longstaff, £5,000; Miss Dawson-Lambton, £500; Miss E. Dawson-Lambton, £500; Mr. J. P. Thomasson, £500; Lady Constance Barne, £150; the Duke of Bedford, £100; Sir E. Cassel, £100; Mr. H. Leonard, £100; Dr. G. B. Longstaff, £100; Mr. Duncan MacKinnon, £100; the Duke of Northumberland, £100; and Mr. S. Vaughan Morgan, £75.

The Royal Astronomical Society has received from Sir William Huggins a copy of the portrait of Galileo at Florence, and from Sir W. J. Herschel, a medallion in Wedgwood ware of Sir William Herschell.

The council of the Royal Institute of British Architects has granted the sum of £50 to the Cretan Exploration Fund towards the completion of Mr. Arthur Evans's excavations at Knossos. Since the appeal issued in December the sum of £1,600 has been raised.

UNIVERSITY AND EDUCATIONAL NEWS.

PRESIDENT HARPER announced in his last quarterly statement that Mr. John D. Rockefeller gave on December 1, \$1,000,000 toward the general endowment fund of the University

of Chicago. Mr. Rockefeller has also given \$250,000 to be used for the general needs of the University during the present academic year.

By the will of Mrs. Lila Currier, \$50,000 will go to Columbia University and \$100,000 to Yale University upon the death of Mr. Edward W. Currier.

By the opinion just handed down by the Supreme Court of Pennsylvania affirming the opinion of the Orphans' Court of Philadelphia, which sustained the will of the late Joseph M. Bennett, the University of Pennsylvania acquires real estate declared to be worth more than \$500,000. The decedent left the property to the University 'to further aid and encourage the trustees in carrying out more practically and thoroughly the coeducation of women and girls.'

THE daily papers renew the reports that negotiations are under way for the amalgamation of the Armour Institute of Technology with the University of Chicago. The plan involves the removal of the Institute to the University campus, where the University will furnish buildings and equipment to the value of \$1,000,000, while the Armour interests will give \$1,500,000 in endowment. Subsequent gifts from the Armours and Mr. Rockefeller are expected to increase the capital of the technology school to \$5,000,000. The school will continue to be known as the Armour Institute of Technology, its policy will be maintained, and the heads of departments will remain practically the same.

COLUMBIA UNIVERSITY has received an anonymous gift of \$10,000 for two scholarships, and one thousand dollars for a course of biological lectures.

MR. WILLIAM JOHNSTON, a Liverpool ship-owner, has given £25,000 to the University of Liverpool, to promote research in pathology and physiology.

A CHAPTER of the scientific honor society Sigma Xi has been organized at the University of California with twenty members of the faculty as charter members.

THE registration at the University of Chicago for the autumn quarter was 2,431, as

compared with 1,961 in 1900 and 1,682 in 1899. The number of students in the graduate schools was 435, of whom 197 were in the Ogden school of science. In the school of arts and literature the numbers of men and women were equal, in the school of science there were 170 men and 27 women.

THE new laboratory building of the department of horticulture of the Iowa State College was formally opened on Saturday evening, February 22.

CABLEGRAMS report that in the disturbances on February 22, at Moscow University, four hundred students, armed with bludgeons, iron bars and revolvers, wrecked the interior of the University buildings, barricaded themselves within, and hung out red flags from the windows. The police and troops forced an entrance into the interior and arrested the ring-leaders of the rioters. A decree of the minister of public instruction has been gazetted, ordering the expulsion from the University and high schools of all students arrested in connection with rioting.

PROFESSOR F. J. E. WOODBRIDGE, now head of the department of philosophy in the University of Minnesota, has been elected to the chair of philosophy at Columbia University vacant by the election of Dr. Nicholas Murray Butler to the presidency.

DR. GEORGE E. DE SCHWEINITZ, professor of ophthalmology in the Jefferson Medical College, has been elected to succeed the late Dr. Norris as professor of ophthalmology in the University of Pennsylvania.

DR. K. VON TUBEUF, chief of the biological division the German Department of Health, has been appointed professor of forestry in the University of Munich.

ERRATA.

THE following errors were overlooked in the proof of Professor Greenhill's paper (SCIENCE, XIV., p. 973, 1902): Eq. (1), for x read ψ p. 3, line 13, for δ read ψ ; eq. (19), for k read κ ; eq. (28), for z^2 read z , and for $E-2$ read $E-z$; eq. (32) *et seq.*, for μ and v read u ; eq. (40), for n read u .

In connection with the work of the committee appointed by the American Association for the Advancement of Science for the establishment of Convocation Week, it seemed desirable to gather some more accurate impression as to the periods of vacation now in vogue at our universities and colleges. It is very difficult from the reading of catalogues or even by the tabulation of days to gather a clear impression of the differences in the academic calendars of various institutions, so that, almost necessarily, resort was taken to a graphic representation of the facts. The accompanying diagram is perhaps sufficient to indicate the main conditions. In this diagram each vertical column represents the calendar year of one institution. The horizontal lines indicate divisions by weeks. The dotted lines indicate the first day of each month of the academic year from September 1, 1901, to August 31, 1902. In each vertical column the black spaces correspond to term time and the white spaces to vacations. As in every case Christmas falls in vacation time, its position is marked by a black line crossing each column. Fifteen institutions are represented in the chart; twelve universities and three technological schools. The selection has been made so as to have as representative a variety as possible.

Examination of the diagram shows at once the entire absence of any uniformity in the practice of our universities as to the make-up of their calendar. Each institution seems to be a law unto itself, and except that they all begin in the latter part of September or the earlier part of October; that they all have a Christmas vacation and that they all end the year's work in June, there is no uniformity of practice. But even within these broad limits there is great variety. Three of the universities, for instance, begin the third week in September; four begin the fourth week in September; and three the first week in October. In the duration of the Christmas vacation there is even greater proportionate variety, the length being from one week to three. In regard to spring vacations a still greater diversity occurs, some of the institutions having none, one having a considerable vacation in the middle of March, another having a considerable vacation in the middle of April. The length of vacation varies from nothing up to ten days. Equally conspicuous is the discordance of the time of closing the work of the year. The practice of Chicago University of partially continuing the work of instruction during the summer time differs from that of other universities, and this is indicated in the diagram by representing the summer period for that university as half black and half white.

An examination of these diagrams must, I think, convince every one that it is a practical problem for our universities to consider whether they should not aim at a greater or perhaps even a complete uniformity in the length of their term times and of their vacation times. There would be many advantages in this and it would be one of the factors which might contribute to facilitate the migration of students from one university to another.

Now that we have an association of a number of the leading universities of the country, the machinery for the proper discussion of the length of the university terms already exists, and it is to be hoped that this association will take up the consideration of this problem, study it thoroughly and, if it seems expedient, introduce a reform in the practice as it now exists.

The national movement in favor of Convocation Week is distinctly in favor of uniformity in the distribution of vacations. It seems to me that the success of the movement in behalf of Convocation Week is complete and that all of our universities will ultimately conform their Christmas vacation to this new demand, as so many of our universities have already done.

Another fact which is very striking in a graphic representation is the very large proportion of time which is wholly given up to vacation. In this respect university students are privileged beings, having a degree of liberty, of exoneration from responsibility and work such as is accorded to young men in no other occupation whatever. In old times when our colleges had, not young men, but boys as students, this great amount of vacation was certainly justified as a measure for the protection of the health of growing boys. But why students of advanced years should be treated as if they were incapable of doing the amount of work which they would have to do if they went into any practical business or profession in life, is not clear. I think it may be safely said that from the standpoint of the benefit to students, the amount of university vacation is very excessive, and when we think how much our young men are now retarded when they go through college and still more if they go through a college and a professional school before they can enter on practical life, we must look upon the

great extent of vacation as an evil. With the vacation shortened it would be easily possible to bring these young men into active life at least a year earlier than is now possible, and that would be an immense gain.

From the professors' point of view the circumstances are very different. To few professors is the vacation time wholly a period of vacation. On the contrary, it is a time which he can utilize for study, for research and for the increase of all his mental equipment upon which his proficiency as a professor depends. Moreover there is often work upon examination papers or upon a committee of one kind or another, which the professor must carry on during the vacations while his students are idling. For the professor the vacation is certainly a great advantage and I think from the standpoint of university service it is an essential factor in maintaining his efficiency. If therefore the vacations are shortened, it seems to me that every university should provide additional liberty for its professors. The tendency has hitherto been rather to demand too much teaching from professors, but if they teach too much they cannot be qualified to teach in the best manner and with the greatest efficacy, because every professor, to remain efficient, must have time for study; he must advance, he must grow intellectually, and from mere teaching he can never grow.

A consideration of the circumstances therefore suggests these two thoughts: first, that for the benefit of the students the amount of vacation at our universities should be diminished; secondly, that if this is done, then, to preserve the efficiency of the professors, the amount of free time accorded them during term should be increased.

CHARLES S. MINOT.

HARVARD MEDICAL SCHOOL, March 5, 1902.

*THE INTELLECTUAL CONDITIONS FOR THE
SCIENCE OF EMBRYOLOGY.*

I.

MUCH has been written, from time to time, about the conditions which must be fulfilled by a scientific account of the generation and regeneration of living things out of eggs, although little has been said about the intellectual conditions. We may, nevertheless, find the study of these conditions both interesting and instructive.

Our chief interest in embryology is the hope for a scientific account of ourselves; but we cannot undertake to account for anything unless we know what it is that we undertake to account for.

My purpose is not to give a scientific account of mind, nor to discount the future progress of science. I do not believe we are likely to know anything about the natural history of mind except what we find out by scientific discovery; nor do I believe we are ever likely to have a complete scientific account of anything, or to reach a point where no new discoveries are needed.

My purpose is a more humble one: to do what I can to keep the way clear for progress in embryology, by trying to free my own mind, and the minds of others, from all notions which imply that embryological science is impossible.

PART I. THE DOCTRINE OF THE CHASM.

The notion which, for reasons which will soon be made clear, I have called the doctrine of the chasm, is dry and difficult and unattractive, and as my only aim is to find a way for the embryologist across the chasms which are said to lie in his path, I have made no attempt to stimulate the interest of the reader, confining myself to the briefest outline which will serve my purpose, even if this outline be more arid than the works in which the doctrine of the chasm is defended.

1. *Among the things of which he hopes to, some day, give an account, the embryologist must include men who think and act.*

Of all the facts that are made known by experiments upon the generation and regeneration of living things, the one we are least likely to doubt is the existence of the experimenter. We may question the value of his results, but we are not likely to doubt that he did, or tried to do, or thought that he did, the things he describes.

The experimental embryologist comes out of an egg, and he must himself be included among the facts of development which are the object of the observations and experiments and reflections by which he seeks to account for the production of living things out of eggs.

Since some of the things that come out of eggs observe, and reflect, and try experiments, the production of living things out of eggs cannot be adequately explained, or accounted for, unless the production out of eggs of things that observe and reflect and try experiments is also explained or accounted for. To make good its claims to our favorable consideration, embryological science must undertake to account, in good time, for minds, in exactly the same sense of the word as that in which it undertakes to account for bodies and brains.

2. *The intellectual powers by the aid of which we make scientific discoveries come out of eggs.*

Honesty, and independence, and accuracy, and determination, and good sense, are essential to sound progress in scientific discovery. The investigator who is no biologist may take his own honesty, and independence, and accuracy, and determination, and good sense, for granted, as ultimate facts that do not need to be accounted for. But honest men, and accurate men, and independent men, and resolute men, and men with good judgment,

all come out of eggs, and the embryologist cannot forget that they are among the natural phenomena of which he hopes to, some day, give a scientific account.

The final and decisive test of any explanation of the generation of living things out of eggs is the account which it gives of the origin and significance of our ability to observe and reflect and try experiments; for no scientific discovery is worthy of confidence, unless our intellectual means for finding out things are sound and trustworthy. Thus, the progress of embryological science must bring us around, sooner or later, by a new path, to the old question: What is science? What is it to know a thing? It may be that we shall find, from this new point of view, something in knowledge that has been neglected, or too little considered, and we may thus be helped to better notions.

3. *No embryologist can, knowingly, hold any opinion which excludes the possibility of embryological science.*

Each student of science must devote himself to some small part of the realm of nature in order to make progress. We study simple phenomena in the hope that we may pass, in time, to those that are more complex and difficult. If astronomers, and chemists, and students of physics, and embryologists, and zoologists, see fit to temporarily lay aside the natural history of mind, as a problem which does not, for the time, interest them, nor seem to concern them, or as something that is too hard for them, no one can doubt their wisdom. But if their methods and results lead them, or seem to lead them, to the conclusion that what has thus been temporarily laid on the shelf can never be taken down from the shelf, is it not clear that there has been a mistake somewhere? Any method of embryological research which leads to the conclusion that there is a 'chasm' which is 'intellectually impass-

able,' between the facts of embryology and the facts of consciousness, is self-condemned, because it denies the possibility of a science of embryology. Any method of embryological research which leads to the conclusion that the phenomena of consciousness are not phenomena at all, but 'epiphenomena,' and the mere empty and meaningless accompaniment, or by-product, of phenomena, is self-condemned; because the phenomena of knowledge—of embryology, and of everything else—are phenomena of consciousness.

4. *Many eminent authorities tell us an embryological account of human minds is impossible.*

It is well known that many writers, who claim to speak of the meaning of modern science with authority, have been led to believe that the facts of consciousness can never be brought back into the system of science.

Thus, for example, Tyndall tells us: "The passage from the physics of the brain to the corresponding facts of consciousness is unthinkable. Granted that a definite thought and a definite molecular action in the brain occur simultaneously, we do not possess the intellectual organ, nor apparently any rudiment of the organ, which would enable us to pass by a process of reasoning from the one phenomenon to the other. They appear together, but we do not know why. Were our minds and senses so expanded, strengthened and illuminated, as to enable us to see and feel the very molecules of the brain; were we capable of following all their motions, all their groupings, all their electrical discharges if such there be; and were we intimately acquainted with the corresponding states of thought and feeling, we should be as far as ever from the solution of the problem, How are these physical processes connected with the facts of consciousness? The chasm between the two

classes of phenomena would still remain intellectually impassable."

If for *brain* we put *egg which gives rise to a brain*, this statement must mean one of two things: Either there is a chasm, which is intellectually impassable, between the facts of embryology and the facts of consciousness; or else there are two sets of embryological facts—physical and psychical—separated by the impassable chasm; and, therefore, two equally independent and distinct sciences of embryology. Tyndall cannot admit that the facts of physics may have their being in a knowing mind, for, in this case, there would not be any chasm.

Professor James, who is also a believer in the chasm, tells us there is a 'link' or bridge, but as he also tells us 'we do not know, and most authorities believe we never shall know, and never can know,' what the link is, or where the bridge is, neither link nor bridge is of much practical use to embryologists.

According to the system of scientific philosophy which finds expression in these extracts, the embryologist may hope to pass from the physics of atoms and molecules and organic matter, to physical eggs and physical men; and, if there be any psychical atoms and molecules and compounds, he may hope to pass from them to psychical eggs and psychical men; but the chasm between the sort of eggs we know and the sort of men we know is intellectually impassable.

Herbert Spencer, who is held to be the philosophical spokesman of modern science, is also a believer in the chasm; and he tells us that mind is 'something without any kinship with other things; and from the sciences which discover, by introspection, the laws of this something there is no passage by transitional steps to the sciences which discover the laws of these other things.'

We may pass, by a process of reasoning, from a physical candle to a physical burn, and, if this system of philosophy is to be trusted, we might, if we knew a psychical candle, pass from it to a psychical pain, but we can never pass from a physical candle to a psychical pain by any intellectual process, nor know a burn hurts in the way we know a flame burns.

5. *The chasm is not an easy thing to understand.*

Many questions are too hard for us, for we are very ignorant, and we have only feeble and incomplete command of the scientific method of finding out things; but these familiar truths are not what Tyndall and Spencer have tried to express in the passages I have quoted. These passages are no humble confession of ignorance. They are very positive assertions that something—an intellectual grand canyon—is very definitely known. We are told that we know—know with certainty—that the method which is used in physical discovery is fundamentally and utterly inadequate for dealing with the relation between bodies and minds—utterly inadequate for dealing with the relation between eggs and the thinking men who come out of eggs. The grand canyon is not merely difficult. It is utterly impassable.

6. *We are told that there is a chasm, because I cannot know the minds of other men in the way I know my own mind.*

Among the reasons which are given for belief in the chasm, the simplest is my alleged inability to know the minds of other men in the way I know my own mind. But I can never know my own body in the way I know the bodies of other men. I can have no more immediate perception that there is in my head a sphenoid bone which has arisen, during my younger stages, through the union of a pre-sphenoid, a basi-sphenoid, two ali-sphenoids, two orbito-sphenoids, and two ptery-

goids, than I can have immediate perception that there is in Timbuctoo a man with a mind as much like my mind as my body is like his body. My conviction that I have passed through embryonic stages like those described in the text-books is even more remotely inferential than my conviction that my own familiar friend has a mind like mine.

The chasm between my embryonic history and that of other human beings is utterly impassable, yet its impassability is practical and not intellectual. I find no more logical difficulty in believing that I could perceive the resemblance between my brain, or my embryonic history, and those of other men, if I were in the proper place at the right time with suitable means of observation, than I find in the belief that I could thus perceive the other side of the moon.

If there is a grand canyon, it must be of a different sort from the chasm between my body and those of other men, for this is not intellectual, but practical.

7. *There is a chasm, we are told, because I know my own mind by introspection.*

It is, unquestionably, through introspection that I know my own mind and this is the reason why we are told that there is an impassable chasm between mind, on the one side, and brains and all other material things, on the other.

A moment's reflection is enough to show that it is through introspection—through comparison of my sensations, and recollections, and expectations, and other mental facts, and through reflection upon them—that I find out anything. If I neither felt nor reflected, I should not know anything. It is through reflection upon my thoughts and feelings that I make scientific discoveries about my mind, and about the minds of other men, and about everything that I know. As I have only this one way to find out anything, it is hard to imagine

where the impassable chasm is, but what chiefly concerns us now is the wide diffusion of belief in its reality.

8. *The chasm is said to be between the things I may know, or might know, and something unknowable.*

The chasm cannot be between my mind and anything I know, or may know, or might know if I had the opportunity, because the things I know are in my mind, and I can never know anything except knowledge. So we are told that it is between things that are knowable and something that is not only unknown and unknowing, but unknowable.

Believers in the chasm do not all put it in the same place. Some declare that we know nothing but the molecular or electrical changes in our ganglion cells. Forgetting the existence of their own thoughts, or else dismissing them as mere 'epiphenomena,' without significance, they tell us that the chasm is between these physiological changes and the real world to which we try to refer them.

We have no immediate knowledge of our own brains, but we do know the thoughts that arise in our minds, and Tyndall tells us the chasm is not between the physiological changes in our brains and the facts of physics, but between thoughts and the physiological changes in our brains.

A third, and, on the whole, a more consistent notion, is that we know *impressions*, but can never know the thing impressing, nor the thing impressed, nor whether the thing impressing and the thing impressed are two different kinds of unknowables, or only two unknowables of the same kind. This is Spencer's opinion, as I understand it, and it is the opinion of many scientific men.

We know phenomena, or appearances, they tell us, but are altogether put off with appearances, and can never know either things or minds as they are in themselves.

We know the eggs in our minds, and the hens in our minds, but as for knowing eggs as they are in themselves or hens as they are in themselves, that, we are told, is forever out of our reach on the other side of the chasm. We may know the human ovum in our minds and the thinking man in our minds, but the human ovum as it is in itself and the thinking man as he is in himself, are utterly unknowable.

When the fact that we know the hens in our minds is joined to the notion that our minds are in our heads, we reach the interesting, but startling, opinion, that the hens we know are the hens inside our heads. Efforts to escape this strange admission by the assertion that we know only the appearance, and not the reality, of hens in our heads, lead one to suspect that the intellectual chasm may not be a grand canyon after all, but only a common bog in which the wayfarer is the more completely mired by his own struggles.

He who believes he can never know anything as it really is, can never know whether what he thinks he believes or disbelieves is really what he thinks it is, rather than something quite different; so the question whether he can believe or disbelieve anything is not without interest, although we need not go into it now.

9. *The chasm is not between the things we know and the things that remain to be known.*

The embryologist is well aware that he cannot hope to find out all there is to learn about hens' eggs, or about his mind, or about anything else; but he attributes this truth to the boundless wealth of nature, and not to any inherent weakness in his methods. In this meaning of the words, he has no expectation, and no hope, that he will ever know a hen's egg as it really is; and if the chasm were only between the things he knows and the things he has not yet found out, he would frank-

ly and humbly admit its existence and its practical impassability. But it is said to be a chasm between things knowable and things utterly and absolutely unknowable, and not a chasm between the things that are known and the things that remain to be known.

The translator of Haeckel's 'Riddles of the Universe' tells us in his preface, that the chasm has been devised by the Roman Catholic theologians for their own evil ends, but it is not kind to lay upon the backs of these heavy-laden and weary creatures a burden which Tyndall and Spencer and others have shown themselves so eager to bear with jaunty dexterity.

It is true that the slow and heavy intellect of the embryologist cannot aspire to the subtle agility which some show in dodging chasms.

"And now," says the author of 'Father Tom and the Pope,' "I have to tell you of a really unpleasant occurrence. If it was a Prodesan that was in it, I'd say that while the Pope's back was turned, Father Tom made free with the two lips of Miss Eliza."

"It is kissing my housekeeper before my face you are, you villain?" says he. "Go down out of this," says he to Miss Eliza; "and do you be packing off with you," says he to Father Tom, "for it's not safe, so it isn't, to have the likes of you in a house where there's temptation in your way."

"Is it me?" says his Riv'rence; "why that would your Holiness be at, at all? Sure I wasn't doing no such thing."

"Would you have me doubt the ividence ov my sinses?" says the Pope; "would you have me doubt the teshimony ov my eyes and ears?" says he.

"Indeed I would so," says his Riv'rence, "if they pretend to have informed your Holiness of any such foolishness."

"Why," says the Pope, "I've seen you

afther kissing Eliza as plain as I see the nose on your face; I heard the smack you gave her as plain as ever I heard thunder."

"And how do you know whether you see the nose on my face or not?" says his Riv'rence, "and how do you know whether what you thought was thunder, was thunder at all? Them operations on the sinses," says he, "comprises only particular corporal motions, connected with certain confused perceptions called sinsations, and isn't to be depended upon at all. If we were to follow them blind guides we might jist as well turn heretics at one't. 'Pon my secret word, your Holiness, it's neither charitable nor orthodox to set up the testimony of your eyes and ears agin the character ov a clergyman. And now see how aisy it is to explain all them phenomena that perplexed you. I ris and went over beside the young woman because the skillit was boiling over, to help her to save the dhrop of liquor that was in it; and as for the noise you heard, my dear man, it was neither more nor less nor myself dhrawing the cork out of this blisshed bottle."

"Don't offer to thrape that upon me!" says the Pope; "here's the cork in the bottle still, as tight as a wedge."

"I beg your pardon," says his Riv'rence, "that's not the cork at all," says he, "I dhrew the cork a good two minutes ago, and it's very purtily spitted on the end of this blessed cork-schrew at this prisint moment; howandiver you can't see it because it's only its real prisence that's in it. But that appearance that you call a cork," says he, "is nothing but the outward species and external qualities of the cortical nathur. Them's nothing but the accidents of the cork that you'r looking at and handling; but, as I tould you afore, the real cork's dhrew, and is here prisent on the end of this nate little

instrument, and it was the noise I made in drawing it, and nothing else, that you mistook for the sound of the *pogue*."

You know there was no contravening what he said; and the Pope couldn't openly deny it. Howandiver he thried to pick a hole in it this way.

"Granting," says he, "that there is the differ you say betwixt the reality of the cork and these cortical accidents; and that it's quite possible, as you allidge, that the threw cork is really present on the end of the schrew, while the accidents keep the mouth of the bottle stopped—still," says he, "I can't onderstand, though willing to acquit you, how the drawing of the real cork, that's onpalpable and widout accidents, could produce the accident of that sinsible explosion I heard jist now."

"All I can say," says his Riv'ence, "is that it was a rale accident any how."

"Ay," says the Pope, "the kiss you gev Eliza, you mane."

"No," says his Riv'ence, "but the report I made."

"What makes you call the blessed quart an irrational quantity?" says the Pope.

"Because it's too much for one and too little for two," says his Riv'ence.

"Clear it of its coefficient, and we'll thry," says the Pope.

"Hand me over the exponent then," says his Riv'ence.

"What's that?" says the Pope.

"The schrew, to be sure," says his Riv'ence.

"What for?" says the Pope.

"To ddraw the cork," says his Riv'ence.

"Sure the cork's dhrew," says the Pope.

"But the sperets can't get out on account of the accidents that's stuek in the neck of the bottle," says his Riv'ence.

"Accident ought to be passable to sperit," says the Pope, "and that makes

me suspect that the reality of the cork's in it afther all."

"That's a barony-masia," says his Riv'ence, "and I'm not bound to answer it. But the fact is, that it's the accidents of the sperits, too, that's in it, and the reality's passed out through the cortical species as you say; for, you may have observed, we've both been in real good sperits ever since the cork was ddrawn, and where else would the real sperits come from if they wouldn't come out of the bottle?"

"Well, then," says the Pope, "since we've got the reality, there's no use in troubling ourselves wid the accidents."

"Oh, begad," says his Riv'ence, "the accidents is very essential, too; for a man may be in the best of sperits, as far as his immaterial part goes, and yet need the accidents of good liquor to hunt the sinsible thirst out of him."

10. *The assertion that each thing has a mind of its own is irrelevant.*

One way of rescuing science from the dilemma of the chasm, which has the approval of many modern students, is to assert that every living thing, or every thing, has its own mind, and does what it does because it chooses; and that eggs and candles are, in fact, psychical eggs and psychical candles.

"Call an organism a machine if you will," says Professor Ward in his recently published Gifford Lectures, "but where is the mind that made it, and, I may add, that works it?" And he answers his question by the assertion (I., p. 294) that the mind that makes the living organism is inside it and identical with it, and that every living thing takes conscious and efficient part in its own production. The context shows that Ward believes it is as a conscious and voluntary agent, and not merely as a part of an intended system of nature, that the hen's egg is said to help to make itself into a chick. The mind that

is said to be 'inside it and identical with it' is an individual and particular mind, and not the *anima mundi*, nor the mind that presides over the universe. The notion that each thing has its own mind, or is a mind, has nothing in common with the opinion that it is in one sustaining mind that we and all things have being.

The notion that now concerns us reaches its logical culmination in Major Powell's assertion that "Every body, whether it be a stellar system or an atom of hydrogen, has consciousness as judgment and choice." If a hen's egg would describe to us the way in which it makes a chick, I should be delighted to listen and learn from it; but, until it does, embryologists must struggle along in the old-fashioned way.

If each thing has its own mind, and is identical with it, there is, of course, no chasm, because we are really studying psychology, when we think we are studying physics. But this way of escape from the chasm leads us into new difficulties, which are just as impassable as the chasm, and very much more practical.

Even if we admit that the hen's egg may have, or be identical with, a mind as good as a hen's mind, the hen's body is so fearfully and wonderfully made that the wisest man, whose mind is assuredly better than a hen's mind, is at present utterly incompetent to make, or even to understand, a hen. If it is by wisdom that hens are made, it must be by a higher wisdom than a hen's, for this cannot attain to such a work.

It is not by studying the consciousness of atoms and molecules, and material things, that we have found out how to make chemical compounds, and machinery and books; and if we are ever to find out how to make living eggs, one may safely predict that it will not be through the study of the judgment and choice of the eggs of sea-urchins and frogs and hens.

Haeckel, who declares that Berkeley, of all men, believed that 'one thing only exists, and that is my own mind,' also tells us of his own belief that "the two fundamental forms of substance, ponderable matter and the ether, are not dead and only moved by extrinsic forces, but they are endowed with sensation and will (though, naturally, of the lowest grade); they experience an inclination for condensation, a dislike of strain; they strive after the one, and struggle against the other." Only they know nothing about it, for Haeckel tells us: "I conceive the elementary psychic qualities of sensation and will which may be attributed to atoms, to be unconscious." Still, while they do not know it, "every shade of inclination, from complete indifference to the fiercest passion, is exemplified in the chemical relation of the various elements towards each other, just as we find in the psychology of man, and especially in the life of the sexes. This fundamental unity of affinity in the whole of nature, from the simplest chemical process to the most complicated love-story, was recognized by the great Greek scientist, Empedocles, in the fifth century B. C., in his theory of 'the love and hatred of the elements.' It receives empirical confirmation from the interesting progress of cellular psychology, the great significance of which we have only learned to appreciate in the last thirty years. On these phenomena we base our conviction that even the *atom* is not without a rudimentary form of sensation and will."

Words are democratic, and one is, intrinsically, as good as another. What common folks call *things*, may be called *minds*, or *abracadabra*, or *x*, by any one who so chooses, provided he know what he means, and make himself understood; but if he thinks that, by calling *things* *minds*, he can find out anything which would not be

within his reach if he called them x , he seems to me to be misled by words.

As an explanation of the generation of chicks from hens' eggs, the fantastic and pantheistic animism of the passages I have quoted is irrelevant and useless, and no student of Berkeley's works, whether his frame of mind be critical or responsive, can confuse it with the sublime conviction of this thinker that it is in one sustaining mind that we and all things have being.

12. *Belief in the chasm may be due to some error in the description of the way in which we find out things.*

There are no paradoxes nor contradictions in nature. When facts seem to contradict one another, better knowledge is continually showing that some mistake has been made. If physical science leads us, or seems to lead us, to the belief that the chasm between an egg and the thinking man who comes out of an egg is intellectually impassable, the embryologist must ask where the mistake is.

It is a hard thing to believe that, beneficial and good as science has shown itself to be, it can lead us into opinions which cannot be maintained and made consistent. Science is justified in her works, and I find it hard to believe that the paradox of the chasm can be due to the method in which discoveries are made, or that this method can involve us in contradictions, and lead to intellectual disaster.

On the other hand, it is not a hard thing to believe that there may be some error or omission in the account which successful scientific investigators give of their method. He who reflects upon the perplexities which come from the misuse of words will find it an easy thing to believe that an account of the way in which things are found out may be so imperfect that it is practically equivalent to error, leading those who try to find out things by following it into contradiction and absurdity. It

may be that the philosophical spokesmen of science have been drawn into paradoxes and contradictions and doubt of the plainest things, because they have mistaken some crude and imperfect account of the way in which we find out things for the way in which we really do find out things. There may be, in knowing, something so familiar and obvious that it is commonly left out of the description of the process of knowing.

13. *We are told that we know things when we comprehend them, but knowledge may be comprehension and something more.*

The eloquent plea for science, as a guide to conduct, with which the author of a new 'Grammar of Science' begins his book, must strike a responsive chord in the mind of every student of nature.

"Apart," he says, "from the increased physical comfort, apart from the intellectual enjoyment which modern science provides for the community, there is another and more fundamental justification for the time and material spent in scientific work. From the standpoint of morality, we have to judge of each human activity by its outcome in conduct."

Something in my own mind vibrated in harmony with the author's words as I read; but, as he is soon led, by his definition of science as *the analysis and classification of facts*, to believe and to teach that our conduct is nothing but a *routine*, over which we have no real control, and for which we have no true responsibility, his premises seem to compel me to look at his book from the *standpoint of morality*, and to *judge of his intellectual activity by its outcome in conduct*.

I am puzzled, in my attempt to do this, by a moral question about the publication and sale of this book. My difficulty is this. The author's definition of science, as the analysis and classification of facts, leads

him to believe, and to teach, that "the universal validity of science depends upon the similarity of the perceptive and reasoning powers of normal civilized men." A writer on the meaning of science, whose name does not appear in our author's bibliography, showed, some two thousand years ago, that the sale of this opinion for money is not honest; for if the verdict of civilized men be the criterion of science, the way to find out what nature really is must be by ballot. This old writer therefore says that our author is disingenuous when he asks us to buy and read his book in the hope of learning something which he is not able to deliver to his customers, since he himself believes we can get it only through the verdict of civilized men. If the 'Grammar of Science' is anything more than a ballot, I see no way to acquit its author of the charge of obtaining money under false pretenses.

Has not the merest savage a criterion of science which will bear him up though all men be against him? May he not appeal to nature in the same confidence that he will bring to his side all normal civilized men who do not wilfully turn away their eyes?

Herbert Spencer, who also tells us knowledge is the analysis and comprehension of facts, tells us, furthermore, that this is one of the proofs that we can never know anything as it really is, because the thing as it really is is separated, by an impassable chasm, from the appearance which is all we can know.

"For if the successive deeper interpretations of nature which constitute advancing knowledge are merely the inclusion of special truths in general truths, and of general truths in truths still more general, it obviously follows that the most general truth, not admitting of inclusion in any other, does not admit of interpretation. Of necessity, therefore, explanation must

eventually bring us down to the inexplicable. The deepest truth we can get at must be unaccountable. Comprehension must become something else than comprehension, before the ultimate fact can be comprehended."

We undoubtedly comprehend a thing when we know it, but it does not follow that we know a thing when we comprehend it. The conclusion does not follow from the premises. Knowledge may be comprehension and something more, and the assertion that comprehension is knowledge, as well as all the books of synthetic philosophy that are built upon this assertion, may, perhaps, turn out to be nothing more than a new illustration of the fallacy of the undistributed middle.

14. *Knowledge must be something more than comprehension, because the known world grows with knowing.*

Here I must stop, for the present, leaving for some future occasion the attempt to find out, in the interest of embryological science, whether this account of knowing is, or is not, complete. But, before I end, I ask you to take away with you, and to consider, this familiar truth: Each scientific discovery shows us new and unsuspected wonders in nature. The unexplained things which are brought to our knowledge by each scientific explanation far outnumber the things it explains. The progress of knowledge is no mere comprehension, or gathering in. It is more like sowing seed than gathering a harvest, for the known world grows with knowing.

We are told that "when every fact, every past or present phenomenon of the universe, every phase of present or past life therein, has been examined, classified, and coordinated with the rest, then the mission of science will be complete." But if we are to judge the future by the past, classification and coordination will always continue to show us more unclassified and uncoor-

minated things than they classify and coordinate.

May it not be because of the inexhaustible bounty of nature, and not because comprehension is knowledge, that we can never know anything as it really is?

Each new encyclopedia is bigger than the one before, and so, no doubt, it will be to the end. If knowledge were nothing more than comprehension, or the analysis and classification of facts, the progress of science should be bringing us nearer to universal knowledge, but each new discovery puts it farther from our grasp than before, and they who know most are most convinced of its unattainableness, not because the reality of things is unknowable, but because of the innumerable multitude of things knowable.

W. K. BROOKS.

JOHNS HOPKINS UNIVERSITY.

THIRD ANNUAL MEETING OF THE BOTANISTS OF THE CENTRAL STATES.*

FIRST SESSION, HULL BOTANICAL LABORATORY, ROOM 13, TUESDAY, 9 A.M.

The meeting was called to order by C. R. Barnes. About seventy botanists were present. J. M. Coulter was elected chairman and Albert Schneider secretary. After a few preliminary remarks the chairman called for the reading of scientific papers, which were presented as follows:

CHARLES F. MILLSPAUGH: 'The Clothing of an Islet.' (No abstract furnished.) Illustrated by lantern slides.

GEORGE H. SHULL: 'Variations in Several Species of *Aster*.' Counts were made of bracts, rays and disk florets in *Aster Shortii* Hook., *A. Nova-Anglia* L., *A. puniceus* L., and *A. prenanthoides* Mühl. The result of these counts gave but a single instance of a maximum falling on a member

* Held in connection with the meeting of the American Society of Naturalists, at the University of Chicago, December 31, 1901, to January 2, 1902.

of the Fibonacci-series, 3, 5, 8, 13, 21, etc., the rays of *Aster Shortii* presenting a strong mode on 13; a general result giving but slight confirmation of Ludwig's results on various other Compositæ. The counting of the parts of heads collected on September 27, 30, October 4 and 8, from a single small plot of *Aster prenanthoides*, and comprising collectively all the heads produced in one season, showed, alike in bracts, rays and disk florets, a constant fall in the mean number and a corresponding shifting of the modes from the beginning to the end of the flowering season. This fact must be taken into account in the determination of place modes. There is a close correlation between the number of rays and the number of bracts, due to the fact that the rays are axillary to the inner bracts. In the four species studied the degree of imbrication of the bracts, and also the difference in form and size between the outer and inner bracts of the head are proportional to the number of bracts which bear no rays in their axils. A complete account of these studies will appear in the *American Naturalist* for February, 1902.

EDWIN B. COPELAND: 'The Influence of Metallic Poisons on Respiration.' Experiments with *Elodea*, *Callitriche*, a crucifer, fish and frog larvæ, using as stimulants copper, zinc, cadmium, silver and mercury, agree in showing that the respiration may be stimulated by a small fraction of a fatal concentration. With increasing concentration the acceleration of CO₂-evolution is greater, sometimes reaching above 25 times the normal. Evolution of CO₂ continues undiminished after plasmolysis is suspended by the poison. Copper and zinc cause the evolution of considerable CO₂ from boiled *Elodea*.

FREDERICK C. NEWCOMBE: 'The Sensory Area of the Roots of Land Plants.' In the roots of land plants, sensitiveness to exter-

nal stimuli has been considered to be confined to the apex and to the elongating zone. The elongating zone in nearly all species is confined to the first 10 mm. of the apex. In studying the phenomena of rheotropism it was found that the region of the root posterior to the elongating zone is sensitive as well as the elongating zone itself. To determine the location of the sensory tissue, various parts of the root were shielded from the flow of the water by enclosure in glass tubes. The roots of the radish, white mustard, buckwheat, sunflower, and popcorn gave good rheotropic curves when stimulated at a distance of 10 mm. to 15 mm. from the limit of the elongating zone.

FRANCIS RAMALEY: 'Mesa Vegetation.' The plants of these long, gently sloping, flat-topped ridges are distributed in characteristic fashion, depending upon the various edaphic conditions presented by different slopes and exposures. Probably the most interesting feature to be noted is the distribution of trees and shrubs. These plants are present on the tops of the mesas at their western ends, absent farther east because of dryness, present on the north and absent on the south slopes. On the south slopes shrubs occur near the top. This portion of the slope, in most hills the driest, is here somewhat moist because the snow remains late in the spring on the flat tops, and in melting the water trickles down the sides of the hill and is absorbed near the top. There is thus more moisture near the top than farther down, and the occurrence of a fringe of shrubs and trees at the top is thus explained. Illustrated by lantern slides.

D. M. MOTTIER: 'The Behavior of the Chromosomes in the Spore Mother Cells of Higher Plants and the homology of the Pollen and Embryo-sac Mother Cells.' The author discussed the behavior of the chromosomes in the pollen mother cells of

the species of *Lilium*, *Podophyllum peltatum* and *Tradescantia Virginica*, and in the embryo-sac of *Lilium Martagon*, with the following results: The earlier view of Farmer and Strasburger, that a double longitudinal division of the chromosomes takes place during the first mitosis, is confirmed. The second longitudinal splitting takes place in a plane at right angles to the first. This is clearly seen during metakinesis; it may occur earlier. There is, therefore, no longitudinal fission of the chromatin spirem during the second mitosis, and no reduction division in the sense of Weismann. In the reconstruction of the daughter nucleus the granddaughter chromosomes unite to form a single chromatin spirem. In *Tradescantia* especially, the granddaughter segments tend to reticulate so that an irregular spirem is the result, and the daughter nucleus approaches the structure of the resting stage. The identity of the individual chromosomes is lost in the daughter nucleus. The first two mitoses in the embryo-sac mother cell are like in character to those in the pollen mother cell, and consequently the micro- and macrospore mother cells are homologous. The type of development of the embryo-sac in which the heterotypic and homotypic mitoses result in four potential macrospores, as for example in *Helleborus*, is regarded as the more primitive, while that found in *Lilium* is considered as a derived form. No case is known in which the pollen mother cell develops directly into the pollen spore. Illustrated by lantern slides.

SECOND SESSION, 2 P.M.

Meeting called to order by the chairman. About seventy-five were present. The chairman read the following message:

Society of Plant Morphology and Physiology in session at Columbia sends greetings to Botanists of Central States at Chicago.

ERWIN F. SMITH, *President*,
WILLIAM F. GANONG, *Secretary*.

A return message was ordered sent to President Erwin F. Smith. The secretary was directed to arrange for contiguous seats for botanists at the annual dinner. Charles F. Millsbaugh extended a formal invitation to all botanists to visit the Field Columbian Museum.

The reading of papers was resumed:

CONWAY MACMILLAN: 'A Marine Biological Station on the Straits of Fuca.' A series of lantern slides were shown illustrating the buildings and surroundings of the Minnesota Seaside Biological Station on the Straits of Fuca. Among the views were a number illustrating the kelp formation of the Vancouver coast and several photomicrographs of the anatomy of *Pterygophora californica* Rupr., a plant upon which particular study had been expended. The excellence of the locality as a field for station activities was pointed out and some of the plans for the coming summer were indicated.

HAROLD L. LYON: 'The Phylogeny of the Cotyledon.' Modern researches in angiospermic embryology have shown the prevalent foliar theory of cotyledons to be untenable. A careful survey of the investigations already recorded has led to the following conclusions. (a) The typical embryos of the Pteridophytes and Angiosperms differentiate into three primary members—the cotyledon, stem and root. (b) Cotyledons are not arrested leaves, but are primarily haustorial organs originating phylogenetically as the nursing-foot in the Bryophytes and persisting throughout the higher plants. (c) The monocotyledonous condition is the primitive one and prevails in the Bryophytes, Pteridophytes, Monocotyls and some Gymnosperms. The two (sometimes more) cotyledons of the Dicotyls are jointly the homologue of the single cotyledon of the Monocotyls. (d) The cotyledon always occurs at the base of

the primary stem. (e) The hypocotyl is a structure peculiar to the Angiosperms, being differentiated between the primary stem and root. (f) The so-called cotyledons of the Pteridophytes, and Gymnosperms, with the exception of *Ginkgo* and the Cyceads, are true foliage-leaves.

E. MEAD WILCOX: 'Valvular Torsion as a Means of Seed-dispersal in *Ricinus*.' For the purpose of securing accurate data regarding the efficiency of valvular torsion for seed-dispersal in *Ricinus*, a plant was selected, growing in an open field. The ground about this plant was divided into four quadrants designated, N.E., S.E., S.W. and N.W. The surface was frequently cultivated so that the seeds would not be blown about by winds after falling. The following table shows the distances to which seeds were thrown, measured from the base of the plant. The plant was 104 cm. in height and the inflorescence, at maturity, was 36 cm. in length:

Distance from Center (cm.)	Number of Seeds.				Totals.
	N. E.	S. E.	S. W.	N. W.	
0-49	9	29	19	11	68
50-99	8	12	16	9	45
100-149	3	7	7	14	31
150-199	5	6	4	3	18
200-249	4	6	4	3	17
250-299	1	2	1	2	6
300-349	0	2	2	0	4
Totals.	30	64	53	42	189

The greatest distance to which any seed was thrown was 325 cm. On 12 of the 19 days upon which observations were made the wind was from the south.

CYRUS A. KING: 'Fertilization and Some Accompanying Phenomena in *Araiospora pulchra*, one of the Aquatic Phycomyces.' *Araiospora* has the habit of *Saprolegnia*, growing attached to twigs in water. Both genus and species were established by Thaxter in 1896. The sexual organs resemble those of the Peronosporinæ.

The oogonia when cut off contain about fifty nuclei, which move toward the periphery while the interior is still a coarse cytoplasmic mesh-work. Patches of fine meshed cytoplasm now arise at various places in the oogonium; these later fuse into one central irregular mass which never loses its mesh-like character. This central structure, which corresponds to bodies previously observed in the Peronosporinæ and *Pythium*, reaches its highest development at the time the sperm nucleus enters. Soon afterwards it begins to spread out into the peripheral ooplasm. Just before the separation of egg from periplasm, the nuclei probably all divide once, mitotically. The egg, when ripe, consists of this previously described central area, which now has a female nucleus imbedded in it, surrounded by a coarse, uniformly vacuolate peripheral portion. Enclosing the egg, though sharply marked off from it, is the periplasm which, at this time, is divided anticleinally into a single layer of cells.

No such structure as an antheridium tube was seen. The fertilizing tube is entirely of oogonial origin. The protoplasm in contact with the oogonial wall where the antheridium is appressed, and where the oogonial papilla is developed, always remains with the ooplasm. Consequently, the plasma membrane of the periplasm, as it lays down a wall between it and the ooplasm, builds the wall of the fertilizing tube. As soon as this tube is formed, the perforation is made by the papilla and a sperm nucleus and some cytoplasm are admitted. As the nuclei approach, both put out beaks which, at least in some cases, fuse. When the wall of the oospore is well developed the latter is binucleate. The important points in the paper are: (a) Fertilization takes place by the union of a single male and female nucleus. (b) An organ of attraction for the sexual nuclei arises in the early development of the

oogonium and its origin, structure and fate is followed. (c) There is no such fertilization tube as is figured in related forms. The tube here is a conjugation tube and the opening a conjugation pore, as Harper has suggested in *Pyronema*. Illustrated by lantern slides.

FREDERICK DEFOREST HEALD: 'The Electrical Conductivity of Plant Juices.' Using the methods of physical chemistry, conductivity measurements were made for the juice expressed from the leaves, stems, roots, etc., of different plants. The following species were used: *Beta vulgaris*, *Solanum tuberosum*, *Allium cepa*, *Raphanus sativus*, *Nuphar advena*, *Cucumis sativus*, *Amarantus retroflexus* and *Portulaca oleracea*. Ash determinations were also made for the juices used and the ash redissolved in distilled water and diluted up to the original volume of the juice from which it was obtained. Specific conductivity determinations were made for the ash solutions. The following conclusions were drawn from the various determinations. (a) Plant juices are comparatively good conductors, the conductivity being due in large measure to the dissolved mineral substances, while the organic compounds play a minor part. (b) The specific conductivity of the juice obtained from the roots of plants is always considerably less than that of the juice obtained from the subaerial parts of the plant. (c) The specific conductivity generally increases progressively from the root upward, although in some cases the sap from the stem has a higher conductivity than that from the leaves. (d) In the majority of cases the specific conductivity is a rough measure of the relative amount of ash present in different parts of the plant. Illustrated by lantern slides.

H. G. TIMBERLAKE: 'Starch Formation in *Cladophora*.' The process of starch formation in *Cladophora* was described as oc-

curing in essentially the same manner as in *Hydrodictyon* (*Annals of Botany*, Dec., 1901). In material killed in various killing fluids, sectioned with a microtome and stained with the safranin gentian-violet orange mixture, stages in the transformation of a portion of a pyrenoid into a starch grain were observed. All the starch grains arise in this manner. There is no distinction in origin between the so-called pyrenoid starch and stroma starch. In these cells starch cannot be said to be the first visible product of photosynthesis, since it is formed from a visible proteid body, the pyrenoid.

B. E. LIVINGSTON: 'Influence of the Osmotic Pressure of the Surrounding Medium upon the Growth and Production of Living Organisms.' A change in the surrounding solution may result in either a physical or a chemical change in the solution contained within the organism. By physical change is to be understood a mere change in general concentration, brought about by absorption or extraction of water. A strong solution will extract water from the organism, a weak one will allow it to be absorbed. By chemical change is meant changes caused by absorption or extraction of solute particles. Change in the water content of the protoplasm may be directly effective by causing a change in its physical properties. For instance, if water is extracted, the viscosity of the protoplasm must be increased. The same change in water content may result in a change in the chemical activity of the protoplasmic solution, since chemical activity, in general, depends upon the concentration of the solution involved. How it comes about is not known, but a review of the literature of experiments upon animals and plants shows that growth is very much retarded by an external solution which extracts water. Especially is the elongation of cells

retarded. The only experiment dealing with the effect of external solutions upon reproduction is that of the author upon *Stigeoclonium*. Zoospores fail to be produced in strong solutions, but are produced in large numbers in weak ones.

H. G. TIMBERLAKE: 'Cell Division in *Riccia fluitans*.' Attention was called to the fact that the cells in the region of the growing point afford excellent material for the study of nuclear and cell division in the liverworts. A distinct cell plate, whose origin and development are the same as that of the spermatophytes, can be made out with very great certainty.

HOWARD S. REED: 'The Ecology of a Glacial Lake.' The lake studied is the remnant of a lake which came into existence at the close of the second glacial period; at that time its extent was considerably greater than at present. As the water level slowly fell, aquatic and semi-aquatic species had the first opportunity to get a foothold and become established upon the land thus uncovered; as a result, the flora of the region shows a scarcity of distinctly terrestrial plants. The plants at the lake are grouped in five concentric zones occupying all the lake bottom less than twenty feet under water and the shores. The zones which have been named from their characteristic plants are as follows: (1) *Potamogeton*, (2) *Nuphar*, (3) *Carex* and *Sphagnum*, (4) *Salix* and *Populus*, (5) *Gramineæ* and *Compositæ*. The position of these zones is not permanent; they are steadily encroaching upon the lake and filling it with the soil they produce. The most important agencies in causing the advance of the zones into the water are soil, light and the morphology of the plants. As the plants make the lake more and more shallow they make it more unfit for themselves and fit for the succeeding zone. The struggle in each zone is less successful on

the landward than on the lakeward side of that zone. The plants engaged in this severe struggle show a marked tendency to mass themselves in solid ranks. Illustrated by lantern slides. The paper is soon to be published in full.

THIRD SESSION, WEDNESDAY, 9 A.M.

The meeting was called to order by the chairman, and without further preliminaries the reading of papers was resumed.

C. E. ALLEN: 'Spindle Formation in the Pollen Mother-Cells of *Larix*.' At an early stage in the prophases of the first nuclear division, fibrous material is present in considerable quantity in the cytoplasm, at first staining with the triple stain like the rest of the cytoplasm. Soon the fibrous material shows a tendency to stain deeply blue. It is now seen to form an irregular reticulum throughout the cytoplasm. The fibers gradually arrange themselves radially to the nucleus; the shorter ones grow in length until a complete system of radial fibers is formed, connecting the nuclear membrane with the plasma membrane. These fibers now fold over, so that many of them come to lie parallel with the nuclear membrane, and in time to form a dense felted layer immediately outside the nucleus. From the felted layer, the multipolar spindle and finally the bipolar spindle are formed, substantially as described by Belajeff and Strasburger. The most important point brought out by the investigation is that there is a fibrous system whose history can be traced from a reticulated stage to that of the completed spindle. No centrosomes could be seen, and the possibility of their presence as cell organs or directive centers seems to be excluded. The changes in the arrangement of the fibrous system seem to be correlated with processes going on within the nucleus.

BRUCE FINK: 'Some Interesting Lichen Formations.' The author made some preliminary statements regarding our present knowledge as to factors upon which ecologic studies may be based. These factors are physical and chemical structures of substrata and the structure of lichen thalli. This introduction was followed by a discussion of some of the more common lichen formations, viz., those of smooth and rough bark, those of the boulders of our prairies, and those of calcareous pebbles or horizontally disposed calcareous rocks and calcareous earth.

H. C. COWLES: 'Ecological Problems connected with Alpine Vegetation.' Alpine problems, like all ecological problems, present two aspects, phytogeographic and morphological. Most previous field studies of alpine vegetation have failed to separate distinct phytogeographic ideas. Properly to interpret alpine conditions it is necessary to distinguish floristic distribution from ecological distribution. Again, ecological distribution has its climatic and edaphic aspects. Alpine conditions have been largely regarded as climatic, and most of the peculiarities of alpine plants, distributional as well as morphological, have been referred to atmospheric factors, such as light, temperature, moisture, air. Perhaps alpine plant forms are in the main to be regarded as the direct result of external atmospheric conditions, as Bonner has shown. The distribution of alpine plants, however, is apparently due in large degree to edaphic conditions. The timber line in general may probably be referred to atmospheric conditions, but the marked gaps and oscillations which usually occur are due in a large measure to soil relations. While xerophytes increase in the alpine parts of mountains, it is to be observed that edaphic as well as climatic factors become more xerophytic upwards. While

changes occur as one traces one type of edaphic formation upwards, these changes are far less marked than are those observed in passing from one edaphic formation to another. Alpine, as well as all ecological problems, can be ultimately settled only by experimentation, and in this great field Bonnier has led the way. The field study of ecology should be regarded chiefly in the light of furnishing an intelligent basis for experiment. Illustrated by lantern slides.

R. A. HARPER: 'Cell Division in Certain Blue-Green Algae.' (No abstract furnished.)

C. R. BARNES: 'The Significance of Transpiration.' In this paper the author seeks to present a new point of view regarding transpiration, taking account of the extensive results of experimentation already attained. The purpose of transpiration is ordinarily held to be double: (a) to cause the influx to the leaves of a large quantity of water, that thereby a sufficient amount of mineral salts may be supplied to the leaves; (b) to concentrate the extremely dilute solutions thus brought to the leaves and so get rid of surplus water. These two phases of the function are held by the author to be, to some degree at least, mutually exclusive. The amount of salts absorbed is certainly dependent upon the living cortex of the rootlets and the mesophyll of the leaves. (For the purpose of the present discussion the xylem bundles may be conceived as furnishing no obstacle to water flow.) If the cortex be freely permeable, equilibrium in the distribution of any given salt will occur, assuming for a time no evaporation from the aerial parts. If then evaporation concentrates the solution the higher diffusion tension of that salt will tend to drive it to those regions where the diffusion tension is lower. This tendency,

therefore, would operate against the further supply of that material to the leaves. If the cortical layers be not freely permeable, the amount absorbed is regulated wholly by protoplasmic activity and cannot be affected directly by the outside supply. The phenomena of selective absorption show that transpiration does not determine in these cases the amount of salts absorbed. The significance of transpiration is to be discovered by examining its origin and tracing its development. Under the present organization of plants exposure of wet cell walls to the atmosphere is indispensable for the solution of necessary gases, oxygen and carbon dioxide, the plant being debarred from waterproofing the cell wall so long as gas absorption is necessary. Transpiration is, therefore, considered as *unavoidable*, though in itself a constant menace to life and activity. Advantage has doubtless been taken of the xylem bundles to facilitate the movement of solutes, but there is no reason to think this essential. Transpiration also has become a protective factor with sun plants, whose temperature is thereby kept within reasonable bounds. (Since reading the paper the author has ascertained that in certain points his view of transpiration coincides with those expressed by Dr. C. E. Bessey in a paper on the function of stomata, published in *SCIENCE*, N. S. 7: 13-16. 1898.)

R. A. HARPER: 'Binucleate Cells in Certain Hymenomyces.' (No abstract furnished. The paper is published in full in the *Botanical Gazette* 33: 1-25. *pl.* 1. 1902.)

JAMES B. POLLOCK: 'An Abnormal Development of the Prothallium of the Pollen Grain in *Picea excelsa*.' The author reported a case of a pollen grain of *Picea excelsa* in which there were four cells formed

in addition to the number usually present. These four additional cells lay in one row along the external wall of the pollen grain, between the partially disintegrated prothallial cells and the external wall, against which the first prothallial cell usually lies. The four additional cells averaged about half as large as the so-called body cell or spermatogenous cell, and the row of four was almost as long as the full width of the central portion of the pollen grain. Against the thin wall which divided the four extra cells from the large cell of the pollen grain, the cells which are usually present in the pollen grain of *Picea excelsa* were arranged in their usual manner. Two partially disintegrated prothallial cells were present, also the stalk cell and spermatogenous cell. Two interpretations are possible as to the meaning of the four extra cells: (a) They may show merely a spontaneous variation of the pollen grain—that is, a variation whose cause is wholly hidden in the present state of our knowledge. In this case the variation would have no special significance in the interpretation of homologies. (b) The four extra cells may represent a reversion to an ancestral form, and could properly be called a prothallium. If this view of the case is the correct one, all the rest of this pollen grain—that is, all that is usually present in the pollen grain—may well stand for a single antheridium, and the so-called prothallial cells are the partially disintegrated cells of the antheridium stalk. The ordinary pollen grain of *Picea excelsa* is then merely an antheridium and has no cells that may be called prothallium. In the nature of the case the proof of the latter interpretation is practically impossible, since only rarely will pollen grains be found to vary in this way. If many pollen grains should be found varying in just this same way the author would be inclined to accept the latter interpretation.

The following business was transacted:

Conway MacMillan presented the following resolution to be laid on the table until the final session: “*Resolved*, That this group hereby organize under the name of the Botanists of the Central States, and resolved, further, that the chairman be empowered to appoint a committee of three, including himself, which shall have full charge of organization, membership qualification and the program for one meeting in 1902 in case it is decided to convene during that year.” After discussion the resolution was tabled for later consideration.

The secretary was asked to read a communication from W. G. Farlow, accompanying copies of the ‘Third Report of the Committee on Securing Better Reviews of Botanical Literature,’ which were then distributed to the botanists present. On request, William Trelease explained the progress in the organization of the International Association of Botanists and especially the plans for conducting the editorial work of the *Botanisches Centralblatt*, now the official publication of the Association. He explained also the financial plans for conducting the *Centralblatt*. It was explained that it was the plan of the *Centralblatt* to publish brief abstracts of all of the more important botanical papers, irrespective of authorship and without comment; prompt cooperation of authors and subeditors would accomplish this.

The discussion of the subject, ‘Cooperation among research laboratories to avoid unnecessary duplication of work,’ was opened by J. M. Coulter and participated in by R. A. Harper, William Trelease and E. E. Bogue.

In the afternoon the botanists met with the American Society of Naturalists and listened to the discussion on the relation of that Society to present and proposed scientific organizations.

FOURTH SESSION, THURSDAY, 10 A.M.

The meeting called to order by the chairman. The resolution of Conway MacMillan was taken from the table and discussed. After amendment it was adopted in this form: "Resolved, That this group hereby organize under the name of the Botanists of the Central States; and resolved, further, that the chairman be empowered to appoint a committee of three, including himself, which shall report to the next meeting of this body a plan of organization." The chairman accordingly appointed as such committee Conway MacMillan, D. M. Mottier and himself.

William Trelease called attention to the fact that as the American Association for the Advancement of Science and the American Society of Naturalists would meet at Washington, D. C., in January, 1903, it would be desirable for the Botanists of the Central States to convene there also at the same time. It was voted that the next meeting be held in Washington, in Convocation Week, 1903. Discussion continued as to the desirability of a general union of botanical societies to constitute a really national organization, thoroughly representative, and with autonomous local sections, *e. g.*, at present Atlantic and Central sections, and as soon as possible Pacific and Gulf sections. Such a plan of organization would combine regional convenience with national authority.

At the close of the discussion the reading of papers was continued.

CLIFTON D. HOWE: 'The Development of the Flora on a Delta Plain in Vermont.' A delta plain formed during or subsequent to the glacial period at the mouth of the Winooski river has been exposed by the gradual subsidence of Lake Champlain. The lake is now 240 feet below the general level of the delta plain. The first terrestrial flora of the plain was a sand beach

flora which crossed the plain with the constantly receding beach. Then came plants which, by continually increasing the amount of humus, prepared the soil for the pitch pine (*Pinus rigida*) forest, now the controlling formation on the plain. The gentle slopes of the ravines in the now much dissected plain are controlled by a mesophytic forest of the maple-beech type. As the erosion brings the plain nearer a base level, conditions will become more and more favorable for the further extension of a mesophytic forest.

CHARLES F. HOTTES: 'Functions of the nucleolus in plants.' (No abstract furnished.)

H. N. WHITFORD: 'The Physiographic Ecology of a Sand Spit Near Cold Spring Harbor, Long Island.' (Read by title.)

J. M. WESTGATE: 'Genetic Development of the Vegetation on an Island in the Kansas River.' In this paper the author reports the results of four years' ecological study of an island in the Kansas river. The location of the island is such that the silt deposits are heavy, and as a consequence the development of the mesophytic flora from the xerophytic flora of the sandy border is rapid. Serial photographs and notes have recorded the more salient features of the changes from year to year. The succession of formations as the mesophytic conditions obtain have been largely verified by comparative studies along the Kansas and other rivers of the Mississippi basin.

All of the botanical papers announced on the printed program were read, with the exception of the one by the chairman, which he passed by. The abstract is as follows:

JOHN M. COULTER: 'Parthenogenesis in Seed Plants.' The term is used in its strict sense as meaning the segmentation of an

unfertilized egg. Two clear cases of parthenogenesis among seed plants have been published, namely, that of *Antennaria*, by Juel, in 1898, and that of certain species of *Alchemilla*, by Murbeck, in 1901. Dr. J. B. Overton, in a thesis about to be published in the *Botanical Gazette*, announces the same phenomenon in *Thalictrum purpurascens*. In this last case the segmentation of fertilized and unfertilized eggs was compared. In the former case the segmentation occurs synchronously with that of the definitive nucleus, while the unfertilized egg delays division until the very numerous free endosperm nuclei are parietally placed. It is surrounded by a very dense mass of granular cytoplasm, and associated with its segmentation are striking changes in the zone of cytoplasm immediately in contact with the egg. Overton suggests the possibility of an enzyme being secreted by the egg, and a digestion of the cytoplasm. If this be the case, substances may well be developed in the changing cytoplasm that will bring about those physical changes in the egg that induce segmentation. Observations in other species were mentioned that indicate the possibility that parthenogenesis may be a much more common phenomenon among seed plants than has been supposed. The suggestion was also made that in any embryo sac rich in cytoplasm a parthenogenetic embryo may arise.

The chairman called attention to the model herbarium and the collection of economic plant products at the Field Columbian Museum, to which the visiting botanists would be admitted free on presentation of their registration cards. In conclusion he spoke of the interest in the meetings, as evidenced by the large number who attended all of the sessions, and of the fact that this third successful meeting of the Botanists of the Central States,

a body without organization, showed that its success depended upon the spontaneous interest taken in botanical work.

ALBERT SCHNEIDER,
Secretary.

SCIENTIFIC BOOKS.

Towers and Tanks for Water Works. By J. N. HAZELHURST, Mem. Am. Soc. C. E. New York, John Wiley & Sons. 8vo. Pp. 216; 19 illustrations.

In this work the author has evidently aimed not only to discuss those features of structural design peculiar to stand-pipe and tank construction, but also to include sufficient information relating to some of the more general matters as to make the volume complete in itself. Out of the eleven chapters of the book he thus devotes two chapters to the consideration of the properties of iron and steel, two to elementary mechanics, one to the subject of foundations, and one to the painting of steel structures. The remaining five chapters deal more specifically with the design and construction of tanks, although they also contain much of a general and elementary character.

While the engineer will find such subjects as foundations, and iron and steel, much more fully treated in special works, it is certainly convenient to have in concise form such information on these subjects as will be of direct application to this particular field of design. The chapter on painting is valuable and quite in place here, owing to the great lack of information on this important subject. The subject of riveting is quite fully treated, and convenient tables are given for the use of the designer.

In the chapters treating of the principles of mechanics and their applications to the design of the structures under consideration there is much to be criticised. This portion of the book is in fact full of the grossest errors of theory, and were it not for the very absurdity of the mistakes it would be unfortunate for such a book to come into the hands of a young engineer. The treatment of tanks is also very incomplete, no consideration being given to six- or eight-post towers and practically none

to the calculation and design of tank bottoms. We are warned, however, in the introduction not to expect 'elaborate calculations and deductions based upon problematical theories and conditions,' but only 'such facts as may have been verified, freed, as nearly as may be possible, from the tons of mathematical rubbish,' etc. The following are, presumably, some of the 'verified facts': On page 59 it is stated that 'the moment of forces about a point may hold each other and establish equilibrium of the body, even though the forces themselves fail to balance.' Also that 'the direction of the resultant of two forces is exerted in a line bisecting the original angle at which the forces met, and the extent of the force exerted by this resultant is the difference between that offered by the two or more original forces, or the moment of those forces.' Again, in Chapter VIII., in the analysis of the stresses in a four-post tower, scarcely any of the stresses have been correctly determined. The tower legs are straight and have an inclination of one in ten; the wind bracing is of the usual type, consisting of horizontal struts and diagonal tie rods. The method of calculating the compression in the struts is as follows: "The inclination of the column being one in ten, one-tenth of the load is transferred to the horizontal member as compression-stress, and the remaining nine-tenths is distributed at the base of the column to the foundation." The column stress being 133.9 tons, the thrust against the strut is therefore 13.39 tons; but, since the thrust from each of the two opposite columns is 13.39 tons, the strut must be designed to resist *twice that or 26.78 tons!* The stress in the strut 'in transferring the wind stress as tensile stress' is not considered, this member being designed only for the compression as above found, together with the stresses due to its own weight. In finding the wind stresses in the diagonals of the upper panel, the stress in each is taken at one-eighth of the total wind pressure on the tank, presumably because there are eight diagonals in the top story of the tower. In this way the stress is computed to be about eight tons, with an assumed wind pressure of seventy tons, whereas the correct stress is about thirty-two tons. Finally the wind stress

in each column is taken as constant from top to bottom.

These and other illustrations which could be given suggest that it might have been better to admit some of the 'mathematical rubbish' so carefully excluded.

F. E. T.

Geometric Exercises in Paper Folding. By T. SUNDARA ROW. Edited and revised by PROFESSORS W. W. BEMAN and D. E. SMITH. Published by the Open Court Publishing Company, Chicago. 1901. Pp. x+148.

In the author's preface to this little work, dated from Madras, India, 1893, the double purpose is set forth 'not only to aid the teaching of geometry in schools and colleges but also to afford mathematical recreation to young and old, in an attractive and cheap form.' Without attempting to develop a geometry as rigidly confined to folding as the Euclidean is to compass-and-ruler work, it is shown how a large number of interesting metrical and positional relations can be illustrated without the use of instruments other than a penknife and scraps of paper, the latter for setting off equal lengths on folds. Sheets of paper adapted to the work accompany the book, and the allusions in the text to certain kindergarten 'gifts' imply the pupil's possession of an equipment of elementary geometric forms. The processes are based on the principle of congruence.

The first nine chapters are devoted to the regular polygons of Euclid's first four books, and to the nonagon. Beginning with the folding of the fundamental square, and progressing through equilateral and other triangles, the Pythagorean theorem and consequent propositions are reached, with certain puzzle squares based thereon. In Chapter X. progressions—arithmetic, geometric and harmonic—are neatly illustrated, as also the summation of certain series. This section is enlivened by the insertion of the legend regarding the duplication of the cube. It would have been an appropriate place to refer to the adaptation of the cissoid and conchoid of Chapter XIV. to the same problem.

In Chapter XI. the numerical value of π

is calculated and the regular polygons treated, in particular those of five and of seventeen sides.

Congruence, symmetry, similarity, concurrence and collinearity are taken up in the next section, and Desargues's, Pascal's, Poncelet's and other famous theorems presented for demonstration.

The remaining chapters treat of conics and other plane curves, with historical notes and references to certain applications, completing in an attractive way a valuable addition to the literature of elementary geometry—a serviceable condensation of mathematical properties, theorems, puzzles and problems. We may be permitted to doubt, however, whether the average student who has attained to that acquaintance with radicals, logarithms and positional geometry which is evidently assumed in Chapters XI–XIV., will often stop to obtain his actual results by folding. In fact the frequent use of the word 'draw' implies the author's permission of a shortcut; but it would probably be an encouragement to the pupil actually to bring his folding into the higher problems if in connection with it the use of the compass, dividers and straight-edge were frankly sanctioned. Simply in the interest of accuracy in folding, a thin rule, preferably of nickel-plated steel, beveled, would be desirable.

Where the claim of the author is so modest and his aim in so high degree attained, the task of criticism is a light one. It is singular that the expression 'equal halves,' if in the original, should have passed two revisers unnoticed; and one could wish that pericycloids, the involute and the cartesian ovals had not been omitted, and that the relative importance of the curves treated were better indicated by the space allotted to them.

The editors have performed a genuine service in bringing this work before an American audience and in such neat and attractive form. The twenty-six exquisite half-tone illustrations with which they have replaced the line drawings of the original, are a decided enrichment of the volume. The practically equal number of footnote references to their own series, in one case duplicated, compels the

question how far permission to edit carries with it advertising privileges.

F. N. WILLSON.

PRINCETON, N. J.,
February, 1902.

Pleuronectes (the Plaice). By F. J. COLE and JAMES JOHNSTONE. Liverpool Marine Biology Committee Memoirs, No. 8. London, Williams & Norgate. Dec., 1901. Pp. 260, 11 plates. Price, 7s.

In these L. M. B. C. Memoirs a single animal or plant type is described by a specialist in such a way as to serve primarily the interests of college and private students of biology and young amateurs. They are, however, far more than mere laboratory guides, being authoritative sources of information based on original work upon species which for the most part are not elsewhere adequately described.

This, the latest memoir of the series, is devoted to an important food fish, the plaice, containing descriptions with excellent figures of the skeleton, abdominal viscera, blood vascular system, nervous system and sense organs, together with appendixes on life history, habits and practical fishery matters. Its chief interest for biologists in general lies in the discussion of the asymmetry of the Heterosomata, or flat fishes, of which the plaice is probably the best known British representative.

In explaining this asymmetry the authors follow Traquair, disposing first of the mischievous assumptions that the left eye has passed either through the substance of the head or over the top of the head to reach its definitive position on the right side of the body. "The fact is," they remark, "that the left eye is *not on the right side at all*. Its presence there is purely illusory. What has happened is that the *whole of the cranium in the region of the orbit has rotated on its longitudinal axis to the right side, until the two eyes, instead of occupying a horizontal plane, have assumed a vertical one, and the left eye is dorsal to the right.*"

The part of the work next in importance to the discussion of the asymmetry is the section devoted to the cranial nerves, which are given a thorough critical treatment. The key to the

comprehension of the cranial nerves is the doctrine of nerve components as developed (chiefly by American students) during the past decade, a doctrine which apparently very few neurologists in Europe have yet really comprehended. The fifty pages of this work devoted to the peripheral nervous system will serve as an admirable and not too technical introduction to this important subject, and will doubtless hasten the day when it will filter down into the text-books.

C. JUDSON HERRICK.

SOCIETIES AND ACADEMIES.

RESEARCH CLUB OF THE UNIVERSITY OF MICHIGAN.

SINCE last reported this Club has held two meetings, one on December 18, 1901, the other on January 8, 1902.

At the former meeting, Dr. A. R. Cushny read a paper on 'Renal Secretion and Diuresis,' in which he first discussed the two chief theories on the subject and then attempted to apply them to the explanation of the diuresis induced by the intravenous injection of saline solutions. When a mixture of sulphate and chloride of sodium in equal parts is injected, the chloride of the urine first exceeds the sulphate in amount, while later the reverse is the case. This is most simply explained by the reabsorption of chloride in the renal tubules, which take up this salt much more readily than the sulphate. When the absorption is accelerated by partial closure of the ureter, which increases the pressure in the tubules, the chloride of the urine diminishes much more than the sulphate. The behavior of the chloride and sulphate of the urine thus confirms Ludwig's theory that the renal tubules are absorptive rather than secretory organs. In the discussion which followed, it was intimated by the reader of the paper that there were grounds to believe that the secretory cells of the renal capsule are unable to discriminate between sulphate and chloride and that the relative amounts of these in the glomerular fluid is determined by their relative proportion in the plasma of the blood.

At the conclusion of Dr. Cushny's paper, Professor Henry C. Adams spoke on 'Trusts.' Giving at first the older classification of busi-

ness and commercial organizations as limited by profitable administration, the speaker devoted his time to the enquiry as to whether conditions have so changed as to make possible the profitable combination into one organization of two or more formerly economically distinct classes of business.

At the meeting of January 8, Dr. Guthe spoke on the action of the coherer with special reference to the investigations which he has published in the *Annalen der Physik*, 4, p. 762, 1901, and in the *Physical Review*, 12, p. 245, 1901.

After a short description of the single contact coherer used by him and an explanation of the so-called decohesion, he calculated how near the metallic surfaces must be brought together in order to produce coherer action. The work of Earhart on sparking distances leads to the conclusion that the insulating layer can only have a thickness of a fraction of the wave-length of sodium light, while the distance corresponding to the critical voltages of different metals, as found by him, must be of molecular dimensions. Thus the thickness of the air film, if the original high resistance is really due to such a film, can be only a very small fraction of its normal value. But it seems unnecessary to assume the presence of a layer of air between the surfaces in all cases in which coherence takes place. The decrease in resistance or actual metallic contact between the coherer particles, Dr. Guthe believed to be due mainly to the welding together of the metals at the point of contact by the heat produced when even a minute quantity of electricity passes through an extremely small area of high resistance.

Dr. Guthe was followed by Dr. S. J. Holmes, who spoke on 'The Habits of Amphipods,' detailing many interesting actions in their life history. Portions of the results obtained by Dr. Holmes have been published in the *Biological Bulletin* and in the *American Journal of Physiology*. The later observations have appeared in abstract in SCIENCE in the report of the Chicago meeting of the Morphological Society.

FREDERICK C. NEWCOMBE,

Secretary.

ZOOLOGICAL CLUB, UNIVERSITY OF CHICAGO.
MEETING OF NOV. 20, 1901.

'Experiments in Grafting *Hydra*': MARY HEFFERAN.

These experiments were carried on during the year 1900 at the University of Chicago, and were based upon the similar work of Rand (1899) and Miss Peebles (1900). A comparison of the behavior of lateral grafts in the two species *Hydra fusca* and *Hydra viridis* showed a marked difference in the process of regulation. In the former, the graft moved up the stock until the head ends of stock and graft were of the same length, forming a Y-shaped figure. Then the two trunks gradually fused into one. A graft inserted very low down on the stock, *i. e.*, in the aboral 1/5, might constrict off from the foot. In *Hydra viridis* the process was quite the contrary. The graft moved down the stock instead of up, and finally separated from it at the foot instead of fusing as in *Hydra fusca*. The difference in size of the two species and the action of capillarity is suggested as an explanation of these different processes. In tangent grafts fusion took place the more readily as the area of union was increased in grafting. When poles were reversed separation took place if the area of union was so large that the polyps were unable to twist around in order that fusion could follow with poles in the same direction. It was impossible to build up *Hydra* of abnormal length by grafting several polyps together end to end. Normal form was regained usually by constriction and separation at the point of grafting, or when the compound was not much more than the ordinary length, by gradual reduction through absorption. In a few cases buds formed on such compounds soon after grafting. These buds arose entirely out of the budding region of the individual components, but within what would be the budding zone of the whole. The general results may be summed up in the words of Wetzel, '95: 'Ueberall zeigt sich ein deutliches Streben, die normal Gestalt wieder herzustellen.'

MEETING OF DEC. 4, 1901.

'Some Observations upon the Eye of *Bdelostoma Stouti*': B. M. ALLEN.

The eyes of this Pacific coast myxinoid show a very primitive structure, which is in reality the result of a complex process of degeneration. The eyeball is found imbedded in a mass of fat about three times its size. In one case, the eye was found to lie some distance beneath the outer surface of the mass of fat. Normally, however, the corneal surface lies on a level with the surface of the fat and is often flattened to form a rather extensive free surface. No eye muscles nor traces of such were discovered. No oculomotor nerves were found. No traces of them are discoverable in embryonic life (Kupffer). There is no trace of a crystalline lens. According to G. C. Price and Kupffer, a rudiment of a lens occurs at a very early stage of embryonic life, but very soon disappears. The choroid and sclerotic coats are represented by a very thin layer of unpigmented, non-vascular connective tissue without any appreciable distinction between corneal and sclerotic portions. The retina remains in the early condition of an optic cup, the outer layer (pigment layer) not being fused with the remaining layers. All specimens showed the layer in question to be widely separated from the bulk of the retina. This pigment layer is composed of a single layer of cubical cells devoid of pigment as far as I could ascertain. A layer corresponding to that of the rods and cones in higher vertebrates is clearly present. The nuclei of these structures (outer nuclear layer) are strikingly well developed and regularly arranged. Certain characteristic cells of the inner nuclear layer could be readily made out. It is impossible at present to give an accurate account of the minute histological details of this or of any other part of the retina, owing to the lack of living material. The ganglionic layer is represented by cells scattered irregularly throughout the inner reticular layer. Fibers from these last named cells can be traced in a more or less direct course to the optic nerve. The outer rim of the optic cup is in many cases differentiated in such a manner as to suggest a rudimentary iris. A structure unmistakably like an iris was found in one specimen examined. The cellular structure of this rudimentary iris is almost identical with

that of the pigment layer. No indications of muscle fibers or pigment are to be seen. Certain deeply staining coagula within the optic cup give evidence of a vitreous body. Some large, clearly marked cells, probably those of the vitreous body, are found attached to the surface of the retina. Evidences of a choroid fissure are to be seen in the fact that the ventral portion of the retina is thinner than the dorsal in almost all specimens. In one case the choroid fissure was found to persist. The most striking feature, however, is the extreme variation. The optic nerve enters the eye at various angles. Variation occurs in all parts of the eye, and is especially notable in the measurements of the thickness of the retina and the dimensions of the eye as a whole.

C. M. CHILD,
Secretary.

BIOLOGICAL SOCIETY OF WASHINGTON.

THE 350th regular meeting was held on Saturday evening, February 22.

C. H. Townsend spoke on 'The Present Status of the Carp in American Waters,' saying that in spite of much adverse comment this fish was rapidly assuming an important place in this country and that no less than \$400,000 worth was sold annually, largely in New York. It was the source of the principal fishery in the Illinois River where the bass had increased in spite of statements that carp destroyed the spawn and young of bass. The speaker believed that when the proper methods of raising and cooking carp were better appreciated it would find much favor and be an important article of food, especially among those who could not afford the prices for the most desirable species. It would be impossible to propagate the finer species of fish on a sufficient scale to keep pace with our growing population and as the carp could be readily raised it would supply the deficiency caused by the lack of other fishes.

C. P. Hartley presented a paper on 'The Pollenation of Immature Flowers,' saying that, in order to save labor, plant breeders sometimes apply pollen to flowers at the time they emasculate them. Because fair success

has often resulted from this method it is now quite universally taken for granted that pollen placed on immature pistils will remain there until the pistils are receptive and then fertilize the flowers. Experiments with tobacco prove that there are flowers that are killed and caused to fall from the plants by being pollenated before their pistils are mature; and microscopic study of flowers so treated shows that the pollen germinates on the stigmas sending pollen tubes down the immature pistils into the ovaries. This growth of pollen tubes in the ovaries among ovules not sufficiently mature to admit of fertilization causes the flowers to fall. Tobacco flowers fall in about thirty-six hours after being prematurely pollenated. If pollenated when almost mature, *i. e.*, eighteen or twenty-four hours before the flowers would have opened, many will set fruit; but if pollenated two, three or even four days before maturity, the flowers invariably fall, separating smoothly from the plant at the base of the peduncles.

Datura flowers are also killed by premature pollenation, though unlike tobacco flowers they do not fall but wither away and fail to develop seeds. Doubtless other kinds of flowers will be found to be injured by premature pollenation. The growth of the pistils of cotton blossoms is checked by premature pollenation and flowers pollenated one day before maturity do not set so many nor produce as good fruits as those pollenated at maturity. Tomato blossoms fail to set fruit when pollenated six days before maturity, the failure being due to loss of vitality in the pollen. If the flowers on becoming mature be again pollenated they set fruits. Orange blossoms pollenated nine days before maturity are not injured but continue their growth and mature good fruits. This is true of seedy as well as of navel oranges and the fact that flowers of the navel oranges so treated result in fruits containing good seeds, proves that the pollen so early placed on the stigmas successfully fertilizes the flowers.

The experiments show that certain kinds of flowers are killed by being pollenated too young; other kinds fail to set fruit because the pollen placed on the young stigma loses its vitality before the pistil becomes receptive,

while still other kinds will set fruits although pollinated while quite immature.

Lyster H. Dewey discussed 'The Identity of Prickly Lettuce,' stating that a plant bearing this common name, and generally considered to be *Lactuca scariola*, was introduced into the United States in the early sixties and spread with such rapidity as to become the most widely distributed exotic weed. During the summer of 1901 specimens of true *L. scariola* with runcinate leaves were received from Hamilton Co., Ohio, and this led to a re-examination of the species. It was at first thought that a common form of the American plant having leaves merely spinulose-margined, but entire or slightly wavy in outline, was *L. virosa* L. This European species however has rather large, oblong-obovate, thin leaves, not twisted to a vertical plane as are the rather thick, firm leaves of our prickly lettuce and further study proved our form to be *L. scariola integrata* Gren. et Gord. A few specimens examined exhibit a gradation between this variety and the typical form.

F. A. Lucas described 'The Armor of *Stegosaurus*,' saying that this consisted of large plates standing on edge on the back and several large spines on the tail. The first Stegosaur, *Omosaurus*, was found in England, and Professor Owen considered that the tail spine belonged on the wrist. The broad dorsal plates found with the first American specimen, belonging to the genus *Stegosaurus*, were thought to have been imbedded in the skin like the much smaller plates of the turtle *Sphargis*. It was soon recognized however that they belonged on the back and the animal was restored with a line of plates down the center of the back. Subsequent study showed clearly that there were two rows of plates, one on either side of the median line, and probably but two pairs of spines on the tail. The most recent comparisons seemed to indicate that the large upright plates were not disposed in pairs, but had an alternating arrangement, although this was unlike the armature or adornment of any other known animal.

F. A. LUCAS.

NEW YORK ACADEMY OF SCIENCES.

SECTION OF GEOLOGY.

THE regular meeting of the Section was held on January 20, with a comparatively large number of members present, and the following program was presented:

Professor R. P. Whitfield read two papers. The first was upon the Ammonite *Heteroceras simplicostatum*, in which he emended and elaborated the description of that species which he had given in the Newton and Jenny Report on the Black Hills, published in 1880, the new observations being based upon material gathered by Dr. E. O. Hovey on an expedition of the American Museum last summer. This material shows conclusively that the three genera *Hamites*, *Ancyloceras* and *Heteroceras* have no independent existence, because single individuals show the distinguishing characters of all three genera combined. This fact had been suspected by the author when at work upon the Newton material twenty-five years ago, and it has been hinted at in the writings of Hyatt and others, but these were the first specimens described which settled the question.

Professor Whitfield's second paper described a new teredo-like shell from the Laramie group of eastern Wyoming, collected by Mr. Barnum Brown, of the American Museum. This teredo, to which the author has given the name *Xylophomya laramiensis*, is more than an inch in diameter, thus ranking with the largest species of the family known.

These two papers may be found in full in the current volume of the *Bulletin of the American Museum of Natural History*.

The third paper of the evening was by Professor James Douglas and gave a description, illustrated by a topographic map and numerous lantern slides, of the famous Rio Tinto group of the copper mines of the Huelva district in Spain. These mines have been worked from time immemorial, the earliest knowledge of them dating from the Phoenicians, who occupied the country in the eleventh century, B.C. The Romans also obtained a large amount of copper from these deposits, and it is an interesting fact that the slags which they left are purer—that is, freer from copper, than

those which are made there to-day. The ore is a copper-bearing pyrite, carrying some silica. The copper-bearing portions run irregularly through the iron pyrites, and the Rio Tinto Company has removed millions of tons of forty-two per cent. iron ore in getting at its copper ore. The iron ore is not profitable at the present time, although it may become so in the distant future. There are some remains of the workings of the ancients here. At Tharsis, in particular, the old shafts are very peculiarly constructed, one at least being spiral to enable the miners to carry the ore on their backs. Shelves were excavated at intervals in the walls of the shaft to enable the men to rest their loads on their weary journey to the surface.

The mines are worked now as open air diggings in circular terraces. They produce about two million tons of ore per year, and it is estimated that there are one hundred and sixty million tons in sight. Some silver-bearing galena is associated with the copper ore. The old-fashioned method of roasting the ore in heaps was kept up until 1893, but the ore is now leached by means of water. This is a long process, requiring four years for its thorough completion, but the copper is leached out so that less than one-fourth of one per cent. is left in the tailings. The great bulk of the world's supply of sulphuric acid is obtained from the Rio Tinto pyrite, which is shipped all over the world for the purpose of manufacturing the acid. Five hundred thousand tons per year are utilized in this way.

The paper was discussed by Dr. Julien and Mr. Howe, and the Section passed a hearty vote of thanks to Professor Douglas for his kindness in giving the paper.

A REGULAR meeting of the Society was held on February 17, with the Chairman, Dr. A. A. Julien, presiding.

The first paper to be read was by Dr. O. P. Hay, on the 'Snout-fishes of Kansas.' In this paper the author presented a brief history of our knowledge of the genus *Protosphyrapna*, and a statement showing what portions of the skeleton were still unknown. Those parts which are best known are the skull, especially

the elongated snout, and the jaws, the shoulder and the caudal and pectoral fins. These parts have seldom been found associated, and there have been established three series of species—one on the teeth, one on the snout and the third on the fins. It is certain that, as new collections are made and studied, some of these subspecies will be reduced to synonymy. The author pointed out various errors on the part of writers in the interpretation of different elements of the skeleton, and illustrated his points by means of specimens.

Dr. A. A. Julien gave an impromptu discussion of the relation of hones to the cutting edge of tools, in the course of which he said that the quality of a hone depended on the size and shape of its component particles, and upon the cement joining the whole together, except in the case of the novaculites from Arkansas, in which the honing quality is due to the sharp edges of minute cavities left by the solution of calcite; and in the case of the Turkey-stone, in which the honing quality is due to veinlets of quartz intersecting a rock which has been formed by silica replacing a granular limestone. A microscopic study shows that the edge of a tool is not regularly serrated, part of it being smooth and part undulatory. Viewed on edge, the sharpest tools are practically straight, while the others are more or less regularly wavy. Viewed in the cross section, a fine edge is seen to be a perfect wedge, while the duller tools show a minute shoulder.

EDMUND O. HOVEY,
Secretary.

SECTION OF BIOLOGY.

At a regular meeting of the Section, held on February 10, Professor W. B. Scott, of Princeton University, presented an illustrated lecture entitled, 'The Origin and Development of South American Mammals.'

The speaker began by expressing his great obligation to Dr. F. Ameghino, as also to Dr. Moreno, director, and to the curators of the La Plata Museum, for their kindness in giving him the freest use of their collections and enabling him to examine all the types of the Santa Cruz mammals.

The fauna of every continent is made up of

two elements, the indigenous forms which were developed in that continent, and the immigrants from other regions. In South America this distinction is easy to draw, because of the remarkable series of Tertiary deposits which are wonderfully rich in well-preserved fossils. The Santa Cruz beds, which are almost certainly referable to the lower Miocene, contain an assemblage of mammals altogether different from those of the northern hemisphere. The fauna consists of Primates and Insectivora, very scantily represented, very numerous Rodents (though all referable to the Hystricomorphs), Marsupials, Edentates and the peculiar South American hoofed animals. The Edentates of this period represent the Gravigrada, Glyptodonts and Armadillos, but no members of the true Sloths or Anteaters have yet been found, a lack of which is probably due to climatic conditions. The Gravigrada, which are very abundant, have forerunners of all the great Pleistocene groups, but are, of course, much less specialized and are relatively small in size. The Glyptodonts, though numerous and well preserved, are not so easily to be brought into relation with the later genera of the same group.

The paper concluded with a brief examination of the remarkable Ungulates, all of which are peculiar to South America, and especial attention was called to Ameghino's discovery, yet unpublished, that in *Nesodon* there are three sets of functional incisors and canines. Incredible as such an observation may be, it seems to be well established.

HENRY E. CRAMPTON,
Secretary.

THE BOSTON SOCIETY OF NATURAL HISTORY.

At a meeting of the Society held January 1, 1902, Dr. George H. Parker gave an account of some experiments which he had conducted on the marine Copepod, *Labidocera aestiva*, with a view to accounting for the fact that it is extremely abundant on the surface of the water along shore at night, but during the hours of daylight is found only down in the deeper waters. After giving a short account of the external structure and method of

locomotion, the speaker described a series of experiments with these copepods in aquaria, from which it appeared that the females are negatively geotactic, their tendency being to swim against rather than with the force of gravity. They were also found to be attracted by a light of small intensity, but repelled by a brilliant illumination. The reactions to light seem to be stronger than those to gravity. The diurnal migration on the part of the females is thus to be explained as being due to their endeavor to seek a region of such depth below the surface of the water as shall have the requisite intensity of light. The males of this species seemed to show no very definite response to light or gravity, though their reactions indicated that they were to a slight degree negatively phototactic, and positively geotactic. By experiments with females enclosed in small glass tubes, which were covered with filter paper and plugged at the ends with cotton, it seemed evident that the females give out some sort of scent which becomes disseminated throughout the immediately surrounding water, and is strongly attractive to the males. The males, then, perform the same diurnal migration as the females, because they are attracted by the scent of the latter, and so follow in their wake. Mr. C. J. Maynard then gave an account of the habits and structure of the Anhinga and the Courlan, two Florida birds. Among the specimens shown was a preparation of the peculiar convolution of the trachea in the adult male of the latter species, a striking secondary sexual character.

At the meeting of January 15, 1902, Mr. William L. W. Field gave an account of a 'Glacial Lake Problem in Southern Vermont.' The region studied covers a portion of the basins of the Black and the Williams rivers, tributaries of the Connecticut. At a certain locality the courses of these two rivers approximate rather closely, and at this region there are two passes connecting the respective river basins, the one very narrow, with steep sides, locally known as Proctorsville Gulf, the other, farther down the valley, much broader and apparently widened to a considerable extent by ice action. From a study of the sedi-

ments and the topographic features, it seemed probable that during the recession of the glacial ice-sheet a lake had been formed, which, as the ice melted out, had discharged first through the upper pass, and later through the lower one. A number of lantern slides were shown in illustration of the topographic features of the area under discussion.

GLOVER M. ALLEN,
Secretary.

DISCUSSION AND CORRESPONDENCE.

THE ENDOWMENT OF RESEARCH.

TO THE EDITOR OF SCIENCE: I have been much impressed by the communication of Mr. H. H. Clayton in your recent issue, in relation to the subject of grants for scientific research, for the reason that his views coincide so closely with mine, based on both theoretical considerations and practical experience.

On two occasions I have been the recipient of such grants, and I confess that on each occasion I labored under a feeling of constant uneasiness for fear that I might not be able to accomplish what others might consider adequate returns for the amount of the grant. This feeling may have no reason for existence and perhaps it does injustice to those who have such funds in charge, but that it exists and that it has a distinct influence upon many applicants can not be questioned. It may perhaps be objected that such persons should not, or at least that they need not, seek to avail themselves of such opportunities, but this, it seems to me, would merely result in debarring many conscientious workers, while at the same time encouraging others not so sensitive.

In regard to the effect of prohibiting the payment of personal expenses out of research funds I may not be considered a competent witness, for the reason that in the two instances mentioned I was not restricted as to the manner in which the grants should be expended and it was never necessary for me to try to draw a hard and fast line between what might be considered purely personal expenses and those which were incurred solely in connection with the actual research work. Had such restrictions been imposed, however, I

believe that I should have hesitated to accept the first grant and know that I should have declined the second, on account of my inability to satisfy myself that I could draw a line so that items on either side could not be questioned or criticized.

In common, as I have reason to believe, with nearly every active scientific worker, I have always had sufficient work under way, or definitely planned, to occupy all my time for months and sometimes for years ahead, and tardiness in completing investigations has more often been due to the element of personal expenses than to any other cause. Such a condition is particularly in evidence where investigations involve the necessity of traveling. Good results can hardly be expected if the investigator is constantly harassed by having to consider whether each item of expense may be conscientiously charged to his research fund or not. The success or failure of an investigation in the field may often depend entirely upon the length of time which can be given to it, or, what is the same thing, to the sum available merely for living expenses.

In regard to laboratory work I can not speak from experience, but I do not see why any different principle should prevail in that connection than in any other. The proper basis for a grant, it seems to me, should be absolute confidence in the recipient, giving him to understand that the amount of the grant was his, to apply in any way which he might think would best accomplish, or assist in accomplishing, the object of his investigations.

ARTHUR HOLLICK.

SCIENTIFIC NOMENCLATURE.

A PRIME characteristic of the scientific mind is the ability to enter into details and to make distinctions, as well as to see the relation between the elements of knowledge. In order that some conception of these distinctions may be communicated to another mind, names must be given to a perpetually increasing list of objects and qualities, with divisions and subdivisions. In natural science, to try to stretch an existing vocabulary and make it cover new conceptions by using old names with new

meanings, is to invite obscurity and misunderstanding.

The unscientific mind may not always appreciate the requirements of classification as an important aid to scientific development. To one who is not a geologist nor an agriculturist, a clod of earth may be sufficiently described by a word of three letters. It is mud, and there is nothing more to be said about it. But the man who has learned to use his eyes (and one need not have a college education to do that) perceives that there may be fifty different kinds of mud; and the scientist who wishes to investigate the subject of soils and the rocks from which they are made, recognizes the necessity of an exact and elaborate nomenclature.

This need comes, in the first place, from the use of terms *as mere tools for facilitating analysis*, and thus favoring the development of a research. In this sense, that is to say, as provisory terms, invented by the investigator for the purpose of mapping out and arranging his work in an orderly way, it is desirable that the vocabulary shall be so full that it may seldom or never be necessary to use names with a double significance. Not all of these names will be retained eventually, but the looker-on must learn to tolerate them, at least during the incipient stage of path-finding investigation.

In the next place, entirely new branches of knowledge require the invention of whole classes of terms, constituting virtually a new language. To dissent from this position, and to require that the new thoughts shall be clothed in familiar forms, is as unreasonable as to require that the proposition of the maximum economy of material in the construction of the bee's cell shall be demonstrated without the use of the differential calculus, or that all psychological propositions shall be stated in terms of one sense, that of sight.

The final forms which shall be given to words expressing necessary and permanently useful distinctions of meaning are a matter which may well concern all scientific workers, whatever their specialties, as well as the general public. It is of course desirable that a new word shall be short, if this desideratum

is compatible with intelligibility. Unfortunately, most of the short-cuts which are proposed from time to time, such as sweeping reforms of an extensive and tremendously cumbersome chemical nomenclature by substituting words of one syllable, break down under a weight of meaningless memorizing which is absolutely prohibitive. Common names of plants and animals become overloaded with so many meanings in different localities as to be equally useless. The prevalent custom of inventing names by joining Greek or Latin words of cognate import, giving to the new term a special and new significance, has the advantage that the word-coinage is, to a degree, self-explanatory, at least to one who has learned a modicum of Greek and Latin words. There is no royal road to knowledge. Scientific descriptions remain unintelligible to the lazy man who hates to use the dictionary. They are free property to all who are willing to take this trouble.

FRANK W. VERY.

ENGINEERING NOTES.

INDUSTRIAL ECONOMICS.

AN interesting and probably important fact, and one which may ultimately have a serious influence upon the relative standing, industrially, of the United States and Great Britain, is reported by English papers. It is the signature of an agreement between the employers and workmen in the machine shops of Great Britain which, on the whole, would seem entirely reasonable, while in the United States the unions have refused to enter into a similarly reasonable arrangement. The initiation of the displacement of British manufacturers from their own markets and from the markets of the world was largely due to the restriction of production and the deprivation of free workmen of the privilege of working at their trades, while, in our own country, restriction of production was almost unknown and freedom of the individual was at least not absolutely destroyed. It now looks possible that the conditions may be reversed.

The British agreement provides that the unions shall not interfere with business management, nor the employers with the proper

functions of the unions; the men may join the unions or remain free as they may choose and the employer may employ union or non-union men; piecework is approved and restriction of output specifically disapproved. No limitation of the number of apprentices is permitted. In case of disagreement regarding any question arising between the two parties, reference and arbitration will be prescribed and work shall not stop when such question arises or during the session of the committees of arbitration.

Had these principles been in force in recent years, it is hardly to be believed that the long and costly strike which finally broke up the former tyranny would have occurred or that Great Britain would have experienced, as now, competition of serious character within her own boundaries.

On the other hand, should the false principles formerly so destructive of British industries find extensive lodgment in the United States, as now seems possible, it can hardly be doubted that the experience of the older country will be repeated in our own. Restriction of production has been a cardinal principle with many associations though, fortunately, not with the most intelligent and well-managed, nor so generally and effectively as to as yet seriously impair the industrial prosperity of the nation. The future of our industrial organization may be found to depend, nevertheless, upon the intelligence, the courage and the firmness of the leaders in the unions and upon their success in the maintenance of right principles in fixing the relations of employer and employee. Freedom in bargaining, independence of the individual who chooses to be free and independent, freedom of the ambitious and industrious and skilful, within or without the union, to secure the full value of his best efforts, and entire freedom to secure maximum output in both quantity and quality are now assured the British workman, for the first time in at least two generations, and, in default of similar freedom and independence and of similar economic practice in the United States, the tables may once more be turned. The spirit of fairness and the intelligence and knowledge

of economical principles displayed by the leaders of the unions of most intelligent and highly skilled workmen in the United States and the rapidity with which a good example makes its impression in this country give assurance that the progress of the country industrially is not likely to be suddenly or soon checked. When an enormous organization like, for example, the Railway Trainmen's Association, makes fair play and industrial peace a cardinal doctrine, and when their associates of the Locomotive Engineer's unions have a record of not more than two or three serious strikes in a generation, it may be fairly anticipated that reason and justice will ultimately prevail generally.

MR. MARCONI'S ACHIEVEMENT.

THE month of February and particularly the 23d and 25th of February, 1902, will undoubtedly become historically recorded as the beginning of what may be known as the Marconian era. It was on the first of these dates that a message was transmitted more than a thousand miles, between a station on the coast of Cornwall and a ship at sea in the midst of the Atlantic, and it was at the second of these dates that distinct signals were repeatedly transmitted over a distance exceeding two thousand miles under similar circumstances and permanently recorded on the tape of the receiving instrument. The practicability of the system of wireless telegraphy operated by Mr. Marconi was thus confirmed as effectively for these enormous distances as it had been, long before, by constant use over shorter ranges, for months together, on the coasts of England, France and the United States.

The Marconi station at Poldhu, Cornwall, has been in use a long time, not simply for the usual work of exchanging messages with ships at sea in that neighborhood, but also in the investigation of the problem of transmission over the ocean, from shore to shore. Weeks before it had been found possible to reach the coast of Newfoundland with distinct signals and Mr. Marconi, returning to England, refitted his apparatus for a test which should be crucial. He left Southamp-

ton on the U. S. M. S. *Philadelphia* February 22d and, with a prearranged system, communicated with his operator at Poldhu, regularly, from a point 250 miles west of the Lizard until reaching mid-ocean, over a thousand miles away, the operator reported "Fine here. Thanks for message!" Thence, to a point 1,551 miles away, messages continued to be intelligible, the last, 'All in order,' indicating that the cessation was due to lack of power in the sending apparatus, not to any defect of construction or adjustment. Single signals nevertheless continued to be recognizable, and were automatically recorded on the tape, until the two operators were separated by 2,099 statute miles. The records of all these messages and signals were properly certified to by the operators and by the officers of the ship, in order that the scepticism manifested at the first announcement of Mr. Marconi's work in Newfoundland might not be given a shadow of an excuse for expression in this instance. During this experiment the messages and signals transmitted to the *Philadelphia* passed over the *Umbria*, following in her wake all the way across the Atlantic, or within easy communicating distance, without being recognized or even detected.

Mr. Marconi is now confident that he has demonstrated that the distance over which his method will prove available is only limited by the power of the sending apparatus. He is preparing to establish at Poldhu ten times as much transmitting power as was available on this occasion. It may probably be admitted as demonstrated that we may anticipate the successful transmission of messages between a ship at sea and the shore, on either hand, from the moment of her setting out on her voyage until her passengers are landed at her destination on the other side of the ocean. Then the previously unavoidable period of anxiety attending the disappearance of ship and crew and passengers, for days together, will be at an end forever. New, or temporary, or moving stations may be established at sea or on land, and a campaign may be conducted, in time of war, with perfect communication between forces and commanders however relatively situated and, with suitable codes, with-

out enlightening the enemy, even if the fact of communication be detected by him at all.

R. H. THURSTON.

ANNUAL REPORT OF THE CONCILIIUM
BIBLIOGRAPHICUM.

THE general statement for 1901 has just been issued from Zürich and shows that Dr. Field's determination to carry this project through is at last beginning to meet with reward. The total number of cards published in 1896 was 3,345, and in 1901, 21,946. The total number of cards issued up to December 31, 1901, is 9,671,500. The total expenditure up to the same date is 119,015 francs, or in round numbers \$23,803. The receipts up to the same date have been 92,484 francs, thus leaving outstanding amounts of upwards of 21,000 francs or something over \$4,000, probably due to losses in the two first years of inauguration, which will soon be covered by the present increasing sales.

The financial standing of the present year shows a great advance over all that have preceded; the increase of subscribers has been so great that whole sets have gone out of print. The prices charged for subscriptions correspond, however, so closely to the actual cost that the increased sales have occasioned increased expenditures to nearly the same amount. It is the generosity of the Swiss Government to which in the main the Concilium owes the present improved state of its finances. While this shows the permanence of the work, it is very desirable that other countries should give similar aid and thus remove the last of the difficulties under which Dr. Field and his staff are struggling.

In consequence of the failure of an expected subsidy, the physiological part of the work has been temporarily suspended, but it is hoped that this impediment will soon be removed.

A recent report of the Swiss Society of Naturalists estimates the saving of time afforded by the great catalogue in the specific case of an investigation on the trout; the report says that in looking up the recent literature of this subject by means of the Concilium catalogues the saving of time was estimated at one half a day, but in regard to other

cases the saving is much greater. If any zoologist familiar with the best bibliographical resources considers how he should go to work to ascertain what has been published in the past five years in regard to some comparatively minute question, such as the fauna of Sumatra, a minute's reflection will suffice to show that it would be a task of many weeks to obtain a complete answer to such a question. Yet a subscriber to the faunistic part of the bibliography of the *Concilium* would require only a few seconds to find the 85 publications dealing with the subject. Some of the latter, indeed, bear titles which would appear to preclude any reference to Sumatra and thus be likely to be missed by the student altogether. These 85 references would have cost the subscriber sixteen cents. Surely no argument is necessary to prove the value of the work nor the extreme cheapness of the service.

The general statement contains a key by which subscribers can verify their subscriptions and rest assured that they have received all that has been last published on any subject. The zoological and anatomical subjects include 760, 8,371 and 2,007 cards respectively during 1901. There are 263 cards on microscopic technique and 155 on general biology.

American subscribers will find it convenient to remit to Mr. Edwin S. Field, 427 Broadway, New York City, and also copies of the general statement for 1901 can be secured.

SCIENTIFIC NOTES AND NEWS.

LORD KELVIN is expected to arrive in New York on April 19. A reception will be given in his honor on the evening of April 21 by Columbia University, the American Institute of Electrical Engineers, the New York Academy of Sciences and other scientific societies.

LORD LISTER and Professor Virchow are among those who have been elected honorary members of the Ghent Medical Society.

DR. N. L. BRITTON, director of the New York Botanical Garden, expects to visit Cuba at the end of the present month, with a view to securing collections for the Garden. Dr. D. T. MacDougal, assistant director, is at present

in Arizona and New Mexico, making collections, particularly of giant cacti.

MR. WILLIAM T. PALMER, of the U. S. National Museum, has been engaged in investigations of the natural history of Cuba.

DR. BRANDES has been appointed scientific director of the Zoological Gardens in Halle and has resigned his position as assistant in the zoological laboratory of the University.

PROFESSOR HERMANN KOBOLD, astronomer in the Observatory at Strassburg, has removed to the Observatory at Kiel.

PROFESSOR H. BECQUEREL lectured in French before the Royal Institution on March 7. His subject was 'Radio-active Bodies.'

DR. SIMON FLEXNER, professor of pathology in the University of Pennsylvania, gave a lecture on March 18 before the Yale Medical Alumni Association on the subject 'Bubonic Plague.'

AN address on 'Immunity' was delivered on March 7 before the students of Jefferson Medical College, Philadelphia, by Dr. W. H. Welch, of the Johns Hopkins University.

AT the meeting of the Michigan Academy of Science to be held at the University of Michigan on March 27, 28 and 29, a public lecture will be given by Major Walter Reed, of the Army Medical Museum, at Washington, chairman of the U. S. Yellow Fever Commission. His subject will be 'Yellow Fever.'

C. N. BROWN, professor of civil engineering in the Ohio State University and dean of the College of Engineering, died on March 6 from nervous prostration. He was forty-four years of age and had been connected with the Ohio State University as instructor and head of the department of civil engineering for the past twenty years.

DR. EMIL SELENKA, honorary professor of zoology and comparative anatomy at the University of Munich, died on January 21.

THE House Committee on Coinage has directed a favorable report to be made on the bill providing for the adoption by the United States of the metric system. It provides that after January 1, 1904, all the departments of the government, in the transaction of all busi-

ness requiring the use of weight and measurement, except in completing the survey of public lands, shall employ and use only the weights and measures of the metric system; and after January 1, 1907, the weights and measures of the metric system shall be the legal standard weights and measures of and in the United States.

THE Entomological Society of Western Pennsylvania was organized at the Carnegie Museum in Pittsburgh on the evening of March 8. Dr. W. J. Holland was elected president, Mr. F. A. Merrick, of New Brighton, secretary, and Dr. D. A. Atkinson, of Pittsburgh, Treasurer. Twenty-three persons participated in the organization. A committee with Herbert H. Smith as chairman was appointed to prepare a constitution and by-laws. The next meeting will be held on April 5.

THE thirteenth session of the International Congress of Americanists will be held in the halls of the American Museum of Natural History, New York City, October 20-25, 1902. The object of the congress is to bring together students of the archeology, ethnology, and early history of the two Americas, and by the reading of papers and by discussions to advance knowledge of these subjects. Communications may be oral or written, and in French, German, Spanish, Italian or English. All debates are expected to be brief, and no paper must exceed thirty minutes in delivery. The papers presented to the congress will, on the approval of the bureau, be printed in the volume of proceedings. Members of the congress are expected to send, in advance of the meeting, the titles and, if possible, abstracts of their papers, to the general secretary. The subjects discussed by the congress relate to: (1) The native races of America, their origin, distribution, history, physical characteristics, languages, inventions, customs and religions, and (2) The history of the early contact between America and the Old World. All persons interested in the study of the archeology, ethnology and early history of the two Americas may become members of the congress by signifying their desire to Mr. Marshall H. Saville, general secretary of the com-

mission of organization, American Museum of Natural History, New York, and remitting either direct to the Treasurer (Mr. Harlan I. Smith, American Museum of Natural History), or through the general secretary, the sum of three dollars. The receipt of the treasurer for this amount will entitle the holder to a card of membership and to all official publications emanating from the thirteenth session of the congress. Mr. Morris K. Jesup is president and the Duke of Loubat vice-president of the commission of organization.

THE American Social Science Association will hold its general meeting in Washington, beginning Monday, April 21, and closing Friday, April 25. Dr. Oscar S. Straus, president of the association, will deliver his address on the first day. The program for April 22 will be devoted to the department of social economy, of which Mr. John Graham Brooks is chairman. The department of jurisprudence, of which Dr. Francis Wayland is chairman, will hold its sessions on the 23d. General George M. Sternberg, chairman of the department of health, will preside at the session on Thursday, April 24. Dr. W. C. Woodward and Professor George M. Kober will make addresses at the morning session and General Sternberg and Mr. Charles F. Weller will be the speakers at the evening session.

THE convocation of the University of the State of New York is to be held at Albany on June 30 and July 1. On Monday evening, June 30, Dr. Nicholas Murray Butler, president of Columbia University, will deliver the principal address, on 'Fundamental Principles of Education in the United States'; on Tuesday President Schurman of Cornell University will open a discussion on 'The Elective System and its Limitations.'

THE Jefferson Memorial and Interstate Good Roads Convention will be held at Charlottesville, Virginia, on April 2, 3 and 4 under the auspices of the Office of Public Road Inquiries of the Department of Agriculture, the National Good Roads Association and the Jefferson Memorial Road Association. The

Southern Railway good roads special train, carrying twenty-two engineers and road experts and equipped with fifteen car loads of the latest improved road-making machinery, will arrive at Charlottesville on March 24, and begin the construction of the Jefferson Memorial Road which will connect the home and tomb of Thomas Jefferson with the University of Virginia, which he founded.

The managers of the New York Botanical Garden have authorized the purchase in Berlin for \$1,600 a collection of botanical works all dated prior to 1800.

The *Osprey* states that an interesting and valuable collection of northeast African birds has been recently received by the U. S. National Museum from Dr. A. Donaldson-Smith of Philadelphia, the well-known African explorer.

An anonymous gift of \$20,000, for the benefit of the Harvard College Observatory, has been received from a friend of the director, Professor Edward C. Pickering, who in announcing the gift says: A very urgent need of the observatory will be relieved at once by this gift. The building provided, nine years ago, for the astronomical photographs, has become wholly inadequate to contain them, owing to their continual and rapid growth. It is proposed to expend about one half of this fund in extending the present building, by the erection of a wing to the east, which will provide for the adequate storing of this collection with its probable increase for many years. These photographs furnish a history of the entire stellar universe for the last twelve years, which is not duplicated elsewhere. Whenever a new object is discovered in any part of the sky, we are therefore able to study its past history during this period. Evidently, provision should be made for extensive use of this collection by large numbers of astronomers. A much larger building, staff and endowment, than our present means permit, would be required for this purpose. Accordingly, the new wing will be so constructed that when these plans are carried out, it can be used for holding the valuable collection of astronomical books (one of the most complete in the world) belonging to the obser-

vatory. These books are now contained in a wooden building fifty years old, and are in danger of destruction by fire at any time. The remainder of the fund will be expended from time to time as urgent needs occur. It is proposed to employ a portion of it at once in studying new objects of interest on the photographs, since without it we have hitherto only been able to examine those of special importance. The value of a fund which will provide for such emergencies must be obvious. The larger plans described above, I hope, indicate the healthy and insatiable appetite of an institution which is always attempting to reach out into untrodden fields, and in which each accession suggests opportunities of still further extending its work into the unknown.

THE thirteenth session of the Biological Laboratory of the Brooklyn Institute of Arts and Sciences, located at Cold Spring Harbor, Long Island, will be held for six weeks beginning July 2, 1902. The following courses of instruction are announced: High School zoology, Drs. C. B. Davenport and S. R. Williams; comparative anatomy, Professor H. S. Pratt, of Haverford College; invertebrate embryology, Professor C. P. Sigerfoos, University of Minnesota; animal biometrics and variation, Dr. Davenport; investigation in zoology, by various instructors; cryptogamic botany, Professor D. S. Johnson, Johns Hopkins University; plant ecology, Mr. S. M. Coulter, Washington University, assisted by Louise B. Dunn, of Columbia University; seminar in the same; bacteriology, Professor F. N. Davis, Bucknell University; investigation in botany; microscopic methods, Mrs. Davenport; nature study, Mr. Roy S. Richardson, High School, Brooklyn, N. Y. Biological discussions, lectures and excursions are arranged for. The tuition is \$25 for the use of the laboratory. Board and room cost \$6 per week. The director of the laboratory, who may be addressed for further details, is Professor C. B. Davenport, the University of Chicago.

THE Ohio State University announces for the 1902 session of its Lake Laboratory at Sandusky, on Lake Erie, courses in zoology, botany, entomology, ornithology, ichthyology,

and vertebrate and invertebrate morphology. The courses of lectures and laboratory instruction open on July 7 and continue for six weeks, but the opportunities of the laboratory are open to investigators from June 15 to September 15. Investigators qualified to carry on independent research work are given the facilities of the laboratory free of expense, but persons desiring this opportunity should apply to the director as early as convenient with statement of the time during which table room is desired. A detailed circular may be had on application to the director, Professor Herbert Osborn, Columbus, Ohio.

A TELEGRAM has been received at the Harvard College Observatory from Professor Hussey at the Lick Observatory stating that from a recent Crossley photograph Professor Perrine finds no evidence of polarization in condensations *A* and *D* of the nebula surrounding Nova Persei.

Nature states that the Russian Geographical Society has awarded this year its Constantine medal to the geologist, K. I. Bogdanovitch, who has spent several years in the exploration of Central Asia and has contributed one large volume to the beautiful series of quarto volumes edited by the Society and devoted to this part of Asia. The Semenov medal has been awarded to Professor Eduard Suess for his new classical work, 'Das Antlitz der Erde,' and the Prjevalsky medal to the zoologist, Professor Zarudnyi, the author of several most valuable works on the birds and also the geography of the Transcasian region, and the author of a work, 'Journey to East Persia,' just published by the Society. The great gold medal of the section of statistics has been awarded to N. V. Slyunin, for his researches into the economical conditions of the inhabitants of the Okhotsk and Kamchatka coasts. Three small gold medals have been awarded to Messrs. N. P. Petrovsky, D. K. Zelenin and M. N. Kositch for ethnographical works published in the excellent ethnographical periodical of the Society, *Zhivaya Starina* (*Living Antiquities*). Professor Gordyaghin, of Kazan, has been awarded the Prjevalsky silver medal for his botanical work in East Russia, and the Sem-

enov silver medal has been awarded to A. K. Bulatovich for his journey to Lake Rudolph. A number of small silver medals have also been awarded, chiefly for meteorological work in connection with the Society's meteorological committee, or for expeditions.

Nature learns from the *Ceylon Observer* that Mr. Alexander Agassiz and his party have returned to Colombo, from their exploration of the Maldives. About three hundred photographs were taken, principally of coral-reef subjects. The principal work done was the sounding of the channels between the lagoons and the development of the plateau on which the atolls of the Maldives have been formed. The principal atolls are separated by comparatively shallow water in the central part of the group, while towards the south, between Hadumati and Suvadiva and Addu, the depths are very much greater—nearly a thousand fathoms. A line was run to the westward of Ari Atoll into fifteen hundred fathoms, and one to the southward of South Male into twelve hundred fathoms, showing that the plateau of the Maldives is much steeper on the west than on the east face. Soundings were also taken between the northern Maldives and Colombo, and they show that the Maldives are separated from the Indian continental slope by a deep bank of the ocean of more than fifteen hundred fathoms in depth. The atolls of the Maldives are said to exhibit the most simple and primitive conditions for the formation of atolls which are found anywhere except in some parts of the Yucatan plateau in the West Indies. Atolls can be found in all stages of growth, from a mere bank rising to a few feet above the plateau to banks within five or six fathoms from the surface or to banks which have just reached the surface and on which sandbanks or islets are beginning to form. Mr. Agassiz says that one reason for the success of his expedition is that the charts published more than seventy years ago are as accurate to-day as they were then. The only changes noticed were changes such as the washing away of banks or the formation of banks since the charts were published; but these are changes without any special importance.

UNIVERSITY AND EDUCATIONAL NEWS.

Mrs. COLLIS P. HUNTINGTON has given \$250,000 to the Harvard Medical School to erect a laboratory of pathology and bacteriology in memory of the late Mr. Huntington. The sum of \$821,225 has now been collected which makes available Mr. John D. Rockefeller's gift of \$1,000,000. The donors to this fund whose gifts are \$5,000 or over are as follows:

Miss Mary S. Ames.....	\$5,000.00
Oliver Ames.....	5,000.00
C. W. Amory.....	10,000.00
Anonymous.....	10,000.00
Robert Bacon.....	25,000.00
Francis Bartlett.....	10,000.00
Mrs. S. Parkman Blake.....	10,000.00
John L. Bremer.....	10,000.00
Mrs. John L. Bremer.....	5,000.00
Miss Sarah Bremer.....	5,000.00
Walter C. Cabot.....	5,000.00
W. Murray Crane.....	5,000.00
George F. Fabyan.....	25,000.00
Mrs. William H. Forbes.....	5,000.00
Augustus Hemenway.....	15,000.00
Francis L. Higginson.....	60,000.00
George Higginson.....	10,000.00
Henry L. Higginson.....	10,000.00
James J. Higginson.....	10,000.00
H. H. Hunnewell.....	12,500.00
Mrs. Collis P. Huntington.....	250,000.00
Eben D. Jordan.....	5,000.00
David P. Kimball.....	5,000.00
Elliott C. Lee.....	25,000.00
Joseph Lee.....	5,000.00
Arthur T. Lyman.....	5,000.00
W. L. Richardson.....	25,000.00
Mr. and Mrs. Frederick C. Shattuck..	50,000.00
David Sears.....	25,000.00
Francis Skinner.....	5,000.00
John T. Spaulding.....	10,000.00
W. S. Spaulding.....	10,000.00
James Stillman.....	100,000.00
Nathaniel Thayer.....	25,000.00

WE noted last week the gift of £25,000 of Mr. William Johnston to University College, Liverpool. We learn from *The British Medical Journal* that the £25,000 is divided as follows: £10,000 is allocated to found a chair of chemical biology, £6,000 at 5 per cent. interest to permanently endow three research fellowships of £100 a year each. Of these fellow-

ships one is to be held by a medical graduate of a colonial university, a second by a graduate of medicine of the United States, and a third by a research student in gynaecology. The remaining £9,000 is to be spent in building a laboratory adjoining the Thompson-Yates laboratories, to accommodate the Tropical School, the professor of chemical biology, experimental medicine, comparative pathology, and serum research departments.

JOHN D. ROCKEFELLER has offered to give \$25,000 to the endowment fund of William Jewell College, Liberty, Mo., provided \$75,000 additional is raised by January 1, 1903.

THE corner stone of the science and administration building of Colorado College has been laid. The building, to cost \$225,000, will be three stories high, 287 feet long and 95 feet wide, the material being sandstone. A natural history museum will be installed in the building, with laboratories for scientific instruction.

THE Laboratory of Chemistry and Metallurgy, at Lafayette College, the gift of Mr. James Gayley of the class of '76, will be dedicated on April 5. The program for the dedicatory exercises includes addresses by President Ira Remsen, of Johns Hopkins University; President Thos. M. Drown, of Lehigh University, and Professor Henry M. Howe, of Columbia University.

THE Science Hall, University of Montana, was practically destroyed by fire on March 14. The building was erected three years ago at a cost of \$100,000. The loss is covered by insurance.

AT a conference of representatives of the governors of King's and Dalhousie colleges, held at Halifax, the joint committees unanimously arrived at a satisfactory basis of amalgamation for the federation of the various colleges in the maritime provinces, which will be submitted to the boards of governors of the various colleges for confirmation.

AT Yale University, Dr. Wesley R. Coe, instructor in comparative anatomy, and Dr. Milton B. Porter, instructor in mathematics, have been appointed to assistant professorships.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

II.

NATURAL HISTORY AND NATURAL KNOWLEDGE.

THE definition of science as the analysis and classification of facts leads the philosophical spokesmen of modern science to believe that an embryological account of thinking men is impossible, because it leads them to believe there is a chasm which is intellectually impassable between the facts of physics and the facts of consciousness.

Since the minds and senses by the aid of which we make scientific discoveries are generated from eggs, the progress of embryological science must bring us around sooner or later to the old question: What is science? What is it to know a thing?

In this paper I shall show the fitness of biological science for helping us to reconsider this great question.

1. *May it not be that we understand a thing when we can tell what it means, and use it?*

Philosophers tell us we understand a thing when we comprehend it, but it is my purpose to ask whether the progress of biological science may not lead us to think, with Berkeley, that we understand a thing when we can tell what it means and use it, and whether this definition of science may

not help us out of the paradoxes of philosophy, and make the way clear for an embryological account of thinking men.

2. *The problem of knowing.*

Our sensations and thoughts and feelings have not taken place anyhow and at random. They have been so related in the past that one has been a sign which has led us to expect others, which have always come about as we expected if our knowledge has been sound and accurate.

When they have thus come about, we have known that *this has not been our doing*. We have known too that it is because it has not been our doing that natural knowledge has been useful to us.

One of the most practical questions that man can ask is this: When, and how far, is our experience a sound basis for confidence in things that we have not experienced—such things, for example, as the animal life of the Cambrian sea, the molecular constitution of matter, and my own embryonic history? Since an answer to this question has been included in past knowing, it must also be included in an account of knowing. It is this question that physical science undertakes to answer by scientific discovery, but the biologist must ask a still more difficult question: How do living beings come to do unconsciously, and without knowing it, the things that are to their advantage? How does a living being get safely through all the chances and changes of life without needing to run its nose into every danger before it avoids it? How do some men learn, from a single experience, what others fail to find out after a lifetime of experience?

3. *Our biological education begins at an early day.*

No institution, no period in the history of science, no stage in intellectual development, can lay claim to the beginnings of biological science. They are to be sought

long before our entrance into laboratories; long before the beginnings of book-learning. Even before we learned articulate speech, the teacher whom the poet has called the grand old nurse took us upon her knee and began the wonderful story of nature for our delight and profit and instruction; that story to which there is no end; in which each chapter, as fresh and new as the first, adds new meaning, new usefulness to all we have been told.

Part, at least, if not the whole, of our early education was biological. We laid the foundations of anatomy and experimental physiology when we learned, through repeated scientific experiments, that it is through eyes that we see, through ears that we hear, through hands that we touch, and that it is good to see and hear and handle things. We were no doubt led, slowly and gradually, through innumerable scientific experiments, to the discovery that, among the changes that go on in nature, some are of peculiar interest and importance to us; and we thus come to set apart in our minds, from among the things of which our senses tell us, certain ones which seem, because of their clear relation to our comfort and discomfort, and because of the quickness with which we learn how to make use of them, to pertain to ourselves, and to constitute our bodies, as distinct from the world around us, which we are thus led to set over against ourselves, as a not-self. It seems to me that it is in this way that we lay a foundation, in the conception of a living body, for all later study of biological science, and no naturalist can doubt the great and permanent value of this conception; yet there is no more fruitful source of paradox and contradiction and absurdity than the words in which we attempt, at a later stage, to describe this scientific discovery; for while a scientific discovery is part of the language of nature, our words

are, unfortunately, an inheritance from the language of scholasticism.

4. *Education is often unconscious.*

One may be educated without knowing it. The teacher who guides instead of driving is nearest the method of nature. The best of all training is that which is acquired with least effort, and some of the choicest fruits of intellectual activity have come when effort and self were lost in the inspiration of creative genius.

The untrained muscles of the infant are educated through exercise, but it is not in self-consciousness that the child and the kitten and the colt and the calf delight in frolics and gambols and sports and games. It is only after the human infant has spent weeks in experimenting that it acquires the useful art of moving its eyes together, and of seeing objects single and solid, instead of flat and tremulous. I do not know whether the child is conscious or unconscious of this lesson in the physiology of vision, but it is, assuredly, not through induction from particulars and deduction from laws that the nutritive and nervous changes come about, through which the muscles of the eyeball become coordinated, yet these are educational changes. So far as education is shown by doing the things that are advantageous, and in avoiding those that are injurious, the ancestral rhizopod, which extends its pseudopodia under the stimulus of fit food, and retracts them on the approach of danger, is educated, for our biological education begins long before our birth, and we are born educated. It is this truth, no doubt, which has led some to the strange notion that life is memory.

5. *The things we do most easily, or most naturally, are not always the wisest things.*

The history of our minds, like that of our bodies, has been such that the things we do most naturally are not in all respects

the best for our present needs. Just as there are bodily parts which, while fitted for past conditions, are no longer useful, and just as we have natural impulses and appetites which now call for repression, so it is also with our minds; for we are in continual danger of a logical fallacy which it is the peculiar work of natural science to correct, since it is an incidental result of our natural history. This is the fallacy known to logicians as the fallacy of the undistributed middle—the fallacy which consists in mistaking a part for a whole.

6. *The fallacy of the undistributed middle is constitutional.*

Our bodies are so constituted that an action which is at first performed with difficulty becomes easier with each repetition, while departure from established custom at the same time grows harder. It is this peculiarity which fits our bodily frame for improvement by practice and training. In this, our minds are like our bodies, for a path which our thoughts have once traversed becomes easier with each new venture, while it grows harder for us to consider what lies beyond the borders of this path.

The facts of nature do not all interest us equally. Some are more attractive to us than others, and we must specialize to make progress in knowledge, so we are continually and unconsciously fixing attention upon some part of nature, for some purpose of our own, and considering it 'in itself,' to the neglect of that which does not interest us, nor seem to concern us.

Our minds, as they have come to us in course of nature, are so constituted that, when we consider a part as if it were the whole, we are in danger of forgetting that it is but a part and not the whole; and if we make this mistake, we may be led into opinions which seem to be the logical conclusions of sound reasoning when they are nothing more than new illustrations of the

threadbare fallacy of the undistributed middle.

7. *Philosophical agnosticism comes from mistaking a part for a whole.*

When, for some purpose of our own, we become interested in a part of nature, neglecting, for the time, as of no interest to us, its interrelations with other things, we may fall unconsciously, from the very nature of our minds, into the belief that what we have treated as if it were independent of the rest of nature, and complete in itself, is really independent and complete. Thus we come to regard mental abstractions as independent things, and then, finding that our abstractions have no independent being outside our minds, we ask the absurd question whether the real world of nature is anything but an abstraction and a chimera of our fancy, and set ourselves to making systems of philosophy to pull us out of the quagmire of agnosticism into which we think we have fallen.

Berkeley shows that it is because we call all sheep and all crows and all triangles and all numbers by generic names, that we think we can know a generic sheep and a generic crow and a generic triangle and a generic number—that is, a sheep and a crow and a triangle and a number which are not individual and particular sheep and crows and triangles and numbers; and he believes that it is nothing but language which makes us so ready to mistake abstractions for independent things, and then to think that because no real thing exists abstractly we can never know anything as it really is; and he shows that 'we need only draw the curtain of words to behold the fairest tree of knowledge, whose fruit is excellent, and within the reach of our hands.' So firmly rooted in our minds is the notion that abstract words stand for *things as they really are*, that Berkeley, who only asks us to use our

utmost endeavors to obtain a clear view of the things we would consider, 'separated from all that dress and encumbrance of words which so much contributes to blind the judgment and divide the attention,' is commonly held to deny the reality of *things*, because he denies that any real thing exists abstractly.

Tyler traces our habit of mistaking abstractions for independent things, and the doubt of the reality of *things* which arises in the mind of the philosopher when he discovers that no real thing exists abstractly to the primitive culture of savages, and it is, no doubt, because there is still much of the savage in us all, that we try to distinguish the appearance of things from those things in themselves of which the appearances are thought to be the ghosts.

May we not trace still farther back the habit of mistaking abstractions for independent things, and ask whether it may not be an unfortunate incidental result of that fitness of living beings for education which is older than the trilobites?

It is not the value nor the reality of generalizations, but their independent, or abstract, reality, that is called in question. A generalization is as real as a pain, and, like a pain, it may have the greatest value, and call our attention to other real and important things which might have escaped notice, and it may thus help us to foresee or direct nature.

If the pain were not my pain it would not be at all; yet, while its being is relative to me, this relation to me is not all the being it has. No fact is more certain than that I do not make my pain, for if it were my doing it could not call my attention to unnoticed things, nor have any value as a warning of danger. Is it not ignorance of this simple truth which has led some to think that our pain is our own doing, and that we need only stop doing it to make an end of it?

All I know about the trilobites and the moons of Jupiter is relative to me; yet the trilobites were real millions of years before any naturalist knew them, and the moons of Jupiter would, no doubt, still be real, even if all life should come to an end upon earth.

8. *Our bodies are real, but their reality is in their interrelations with our environment.*

The child's discovery that its body is of peculiar interest and importance to it, and peculiarly within its control, is a real scientific discovery. Living things are real things, and we can never know too much about them; but their reality is in their interrelations with the rest of nature, and not in themselves, nor in their relations to us. Surely this is good sense and good science. No physiologist who studies the waste and repair of living bodies, no naturalist who knows living beings in their homes, no embryologist who studies the influence of external conditions upon development, can, for an instant, admit that living beings are self-sufficient or self-sustaining, or that their being is in themselves; for the line we draw, for better study, between living beings and the external world, is not one that we find in nature, but one that we make for our own purposes.

The external world of a living thing is as much a part of it as its histological structure. If the environment of its body, or of any cell within its body, were different, neither cell nor body would be what it is, and if they had no environment they would not be at all, for neither eggs nor seeds nor desiccated rotifers exist abstractly. A self-sufficient and self-contained living thing is as fabulous as a griffin or a centaur, but no naturalist thinks for an instant that this truth casts any doubt upon the real existence of living things.

If the being of a living thing is in its interrelations with the world around it, as Berkeley tells us it is, and not in its interrelations with us, as the philosophers tell us it is, is it not clear that we can never hope to know all there is to know about it? But is it not equally clear that, so far as we do know it, we know it as it is?

Does the responsibility for the notion that we can never know a living being as it really is rest upon the shoulders of the naturalist who knows that its being is dependent and relative? Is it not rather to be laid to the charge of the philosopher who believes in its abstract or independent existence, and is led to doubt its reality by the discovery that abstractions have no independent existence?

Locke reminds us that "we see and perceive some of the motions and grosser operations of things here about us, but whence the streams come that keep all these curious machines in motion and repair, how conveyed and modified, is beyond our notice and apprehension; and the great parts and wheels, as I may say, of this stupendous fabric of the universe may, for aught we know, have such a connection and dependence in their influences and operations one upon another, that perhaps things in this our mansion would put on quite another face, and cease to be what they are, if some one of the stars or great bodies, incomprehensibly remote from us, should cease to be, or to move, as it does. This is certain: things, however absolute and entire they seem in themselves, are but retainers to other parts of nature, for that which they are most taken notice of by us. Their observable qualities, actions and powers are owing to something without them; and there is not so complete and perfect a part that we know of nature, which does not owe the being it has, and the excellencies of it, to its neighbours; and

we must not confine our thoughts within the surface of any body, but look a great deal farther, to comprehend perfectly those qualities that are in it."

9. *The being of things is real, but is it in themselves, or in their interrelations?*

Is it as a self-contained and self-sufficient being, or as part of the universe, that the stone illustrates the law of gravitation?

When Sir Isaac Newton made his speech about the child and the pebble: "Did he mean," asks Dr. Holmes, "to speak slightly of a pebble? Of a spherical solid which stood sentinel over its compartment of space before the stone that became the pyramids had grown solid, and has watched it until now! A body which knows all the currents of force that traverse the globe; which holds by invisible threads to the ring of Saturn and the belt of Orion! A body from the contemplation of which an archangel could infer the entire inorganic universe as the simplest of corollaries! A throne of the all-pervading Deity, who has guided its every atom since the rosary of heaven was strung with beaded stars!

"The divinity student honored himself by the way in which he received this. He did not swallow it at once, nor did he reject it; but he took it as the pickeral takes the bait, and carried it off with him to his hole (in the fourth story) to deal with at his leisure."

10. *May not the notion that our minds are in our heads be due to the fallacy of the undistributed middle?*

Our welfare and our existence depend upon the soundness and safety of our brains, and knowledge of real brains and their functions is of the utmost value and importance, but would it have any value if, knowing only the appearance of brains in our minds, we were altogether put off with false appearances, and could never know brains as they are in themselves?

If the being of a living brain is not in itself, but in its interrelations with nature, we do know brains as they really are when we discover these interrelations; but if the being of a brain is not absolute and independent, but dependent and relative, what are we to think of the notion that our minds are shut up inside our heads? May not this also be an illustration of the fallacy of the undistributed middle? My mind to me a kingdom is, but I find no reason to think this kingdom is a microcosm—a little world set over against the great kingdom of nature. My kingdom is the great universe itself, the starry heavens, and the geological history of the earth, and everything else I know, and my mind grows as more and more of nature becomes mine by right of discovery. So far as I know the Ichthyosaurus and the rings of Saturn, these things are in my mind; and if the things I know were really shut up in my skull, these things would be inside my skull; but there is no room there for real whales and real megatheriums, so philosophers tell me I can never know anything as it really is, because the only universe I can think of or consider is the one I know.

Stone walls do not a prison make, nor iron bars a cage. May we not owe to the fallacy of the undistributed middle—to our useful ability to fix our attention upon a part of nature, and to temporarily neglect that which does not for the time interest us nor seem to concern us, and to the carelessness which permits us to think that what we have considered by itself for our own purposes is really self-contained and self-sufficient—may it not be to this that we owe the notion of a mind shut up in a head, and knowing nothing but the dissected and distorted shadows which the unknown and unknowable real world casts on the walls of its prison through its narrow and grated windows?

11. *Illusions and hallucinations do not show that the world I know is unreal, nor do they show that its reality is relative to me.*

Deceptions and illusions and hallucinations are not unreal. They are matters of fact of which the physiologist and the pathologist and the physician are finding out the meaning, and finding too a way to make use of this meaning, by scientific discovery, while common folks mistake their meaning, just as we mistake the meaning of other matters of fact when we think we know more than we have found out.

Comprehension is the gathering in of generalizations into a hypothesis, but while any plausible hypothesis may satisfy idle curiosity, it has no scientific status unless it leads to the discovery of facts and the control of nature.

When the ignorant man who has lost his foot feels the sensation which he has learned to call pain in his toes, he says his foot is uneasy in its grave. When the learned philosopher tells him his pain is an illusion, he may justly declare that he knows his own feelings better than any one else, however learned. The pain is real, but when he satisfies himself with the notion that his foot is uneasy, he mistakes a hypothesis for a fact, like the philosopher, while the man of science discovers that the sensory nerve is irritated somewhere else than at its endings in the toes.

12. *Instead of showing that we can never know anything as it really is, may not the notion that knowledge is comprehension be a new illustration of the fallacy of the undistributed middle?*

We comprehend things when we know them, but it does not follow that when we comprehend them we know them, for knowledge may be comprehension and something more.

The resemblances between things are summarized by classifying or comprehend-

ing them, but Loeke has reminded us that knowledge is the discovery of resemblances and differences. So far as we know nature, it exhibits universal order in endless diversity; not order here and diversity there, but order in diversity. Can we know any two things are alike without knowing they are different? We may, for some purpose of our own, fix our attention upon the order of nature, neglecting the diversity, but things do not cease to be because they do not, for the time, seem to concern us.

Are the order of nature and the diversity of nature either two things or one thing seen from two standpoints? Are they not rather two narrow and imperfect views of the natural world which lies before our eyes? Have we any way to find out either the unity of nature or the diversity of nature except scientific discovery? May not the notion that while we discover the laws of nature, we deduce from these laws the diversity of nature, and our control of nature, be an illustration of the fallacy of the undistributed middle? Is a scientific law anything more than a summary of past experience, *joined to confidence in the continuity of nature?* Do we ever know that we can foresee or control nature, even in repeating the simplest scientific experiment, until we have succeeded?

13. *Biological science is peculiarly fitted for calling to our attention the diversity of nature.*

While analytical science is making marvellous revelations of the order which pervades the apparent disorder of nature, showing us, by the method of analysis and generalization, the most astonishing proof of order and regularity in the course of events which had seemed to be chaotic, biological science is continually recalling to our attention the diversity of the statistical data, and making equally marvellous

and equally instructive, revelations of the inexhaustible variety of nature. We talk about humanity, but we know and deal with Peter and Henry and Thomas and Black Jim and Yellow John. We need proper names for all the animals that we are well acquainted with. The zoologist tells us about the genus *Equus*, but if he has any practical dealings with horses, he never says one horse is the same as another, or even that a horse is the same to-day as he was yesterday, for even if he be neither sick nor lame nor hungry, he is one day nearer the end of his usefulness.

The botanist talks learnedly of *Chrysanthemum indicum*, but the florist sells golden wedding and ivory and fair dawn and snow queen and hundreds of others. For many scientific purposes it is necessary to give proper names, or designating numbers, to seedling plants, and it may be that if the chemist were dealing with individuals, instead of averages, he might need proper names to tell to others his discoveries about molecules and atoms.

14. *Are identity and diversity absolute or relative?*

To-day's sun is the same as yesterday's, yet the changes which go on in the sun, from day to day, are, no doubt, violent and rapid beyond our utmost means of measurement or expression. We say to-day's sun is the same as yesterday's when we are interested in the dawn and the daylight, and in the flight of time, and in the change of seasons, and in the transit of Venus, and in the stability of the solar system; but we say it is not the same when we are interested in sun-spots, and in the fall of meteorites, and in combustion and the dissipation of energy. When we say the solar system is stable, we do not mean that it is really stable. We only mean that the course of its progress from some past condition to some future condition has no obvious practical relation to our own affairs.

We seldom lose sight of the diversity, or individuality, of familiar living things in our interest in their resemblances. We do not say one horse is the same as another between the shafts. We say he is as good as another, or will serve, or that he is the same *substantially*, meaning, by these words, the *same substantially*, or *the same in substance*, that, while he is not the same, we will accept him as a substitute; but no one with worldly wisdom trusts the strange horse, even so far, before he has tested his opinions, and those of the horse dealer, by scientific experiment and verification.

Biological science has peculiar fitness for guarding us from the fallacy of the undistributed middle, and for teaching us that it is only through verification that guesses become knowledge, because its subject matter lies midway between those 'exact' sciences in which we are told that figures cannot lie, on the one hand, and, on the other, those social and political sciences which show us continually how easily one may lie with figures. When we have verified a hypothesis so often that we are 'satisfied,' we call it a 'law of nature,' and we build as firmly upon it, and trust to it as implicitly, and govern our actions by it as unhesitatingly, as if it were certain, and in all that concerns our conduct we make little or no difference between it and certain knowledge. In this, experience is continually demonstrating our wisdom, but if the discovery that hypotheses have no independent existence leads us to believe that we can never know the real world of nature, is it not time to reexamine our notions?

The laws of nature are real, but their reality is not independent nor absolute, because the unity of nature is unity in diversity, and diversity in unity.

If the views that are here advanced—views that are in no way original with me—are accepted; if the reality of the nat-

ural world is in the interrelations between things, and not in unknown and unknowable things as they are in themselves; does it not follow that scientific discovery is the only way to learn the differences between things, just as it is the only way to learn the resemblances between things? When we say two things are the same, must we not also say what are the relations with reference to which they are the same? When we say they are different, must we not also say what are the relations with reference to which they are different? Is there any way except scientific discovery to find this out?

15. *The biological problem of species.*

Fifty years ago many naturalists thought that all living things of a kind are fundamentally and absolutely alike in certain specific characters, and that it is only in characters that are not specific that they differ; but more exact study has failed to show us, in any living being, any characteristic whatever which does not exhibit diversity from others of its kind, as well as resemblances; for the notion that certain characters are generic, while others are differential, is an illustration of the fallacy of the undistributed middle, as is also the attempt to analyze living beings into *characters*.

After the long controversy between those who asserted the immutability of species, and those who declared that species are mutable, seemed to be happily ended by the scientific demonstration that species have a natural history, there arose a new school of naturalists, who asserted that species have no existence in nature because no two living beings are identical in any respect whatever. At the present day, many naturalists are returning to a modification of the old notion of species, and are teaching that while the mutability of species is due to changes in the interrelations between living beings and the

world around them, stability is inherent in the living beings, *as they are in themselves* by birth.

If the view which is here advanced be correct, the specific stability of the individuals of a species is real, and as independent of us as the stability of the sun in the heavens, but when we say the individuals of a species are alike, we must also say what are the relations with reference to which they are alike, for the stability of species and the mutability of species are not two facts, nor the same fact from two points of view, but two narrow and imperfect views of the same fact.

Thus, for example, individual sheep are alike for certain purposes of the zoologist and the paleontologist. They are alike to the embryologist and to the anatomist, and to the physiologist, so far as these scientific students are not concerned with their differences. They are, no doubt, alike to the hungry wolf, and to the geese that graze in the same pasture—to their competitors and enemies in the struggle for existence. They are alike in their sexual affinity, so far as there is no sexual selection. They are alike in the physiology of reproduction, and in their physiological activity in general, so far as they do not differ in fertility and in constitution. On the other hand, they are different to the stock-breeder, and to the shepherd, to the shepherd's dog, to their lambs, and, no doubt, to each other.

As we learn more about sheep, we learn more about their identity and more about their diversity, but this does not show that the identity and diversity are in us and not in nature. It only shows that neither the identity nor the diversity has any independent existence in nature abstracted from the living beings.

16. *Are inheritance and variation two processes, or two partial and imperfect views of the same process?*

If no two individual living beings are alike; if the stability of biological types means that the aberrant have been exterminated in the struggle for existence, and if the modification of a type is an indication of a change in the standard of extermination; are not inheritance and variation two partial and imperfect views of the selective process? When the embryologist seeks in the germ for the material basis of inheritance, and for the mechanism of variation, is he not searching for something which has no independent existence? Must he not seek, in the interrelations between living beings and their environment, and not in the living beings *as they are in themselves*, for that of which he is in search? Do not they who think that natural selection must be supplied with the raw material by a mechanism for variation before it can do anything, both personify the selective process and forget the diversity of nature?

17. *Does physical analysis give an adequate account of the organization of living bodies?*

Physical analysis resolves organized beings into organs and tissues and cells and physiological units, but does this analysis give an adequate account of organization?

The bodies of two allied animals are alike in structure. They are composed of organs which are said to exhibit fundamental unity *behind* superficial diversity, for they are practically identical in history, and for most of the purposes of the anatomist and the physiologist and the zoologist. From this point of view, and from many others, they are identical in structure, yet the differences between them do not cease to be because they do not concern us, nor because they escape our notice, for while the identity is real and important and significant, it has no abstract, or independent, reality.

'Were the heart of one man,' says Maudsley, 'to be placed in the body of another, it would probably make no difference in the circulation of the blood, but it might make a real difference in the temper of his mind.' Does not the analogy of nature lead us to ask whether it might not be expected to make a difference in the circulation of his blood as well as in the temper of his mind? If our knowledge of hearts were as minute and individual as our knowledge of men, might we not need a proper name for each heart as much as we need one for each man?

If the interest of the histologist in the resemblances between the tissues of one animal and those of another leads him to lose sight of their constitutional differences, he is in danger of mistaking an abstraction for a reality, for while the scientific basis of histology in the resemblances between the tissues of one animal and those of another is real and significant, it has no abstract, or independent, reality.

"From the morphological standpoint," says Hertwig, quoting from de Vries, "we may properly regard the cell, apart from the organism, as an individual, but we must not forget that it is by abstraction that we do so. Physiologically the cell is an individual only when actually isolated and independent of an organism. From this standpoint, every abstraction is a blunder."

When we say a multicellular organism is a unit, must we not also say what are the relations with reference to which it is a unit? When we say its constituent cells are units, must we not also say what are the conditions with reference to which they are units? Have we any way to find these things out except scientific discovery?

18. *Is cell-differentiation inherent or induced?*

A thoughtful and distinguished naturalist tells us that while the differentiation of

the cells which arise from the egg is sometimes inherent in the egg, and sometimes induced by the conditions of development, it is more commonly mixed; but may it not be the mind of the embryologist, and not the natural world, that is mixed? Science does not deal in compromises, but in discoveries. When we say the development of the egg is inherent, must we not also say what are the relations with reference to which it is inherent? When we say it is induced, must we not also say what are the relations with reference to which it is induced? Is there any way to find this out except scientific discovery?

19. *Are the beneficial effects of practice and training and education and opportunity innate or superadded?*

Can we hope to answer this question, *a priori*, by deduction from hypotheses? Is there any more value in Weismann's demonstration that acquired characters cannot be inherited than there is in Haeckel's declaration that the inheritance of acquired characters is a necessary axiom of the monistic creed?

Such facts as are in my possession seem to me to show that, while we need opportunities to make the best of our natural abilities, no one can do his part in any station in life without natural aptitude. As my opinion is not a deduction from a hypothesis, I hold it lightly, and subject to revision and correction.

20. *May not the biological notion of a living substance be an illustration of the fallacy of the undistributed middle?*

When we say all living things are alike in substance, I cannot discover that we mean anything more than we mean when, admitting some report of a conversation as a substitute for the truth for some purpose that we have in view, we say it is the same in substance as the original conversation.

The modern naturalist is so well aware

of the endless diversity of living things that he never—that is, hardly ever—thinks that because one amœba, or one yeast-plant, or one horse, will serve certain purposes of experiment, and demonstration, and instruction, as well as another, they are alike in any respect whatever.

21. *Conclusion.*

As my only purpose is to do what I can to make the way clear for the progress of embryological science, by trying to free my own mind, and the minds of others, from all notions which imply that embryological science is impossible, and not to give a natural history of mind, I have passed by many important aspects of human knowledge without notice. But, before I close, I ask you to take away with you, and to consider, this familiar fact: Philosophers tell us we may come at truth by deducing it from certain first principles which are self-evident to the normal man, and they talk about the normal man as if he were a prominent citizen, the familiar acquaintance of all who have any claim to be considered men of intellect, and a well-known face even to the common herd. The naturalist declares he knows no such person, that all men are individual and particular men, and the normal man a fictitious character, and a statistical average without opinions.

If the naturalist is honest with himself, it seems to me that he cannot fail to come in time to hold his most cherished convictions subject to revision, and to value them only when they are verified by laying them alongside nature, and to regard absolute truth and necessary truth as meaningless words, because the being of things is not absolute but relative to everything else in nature.

The truth that knowledge is not absolute, but relative, is held to be the final and conclusive proof that we can never know anything as it really is, for we are

told that the reality behind the phenomena of sense must be unknown and unknowable, because we can never come at absolute truth. But may not the naturalist be moved to ask whether the conclusion follows from the premises? May it not prove to be only the final transformation of the protean fallacy of the undistributed middle? Instead of showing that we can never know anything as it really is, may not the relativity of knowledge show that nature, as it really is, is relative and dependent—that its being is not in itself? “As no man fording a swift stream,” says Huxley, putting into vigorous English a thought that has often found expression; “as no man fording a swift stream can dip his foot twice in the same water, so no man can, with exactness, affirm of anything in the sensible world that it is. As he utters the words, nay, as he thinks them, the predicate ceases to be applicable; the present has become the past; the ‘is’ should be ‘was,’ and the more we learn of the nature of things, the more evident is it that what we call rest is only unperceived activity. Thus the most obvious attribute of the cosmos is its impermanence. It assumes the aspect not so much of a permanent entity as of a changeful process, in which naught endures save the flow of energy and the rational order which pervades it.”

Every reflective student will, no doubt, feel a responsive chord vibrating in his own thoughts in unison with those of Huxley; but should he not ask himself whether the words, ‘*flow of energy and the rational order which pervades it,*’ mean anything, except that the reality in which the flowing river of nature endures and has its being is rational energy, the energy of a reason, the activity of a mind?

Biological science seems to me to show, with ever-increasing emphasis, that it is in one sustaining mind that we ourselves, and

all we know, or can hope to know, have being. Even if this be neither absolute truth nor necessary truth, may it not be that still better truth, a scientific discovery; and the greatest of all scientific discoveries because it has, so far, been verified in every act of knowing?

W. K. BROOKS.

JOHNS HOPKINS UNIVERSITY.

THE NATURE OF NERVE STIMULATION AND OF CHANGES IN IRRITABILITY.*

As the conclusions of this paper supplement those of Professor Loeb, and as he is unable at present to publish an account of his work simultaneously with mine, a brief statement of the relationship of our work appears to us both to be desirable.

It is well known that Professor Loeb has for the past several years been applying the conclusions of physical chemistry in the investigation of the phenomena of life, as he was convinced that these conclusions would clear up many physiological phenomena. Of the several discoveries which have rewarded his insight there are two of apparently the most fundamental nature. One of these was made several years ago and published in *Fick's Festschrift* in 1899. It consisted in the demonstration that muscle would only beat rhythmically in solutions of electrolytes. This practically established the fact that contractility was in its essence an electrical phenomenon. About two years ago he expressed to me the opinion that other life phenomena were electrical, and not chemical or thermodynamical. A second fundamental generalization was made last summer at Woods Holl and published in *Pflüger's Archiv*, Volume 88, 1901, to the effect that the toxic and antitoxic action of salts was a function of the number and sign of the elec-

* This paper was prepared for publication early in January, but has been delayed in its appearance.

trical charges their ions bore. During the summer, and later in a lecture before the Medical Society of the University of Chicago, he applied these results to the action of toxins and antitoxines. He was, however, unable to discover any series of facts for the anions similar to those he established for the kations, and he referred the poisonous action of a pure sodium chloride solution to the monovalent kations the salt possessed instead of to the anions. In his work on muscle, also, the stimulating action of sodium chloride was referred to the sodium ions and I provisionally adopted the same explanation in my preliminary paper on the action of salts on nerves published in the *Journal of the Boston Society of Medical Sciences* last spring: Professor Loeb's attention was thus drawn chiefly to the kations. He attributed the undoubtedly greater stimulating action of the bivalent and trivalent anion sodium salts to their calcium-precipitating properties, having been brought to this conclusion by the peculiar action of fluorine.

In 1897 Professor Loeb directed my attention to physical chemistry, and his results on muscle appeared so remarkable that I began, three years ago, a study of the stimulating action of salts on nerves. The relationships were so complex that a long series of observations were necessary, but, during the spring of 1901, I published a preliminary paper in which, owing to incomplete results, I fell into several errors. The stimulating action of the higher anions was provisionally referred to the hydroxyl ions the solutions generally contained, and the peculiar activity of sodium compounds to the diffusion of Na ions into the muscle.

Further experiments showed me that certain of the conclusions were wrong. After reading Hardy's paper on 'Colloidal Solutions' and hearing Professor Loeb's lecture on the possible importance of the

valence of ions, and more particularly of the kations, in determining their poisonous character, I had the opportunity of putting together my experiments. After computing the degree of hydrolysis and the number of H and OH ions in the solutions, it appeared that it was not the OH ions which were the cause of the stimulating action of the borates and citrates. The resemblance of my results to those of Hardy on colloidal solutions was apparent, and, apart from certain exceptions left for future investigation, I was led to infer that stimulation was due to the negative ions, and that the positive ions prevented stimulation; and also that as the stimulating action of the anions generally increased with an increase in valency, the stimulation was due to the electrical charges the ions bore. Following out this idea, which, as will be seen, was the extension of Loeb's idea of the importance of valence, the electrical relationships of nerves, the nature of stimulation and of changes in irritability and the nature of the nerve impulse appeared in a new light. The main results and conclusions were presented before the Medical Society of this University on December 2.

Meanwhile, unknown to me, Professor Loeb had begun to doubt that the calcium precipitation by the higher anions was the real cause of their action. Upon hearing my results and conclusions he perceived that they agreed with his facts as well.* It is with gratitude that I acknowledge my indebtedness to Professor Loeb, who showed me in which direction to look and who as a pioneer has opened one of the most fruitful fields of science. My own conclusions supplement and, it seems to me, make more precise those general ideas which were guiding him.

* Since this paper was sent to the editor, Professor Loeb has published in the February number of the *American Journal of Physiology* a portion of his results on muscle.

My observations were made on the sciatic nerve of the frog and stimulation of the nerve was shown by the contractions of the gastrocnemius muscle. I have tried about nine hundred experiments on frogs at different seasons of the year, so that the observations are numerous enough to offset most individual variations. The nerves were immersed for the greater part of their length in the solutions to be tested.

1. Nerves are stimulated by the withdrawal of water. The non-electrolytes sugar, urea and glycerine will stimulate if the osmotic pressure of their solutions is equal to, or greater than, twelve atmospheres. This is more than twice the osmotic pressure of the nerve. Nearly all electrolytes tested, quite irrespective of their nature, will also stimulate if their solutions are as concentrated as this. The nerve always increases in irritability (katelectrotonus) before impulses large enough to cause the muscle to contract are generated. After complete loss of irritability in the non-electrolytes the nerves will be completely restored by placing them in M/8 sodium chloride solution. These facts demonstrate anew the truth of the generally accepted opinion of physiologists that the change in the nerve which generates the nerve impulse can be set up by the withdrawal of water.

2. All salts of H, Li, K and NH_4 which were tested of which the anions are monovalent, such as KCl, KBr, KI, LiCl, NH_4Cl , and others; all salts of bivalent cations united to monovalent or bivalent anions, such as MgCl_2 , MgSO_4 , $\text{Mg}(\text{NO}_3)_2$, ZnCl_2 , ZnSO_4 , BaCl_2 , $\text{Ba}(\text{NO}_3)_2$, CuSO_4 , SrCl_2 ; all salts of trivalent cations united to monovalent anions, such as Fe_2Cl_6 and Al_2Cl_6 will generally stimulate if their solutions have an osmotic pressure of twelve atmospheres or over. In solutions weaker than this they all annihilate nerve irritability without stimulation, H, K and

Fe_3 salts most rapidly. Irritability may generally be restored, if the nerves are not left too long in the solutions, by immersion in M/8 NaCl solutions. All these salts, therefore, stimulate by withdrawing water. The salts themselves will in each case destroy irritability.

3. All acids tested with the exceptions (possibly) of phosphoric and oxalic will not stimulate, except in solutions of high osmotic pressure (twelve atmospheres) Hydrogen ions do not appear hence to stimulate the nerve. On the contrary in weaker solutions tested, nerve irritability was lost without stimulation. This confirms Grützner and others. My experiments, however, are not complete on this point.

4. Alkalies such as NaOH, LiOH, KOH, $\text{Ba}(\text{OH})_2$ will stimulate in approximately N/20 solutions. The hydroxyl ion, in other words, at certain concentrations stimulates the nerve.

5. If we compare the stimulating action of NaCl, NaBr, and NaI we find that these salts stimulate even in solutions of the same osmotic pressure as the nerve. The stimulating action of the salts increases as we pass from the chloride to the iodide. Hence stimulation is in some way a function of the anion, because the rate of diffusion of these salts is approximately the same and the number of Na ions is constant. It is not a function of the atomic weight, since the fluoride stimulates more than the chloride or iodide. These observations confirming Grützner led to the conclusion that the stimulating action of salts is due to their anions. On comparing the action of Na_2SO_4 , $\text{Na}_2\text{C}_2\text{O}_4$, Na_2HASO_4 and other bivalent anion salts we find that these are more powerful than the monovalent anions; and the trivalent anion salts such as sodium ferricyanide, sodium citrate and Na_3PO_4 are still more powerful than the bivalent anion salts. Thus NaCl and NaBr

will stimulate slowly in solutions of one gram molecule to 8,000 c.c.; Na_2SO_4 in one gram molecule to 25,000 c.c.; and Na_3 citrate in solutions of one gram molecule to 50,000 c.c. The power of stimulation as indicated by the prolonged tetanic and simple contractions of the muscle extending over hours is also greater than that of the monovalent salts. These observations clearly support the inference that stimulation is a function of the anions and also establish the fact that it is a function of the charges the ions bear. They thus support Løeb's general idea that valence or the electrical charges of ions determine their physiological action, but demonstrate that it is the negative ions which stimulate. As will presently be shown, however, valence, as such, possibly has no direct influence, but only indirectly determines the action of these ions.

6. The conclusions just drawn led me to infer that the positive ions must prevent stimulation and render the nerve non-irritable. This is shown to be the case by a comparison of HCl , LiCl , KCl , NH_4Cl and NaCl . The last salt stimulates; in the others the chlorine ion will not stimulate and the nerves lose their irritability. This can only be explained, I believe, by assuming that the stimulating action of the chlorine ion is overbalanced by the non-stimulating action of the positive ion, and of these positive ions it appears that H overbalances most, K less, Li still less and NH_4 least. If this idea is true it should be possible, by combining these positive ions with di- and trivalent more potent anions, to obtain a stimulating compound. This is indeed the case. KCl never stimulates except by the withdrawal of water; K_2SO_4 will occasionally stimulate the most irritable nerves in solutions of about the osmotic pressure of the nerve; K_3 citrate and K_3 ferrieyanide will stimulate in solutions of a gram molecule to 22,000 c.c.,

of which the osmotic pressure is less than that of the nerve. The same is true for other salts. Li_3 citrate stimulates in a gram molecule to 30,000 c.c. and $(\text{NH}_4)_3$ citrate in a gram molecule to 40,000 c.c. We thus come to the conclusion that stimulation is due to the negative charge of the anions and that the kations prevent stimulation. It follows from this that the chemical properties of an acid or a salt are determined by the balance between the anion and the kation. In NaCl the ions are nearly equivalent, but the chlorine slightly overbalances. This idea of the mutual antagonism of the anion and kation may possibly throw light on chemical processes and properties generally.

7. KMnO_4 , NaMnO_4 , and NaClO_3 will stimulate in solutions of a gram molecule to 12,000 c.c. This stimulation is possibly due to the liberation of some bivalent oxygen anions.

8. These results are similar to those of Hardy and others on colloidal solutions. Colloidal solutions, the particles of which are positively charged are precipitated by OH ions and anions and the precipitating action of these anions is in proportion to a power of their valence. They seem to be held in solution by hydrogen and possibly other positive ions. As it is well known that protoplasm contains colloids in solution, a fact Hardy has particularly emphasized, it occurred to me that stimulation might be due either to a gelation of the colloids or to their passage into solution. Løeb has frequently mentioned his belief that a variation in the state of the colloids in protoplasm is of importance in protoplasmic activity and particularly irritability. He and others have repeatedly described processes of liquefaction of protoplasm, and several years ago he attempted to refer changes in irritability to an alteration in the viscosity of protoplasm. I infer that stimulation consists in a

passage of the particles from the solution to or toward the gel, and that if we can prevent gelation stimulation is prevented and irritability is lost. This is indicated by the following facts among others:

The nerve contains colloids. Colloidal solutions, the particles of which carry positive charges, are precipitated by negative ions. Nerve irritability is increased by cooling and diminished by warming. The stability of the hydrosol is probably diminished by cold and increased, like common gelatine, by moderate warmth. Also when coagulation by heat occurs the nerve is stimulated. Coagulation is but the formation of an irreversible gel. Darwin's observations on *Drosera* and other plants by optical evidence demonstrates also this gelation. Darwin observed in his work on 'Insectivorous Plants' that the passage of the impulse over plant cells, which corresponds to the nerve impulse in animals, was accompanied by a visible precipitation or gelation of the protoplasm, the nature of which he did not understand, but which he called aggregation. He states that the molecular change supposed to occur in nerves may thus actually be seen in plant cells. There can be no doubt that he was right in comparing this change to the nerve impulse. He found that it was produced most readily by the citrates and phosphates, and was checked by Ba, K and other such salts. Thus his facts correspond closely with those I have found for the nerve. Aggregation was prevented by ether, by CO_2 or lack of oxygen. It could be produced by the extraction of water. His description of the process leaves little doubt that he is describing the formation of a reversible gel. The aggregated particles afterwards dissolved. The action of anesthetics and the electrical phenomena of the nerve also support the idea that stimulation is a process of gelation. This will be discussed later.

These facts indicate the truth of the following general statements:

I. Protoplasm consists essentially of a colloidal solution, the particles of which are positively charged. It is a reversible hydrosol.

II. Stimulation consists in the passing of the solution to or toward the gel. Irritability is reduced or abolished if we make the sol state more stable, or if gelation is complete. In other words, irritability varies inversely with the stability of the hydrosol.

9. Electrical stimulation. If stimulation is due, as I believe, to the negative charges the ions bear and is prevented by the positive, the identity of electrical and chemical stimulation is thus demonstrated. It makes no difference whether we put the negative charges into the nerve on ions or whether by touching the nerve with electrodes we bring about, so to speak, a surplus of positive charges at one pole and negative at the other. The end result is the same. It is thus plain why the stimulus begins at the negative electrode, or kathode. In this region by the action of the kathode, the negativity of the nerve is increased and gelation occurs. In what manner this negativity is increased will be discussed in the full paper, but it may be due indirectly to the hydroxyl ions. Electrotonus is also explained. By the passage of the current the negative charges are in excess or preponderate in their action near the kathode and positive charges preponderate near the anode. The stability of the hydrosol is diminished near the former and increased near the latter. Irritability is altered as just explained. These conclusions are supported by Hardy's observations on the movement of colloidal particles in the electric current and their precipitation at the kathode if positively charged. If the nerve is already near gelation (very irritable by cold or drying) we may have

gelation occurring sufficiently abruptly to cause tetanus during the passage of the current. A true condition of katelectrotonus may also be produced by taking water from the nerve.

10. The current of injury may also be explained on this hypothesis. At the cut end aggregation or gelation is taking place as a result of the disturbance of the mechanical conditions of the nerve. Here positively charged colloids are going out of solution and negative charges are temporarily set free. The cut end becomes negative to the uninjured portion. This conclusion is supported by the fact that warming the nerve locally causes the warmed portion to become electro-positive to the unwarmed, and cooling it causes the cooled portion to be electro-negative to the rest of the nerve. It is similar to what occurs when zinc goes into solution. The undissolved zinc becomes negative to the solution. It is also well known that if by heat we produce an irreversible gel (artificial heat section) of the nerve, the coagulated portion is negative to the rest.*

11. Mechanical stimulation may possibly be understood as follows: By the mechanical coalescence of the neighboring colloidal particles their surfaces become less than the sum of the surfaces of the separated particles. A portion of the negative charges formerly induced in the water surrounding each particle is accordingly set free. These immediately act like negatively charged ions and precipitate the next layer of colloids. The process may possibly be similar to that which occurs on jarring an unstable hydrosol or a supersaturated solution. The observations of Darwin and others show that jarring will bring about aggregation in protoplasm.

12. The nerve impulse may consist in

* The relation of this explanation to Waller's idea that the cut end is positive will be discussed in the full paper.

the following process. By the precipitation of each layer of colloids negative charges are regenerated; these precipitate the next layer of colloids and are again regenerated, and so on. That something of this sort occurs is indicated by the following facts:

(a) Darwin's observation that the passing of the impulse in plant cells is accompanied by a progressive precipitation.

(b) The facts that negative charges are set free in the nerve by the action of each successive segment. These charges constitute the negative variation.

(c) The fact that negative charges precipitate positively charged colloids.

(d) The fact that negative charges stimulate the nerve.

(e) The fact shown by the action of ether and other poisons that the negative variation is not a simple movement of inorganic ions, but is dependent for its propagation upon the state of irritability (state of the colloids) of the nerve. This fact has already led many physiologists to infer that the negative variation stimulates each successive segment of the nerve and is regenerated by the change it itself has brought about.

13. The action of anæsthetics. This consists, on the hypothesis so far sketched, in increasing the stability of the hydrosol or solution, and so preventing precipitation. There can be no doubt that the anæsthetics have this action as is shown by the following facts: Darwin observed that they prevent the process of aggregation or precipitation in plant cells, and it has been shown by Loeb, Budgett, Zoethout and others that they liquefy or dissolve the cells of infusoria and other animals and egg cells. The effect of a mixture of ether and water on starfish eggs is remarkable. The egg dissolves in it very rapidly. Furthermore, Overton and Meyer have shown that the anæsthetizing action of substances is pro-

portional to their fat-dissolving powers. The colloids in protoplasm are in all likelihood fat or lecithin proteid combinations like the sheath of the red blood corpuscles, and like the latter they are, no doubt, more soluble in ether and water than in water alone. So far as I can see, this explanation of the action of anesthetics is in harmony with the facts. It supports the general conclusions drawn as to the meaning of changes in irritability and it explains the often-noted similarity of action between hydrogen ions, certain poisons, potassium ions and the anesthetics. All these substances increase the stability of the hydro-sol and liquefy protoplasm.

14. Stimulation by light and ether vibrations. In paragraph 5 it was stated that, in my opinion, stimulation by the negative ion was not due primarily to the valence of the ion. It is not the charge itself, but its motion, which determines stimulation. This is shown, I believe, by the variation between the action of fluorine, chlorine, bromine and iodine, and between potassium, sodium and hydrogen. The hydroxyl ion, although monovalent, stimulates like a bivalent anion. Since the fact is apparently established that it is the electrical charge which stimulates, and not the atom with which it is associated, and also since the charge associated with chlorine does not differ in nature from that associated with fluorine, the difference in action between these ions can only be due to something the charge does; in other words, to the motion of the charge or of the atom with which it is associated. When a charge is moved it produces a disturbance in the ether. It is well known to all that the vibrations of the ether will produce those changes in protoplasm which the ions produce, and further the character of the change in protoplasm produced by light varies with the wave-length or the number of impacts per second. Violet light or the

ultra-violet rays stimulate protoplasm, while the red rays as a rule do so very feebly or inhibit movement. By the electromagnetic theory of light the ether disturbances which we call light must be due to the movement of electrons or charges in the sun, either constituting a part of the sun's atoms or associated with these atoms. In other words, it is not the presence of the charges in the sun which stimulates protoplasm, but the movements of the charges.

These facts are ground enough for the hypothesis that it is not the charges or the number of charges, but the movements of the charge which produce the change in protoplasm called stimulation, and, I may add, which must determine chemical action as well. This idea will agree, I believe, with the suggestions of J. J. Thomson, Larmor, Nerst and others in regard to the association between atoms and electrons. This motion of the electron may be either translatory on the atom, which will agree with the kinetic theory of solutions, or it may be a rotatory motion. For various reasons I am inclined to assume that the charge is either revolving with the atom or about it, but a detailed consideration of this point will be given in the full paper. Knowing, however, that charges in motion affect the ether; that the impulses thus given produce chemical changes; that substances in solution or as solids actually give out what we call ether vibrations; having established the fact that monovalent ions differ among themselves in stimulating action, although the charges are the same on each, and also that ions stimulate by the charges and not by the atoms, I see no escape from the conclusion that it is not the charge, but its motion and its sign, which ultimately determines its action. In other words, chemical stimulation and light stimulation are identical.

UNIVERSITY OF CHICAGO.

NODULES AND MOLECULES OF RED BLOOD-CORPUSCLES.

DESCRIPTIONS of human blood usually give the general form and dimensions and behavior of the red corpuscles, emphasizing the fact that mammalian blood in the mature condition is negatively characterized by the absence of nuclei. They fail, however, to note the presence of minute nodules, like excessively minute nuclei, one for each corpuscle as a general rule. These bodies, which are not always central in the corpuscle, appear under the microscope as dark rings, each with a bright, yellowish center. On first seeing them in coagulated human blood, I was puzzled by their being unexpected. Afterwards I found a row of them visible in profile along the edge of a layer of blood that had got bent up. In this case they were like minute mammæ, spherules protruding so as to show the yellow hue without a dark border. They soon came to be the best evidence of the presence of blood, being seen under the microscope at regular distances, as marking the component corpuscles of the clot; and they persist as the last recognizable parts of disintegrating blood.

Not being able to find any reference to them in our own language, I was directed by my colleague, Professor C. F. W. McClure, to an article on them by A. Negri in the *Anatomischer Anzeiger* of 1899, p. 33. That article referred to their discovery and description by Petrone of Catania in 1897; and reported an examination of human and dog's blood, comparing the nucleated condition of the red corpuscles of the foetal blood with the non-nucleated condition in the adult. And after describing the form, aspect and position in the mature blood, of the bodies to which we may assign the name 'blood-nodules,' it described and figured a small body attached to the nucleus in the foetal blood; adding that this is the body which after

decay of the nucleus itself in mammals persists in the adult, and that it is not found in non-mammals.

After studying the account of Hæmoglobin, by Gangee in the first volume of Schaefer's 'Text-book of Physiology,' I attempted to apply the results of the chemical work and the spectroscopic examination by recent authors to the problem of the molecular constitution of the blood corpuscle. According to Hüffner and others the hæmoglobin molecule is, chemically speaking, very large, numbering 16,669 as its molecular equivalent; and the explanation of this largeness is that it carries one atom of iron, which, being itself heavy, 56, requires a large vehicle, just as a gunboat is large because it is to carry a heavy cannon. The final cause of this arrangement appears to be that the molecule of hæmoglobin may insorb a molecule of oxygen gas, becoming specially associated with its atom of iron, in the form of FeO_2 , receiving the charge of oxygen at the lungs, and afterwards discharging it into the tissues. This suggested the possibility of determining in an approximate way the absolute size of the molecule of hæmoglobin. I understand that this has not hitherto been done for any proteid; and the method here employed is general, and may be used wherever an organic substance combines in definite proportions with a gas.

Having measured the volume of the red blood-corpuscle, and taking 31 per cent. as its quantum of hæmoglobin, and 1.29 as the specific gravity (estimated from the whole corpuscle being about 1.09 sp. gr., of which 69 per cent. is water), I made out in milligrams the weight of the hæmoglobin for one corpuscle. Applying to this the well-established constant that one milligram of hæmoglobin insorbs 1.334 cubic millimeters of oxygen gas estimated at 0°C. and 760 mm. pressure, the product of these gave the volume of oxygen gas in-

sorbed by the single corpuscle as its full charge. Nernst's 'Theoretische Chemie' (1900, p. 394) gives the most reliable estimate of the number of molecules of oxygen, or any other gas, in a cubic millimeter at standard temperature and pressure. This is 55 thousand millions of millions (which may be written 55TMM). Calculated from this, the oxygen taken in by the single blood corpuscle as a full charge is found to be about 28 hundred millions of molecules. But as the combination is known to be regularly one molecule of the gas to one molecule of hæmoglobin, this result, or in round numbers three thousand millions, is approximately the number of hæmoglobin molecules in the blood-corpuscle (3 TM).

Dividing this last number into the volume of the hæmoglobin in a corpuscle, we obtain the volume of the cubic 'room' assigned by chemists to each molecule, and the cube root of this will give the length of the imaginary walls of said room, also nearly the diameter of the molecule regarded as a sphere in a solid state. The volume is approximately $1/10^{17}$ cubic millimeters, and the linear dimension of the side of a molecule 'room' is about $1/500,000$ of a millimeter. The 'rooms' of the oxygen molecules in the gaseous condition are much larger than these, because the gases rejoice in spacious apartments; in fact, the volume of gas which is insorbed by the blood is nearly twice as great as that of the devouring hæmoglobin.

Nernst states that by multiplying the absolute atomic weight of hydrogen upon the molecular formula of any proteid, we may obtain the absolute weight of the proteid. This involves, we think, the assumption that no condensation has occurred in building up proteid molecules. In order to test the rule by hæmoglobin, we find that this rule gives as the absolute molecular weight $1.35 \times (10)^{-17}$ of a milligram. By

the method of the quantitative absorption given above of oxygen the value comes out as $1.30 \times (10)^{-17}$ of a milligram. The two results differ by less than 4 per cent. This close harmony does not prove that the estimated weight of the atom of hydrogen is right, for it enters into both methods; but it does prove non-condensation, and also confirms the quantitative results of Hüffner and others as to the absorption of oxygen. It may be added that the oxygen absorbed is, when estimated in its fluid form, about $1/470$ the volume of the absorbing hæmoglobin.

But probably if the oxygen were examined in the liquefied or solidified condition, its molecular sphere of action would be found not to be so very widely divergent from its rightful proportion of 32 to 16,669.

PRINCETON UNIVERSITY.

SCIENTIFIC BOOKS.

Leçons sur les séries divergentes. Par ÉMILE BOREL, maître de conférences à l'École Normale Supérieure. Paris, Gauthier-Villars. 1901. Pp. vi+182.

La Série de Taylor et son prolongement analytique. Par JACQUES HADAMARD. Scientia, série physico-mathématique. Chartes, imprimerie Durand. 1901. Pp. viii+102.

These two works can appropriately be classed together, on account of both their authorship and their contents. Among the younger French mathematicians who have taken their doctors' degrees within the past dozen years none are to-day more conspicuous than Hadamard and Borel. Their theses were published in 1892 and 1894 respectively. A few years later both writers were recipients of prizes from the French Academy of Sciences. In 1896 Hadamard received the 'Prix Bordin' for his work on geodesics, while Borel won the 'Grand Prix des sciences mathématiques' in 1898 for his investigations upon divergent series. Recently also they have been bracketed in a list of nominees to fill a vacancy in the Academy of Sciences.

We have here to consider two representative

works. Each has the special interest that it is devoted to that branch of the theory of functions in which its author first attained distinction. Hadamard aims to give a concise, almost an encyclopedic, résumé of the present state of our knowledge concerning the analytic continuation of Taylor's series. Borel, on the other hand, gives a more detailed exposition of a single chapter of this subject, the divergent series. On this account his book will have the greater interest for the mathematical public and will be reviewed at somewhat greater length.

Two other works of equal size and somewhat similar character have been previously published by Borel, his 'Leçons sur la théorie des fonctions' (treating the 'Éléments de la théorie des ensembles et applications') and his 'Leçons sur les fonctions entières.' Together with the present work they form a unique series, embodying the results of much recent investigation in the theory of functions. It is indeed a piece of rare good fortune in any province of mathematics to have the important recent work thus promptly picked out and thrown into accessible form by such a mathematician as Borel. For this reason the publication of these lectures cannot be too warmly welcomed.

It is safe to say that no previous book upon divergent series has ever been written. Borel opens up a field of research which is still very new and promises rich reward to the investigator. In the process of evolution the divergent series has passed through several curious stages of development. At first a divergent series was accepted on faith and used with great *naïveté*. Thus Leibnitz, for example, when considering the expansion of $1/(1+x)$ into the series $1-x+x^2-x^3+\dots$ remarks that if $x=1$, the sum of n terms takes alternately the values 1 and 0, and the sum of the series must therefore be equal to the mean value $\frac{1}{2}$. After the introduction of exact analysis by Cauchy and Weierstrass such a loose mode of treatment could no longer be tolerated. The mass of inconsistencies to which it would lead was clearly perceived, and a divergent series was therefore considered by the mathematician to be meaningless, good for

nothing but to be thrown away. However, a few of the great mathematicians were visibly perturbed over the situation. Thus we find Cauchy complaining in 1821:

"J'ai été forcé d'amettre diverses propositions qui paraîtront peut-être *un peu dures*; par exemple, qu'une série divergente n'a pas de somme."

We know also that Abel was only prevented by his premature death from attacking the problem. But the view that a divergent series had no place in mathematical analysis soon became orthodox, and search after a legitimate basis for its use was abandoned. Nevertheless the astronomers, in utter disregard of this opinion, still continued to employ divergent series and to obtain from them a sufficient degree of approximation for practical purposes.

The impetus to a new mathematical treatment of the subject may be said to have come simultaneously from Stieltjes and Poincaré, although prior to this, in 1880, the legitimacy of the conclusion of Leibnitz had been established by Frobenius in a memoir which was suggestive of the beautiful theory developed later by Borel. According to the new view a divergent power-series is considered as having value in two distinct ways, either as enabling one to find an approximate value of some corresponding function (Poincaré and Stieltjes) or as a source of another algorithm which is convergent and therefore defines a proper function (Stieltjes, 1894).

The treatise of Borel begins with an interesting historical introduction. The body of the book can be divided roughly into four parts, which take up successively the four chief theories of divergent series; the asymptotic theory of Poincaré, the continued fraction theory of Stieltjes, the theory of Borel—characterized by the use of definite integrals containing a parameter z —, and, finally, the theory of Mittag-Leffler. The crowning achievement is without doubt Borel's own work, and his presentation of it is the most interesting feature of the book. No adequate idea, however, of the treatment of Stieltjes can be obtained without direct reference to the famous memoir of 1894, as Borel frankly

states. This inadequacy of presentation is offset by the addition of an important supplement which Borel himself contributes to the theory of Stieltjes. We regret the omission of the method of Lindelöf. Its dismissal with a half dozen lines and without even a reference to his article in the *Acta Societatis Fennicae* is possibly due to a certain haste in preparation which we have fancied we have detected in several places. While the method of conformal representation (or transformation of the variable) which Lindelöf employs has been applied only to a restricted class of divergent series, it seems probable that it could be developed so as to give a more general theory.

On account of its somewhat abstract character Borel's treatise will probably be of greater interest to the pure mathematician than to the astronomer or student of applied mathematics. Few applications of the various theories have been given, probably because but few applications have yet been made, except in the case of the asymptotic theory of Poincaré. The author leaves us in some uncertainty as to how far his own theory has been carried and applied to differential equations. We hope that in a subsequent edition 'the important applications will be more fully developed.

We turn now to the little book of Hadamard. This is one of a series of short monographs published under the general title 'Scientia' and devoted to the 'Exposé et développement des questions scientifiques à l'ordre du jour.' The special topic taken up by Hadamard, as has already been stated, is the analytic continuation of a power-series, $a_0 + a_1z + a_2z^2 + \dots$. In the consideration of this question two problems of the greatest importance and difficulty present themselves. These are: (1) The determination of the nature and position of the singular points of the analytic function defined by the series, and (2) the calculation of the value of the function at points exterior to the circle of convergence.

Hadamard has had the extremely difficult task of compressing into a few pages what has been done on these problems. In this he

has succeeded admirably. It is extraordinary what an amount of information is packed away in the space of one hundred pages. Yet the work is no dry compilation of facts. Nowhere is the skill of the author more fully shown than in the manner in which he has woven his materials together. The theorems are analyzed, their significance is pointed out, and their demonstrations are outlined sufficiently to show the manner in which the subject is treated. Attention should also be called to the excellent bibliography with which the book opens and to which reference is constantly made. In correlating the one hundred and fifty memoirs here included Hadamard has performed a very important service. His admirable report is not suited to the reader who has little acquaintance with the general subject, but to the specialist and investigator it will be invaluable.

E. B. VAN VLECK.

The Elementary Principles of Chemistry. By A. V. E. YOUNG, Professor of Chemistry in Northwestern University. New York, D. Appleton & Company, 1901.

This book differs so radically from those in general use that if reviewed at all, it must be at some length. The author has used this method successfully for thirteen years; his object being to instruct the student during the first year by this method, which he calls the quantitative method. He says that its inception is due to Professor Josiah P. Cooke, of Harvard; he believes it 'both scientifically and pedagogically an improvement on prevailing methods.' The presentation of a topic in the text is to be studied by the student after performing the laboratory experiment illustrating the same.

The first 97 pages of the book are devoted to the physical and chemical properties of substances and to simple theoretic chemistry, including the fundamental quantitative laws of chemical action, the gas laws, atomic and molecular theory, kinetic theory of gases, structure and stereoisomerism. The author lays particular stress on the quantitative laws, and also on the laws of Gay Lussac, Dulong and Petit, Mitscherlich and Raoult, as illus-

trating the relation between equivalent weights and certain specific properties. The remainder of the book (147 pages) is 'On the relation between the properties of the elements in general and their combining weights; description of the first twenty-five elements and some of their compounds.' These elements are those comprised in the first three horizontal series of Mendeléeff's chart of the periodic system. The properties of the commoner elements of this selection and their compounds are described in considerable detail. Here the book proper ends. A second part (106 pages) gives the experimental illustrations and instruction in details of laboratory work. The book is illustrated by full-page portraits of many of the chemists and physicists mentioned.

This is indeed a different treatment from that commonly followed. A course in chemistry in which copper, mercury, silver and lead are ignored, while beryllium and cobalt find consideration is not common. Yet this does not prove that it is wrong. The author lays chief stress on general laws. The student's comprehension of a law is based on a roughly quantitative experiment illustrating it which he performs before studying the law. The experiments merit attention; they are well devised and easy to perform. The author illustrates these laws further by the behavior of a number of elements, including important metals, and most of the important acid-forming elements.

It is not the object of a college course in science to form specialists, and the question may be fairly asked whether the mental discipline and the capacity to pursue the study of chemistry afforded by this method are not of equal value, or (as the author believes) of greater value than can be obtained by the prevailing method. To those who agree with the author this book should be welcome.

The book has one grave defect, in omitting all mention of electrolytic dissociation. The author anticipates criticism in a passage on page eight of a pamphlet called 'Suggestions to Teachers' which accompanies the book; he says: 'Some perhaps would wish to include osmotic pressure and the electrical phenom-

ena of conductivity, etc., together with the theory of ionization, but I have judged it impracticable to illustrate these phenomena experimentally without displacing other matter or going beyond the reasonable scope of one year's work.' To this the obvious answer is, that with our present knowledge it would be better to displace other matter, if need be, than to omit anything so fundamental and so easy of illustration as electrolytic dissociation, from a book called 'Elementary Principles of Chemistry.' With the hope that this gap may be filled in the next edition, the reviewer commends Professor Young's book to the attention of college and advanced high school teachers, who will find it suggestive.

E. RENOUF.

Studies in Evolution. By CHARLES EMERSON BEECHER. New York, Charles Scribner's Sons. 1901.

This is a notable volume. It is one of the series of the Bicentennial Publications of Yale University, and consists mainly of reprints of occasional papers selected from previous publications of the Laboratory of Invertebrate Paleontology, Peabody Museum. The most important are those on the structure and development of trilobites, and the 'Studies in the Development of the Brachiopoda.'

The aim of the first essay, 'On the Origin and Significance of Spines,' is an attempt, in the terms of ontogeny, phylogeny and chronology, to apply the general law of evolution to the spines of plants and animals. The discussion is a very interesting one, and we think Dr. Beecher satisfactorily shows from a great number of cases discovered by numerous observers that spines are a characteristic of the old age, both of the individual and of the type. In old age the organism, during the senescence of the type, 'blossoms out with a galaxy of spines, and with further decadence produces extravagant vagaries of spines, but in extreme senility comes the second childhood, with its simple growth and the last feeble infantile exhibit of vital power.'

We are inclined to think that the author is a little too hospitable to Wallace's notion that spines on desert plants may originate from

the attacks of snails and browsing cattle. Our observations in the North African area, from Morocco to Egypt, on the edge of the Sahara in southern Algeria, and in Palestine, lead us to fully endorse the view of the Rev. Dr. Henslow, that in desert areas where plants are especially spiny or thorny, there are few snails, and a general absence of cattle. Over a century ago Pallas, and afterwards L. Ragner, in a paper published in 1792 (II., p. 101) in the very rare *Journal d'Histoire Naturelle*, edited by Lamarck and others, attributed the spiny growth of desert plants to the dryness of the soil. His observations appear to have been entirely overlooked by modern writers. A second article (p. 354), written by De Ramatuelle, is thoroughgoing in its evolutionary tone, barring perhaps the speculations as to the origin of the spines from 'germes particuliers.'

Professor Beecher's splendid discovery of the nature of the appendages of trilobites and of other important points in their anatomy has entitled him to the lasting gratitude both of paleontologists and zoologists. This reprint of his original papers and illustrations is very opportune. It is possible, however, that the last word has not been said as to the nature of the larval trilobites or as to the position of the trilobites in nature. How the protaspis stage of trilobites can be likened to the nauplius of crustacea, and why trilobites should be placed among crustacea, we do not understand. That the presence of antennæ necessarily obliges us to regard trilobites as crustacea, when all the succeeding appendages of the body are of the same general type, not being differentiated into specialized mandibles, maxillæ, maxillipedes, thoracic and abdominal legs, as they are in Crustacea, including the Phyllopora (though in them the appendages of the trunk are alike), does not seem logical. We would prefer to regard the trilobites, merostomes and Arachnida as members of a phylum quite distinct from that of the Crustacea. Is it not probable that the rather artificial phylum of Arthropoda will eventually have to be divided into three phyla? The resemblances in trilobites to Crustacea seem to us to be a case of convergence. The

papers on Brachiopoda are likewise of great interest and value, and are crowded with valuable suggestions. The line of thought is largely based on the work of the late Dr. A. Hyatt, whose philosophical and scholarly methods have had such a happy and fruitful influence on the new generation of paleontologists.

A. S. PACKARD.

SOCIETIES AND ACADEMIES.

THE AMERICAN PHILOSOPHICAL SOCIETY.

THE scientific program of the general meeting to be held next week is as follows:

Thursday, April 3, 10:00 o'clock.

'The President's Address': Gen. ISAAC J. WISTAR.

'Origin of the Oligocene and Miocene Deposits of the Great Plains': Professor JOHN B. HATCHER, of Pittsburg.

'The Upper Cretaceous and Lower Tertiary Section of Central Montana': Mr. EARL DOUGLASS, of Princeton.

'Evolution and Distribution of the Proboscidea in America': Professor HENRY F. OSBORN, of New York.

'On South American Mammals': Professor WILLIAM B. SCOTT, of Princeton.

'The Mammals of Pennsylvania and New Jersey': Mr. SAMUEL N. RHOADS, of Audubon, N. J.

'The Identity of the Whalebone Whales of the Western North Atlantic': Dr. FREDERICK W. TRUE, of Washington.

Afternoon Session, 2:00 o'clock.

'On the Molluscan Fauna of the Patagonian Formation': Dr. H. VON IJERING, of São Paulo, Brazil.

'A Comparison Between the Ancient and Recent Molluscan Fauna of New England': Professor EDWARD S. MORSE, of Salem, Mass.

'Distribution of Fresh Water Decapods and its bearing upon Ancient Geography': ARNOLD E. ORTMANN, Ph.D., of Princeton.

'Systematic Geography': Professor WILLIAM MORRIS DAVIS, of Cambridge, Mass.

'On Drift Casks in the Arctic Ocean': Mr. HENRY G. BRYANT, of Philadelphia.

'The Isthmian Canals': Professor LEWIS M. HAUPT, of Philadelphia.

8:00 o'clock at the Free Museum of Science
and Art.

'The Relation of the American University to Science': President HENRY S. PRITCHETT, of Boston.

'The Advancement of Knowledge by the Aid of the Carnegie Institution': President DANIEL C. GILMAN, of Baltimore.

Friday, April 4, 10:00 o'clock.

'Historical Investigation of the Supposed Changes in the Color of Sirius since the Epoch of the Greeks and Romans': T. J. J. SEE, Ph.D., of Washington.

'Recent Progress in the Lunar Theory': Professor ERNEST W. BROWN, F.R.S., of Haverford, Pa.

'On a New Method of Transiting Stars': Professor MONROE B. SNYDER, of Philadelphia.

'On the Evolution of Martian Topography': Mr. PERCIVAL LOWELL, of Flagstaff, Arizona.

'Results of Observation with the Zenith Telescope at the Sayre Observatory': Professor CHARLES L. DOOLITTLE, of Philadelphia.

'On the Spectra of Gases at High Temperature': Professor JOHN TROWBRIDGE, of Cambridge, Mass.

'On Some Equations pertaining to the Propagation of Heat in an Infinite Medium': Professor A. STANLEY MACKENZIE, of Bryn Mawr, Pa.

Afternoon Session, 2:00 o'clock.

'The Direction of Evolution in Color-Marks in Rock Pigeons': Professor CHARLES O. WHITMAN, of Chicago.

'On Biological Heredity and Organic Evolution': Professor GIUSEPPE SERGI, of Rome, Italy.

'Is Scientific Naturalism Fatalism?' A one-minute paper: Professor WILLIAM KEITH BROOKS, of Baltimore.

'On *Dichotoma*, a new genus of Hydroid Jelly-Fish': Professor WILLIAM KEITH BROOKS, of Baltimore.

'On the Continuity of Protoplasm': Professor HENRY KRAEMER, of Philadelphia.

'Further Experiments on the Physiological Action of Ions': Dr. JACQUES LOEB, of Chicago.

'The Embryology of a Brachiopod': Professor EDWIN GRANT CONKLIN, of Philadelphia.

'Relationship of the Gordiacea': Professor THOMAS H. MONTGOMERY, JR., of Philadelphia.

'The Spermatogenesis of *Oniscus Asellus* Linn., with especial reference to the history of the Chromatin': M. LOUISE NICHOLS, Ph.D., of Philadelphia.

Saturday, April 5, 10:00 o'clock.

'The International Catalogue of Scientific Literature': CYRUS ADLER, Ph.D., of Washington.

'A Classification of Economics': Professor LINDLEY MILLER KEASBEY, of Bryn Mawr, Pa.

'Experiments on Cytolysis': Professor SIMON FLEXNER, of Philadelphia.

'On Osteitis Deformans': Professor JAMES C. WILSON, of Philadelphia.

'The Influence of Acute Alcohol Intoxication upon Certain Factors involved in the Phenomena of Hæmolysis and Bacteriolysis': Professor A. C. ABBOTT, of Philadelphia.

'Blindness from Congenital Malformation of the Skull': CHARLES A. OLIVER, M.D., of Philadelphia.

'Race Elements in American Civilization' (illustrated by German Examples): Professor M. D. LEARNED, of Philadelphia.

THE AMERICAN ELECTRO-CHEMICAL SOCIETY.

ARRANGEMENTS for the first general meeting of the American Electro-chemical Society, to be held at Philadelphia on April 3, 4 and 5, are as follows:

Thursday afternoon, April 3, 2 P.M. Visits to places of interest.

Thursday evening, April 3, 8 P.M., at the Manufacturer's Club, inaugural meeting. This meeting will be devoted to the organization of the Society, adoption of a constitution and by-laws, election of officers, determining times and places of future meetings, discussing the question of publishing the transactions, etc.

Friday morning, April 4, 9 A.M., at the lecture hall of the John Harrison Laboratory of Chemistry of the University of Pennsylvania. Reading and discussion of the following papers:

'A University Course in Electro-chemistry': Professor JOSEPH W. RICHARDS, Ph.D., Lehigh University, Bethlehem, Pa.

'Electrodes': CLARENCE L. COLLINS, 2d, Niagara Falls, N. Y.

'Note on the Gladstone Tribe Couple': Professor WILDER D. BANCROFT, Ph.D., Cornell University, Ithaca, N. Y.

'The Nascent State': C. J. REED, Philadelphia, Pa.

'The Electrolytic Reduction of Lead': PEDRO G. SALOM, Ph.D., Philadelphia, Pa.

'Electrodeless Conduction in Electrolytes':
CARL HERING, Philadelphia, Pa.

'On the Electrolysis of Sodium Nitrate and the Composition of the Developed Gases': C. W. VOLNEY, Ph.D., Keyport, N. J.

Professor CHAS. A. DOREMUS, M.D., Ph.D.,
Subject to be announced.

Friday afternoon, April 4, 2 P.M., at the
John Harrison Laboratory.

'Current Electro-chemical Theories': Professor
LOUIS KAHLBERG, Ph.D., University of Wisconsin,
Madison, Wis.

'A Zinc-Bromine Storage Battery': HERBERT
H. DOW, Midland, Mich.

'Continuous Electrolysis of Solutions of
Metals': N. S. KEITH, Ph.D., New York City.

'A Method of Electrolytic Production of Zinc
from its Ores': SAMUEL S. SADTLER, Philadelphia,
Pa.

'The Electrolytic Rectifier': Professor C. F.
BURGESS, University of Wisconsin, and CARL
HAMBUECHEN, Madison, Wis.

'On the Relative Speed of the Ions in Solutions
of Silver Nitrate in Pyridine and Aceto-nitrile':
HERMAN SCHLUNDT, Ph.D., Madison, Wis.

'Fall of Potential in Electrolytes': CARL HER-
ING, Philadelphia, Pa.

'Caustic Alkalies and Chlorine by the Dry
Electrolytic Process': CHAS. E. ACKER, Niagara
Falls, N. Y.

Friday evening, April 4, after 8 P.M., at the
Manufacturer's Club, 1409 Walnut Street.
Informal reception.

Saturday morning, April 5, 9 A.M., at the
John Harrison Laboratory. Reading and
discussion of the following papers:

'On a New Type of Electrolytic Meter': KON-
RAD NORDEN, Ph.D., New York City.

'The Reversible Copper Oxide Plate': WOOLSEY
McA. JOHNSON, Hartford, Conn.

'A Thermodynamical Note on the Theory of the
Edison Battery': E. F. ROEBER, Ph.D., Philadel-
phia, Pa.

'Electrolysis of an Aqueous Solution by Alternat-
ing Current': Professor JOS. W. RICHARDS,
Ph.D., Lehigh University, Bethlehem, Pa.

'The Atom of Electro-chemistry': ARVID
REUTERDAHL, Providence, R. I.

Saturday afternoon will be devoted to visits
to places of interest.

THE GEOLOGICAL SOCIETY OF WASHINGTON.

At the meeting of the Society on February
26, the first paper, by Mr. T. W. Vaughan, was
entitled 'Earliest Tertiary Coral Reefs in the
Antilles and United States.' Mr. Vaughan
made a few remarks in order to indicate when,
during Tertiary time, the physical conditions
in the regions mentioned in the title of his
communication first became suitable for the
formation of coral reefs. A few species of
reef-building genera occur in the Midway
(basal Eocene) beds of Alabama, and taken as
a whole the Eocene corals of the United States
characterize only moderately deep or shallow
water; but strictly speaking, no Eocene coral
reefs are known in the United States. Reef-
building genera occur in the Vicksburgian
(Lower) Oligocene at Vicksburg, Mississippi.
The temperature of the water was at least sub-
tropical and the depth was not great, probably
not too great for the formation of reefs; but
some other condition, probably such as muddi-
ness of water, prevented their formation. The
Coral limestone at Salt Mountain, Alabama,
is a coral reef limestone, but its precise strati-
graphic position has not been determined. It
is either uppermost Lower Oligocene or basal
Upper Oligocene. The Upper Oligocene in the
United States was initiated by an extensive
development of coral reefs. They occur in
southwestern Georgia along the Flint River,
the Tampa silex beds of Tampa, Florida, and
at numerous other localities in Florida. The
fauna is rich in genera, species and individ-
uals. Reefs of the same age are very abun-
dant in the Antilles. They occur in Cuba in
the vicinity of Havana, Matanzas, Santiago
and other places. They probably are present
in the island of Haiti. Other islands in which
Upper Oligocene rocks exist are Porto Rico,
Antigua and Arube (Dutch West Indies).

There are no Miocene coral reefs in the
United States, the temperature of the water
being too cold. The species of corals known
grew in water only a few fathoms in depth.
It is not at present known whether or not
Miocene reefs existed in the West Indies.
Apparently during Miocene time the Antilles
stood much higher than at present; therefore

if any did exist they would at present be submerged.

Pliocene reefs were extensively developed along the Florida coast, for instance, along the Caloosahatchee River. The genera of the Pliocene corals are the same as those at present living in the Floridian and Antillean seas, but often there are appreciable specific differences between the Pliocene and recent representatives of the same genus.

Mr. Bailey Willis spoke on the 'Conditions of Overthrust in the Northern Rockies.' After restating the facts relating to the overthrust of Algonkian strata upon Cretaceous with a displacement of more than seven miles, along the eastern flank of the northern Rocky Mountains in northwestern Montana, Mr. Willis presented a hypothesis of origin and development of this structure. It is assumed that in Cretaceous time Algonkian strata in this region were essentially flat, and in consequence of subsidence were buried under Dakota and Pierre sediments, with a shore line not far from the position of the present mountain range. Algonkian strata beneath the marine area being depressed and beneath the land area being raised, they were bent parallel to the general trend of the shore. When later the strata were compressed, the initial bend determined an anticline in this same position. Erosion of the arch cut deeply into Algonkian beds and left the edges exposed and free to move. Continued compression resulted in their being thrust upward and northeastward upon the eroded surface, until Algonkian limestones came to rest upon Cretaceous areas. The structure closely resembles the Rome fault, Georgia. The date of development is inferred to have been early Tertiary.

Mr. F. E. Matthes presented a paper on 'Glacial Erosion in the Northern Rockies.' The range was shown to have been deeply dissected before the advent of the glaciers. The valleys were nearing maturity and had low gradients; the glaciers which subsequently occupied them had therefore but little fall from their sources to their distal ends. They moved slowly and were of considerable thickness. The lengths of the various trunk

glaciers were small in proportion to the large névé areas which they drained.

The frequent occurrence of many valleys radiating from one point was shown on the map. The effect of this arrangement upon the valley glaciers was shown to have been a general retardation of their flow and a consequent increase in thickness above their junction. Some attained a thickness of over 3,000 feet in some parts of their course.

The radiating system of ravines at the heads of valleys was shown to be particularly favorable to the development of cirques. At least two sets of cirques at different elevations are found in these mountains, indicating oscillations of the névé line to as low as 6,000 feet altitude.

The definitions of the snow line as given in three text-books now in use were compared and found to be greatly at variance with each other. A new definition was favored in which the topographic element is given due weight, and which makes the snow line virtually coincident with the névé line as found on glaciers.

The tendency of glaciers to flatten the grades of their channels, beginning at the upper ends, was shown to be productive of the step-like profiles of glaciated valleys. The cause of this tendency was sought in certain motions in the interior of the glaciers, the explanation of which was not attempted.

The widening of the valleys by cliff recession was emphasized as an important factor in producing discordance between valleys. Discordance was shown to be produced by (1) deepening of main valley, (2) widening of main valley; and to be diminished by (3) deepening of side valley. Cases were pointed out on the contour maps of valleys meeting with discordances ranging between 300 and 1,500 feet; also of several meeting with perfect accordance. Nor were the discordances always in inverse ratio to the drainage areas of the respective valleys.

The conclusion was reached that in no case could the discordance of a side valley be taken as a measure of the deepening of the main valley.

ALFRED H. BROOKS,
Secretary.

NEW YORK ACADEMY OF SCIENCES.

PUBLIC LECTURE.

ON February 26 a public lecture was presented under the auspices of the Section of Biology, by Professor Bashford Dean, of Columbia University, entitled 'Journeys of a Naturalist through Japan and the Philippines.'

Professor Dean referred to the zoological relations of the Japanese archipelago with the adjacent continent on the one hand, and with the island series on the other—*i. e.*, (1) the Aleutian, (2) through the Bonin Islands with the region of New Guinea, and (3) through the Liu Chiu Islands with Formosa and the Philippines. The importance of the line of Blakiston separating the Hokkaido from the southern islands was emphasized.

Especial attention was called to the favorable facilities for zoological work which are offered in the region of Misaki, near the mouth of the Bay of Tokyo, and to the work of the Marine Laboratory of the Imperial University in this region. Dr. Dean had an opportunity of examining the centers of animal artificialization, an art in which the Japanese have been so eminently successful. Especially praiseworthy is the method of oyster-culture practiced in the Inland Sea near Hiroshima; hardly less interesting were the establishments in which varieties of gold fish are propagated; and even more striking were those for the cultivation of the breed of Tosa fowls, in favorable specimens of which the tail feathers attain the great length of fifteen feet. Success in the maintenance of this breed appears to be due to the selection of those fowls in which moulting occurs irregularly, and the effort is made to entirely suppress the moult in that region of the fowl where long feathers are to be produced. In referring to a journey in the Philippines, Professor Dean described many interesting experiences, particularly those at Maujujod, where living specimens of *Nautilus* were obtained.

HENRY E. CRAMPTON,
Secretary.

THE ACADEMY OF SCIENCE OF ST. LOUIS.

At the meeting of the Academy of Science of St. Louis on the evening of February 17, Dr. Gellert Alleman, of Washington University, delivered an address on 'The Chemical Constitution and the Manufacture of Portland Cements.' The growth of the cement industry was treated, the various steps of development being shown by lantern slides illustrating past and present types of machinery employed in its manufacture. Several slides were shown giving tabulated results of a number of analyses of different commercial Portland cements.

Mr. Charles Espenschied read a letter from Mr. Seymour Carter, of Hastings, Minnesota, in which was described a method of Professor Anderson, of Columbia University, by which it was stated that cereals could be directly transformed to food-stuffs. The process consists of enclosing the cereal to be treated in a hermetically sealed vessel and subjecting it to a temperature of about 450° F. for a certain time, and immediately thereafter opening the vessel, when it is found that the grains expand to six or eight times their normal size. The inventor states that the process does not alter the composition of the cereal. Samples of several cereals treated in this manner were shown.

Two persons were elected to active membership.

WILLIAM TRELEASE,
Recording Secretary.

THE TORREY BOTANICAL CLUB.

At the meeting of the Club on January 29, the first paper was by Dr. Britton, entitled, 'Notes on the Crassulaceæ,' and is to appear in print, being a part of a contribution toward the projected 'Systematic Botany of North America.' Remarks followed by Dr. C. C. Curtis, Dr. Rydberg, Dr. Small, Dr. MacDougal and Mrs. Britton. The distribution of the Crassulaceæ was commented on, Dr. Britton speaking of the isolated colonies of high mountain species, which seem to have been continuously highly interbred, so producing highly specialized species.

The second paper, by Mr. F. S. Earle, entitled, 'New Genera of Fungi,' founded on rep-

representatives from California and New Mexico, will soon appear in the Garden *Bulletin*.

Dr. Earle also exhibited a rosebush from under glass at the Garden, the roots of which have been attacked by a fungus now under examination and cultures of which were exhibited. The mycelium was abundant in the fibrous roots; also in the bark and cambium immediately above ground, and had caused sudden yellowing and dropping of the leaves.

Dr. MacDougal recalled the suggestion that potatoes are the result of fungal infection of the underground stem; it is said that no one has ever examined a potato tuber without finding fungus traces in it. In many cases of precocious blooming among both wild and cultivated plants, the cause is stimulus from similar infection.

Dr. MacDougal also exhibited specimens of two remarkable Alpine xerophytes from an altitude of 4,000 feet on New Zealand mountains, known as vegetable-sheep, *Raoulia* and *Haastia*, composites between which belongs *Gnaphalium* in order of affinity.

Dr. Rydberg spoke of a Rocky Mountain phlox with similar growth in cushion-like masses.

Mrs. Britton reported on the progress of her studies of a *Vittaria* collection made by Dr. Britton at St. Kitts, and exhibited drawings, and the present indication that two different specific names have been in use for different stages of the same life-history.

EDWARD S. BURGESS,
Secretary.

THE NORTHEASTERN SECTION OF THE AMERICAN
CHEMICAL SOCIETY.

THE regular monthly meeting of the Section was held on February 27 in the physics lecture room of the Massachusetts Institute of Technology, Professor L. P. Kinnicutt presiding. Professor Henry P. Talbot addressed the Society on 'The Recorded History of the Members of the Argon Group.' The general history, the methods of isolation and identification of these gases, together with their physical properties, and their position in the periodic system were all carefully reviewed up to the present time.

HENRY FAY,
Secretary.

THE ONONDAGA ACADEMY OF SCIENCE.

THE Academy met in the historical rooms in Syracuse on Friday, Feb. 21, 1902. Dr. W. M. Beauchamp gave the presidential address on the 'Peopling of Early America.' He gave a résumé of the early investigations, touching briefly on the different theories proposed, and emphasizing the fact that the answer to the problem lies in the researches into the languages, customs and manners of the present nations and the archeological remains. Dr. Beauchamp gave many interesting items from his extended observations on the native tribes of New York State.

T. C. HOPKINS,
Corresponding Secretary.

DISCUSSION AND CORRESPONDENCE.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT
OF SCIENCE: ANTHROPOLOGY.

THE fifty-first meeting of the American Association for the Advancement of Science will be held at Pittsburgh, Pa., on June 28 and July 3, 1902. Mr. Stewart Culin, of the University of Pennsylvania, will preside over the Section of Anthropology.

Anthropologists are cordially invited to attend and contribute papers upon subjects connected with their fields of research. Several members of the Section have informally expressed the desire that some special effort should be made by the museum and field workers of the Section to present papers on the collections of importance with which they are familiar.

In order that a preliminary sectional program may be distributed in advance of the meeting, titles of communications should be sent to the secretary as soon as possible. Abstracts of papers, or the papers themselves, may be sent later at the convenience of the authors, who are reminded that no title will appear in the final program until the paper, either in full or in abstract, has been passed upon by the sectional committee.

HARLAN I. SMITH,
Secretary of Section H, Anthropology.
AMERICAN MUSEUM OF NATURAL
HISTORY, NEW YORK.

FELIS OREGONENSIS RAF. AGAIN!

IN his recent 'Revision of the Pumas' (*Proc. Wash. Acad. Sci.*, pp. 577-600), Dr. C. Hart Merriam devotes over a page to the inapplicability of the above name and to censuring my action in bringing it forward to replace *F. hipposlestes olympus* given by himself in 1897. He states that it is a 'fallacious interpretation of our principles of nomenclature' to replace a name well characterized and accompanied by definite type and locality, by an older one deficient in these respects. This statement will, I think, be questioned by many zoologists who have erred in this way more than I.

Personally, I would be only too glad to throw out of consideration all the names proposed by Rafinesque and others of his time, as it would save us a deal of trouble, but if we recognize the principles of priority I see no excuse for such action, and such questions as the present one resolve themselves entirely into a consideration of the applicability of the older name.

This is largely a matter of individual opinion and in the absence of any tribunal for the consideration of a uniform nomenclature for our mammals individual preference will prevail. However a few words regarding Dr. Merriam's stand may not be out of place.

In Rafinesque's first paper he undoubtedly has in mind the *Felis concolor* group, that will be admitted on all hands.

In his second paper he names a variety of the puma (as mentioned in the first paper) from northwestern United States (Oregon by implication). The absence of a definite type locality in no way invalidates the name if otherwise satisfactorily diagnosed. We have many names now in use with just as vague type localities.

The description is very brief, but as good as many other early diagnoses and to my mind clearly indicates the same animal later characterized by Dr. Merriam. Moreover, I do not think it is 'grossly incorrect.'

Rafinesque says 'Dark brown, nearly black on the back, belly white.'

Dr. Merriam says 'Dark rufous brown, darkest along middle of back, backs of ears black,

tip of tail blackish, breast and inguinal region soiled whitish, anterior part of throat white.'

Rafinesque had no 'manual of colors' and was of course not as exact as our present-day systematists, but it seems to me that his description is sufficiently accurate.

As to Dr. Merriam's argument that he probably never saw a specimen of the animal, we have positively no evidence one way or the other, and the fact does not affect the validity of the name nor do Dr. Merriam's further remarks about the other unrecognized cats that Rafinesque speaks of. The descriptions of *Cervus macrourus* and *C. hemionus* of the same author which are recognized and adopted by Dr. Merriam are associated with a lot of unidentifiable descriptions, and are admittedly based upon descriptions of travelers, while the diagnoses are no better than that of *Felis oregonensis*. If one stands, so should the others, in my estimation.

I might add that, so far as I am aware, every one who has written on this puma since my note appeared in SCIENCE has followed my views, even Dr. Merriam himself, who adopted the name *oregonensis* without comment, in his 'Biological Survey of Mt. Shasta' (p. 104).

As to the statement that no name based on hearsay accounts of travelers would be accepted if published to-day, we might suggest some recent cases that come pretty near to this, such as *Equus johnsoni*, which was based upon hearsay accounts of native Africans and two strips of skin, and *Macrius amissus* (SCIENCE, December 13), on a photograph and regretful recollections of a fish that was lost overboard after having been captured!

WITMER STONE.

ACADEMY OF NATURAL SCIENCES,
PHILADELPHIA, PA.

A VERY SENSITIVE THERMOSTAT.

FOR many forms of scientific investigation constancy of temperature is required. Such constancy may be secured, within a few hundredths of a degree, by several types of thermostat. For certain inquiries undertaken by the writer relative to the so-called 'critical' phenomena of liquids and gases, a much greater degree of accuracy was necessary.

To meet this demand, a thermostat was devised, of which a description will shortly appear in the *Journal of Physical Chemistry*. The regulator of this instrument functionates so perfectly that the temperature can be kept continuously at the same thousandth of a degree for hours at a time. It is so constructed moreover as to be capable of adjustment, within one or two hundredths of a degree, to any desired temperature over a range of about fifty degrees.

The most important factors which make such fineness of regulation possible are the following:

1. An extremely efficient circulation in the bath, which eliminates all local differences of temperature large enough to be readable.

2. Such a construction of the regulator that the expansive medium feels each minutest change of temperature and reacts promptly to it.

3. Provision for supplying the bath at all times with just the amount of heat needed, and no more. The regulation does not consist in alternately admitting and shutting off the inflow of heat, but in a 'throttling' of the same.

The extreme accuracy of function mentioned above is naturally obtained only when the thermostat is shielded from sudden changes of radiation. But excellent results are possible without such protection. Without the use of any insulation whatever, the bath can be held at a temperature of thirty or forty degrees within a hundredth of a degree.

W. P. BRADLEY.

WESLEYAN UNIVERSITY.

SCIENTIFIC NOMENCLATURE.

TO THE EDITOR OF SCIENCE: In SCIENCE for March 21, I find an article on 'Scientific Nomenclature,' by Mr. Frank W. Very, which concludes with the following words:

Scientific descriptions remain unintelligible to the lazy man who hates to use the dictionary. They are free property to all who are willing to take this trouble.

On other pages of SCIENCE for March 21 (pp. 458 and 459), I find the words 'ecology' and 'ecological.' As I had never seen them

before, I said to myself: 'Here is my chance to vindicate Mr. Very's judicious hint about the lazy man and the dictionary.' So I turned to the Century dictionary, but did not find ecology or ecological. I next had recourse to the new English dictionary of Murray, without success, and then to the new edition of Webster, published the present year. None of these contain the words above mentioned. Recourse to Liddell & Scott's Greek lexicon was equally unavailing. I am moved, therefore, to ask you for an explanation of this new term.

HORACE WHITE.

NEW YORK,
March 22, 1902.

[Ecology has doubtless been coined from the same word as economics, being the branch of zoology or botany that is concerned with the dwelling place or distribution of animals or plants. It will probably come as a shock to biologists to learn that this word is not to be found in recent dictionaries, as it is used in elementary books and courses. The word appears to be post-Darwinian; perhaps some reader can tell us when and where it was first used.—EDITOR.]

BOTANICAL NOTES.

A POPULAR BOOK ON TREES.

WHATEVER tends to popularize a knowledge of our trees is to be commended. Any book which induces a considerable number of people to give more attention to the structure and habits of trees deserves our hearty approval. It is true that too often these popular books are so full of blunders that the scientific man is constantly irritated as he runs over the pages, and as a consequence he is too often unable to see the great body of valuable matter hidden beneath the superficial errors. We have had within the last year or two a number of useful books dealing with plants of various kinds from mushrooms and ferns to wild flowering herbs, shrubs and trees. Now, another book is brought out by Knight and Millet, of Boston, under the title of 'Studies of Trees in Winter,' by Annie Oakes Huntington, with an introduction by Professor Sargent. The fact that so eminent a botanist

has thought it worth his while to write an introduction to the book at once bespeaks our good opinion. A glance at the pages is sufficient to show that in this we are not mistaken. There is, first, a short chapter giving such information as is necessary in the study of the tree in winter, followed by fourteen chapters on groups of trees, as 'The Horse-chestnut' (including also the Ohio buckeye), 'The Maples' (including seven species), 'The Ashes' (four species), 'The Walnuts and Hickories' (six species), etc. The illustrations are exquisite, consisting of 'half-tone' reproductions of characteristic photographs. The colored plates are especially fine, that of a cross-section of an oak trunk being really so perfect that one must run his hand over the plate to convince himself that it is not an actual section of the wood. While the book is printed and bound in a style quite too elegant for a text-book for schools, the subject matter is well adapted for such usage. A less expensive edition for schools should be brought out by the publishers, and in such form it should have wide use in the public schools.

GATTINGER'S FLORA OF TENNESSEE.

It speaks well for a state when its legislature authorizes the publication of a book on technical botany. This was done a little less than a year ago by the legislature of Tennessee in 'an act for the acceptance by the state of a work on botany prepared by Dr. A. Gattinger, and to make an appropriation for its publication and distribution.' The result is before us in the form of a neatly printed book of nearly three hundred pages. That the pages are marred by too many typographical slips is not the fault of the generous-minded men who made provision for its publication, nor of the venerable author, but of the inexperienced printer, to whom much of what he put into type must have been quite unintelligible. The book opens with about twenty pages of prefatory matter, in part historical; the remainder is devoted to a discussion of regional distribution of plants, and this is followed by about 160 pages devoted to an annotated list of the Pteridophyta and Spermatophyta of the state. Following this are
