Red Cornelian. Take of the compoſitions mentioned under *Colouring of* GLASS two pounds; of glaſs of antimony one pound; of the calcined vitriol called *ſcarlet oker* two ounces; and of manganeſe one dram. Fuſe the glaſs of antimony and manganeſe with the compoſition; then powder them, and mix them with the other, by grinding them together, and fuſe them with a gentle heat.

White Cornelian. Take of the compoſition juſt referred to two pounds; and of yellow oker well waſhed two drams; and of calcined bones one ounce. Mix them, and fuſe them with a gentle heat.

Diamond. Take of the white ſand ſix pounds; of red-lead four pounds; of pearl aſhes purified three pounds; of nitre two pounds; of arſenic five ounces; and of manganeſe one ſcruple. Powder and fuſe them.

Eagle-marine. Take ten pounds of the compoſition under GLASS; three ounces of copper highly calcined with ſulphur; and one ſcruple of zaffer. Proceed as before.

Emerald. Take of the ſame compoſition with the laſt nine pounds; three ounces of copper precipitated from aquafortis; and two drams of precipitated iron. See EMERALD.

Garnet. Take two pounds of the compoſition under GLASS; two pounds of the glaſs of antimony, and two drams of manganeſe. For vinegar garnet, take of the compoſition for paſte, deſcribed in this article, two pounds; one pound of glaſs of antimony, and half an ounce of iron, highly calcined; mix the iron with the uncoloured paſte, and fuſe them; then add the glaſs of antimony powdered, and continue them in the heat till the whole is incorporated.

Gold or *full yellow.* Take of the compoſition for paſte ten pounds, and one ounce and a half of iron ſtrongly calcined; proceeding as with the others.

Deep purple. Take of either of the compoſitions for paſte ten pounds; of manganeſe one ounce; and of zaffer half an ounce.

Ruby. Take one pound of either of the compoſitions for paſte, and two drams of *calx Caſſii*, or precipitation of gold by tin; powder the paſte, and grind the calx of gold with it in a glaſs, flint, or agate mortar, and then fuſe them together. A cheaper ruby paſte may be made with half a pound of either of the above compoſitions, half a pound of glaſs of antimony, and one dram and a half of the calx of gold; proceeding as before,

Sapphire. Take of the compoſition for paſte ten pounds: of zaffer three drams and one ſcruple; and of the *calx Caſſii* one dram. Powder and fuſe them. Or the ſame may be done, by mixing with the paſte one-eighth of its weight of ſmalt.

Topaz. Take of the compoſitions under GLASS ten pounds, omitting the ſaltpetre; and an equal quantity of the *Gold-coloured hard* GLASS. Powder and fuſe them. See TOPAZ.

Turquoiſe. Take of the compoſition for blue paſte already deſcribed, ten pounds; of calcined bone, horn, or ivory, half a pound. Powder and fuſe them.

Opake white. Take of the compoſition for paſte ten pounds; and one pound of calcined horn, ivory, or bone; and proceed as before.

Semitranſparent white, like opal. See OPAL.

To

Gem. To the above we ſhall add the following receipts and proceſſes, contained in a Memoir by M. Fontanieu of the Royal Academy of Sciences at Paris, and ſaid to have met with much approbation. Gem

I. *Of the Baſes.* Although the different calces of lead are all adapted to produce the ſame effect in vitrification; yet M. Fontanier prefers lead in ſcales, and next to that minium, as being the moſt conſtantly pure. It is neceſſary to ſift through a ſilk ſieve the preparations of lead one wiſhes to make uſe of in the vitrification, in order to ſeparate the groſſer parts, as alſo the lead found in a metallic ſtate when white lead in ſcales is employed.

The baſe of factitious gems is calx of lead and rock-cryſtal, or any other ſtone vitrifiable by the calces already mentioned. Pure ſand, flint, and the tranſparent pebbles of rivers, are ſubſtances equally fit to make glaſs: but as it is firſt neceſſary to break the maſſes of cryſtal, ſtones, or pebbles, into ſmaller parts; ſo by this operation particles of iron or copper are frequently introduced, and to theſe duſt or greaſy matters are alſo apt to adhere. Our author therefore begins by putting the pounded cryſtal or pebbles into a crucible, which he places in a degree of heat capable of making the maſs red-hot; he then pours it into a wooden bowl filled with very clear water; and ſhaking the bowl from time to time, the ſmall portions of coals furniſhed by the extraneous bodies ſwim on the ſurface of the water, and the vitrifiable earth, with the iron, &c. reſts on the bottom. He then decants the water; and having dried the maſs, he pounds it, ſifts the powder through the fineſt ſilk ſieve: he then digeſts the powder during four or five hours with marine acid, ſhaking the mixture every hour. After having decanted the marine acid from the vitrifiable earth, he waſhes the latter until the water no longer reddens the tincture of tournſol. The ſaid earth being dried, is paſſed through a ſilk ſieve, and is then fit for uſe. Nitre, ſalt of tartar, and borax, are the three ſpecies of ſalts that enter with quartz and the ſeveral calces of lead into M. Fontanieu's vitrifications.

Much of the ſucceſs in the art of making coloured ſtones depends on the accurate proportion of the ſubſtances made uſe of to form the cryſtal which ſerves as a baſe to the factitious ſtones. After having tried a great variety of receipts, our author found they might be reduced to the following.

1. Take two parts and a half of lead in ſcales, one part and a half of rock-cryſtal or prepared flints, half a part of nitre, as much borax, and a quarter part of glaſs of arſenic. Theſe being well pulverized and mixed together, are to be put into a Heſſian crucible, and ſubmitted to the fire. When the mixture is well melted, pour it into cold water: then melt it again a ſecond and a third time; taking care, after each melting, to throw it into freſh cold water, and to ſeparate from it the lead that may be revived. The ſame crucible ſhould not be uſed a ſecond time, becauſe the glaſs of lead is apt to penetrate it in ſuch a manner as to run the riſk of loſing the contents. One muſt alſo be careful to cover the crucible well, to prevent any coals getting into it, which would reduce the calx of lead, and ſpoil the compoſition.

2. Take two parts and a half of white ceruſs, one part of prepared flints, half a part of ſalt of tartar, and a quarter part of calcined borax: melt the mixture in a Heſſian crucible, and then pour it into cold water; it is then to be melted again, and waſhed a ſecond and a third time, the ſame precautions being obſerved as for the firſt baſe.

3. Take two parts minium, one part rock-cryſtal, half a part of nitre, and as much ſalt of tartar: this mixture being melted, muſt be treated as the former.

4. Take three parts of calcined borax, one part of prepared rock-cryſtal, and one part of ſalt of tartar; theſe being well mixed and melted together, muſt be poured into warm water: the water being decanted and the maſs dried, an equal quantity of minium muſt be added to it; it is then to be melted and waſhed ſeveral times as directed above.

5. That called by our author the *Mayence baſe*, and which he conſiders as one of the fineſt cryſtalline compoſitions hitherto known, is thus compoſed: Take three parts of fixed alkali of tartar, one part of rock-cryſtal or flint pulverized: the mixture to be well baked together, and then left to cool. It is afterwards poured into a crucible of hot water to diſſolve the fritt; the ſolution of the fritt is then received into a ſtone-ware pan, and aquafortis added gradually to the ſolution till it no longer effervеſces: this water being decanted, the fritt muſt be waſhed in warm water till it has no longer any taſte: the fritt is then dried, and mixed with one part and a half of fine ceruſs or white lead in ſcales; and this mixture muſt be well levigated with a little diſtilled water. To one part and a half of this powder dried add an ounce of calcined borax: let the whole be well mixed in a marble mortar, then melted and poured into cold water as the other baſes already deſcribed. Theſe fuſions and lotions having been repeated, and the mixture dried and powdered, a 12th part of nitre muſt be added to it, and then melted for the laſt time; when a very fine cryſtal will be found in the crucible.

6. As a compoſition for furniſhing very fine white ſtones: Take eight ounces of ceruſs, three ounces of rock-cryſtal pulverized, two ounces of borax finely powdered, and half a grain of manganeſe; having melted and waſhed this mixture in the manner directed above, it will produce a very fine white cryſtal.

II. *Of the Colours.* The calces of metals, as already obſerved, are the ſubſtances employed to colour factitious gems; and on the preparation of theſe calces depends the vividneſs of their colours.

a, From *Gold.*] To obtain the mineral purple known by the name of *precipitate of Caſſius*, M. Fontanieu employs the following different proceſſes.

1. Diſſolve ſome pure gold in aqua regia, prepared with three parts of precipitated nitrous acid and one part of marine acid; and to haſten the diſſolution, the matraſs ſhould be placed in a ſand-bath. Into this ſolution pour a ſolution of tin in aqua regia. The mixture becomes turbid, and the gold is precipitated with a portion of the tin, in the form of a reddiſh powder; which, after being waſhed and dried, is called *precipitate of Caſſius.*—The aqua regia employed to diſſolve the tin is compoſed of five parts nitrous acid and one part of marine acid: to eight ounces of this aqua regia are added ſixteen ounces of diſtilled

Gem. distilled water. Some leaves of Malacca tin, about the size and thickness of a sixpence, is then put into this diluted aqua regia, till it will dissolve no more of them: which operation, our author observes, requires commonly twelve or fourteen days; though it might probably be hastened by beating the tin still thinner, and then rolling it into the form of a hollow cylinder, or turning it round into spiral convolutions, and thus exposing a greater extent of surface to the action of the menstruum. In order to prepare more readily the precipitate of Cassius, M. Fontanieu puts into a large jug eight ounces of solution of tin, to which he adds four pints of distilled water: he afterwards pours into this metallic lye some solution of gold, drop by drop, taking care to stir the whole with a glass tube: when the mixture becomes of a deep purple colour, he ceases dropping the solution of gold; and in order to hasten the precipitation of the mineral purple, pours into the mixture a pint of fresh urine. Six or seven hours after, the precipitate is collected at the bottom of the vessel: the fluid is then decanted; and the precipitate, washed once or twice, is dried till it becomes a brown powder.

2. Pour into a vessel of fine tin with a thick bottom four ounces of the solution of gold; three minutes after add two pints of distilled water. Let this mixture stand in the tin vessel during seven hours, taking care to stir it every hour with a glass tube; afterwards pour it into a conical glass jug, and add to it a pint of new urine: the mineral purple is soon precipitated, and then is to be washed and dried.

3. Distil in a glass cornute placed in a bath of ashes, some gold dissolved in aqua regia, made with three parts nitrous and one part marine acid; when the acid is passed over and the gold contained in the cornute appears dry, leave the vessel to cool, then pour into it some new aqua regia, and proceed to distil as before. Replace the aqua regia twice upon the gold and distil the same. After these four operations, pour by little and little into the cornute some oil of tartar *per deliquium*, which will occasion a brisk effervescence: when this ceases, distil the mixture till it becomes dry, and then put some warm water into the cornute. Shake the whole, and pour it into a cucurbit, when a precipitate is deposited the colour of which is sometimes brown and sometimes yellow: After having washed this precipitate, dry it. Our author says, this mineral purple was much superior to the foregoing, since two grains of it only were sufficient to an ounce of the base, whilst it required of the other two a 20th part of the base. And he adds, that he found a means of exalting the colour of the precipitate of Cassius, by putting to it a sixth part of its weight of glass of antimony finely powdered, and of nitre in the proportion of a dram to eight ounces of the base.

b, From *Silver*.] The calx of silver, being vitrified, produces a yellowish grey colour. This calx enters only into the composition of the yellow artificial diamond and the opal. M. Fontanieu introduces it into the base in the form of luna cornea.

In order to prepare it, he directs to dissolve the silver in precipitated nitrous acid, and afterwards to pour into it a solution of sea salt: a white precipitate is obtained; which, being washed and dried, melts very readily in the fire, and is soon volatilized if not mixed with vitrifiable matters. To make the yellow diamond, 25 grains of this luna cornea are put to an ounce of the fourth base: the dose of silver may be diminished according to the shade of yellow that one wishes to procure. Gem.

c, From *Copper*.] The calx of copper imparts to white glass the finest green colour; but if this metal be not exactly in a state of calx, it produces a brownish red colour. *Mountain blue*, *verdigris*, and the residue of its distillation, are the different preparations of copper which our author employs to make the artificial emeralds.

d, From *Iron*.] Although it has been asserted, that the calces of iron introduce a very fine transparent red colour into white glass, M. Fontanieu could only obtain from it a pale red a little opake. The calx of iron that he employed was in the proportion of the 20th part of the base.

There are several ways of preparing the calx of iron called *crocus Martis*, or *saffron of Mars*. In general, it is necessary that this metal be so far deprived of its phlogiston, that the magnet ceases to attract it: thus one may use the scales of iron found upon the bars of the furnaces, which serve to distil aquafortis. By digesting filings of steel with distilled vinegar, then evaporating and replacing the vinegar 10 or 12 times upon these filings and drying them alternately, a calx of iron is obtained, which must be sifted through a silk sieve, and then calcined. The calx of iron thus obtained by the vinegar, our author says, only introduced into his bases a green colour inclining to a yellow.

By the following process a saffron of Mars of the finest red colour is obtained: Let an ounce of iron filings be dissolved in nitrous acid in a glass cornute, and distilled over a sand-bath to dryness. After having replaced the acid or the dry calx, and re-distilled it a second and a third time, it is then edulcorated with spirits of wine, and afterwards washed with distilled water.

e, From the *Magnet*.] It is necessary to calcine the magnet before it be introduced into the vitrifications: Having therefore torrified the magnet during two hours, it must be washed and dried. It is only employed in the composition of the opal.

f, From *Cobalt*.] The calx of cobalt is only proper to introduce a blue colour into glass; but this semimetal is rarely found free from iron and bismuth, and therefore it is first necessary to separate them from it. This is done by calcining the ore of cobalt in order to disengage the arsenic: afterwards the calx must be distilled in a cornute with sal ammoniac, and the iron and the bismuth are found sublimed with this salt. The distillation must be repeated with the sal ammoniac till this salt is no longer coloured yellow. The cobalt which remains in the cornute is then calcined in a potsherd, and becomes a very pure calx; which being introduced into the base, in the proportion of a 900th part, gives it a very fine blue colour, the intensity of which may be increased at discretion by the addition of calx of cobalt. In order to prepare *black enamel* resembling that which is called *black agate* of Iceland; melt together a pound and a half of one of the bases, two ounces of the calx of cobalt, two ounces of

crocus

Gem. *crocus Martis*, prepared with vinegar, and two ounces of manganese. Gem.

g, From *Tin*.] The calx of tin is not vitrifiable alone, and when deprived of phlogiston is of a white colour; it renders opake the glass with which it is melted, and forms white enamel. For this purpose, calcine the putty of tin; then wash and dry it, and sift it through a silk sieve. Take six pounds of the second base, the same quantity of the calcined putty of tin, and 48 grains of manganese.

h, From *Antimony*.] Antimony is only susceptible of vitrification when its calx contains phlogiston, and then it produces a reddish or hyacinth coloured glass; but if the antimony be in a state of absolute calx, such as the diaphoretic antimony, then it is no longer vitrifiable, and may be substituted for calx of tin to make white enamel. M. Fontanieu introduces the glass of antimony in the composition of artificial topazes. For the *oriental topaz*, he takes 24 ounces of the first bases and five drachms of the glass of antimony. To imitate the *topaz of Saxony*, he adds to each ounce of the base five grains of the glass of antimony. For the *topaz of Brazil*, he takes 24 ounces of the first base, one ounce 24 grains of glass of antimony, and 8 grains of the *precipitate of Cassius*.

i, From *Manganese*.] This mineral, employed in a small quantity, renders the glass whiter; a larger quantity produces a very fine violet colour, and a still larger dose of it renders the glass black and opake.

There are two ways of preparing manganese, 1. The most simple consists in exposing it to a red heat, and then quenching it with distilled vinegar; it is afterwards dried and powdered, in order to pass it through a silk sieve. 2. Haudiquer de Blancour describes the second manner of preparing the manganese, proper to furnish a red colour, and names it *fusible manganese*. Take of manganese of Piedmont one pound; torrify and pulverize it; then mix it with a pound of nitre, and calcine the mixture during 24 hours; afterwards wash it repeatedly in warm water, till the water of the lyes has no longer any taste; dry the manganese, and mix with it an equal weight of sal ammoniac; levigate this mixture on a slab of porphyry with oil of vitriol diluted with water to the strength of vinegar. Dry the mixture, and introduce it into a cornute; distil by a graduated fire; and when the sal ammoniac is sublimed, weigh it, and add to the mixture an equal quantity. Then distil and sublime as before, and repeat the operation six times, being careful at each time to mix the sal ammoniac and the manganese upon the porphyry with diluted oil of vitriol.

At Tournhault in Bohemia, there is sold a fusible glass of a yellow colour, very like that of the topaz of Brazil, which, when exposed to a degree of fire in a cupel sufficient to redden it, becomes of a very fine ruby colour, more or less deep according to the degree of fire to which it has been exposed. Our author assayed this glass, and found it to contain a great deal of lead, but was not able to discover any gold in it.

III. *Of the different degrees of Fire necessary for Factitious Gems.* Our author observes, that there are three degrees of heat very different in their energy. The fire kept up in the wind furnaces in the laboratories of chemists, is less active than that whose effect is accelerated by the means of bellows; and a fire supported by wood, and kept up during 60 hours without interruption, produces singular effects in vitrification, and renders the glass finer and less alterable.

When recourse is had to the forge, in order to operate a vitrification, it is necessary to turn about the crucible from time to time, that the mass may melt equally. Some coal also should be replaced, in proportion as it consumes towards the nozel of the bellows; for without this precaution, we should run the risk of cooling the crucible opposite to the flame, and probably of cracking it, when all the melted mass running among the coals would be totally lost. Though this is the readiest way of melting, it should not be employed out of choice; for the crucible often breaks, or coals get into it, and reduce the calx of lead to a metallic state.

The wind-furnace is either square or round. A small cake of baked clay or brick, of the thickness of an inch, is placed upon the grate; and upon this cake is placed the crucible, surrounded with coals. The degree of heat produced by this furnace is much less than that of the forge: but in order to succeed in the vitrification, M. Fontanieu recommends the use of a furnace described by Kunckel, which, with some necessary alterations, is represented on Plate CCXX. The interior part is so disposed, that we may place crucibles at three different heights; and the name of *chambers* is given to those steps upon which the crucibles are placed. Fig. 4. is a plan of the kiln at the first chamber, and fig. 5. a plan of the kiln where the fire is placed. Fig. 6. exhibits the elevation; A the ash-pit; B the door to put in the wood; C the door of the first chamber; D the door of the second chamber; E the third chamber; F the flue or chimney; GG iron-hoops which surround the kiln to strengthen it. Fig. 7. is a section of the kiln: H the ash-pit with its air-hole; I the chamber for the fire with an air-hole; K the first chamber for the crucibles; L the second chamber; M the dome; N the chimney; OO air-holes.

It is obvious, that the degree of heat cannot be equal in the said three chambers. The chamber K is that where the heat is greatest, afterwards in that of L, and lastly, in that of M. We should begin by placing the crucibles according to their size, in these different chambers; by which means the best effect in vitrification is produced.

In order to conduct the fire well, only three billets of white wood should be put into the furnace at a time for the first 20 hours, four billets at a time for the next 20 hours, and six billets for the last 20 hours; in all 60 hours. The furnace is then left to cool, care being taken to stop the air-holes with some lute; and, in about 48 hours after, when the kiln is quite cold, the crucible is to be withdrawn.

IV. *The Compositions.* 1. For the white diamond: Take the base of Mayence. This crystal is very pure, and has no colours.

2. For the yellow diamond: to an ounce of the fourth base, add for colour 25 grains of luna cornea or 10 grains of glass of antimony.

3. For the emerald: 1. To 15 ounces of either of the bases, add for colour one dram of mountain-blue and six

Gem. grains of glaſs of antimony; or, 2. To an ounce of the ſecond baſe, add for colour 20 grains of glaſs of antimony and three grains of calx of cobalt.

4. For the ſapphire: To 24 ounces of the Mayence baſe, add for colour two drams 46 grains of the calx of cobalt.

5. For the amethiſt: To 24 ounces of the Mayence baſe, add for colour four drams of prepared manganeſe and four grains of precipitate of Caſſius.

6. For the beril: To 24 ounces of the third baſe, add for colour 96 grains of glaſs of antimony and four grains of calx of cobalt.

7. For the black agate: To 24 ounces of either of the baſes, add two ounces of the mixture directed above in par. *f*.

8. For the opal: To an ounce of the third baſe, add for colour 10 grains of luna cornea, two grains of magnet, and 26 grains of abſorbent earth.

9. For the oriental topaz: To 24 ounces of the firſt or third baſe, add for colour five drams of glaſs of antimony.

10. For the topaz of Saxony: To 24 of the ſame baſe, add for colour ſix drams of the glaſs of antimony.

11. For the topaz of Braſil: To 24 ounces of the ſecond or third baſe, add for colour one ounce 24 grains of the glaſs of antimony and eight grains of precipitate of Caſſius.

12. For the hyacinth: To 24 ounces of the baſe made with rock-cryſtal, add for colour two drams 48 grains of glaſs of antimony.

13. For the oriental ruby: 1. To 16 ounces of the Mayence baſe, add for colour a mixture of two drams 48 grains of the precipitate of Caſſius, the ſame quantity of crocus Martis prepared in aquafortis, the ſame of golden ſulphur of antimony and of fuſible manganeſe, with the addition of two ounces of mineral cryſtal; or, 2. To 20 ounces of the baſe made with flint, add half an ounce of fuſible manganeſe and two ounces of mineral cryſtal.

14. For the balaſs ruby: 1. To 16 ounces of the Mayence baſe, add the above colouring powder, but diminiſhed a fourth part; or, 2. To 20 ounces of the baſe made with flints, add the ſame colouring powder, but with a fourth leſs of the manganeſe.

The *factitious* gems are eaſily diſtinguiſhed from the *natural*, by their ſoftneſs and fuſibility; by their ſolubility in acids; by their cauſing only a ſingle refraction of the rays of light; and, in many caſes, by their ſpecific gravity, which exceeds 2.76 in all precious gems of the firſt order, as the diamond, ruby, ſapphire, &c.

Imitation of Antique GEMS. There has been at different times a method practiſed by particular perſons of taking the impreſſions and figures of antique gems, with their engravings, in glaſs of the colour of the original gem. This has always been eſteemed a very valuable method, and greatly preferable to the more ordinary ones of doing it on ſealing-wax or brimſtone: but, to the misfortune of the world, this art being a ſecret only in the hands of ſome particular perſons who got their bread by it, died with them, and every new artiſt was obliged to re-invent the method; till at length Mr Homberg, having found it in great perfection, gave the whole proceſs to the world to be no more forgotten or loſt; and ſince that time it has been very commonly practiſed in France, and ſometimes in other places. Gem.

Mr Homberg was favoured in his attempts with all the engraved gems of the king's cabinet; and took ſuch elegant impreſſions, and made ſuch exact reſemblances of the originals, and that in glaſſes ſo artfully tinged to the colour of the gems themſelves, that the niceſt judges were deceived in them, and often took them for the true antique ſtones. Theſe counterfeit gems alſo ſerve, as well as the original ones, to make more copies from afterwards; ſo that there is no end of the numbers that may be made from one; and there is this farther advantage, that the copy may be eaſily made perfect, though the original ſhould not be ſo, but ſhould have ſuſtained ſome damage from a blow or otherwiſe.

The great care in the operation is to take the impreſſion of the gem in a very fine earth, and to preſs down upon this a piece of proper glaſs, ſoftened or half melted at the fire, ſo that the figures of the impreſſion made in the earth may be nicely and perfectly expreſſed upon the glaſs. In general, the whole proceſs much reſembles that of the common founders. But when it is brought to the trial, there is found a number of difficulties which were not to be foreſeen, and which would not at all affect the common works of the founder. For his purpoſe, every earth will ſerve that is fine enough to receive the impreſſions, and tough enough not to crack in the drying: theſe all ſerve for their uſe, becauſe the metals which they caſt are of a nature incapable of mixing with earth, or receiving it into them, even if both are melted together, ſo that the metal always eaſily and perfectly ſeparates itſelf from the mould; but it is very difficult in theſe caſts of glaſs. They are compoſed of a matter which differs in nothing from that of the mould, but that it has been run into this form by the force of fire, and the other has not yet been ſo run, but is on any occaſion ready to be ſo run, and will mix itſelf inſeparably with the glaſs in a large fire: conſequently, if there be not great care uſed, as well in the choice of the glaſs as in the manner of uſing it, when the whole is finiſhed there will be found great difficulty in the ſeparating the glaſs from the mould, and often this cannot be done without wholly deſtroying the impreſſion.

All earths run more or leſs eaſily in the fire as they are more or leſs mixed with ſaline particles in their natural formation. As all ſalts make earths run into glaſs, and as it is neceſſary to uſe an earth on this occaſion for the making a mould, it being alſo neceſſary to the perfection of the experiment that this earth ſhould not melt or run, it is our buſineſs to ſearch out for this purpoſe ſome earth which naturally contains very little ſalt. Of all the ſpecies of earth which Mr Homberg examined on this occaſion, none proved ſo much diveſted of ſalts, or ſo fit for the purpoſe, as the common tripela, or TRIPOLI, uſed to poliſh glaſs and ſtones. Of this earth there are two common kinds; the one reddiſh, and compoſed of ſeveral flakes or ſtrata; the other yellowiſh, and of a ſimple ſtructure. Theſe are both to be had in the ſhops. The latter kind is from the Levant; the former is found in England, France, and many other places. This tripela muſt be choſen ſoft and ſmooth to the touch, and not mixed

Gem. with ſandy or other extraneous matter. The yellowiſh kind is the beſt of the two, and is commonly called *Venetian tripoli*. This receives the impreſſions very beautifully; and never mixes with the glaſs in the operation, which the red kind ſometimes does. Mr Homberg uſually employed both kinds at once in the following manner: firſt, powder a quantity of the red tripela in an iron mortar, and ſifting it through a fine ſieve ſet it by for uſe; then ſcrape with a knife a quantity of the yellow tripela into a ſort of powder, and afterwards rub it till very fine in a glaſs mortar with a glaſs peſtle. The finer this powder is, the finer will be the impreſſion, and the more accurately perfect the caſt. The artificer might naturally ſuppoſe, that the beſt method to obtain a perfect fine powder of this earth, would be by waſhing it in water; but he muſt be cautioned againſt this. There is naturally in this yellowiſh tripoli a ſort of unctuoſity, which when it is formed into a mould keeps its granules together, and gives the whole an uniform gloſſy ſurface: now the waſhing the powder takes away this unctuoſity; and though it renders it much finer, it makes it leave a granulated ſurface, not this ſmooth one, in the mould; and this muſt render the ſurface of the caſt leſs ſmooth. Gem.

When the two tripelas are thus ſeparately powdered, the red kind muſt be mixed with ſo much water as will bring it to the conſiſtence of paſte, ſo that it may be moulded like a lump of dough between the fingers: this paſte muſt be put into a ſmall crucible of a flat ſhape, and about half an inch or a little more in depth, and of ſuch a breadth at the ſurface as is a little more than that of the ſtone whoſe impreſſion is to be taken. The crucible is to be nicely filled with this paſte lightly preſſed down into it, and the ſurface of the paſte muſt be ſtrewed over with the fine powder of the yellow tripela not wetted. When this is done, the ſtone, of which the impreſſion is to be taken, muſt be laid upon the ſurface, and preſſed evenly down into the paſte with a finger and thumb, ſo as to make it give a ſtrong and perfect impreſſion; the tripela is then to be preſſed nicely even to its ſides with the fingers, or with an ivory knife. The ſtone muſt be thus left a few moments, for the humidity of the paſte to moiſten the dry powder of the yellow tripela which is ſtrewed over it: then the ſtone is to be carefully raiſed by the point of a needle fixed in a handle of wood; and the crucible being then turned bottom upwards, it will fall out, and the impreſſion will remain very beautifully on the tripela.

If the ſides of the cavity have been injured in the falling out of the ſtone, they may be repaired; and the crucible muſt then be ſet, for the paſte to dry, in a place where it will not be incommoded by the duſt.

The red tripoli being the more common and the cheaper kind, is here made to fill the crucible only to ſave the other, which alone is the ſubſtance fit for taking the impreſſion. When the ſtone is taken out, it muſt be examined, to ſee whether any thing be lodged in any part of the engraving, becauſe if there be any of the tripela left there, there will certainly be ſo much wanting in the impreſſion. When the crucible and paſte are dry, a piece of glaſs muſt be choſen of a proper colour, and cut to a ſize proper for the figure; this muſt be laid over the mould, but in ſuch a manner that it does not touch the figures, otherwiſe it would ſpoil them. The crucible is then to be brought near the furnace by degrees, and gradually heated till it cannot be touched without burning the fingers; then it is to be placed in the furnace under a muffle, ſurrounded with charcoal. Several of theſe ſmall crucibles may be placed under one muffle; and when they are properly diſpoſed, the aperture of the muffle ſhould have a large piece of burning charcoal put to it, and then the operator is to watch the proceſs, and ſee when the glaſs begins to look bright: this is the ſignal of its being fit to receive the impreſſion. The crucible is then to be taken out of the fire; and the hot glaſs muſt be preſſed down upon the mould with an iron inſtrument, to make it receive the regular impreſſion: as ſoon as this is done, the crucible is to be ſet at the ſide of the furnace out of the way of the wind, that it may cool gradually without breaking. When it is cold, the glaſs is to be taken out, and its edges ſhould be grated round with pincers, which will prevent its flying afterwards, which is an accident that ſometimes happens when this caution has been omitted, eſpecially when the glaſs is naturally tender. The different coloured glaſſes are of different degrees of hardneſs, according to their compoſition; but the hardeſt to melt are always the beſt for this purpoſe, and this is known by a few trials. Gem.

If it be deſired to copy a ſtone in relief which is naturally in creux, or to take one in creux which is naturally in relief; there needs no more than to take an impreſſion firſt in wax or ſulphur, and to mould that upon the paſte of tripela inſtead of the ſtone itſelf: then proceeding in the manner before directed, the proceſs will have the deſired ſucceſs.

A more ſimple and eaſy method than the above, is by taking the caſts in gypſum, or Plaſter of Paris as it is commonly called. For this purpoſe, the gypſum muſt be finely pulveriſed, and then mixed with clear water to the conſiſtence of thick cream. This is poured upon the face of the gem or ſeal of which the impreſſion is wanted, and which muſt be previouſly moiſtened with oil to facilitate the ſeparation of the caſt; and in order to confine the liquid plaſter, it is only neceſſary to pin a ſlip of oiled paper round the ſides of the ſeal by way of a cap or rim. When the plaſter is dry, it is to be taken off, and ſet before the mouth of the furnace, in order to free it entirely from moiſture; when it is fit to be uſed as a matrix in the ſame way as that formed with the tripoli earths. Only no crucible or other receptacle is at all neceſſary; the caſts being formed like ſo many ſmall cakes half an inch thick, and thus put into the furnace with the bits of glaſs upon them. The glaſs, after coming to a proper heat, is preſſed down upon the mould with an iron ſpatula to receive the deſired impreſſion, the preſſure requiſite being more or leſs according to the ſize of the ſtone. This method has been long practiſed very ſucceſsfully, and with no ſmall emolument, by that ingenious ſeal-engraver Mr Deuchar of Edinburgh. The only reſpect in which it is inferior to the other more operoſe and expenſive methods, conſiſts in the chance of air-bubbles ariſing in pouring on the plaſter; which chance, however, is leſs in proportion to the fineneſs of the gypſum employed. When air-bubbles do occur, the caſts may be laid aſide, as it is ſo eaſy to replace them.

The application of paſtes to multiply and preſerve the impreſſions of camaieux and intaglios, is an object very intereſting to artiſts and to antiquaries, as well as to men of learning and taſte in the fine arts.

Gem. This art, though only lately reſtored in any degree of perfection, is of very conſiderable antiquity. The great prices which the ancients paid for the elegant gems engraved by the celebrated Greek artiſts, could not but early ſuggeſt to them the idea of multiplying their numbers, by taking off their impreſſions in wax, in ſulphur, in plaſter, or in clay; but more particularly in coloured glaſs, or that vitrified ſubſtance commonly called *paſte*.

As the impreſſions on paſte are durable, and imitate the colours and brilliancy of the original ſtones, they ſerve the ſame purpoſes as the gems themſelves. This art was therefore practiſed not only by the Greeks, but by all the nations who cultivated Grecian taſte.

Many of the fineſt gems of antiquity are now loſt, and their impreſſions are to be found only on ancient paſtes. Great therefore is the value of theſe paſtes. Numerous collections of them have been formed by the curious. Inſtances of this are found in the Florentine Muſæum, in Stoſch's work on ancient gems with inſcriptions, in Winckelmann's deſcription of Stoſch's cabinet, and in the noble collection of Mr Charles Townley in London.

The art of taking impreſſions of gems ſeems not to have been altogether loſt even in the Gothic ages; for Heraclius, who probably lived in the ninth century, and wrote a book *De coloribus et artibus Romanorum*, teaches in very plain though not elegant terms how to make them. Indeed, ſome of the few perſons who then poſſeſſed this art, taking advantage of the ignorance of the times, ſold paſtes for original gems. Thus the famous emerald of the abbey of Reichnaw near Conſtance, although a preſent made by Charlemain, is now found to be a piece of glaſs. And thus the celebrated emerald vaſe in the cathedral of Genoa is likewiſe found to be a paſte (A). The Genoeſe got this vaſe at the taking of Ceſarea in the year 1101 as an equivalent for a large ſum of money; nor was any impoſition then ſuſpected, for in the year 1319 they pawned it for 1200 marcs of gold.

But this ingenious art, revived indeed in Italy in the time of Laurence of Medici and Pope Leo X. was not cultivated in an extenſive manner till the beginning of the preſent century, when M. Homberg reſtored it, as already mentioned. In this he is ſaid to have been greatly aſſiſted and encouraged by the then duke of Orleans regent of France, who uſed to amuſe himſelf with that celebrated chemiſt in taking off impreſſions in paſte from the king of France's, from his own, and other collections of gems.

According to the French Encyclopediſts, M. Clachant the elder, an engraver of ſome note, who died at Paris in 1781, learned this art from his royal highneſs, to whoſe houſehold his father or he ſeems to have belonged. Madamoiſelle Feloix next cultivated this art, and it is believed ſtill carries it on. She had been taught by her father, who in quality of garçon de chambre to the regent had often aſſiſted in the laboratory of his maſter, where he acquired this knowledge. Her collection conſiſts of 1800 articles.

Baron Stoſch, a Pruſſian, who travelled over Europe in queſt of original engraved ſtones and impreſſions of ancient gems, for the elegant work which he publiſhed and Picart engraved (B), was well acquainted with this art. He had taught it to his ſervant Chriſtian Dehn, who ſettled at Rome, where he made and ſold his well known ſulphur impreſſions and paſtes. He had collected 2500 articles. Dolce ha, arranged them in a ſcientific order, and given a deſcriptive catalogue of them. Gem.

It was chiefly from Dehn's collection that the taſte for ſulphurs and paſtes has become ſo univerſal. They are great objects of ſtudy, and often require much learning to explain them. They have unqueſtionably ſerved to extend and improve the art of engraving on ſtones; and have been of infinite uſe to painters, to ſtatuaries, and to other artiſts, as well as to men of claſſical learning and fine taſte.

It is very difficult to take off impreſſions, and perfectly to imitate various coloured cameos. It cannot be properly done in wax, ſulphur, plaſter, or glaſs of one colour only. The difficulties ariſing from their ſize and form, and from the various nature of the different ſorts of glaſs, which do not well unite into different ſtrata, are very numerous: nor could the compleateſt ſucceſs in this chemical and mechanical branch of the art produce a tolerable cameo. Impreſſions or imitations, if unaſſiſted by the tool of the engraver, do not ſucceed; becauſe the undercutting and deep work of moſt of the originals require to be filled up with clay or wax, that the moulds may come off ſafe without injuring them. Hence the impreſſions from theſe moulds come off hard and deſtitute of delicacy, ſharpneſs, and preciſion of outline, till the underworking of the moulder is cut away. But Mr Reiffenſtein at Rome, by his genius, perſeverance, and the aſſiſtance of able artiſts, has overcome theſe difficulties; and has had the ſatisfaction of ſucceeding, and producing variegated cameos which can hardly be diſtinguiſhed from the originals.

Mr Lippart of Dreſden, an ingenious glazier, and an enthuſiaſt in the fine arts, practiſed this branch not unſucceſsfully; but not finding ſufficient encouragement for his paſtes of coloured glaſs, or perhaps from local difficulties in making them well and cheap, he abandoned this art. He ſubſtituted in its place impreſſions of fine white alabaſter or ſelenite plaſter. Such impreſſions, when carefully ſoaked in a ſolution of white Caſtile ſoap, then dried, and rubbed over with a ſoft bruſh, take a very agreeable poliſh. They ſhow the work perhaps to better advantage than red or white ſulphurs do; but they are not ſo durable, and are liable to be defaced by rubbing.

Of theſe impreſſions Mr Lippart publiſhed three different collections, each of them containing 1000 articles; and to the merit of having increaſed the number of Madamoiſelle Feloix and Chriſtiano Dehn's collections, which are all inſerted in his, he added that of employing two learned Germans to arrange and deſcribe them. The firſt thouſand were arranged and deſcribed by the late profeſſor Chriſt at Leipſic, and the ſecond and third thouſand by profeſſor Heine

(A) See M. de la Condamine's Diſſ. in Memoir. de l'Acad. Roy. de Paris, 1757.

(B) Gemmæ antiquæ coloratæ, ſculptorum nominibus inſignitæ, re inciſæ, per Bernardum Picart. Amſtelodam. 1724, folio.

Gem. Heine at Goettingen. Nor did Mr Lippart ſtop here: but to make the ſtudy of antiquity more eaſy and acceptable to artiſts, he ſelected out of the whole collection of 3000, a ſmaller one of 2000 of the beſt and moſt inſtructive ſubjects, of which he himſelf drew up and publiſhed a deſcription in German.

But of all the artiſts and ingenious men who have taken impreſſions of engraved gems in ſulphur and in paſte, no one ſeems to have carried that art to ſuch perfection as Mr James Taſſie, a native of Glaſgow but who has reſided in London ſince the year 1766. His knowledge in various branches of the fine arts, particularly in that of drawing, naturally led him to it. The elegant portraits which he models in wax, and afterwards moulds and caſts in paſte, which entirely reſemble cameos, are well known to the public.

Mr Taſſie, profiting of all the former publications of this ſort, and by expence, induſtry, and acceſs to many cabinets in England and other kingdoms to which former artiſts had not obtained admiſſion, has now increaſed his collection of impreſſions of ancient and modern gems to the number of above 15,000 articles. It is the greateſt collection of this kind that ever exiſted; and ſerves for all the purpoſes of artiſts, antiquaries, ſcholars, men of taſte, and even philoſophers. The great demand for his paſtes was perhaps owing in the beginning to the London jewellers, who introduced them into faſhion by ſetting them in rings, ſeals, bracelets, necklaces, and other trinkets.

The reputation of this collection having reached the empreſs of Ruſſia, ſhe was pleaſed to order a complete ſet; which being accordingly executed in the beſt and moſt durable manner, were arranged in elegant cabinets, and are now placed in the noble apartments of her imperial majeſty's ſuperb palace at Czarſkoe Zelo.

Mr Taſſie, in executing this commiſſion, availed himſelf of all the advantages which the improved ſtate of chemiſtry, the various ornamental arts, and the knowledge of the age, ſeemed to afford. The impreſſions were taken in a beautiful white enamel compoſition, which is not ſubject to ſhrink or form air-bladders; which emits fire when ſtruck with ſteel, and takes a fine poliſh; and which ſhows every ſtroke and touch of the artiſt in higher perfection than any other ſubſtance. When the colours, mixed colours, and nature of the reſpective originals, could be aſcertained, they were imitated as completely as art can imitate them; inſomuch that many of the paſte intaglios and cameos in this collection are ſuch faithful imitations, that artiſts themſelves have owned they could hardly be diſtinguiſhed from the originals. And when the colour and nature of the gems could not be authenticated, the paſtes were executed in agreeable, and chiefly tranſparent, colours; conſtant attention being beſtowed to preſerve the outlines, extremities, attributes, and inſcriptions.

It was the learned Mr Raſpe (from whom this account (c) is taken) who arranged this great collection, and made out the deſcriptive catalogue. His arrangement is nearly the ſame with that of the late Abbé Winkelmann, in his deſcription of the gems which belonged to Baron Stoſch. But as modern works were inſerted in this collection, he found it neceſſary to make a few alterations, and added ſome diviſions to thoſe of M. Winkelmann, as will appear from the following conſpectus, with which we ſhall conclude this detail. Gem, Gemara.

I. Ancient Art and Engravings.
- Egyptian. Hieroglyphics, ſacred animals, divinities, prieſts.
- Baſilidian, Gnoſtic, and other taliſmans, &c.
- Oriental and barbarous ancient and modern engravings.
- Greek and Roman originals, copies, and imitations (the Etruſcan are claſſed with the Greek works.)
- A, Mythology or fabulous age. Gods, inferior divinities, religious ceremonies.
- B, Heroic age before the ſiege of Troy.
- C, Siege of Troy.
- D, Hiſtoric age. Of Carthage, Greece, Rome, ſubjects unknown.
- E, Fabulous animals and chimeras.
- F, Vaſes and urns.

II. Modern Art and Engravings.
- A, Religious ſubjects.
- B, Portraits of kings and ſovereigns.
- C, Portraits of illuſtrious men in alphabetical order.
- D, Portraits unknown.
- E, Devices and emblems.
- F, Cyphers, arms, ſupporters, and medley of modern hiſtory.

GEMARA, or GHEMARA, the ſecond part of the TALMUD.

The word גמרה, *gemara*, is commonly ſuppoſed to denote a ſupplement; but in ſtrictneſs it rather ſignifies complement, perfection: being formed of the Chaldee גמר, *gemar* or *ghemar*, "to finiſh, perfect, or complete any thing."

The rabbins call the Pentateuch ſimply the *law*: the firſt part of the Talmud, which is only an explication of that law, or an application thereof to particular caſes, with the deciſions of the ancient rabbins thereon, they call the *Miſchna*, i. e. "ſecond law:" and the ſecond part, which is a more extenſive and ample explication of the ſame law, and a collection of deciſions of the rabbins poſterior to the Miſchan, they call *Gemara*, q. d. "perfection, completion, finiſhing;" becauſe they eſteem it the finiſhing of the law, or an explication beyond which there is nothing farther to be deſired.

The Gemara is uſually called ſimply *Talmud*, the common name of the whole work. In this ſenſe we ſay, there are two Gemaras or Talmuds; that of Jeruſalem and that of Babylon: though in ſtrictneſs the Gemara is only an explication of the Miſchna, given by the Jewiſh doctors in their ſchools; much as the commentaries of our ſchool-divines on St Thomas, or the maſter of the ſentences, are an explication of the writings of thoſe authors.

A commentary, Monſ. Tillemont obſerves, was wrote on the Miſchna, by one Jochanan, whom the Jews place about the end of the ſecond century: but Fa. Morin

(c) Account of the preſent ſtate and arrangement of Mr James Taſſie's collection of paſtes and impreſſions from ancient and modern gems, by R. C. Raſpe, London, 1786, 8vo.

Gemini, Geminiani

Morin proves, from the work itſelf, wherein mention is made of the Turks, that it was not wrote till the time of Heraclius, or about the year 620; and this is what is called the *Gemara*, or *Talmud of Jeruſalem*, which the Jews do not uſe or eſteem much becauſe of its obſcurity.

They ſet a much greater value on the Gemara, or Talmud of Babylon, begun by one Aſa; diſcontinued for 73 years, on occaſion of the wars with the Saracens and Perſians; and finiſhed by one Joſa, about the cloſe of the ſeventh century. See TALMUD.

Though the name Talmud, in its latitude, includes both the Miſchna and the two Gemaras, yet it is properly that of Aſa and Joſa alone which is meant under that name. This the Jews prize above all their other writings, and even ſet it on a level with ſcripture itſelf: in effect, they conceive it as the word of God, derived by tradition from Moſes, and preſerved without interruption to their time. R. Jehuda, and afterwards R. Johanan, R. Aſa, and R. Joſa, fearing the traditions ſhould be loſt in the diſperſion of the Jews, collected them into the Miſchna and the Gemara. See CARAITES and RABBINISTS.

GEMINI, in aſtronomy, the TWINS; a conſtellation or ſign of the zodiac, the third in order, repreſenting Caſtor and Pollux; and it is marked thus, ♊. The ſtars in the ſign Gemini, in Ptolemy's catalogue, are 25; in Tycho's, 25; in Hevelius's, 38; in the Britannic Catalogue, 85.

GEMINIANI, a celebrated muſician and compoſer, was born at Lucca in the year 1680. He received his firſt inſtructions in muſic from Aleſſandro Scarlatti; and after that became a pupil of Carlo Ambroſio Lunati, ſurnamed *Il Gobbo*, a moſt celebrated performer on the violin; after which he became a diſciple of Corelli, and under him finiſhed his ſtudies on that inſtrument. In the year 1714, he came to England; where in a ſhort time he ſo recommended himſelf by his exquiſite performance, that all who profeſſed to love and underſtand muſic were captivated with hearing him. Many of the nobility laid claim to the honour of being his patrons; but he ſeemed chiefly to attach himſelf to Baron Kilmanſegge, chamberlain to king George I. as elector of Hanover, and a favourite of that prince. In 1716, he publiſhed and dedicated to his patron 12 ſonatas *a violino violone e cembalo*: the firſt ſix with fugues and double ſtops as they are vulgarly called; the laſt with airs of various meaſures, ſuch as allemandes, courants, and jiggs. This publication was ſo well reliſhed by the baron, that he mentioned Geminiani to the king as an excellent performer; in conſequence of which our muſician had the honour to perform before his majeſty, in concert with the celebrated Handel, who played on the harpſichord. But though Geminiani was exceedingly admired, yet he had not a talent at aſſociating muſic with poetry, nor do we find that he ever became a public performer: he was therefore obliged to depend for his ſubſiſtence on the friendſhip of his patrons, and the profits which accrued to him from teaching. He had alſo the misfortune to be an enthuſiaſt in painting; and the verſatility of his temper was ſuch, that, in order to gratify this paſſion, he not only ſuſpended his ſtudies, and neglected to exerciſe his talents, but involved himſelf in debts. In 1727, he was offered the place of maſter and compoſer of the ſtate-muſic in Ireland; but this could not be conferred on a Catholic, and Geminiani refuſed to change his religion: upon which it was given to Matthew Dubourg, a young man who had been one of his pupils, and was a celebrated performer on the violin. Geminiani then ſet himſelf to compoſe parts to the *opera quinta* of Corelli; or, in other words, to make concertos of the firſt ſix of his ſolos. This work he completed, and, with the help of a ſubſcription, at the head of which were the names of the royal family, publiſhed in 1726. In 1732, he publiſhed his *opera ſeconda*, which contains a celebrated minuet that goes by his name. He publiſhed many other pieces, the profits of which did not much mend his circumſtances; but this perhaps was owing to his rambling diſpoſition and enthuſiaſtic fondneſs of painting. He was alſo an utter ſtranger to the buſineſs of an orcheſtra, and had no idea of the labour and pains neceſſary in the inſtruction of fingers for the performance of muſic to which they were ſtrangers. The conſequence of this was, that a *concerto ſpirituale*, which he had advertiſed for his own benefit in 1748, failed in the performance. The audience, however, compaſſionated his diſtreſs, and ſat very ſilent till the books were changed; when the performance was continued with compoſitions of the author's own, and which he executed in ſuch a manner as was never forgot. The profits ariſing from this performance enabled him to take a journey to Paris; where he ſtaid long enough to get plates engraven for a ſcore of ſolos, and the parts of two operas of concertos. About the year 1755 he returned to England, and advertiſed them for ſale. In 1761, Geminiani went over to Ireland; and was kindly entertained there by Mr Matthew Dubourg, who had been his pupil, and was then maſter of the king's band in Ireland. This perſon through the courſe of his life had ever been diſpoſed to render him friendly offices; and it was but a ſhort time after Geminiani's arrival at Dublin that he was called upon to do him the laſt. It ſeems that Geminiani had ſpent many years in compiling an elaborate treatiſe on muſic, which he intended for publication; but ſoon after his arrival at Dublin, by the treachery of a female ſervant, who, it was ſaid, was recommended to him for no other end than that ſhe might ſteal it, it was conveyed away, and could not be recovered. The greatneſs of this loſs, and his inability to repair it, made a deep impreſſion on his mind; and, as is conjectured, haſtened his end; at leaſt he ſurvived it but a ſhort time, ending his days on the 17th of September 1762. The following liſt compriſes the whole of his publications, except two or three articles of ſmall account. Twelve ſolos for a violin, *opera prima*; ſix concertos in ſeven parts, *opera ſeconda*; ſix concertos in ſeven parts, *opera terza*; twelve ſolos for a violin, *opera quarta*; ſix ſolos for a violencello, *opera quinta*; the ſame made into ſolos for a violin; ſix concertos from his *opera quarta*; ſix concertos in eight parts, *opera ſettima*; rules for playing in taſte; a treatiſe on good taſte; the art of playing the violin; 12 ſonatas from his firſt ſolos, *opera undecima*; Ripieno parts to ditto; leſſons for the harpſichord; *Guida Armonica*; ſupplement to ditto; the art of accompaniment, two books; his firſt two operas of concertos in ſcore; and the enchanted foreſt.—Of his ſolos the *opera prima* is eſteemed

Gemma

ed the beſt. Of his concertos ſome are excellent, others of them ſcarce paſs the bounds of mediocrity. The ſixth of the third opera not only ſurpaſſes all the reſt, but, in the opinion of the beſt judges of harmony, is the fineſt inſtrumental compoſition extant.

GEMMA, or Bud, in botany; a compendium or epitome of a plant, ſeated upon the ſtem and branches, and covered with ſcales, in order to defend the tender rudiments incloſed from cold and other external injuries, till, their parts being unfolded, they acquire ſtrength, and render any further protection unneceſſary.

Buds, together with bulbs, which are a ſpecies of buds generally ſeated upon or near the root, conſtitute that part of the herb called by Linnæus *hybernacula;* that is, the winter-quarters of the future vegetable: a very proper appellation, as it is during that ſevere ſeaſon that the tender rudiments are protected in the manner juſt mentioned.

Plants, conſidered in analogy to animals, may properly enough be reckoned both viviparous and oviparous. Seeds are the vegetable eggs; buds, living fetuſes, or infant-plants, which renew the ſpecies as certainly as the ſeed

Buds are placed at the extremity of the young ſhoots, and along the branches, being fixed by a ſhort footſtalk upon a kind of brackets, the remainder of the leaves, in the wings or angles of which the buds in queſtion were formed the preceding year. They are ſometimes placed ſingle; ſometimes two by two, and thoſe either oppoſite or alternate; ſometimes collected in greater numbers in whirls or rings.

With reſpect to their conſtruction, buds are compoſed of ſeveral parts artificially arranged. Externally, we find a number of ſcales that are pretty hard, frequently armed with hairs, hollowed like a ſpoon, and placed over each other like tiles. Theſe ſcales are fixed into the inner plates of the bark, of which they appear to be a prolongation. Their uſe is to defend the internal parts of the bud; which, being unfolded, will produce, ſome, flowers, leaves, and ſtipulæ; others, footſtalks and ſcales. All theſe parts, while they remain in the bud, are tender, delicate, folded over each other, and covered with a thick clammy juice, which is ſometimes reſinous and odoriferous, as in the tacahamac-tree. This juice ſerves not only to defend the more tender parts of the embryo-plant from cold, the aſſaults of inſects, and other external injuries; but likewiſe from exceſſive perſpiration, which, in its young and infant ſtate, would be very deſtructive. It is conſpicuous in the buds of horſe-cheſnut, poplar, and willow trees.

In general, we may diſtinguiſh three kinds of buds; that containing the flower, that containing the leaves, and that containing both flower and leaves.

The firſt, termed *gemma florifera*, and by the French *bouton a fleur* or *a fruit*, contains the rudiments of one or ſeveral flowers, folded over each other, and ſurrounded with ſcales. In ſeveral trees, this kind of bud is commonly found at the extremity of certain ſmall branches, which are ſhorter, rougher, and leſs garniſhed with leaves, than the reſt. The external ſcales of this ſpecies of bud are harder than the internal; both are furniſhed with hairs, and in general more ſwelled than thoſe of the ſecond ſort. The bud containing the flower too is commonly thicker, ſhorter, almoſt ſquare, leſs uniform, and leſs pointed; being generally terminated obtuſely. It is called by Pliny *oculus gemmæ;* and is employed in that ſpecies of grafting called *inoculation*, or *budding*. Gemma.

The ſecond ſpecies of bud, *viz.* that containing the leaves, termed *gemma folifera*, and by the French *bouton a feuilles* or *a bois*, contains the rudiments of ſeveral leaves, which are variouſly folded over each other, and outwardly ſurrounded by ſcales, from which the ſmall ſtipulæ that are ſeated at the foot of the young branches are chiefly produced. Theſe buds are commonly more pointed than the former ſort. In the hazel-nut, however, they are perfectly round; and in horſe-cheſnut, very thick.

The third ſort of bud is ſmaller than either of the preceding; and produces both flowers and leaves, tho' not always in the ſame manner. Sometimes the flowers and leaves are unfolded at the ſame time. This mode of the flower and leaf bud is termed by Linnæus *gemma folifera & florifera*. Sometimes the leaves proceed or emerge out of this kind of bud upon a ſmall branch, which afterwards produces flowers. This mode of the flower and leaf bud is termed by Linnæus *gemma folifera-florifera*, and is the moſt common bud of any.

Such buds as produce branches adorned only with leaves are called *barren;* ſuch as contain both leaves and flowers, *fertile*. From the bulk of the bud we may often with eaſe foretel whether it contains leaves only, or leaves and flowers together, as in cherry and pear trees.

Neither the buds produced on or near the root, called by ſome authors *turiones*, nor thoſe produced on the trunk, and from the angles or wings of the leaves, contain, in ſtrict propriety, an entire delineation of the plant; ſince the roots are wanting; and in various buds, as we have ſeen, ſhoots are contained with leaves only, and not with flowers: but as a branch may be conſidered as a part ſimilar to the whole plant, and, if planted, would in proceſs of revegetation exhibit or produce roots and flowers, we may in general allow, that the bud contains the whole plant, or the principles of the whole plant, which may be unfolded *ad libitum;* and thus reſembles the ſeed in containing a delineation of the future plant in embryo: for although the bud wants a radicle, or plumula, of which the ſeed is poſſeſſed, yet it would undoubtedly form one, if planted in the earth. But as the medullary part adhering to the bud is too tender, and by the abundance of juice flowing into it from the earth would be diſpoſed to putrefaction, the buds are not planted in the ſoil, but generally inſerted within the bark of another tree; yet placed ſo that the production of the marrow, or pith, adhering to them, may be inſerted into the pith of the branch in which the fiſſure or cleft is made; by which means there is a large communication of juice. This propagation by gems or buds, called *inoculation*, is commonly practiſed with the firſt ſort of buds above deſcribed.

From the obvious uſes of the buds, we may collect the reaſon why the ſupreme Author of nature has granted this ſort of protection to moſt of the trees that are natives of cold climates: and, on the other hand, denied it to ſuch as, enjoying a warm benign atmoſphere, have not the tender parts of their embryo-

Gemma. Gemmati.

ſhoots expoſed to injuries and depredations from the ſeverities of the weather. Of this latter kind are the plants of the following liſt; ſome of them very large trees; others ſmaller woody vegetables, of the ſhrub and under-ſhrub kind: Citron, orange, lemon, caſſava, mock-orange, blad-apple, ſhrubby ſwallow-wort, alaternus, ſhrubby geraniums, berry bearing alder, Chriſt's-thorn. Syrian mallow, baobab or Ethiopian ſour-gourd, juſticia, mild ſena, the acacias and ſenſitive plant, coral-tree, ſtinking bean-trefoil, medicago, oleander, viburnum, ſumach, ivy, tamariſk, heath, Barbadoes cherry, lavatera, rue, ſhrubby nightſhades, Guinea henweed, cypreſs, lignum vitæ, and ſavine a ſpecies of juniper.

On annual plants, whoſe root as well as ſtalk periſhes after a year, true buds are never produced; in their ſtead, however, are protruded ſmall branches, like a little feather, from the wings of the leaves, which wither without any farther expanſion if the plants climb and have no lateral branches; but if, either by their own nature or from abundance of ſap, the plants become branched, the ramuli juſt mentioned obtain an increaſe ſimilar to that of the whole plant.

The ſame appearance obtains in the trees of warm countries, ſuch as thoſe enumerated in the above liſt, in which a plumula, or ſmall feather, ſends forth branches without a ſcaly covering; as, in ſuch countries, this tender part requires no defence or protection from cold. A ſcaly covering then is peculiar to buds, as it protects the tender embryo incloſed from all external injuries. When we therefore ſpeak of trees having buds that are naked or without ſcales, our meaning is the ſame as if we had ſaid that they have no buds at all.

The buds that are to be unfolded the following year, break forth from the evolved buds of the preſent year, in ſuch a manner as to put on the appearance of ſmall eminences in the wings or angles of the leaves. Theſe eminences or knots grow but little during the ſummer; as, in that ſeaſon, the ſap is expended on the increaſe of the parts of the plant: but in autumn, when the leaves begin to wither and fall off, the buds, placed on the wings, increaſe; and the embryo-plant contained in the bud is ſo expanded, that the leaves and flowers, the parts to be evolved the following year, are diſtinctly viſible. Thus in horſe-chefnut the leaves, and in cornel-tree the flowers, are each to be obſerved in their reſpective buds.

As each bud contains the rudiments of a plant, and would, if ſeparated from its parent vegetable, become every way ſimilar to it; Linnæus, to ſhow the wonderful fertility of nature, has made a calculation, by which it appears, that, in a trunk ſcarce exceeding a ſpan in breadth, 10,000 buds (that is, herbs) may be produced. What an infinite number, then, of plants might be raiſed from a very large tree!

GEMMATIO, from *gemma*, "a bud;" a term uſed by Linnæus, expreſſive of the form of the buds, their origin, and their contents. It includes both thoſe properly called *buds*, and thoſe which are ſeated at the roots, ſtyled *bulbs*.

As to the origin of buds, they are formed either of the footſtalks of the leaves, of ſtipulæ, or of ſcales of the bark. Their contents have been already diſcovered, in the preceding article, to be either flowers, leaves, or both.

GEMONIÆ SCALÆ, or *Gradus Gemonii*, among the Romans, was much the ſame as gallows or gibbet in England.—Some ſay they were thus denominated from the perſon who raiſed them; others, from the firſt criminals that ſuffered on them; and others, from the verb *gemo*, "I ſigh or groan." Gemoniæ Gender.

The *gradus gemonii*, according to Publius Victor or Sextus Rufus, was a place raiſed on ſeveral ſteps, from whence they precipitated their criminals; others repreſent it as a place whereon offenders were executed, and afterwards expoſed to public view. The *gemoniæ ſcalæ* were in the tenth region of the city, near the temple of Juno. Camillus firſt appropriated the place to this uſe, in the year of Rome 358.

GENDARMES, or GEN D'ARMES, in the French armies, a denomination given to a ſelect body of horſe, on account of their ſucceeding the ancient gendarmes, who were thus called from their being completely clothed in armour; (ſee *Scots* GENDARMES, *infra*.) Theſe troops were commanded by captain-lieutenants, the king and the princes of the blood being their captains: the king's troop, beſides a captain-lieutenant, has two ſubheutenants, three enſigns, and three guidons.

Grand GENDARMES, latterly were a troop compoſed of 250 gentlemen; the king himſelf was their captain, and one of the firſt peers their captain-heutenant, who has under him two lieutenants, three enſigns, three guidons, and other officers.

Small GENDARMES, were the Scots gendarmes, the queen's, the dauphin's, the gendarmes of Anjou, Burgundy, the Engliſh and Flemiſh gendarmes, having each a captain-lieutenant, ſub-lieutenant, enſign, guidon, and quarter-maſter.

Scots GENDARMES, were originally inſtituted by Charles VII. of France, about the middle of the 5th century, and formed a part of his guard; in which ſtation alſo they acted under other princes. It was their prerogative to take precedence of all the companies of the gendarmerie of France; and, on particular occaſions, they even preceded the two companies of the king's mouſquetaires. The ſons of the Scottiſh monarchs were the uſual captains of this company; and, after Mary's acceſſion to the throne, its command belonged to them as a right. It was thence that James VI. made a claim of it for his ſon prince Henry. This honour, and its emoluments, were alſo enjoyed by Charles I. and the next in command to this prince was Louis Stuart duke of Lennox. George Gordon marquis of Huntly ſucceeded the duke of Lennox in the year 1624, and took the title of captain or commander in chief when Charles I. mounted the Engliſh throne. It is not certain whether Charles II. was ever captain of this company; but it was conferred on his brother the duke of York, who was captain of the Scots gendarmes till the year 1667, when he reſigned his commiſſion into the hands of the French king. Since that time no native of Great Britain has enjoyed this command. See *Scot's* GUARDS. *Stuart's Conſtit. of Scotland.*

All the different gendarmeries are now aboliſhed, in conſequence of the reforming ſyſtems that have lately taken place in France.

GENDER, among grammarians, a diviſion of nouns, or names, to diſtinguiſh the two ſexes.

This was the original intention of gender: but afterwards

Gendre ‖ Genep.

wards other words, which had no proper relation either to the one ſex or the other, had genders aſſigned them, rather out of caprice than reaſon; which is at length eſtabliſhed by cuſtom. Hence genders vary according to the languages, or even according to the words introduced from one language into another. Thus, *arbor* in Latin is feminine, but *arbre* in French is maſculine; and *dens* in Latin is maſculine, but *dent* in French is feminine.

The oriental languages frequently neglect the uſe of genders, and the Perſian language has none at all.

The Latins, Greeks, &c. generally content themſelves to expreſs the different genders by different terminations; as *bonus equus*, "a good horſe;" *bona equa*, "a good mare," &c. But in Engliſh we frequently go further, and expreſs the difference of ſex by different words: as boar, ſow; boy, girl; buck, doe; bull, cow; cock, hen; dog, bitch, &c.—We have only about 24 feminines, diſtinguiſhed from the males, by the variation of the termination of the male into *eſs*; of which number are abbot, abbeſs; count, counteſs; actor, actreſs; heir, heireſs; prince, princeſs, &c. which is all that our language knows of any thing like genders.

The Greek and Latin, beſides the maſculine and feminine, have the neuter, common, and the doubtful gender; and likewiſe the epicene, or promiſcuous, which under one ſingle gender and termination includes both the kinds.

GENDRE (Louis le), an eſteemed hiſtorian, born at Roan. He became canon of Notre Dame at Paris, ſubchanter of the ſame church, and abbot of Notre Dame at Claire Fontaine in the dioceſe of Chartres. He wrote a great number of works; the principal of which are: 1. The Manners and Cuſtoms of the French, in the different times of that monarchy. 2. An Hiſtory of France, in three volumes folio, and in ſeven volumes duodecimo. 3. The Life of Cardinal d'Amboiſe. He died in 1733, aged 78.

GENDRE (Gilbert Charles le), marquis of St Aubin, counſellor in the parliament of Paris, and afterwards maſter of requeſts in the king's houſehold. He wrote ſeveral works; but is chiefly diſtinguiſhed by his *Traite de l'opinion*, 9 vols 12mo; a curious performance, proving, by hiſtoric examples, the empire of opinion over the works of art and ſcience. He died at Paris in 1746, aged 59.

GENEALOGY, an enumeration of a ſeries of anceſtors; or a ſummary account of the relations and alliances of a perſon or family, both in the direct and collateral line.

The word is Greek, γενεαλογια; which is formed of γενος, "race or lineage," and λογος, "diſcourſe."

In divers chapters and military orders, it is required that the candidates produce their genealogy, to ſhow that they are noble by ſo many deſcents.

GENEALOGICA ARBOR, or *Tree of Conſanguinity*, ſignifies a genealogy or lineage drawn out under the figure of a tree, with its root, ſtock, branches, &c. The genealogical degrees are uſually repreſented in circles, ranged over, under, and aſide each other. This the Greeks called *ſtemmata*, a word ſignifying crown, garland, or the like. See the articles CONSANGUINITY and DESCENT, and the plates there referred to.

GENEP, a ſtrong town of Germany, in the circle of Weſtphalia, ſubject to the king of Pruſſia. E. Long. 4. 29. N. Lat. 51. 42.

General.

GENERAL, an appellation given to whatever belongs to a whole genus.

General Aſſembly. See ASSEMBLY.

General Charge, in law. See *Charge to enter Heir*.

General Terms, among logicians, thoſe which are made the ſigns of general ideas. See LOGIC and METAPHYSICS.

General Warrant. See WARRANT.

General of an Army, in the art of WAR, he who commands in chief. See the article WAR, where his office and duties are particularly explained.

General of the Artillery. See ORDNANCE.

General of Horſe, and *General of Foot*, are poſts next under the general of the army, and theſe have upon all occaſions an abſolute authority over all the horſe and foot in the army.

Adjutant-General, one who attends the general, aſſiſts in council, and carries the general's orders to the army. He diſtributes the daily orders to the majors of brigade. He is likewiſe charged with the general detail of the duty of the army. The majors of brigade ſend every morning to the adjutant-general an exact return, by battalion and company, of the men of his brigade. In a day of battle the adjutant-general ſees the infantry drawn up; after which, he places himſelf by the general, to receive any orders which may regard the corps of which he has the detail. In a ſiege, he orders the number of workmen demanded, and ſigns the warrant for their payment. He receives the guards of the trenches at their rendezvous, and examines their condition; he gives and ſigns all orders for parties. He has an orderly ſerjeant from each brigade of infantry in the line, to carry ſuch orders as he may have occaſion to ſend from the general.

Lieutenant-General, is the next in command after the general; and provided he ſhould die or be killed, the order is, that the oldeſt lieutenant-general ſhall take the command. This office is the firſt military dignity after that of a general. One part of their function is, to aſſiſt the general with their counſel: they ought therefore, if poſſible, to poſſeſs the ſame qualities with the general himſelf; and the more, as they often command armies in chief.

The number of lieutenant-generals have been multiplied of late in Europe, in proportion as the armies have become numerous. They ſerve either in the field, or in ſieges, according to the dates of their commiſſions. In battle, the oldeſt commands the right wing of the army, the ſecond the left wing, the third the centre; the fourth the right wing of the ſecond line, the fifth the left wing, the ſixth the centre; and ſo on. In ſieges, the lieutenant-generals always command the right of the principal attack, and order what they judge proper for the advancement of the ſiege during the 24 hours they are in the trenches; except the attacks, which they are not to make without an order from the general in chief.

Lieutenant-General of the Ordnance. See ORDNANCE.

Lieutenant-General of Artillery, is, or ought to be, a very great mathematician, and an able engineer; to know all the powers of artillery; to underſtand the attack and defence of fortified places, in all its different

General ‖ Generate.

rent branches; how to diſpoſe of the artillery in the day of battle to the beſt advantage; to conduct its march and retreat; as alſo to be well acquainted with all the numerous apparatus belonging to the train, and to the laboratory, &c.

Major-General, the next officer to the lieutenant-general. His chief buſineſs is to receive orders from the general, or in his abſence from the lieutenant-general of the day; which he is to diſtribute to the brigade-majors, with whom he is to regulate the guards, convoys, detachments, &c. On him the whole fatigue and detail of duty of the army roll. It is the major-general of the day who is charged with the encampment of the army, who places himſelf at the head of it when they march, who marks out the ground of the camp to the quarter-maſter-general, and who places the new guards for the ſafety of the camp.

The day the army is to march, he dictates to the field-officers the order of the march, which he has received from the general, and on other days gives them the parole.

In a fixed camp he is charged with the foraging, with reconnoitring the ground for it, and poſting the eſcorts, &c.

In ſieges, if there are two ſeparate attacks, the ſecond belongs to him; but if there is but one, he takes, either from the right or left of the attack, that which the lieutenant-general has not choſen.

When the army is under arms, he aſſiſts the lieutenant-general, whoſe orders he executes.

If the army marches to an engagement, his poſt is at the head of the guards of the army; until they are near enough to the enemy to rejoin their different corps; after which he retires to his own proper poſt: for the major-generals are diſpoſed on the order of battle as the lieutenant-generals are; to whom, however, they are ſubordinate, for the command of their diviſions. The major-general has one aid-de-camp, paid for executing his orders.

General is alſo uſed for a particular march, or beat of drum; being the firſt which gives notice, commonly in the morning early, for the infantry to be in readineſs to march.

General is likewiſe an appellation by which officers in law, in the revenues, &c. are diſtinguiſhed; as, *attorney-general*, *ſolicitor-general*, &c. *receiver-general*, *comptroller-general*, &c. See Attorney, &c.

General is alſo uſed for the chief of an order of monks; or of all the houſes and congregations eſtabliſhed under the ſame rule. Thus we ſay, the general of the Franciſcans, Ciſtertians, &c.

GENERALISSIMO, called alſo *captain-general*, and ſimply *general*, is an officer who commands all the military powers of a nation; who gives orders to all the other general officers; and receives no orders himſelf but from the king.

Monſ. Balzac obſerves, that the cardinal de Richelieu firſt coined this word, of his own abſolute authority, upon his going to command the French army in Italy.

GENERATE, in muſic, is uſed to ſignify the operation of that mechanical power in nature, which every ſound has in producing one or more different ſounds. Thus any given ſound, however ſimple, produces along with itſelf, its octave, and two other ſounds extremely ſharp, viz. its twelfth above, that is to ſay, the octave of its fifth; and the other the ſeventeenth above, or, in other words, the double octave of its third major.

Generated ‖ Generation.

Whether we ſuppoſe this procreation of ſounds to reſult from an aptitude in the texture and magnitude of certain particles in the air, for conveying to our ears vibrations that bear thoſe proportions one to another, as being determined at once by the partial and total oſcillations of any muſical ſtring; or from whatever economy of nature we chooſe to trace it; the power of one ſound thus to produce another, when in action, is ſaid to *generate*. The ſame word is applied, by Signior Tartini and his followers, to any two ſounds which, ſimultaneouſly heard, produce a third.

GENERATED, or Genited, is uſed, by ſome mathematical writers, for whatever is produced, either in arithmetic, by the multiplication, diviſion, or extraction of roots; or in geometry, by the invention of the contents, areas, and ſides; or of extreme and mean proportionals, without arithmetical addition and ſubtraction.

GENERATING line, or figure, in geomerty, is that which, by its motion of revolution, produces any other figure, plane or ſolid. See Genesis.

GENERATION, in phyſiology, the act of procreating and producing a being ſimilar to the parent. See Anatomy, n° 109, 110.

Generation of Fiſhes. See *Comparative Anatomy*, n° 154. and Ichthyology.

Generation of Plants. See Botany, ſect. v.

Generation of Inſects. See *Comparative Anatomy*, p. 274. and Entomology, ſect. ii.

Parts of Generation. See Anatomy, n° 107, 108.

Generation, in mathematics, is uſed for formation or production. Thus we meet with the generation of equations, curves, ſolids, &c.

Generation, in theology. The Father is ſaid by ſome divines to have produced his Word or Son from all eternity, by way of generation; on which occaſion the word *generation* raiſes a peculiar idea: that proceſſion, which is really effected in the way of underſtanding, is called *generation*, becauſe in virtue thereof, the Word becomes like to him from whom he takes this original; or, as St Paul expreſſes it, is the figure or image of his ſubſtance, *i. e.* of his being and nature. And hence it is, they ſay, that the ſecond Perſon in the Trinity is called the Son.

Generation is alſo uſed, though ſomewhat improperly, for genealogy, or the ſeries of children iſſued from the ſame ſtock. Thus the goſpel of St Matthew commences with the book of the generation of Jeſus Chriſt, &c. The latter and more accurate tranſlators, inſtead of *generation* uſe the word *genealogy*.

Generation is alſo uſed to ſignify a people, race, or nation, eſpecially in the literal tranſlations of the ſcripture, where the word generally occurs wherever the Latin has *generatio*, and the Greek γενεα. Thus, "A wicked and perverſe generation ſeeketh a ſign," &c. "One generation paſſes away, and another cometh," &c.

Generation is alſo uſed in the ſenſe of an age, or the ordinary period of man's life. Thus we ſay, "to the third and fourth generation." In this ſenſe hiſtorians uſually reckon a generation the ſpace of 33 years or thereabouts. See Age.

Generator || Genesis

Herodotus makes three generations in an hundred years; which computation appears from the later authors of political arithmetic to be pretty juſt.

GENERATOR, in muſic, ſignifies the principal ſound or ſounds by which others are produced. Thus the loweſt C for the treble of the harpſicord; beſides its octave, will ſtrike an attentive ear with its twelfth above, or G in alt, and with its ſeventeenth above, or E in alt. The C, therefore, is called their *generator*, the G and E its products or harmonics. But in the approximation of chords, for G, its octave below is ſubſtituted, which conſtitutes a fifth from the generator, or loweſt C; and for E, is likewiſe ſubſtituted its fifteenth below, which, with the above mentioned C, forms a third major. To the loweſt notes, therefore, exchanged for theſe in alt by ſubſtitution, the denominations of products or harmonics are likewiſe given, whilſt the C retains the name of their *generator*. But ſtill according to the ſyſtem of Tartini, two notes in concord, which when ſounded produce a third, may be termed the *concurring generators* of that third. (See *Generation Harmonique, par M. Rameau*; ſee alſo that delineation of Tartini's ſyſtem called *The power and principles of harmony.*)

GENERICAL NAME, in natural hiſtory, the word uſed to ſignify all the ſpecies of natural bodies, which agree in certain eſſential and peculiar characters, and therefore all of the ſame family or kind; ſo that the word uſed as the generical name equally expreſſes every one of them, and ſome other words expreſſive of the peculiar qualities or figures of each are added, in order to denote them ſingly, and make up what is called the ſpecific name. See BOTANY and ZOOLOGY.

GENESIS, the firſt book of the Old Teſtament, containing the hiſtory of the creation, and the lives of the firſt patriarchs.

The book of Geneſis ſtands at the head of the Pentateuch. Its author is held to be Moſes: it contains the relation of 2369 years, viz. from the beginning of the world to the death of Joſeph. The Jews are forbidden to read the beginning of Geneſis, and the beginning of Ezekiel, before 30 years of age.

The Hebrews called this book *Bereſchith*, becauſe it begins with that word, which in their language ſignifies *in principio*, or "in the beginning." The Greeks gave it the name *Geneſis*, γενεσις, *q. d.* production, generation, becauſe it begins with the hiſtory of the production or generation of all beings.

This book, beſides the hiſtory of the creation, contains an account of the original innocence and fall of man; the propagation of mankind; the riſe of religion; the general defection and corruption of the world; the deluge; the reſtoration of the world; the diviſion and peopling of the earth; and the hiſtory of the firſt patriarchs to the death of Joſeph. It was eaſy for Moſes to be ſatisfied of the truth of what he delivers in this book, becauſe it came down to him thro' a few hands: for from Adam to Noah there was one man, viz. Methuſelah, who lived ſo long as to ſee them both: in like manner Shem converſed with Noah and Abraham; Iſaac with Abraham and Joſeph, from whom the records of this book might eaſily be conveyed to Moſes by Amram, who was contemporary with Joſeph.

GENESIS, in geometry, denotes the formation of a line, plane, or ſolid, by the motion or flux of a point, line, or ſurface. See FLUXIONS.

Geneſis || Geneva.

The geneſis or formation, *e. gr.* of a globe or ſphere, is conceived by ſuppoſing a ſemicircle to revolve upon a right line, drawn from one extreme thereof to the other, called its axis, or axis of circumvolution: the motion or revolution of that ſemicircle is the geneſis of the ſphere, &c.

In the geneſis of figures, &c. the line or ſurface that moves is called the *deſcribent*; and the line round which, or, according to which, the revolution or motion is made, the *dirigent*.

GENET, GENNET, or *Jennet*, in the manege, denotes a ſmall-ſized well-proportioned Spaniſh horſe.

To ride *a la genette*, is to ride after the Spaniſh faſhion, ſo ſhort, that the ſpurs bear upon the horſe's flank.

GENETHLIA, in antiquity, a ſolemnity kept in memory of ſome perſon deceaſed.

GENETHLIACI, in aſtrology, perſons who erect horoſcopes or pretend to foretel what ſhall befal a man by means of the ſtars which preſided at his nativity. The word is formed of the Greek γενεθλη, *origin, generation, nativity*.

The ancients called them *Chaldæi*, and by the general name *mathematici*: accordingly, the ſeveral civil and canon laws, which we find made againſt the mathematicians, only reſpect the *genethliaci* or aſtrologers.

They were expelled Rome by a formal decree of the ſenate; and yet found ſo much protection from the credulity of the people, that they remained therein unmoleſted. Hence an ancient author ſpeaks of them as *hominum genus, quod in civitate noſtra ſemper & vetabitur, & retinebitur*.

GENETTE, in zoology. See VIVERRA.

GENEVA, a city of Switzerland, on the confines of France and Savoy, ſituated in 6° E. Long. and 46° 12′ 9″ N. Lat. It ſtands on the banks of the river Rhone, juſt at the place where the latter iſſues from the lake which takes its name from the city; and part of it is built on an iſland in the river. It is handſome, well fortified, and pretty large; the ſtreets in general are clean and well paved, but the principal one is encumbered with a row of ſhops on each ſide between the carriage and foot-paths. The latter is very wide, and protected from the weather by great wooden penthouſes projecting from the roofs; which, though very convenient, give the ſtreet a dark and dull appearance. The houſes are generally conſtructed of freeſtone, with baſements of limeſtone; the gutters, ſpouts, ridges, and outward ornaments, being made of tinned iron. Some of them have arched walks or piazzas in front. The place called *Treille* is very agreeable, being planted with linden trees, and commanding a fine proſpect of the lake, with ſeveral ranges of rocks riſing behind one another, ſome covered with vineyards and herbage, and others with ſnow, having openings between them. Immediately below Geneva the Rhone is joined by the Arve, a cold and muddy ſtream riſing among the Alps, and deriving a conſiderable part of its waters from the Glaciers. The Rhone is quite clear and tranſparent, ſo that the muddy water of the Arve is diſtinguiſhable from it even after they have flowed for ſeveral miles together. There are four bridges

Geneva. over the Rhone before it joins the Arve; and from it the city is supplied with water by means of an hydraulic machine, which raiſes it 100 Paris feet above its level. The principal buildings are, 1. The Maiſon de Ville, or town-houſe, a plain ancient edifice, with large rooms, in which the councils aſſemble, and public entertainments are held; and in one of them a weekly concert is held by ſubſcription during the winter. The aſcent to the upper ſtory is not by ſteps but a paved acclivity; which, however, is ſo gentle, that horſes and mules can go up to the top. 2. The church of St Peter's, formerly the cathedral, is an ancient Gothic building, with a modern portico of ſeven large Corinthian columns of red and white marble from Roche. The only thing remarkable in the inſide is the tomb of Henry duke of Rohan. 3. The arſenal is in good order, and ſupplied with arms ſufficient for 12,000 men. There are many ancient ſuits of armour; and the ſcaling ladders, lanthorns, hatchets, &c. uſed by the Savoyards in their treacherous attempt on the city in the year 1602, to be afterwards noticed, are here preſerved The magazines contain 110 cannons beſides mortars. 4. The hoſpital is a large handſome building, by which and other charities near 4000 poor people are maintained. 5. The fortifications on the ſide of Savoy are of the modern conſtruction, but are commanded by ſome neighbouring grounds. On the ſide of France they are old faſhioned, and at any rate are rather calculated to prevent a ſurpriſe than to ſuſtain a regular ſiege. There are three gates, towards France, Savoy, and Switzerland; and the acceſs to the lake is guarded by a double jetty and chain.

The territory belonging to this city contains about ſeven ſquare leagues, and is divided into nine pariſhes; the town is by far the moſt populous in Switzerland, having about 30,000 inhabitants, of whom, however, 5000 are generally ſuppoſed to be abſent. It has a ſmall diſtrict dependent upon it, but this does not contain above 16,000. The adjacent country is extremely beautiful, and has many magnificent views ariſing from the different poſitions of the numerous hills and mountains with regard to the town and lake. The inhabitants were formerly diſtinguiſhed into four claſſes, viz. citizens, burgeſſes, inhabitants, and natives; and ſince the revolution in 1782, a fifth claſs, named *domicilias*, have been added, who annually receive permiſſion from the magiſtrates to reſide in the city. The citizens and burgeſſes alone, however, are admitted to a ſhare in the government; thoſe called *inhabitants* are ſtrangers allowed to ſettle in the town with certain privileges; and the *natives* are the ſons of thoſe inhabitants, who poſſeſs additional advantages. The people are very active and induſtrious, carrying on an extenſive commerce.

1 State of learning in Geneva.

This city is remarkable for the number of learned men it has produced. The reformed doctrines of religion were very early received in it, being preached there in 1533 by William Farel and Peter Viret of Orbe, and afterwards finally eſtabliſhed by the celebrated John Calvin. Of this reformer Voltaire obſerves, that he gave his name to the religious doctrines firſt broached by others, in the ſame manner that Americus Veſputius gave name to the continent of America which had formerly been diſcovered by Columbus. It was by the aſſiduity of this celebrated reformer, and the influence that he acquired among the citizens, that a public academy was firſt eſtabliſhed in the city, where he, Theodore Beza, and ſome of the more eminent firſt reformers, read lectures with uncommon ſucceſs. The intolerant ſpirit of Calvin is well known; but little of it now appears in the government of Geneva: on the contrary, it is the moſt tolerating of all the ſtates in Switzerland, being the only one of them which permits the public exerciſe of the Lutheran religion. The advantages of the academy at Geneva are very conſpicuous among the citizens at this day, even the lower claſs of them being exceedingly well informed; ſo that, according to Mr Coxe, there is not a city in Europe where learning is ſo generally diffuſed. "I received great ſatisfaction (ſays he) in converſing even with ſeveral tradeſmen upon topics both of literature and politics; and was aſtoniſhed to find in this claſs of men ſo uncommon a ſhare of knowledge; but the wonder ceaſes when we are told that all of them were educated at the public academy." In this ſeminary the induſtry and emulation of the ſtudents are excited by the annual diſtribution of prizes to thoſe who diſtinguiſh themſelves in each claſs. The prizes conſiſt of ſmall medals, but are conferred with ſuch ſolemnity as cannot fail to produce a ſtriking effect on the minds of youth. There is alſo a public library to which the citizens have acceſs, and which undoubtedly tends greatly to that univerſal diffuſion of learning ſo remarkable among the inhabitants. It was founded by Bonnivard, remarkable for his ſufferings in the cauſe of the liberties of his country. Having been a great antagoniſt of the dukes of Savoy, againſt whom he aſſerted the independence of Geneva, he had the misfortune at laſt to be taken priſoner, and was impriſoned for ſix years in a dungeon below the level of the lake, in the caſtle of Chillon, which ſtands on a rock in the lake, and is connected with the land by a drawbridge. In 1536 this caſtle was taken from Charles III. of Savoy by the canton of Berne, aſſiſted by the Genevans, who furniſhed a frigate (their whole naval force) to beſiege it by ſea. Bonnivard was now taken from his dungeon, where by conſtant walking backward and forward, his only amuſement, he had worn a hollow in the floor which conſiſted of ſolid rock. Bonnivard conſidered the hardſhips he had endured as ties which endeared him to the city, and became a principal promoter of the reformation by the mild methods of perſuaſion and inſtruction. He cloſed his benefactions by the gift of his books and manuſcripts, and bequeathing his fortune towards the eſtabliſhment and ſupport of the ſeminary. His works, which chiefly relate to the hiſtory of Geneva, are ſtill preſerved with great care and reverence. The library contains 25,000 volumes, with many curious manuſcripts, of which an account has been publiſhed by the reverend M. Sennebier the librarian, who has likewiſe diſtinguiſhed himſelf by ſeveral literary works. Meſſrs Bonnet, Sauſſure, Mallet, and de Luc, are the other moſt diſtinguiſhed literary geniuſes of which Geneva can boaſt. The laſt is particularly remarkable for the perfection to which he has brought the barometer, and which is now ſo great, that very little ſeems poſſible to be done by any body elſe. His cabinet merits the attention of naturaliſts, as containing many rare and curious ſpecimens of foſſils, which ſerve to illuſtrate the theory of the globe.

2 Account of de Luc's cabinet.

It

Geneva. It may be divided into three parts: 1. Such as enable the naturaliſt to compare the petrefactions of animals and vegetables with the ſame bodies which are ſtill known to exiſt in our parts of the globe. 2. To compare theſe petrefactions of animals with the ſame bodies which are known to exiſt in different countries. 3. To conſider the petrefactions of thoſe bodies which are no longer known to exiſt. The ſecond part comprehends the ſtones under three points of view: 1. Thoſe of the primitive mountains, which contain no animal bodies; 2. Thoſe of the ſecondary mountains, which contain only marine bodies; 3. Thoſe which contain terreſtial bodies. The third part contains the lavas and other volcanic productions; which are diſtinguiſhed into two claſſes: 1. Thoſe which come from volcanoes now actually burning; 2. Thoſe from extinguiſhed volcanoes.

3 Hiſtory and government of Geneva. In the time of Charles the Great, the city and territory of Geneva made part of his empire; and, under his ſucceſſors, it became ſubject to the German emperors. By reaſon of the imbecility of theſe princes, however, the biſhops of Geneva acquired ſuch authority over the inhabitants, that the emperor had no other means of counterbalancing it than by augmenting the privileges of the people. In theſe barbarous ages alſo the biſhops and counts had conſtant diſputes, of which the people took the advantage; and by ſiding ſometimes with one, and ſometimes with the other, they obtained an extenſion of their privileges from both. The houſe of Savoy at length purchaſed the territory, and ſucceeded the counts with additional power: againſt them therefore the biſhops and people united in order to reſiſt their encroachments; and, during this period, the government was ſtrangely complicated by reaſon of the various pretenſions of the three parties. The counts of Savoy, however, had at laſt the addreſs to diſſolve the union between the biſhops and citizens, by procuring the epiſcopal ſee for their brothers, and even their illegitimate children; by which means their power became gradually ſo extenſive, that towards the commencement of the 16th century, Charles III of Savoy (though the government was accounted entirely republican) obtained an almoſt abſolute authority over the people, and exerciſed it in a moſt unjuſt and arbitrary manner. Thus violent commotions took place; and the citizens became divided into two parties, one of which, viz. the patriots, were ſtyled *Eidgenoſſen* or *confederates*; the partiſans of Savoy being diſgraced by the appellation of *Mammelucs* or *ſlaves*. The true period of Genevan liberty may therefore be conſidered as commencing with the treaty concluded with Berne and Friburg in the year 1526; in conſequence of which the duke was in a ſhort time deprived of his authority, the biſhop driven from the city, and the reformed religion and a republican form of government introduced. A long war commenced with Savoy on this account; but the Genevans proved an overmatch for their enemies by their own bravery and the aſſiſtance of the inhabitants of Berne. In 1584, the republic concluded a treaty with Zurich and Berne, by which it is allied to the Swiſs cantons. The houſe of Savoy made their laſt attempt againſt Geneva in 1602, when the city was treacherouſly attacked in the night-time during a profound peace. Two hundred ſoldiers had ſcaled the walls, and got into the town before any alarm was given; but they were repulſed by the deſperate valour of a few citizens, who periſhed in the encounter. A petard had been faſtened to one of the gates by the Savoyards; but the gunner was killed before it could be diſcharged. The war occaſioned by this treachery was next year concluded by a ſolemn treaty, which has ever ſince been obſerved on both ſides; though the independence of Geneva was not formally acknowledged by the king of Sardinia till the year 1754. Geneva.

The reſtoration of tranquillity from without in conſequence of the above treaty, was however ſoon followed by the flames of internal diſcord, ſo common in popular governments; ſo that during the whole of the laſt century the hiſtory of Geneva affords little more than an account of the ſtruggles betwixt the ariſtocratical and popular parties. About the beginning of the preſent century the power of the Grand Council was become almoſt abſolute; but in order to reſtrain its authority, an edict was procured in 1707 by the popular party, enacting, that every five years a general council of the citizens and barghers ſhould be ſummoned to deliberate upon the affairs of the republic. In conſequence of this law a general aſſembly was convened in 1712; and the very firſt act of that aſſembly was to aboliſh the edict by which they had been convened. A proceeding ſo extraordinary can ſcarcely be accounted for on the principles of popular fickleneſs and inconſtancy. Rouſſeau, in his Miſcellaneous Works, aſcribes it to the artifices of the magiſtrates, and the equivocal terms marked upon the billets then in uſe. For the queſtion being put, "Whether the opinion of the councils for aboliſhing the periodical aſſemblies ſhould paſs into a law?" the words *approbation* or *rejection*, put upon the billets by which the votes were given, might be interpreted either way. Thus, if the billet was choſen on which the word *approbation* was written, the opinion of the councils which rejected the aſſemblies was approved; and by the word *rejection*, the periodical aſſembly was rejected of courſe. Hence ſeveral of the citizens complained that they had been deceived, and that they never meant to reject the general aſſembly, but only the opinion of the councils.

In conſequence of the abolition of the general aſſemblies the power of the ariſtocratical party was greatly augmented; till at length the inhabitants exerting themſelves with uncommon ſpirit and perſeverance, found means to limit the power of the magiſtrates, and enlarge their own rights. In 1776, as Mr Cox informs us, the government might be conſidered as a mean betwixt that of the ariſtocratical and popular cantons of Switzerland. The members of the ſenate, or little council of 25, enjoyed in their corporate capacity ſeveral very conſiderable prerogatives. By them half the members of the great council were named; the principal magiſtrates were ſupplied from their own body; they convoked the great and general councils, deliberating previouſly upon every queſtion which was to be brought before theſe councils. They were veſted alſo with the chief executive power, the adminiſtration of finances, and had in a certain degree the juriſdiction in civil and criminal cauſes. Moſt of the ſmaller poſts were likewiſe filled by them; and they enjoyed the ſole privilege of conferring the burgherſhip. Theſe, and other prerogatives, however, were balanced by thoſe of the great council and the privileges of the general 4 Sketch of the government in 1776.

Geneva. neral council. The former had a right to chooſe the members of the ſenate from their own body; receiving appeals in all cauſes above a certain value, pardoning criminals, &c. beſides which they had the important privilege of approving or rejecting whatever was propoſed by the ſenate to be laid before the people.

The general council or aſſembly of the people, is compoſed of the citizens and burghers of the town; their number in general amounting to 1500, though uſually not more than 1200 were preſent; the remainder reſiding in foreign countries, or being otherwiſe abſent. It meets twice a-year, chooſes the principal magiſtrates, approves or rejects the laws and regulations propoſed by the other councils, impoſes taxes, contracts alliances, declares war or peace, and nominates half the members of the great council, &c. But the principal check to the power of the ſenate aroſe from the right of *re-election*, or the power of annually expelling four members from the ſenate at the nomination of the *ſyndics* or principal magiſtrates, and from the right of repreſentation. The ſyndics are four in number, choſen annually from the ſenate by the general council; and three years elapſe before the ſame members can be again appointed. In chooſing theſe magiſtrates, the ſenate appointed from its own body eight candidates, from whom the four ſyndics were to be choſen by the general council. The latter, however, had it in their power to reject not only the firſt eight candidates, but alſo the whole body of ſenators in ſucceſſion: in which caſe, four members of the ſenate retired into the great council; and their places were filled by an equal number from that council. With regard to the power of repreſentation, every citizen or burgher had the privilege of applying to the ſenate in order to procure a new regulation in this reſpect, or of remonſtrating againſt any act of the magiſtracy. To theſe remonſtrances the magiſtrates were obliged to give an explicit anſwer; for if a ſatisfactory anſwer was not given to one, a ſecond was immediately preſented. The repreſentation was made by a greater or ſmaller number of citizens according to the importance of the point in queſtion.

5 Account of the revolution in 1782.

Since the 1776, however, ſeveral changes have taken place. This right of *re-election*, which the ariſtocratical party were obliged to yield to the people in 1768, ſoon proved very diſagreeable, being conſidered by the former as a kind of oſtraciſm; for which reaſon they catched at every opportunity of procuring its abolition. They were now diſtinguiſhed by the title of *negatives*, while the popular party had that of *repreſentants*; and the point in diſpute was the compilation of a new code of laws. This meaſure the negatives oppoſed, as ſuppoſing that it would tend to reduce their prerogatives; while, on the other hand, the repreſentants uſed their utmoſt endeavours to promote it, in hopes of having their privileges augmented by this means. At laſt, in the month of January 1777, the negatives were obliged to comply with the demands of their antagoniſts; and a committee for forming a new code of laws was appointed by the concurrence of the little, great, and general councils. The committee was to laſt for two years, and the code to be laid before the three councils for their joint approbation or rejection. A ſketch of the firſt part of the code was preſented to the little and great councils on the firſt of September 1779, that they might profit by their obſervations before it was preſented to the general council. Great diſputes aroſe; and at length it was carried by the negatives that the code ſhould be rejected and the committee diſſolved. The oppoſite party complained of this as unconſtitutional, and violent diſputes enſued; the iſſue of which was, that the great council offered to compile the code, and ſubmit it to the deciſion of the public. This did not give ſatisfaction to the popular party, who conſidered it as inſidious: the contentions revived with more fury than ever, until at length the negatives ſuppoſing, or pretending to ſuppoſe, that their country was in danger, applied to their guarantees, France, Zurich, and Berne, intreating them to protect the laws and conſtitution. This was productive of no good effect; ſo that the negatives found no other method of gaining their point than by ſowing diſſenſion among the different claſſes of inhabitants. The *natives* were diſcontented and jealous on account of many excluſive privileges enjoyed by that claſs named *citizens*: they were beſides exaſperated againſt them for having, in 1770, baniſhed eight of the principal natives, who pretended that the right of burgherſhip belonged to the natives as well as to the citizens, and demanded that this right ought to be gratuitouſly conferred inſtead of being purchaſed. The negatives, in hopes of making ſuch a conſiderable addition to their party, courted the natives by all the methods they could think of, promiſing by a public declaration that they were ready to confer upon them thoſe privileges of trade and commerce which had hitherto been confined excluſively to the citizens. The deſigns of the negatives were likewiſe openly favoured by the court of France, and diſpatches were even written to the French reſident at Geneva to be communicated to the principal natives who ſided with the ariſtocratic party. The attorney-general, conceiving this mode of interference to be highly unconſtitutional, preſented a ſpirited remonſtrance; by which the French court were ſo much diſpleaſed, that they procured his depoſition from his office; and thus their party was very conſiderably increaſed among the natives. The repreſentants were by no means negligent in their endeavours to conciliate the favour of the ſame party, and even promiſed what they had hitherto oppoſed in the ſtrongeſt manner, viz. to facilitate the acquiſition of the burgherſhip, and to beſtow it as the recompence of induſtry and good behaviour. Thus two parties were formed among the natives themſelves; and the diſſenſions becoming every day worſe and worſe, a general inſurrection took place on the 5th of February 1781. A diſpute, accompanied with violent reproaches, having commenced betwixt two neighbouring and oppoſite parties of natives, a battle would have immediately taken place, had it not been for the interpoſition of the ſyndics on the one ſide, and the chiefs of the repreſentants on the other. The tumult was beginning to ſubſide, when a diſcharge of muſquetry was heard from the arſenal. Some young men who ſided with the negatives, having taken poſſeſſion of the arſenal, had fired by miſtake upon ſeveral natives of their own party, and had killed one and wounded another. This was conſidered by the repreſentants as the ſignal for a general inſurrection, on which they inſtantly took up arms and marched in three columns to the arſenal; but finding

Geneva.

Genera finding there only a few young men who had raſhly fired without orders, they permitted the reſt to retire without moleſtation. In the opinion of ſome people, however, this affair was preconcerted, and the repreſentants are ſaid to have been the firſt aggreſſors.

The repreſentants having thus taken up arms, were in no haſte to lay them down. They took poſſeſſion of all the avenues to the city; and their committee being ſummoned next morning by the natives to fulfil their engagements with reſpect to the burgherſhip, they held ſeveral meetings with the principal negatives on that ſubject, but without any ſucceſs: for though the latter readily agreed to an augmentation of the commercial privileges of the natives, they abſolutely refuſed to facilitate the acquiſition of the burgherſhip. The committee, however, embarraſſed and alarmed at the number and threats of the natives, determined to abide by what they had promiſed; drew up an edict permitting the natives to carry on trade, and to hold the rank of officers in the military aſſociations; and conferred the burgherſhip on more than 100 perſons taken from the natives and inhabitants, and even from the peaſants of the territory. This was approved by the three councils; the negatives, dreading the power of their adverſaries, who had made themſelves maſters of the city, not daring to make their appearance.

Thus the popular party imagined that they had got a complete victory; but they ſoon found themſelves deceived. They were prevailed upon by the deputies from Zurich and Berne (who had been ſent to conciliate the differences) to lay down their arms; and this was no ſooner done, than theſe ſame deputies declared the edict in favour of the natives to be null and illegal. The ſenate declared themſelves of the ſame opinion; and maintained, that the aſſent of the councils had been obtained only through fear of the repreſentants who were under arms, and whom none at that time durſt oppoſe. The repreſentants, exaſperated by this proceeding, preſented another remonſtrance on the 18th of March 1782, ſummoning the magiſtrates once more to confirm the edict; but a month afterwards received the laconic anſwer, that "government was neither willing nor able to confirm it." The natives, now finding themſelves diſappointed in their favourite object at the very time they had ſuch ſtrong hopes of obtaining it, behaved at firſt like frantic people; and theſe tranſports having ſubſided, an univerſal tumult took place. The moſt moderate of the popular party endeavoured in vain to allay their fury, by diſperſing themſelves in different quarters of the city; and the citizens, finding themſelves at laſt obliged either to abandon the party of the natives or to join them openly, haſtily adopted the latter meaſure; after which, as none could now oppoſe them, the officers of the repreſentants took poſſeſſion of the town, and quelled the inſurrection. Various negociations were carried on with the negatives in order to prevail upon them to ratify the edict, but without ſucceſs: on which a few of the magiſtrates were confined by the popular party along with the principal negatives; and as they juſtly expected the interference of France on account of what they had done, they reſolved to prolong the confinement of the priſoners, that they might anſwer the purpoſe of hoſtages for their own ſafety. In the mean time the body of citizens, deceived by the pretences of the popular party, acted as if their power was already eſtabliſhed and permanent. In conſequence of this, they depoſed ſeveral members of the great and little councils, appointing in their room an equal number of perſons who were favourable to the cauſe of the repreſentants. The great council thus new modelled, executed the edict for conferring the burgherſhip upon a number of the natives; and appointed a committee of ſafety, compoſed of eleven members, with very conſiderable authority. By this committee the public tranquillity was re-eſtabliſhed; after which, the fortifications were ordered to be repaired; and the people were buoyed up by the moſt dangerous notions of their own proweſs, and a confidence that France either durſt not attack them or did not incline to do ſo. In conſequence of this fatal error, they refuſed every offer of reconciliation which was made them from the other party; until at laſt troops were diſpatched againſt them by the king of Sardinia and the canton of Berne; and their reſpective generals, Meſſrs de la Marmora and Lentulus, being ordered to act in concert with the French commander M. de Jaucourt, who had advanced to the frontiers with a conſiderable detachment. The Genevans, however, vainly puffed up by a confidence in their own abilities, continued to repair their fortifications with indefatigable labour; the peaſants repaired from all quarters to the city, offering to mount guard and work at the fortifications without any pay; women of all ranks crowded to the walls as to a place of amuſement, encouraging the men, and even aſſiſting them in their labour. The beſiegers, however, advanced in ſuch force, that every perſon of diſcernment foreſaw that all reſiſtance would be vain. The French general Jaucourt, on the 29th of June 1782, diſpatched a meſſage to the Syndics; in which he inſiſted on the following humiliating conditions: 1. That no perſon ſhould appear on the ſtreets under pain of military puniſhment. 2. That a certain number of citizens, among whom were all the chiefs of the repreſentants, ſhould quit the place in 24 hours. 3. That all arms ſhould be delivered to the three generals. 4. That the depoſed magiſtrates ſhould be inſtantly re-eſtabliſhed: And, laſtly, That an anſwer ſhould be returned in two hours. By this meſſage the people were thrown into the utmoſt deſpair; and all without exception reſolved to periſh rather than to accept of terms ſo very diſgraceful. They inſtantly hurried to the ramparts with a view of putting their reſolution in force; but in the mean time the Syndics found means to obtain from the generals a delay of 24 hours. During this interval, not only men of all ages prepared for the approaching danger, but even women and children tore the pavement from the ſtreets, carrying the ſtones up to the tops of the houſes, with a view of rolling them down upon the enemy in caſe they ſhould force their way into the town. About 80 women and girls, dreſſed in uniforms, offered to form themſelves into a company for the defence of their country. The committee of ſafety accepted their ſervices, and placed them in a barrack ſecured from the cannon of the beſiegers. The negatives were greatly alarmed at this appearance of deſperate reſiſtance; and ſome of the moſt moderate among them endeavoured, but without ſucceſs, to effect a reconciliation. At the hour Genera.

in

Geneva. in which it was expected that the attack would begin, the ramparts were filled with defenders; and though the moſt zealous of the popular party had calculated only on 3000, upwards of 5000 appeared in the public cauſe. The French general, however, juſtly alarmed for the priſoners, who were now in imminent danger, again prolonged the period propoſed for the capitulation. By theſe repeated delays the ardour of the defendants began to abate. The women firſt began to figure to themſelves the horrors of a town taken by aſſault, and given up to an enraged and licentious ſoldiery; many timid perſons found means not only to diſguiſe their own fears, but to inſpire others with them under the pretence of prudence and caution: at laſt the committee of ſafety themſelves, who had ſo ſtrenuouſly declared for hoſtilities, entirely changed their mind. Being well apprized, however, that it would be dangerous for them to propoſe ſurrendering in the preſent temper of the people, they aſſembled the citizens in their reſpective circles, repreſenting, that if the city ſhould be attacked in the night, it would be no longer poſſible to convene them: for which reaſon they recommended to them that each circle ſhould nominate ſeveral deputies with full authority to decide in their ſtead; adding, that they ought rather to appoint thoſe perſons who from their age and reſpectable character were capable of aſſiſting their country by their advice, while others were defending it by their valour. Thus a new council, compoſed of about 100 citizens, was formed; in which the chiefs, by various manœuvres, firſt intimidating, and then endeavouring to perſuade the members of the neceſſity of ſurrendering, at laſt found means to take the thoughts of the people entirely off the defence of the city, and engage them in a ſcheme of general emigration. A declaration was drawn up to be delivered to the Syndics with the keys of the city, the chiefs ſummoned the principal officers from their poſts, ordered the cannon of ſeveral batteries to be rendered unfit for ſervice, and at laſt took care of themſelves by quitting the town. The people were in the utmoſt deſpair; and left the town in ſuch multitudes, that when the Sardinians entered it in the morning, they found it almoſt deſerted. This was followed by the reſtoration of the former magiſtrates, a complete ſubjection of the popular party, and the eſtabliſhment of a military government.

6 New conſtitution eſtabliſhed.

The changes which took place on this occaſion were as follow: 1. An abolition of the right of re-election. 2. The abolition of that right by which the general council nominated half the vacancies in the great council. 3. The right of remonſtrating was taken from the citizens at large, and veſted in 36 adjuncts, who might be preſent in the great council the firſt Monday of every month. They enjoyed a right of repreſentation, and in conſequence of that had a deliberative voice; but on the whole were ſo inſignificant, that they were nicknamed *Les Images*, or "The Shadows." 4. The introduction of the grabeau, or annual confirmation of the members of the ſenate and of the great council, veſted entirely in the latter. By this law part of the authority both of the ſenate and general council was transferred to the great council; and by ſubjecting the ſenate to this annual reviſion, its power was greatly leſſened, and it was made in fact dependent upon the general council. 5. The circles or clubs in which it was cuſtomary to convene the citizens, and all public aſſemblies whatever, were prohibited; and ſo rigorouſly was this carried into execution, that the ſociety of arts was prohibited from meeting: 6. The militia were aboliſhed; firing at marks, even with bows and arrows, was prohibited; and the town, inſtead of being guarded by the citizens, was now put under the care of 1000 foreign ſoldiers, whoſe colonel and major were both to be foreigners. Theſe troops were to take an oath of fidelity to the republic, and of obedience to the great council and the committee of war; but were under the immediate command and inſpection of the latter, and ſubject to the ſuperior control of the former. 7. No perſon was permitted to bear arms, whether citizen, native, or inhabitant. 8. Several taxes were impoſed without the conſent of the general council; but in time to come it was provided, that every change or augmentation of the revenue ſhould be ſubmitted to that body. 9. Several privileges with regard to trade and commerce, formerly poſſeſſed by the citizens alone, were now granted both to citizens and inhabitants.

Geneva

It is not to be ſuppoſed that this revolution would be agreeable to people who had ſuch a ſtrong ſenſe of liberty, and had been accuſtomed to put ſuch a value upon it, as the Genevans. From what has been already related, it might ſeem reaſonable to conclude, that an almoſt univerſal emigration would have taken place: but after their reſentment had time to ſubſide, moſt of thoſe who fled at firſt, thought proper to return; and, in the opinion of Mr Coxe, not more than 600 finally left their country on account of the revolution in 1782. The emigrants principally ſettled at Bruſſels and Conſtance, where they introduced the arts of printing linens and watchmaking. Soon after the revolution, indeed, a memorial, ſigned by above 1000 perſons of both ſexes, all of them either poſſeſſed of ſome property or verſed in trade or manufactures, was preſented to the earl of Temple, then lord lieutenant of Ireland, expreſſing a deſire to ſettle in that kingdom. The propoſal met with general approbation; the Iriſh parliament voted L. 50,000 towards defraying the expences of their journey, and affording them a proper ſettlement in the iſland. Lands were purchaſed for L. 8000 in a convenient ſituation near Waterford; part of New Geneva was actually completed at the expence of L. 10,000; a charter was granted with very conſiderable privileges; the ſtandard of gold was altered for the accommodation of the watch manufacturers; and the foundation of an academy laid upon an uſeful and liberal plan. Several Genevans landed in Ireland in the month of July 1783; but when the nation had expended near L. 30,000 on the ſcheme, it was ſuddenly abandoned. This ſeems principally to have been owing to the delays neceſſarily occaſioned in the execution of ſuch a complicated plan; and in ſome degree alſo by the high demands of the Genevan commiſſioners, who required many privileges inconſiſtent with the laws of Ireland. By theſe delays the Genevans, whoſe character ſeems not to be *perſeverance*, were induced to abandon the ſcheme, and return to their former place of reſidence. Even the few who had already landed, though maintained at the public expence, were diſcontented at not finding the new town prepared for their

7 Scheme of ſettling a number of Genevans in Ireland.

recep-

reception; and as these among the proposed emigrants who possessed the greatest share of property had already withdrawn their names, the remainder did not choose to remain in a country where they had not capital sufficient to carry on any considerable trade or manufacture. A petition was then presented by the Genevan commissioners, requesting that L. 10,000 of the L. 50,000 voted might be appropriated to the forming a capital: but as this had been voted for other purposes, the petition was of course rejected; in consequence of which, the Genevans relinquished the settlement by an address, and soon after quitted the island.

The people of Old Geneva, though returned to their former place of abode, were far from being inclined to submit to the yoke with patience. They were obliged to pay heavy taxes for maintaining a military force expressly calculated to keep themselves in subjection; and so intolerable did this appear, that in a few years every thing seemed ready for another revolution. The success of this seemed more probable than that of the former, as France was not now in a condition to interfere as formerly. The general ferment soon rose to such a height, that government was obliged to call in the aid of the military to quell a tumult which happened in the theatre. This produced only a temporary tranquillity; another tumult took place on the 26th of January 1789, on account of the publication of an edict raising the price of bread a farthing per pound. On this the people instantly rose; plundered the bakers shops; and next day a carriage loaded with bread and escorted by soldiers was plundered in its way to the distribution office. The soldiers fired on the populace, by which one man was killed and another wounded: but the tumult still increasing, the soldiers were driven away; and the body of the deceased was carried in a kind of procession before the town-house, as a monument of the violence and oppression of the aristocratic party. The magistrates in the mean time spent their time in deliberation, instead of taking any effectual method of quelling the insurrection. The people made the best use of the time afforded them by this delay of the magistrates: they attacked and carried two of the gates, dangerously wounding the commanding officer as he attempted to allay the fury of both parties. At last the magistrates dispatched against them a considerable body of troops, whom they thought the insurgents would not have the courage to resist; but in this they found themselves deceived. The people had formed a strong barricade, behind which they played off two fire pumps filled with boiling water and soap lyes against the extremities of two bridges which the military had to cross before they could attack them. The commanding officer was killed and several of his men wounded by the discharge of small arms from windows; and the pavement was carried up to the tops of houses in order to be thrown down upon the troops if they should force the barricades and penetrate into the streets. The tumult in the mean time continued to increase, and was in danger of becoming universal; when the magistrates, finding it would be impossible to quell the insurgents without a great effusion of blood, were reduced to the necessity of complying with their demands. One of the principal magistrates repaired in person to the quarter of St Gervais, proclaimed an edict for lowering the price of bread, granted a general amnesty, and released all the insurgents who had been taken into custody. Thus a momentary calm was produced; but the leaders of the insurrection, sensible that the magistrates were either unable or unwilling to employ a sufficient force against them, resolved to take advantage of the present opportunity to procure a new change of government. A new insurrection, therefore, took place on the 29th of the month, in which the soldiers were driven from their posts, disarmed, and the gates seized by the people. The magistrates then, convinced that all opposition was fruitless, determined to comply with the demands of their antagonists in their full extent; and the aristocratical party suddenly changing their sentiments, renounced in a moment that system to which they had hitherto so obstinately adhered. On the application of the solicitor general, therefore, for the recovery of the ancient liberties of the people, the permission of bearing arms, re-establishment of the militia, and of their circles or political clubs, the removal of the garrison from the barracks, and the recall of the representants who were banished in 1782; these moderate demands were received with complacency, and even satisfaction. The preliminaries were settled without difficulty, and a new edict of pacification was published under the title of *Modifications a l'Edition de* 1782, and approved by the senate, great council, and general council. So great was the unanimity on this occasion, that the modifications were received by a majority of 1321 against 52. The pacification was instantly followed by marks of friendship betwixt the two parties which had never been experienced before; the sons of the principal negatives frequented the circles of the burghers; the magistrates obtained the confidence of the people; and no monument of the military force so odious to the people will be allowed to remain. "The barracks of the town-house (says Mr Coxe) are already evacuated, and will be converted into a public library; the new barracks, built at an enormous expence, and more calculated for the garrison of a powerful and despotic kingdom than for a small and free commonwealth, will be converted into a building for the university. The reformation of the studies, which have scarcely received any alteration since the time of Calvin, is now in agitation. In a word, all things seem at present to conspire for the general good; and it is to be hoped that both parties, shocked at the recollection of past troubles, will continue on as friendly terms as the jealous nature of a free constitution will admit."

Geneva Lake.

Geneva Lake. This lake is in the shape of a crescent; along the concave side of which Mr Coxe travelled 54 miles. Switzerland forms the hollow, and Savoy the convex part; the greatest breadth being about 12 miles. The country on the side of Savoy is full of high and craggy mountains; but from Geneva to the environs of Lausanne it slopes to the margin of the lake, and is very rich and fertile. The banks rise considerably in the neighbourhood of Lausanne, and form a most beautiful terrace, with a rapid descent a few miles beyond the town. A plain begins in the neighbourhood of Vevay, which continues for a great way beyond the end of the lake, but contracting towards the water by the approach of the mountains.

Geneva, Genial.

The lake itſelf appears at a diſtance of a beautiful blue colour, and the water is very clear and tranſparent. Near Geneva the coaſt of the lake abounds with pebbles; between that city and Lauſanne it is ſandy; from thence to Chillon it is bounded by hard calcareous rocks; and the extremity of the ſhore is a marſh formed by mud collected from the river Rhone. The greateſt depth of this lake found by M. de Luc is 160 fathoms. Here the birds called *tippet grebes* make their appearance in December, and retire in February to other places where they breed. They make floating neſts of reeds; but as the lake of Geneva affords none of theſe, they are obliged to migrate to other places where they grow. Their ſkins are much eſteemed, and ſell for 12 or 14 s. each. The lake of Geneva, like all others ſituated between mountains, is ſubject to ſudden ſtorms.

GENEVA, or *Gin*, among diſtillers, an ordinary malt ſpirit, diſtilled a ſecond time, with the addition of ſome juniper-berries.

Originally, the berries were added to the malt in the grinding; to that the ſpirit thus obtained was flavoured with the berries from the firſt, and exceeded all that could be made by any other method. At preſent, they leave out the berries entirely, and give their ſpirits a flavour by diſtilling them with a proper quantity of oil of turpentine; which, though it nearly reſembles the flavour of juniper-berries, has none of their valuable virtues.

GENEVIEVE, fathers or religious of; the name of a congregation of regular canons of the order of St Auguſtine, eſtabliſhed in France.

The congregation of St Genevieve is a reform of the Auguſtine canons. It was begun by St Charles Faure, in the abbey of St Vincent de Senlis, of which he was a member in the year 1618.

In the year 1634, the abbey was made elective; and a general chapter, compoſed of the ſuperiors of 15 houſes who had now received the reform, choſe F. Faure coadjutor of the abbey of St Genevieve, and general of the whole congregation. Such were its beginnings.

It has ſince increaſed very much, and it now conſiſts of above a hundred monaſteries; in ſome whereof the religious are employed in the adminiſtration of the pariſhes and hoſpitals; and in others in the celebration of divine ſervice, and the inſtruction of eccleſiaſtics in ſeminaries for the purpoſe.

The congregation takes its name from the abbey of St Genevieve, which is the chief of the order, and whoſe abbot is the general thereof. The abbey itſelf took its name from St Genevieve, the patroneſs of the city of Paris, who died in the year 512. Five years after her death, Clovis erected the church of St Genevieve, under the name and invocation of St Peter, where her relics are ſtill, or were till lately, preſerved, her ſhrine viſited, and her image carried with great proceſſions and ceremonies upon extraordinary occaſions, as when ſome great favour is to be intreated of heaven.

GENGISKHAN, the renowned ſovereign of the Moguls, a barbarous and bloody conqueror. See JENGHIZ KHAN, and *(Hiſtory of the)* MOGULS.

GENIAL, an epithet given by the Pagans to certain gods who were ſuppoſed to preſide over generation.

The genial gods, ſays Feſtus, were earth, air, fire, and water. The twelve ſigns, together with the ſun and moon, were ſometimes alſo ranked in the number.

GENII, a ſort of intermediate beings, by the Mahometans believed to exiſt, between men and angels. They are of a groſſer fabric than the latter, but much more active and powerful than the former. Some of them are good, others bad, and they are capable of future ſalvation or damnation like men. The Orientals pretend that theſe genii inhabited the world many thouſand years before the creation of Adam, under the reigns of ſeveral princes, who all bore the common name of Solomon: that falling at length into an almoſt general corruption, Eblis was ſent to drive them into a remote part of the earth, there to be confined: and that ſome of that generation ſtill remaining were by Tahmurath, one of the ancient kings of Perſia, forced to retreat into the famous mountain of *Kaf*; of whoſe ſucceſſions and wars they have many fabulous and romantic ſtories. They alſo made ſeveral ranks and degrees among this kind of beings (if they are not rather different ſpecies); ſome being abſolutely called *Jin*; ſome *Peri*, or fairies; ſome *Div*, or giants; and other *Tacwins*, or fates.

GENIOGLOSSI, in anatomy. See ANATOMY, *Table of the Muſcles*.

GENIOHYOIDÆUS, in anatomy. *Ibid.*

GENIOSTOMA, in botany: A genus of the monogynia order, belonging to the pentandria claſs of plants. The calyx is a turbinated quinquefid perianthium; the corolla monopetalous and tubular; the ſtamina five ſhort filaments; the antheræ oblong; the ſeeds very numerous and ſubangulated, placed on a filiform receptacle.

GENIPPA, in botany: A genus of the monogynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 30th order, *Contortæ*. The corolla is wheel-ſhaped; the ſtigma club-ſhaped; the berry bilocular; the ſeeds neſtling in a carnous heart-ſhaped ſubſtance.

GENISTA, BROOM, or DYERS-WEED: A genus of the decandria order, belonging to the diadelphia claſs of plants; and in the natural method ranking under the 32d order, *Papilionaceæ*. The calyx is bilabiate, the upper lip bidented, the under one tridentate; the vexillum is oblong and reflexed, or turned back from the piſtil and ſtamina. There are ſeveral ſpecies; of which the moſt remarkable are, the cytiſo-geniſta, or common broom; and the tinctoria, or dyers weed.—The firſt is too well known to need deſcription. Its young flowers are ſometimes preſerved as pickles; and the plant, when burnt, affords a tolerably pure alkaline ſalt. Dr Mead relates the caſe of a dropſical patient that was cured by taking half a pint of a decoction of green broom tops, with a ſpoonful of whole white muſtard ſeed, every morning and evening. The patient had been tapped three times, and tried the uſual remedies before. An infuſion of the ſeeds, drank freely, has been known to produce ſimilar happy effects; but theſe are by no means to be expected in every inſtance. Cows, horſes, and ſheep, refuſe the plant.—2. The tinctoria is alſo a native of Britain.

Genital Genius.

It rises with shrubby stalks three feet high, garnished with spear-shaped leaves placed alternate, and terminated by several spikes of yellow flowers, succeeded by pods. The branches of the plant are used by dyers for giving a yellow colour; from whence it is called *dyers-broom*, *green-wood*, *wood-waxen*, or *dyers-weed*. A dram and an half of the powdered seeds operates as a mild purgative. A decoction of the plant is diuretic; and, like the former, has proved serviceable in dropsical cases. Horses, cows, goats, and sheep, eat it.

GENITAL, an appellation given to whatever belongs to the parts of generation. See ANATOMY, n° 107, 108.

GENITES, among the Hebrews, those descended from Abraham, without any mixture of foreign blood.

The Greeks distinguished by the name of *genites* such of the Jews as were issued from parents, who, during the Babylonish captivity, had not allied with any gentile family.

GENITIVE, in grammar, the second case of the declension of nouns. The relation of one thing considered as belonging in some manner to another, has occasioned a peculiar termination of nouns called the *genitive case*; but in the vulgar tongues they make use of a sign to express the relation of this case. In English they prefix the particle *of*, in French *de* or *du*, &c. Though in strictness there are no cases in either of these languages; inasmuch as they do not express the different relations of things by different terminations, but by additional prepositions, which is otherwise in the Latin.

GENIUS, a good or evil spirit or dæmon, whom the ancients supposed set over each person, to direct his birth, accompany him in life, and to be his guard. See DÆMON.

Among the Romans, Festus observes, the name *genius* was given to the god who had the power of doing all things, *deum qui vim obtineret rerum omnium gerendarum*; which Vossius, *de Idol.* rather chooses to read *genendarum*, who has the power of producing all things; by reason Censorinus frequently uses *gerere* for *gignere*.

Accordingly, St Augustin *de Civitat. Dei*, relates, from Varro, that the genius was a god who had the power of generating all things; and presided over them when produced.

Festus adds, that Aufustius spake of the genius as the Son of God, and the Father of men, who gave them life; others, however, represented the genius as the peculiar or tutelary god of each place: and it is certain, the last is the most usual meaning of the word. The ancients had their *genii* of nations, of cities, of provinces, &c. Nothing is more common than the following inscription on medals, GENIUS POPULI ROM. "the genius of the Roman people;" or GENIO POP. ROM. "to the genius of the Roman people." In this sense, *genius* and *lar* were the same thing; as, in effect, Censorinus and Apulius affirm they were. See LARES and PENATES.

The Platonists, and other eastern philosophers, supposed the *genii* to inhabit the vast region or extent of air between earth and heaven. They were a sort of intermediate powers, who did the office of mediators between gods and men. They were the interpreters and agents of the gods; communicated the wills of the deities to men; and the prayers and vows of men to the gods. As it was unbecoming the majesty of the gods to enter into such trifling concerns; this became the lot of the *genii*, whose nature was a mean between the two; who derived immortality from the one, and passions from the other; and who had a body framed of an aërial matter. Most of the philosophers, however, held, that the genii of particular men were born with them, and died; and Plutarch attributes the ceasing of oracles partly to the death of the genii. See ORACLE.

Genius.

The heathens, who considered the genii as the guardians of particular persons, believed that they rejoiced and were afflicted at all the good and ill fortune that befel their wards. They never, or very rarely, appeared to them; and then only in favour of some person of extraordinary virtue or dignity. They likewise held a great difference between the genii of different men; and that some were much more powerful than others: on which principle it was, that a wizard in *Appian* bids Anthony keep at a distance from Octavius, by reason Anthony's genius was inferior to and stood in awe of that of Octavius. There were also evil genii, who took a pleasure in persecuting men, and bringing them evil tidings: such was that in *Paterculus*, &c. which appeared to Brutus the night before the battle of Philippi. These were also called *larvæ*, and *lemures*. See LARVÆ and LEMURES.

GENIUS, in matters of literature, &c. a natural talent or disposition to do one thing more than another; or the aptitude a man has received from nature to perform well and easily that which others can do but indifferently and with a great deal of pains.

To know the bent of nature is the most important concern. Men come into the world with a genius determined not only to a certain art, but to certain parts of that art, in which alone they are capable of success. If they quit their sphere, they fall even below mediocrity in their profession. Art and industry add much to natural endowments, but cannot supply them where they are wanting. Every thing depends on genius. A painter often pleases without observing rules; whilst another displeases though he observes them, because he has not the happiness of being born with a genius for painting.

A man born with a genius for commanding an army, and capable of becoming a great general by the help of experience, is one whose organical conformation is such, that his valour is no obstruction to his presence of mind, and his presence of mind makes no abatement of his valour. Such a disposition of mind cannot be acquired by art: it can be possessed only by a person who has brought it with him into the world. What has been said of these two arts may be equally applied to all other professions. The administration of great concerns, the art of putting people to those employments for which they are naturally formed, the study of physic, and even gaming itself, all require a genius. Nature has thought fit to make a distribution of her talents among men, in order to render them necessary to one another; the wants of men being the very first link of society: she has therefore pitched upon particular persons, to give them aptitude to perform rightly

Genius, Genoa.

ſome things which ſhe has rendered impoſſible to others; and the latter have a greater facility granted them for other things, which facility has been refuſed to the former. Nature, indeed, has made an unequal diſtribution of her bleſſings among her children; yet ſhe has diſinherited none; and a man diveſted of all kinds of abilities, is as great a phenomenon as an univerſal genius.

From the diverſity of genius, the difference of inclination ariſes in men, whom nature has had the precaution of leading to the employments for which ſhe deſigns them, with more or leſs impetuoſity in proportion to the greater or leſſer nomber of obſtacles they have to ſurmount in order to render themſelves capable of anſwering this vocation. Thus the inclinations of men are ſo very different, becauſe they follow the ſame mover, that is, the impulſe of their genius. This, as with the painter, is what renders one poet pleaſing, even when he treſpaſſes againſt rules; while others are diſagreeable, notwithſtanding their ſtrict regularity.

The genius of theſe arts, according to the abbe du Bos conſiſts in a happy arrangement of the organs of the brain; in a juſt conformation of each of theſe organs; as alſo in the quality of the blood, which diſpoſes it to ferment, during exerciſe, ſo as to furniſh plenty of ſpirits to the ſprings employed in the functions of the imagination. Here he ſuppoſes that the compoſer's blood is heated: for that painters and poets cannot invent in cool blood; nay, that it is evident they muſt be wrapt into a kind of enthuſiaſm when they produce their ideas. Ariſtotle mentions a poet who never wrote ſo well as when his poetic fury hurried him into a kind of frenzy. The admirable pictures we have in Taſſo of Armida and Clorinda, were drawn at the expence of a diſpoſition he had to real madneſs, into which he fell before he died. "Do you imagine (ſays Cicero), that Pacuvius wrote in cold blood? No, it was impoſſible. He muſt have been inſpired with a kind of fury, to be able to write ſuch admirable verſes."

GENOA, a city of Italy, and capital of a republic of the ſame name, ſituated in E. Long. 9. 30. N. Lat. 44. 30.—By the Latin authors it is very frequently, though corruptly, called *Janua*; and its preſent territories made part of the ancient Liguria. The era of its foundation is not known. In the time of the ſecond Punic war it was a celebrated emporium; and having declared for the Romans, was plundered and burnt by Mago the Carthaginian. It was afterwards rebuilt by the Romans; and with the reſt of Italy continued under their dominions till the decline of the weſtern empire in 476. Soon after, it fell under the power of Theodoric the Oſtrogoth; who having defeated the uſurper Odoacer, became king of Italy. This happened in the year 498; and in a ſhort time, the Goths being almoſt entirely ſubdued by Beliſarius the emperor Juſtinian's general, Genoa was reannexed to the Roman empire. In 1638, it was plundered and burnt by the Lombards, whoſe king Protharis erected it into a provincial dukedom.

The Lombards continued maſters of Genoa till the year 774, when they were conquered by Charles the Great, ſon to Pepin king of France. He reduced Liguria to the ancient bounds ſettled by Auguſtus, and erected it into a marquiſate; appointing his relation *Audemarus* the firſt count or margrave. Genoa at this time being diſtinguiſhed for its wealth and populouſneſs, began to give its name to the whole coaſt; and continued under the dominion of theſe counts for about 100 years, till the race of the Pepins became entirely extinct in Italy, and the empire was transferred to the German princes.—In the year 935 or 936, while the Genoeſe forces were abſent on ſome expedition, the Saracens ſurpriſed the city, which they plundered and burnt, putting to death a great number of the inhabitants, and carrying others into captivity. Having embarked their captives, together with an immenſe booty, they ſet ſail for Africa: but the Genoeſe immediately returning, purſued the invaders; and having entirely defeated them, recovered all the captives and booty, and took a great many of the enemy's ſhips. Genoa.

About the year 950, the Franks having loſt all authority in Italy, the Genoeſe began to form themſelves into a republic, and to be governed by their own magiſtrates, who were freely elected, and took the name of *Conſuls*. In order to ſupport their independence, they applied themſelves with great aſſiduity to commerce and navigation; and being apprehenſive that ſome of the German emperors, who frequently entered Italy as invaders, might renew their pretenſions to their ſtate, they conſented to acknowledge Berengarius III. duke of Friuli, who had been elected emperor by a party of Italian nobles. Berengarius, who had much ado to maintain himſelf in his new dignity, endeavoured by his conceſſions to enlarge the number of his friends and adherents; and accordingly made no difficulty to confirm the new republic in all its rights and privileges. After this the Genoeſe began to extend their commerce from Spain to Syria, and from Egypt to Conſtantinople; their veſſels, according to the cuſtom of theſe times, being fitted for fighting as well as merchandiſe. Having thus acquired great reputation, they were invited in 1017, by the Piſans, who had likewiſe formed themſelves into a republic, to join with them in an expedition againſt Sardinia, which had been conquered by the Moors. In this expedition they were ſucceſsful; the iſland was reduced; but from this time an enmity commenced between the two republics, which did not end but with the ruin of the Piſans.

The firſt war with Piſa commenced about 30 years after the Sardinian expedition, and laſted 18 years; when the two contending parties having concluded a treaty of peace, jointly ſent their forces againſt the Moors in Africa, of whom they are ſaid to have killed 100,000. The Genoeſe were very active in the time of the cruſades, and had a principal ſhare in the taking of Jeruſalem. They alſo waged conſiderable war with the Moors in Spain, of whom they generally got the better. They alſo prevailed againſt the neighbouring ſtates; and, in 1220, had enlarged their territories beyond the ſkirts of the Apennines, ſo that the reſt of Italy looked upon them with a jealous eye: but in 1311 the factions which had for a long time reigned in the city, notwithſtanding all its wealth and power, induced the inhabitants to ſubmit themſelves for 20 years to the dominion of Henry VII. emperor of Germany. That emperor, however, died in Auguſt 1312; and the vicar he had left, ſoon after went to Piſa, up-

Genoa. on which the diſſentions in Genoa revived with greater fury than ever. In 1317, a quarrel happened between the families of Spinola and Doria; which came to ſuch an height, that both parties fought in the ſtreets for 24 days without intermiſſion, raiſed battering engines againſt each others houſes, and filled the city with blood. At laſt the Spinolæ quitted the city, and retired to their territories in the Apennine mountains. The civil war continued till the year 1331; when, by the mediation of the king of Naples, it was concluded, that all exiles ſhould return to the city; that the republic ſhould be governed by the king's vicar; and all the offices of the ſtate be equally divided between the Guelfs and the Gibellines, the two contending parties.

By this ruinous war, the coaſt of Genoa, formerly adorned with palaces and vineyards, was now reduced to the appearance of a barren waſte. So great was the general deſolation, that, according to Petrarch, the ſpectators who ſailed along were ſtruck with aſtoniſhment and horror. Villani, a cotemporary author, relates, that it was ſuppoſed by the learned, that greater exploits had not been performed at the ſiege of Troy; and that the loſſes each party had ſuſtained would have been ſufficient to have purchaſed a kingdom, the Genoeſe republic being in his time the richeſt and moſt powerful ſtate in Chriſtendom. The annaliſt Stella informs us, that, before the war, the moſt extravagant profuſion and luxury prevailed among the Genoeſe: but that, towards the end, many noble families were reduced to indigence and poverty; ſo that, about 100 years after, it became faſhionable for the nobles to live in a plain manner, without any ſhow or magnificence.

In 1336, both parties, ſuſpending their mutual animoſities, ſent two fleets of 20 galleys each into the German ocean, to the aſſiſtance of the king of France, who was engaged in a war with Edward III. king of England. This naval expedition proved the cauſe of a moſt remarkable revolution in the Genoeſe government. The ſailors of the fleet, thinking themſelves injured by their officers, whom they accuſed of defrauding them of their pay, proceeded to an open mutiny; and, having expelled the admiral, and other commanders, ſeized the galleys. The king of France being choſen arbitrator, decided in favour of the officers, and impriſoned 16 of the chiefs of the mutineers. Upon this ſeveral of the ſailors left the fleet, and returned to Genoa; where they went round the coaſts, repeating their mutinous complaints, which were greatly hearkened to, upon a falſe report that the mutineers who had been impriſoned were broke upon the wheel. The factious ſpirit increaſed; and at laſt the Genoeſe inſiſted in a tumultuous manner for having an abbot of their own chooſing, and 20 of the people with the conſent of the captains of the republic aſſembled for that purpoſe. While the mob were impatiently expecting their deciſion, a mechanic, generally accounted a fool, mounted a wooden bench, and called out that one Simon Bucanigree ſhould be choſen abbot. This being inſtantly echoed by the populace, he was firſt declared *abbot*, then *lord*, and at laſt *duke* of Genoa.

This new expedient did not at all anſwer the purpoſe. The diſſentions continued as violent as ever, notwithſtanding the power of the new magiſtrates; and by theſe perpetual diviſions the republic was at laſt ſo much weakened, that in 1390 the king of France was declared Lord of Genoa. Under the French government, however, they ſoon became exceedingly impatient; and, in 1422, the duke of Milan obtained the ſovereignty. With this ſituation they were equally diſpleaſed, and therefore revolted in 1436. Twenty-two years after, finding themſelves preſſed by a powerful fleet and army ſent by Alphonſo king of Naples, they again conferred the ſovereignty of their ſtate upon the king of France. In 1460, they revolted from the French; and, four years after, put themſelves again under the protection of the duke of Milan; from whom they revolted in 1478. He was again declared ſovereign of the republic in 1488; and, 11 years after, the city and territories of Genoa were conquered by Louis XII. of France. Genoa.

The almoſt unparalleled fickleneſs of the Genoeſe diſpoſition was not to be corrected by this misfortune. They revolted in 1506; but next year were again ſubdued by Louis. Six years after, they again revolted; and in 1516, the city was taken and plundered by the Spaniards. In 1528, Andrew Doria, a Genoeſe admiral in the ſervice of the French, undertook to reſcue his country from the dominion of foreign princes, and reſtore it to its liberty. Knowing well the fickle diſpoſition of his countrymen, he took all occaſions of exciting diſcontents among them againſt the government. He perſuaded them, that the French (who had again obtained the ſovereignty) had left them only a ſhadow of liberty, while they pretended to protect them from their enemies. To the nobility he repreſented the diſgrace of ſuffering the government to be veſted in the hands of foreigners leſs worthy of authority than themſelves. Thus he ſoon formed a ſtrong faction, and formed his plan; for the execution of which he took the moſt proper time, namely, when almoſt three-fourths of the French garriſon had been carried off by the plague. He advanced with 500 men; and his friends having opened the gates of the city to him, he ſeized the principal poſts, and thus became maſter of it without drawing his ſword. The garriſon retired to the forts, where they ſoon after capitulated, and being driven out of the city, Doria re-eſtabliſhed the ancient form of government. See DORIA.

The republic hath ſince continued to preſerve her liberty, though greatly fallen from her ancient ſplendor, and now become a very inconſiderable ſtate. In 1684, the Genoeſe had the misfortune to fall under the reſentment of Louis XIV. at which time the city was almoſt deſtroyed by a formidable bombardment. In the year 1688, it was bombarded by admiral Byng, and forced to capitulate; but there were at that time no views of making a permanent conqueſt of the city. In 1730, the iſland of Corſica revolted from the Genoeſe, and could never afterwards be reduced by them; for which reaſon it was ſold to the French, who in the year 1770 totally reduced it.

The Genoeſe territories extend along that part of the Mediterranean ſea, commonly called the *gulph of Genoa*, about 152 miles; but their breadth is very unequal, being from eight to about 20 miles. Where they are not bounded by the ſea, the following ſtates and countries, taking them from weſt to eaſt, are their

Genoa. boundaries, viz. Piedmont, Montferat, Milan, Placentia, Parma, the dukedom of Tuſcany, and the republic of Lucca. This tract, though a great part of it is mountainous, and ſome of that barren enough, yet produces plenty of excellent fruit, good paſture, wood, garden-ſtuff, and mulberry-trees, with ſome wine and oil, but little corn. What they want of the laſt, they have either from Lombardy, Sicily, or Naples.

Genoa ſtands on the coaſt of the Mediterranean ſea, at the bottom of a little gulph, partly on the flat, and partly on the declivity, of a pleaſant hill; in conſequence of which, it appears to great advantage from the ſea. It is defended on the land ſide by a double wall, which in circumference is about ten Italian miles. Two of the ſtreets conſiſt entirely of a double ſtraight row of magnificent palaces. The others, though clean and well paved, are crooked and narrow. The palaces of the nobility are almoſt all of marble, and many of them are painted on the outſide. That there ſhould be ſuch a profuſion of marble here, is not to be wondered at, as the neighbouring hills abound with it. The city contains a vaſt number of palaces, churches, and convents, and ſeveral hoſpitals. The palace where the doge reſides, and where the great and little council, and the two colleges of the procuratori and governatori aſſemble, is a large ſtone building in the centre of the city: but it contains ſome fine paintings in freſco; two ſtatues of Andrew and John Doria in white marble; and an arſenal, in which are ſaid to be arms for thirty-four thouſand men, with a ſhield, containing one hundred and twenty piſtol-barrels, and thirty-three coats of mail, which, it is pretended, were worn by as many Genoeſe heroines in a croiſade. Of the churches, the fineſt are thoſe of the Annunciation, St Mary Carignan, St Dominic, and St Martha. In the cathedral is a diſh made of a ſingle emerald. All the inhabitants here, except the principal ladies, who are carried in chairs, walk on foot, on account of the narrowneſs or ſteepneſs of the ſtreets. The fortifications of the city, towards the ſea, are remarkably ſtrong. There are two fine ſtone-bridges over the rivers Bonzevera and Biſagno, the firſt whereof waſhes the weſt, and the other the eaſt ſide of the city, within which there is alſo a ſurpriſing ſtone-bridge joining two hills. The harbour, though large, is far from being ſafe; but no care or expence have been ſpared to render it as ſafe and commodious as poſſible. The wind to which it is moſt expoſed, is that called *Labeccio*, or the ſouth-weſt. The place where the republic's galleys lie, is called the Darſena, where are a great number of Turkiſh ſlaves. On a rock, on the weſt ſide of the harbour, is the fanal or light-houſe, a high tower, on the top of which is a lanthorn, containing thirty-ſix lamps. The trade of Genoa is chiefly in velvets, damaſks, pluſh, and other ſilks, brocades, lace, gloves, ſweetmeats, fruits, oil, Parmeſan cheeſe, anchovies, and medicinal drugs from the Levant; but the badneſs of the harbour, and the high price of commodities, greatly check its commerce. In 1751, Genoa was declared a free port for ten years, under certain reſtrictions: in that called *Porto Franco*, any merchant may have a ware-houſe, and import or export goods duty-free; but ſuch as are diſpoſed of in the city, or on the continent, are taxed pretty high. The nobility are allowed to trade in the wholeſale way; to carry on velvet, ſilk, and cloth manufactures; and to have ſhares in merchant-ſhips: and ſome of them, as the Palavacini, are actually the greateſt merchants in Genoa. Another very profitable article of trade carried on by them is banking, and dealing in bills of exchange. A new academy of painting, ſculpture, civil and military architecture, was inſtituted here in 1751. One may walk the ſtreets of Genoa in the night with the greateſt ſafety, which is more than can be ſaid of many cities in Italy. Exceſſive ſplendor and luxury are, in ſeveral reſpects, reſtrained by ſalutary laws. No beggars are permitted to aſk alms in Genoa, and the inns are better than thoſe at Turin. When a ſingle perſon is buried, a kind of garland of all ſorts of artificial flowers is placed on the coffin. The Genoeſe in general are eſteemed crafty, induſtrious, and inured to labour above the other Italians. Genſing, Gentiana.

GENSING. See PANAX.

GENTIANA, GENTIAN, in botany: A genus of the digynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 20th order, *Rotaceæ*. The corolla is monopetalous; the capſule bivalved and unilocular; there are two longitudinal receptacles. The moſt remarkable ſpecies are the following:

1. The lutea, or common gentian of the ſhops. It is a native of the mountainous parts of Germany; from whence the roots, the only part uſed in medicine, are brought to this country. Theſe have a yellowiſh-brown colour, and a very bitter taſte. The lower leaves are of an oblong oval ſhape, a little pointed at the end, ſtiff, of a yellowiſh green, and have five large veins on the back of each. The ſtalk riſes four or five feet high, garniſhed with leaves growing by pairs at each joint, almoſt embracing the ſtalk at their baſe. They are of the ſame form with the lower, but diminiſh gradually in their ſize to the top. The flowers come out in whirls at the joints on the upper part of the ſtalks, ſtanding on ſhort foot-ſtalks, whoſe origin is in the wings of the leaves. They are of a pale yellow colour.—The roots of this plant are very frequently uſed in medicine as ſtomachic bitters. In taſte they are leſs exceptionable than moſt of the ſubſtances of this claſs. Infuſions of gentian-root flavoured with orange-peel, are ſufficiently grateful. Some years ago a poiſonous root was diſcovered among the gentian brought to London; the uſe of which occaſioned violent diſorders, and in ſome caſes death. This root is eaſily diſtinguiſhed from the gentian, by its being internally of a white colour, and void of bitterneſs.

2. The centaureum, or leſſer centaury of the ſhops, is a native of many parts of Britain. It grows on dry paſtures; and its height is commonly proportioned to the goodneſs of the ſoil, as in rich ſoils it will grow to the height of a foot, but in poor ones not above three or four inches. It is an annual plant, with upright branching ſtalks, garniſhed with ſmall leaves, placed by pairs. The flowers grow in form of an umbel at the top of the ſtalk, and are of a bright purple colour. They come out in July, and the ſeed ripens in autumn. The plant cannot be cultivated in gardens. The tops are an uſeful aperient bitter, in which view they are often uſed in the preſent practice of medicine.

entilis.

GENTILE, in matters of religion, a Pagan, or worſhipper of falſe gods.

The origin of this word is deduced from the Jews, who called all thoſe who were not of their name גוים *gojim*, i. e. *gentes*, which in the Greek tranſlations of the Old Teſtament is rendered τα εθνη; in which ſenſe it frequently occurs in the New Teſtament; as in Matth. vi. 32. "All theſe things the nations or Gentiles ſeek." Whence the Latin church alſo uſed *gentes* in the ſame ſenſe as our *Gentiles*, eſpecially in the New Teſtament. But the word *gentes* ſoon got another ſignification, and no longer meant all ſuch as were not Jews; but thoſe only who were neither Jews nor Chriſtians, but followed the ſuperſtitions of the Greeks and Romans, &c. In this ſenſe it continued among the Chriſtian writers, till their manner of ſpeech, together with their religion, was publicly and by authority received in the empire; when *gentiles*, from *gentes*, came into uſe: and then both words had two ſignifications, viz. in treatiſes or laws concerning religion, they ſignified Pagans, neither Jews nor Chriſtians; and in civil affairs, they were uſed for all ſuch as were not Romans.

GENTILE, in the Roman law and hiſtory, a name which ſometimes expreſſes what the Romans otherwiſe called *barbarians*, whether they were allies of Rome or not: but this word was uſed in a more particular ſenſe for all ſtrangers and foreigners not ſubject to the Roman empire.

GENTILESCHI (Horatio), an Italian painter, was born at Piſa in 1563. After having made himſelf famous at Florence, Rome, Genoa, and other parts of Italy, he removed to Savoy; from whence he went to France, and at laſt, upon the invitation of Charles I. came over to England. He was well received by that king, who appointed him lodgings in his court, together with a conſiderable ſalary; and employed him in his palace at Greenwich, and other public places. The moſt remarkable of his performances in England, were the ceilings of Greenwich and York-houſe. He did alſo a Madona, a Magdalen, and Lot with his two daughters, for king Charles; all which he performed admirably well. After the death of the king, when his collection was expoſed to ſale, nine pictures of Gentileſchi were ſold for 600 l. and are now ſaid to be the ornaments of the hall in Marlborough-houſe. His moſt eſteemed piece abroad was the portico of cardinal Bentivoglio's palace at Rome. He made ſeveral attempts in face-painting, but with little ſucceſs; his talent lying altogether in hiſtories, with figures as big as the life. He was much in favour with the duke of Buckingham, and many others of the nobility. After 12 years continuance in England, he died here at 84 years of age, and was buried in the queen's chapel at Somerſet-houſe. His print is among the heads of Vandyke, he having been drawn by that great maſter. He left behind him a daughter, *Artemiſia Gentileſchi*, who was but little inferior to her father in hiſtory-painting, and excelled him in portraits.

GENTILIS (Albericus), profeſſor of civil law at Oxford; an Italian by birth. He had quitted Italy with his father, on account of religion. He wrote ſeveral works; three books, in particular, *De jure belli*, which have not been unſerviceable to Grotius. He died at London in 1608. Gentilis, Gentlemen.

GENTILIS (Scipio), brother to the former, and as celebrated a civilian as he, forſook his native country that he might openly profeſs the Proteſtant religion. He was counſellor of the city of Nuremberg, and profeſſor of law with uncommon reputation. He was a great humaniſt; and in his lectures, as well as books, mixed the flowers of polite learning with the thorns of the law. He died in 1616.

GENTLEMAN. Under this denomination are comprehended all above the rank of yeomen*, whereby noblemen are truly called *gentlemen*. * See *Commonalty*.

A gentleman is uſually defined to be one, who, without any title, bears a coat of arms, or whoſe anceſtors have been freemen: and by the coat that a gentleman giveth, he is known to be, or not to be, deſcended from thoſe of his name that lived many hundred years ſince.

The word is formed of the French *gentilhomme*; or rather of *gentil*, "fine, faſhionable, or becoming;" and the Saxon *man*, q. d. *honeſtus*, or *honeſto loco natus*.—The ſame ſignification has the Italian *gentilhuomo*, and the Spaniſh *hidalgo*, or *hijo dalgo*, that is, the ſon of ſomebody, or of a perſon of note.—If we go farther back, we ſhall find *gentleman* originally derived from the Latin *gentilis homo*; which was uſed among the Romans for a race of noble perſons of the ſame name, born of free or ingenuous parents, and whoſe anceſtors had never been ſlaves or put to death by law. Thus Cicero in his *Topics*, "*Gentiles ſunt, qui inter ſe eodem ſunt nomine, ab ingenuis oriundi, quorum majorum nemo ſervitutem ſervivit, qui capite non ſunt diminuti*, &c. —Some hold that it was formed from *gentile*, i. e. pagan; and that the ancient Franks, who conquered Gaul, which was then converted to Chriſtianity, were called *gentiles* by the natives, as being yet heathens.—Others relate, that towards the declenſion of the Roman empire, as recorded by Ammianus Marcellinus, there were two companies of brave ſoldiers, the one called *gentilium*, and the other *ſcutariorum*; and that it was hence we derive the names *gentleman* and *eſquire*. See ESQUIRE.—This ſentiment is confirmed by Paſquire, who ſuppoſes the appellation *gentiles* and *ecuyers* to have been tranſmitted to us from the Roman ſoldiery; it being to the *gentiles* and *ſcutarii*, who were the braveſt of the ſoldiery, that the principal benefices and portions of lands were aſſigned. See BENEFICE. —The Gauls obſerving, that during the empire of the Romans, the *ſcutarii* and *gentiles* had the beſt tenements or appointments of all the ſoldiers on the frontiers of the provinces, became inſenſibly accuſtomed to apply the ſame names, *gentilhommes* and *ecuyers*, to ſuch as they found their kings gave the beſt proviſions or appointments to.

GENTLEMAN Uſher of the Black Rod. See ROD.

GENTLEMEN of the Chapel; officers whoſe duty and attendance is in the royal chapel, being in number 32. Twelve of them are prieſts; the other 20, commonly called *clerks of the chapel*, aſſiſt in the performance of divine ſervice. One of the firſt 12 is choſen for confeſſor of the houſehold; whoſe office is to read prayers every morning to the houſehold ſervants, to viſit the ſick, examine and prepare communicants, and adminiſter

Gentoos. niſter the ſacrament. One of 20 clerks, well verſed in muſic, is choſen firſt organiſt, who is maſter of the children, to inſtruct them in muſic, and whatever elſe is neceſſary for the ſervice of the chapel; a ſecond is likewiſe an organiſt; a third a lutaniſt; and a fourth a violiſt. There are likewiſe three vergers, ſo called from the ſilver rods they carry in their hands; being a ſerjeant, a yeoman, and groom of the veſtry: the firſt attends the dean and ſub-dean, and finds ſurplices and other neceſſaries for the chapel; the ſecond has the whole care of the chapel, keeps the pews, and ſeats the nobility and gentry; the groom has his attendance within the chapel-door, and looks after it.

GENTOOS, in modern hiſtory, according to the common acceptation of the term, denote the profeſſors of the religion of the bramins or brachmans, who inhabit the country called *Hindoſtan*, in the Eaſt Indies, from the word *ſtan*, a "region," and *hind* or *hindoo*; which Feriſhteh, as we learn from colonel Dow's tranſlation of his hiſtory, ſuppoſes to have been a ſon of Ham the ſon of Noah. It is obſerved, however, that Hindoo is not the name by which the inhabitants originally ſtyled themſelves; but according to the idiom of the *ſchanſcrit* which they uſe, *jumbodeep*, from *jumboo*, a "jackall," an animal common in their country; and *deep*, a large portion of land ſurrounded by the ſea; or *bhertekhunt*, from *khunt*, i. e. "a continent," and *bherrhut*, the name of one of the firſt Indian rajahs. It is alſo to be obſerved, that they have aſſumed the name of *Hindoos* only ſince the era of the Tartar government, to diſtinguiſh themſelves from their conquerors the Muſſulmen. The term *Gentoo* or *Gent*, in the Schanſcrit dialect, denotes *animal* in general, and in its more confined ſenſe *mankind*, and is never appropriated particularly to ſuch as follow the doctrines of Brhima. Theſe are divided into four great tribes, each of which has its own ſeparate appellation; but they have no common or collective term that comprehends the whole nation under the idea affixed by the Europeans to the word *Gentoo*. Mr Halhed, in the preface to his tranſlation of the Code of Gentoo Laws, conjectures, that the Portugueſe, on their firſt arrival in India, hearing the word frequently in the mouths of the natives, as applied to mankind in general, might adopt it for the domeſtic appellation of the Indians themſelves, or perhaps their bigotry might force from the word *Gentoo* a fanciful alluſion to Gentile or Pagan. The Hindoos, or Gentoos, vie with the Chineſe as to the antiquity of their nation. They reckon the duration of the world by four jogues, or diſtinct ages: the firſt is the Suttee jogue, or age of purity, which is ſaid to have laſted about 3,200,000 years; during which the life of man was 100,000 years, and his ſtature 21 cubits: the ſecond, the Tirtah jogue, or the age in which one-third of mankind were reprobate; which conſiſted of 2,400,000 years, when men lived to the age of 10,000 years: the third, the Dwapar-jogue, in which half of the human race became depraved; which endured to 600,000 years, when mens lives were reduced to 1000 years: and fourthly, the Collee jogue, in which all mankind were corrupted, or rather diminiſhed, which the word *collee* imports. This is the preſent era, which they ſuppoſe will ſubſiſt for 400,000 years, of which near 5000 are already paſt; and man's life in this period is limited to 100 years. It is ſuppoſed by many authors, that moſt of the Gentoo *ſhaſters*, or ſcriptures, were compoſed about the beginning of the Collee jogue: but an objection occurs againſt this ſuppoſition, viz. that the ſhaſters take no notice of the deluge; to which the bramins reply, that all their ſcriptures were written before the time of Noah, and the deluge never extended to Hindoſtan. Nevertheleſs, it appears from the ſhaſters themſelves, that they claim a much higher antiquity than this; inſtances of which are recited by Mr Halhed. Gentoos

The doctrine of tranſmigration is one of the diſtinguiſhing tenets of the Gentoos. With regard to this ſubject, it is their opinion, according to Mr Holwell, that thoſe ſouls which have attained to a certain degree of purity, either by the innocence of their manners or the ſeverity of their mortifications, are removed to regions of happineſs proportioned to their reſpective merits; but that thoſe who cannot ſo far ſurmount the prevalence of bad example, and the powerful degeneracy of the times, as to deſerve ſuch a promotion, are condemned to undergo continual puniſhment in the animation of ſucceſſive animal forms, until, at the ſtated period, another renovation of the four jogues ſhall commence, upon the diſſolution of the preſent. They imagine ſix different ſpheres above this earth; the higheſt of which, called *ſuttee*, is the reſidence of Bhrima and his particular favourites. This ſphere is alſo the habitation of thoſe men who never uttered a falſehood, and of thoſe women who have voluntarily burned themſelves with their huſbands; the propriety of which practice is expreſsly enjoined in the code of the Gentoo laws. This code, printed by the Eaſt-India Company in 1776, is a very curious collection of Hindoo juriſprudence, which was ſelected by the moſt experienced pundits or lawyers, from curious originals in the Schanſcrit language, who were employed for this purpoſe from May 1773 to February 1775; afterwards tranſlated into the Perſian idiom, and then into the Engliſh language by Mr Halhed.

The ſeveral inſtitutes contained in this collection are interwoven with the religion of the Gentoos, and revered as of the higheſt authority. The curious reader will diſcover an aſtoniſhing ſimilarity between the inſtitutes of this code and many of the ordinances of the Jewiſh law; between the character of the bramins or prieſts, and the Levites; and between the ceremony of the ſcape-goat under the Moſaic diſpenſation, and a Gentoo ceremony called the *aſhummed jug*, in which a horſe anſwers the purpoſe of the goat. Many obſolete cuſtoms and uſages alluded to in many parts of the Old Teſtament, may alſo receive illuſtrations from the inſtitutes of this code. It appears from the code, that the bramins, who are the prieſts and legiſlators of the country, have reſigned all the ſecular and executive power into the hands of another caſt or tribe; and no bramin has been properly capable of the magiſtracy ſince the time of the ſuttee jogue. The only privilege of importance which they have appropriated to themſelves, is an exemption from all capital puniſhment: they may be degraded, branded, impriſoned for life, or ſent into perpetual exile; but it is every where expreſsly ordained, that a bramin ſhall not be put to death on any account whatſoever.

We

We have already obſerved, that the Hindoos are divided into four great and original tribes, which, according to the Gentoo theology, proceeded from the four different members of Brhima, the ſuppoſed immediate agent of the creation under the ſpirit of the Almighty. Theſe tribes are the bramins, which proceeded from his mouth, and whoſe office is to pray, read, and inſtruct; the Chehteree, which proceed from his arms, whoſe office is to draw the bow, to fight, and to govern; the Bice, proceeding from the belly or thighs, who are to provide the neceſſaries of life by agriculture and traffic; and the Sooder, from the feet, which are ordained to labour, ſerve, and travel.

Few Chriſtians, ſays the tranſlator of the Gentoo code, have expreſſed themſelves with a more becoming reverence of the grand and impartial deſigns of Providence in all its works, or with a more extenſive charity towards all their fellow-creatures of every profeſſion, than the Gentoos. It is indeed an article of faith among the bramins, that God's all merciful power would not have permitted ſuch a number of different religions, if he had not found a pleaſure in beholding their varieties.

GENUFLEXION, (of *genu*, "knee," and *flecto* "I bend,") the act of bowing or bending the knee; or rather of kneeling down.

The Jeſuit Roſweyd, in his Onomaſticon, ſhows, that genuflexion, or kneeling, has been a very ancient cuſtom in the church, and even under the Old Teſtament diſpenſation; and that this practice was obſerved throughout all the year, excepting on Sundays, and during the time from Eaſter to Whitſuntide, when kneeling was forbid by the council of Nice.

Others have ſhown, that the cuſtom of not kneeling on Sundays had obtained from the time of the apoſtles, as appears from St Irenæus, and Tertullian; and the Ethiopic church, ſcrupulouſly attached to the ancient ceremonies, ſtill retains that of not kneeling at divine ſervice. The Ruſſians eſteem it an indecent poſture to worſhip God on the knees. Add, that the Jews uſually prayed ſtanding. Roſweyd gives the reaſons of the prohibition of genuflexion on Sundays, &c. from St Baſil, Anaſtaſius, St Juſtin, &c.

Baronius is of opinion, that genuflexion was not eſtabliſhed in the year of Chriſt 58, from that paſſage in Acts xx. 36. where St Paul is expreſsly mentioned to kneel down at prayer; but Saurin ſhows, that nothing can be thence concluded. The ſame author remarks, alſo, that the primitive Chriſtians carried the practice of genuflexion ſo far, that ſome of them had worn cavities in the floor where they prayed: and St Jerome relates of St James, that he had contracted a hardneſs on his knees equal to that of camels.

GENUS, among metaphyſicians and logicians, denotes a number of beings which agree in certain general properties common to them all: ſo that a genus is nothing elſe but an abſtract idea, expreſſed by ſome general name or term. See Logic and Metaphysics.

Genus, is alſo uſed for a character or manner applicable to every thing of a certain nature or condition: in which ſenſe it ſerves to make capital diviſions in divers ſciences, as medicine, natural hiſtory, &c.

Genus, in rhetoric. Authors diſtinguiſh the art of rhetoric, as alſo orations or diſcourſes produced thereby, into three genera or kinds, demonſtrative, deliberative, and judiciary. To the demonſtrative kind belong panegyrics, genethliacons, epithalamiums, funeral harangues, &c. To the deliberative kind belong perſuaſions, diſſuaſions, commendations, &c. To the judiciary kind belong defences and accuſations.

Genus, in medicine. See Medicine, under the *Noſology*.

Genus, in natural hiſtory, a ſubdiviſion of any claſs or order of natural beings, whether of the animal, vegetable, or mineral kingdoms, all agreeing in certain common characters. See Botany and Zoology.

Genus, in muſic, by the ancients called *genus melodiæ*, is a certain manner of dividing and ſubdividing the principles of melody; that is, the conſonant and diſſonant intervals, into their concinnous parts.

The moderns conſidering the octave as the moſt perfect of intervals, and that whereon all the concords depend, in the preſent theory of muſic, the diviſion of that interval is conſidered as containing the true diviſion of the whole ſcale.

But the ancients went to work ſomewhat differently: the diateſſaron, or fourth, was the leaſt interval which they admitted as concord; and therefore they ſought firſt how that might be moſt conveniently divided; from whence they conſtituted the diapente and diapaſon.

The diateſſaron being thus, as it were, the root and foundation of the ſcale, what they called the *genera*, or kinds, aroſe from its various diviſions; and hence they defined the *genus modulandi* to be the manner of dividing the tetrachord and diſpoſing its four ſounds as to ſucceſſion.

The genera of muſic were three, the enharmonic, chromatic, and diatonic. The two firſt were variouſly ſubdivided: and even the laſt, tho' that is commonly reckoned to be without any ſpecies, yet different authors have propoſed different diviſions under that name, without giving any particular names to the ſpecies as was done to the other two.

For the characters, &c. of theſe ſeveral genera, ſee Enharmonic, Chromatic, and Diatonic.

GEOCENTRIC, in aſtronomy, is applied to a planet, or its orbit, to denote it concentric with the earth, or as having the earth for its centre, or the ſame centre with the earth.

GEOFFRÆA, in botany: A genus of the decandria order, belonging to the diadelphia claſs of plants; and in the natural method ranking under the 32d order, *Papilionaceæ*. The calyx is quinquefid, the fruit an oval plum; the kernel compreſſed. There is only one ſpecies, viz. the inermis, or cabbage-bark tree, which is a native of Braſil and Jamaica. The wood of this tree is uſed in building; but it is chiefly valued for its bark, which is adminiſtered as an anthelmintic medicine. From this medical property it is alſo called the *worm bark tree*. This bark is of a grey colour externally, but black and furrowed on the inſide. It has a mucilaginous and ſweetiſh taſte, and a diſagreeable ſmell. It is given in caſes of worms, in form of powder, decoction, ſyrup, and extract. The decoction is preferred; and is made by ſlowly boiling an ounce of the freſh dried bark in a quart of water, till it aſ-

ſume.

Geoffrey.

fume the colour of Madeira wine. This ſweetened is the ſyrup; evaporated, it forms an extract. It commonly produces ſome ſickneſs and purging; ſometimes violent effects, as vomiting, delirium, and fever. Theſe laſt are ſaid to be owing to an over-doſe, or to drinking cold water; and are relieved by the uſe of warm-water, caſtor oil, or a vegetable acid. It ſhould always be begun in ſmall doſes. But when properly and cautiouſly adminiſtered, it is ſaid to operate as a very powerful anthelmintic, particularly for the expulſion of the lumbrici, which are a very common cauſe of diſeaſe in the Weſt-India iſlands; and there it is very frequently employed. But it has we believe been but little uſed in Britain.

GEOFFREY of Monmouth, biſhop of St Aſaph, called by our ancient biographers *Gallofridus Monumetenſis*. Leland conjectures that he was educated in a Benedictine convent at Monmouth, where he was born; and that he became a monk of that order. Bale, and after him Pits, call him archdeacon of Monmouth; and it is generally aſſerted that he was made biſhop of St Aſaph in the year 1151 or 1152, in the reign of king Stephen. His hiſtory was probably finiſhed after the year 1138. It contains a fabulous account of Britiſh kings, from the Trojan Brutus to the reign of Cadwallader in the year 690. But Geoffrey, whatever cenſure he may deſerve for his credulity, was not the inventor of the ſtories he relates. It is a tranſlation from a manuſcript written in the Britiſh language, and brought to England from Armorica by his friend Gualter, archdeacon of Oxford. But the atchievements of king Arthur, Merlin's prophecies, many ſpeeches and letters, were chiefly his own addition. In excuſe for this hiſtorian, Mr Wharton judiciouſly obſerves, that fabulous hiſtories were then the faſhion, and popular traditions a recommendation to his book.

Geoffr Geogr phio

GEOFFROY (Stephen Francis), a celebrated phyſician, botaniſt, and chemiſt, born at Paris in 1672. After having finiſhed his ſtudies, he travelled into England, Holland, and Italy. In 1704, he received the degree of doctor of phyſic at Paris; and at length became profeſſor of chemiſtry, and phyſician of the Royal College. He was a member of the Royal Society of London, and of the Academy of Sciences. He wrote, 1. Several very curious Theſes in Latin, which were afterwards tranſlated into French. 2. An excellent treatiſe, intitled *Tractatus de Materia Medica, ſive de Medicamentorum ſimplicium hiſtoria, virtute, delectu, et uſu.* He died at Paris, in 1731.

GEOGRAPHICAL mile, the ſame with the ſea-mile; being one minute, or the 60th part of a degree of a great circle on the earth's ſurface.

GEOGRAPHY.

GEOGRAPHY (γεωγραφια, from γη *terra*, and γραφω *ſcribo*); the doctrine or knowledge of the earth, both as in itſelf, and as to its affections; or a deſcription of the terreſtrial globe, and particularly of the known and inhabitable parts thereof, with all its different diviſions. See Earth and Astronomy.

Sect. I. *Hiſtory of the Science.*

At what time the ſcience of geography began firſt to be ſtudied among mankind is entirely uncertain. It is generally agreed, that the knowledge of it was derived to the Greeks, who firſt of the European nations cultivated this ſcience, from the Egyptians or Babylonians; but it is impoſſible to determine which of theſe two nations had the honour of the invention. Herodotus tells us, that the Greeks firſt learned the pole, the gnomon, and the 12 diviſions of the day, from the Babylonians. By Pliny, and Diogenes Laertius, however, we are told, that Thales of Miletus firſt found out the paſſage of the ſun from tropic to tropic; which he could not have done without the aſſiſtance of a gnomon. He is ſaid to have been the author of two books, the one on the tropic, and the other on the equinox; both of which he probably determined by the gnomon; and by this he was led to the diſcovery of the four ſeaſons of the year, which are determined by the ſolſtices and equinoxes.

1 Seaſons of the year diſcovered by Thales.

Thales divided the year into 365 days; which was undoubtedly a method diſcovered by the Egyptians, and communicated by them to him. It is ſaid to have been invented by the ſecond Mercury, ſurnamed *Triſmegiſtus*, who, according to Euſebius, lived about 50 years after the *Exodus*. Pliny tells us expreſsly, that this diſcovery was made by obſerving when the *ſhadow returned to its marks*; a clear proof that it was done by the gnomon. Thales alſo knew the method of determining the height of bodies by the length of their ſhadows, as appears by his propoſing this method for meaſuring the height of the Egyptian pyramids. Hence many learned men have been of opinion, that as the uſe of the gnomon was known in Egypt long before the dawn of learning in Greece, the pyramids and obeliſks, which to common travellers appeared only to be buildings of magnificence, were in reality as many ſun-dials on a very large ſcale, and built with a deſign to aſcertain the ſeaſon of the year, by the variation of the length of their ſhadows: and, in confirmation of this opinion, it was found by M. Chazelles in 1694, that the two ſides, both of the larger and ſmaller pyramids, ſtood exactly north and ſouth; ſo that, even at this day, they form true meridian lines.

2 Conjec concer the uſe the Eg tian py mids a obeliſk

From the days of Thales, who flouriſhed in the ſixth century before Chriſt, very little ſeems to have been done towards the eſtabliſhment of geography for 200 years. During this period, there is only one aſtronomical obſervation recorded; namely, that of Meton and Euctemon, who obſerved the ſummer ſolſtice at Athens, during the archonſhip of Apſeudes, on the 21ſt of the Egyptian month Phamenoth, in the morning, being the 27th of June 432 B. C. This obſervation was made by watching narrowly the ſhadow of the gnomon, and was done with a deſign to fix the beginning of their cycle of 19 years.

Timocharis and Ariſtillus, who began to obſerve about 295 B. C. ſeem to have been the firſt who attempted

Long and l tudes term

History. tempted to fix the longitudes and latitudes of the fixed ſtars, by conſidering their diſtances from the equator. One of their obſervations gave riſe to the diſcovery of the preceſſion of the equinoxes, which was firſt obſerved by Hipparchus about 150 years after; and he made uſe of Timocharis and Ariſtillus's method, in order to delineate the parallels of latitude, and the meridians on the ſurface of the earth; thus laying the foundation of the ſcience of geography as we have it at preſent.

But though the latitudes and longitudes were thus introduced by Hipparchus, they were not attended to by any of the intermediate aſtronomers till the days of Ptolemy. Strabo, Vitruvius, and Pliny, have all of them entered into a minute geographical deſcription of the ſituation of places, according to the length of the ſhadows of the gnomon, without taking the leaſt notice of the degrees and minutes of longitude and latitude.

The diſcovery of the longitudes and latitudes immediately laid a foundation for making maps, or delineations of the ſurface of the earth *in plano*, on a very different plan from what had been attempted before. Formerly the maps were little more than rude outlines and topographical ſketches of different countries. The earlieſt were thoſe of Seſoſtris, mentioned by Euſtathius; who ſays, that "this Egyptian king, having traverſed great part of the earth, recorded his march in maps, and gave copies of his maps not only to the Egyptians, but to the Scythians, to their great aſtoniſhment."—Some have imagined, that the Jews made a map of the Holy Land, when they gave the different portions to the nine tribes at Shiloh: for Joſhua tells us, that they were ſent to walk through the land, and that they *deſcribed it in ſeven parts in a book*; and Joſephus tells us, that when Joſhua ſent out people from the different tribes to meaſure the land, he gave them, as companions, perſons well ſkilled in geometry, who could not be miſtaken in the truth.

4 counts the anci- maps.

The firſt Grecian map on record is that of Anaximander, mentioned by Strabo, lib. i. p. 7. It has been conjectured by ſome, that this was a general map of the then known world, and is imagined to be the one referred to by Hipparchus under the deſignation of the *ancient map*. Herodotus minutely deſcribes a map made by Ariſtagoras tyrant of Miletus, which will ſerve to give us ſome idea of the maps of thoſe ages. He tells us, that Ariſtagoras ſhowed it to Cleomenes king of Sparta, with a view of inducing him to attack the king of Perſia; even in his palace at Suſa, in order to reſtore the Ionians to their ancient liberty. It was traced upon braſs or copper, and contained the intermediate countries which were to be traverſed in that march. Herodotus tells us, that it contained "the whole circumference of the earth, the whole ſea or ocean, and all the rivers:" but theſe words muſt not be underſtood literally. From the ſtate of geography at that time, it may be fairly concluded that by the *ſea* was meant no more than the Mediterranean; and therefore, the earth or land ſignified the coaſts of that ſea, and more particularly the Leſſer Aſia, extending towards the middle of Perſia. The rivers were the Halys, the Euphrates, and Tigris, which Herodotus mentions as neceſſary to be croſſed in that expedition. It contained one ſtraight line, called the *Royal High-way*, which took in all the ſtations or places of encampment from Sardis to Suſa. Of theſe there were 111 in the whole journey, containing 13,500 ſtadia, or 1687½ Roman miles of 5000 feet each. History.

Theſe itinerary maps of the places of encampment were indiſpenſably neceſſary in all armies. Athenæus quotes Bæton as author of a work intitled, *The encampments of Alexander's march*; and likewiſe Amyntas to the ſame purpoſe. Pliny tells us, that Diognetus and Bæton were the ſurveyors of Alexander's marches, and then quotes the exact number of miles according to their menſuration; which he afterwards confirms by the letters of Alexander himſelf. It likewiſe appears, that Alexander was very careful in examining the meaſures of his ſurveyors, and took care to employ the moſt ſkilful in every country for this purpoſe. The ſame author alſo acquaints us, that a copy of this great monarch's ſurveys was given by Xenocles his treaſurer to Patrocles the geographer, who, as Pliny informs us, was admiral of the fleets of Seleucus and Antiochus. His book on geography is often quoted both by Strabo and Pliny; and it appears, that this author furniſhed Eratoſthenes with the principal materials for conſtructing his map of the oriental part of the world.

5 Parallel of latitude how drawn at firſt.

Eratoſthenes was the firſt who attempted to reduce geography to a regular ſyſtem, and introduced a regular parallel of latitude. This was traced over certain places where the longeſt day was of the ſame length. He began it from the ſtraits of Gibraltar; and it thence paſſed through the Sicilian ſea, and near the ſouthern extremities of Peloponneſus. From thence it was continued through the Iſland of Rhodes and the Bay of Iſſus; and there entering Cilicia, and croſſing the rivers Euphrates and Tigris, it was extended to the mountains of India. By means of this line, he endeavoured to rectify the errors of the ancient map, ſuppoſed to be that of Anaximander. In drawing this parallel, he was regulated by obſerving where the longeſt day was fourteen hours and an half, which Hipparchus afterwards determined to be the latitude of 36 degrees.

The firſt parallel through Rhodes was ever afterwards conſidered with a degree of preference, like the foundation ſtone of all ancient maps; and the longitude of the then known world was often attempted to be meaſured in ſtadia and miles, according to the extent of that line, by many ſucceeding geographers. Eratoſthenes ſoon after attempted not only to draw other parallels of latitude, but alſo to trace a meridian at right angles to theſe, paſſing through Rhodes and Alexandria, down to Syene and Meroë; and as the progreſs he thus made tended naturally to enlarge his ideas, he at laſt undertook a ſtill more arduous taſk, namely, to determine the circumference of the globe, by an actual meaſurement of a ſegment of one of its great circles. To find the meaſure of the earth is indeed a problem which has probably engaged the attention of aſtronomers and geographers ever ſince the globular figure of it was known. Anaximander is ſaid to have been the firſt among the Greeks who wrote upon this ſubject. Archytas of Tarentum, a Pythagorean, famous for his ſkill in mathematics and mechanics, is ſaid alſo to have made ſome attempts in this way; and Dr Long conjectures, that theſe are

6 Attempts to determine the extent of the earth's circumference.

History. the authors of the moſt ancient opinion that the circumference of the earth is 400,000 ſtadia. Ariſtarchus of Samos is thought to have conſidered the magnitude of the earth as well as of the ſun and moon. Archimedes makes mention of the ancients who held the circumference of the earth to be 30,000 ſtadia; but it does not appear what methods were made uſe of by theſe very ancient geographers to ſolve the problem. Probably they attempted it by obſervations of ſtars in the zenith or in the horizon, and actual menſuration from ſome part of the circumference of the earth. A proof of this we have from what Ariſtotle writes in his treatiſe *De Cælo*; that we have different ſtars paſs through our zenith, according as our ſituation is more or leſs northerly; and that in the ſouthern parts of the earth we have ſtars come above our horizon, which if we go northward will no longer be viſible to us. Hence it appears, that there are two ways of meaſuring the circumference of the earth; one by obſerving ſtars which paſs through the zenith of one place, and do not paſs through that of another; the other, by obſerving ſome ſtars which come above the horizon of one place, and are obſerved at the ſame time to be in the horizon of another. Eratoſthenes at Alexandria in Egypt made uſe of the former method. He knew that at the ſummer ſolſtice the ſun was vertical to the inhabitants of Syene, a town on the confines of Ethiopia, under the tropic of Cancer, where they had a well built for that purpoſe, on the bottom of which the rays of the ſun fell perpendicularly the day of the ſummer ſolſtice: he obſerved by the ſhadow of a wire ſet perpendicularly in an hemiſpherical baſon, how much the ſun was on the ſame day at noon diſtant from the zenith of Alexandria; and found that diſtance to be one-50th part of a great circle in the heavens. Suppoſing then Syene and Alexandria to be under the ſame meridian, he concluded the diſtance between them to be the 50th part of a great circle upon the earth; and this diſtance being by meaſure 5000 ſtadia, he concluded the circumference of the earth to be 250,000 ſtadia; but as this number divided by 360 would give 694⅔ ſtadia to a degree, either Eratoſthenes himſelf or ſome of his followers aſſigned the round number 700 ſtadia to a degree; which multiplied by 360, makes the circumference of the earth 252,000 ſtadia; whence both theſe meaſures are given by different authors as that of Eratoſthenes.

7 Moſt ancient opinions on this ſubject.

8 Method uſed by Eratoſthenes.

9 By Poſidonius. In the time of Pompey the Great, Poſidonius made an attempt to meaſure the circumference of the earth by the method of horizontal obſervations. He knew that the ſtar called *Canopus* was but juſt viſible in the horizon of Rhodes, and that at Alexandria its meridian height was the 48th part of a great circle in the heavens, or 7½ deg.; which ſhows what part of a great circle upon the earth the diſtance between thoſe places amounts to. Suppoſing them both to be under the ſame meridian, and the diſtance between them to be 5000 ſtadia, the circumference of the earth will be 240,000 ſtadia; which is the firſt meaſure of Poſidonius. According to Strabo, Poſidonius made the meaſure of the earth to be 180,000 ſtadia, at the rate of 500 ſtadia to a degree. The reaſon of this difference is thought to be, that Eratoſthenes meaſured the diſtance between Rhodes and Alexandria, and found it to be but 3750 ſtadia: taking this for a 48th part of the earth's circumference, which is the calculation of Poſidonius, the whole circumference will be 180,000 ſtadia. This meaſure was received by Marinus of Tyre, and is uſually aſcribed to Ptolemy. Poſidonius's method, however, is found to be exceedingly erroneous, on account of the uncertainty of refraction in the ſtars which are near the horizon. Caſſini remarks, that taking exactly the mean betwixt the laſt dimenſions of Eratoſthenes and Poſidonius, a degree of a great circle upon the earth will be 600 ſtadia, and a minute of a degree 10 ſtadia, which is juſt a mile and a quarter of the ancient Roman meaſure and a mile of the modern meaſure.

Several geographers after the time of Eratoſthenes and Poſidonius have made uſe of the different heights of the pole in diſtant places under the ſame meridian to find the dimenſions of the earth. About the year 800, the khalif Almamun had the diſtance meaſured of two places two degrees aſunder, and under the ſame meridian, in the plains of Sinjar near the Red Sea. The reſult of the matter was, that the mathematicians employed found the degree at one time to conſiſt of 56 miles, at another of 56⅔, or, as ſome will have it, 56¾ miles.

10 By the khalif Almamun.

11. By Fernelius. The next attempt to find the circumference of the earth was in 1525 by Fernelius, a learned French phyſician. To attain his purpoſe, he took the height of the pole at Paris, going from thence directly northwards, until he came to the place where the height of the pole was one degree more than at that city. The length of the way was meaſured by the number of revolutions made by one of the wheels of his carriage; and after proper allowances for the declivities and turnings of the road, he concluded that 68 Italian miles were equal to a degree on the earth.

12. By Snellius. Snellius, an eminent Dutch mathematician, ſucceeded Fernelius in his attempts to meaſure the circumference of the earth. Having taken the heights of the pole at Alcmaer and at Bergen-op-zoom, he found the difference to be 1° 11′ 30″. He next meaſured the diſtance betwixt the parallels of theſe two places, by taking ſeveral ſtations and forming triangles; by means of which he found the degree to conſiſt of 341,676 Leyden feet. Having meaſured the diſtance betwixt the parallels of Alcmaer and Leyden, which differ only half a degree in their latitude, the calculation came out 342,120 Leyden feet to a degree. Hence he aſſigned the round number 342,000 Leyden feet to a degree: which, according to Picard, amounts to 55,021 French toiſes.

13 Mr Norwood's calculation. In 1635, Mr Norwood, an Engliſhman, took the elevations of the pole at London and at York; and having meaſured the diſtance betwixt the two parallels, aſſigned 69½ miles and two poles to a degree; each pole being reckoned 16½ feet.

14 Calculations by Ricciolus. After the year 1654, Ricciolus made uſe of ſeveral methods to determine the circumference of the earth; from all which he concluded, that one degree contained 64,363 Bologna paces, which are equivalent to 61,650 French toiſes. The moſt remarkable attempt, however, was that of the French mathematicians, who employed teleſcopic ſights for the purpoſe, which had never been done before. Theſe are much the beſt; as by them the view may be directed to an object at a greater diſtance, and towards any point with more certainty;

15 By the French academicians.

History. certainty; whence the triangles for measuring distances may be formed with greater accuracy than otherwise can be done. In consequence of this improvement, the fundamental base of their operations was much longer than that made use of by Snellius or Ricciolus. The distance measured was between the parallels of Sourdon and Malvoisine; between which the difference of the polar altitude is somewhat more than one degree; and the result of the whole was, that one degree contained 57,060 French toises. As this problem can be the more accurately determined in proportion to the length of the meridian line measured, the members of the Royal Academy prolonged theirs quite across the kingdom of France, measuring it trigonometrically all the way. This work was begun in the year 1683, but was not finished till 1718. They made use of Picard's fundamental base, as being measured with sufficient accuracy; and an account of the whole was published by Cassini in the year 1720. In this work some mistakes were detected in the calculations of Snellius; and it was likewise shown, that there are errors in those of Ricciolus, owing principally to the latter having taken too short a fundamental base, and not having paid sufficient attention to the effects of refraction. Though Snellius, however, had made some mistakes in his calculations, there is no reason to doubt the accuracy of his observations. Holland, by reason of its flatness, is the fittest country in Europe for measuring an arc of the meridian; and Snellius had an uncommon opportunity of observing the exactness of his fundamental base, *viz.* the distance betwixt one tower at Leyden and another at Souterwode. A frost happened just after the country round Leyden had been overflowed; by which means he was enabled to take two stations upon the ice, the distance between which he carefully measured three times over; and then from these stations he observed the angles which the visual rays pointing at those towers made with the straight line upon the ice. From these considerations professor Muschenbroek was induced to make new calculations and form triangles upon the fundamental base of Snellius, which he did in the year 1700; and from these he assigns 57,033 toises to a degree, which is only 27 less than had been done by the academicians.

16 Inaccuracy of the ancient maps.

The investigation of this problem of the circumference of the earth was essentially necessary for determining the radical principles of all maps; that of Eratosthenes, though the best of which antiquity can boast, was nevertheless exceedingly imperfect and inaccurate. It contained little more than the states of Greece, and the dominions of the successors of Alexander, digested according to the surveys above mentioned. He had seen, indeed, and has quoted, the voyages of Pytheas into the great Atlantic ocean, which gave him some faint idea of the western parts of Europe; but so imperfect, that they could not be realised into the outlines of a chart. Strabo tells us, that he was extremely ignorant of Gaul, Spain, Germany, and Britain. He was equally ignorant of Italy, the coasts of the Adriatic, Pontus, and all the countries towards the north. We are also told by the same author, that Eratosthenes made the distance between Epidamnus or Dyrrhachium on the Adriatic, and the bay of Thermæ on the Ægean sea, to be only 900 stadia, when in reality it was above 2000; and in another instance, he had enlarged the distance from Carthage to Alexandria to 15,000 stadia, when in reality it was no more than 9000. History.

Such was the state of geography and the nature of the maps prior to the time of Hipparchus; who made a closer connection between geography and astronomy, by determining the longitudes and latitudes from celestial observations. It must be owned, however, that the previous steps to this new projection of the sphere had been in a great measure made easy by Archimedes, upwards of 50 years before the time of Hipparchus, when he invented his noble theorems for measuring the surface of a sphere and its different segments.

It appears that war has been generally the occasion of making the most accurate maps of different countries; and therefore geography made great advances from the progress of the Roman arms. In all the provinces occupied by that people, we find that camps were every where constructed at proper intervals, and roads were raised with substantial materials, for making an easier communication between them; and thus civilization and surveying were carried on according to system throughout the extent of that large empire. Every new war produced a new survey and itinerary of the countries where the scenes of action passed; so that the materials of geography were accumulated by every additional conquest. Polybius tells us, that at the beginning of the second Punic war, when Hannibal was preparing his expedition against Rome, the countries through which he was to pass were carefully measured by the Romans. Julius Cæsar caused a general survey of the Roman empire to be made, by a decree of the senate. Three surveyors, Zenodoxus, Theodotus, and Polyclitus, had this task assigned them, and are said to have completed it in 25 years. The Roman itineraries that are still extant, also show what care and pains they had been at in making surveys in all the different provinces of their empire; and Pliny has filled the third, fourth, and fifth books of his Natural History with the geographical distances that were thus measured. We have likewise another set of maps still preserved to us, known by the name of the *Peutingerian Tables*, published by Welser and Bertius, which give a sufficient specimen of what Vegetius calls the *Itinera Picta*, for the clearer direction of their armies in their march.

The Roman empire had been enlarged to its greatest extent, and all its provinces well known and surveyed, when Ptolemy, in the reign of Antoninus Pius, about 150 years after Christ, composed his system of geography. The principal materials he made use of for composing this work, were *the proportions of the gnomon to its shadows*, taken by different astronomers at the times of the equinoxes and solstices; calculations founded upon the length of the longest days; the measures or computed distances of the principal roads contained in their surveys and itineraries; and the various reports of travellers and navigators, who often determined the distances of places by hearsay and conjecture. All these were compared together, and digested into one uniform body or system; and afterwards were translated by him into a new mathematical language, expressing the different degrees of longitude and latitude, according to the invention of

History.

Hipparchus, but which Ptolemy had the merit of carrying into full practice and execution, after it had been neglected for upwards of 250 years. With such imperfect and inaccurate materials, it is no wonder to find many errors in Ptolemy's system. Neither were these errors such as had been introduced in the more distant extremities of his maps, but even in the very centre of that part of the world which was the best known to the ancient Greeks and Romans, and where all the famed ancient astronomers had made their observations.—Yet this system, with all its imperfections, continued in vogue till the beginning of the present century. The improvements in geography which at that time, and since, have taken place, were owing to the great progress made in astronomy by several eminent men who lived during that period. More correct methods and instruments for observing the latitude were found out; and the discovery of Jupiter's satellites afforded a much easier method of finding the longitudes than was formerly known. The voyages made by different nations also, which were now become much more frequent than formerly, brought to the knowledge of the Europeans a vast number of countries utterly unknown to them before. The late voyages of Captain Cooke, made by order of his Britannic Majesty, have contributed more to the improvement of geography than any thing that has been done during the present century; so that now the geography of the utmost extremities of the earth is in a fair way of being much better known to the moderns than that of the most adjacent countries was to the ancients. This, however, must be understood only of the sea-coasts of these countries; for, as to their internal geography, it is less known now than before, except in a very few places.

17 Geography still imperfect.

On the whole, it may be observed, that geography is a science even yet far from perfection. The maps of America and the eastern parts of Asia are, perhaps, more unfinished than any of the rest. Even the maps of Great Britain and Ireland are very imperfect and unsatisfactory; and the numbers we have of them, varied, and republished, without any real improvement, justly confirm an observation made by Lord Bacon, namely, that an opinion of plenty is one of the causes of want. The late Dr Bradley was of opinion, that there were but two places in England whose longitude might be depended upon as accurately taken; and that these were the observatory at Greenwich, and Serburn-castle the seat of the earl of Macclesfield in Oxfordshire; and that their distance was one degree in space, or four minutes in time. Even this was found to be inaccurate, the distance in time being observed by the late transit of Venus to be only three minutes and 47 seconds. It were well, however, if there were no greater errors with regard to other places; but if we examine the longitude of the Lizard, we shall find scarce any two geographers that agree concerning it; some making it 4 40′ from London; others 5°, and 5° 14′; while some enlarge it to 6°. Our best maps are therefore still to be considered as unfinished works, where there will always be many things to be added and corrected, as different people have an opportunity.

Sect. II. *Principles and Practice of Geography.*

Principle and Practice.

The fundamental principles of geography are, the spherical figure of the earth; its rotation on its axis; its revolution round the sun; and the position of the axis or line round which it revolves, with regard to the celestial luminaries. That the earth and sea taken together constitute one vast sphere, is demonstrable by the following arguments. 1. To people at sea, the land disappears, though near enough to be visible were it not for the intervening convexity of the water. 2. The higher the eye is placed, the more extensive is the prospect; whence it is common for sailors to climb up to the tops of the masts to discover land or ships at a distance. But this would give them no advantage were it not for the convexity of the earth; for, upon an infinitely extended plane objects would be visible at the same distance whether the eye were high or low; nor would any of them vanish till the angle under which they appeared became too small to be perceptible. 3. To people on shore, the mast of a ship at sea appears before the hull; but were the earth an infinite plane, not the highest objects, but the biggest, would be longest visible; and the mast of a ship would disappear by reason of the smalness of its angle long before the hull did so. 4. The convexity of any piece of still water of a mile or two extent may be perceived by the eye. A little boat, for instance, may be perceived by a man who is any height above the water; but if he stoops down and lays his eye near the surface, he will find that the fluid appears to rise and intercept the view of the boat entirely. 5. The earth has been often sailed round; as by Magellan, Drake, Dampier, Anson, Cook, and many other navigators; which demonstrates that the surface of the ocean is spherical; and that the land is very little different, may easily be proved from the small elevation of any part of it above the surface of the water. The mouths of rivers which run 1000 miles are not more than one mile below their sources; and the highest mountains are not quite four miles of perpendicular height: so that, though some parts of the land are elevated into hills, and others depressed into valleys, the whole may still be accounted spherical. 6. An undeniable and indeed ocular demonstration of the spherical figure of the earth is taken from the round figure of its shadow which falls upon the moon in the time of eclipses. As various sides of the earth are turned towards the sun during the time of different phenomena of this kind, and the shadow in all cases appears circular, it is impossible to suppose the figure of the earth to be any other than spherical. The inequalities of its surface have no effect upon the earth's shadow on the moon; for as the diameter of the terraqueous globe is very little less than 8000 miles, and the height of the highest mountain on earth not quite four, we cannot account the latter any more than the 2000th part of the former; so that the mountains bear no more proportion to the bulk of the earth, than grains of dust bear to that of a common globe.

18 Proofs of the round figure of the earth.

19 Phenomena from the globular figure of the earth

A great many of the terrestrial phenomena depend upon the globular figure of the earth, and the position of its axis with regard to the sun; particularly the rising

Principles and Practice.

rising and setting of the celestial luminaries, the length of the days and nights, &c. A general explanation of these is given under the article ASTRONOMY; but still it belongs to geography to take notice of the difference betwixt the same phenomena in different parts of the earth. Thus, though the sun rises and sets all over the world, the circumstances of his doing so are very different in different countries. The most remarkable of these circumstances is the duration of the light not only of the sun himself, but of the twilight before he rises and after he sets. In the equatorial regions, for instance, darkness comes on very soon after sunset; because the convexity of the earth comes quickly in between the eye of the observer and the luminary, the motion of the earth being much more rapid there than any where else. In our climate the twilight always continues two hours or thereabouts, and during the summer-season it continues in a considerable degree during the whole night. In countries farther to the northward or southward, the twilight becomes brighter and brighter as we approach the poles, until at last the sun does not appear to touch the horizon, but goes in a circle at some distance above it for many days successively. In like manner, during the winter, the same luminary sinks lower and lower, until at last he does not appear at all; and there is only a dim twinkling of twilight for an hour or two in the middle of the day. By reason of the refraction of the atmosphere, however, the time of darkness, even in the most inhospitable climates, is always less than that of light; and so remarkable is the effect of this property, that in the year 1682, when some Dutch navigators wintered in Nova Zembla, the sun was visible to them 16 days before he could have been seen above the horizon had there been no atmosphere, or had it not been endowed with any such power. The reason of all this is, that in the northern and southern regions only a small part of the convexity of the globe is interposed betwixt us and the sun for many days, and in the high latitudes none at all. In the warmer climates the sun has often a beautiful appearance at rising and setting, by reason of the refraction of his light through the vapours which are copiously raised in those parts. In the colder regions, halos, parhelia, aurora borealis, and other meteors, are frequent; the two former owing to the great quantity of vapour continually flying from the warm regions of the equator to the colder ones of the poles. The aurora borealis is owing to the electrical matter imbibed by the earth from the sun in the warm climates, and going off through the upper regions of the atmosphere to the place from whence it came. In the high northern latitudes, thunder and lightning are unknown, or but seldom heard of; but the more terrible phenomena of earthquakes, volcanoes, &c. are by no means unfrequent. These, however, seem only to affect islands and the maritime parts of the continent. See the articles EARTHQUAKE and VOLCANO.

Notwithstanding the seeming inequality in the distribution of light and darkness, however, it is certain, that throughout the whole world there is nearly an equal proportion of light diffused on every part, abstracting from what is absorbed by clouds, vapours, and the atmosphere itself. The equatorial regions have indeed the most intense light during the day, but the nights are long and dark; while, on the other hand, in the northerly and southerly parts, though the sun shines less powerfully, yet the length of time that he appears above the horizon, with the greater duration of the twilight, makes up for the seeming deficiency.

Principles and Practice.

Were the earth a perfect plane, the sun would appear to be vertical in every part of it: For in comparison with the immense magnitude of that luminary, the diameter of this globe itself is but very small: and as the sun, were he near to us, would do much more than cover the whole earth; so, though he were removed to any distance, the whole diameter of the latter would make no difference in the apparent angle of his altitude. By means of the globular figure of the earth also, along with the great disparity between the diameters of the two bodies, some advantage is given to the day over the night: for thus the sun, being immensely the larger of the two, shines upon more than one half of the earth; whence the unenlightened part has a shorter way to go before it again receives the benefit of his rays. This difference is greater in the inferior planets Venus and Mercury than the earth.

To the globular figure of the earth likewise is owing the long moon-light which the inhabitants of the polar regions enjoy, the general reason of which is given under the article ASTRONOMY, n° 373. The same thing likewise occasions the appearance and disappearance of certain stars at some seasons of the year in some countries; for were the earth flat, they would all be visible in every part of the world at the same time. Hence most probably has arisen the opinion of the influence of certain stars upon the weather and other sublunary matters. In short, on the globular figure of the earth depends the whole present appearance of nature around us; and were the shape of the planet we inhabit to be altered to any other, besides the *real* differences which would of consequence take place, the *apparent* ones would be so great that we cannot form any idea of the face which nature would then present to us.

20 Circles supposed to be drawn on the earth's surface.

In geography the circles which the sun apparently describes in the heavens are supposed to be extended as far as the earth, and marked on its surface; and in like manner we may imagine as many circles as we please to be described on the earth, and their planes to be extended to the celestial sphere, till they mark concentric ones on the heaven. The most remarkable of those supposed by geographers to be described in this manner are the following.

21 Horizon.

1. *The Horizon.* This is properly a double circle, one of the horizons being called the *sensible*, and the other the *rational*. The former comprehends only that space which we can see around us upon any part of the earth; and which is very different according to the difference of our situation. The other, called the *rational*, is a circle parallel to the former, and passing through the centre of the earth supposed to be continued as far as the celestial sphere itself. To the eyes of spectators, there is always a vast difference between the sensible and rational horizons; but by reason of the immense disparity betwixt the size of the earth and celestial sphere, planes of both circles may be considered as coincident. Hence, in geography, when the horizon, or plane of the horizon is spoken of, the rational

Principles and Practice.

tional is always underſtood, when nothing is ſaid to the contrary. By reaſon of the round figure of the earth, every part has a different horizon. The poles of the horizon, that is, the points directly above the head, and oppoſite to the feet of the obſerver, are called the *zenith* and *nadir*.

22 Vertical circles or azimuths.

2. A great circle deſcribed upon the ſphere of the heaven, and paſſing through the two vertical points, is called a *vertical circle*, or an azimuth; and of theſe we may ſuppoſe as many as we pleaſe all round the horizon. Sometimes they are alſo called *ſecondaries* of the horizon; and in general any great circle, drawn through the poles of another, is called its *ſecondary*. In geography every circle obtains the epithet of *great* whoſe plane paſſes through the centre of the earth; in other caſes they are called *leſſer circles*. The altitudes of the heavenly bodies are meaſured by an arch of the azimuth or vertical circle intercepted between the horizon and the body itſelf.

23 Exact method of obſerving the altitudes of the ſun or moon.

The method of taking them is explained under the article ASTRONOMY, n° 379; but a more accurate method with regard to the ſun and moon, is for two perſons to make their obſervations at the ſame time; one of them to obſerve the altitude of the upper limb, the other of the lower limb of the luminary; the mean betwixt theſe two giving the true height of the centre. The ſame thing may alſo be done accurately by one obſerver, having the apparent diameter of the luminary given. For, having found the height of the upper edge of the limb by the quadrant, take from it half his diameter, the remainder is the height of his centre; or having found the altitude of his lower edge, add to it half the diameter, and the ſum is the height of the centre as before. When the obſervations are made with a large inſtrument, it will be convenient to uſe a ſextant, or ſixth part of a circle, rather than a quadrant, as being leſs unwieldy.

24 Almucantars.

3. *Almucantars* are circles ſuppoſed to be drawn upon the ſphere parallel to the horizon, and grow leſs and leſs as they approach the vertical points, where they entirely vaniſh. The apparent diſtances betwixt any two celeſtial bodies are meaſured by ſuppoſing arches of great circles drawn through them, and then finding how many degrees, minutes, &c. of theſe circles are intercepted between them.

25 Apparent diſtances of celeſtial bodies how meaſured.

The apparent diameter of the ſun's diſk is found by a circle of diſtance drawn through the centre of it; and the number of minutes continued between the two oppoſite points of that part of the circle which paſſes through the centre is the meaſure of the apparent diameter. The apparent diameter of the ſun may be found by two obſervers, one taking the altitude of the upper, and the other of the lower edge of the limb; the difference betwixt the two being the diameter required; or,

26 Senſible horizon defined.

4. Sometimes the viſible horizon is conſidered only with regard to the objects which are upon the earth itſelf; in which caſe we may define it to be a leſſer circle on the ſurface of the earth, comprehending all ſuch objects as are at once viſible to us; and the higher the eye, the more is the viſible horizon extended. It is moſt accurately obſerved, however, on the ſea, on account of the abſence of thoſe inequalities which at land render the circle irregular; and for this reaſon it is called ſometimes the horizon of the ſea; and may be obſerved by looking through the ſights of a quadrant at the moſt diſtant part of the ſea then viſible.

In making this obſervation, the viſual rays AD and AE, fig. 2. will, by reaſon of the ſpherical ſurface of the ſea, always point a little below the true ſenſible horizon SS; and conſequently below the rational horizon which is parallel to it, and ſuppoſed to be coincident with it. The quadrant ſhows the depreſſion of the horizon of the ſea below the true horizon; and it is obvious from the figure, that the higher the eye is, the greater muſt this depreſſion be. The depreſſion of the horizon of the ſea, however, is not always the ſame, even though there be no variation in the height of the eye. The difference indeed is but ſmall, amounting only to a few ſeconds, and is owing to a difference in the atmoſphere, which ſometimes refracts more than at others. Without refraction, the viſual ray would be AE, and in that caſe E is the moſt diſtant point which could be ſeen; but by refraction, the ray FG, coming from the point G, may be ſeen at F, ſo as to go on from thence in the line FA; and then the view is extended as far as G, and the depreſſion of the horizon of the ſea is in the line AF, which points higher than AE, but extends the view farther. From an inſpection of the figure it is evident, that if the refraction were greater, the view would be extended ſtill farther, as to M; though the depreſſion of the horizon of the ſea would then be leſs, as is ſhown by the line ALM: whence alſo it appears, that by reaſon of the difference of refraction in the air, our horizon is ſometimes more extenſive than at others.

Principles and Practice.

Plate CCXI.

27 Depreſſion of the horizon of the ſea.

28 Equator.

5. The *equator* is a great circle upon the earth, every part of which is equally diſtant from the poles or extremities of the imaginary line on which the earth revolves. In the ſea-language it is uſually called the *line*, and when people ſail over it they are ſaid to croſs the line.

29 Meridians.

6. The *meridian* of any place is a great circle on the earth drawn through that place and both poles of the earth. It cuts the horizon at right angles, marking upon it the true north and ſouth points; dividing alſo the globe into two hemiſpheres called the *eaſtern* and *weſtern* from their relative ſituation to that place and to one another. The poles divide the meridians into two ſemicircles; one of which is drawn through the place to which the meridian belongs, the other through that point of the earth which is oppoſite to the place. By the meridian of a place geographers and aſtronomers often mean that ſemicircle which paſſes through the place; and which may therefore be called the *geographical meridian*. All places lying under this ſemicircle are ſaid to have the ſame meridian; the ſemicircle oppoſite to this is called the *oppoſite meridian*. The meridians are thus immoveably fixed to the earth as much as the places themſelves on its ſurface; and are carried along with it in its diurnal rotation. When the geographical meridian of any place is, by the rotation of the earth, brought to point at the ſun, it is noon or mid-day at that place; in which caſe, were the plane of the circle extended, it would paſs through the middle of the luminary's diſk. Suppoſing the plane of the meridians to be extended to the ſphere of the fixed ſtars, in that caſe, when by the rotation of the earth the meridian comes to any point in the heavens, then, from the apparent motion of the heavens, that point is ſaid to come to the meridian. The rotation of the earth is from weſt to eaſt; whence the celeſtial bodies appear to move the contrary

Principles and Practice.

trary way. East and west, however, are terms merely relative; since a place may be west from one part of the earth, and east from another; but the true east and west points from any place are those where its horizon cuts the equator.

30 True east and west points.

7. All places lying under the same meridian are said to have the same *longitude*, and those which lie under different meridians to have different longitudes; the difference of longitude being reckoned eastward or westward on the equator. Thus if the meridian of any place cuts the equator in a point 15 degrees distant from another, we say there is a difference of 15° longitude betwixt these two places. Geographers usually pitch upon the meridian of some remarkable place for the first meridian; and reckon the longitude of all others by the distance of their meridians from that which they have pitched upon as the first; measuring sometimes eastward on the equator all round the globe, or sometimes only one half east and the other west; according to which last measurement, no place can have more than 180° longitude either east or west. By the ancient Greek geographers the first meridian was placed in *Hera* or *Junonia*, one of the *Fortunate Islands* as they were then called; which is supposed to be the present island of Teneriffe, one of the Canaries. These islands being the most westerly part of the earth then known, were on that account made the seat of the first meridian, the longitude of all other places being counted eastward from them. The Arabians, ambitious of having the first meridian taken from them, fixed it at the most westerly part of the continent of Africa. Some later geographers placed the first meridian in the island of Corvo, one of the Azores (A); because at that time the magnetic needle on the island just mentioned pointed due north without any variation; and it was not then known that the needle itself was subject to variation, as has since been discovered. Bleau replaced the first meridian in the isle of Teneriffe; and to ascertain the place more exactly, caused it to pass through the famous mountain of that island, called the *peak* from *el-pico*, "a bird's beak." Among modern geographers, however, it is now become customary for each to make the first meridian pass through the capital of his own country; a practice, however, which is certainly improper, as it is thus impossible for the geographers of one nation to understand the maps of another without a troublesome calculation, which answers no purpose. By the British geographers the royal observatory at Greenwich is accounted the place of the first meridian.

31 Longitude and first meridian.

8. If we suppose 12 great circles, one of which is the meridian to a given place, to intersect each other at the poles of the earth, and divide the equator into 24 equal parts, these are the *hour-circles* of that place. These are by the poles divided into 24 semicircles, corresponding to the 24 hours of the day and night. The distance betwixt each two of these semicircles is 15°, being the 24th part of 360; and by the rotation of the earth, each succeeding semicircle points at the sun one hour after the preceding; so that in 24 hours all the semicircles point successively at the sun. Hence it appears that such as have their meridian 15° east from any other, have likewise noon one hour sooner, and the contrary; and in like manner every other hour of the natural day is an hour sooner at the one place than at the other. Hence, from any instantaneous appearance in the heavens observed at two distant places, the difference of longitude may be found, if the hour of the day be known at each place. Thus the beginning of an eclipse of the moon, when the luminary first touches the shadow of the earth, is an instantaneous appearance, as also the end of an eclipse of this kind when the moon leaves the shadow of the earth, visible to all the inhabitants on that side of the globe. If therefore we find, that at any place an eclipse of the moon begins an hour sooner than at another, we conclude that there is a difference of 15° of longitude between the two places. Hence also were a man to travel or sail round the earth from west to east, he will reckon one day more to have passed than they do who stay at the place from whence he set out; so that their Monday will be his Tuesday, &c. On the other hand, if he sails westward, he will reckon a day less, or be one day in the week later, than those he leaves behind.

Principles and Practice.

9. The equator divides the earth into two hemispheres called the *northern* and *southern*: all places lying under the equator are said to have no latitude; and all others to have north or south latitude according to their situation with respect to the equator. The *latitude* itself is the distance from the equator measured upon the meridian, in degrees, minutes, and seconds. The complement of latitude is the difference between the latitude itself and 90°, or as much as the place itself is distant from the pole; and this complement is always equal to the elevation of the equator above the horizon of the place. The elevation of the pole of any place is equal to the latitude itself.

33 Of the latitude.

An inhabitant of the earth who lives at either of the poles, has always one of the celestial poles in his zenith and the other in his nadir, the equator coinciding with the horizon: hence all the celestial parallels are also parallel to the horizon; whence the person is said to live in a parallel sphere, or to have a parallel horizon

34 Of a parallel sphere.

Those who live under the equator have both poles in the horizon, all the celestial parallels cutting the horizon at right angles; whence they are said to live in a right sphere, or to have a right horizon.

35 Right sphere.

Lastly, those who live between either of the poles and the equator are said to live in an oblique sphere, or to have an oblique horizon; because the celestial equator cuts his horizon obliquely, and all the parallels in the celestial sphere have their planes oblique to that of the horizon. In this sphere some of the parallels intersect the horizon at oblique angles, some are entirely above it, and some entirely below it; all of them, however, so situated, that they would obliquely intersect the plane of the horizon extended.

36 Oblique sphere.

The largest parallel which appears entire above the horizon of any place in north latitude is called by the ancient astronomers the *arctic circle* of that place; within

37 Arctic and antarctic circle.

(A) These islands had their name from the number of goshawks found there; the word *azor* in Spanish signifying a "goshawk."

Principles and Practice.

within this circle, *i. e.* between it and the arctic pole, are comprehended all the ſtars which never ſet in that place, but are carried perpetually round the horizon in circles parallel to the equator. The largeſt parallel which is hid entire below the horizon of any place in north latitude was called the *antarctic circle* of that place by the ancients. This circle comprehends all the ſtars which never riſe in that place, but are carried perpetually round below the horizon in circles parallel to the equator. In a parallel ſphere, however, the equator may be conſidered as both *arctic* and *antarctic* circle; for being coincident with the horizon, all the parallels on one ſide are entirely above it, and thoſe on the other entirely below it. In an oblique ſphere, the nearer any place is to either of the poles, the larger are the arctic and antarctic circles, as being nearer to the celeſtial equator, which is a great circle. In a right ſphere, the arctic and antarctic circles have no place; becauſe no parallel appears either entirely above or below it. By the arctic and antarctic circles, however, modern geographers in general underſtand two fixed circles at the diſtance of $23\frac{1}{2}$ degrees from the pole. Theſe are ſuppoſed to be deſcribed by the poles of the ecliptic, and mark out the ſpace all round the globe where the ſun appears to touch the horizon at midnight in the ſummer time, and to be entirely ſunk below it in the winter. Theſe are alſo called the *polar circles*. By the ancients the arctic circle was called *maximus ſemper apparentium*, and *circulus perpetuæ apparitionis*; the antarctic circle, on the other hand, being named *maximus ſemper occultorum*, and *circulus perpetuæ occultationis*.

38 Appearances to the inhabitants of a parallel, right, and oblique ſphere.

According to the different poſitions of the globe with regard to the ſun, the celeſtial bodies will exhibit different phenomena to the inhabitants. Thus, in a parallel ſphere, they will appear to move in circles round the horizon; in a right ſphere, they would appear to riſe and ſet as at preſent, but always in circles cutting the horizon at right angles; but in an oblique ſphere, the angle varies according to the degree of obliquity, and the poſition of the axis of the ſphere with regard to the ſun. The phenomena thence ariſing will be ſufficiently underſtood from what is ſaid under the article ASTRONOMY, n° 345, &c. From thence we will eaſily perceive the reaſon of the ſun's continual change of place in the heavens: but though it is certain that this change takes place every moment, the vaſt diſtance of the luminary renders it imperceptible for ſome time, unleſs to very nice aſtronomical obſervers. Hence we may generally ſuppoſe the place of the ſun to be the ſame for a day or two together, tho' in a conſiderable number of days it becomes exceedingly obvious to every body. When he appears in the celeſtial equator, his motion appears for ſome time to be in the plane of that circle, though it is certain that his place there is only for a ſingle moment; and in like manner, when he comes to any other point of the heavens, his apparent diurnal motion is in a parallel drawn throughout. Twice a-year he is in the equator, and then the days and nights are nearly equal all over the earth. This happens in the months of March and September; after which the ſun proceeding either northward or ſouth, according to the ſeaſon of the year and the poſition of the obſerver, the days become longer or ſhorter than the nights, and

Principles and Practice.

ſummer or winter come on, as is fully explained under the article ASTRONOMY. The receſſion of the ſun from the equator either northward or ſouthward is called his *declination*, and is either north or ſouth according to the ſeaſon of the year; and when this declination is at its greateſt height, he is then ſaid to be in the tropic, becauſe he begins to turn back (the word *tropic* being derived from the Greek τρεπω *verto*).

39 Sun's declination.

40 Of the tropics, &c.

The ſpace between the two tropics, called the *torrid zone*, extends for no leſs than 47 degrees of latitude all round the globe; and throughout the whole of that ſpace the ſun is vertical to ſome of the inhabitants twice a-year, but to thoſe who live directly under the tropics only once. Throughout the whole torrid zone alſo there is little difference between the length of the days and nights. The ancient geographers found themſelves conſiderably embarraſſed in their attempts to fix the northern tropic; for though they took a very proper method, namely, to obſerve the moſt northerly place where objects had no ſhadow on a certain day, yet they found that on the ſame day no ſhadow was caſt for a ſpace of no leſs than 300 ſtadia. The reaſon of this was, the apparent diameter of the ſun; which being about half a degree, ſeemed to extend himſelf over as much of the ſurface of the earth, and to be vertical every where within that ſpace.

When the ſun is in or near the equator, he ſeems to change his place in the heavens moſt rapidly; ſo that about the equinoxes one may very eaſily perceive the difference in a day or two: but as he approaches the tropics this apparent change becomes gradually ſlower; ſo that for a number of days he ſcarce ſeems to move at all. The reaſon of this may eaſily be underſtood from any map on which the ecliptic is delineated: for by drawing lines through every degree of it parallel to the equator, we ſhall perceive them gradually approach nearer and nearer each other, until at laſt, when we approach the point of contact betwixt the ecliptic and tropic, they can for ſeveral degrees ſcarce be diſtinguiſhed at all.

41 Diviſion of the earth's ſurface into climates.

From an obſervation of the diverſity in the length of the days and nights, the riſing and ſetting of the ſun, with the other phenomena already mentioned, the ancient geographers divided the ſurface of the earth into certain diſtricts, which they called *climates*; and inſtead of the method of deſcribing the ſituation of places by their latitude and longitude as we do now, they contented themſelves with mentioning the climate in which they were ſituated. When more accuracy was required, they mentioned alſo the beginning, middle, and ending of the climates. This diſtinction, however, was certainly very vague and inaccurate: for the only method they had of determining the difference was by the length of the day; and a climate, according to them, was ſuch a ſpace as had the day in its moſt northerly part half an hour longer than in the moſt ſoutherly. For the beginning of their firſt climate they took that parallel under which the day is twelve hours and three quarters long, thoſe parts of the world which lie nearer the equator not being ſuppoſed to be in any climate; either becauſe in a looſe ſenſe they may be conſidered as in a right ſphere, or becauſe they were unknown, or thought to be uninhabitable by reaſon of the heat. The northern climates were generally ſuppoſed to be ſeven; which muſt

Principles and Practice.

have an equal number of ſouthern climates correſponding with them. The names of the northern climates, according to the ancients, were as follow: 1. Meroe. 2. Syene in Egypt. 3. Alexandria in Egypt. 4. Rhodes. 5. Rome; or, according to others, a parallel drawn through the Helleſpont. 6. The parallel paſſing through the mouth of the river Boriſthenes. 7. The Riphean mountains.—Each of theſe places was ſuppoſed to be in the middle of the climate; and as the ſouthern parts of the globe were then very little known, the climates to the ſouthward of the equator were ſuppoſed to be as far diſtant from that circle as the northern ones; in conſequence of which they took their names from the latter.

A parallel was ſaid to paſs through the middle of a climate when the day under that parallel is a quarter of an hour longer than that which paſſes through the moſt ſoutherly part. Hence it does not divide the ſpace into two equal parts, but that part next the equator will always be the larger of the two; becauſe the farther we recede from that circle, the leſs increaſe of latitude will be ſufficient to lengthen the day a quarter of an hour. Thus, in every climate there are three parallels; one marking the beginning, the ſecond the middle, and the third the ending of the climate; the ending of one being always the beginning of another. Some of the ancients divided the earth by theſe parallels; others by a parallel did not mean a mere line, but a ſpace of ſome breadth: and hence the parallel may be underſtood as the ſame with half a climate.

This method of dividing the ſurface of the earth into climates, though now very much diſuſed, has been adopted by ſeveral modern geographers. Some of theſe begin their climates at the equator, reckoning them by the increaſe of half an hour in the length of the day northward. Thus they go on till they come to the polar circles, where the longeſt day is 24 hours: betwixt theſe and the poles they count the climates by the increaſe of a natural day in the length of time that the ſun continues above the horizon, until they come to one where the longeſt day is 15 of ours, or half a month; and from this to the pole they count by the increaſe of half months or whole months, the climates ending at the poles where the days are ſix months long. The climates betwixt the equator and the polar circles are called *hour-climates*, and thoſe between the polar circles and the poles are called *month-climates*.—In common language, however, we take the word *climate* in a very different ſenſe; ſo that, when two countries are ſaid to be in different climates, we underſtand only that the temperature of the air, ſeaſons, &c. are different.

42 Different names given to people from the poſition of their ſhadows.

From the difference in the length and poſitions of the ſhadows of terreſtrial ſubſtances, ancient geographers have given different terms to the inhabitants of certain places of the earth; the reaſon of which will be eaſily underſtood from the following conſiderations. 1. Since the ſun in his apparent annual revolution never removes farther from the equator than 23½ degrees, it follows, that none of thoſe who live without that ſpace, or beyond the tropics, can have the luminary vertical to them at any ſeaſon of the year. 2. All who live between the tropics have the ſun vertical twice a-year, though not all at the ſame time. Thus, to thoſe who live directly under the equator, he is directly vertical in March and September at the time of the equinox. If a place is in 10° north latitude, the ſun is vertical when he has 10° north declination; and ſo of every other place. 3. All who live between the tropics have the ſun at noon ſometimes north and ſometimes ſouth of them. Thus, they who live in a place ſituated in 20° north latitude, have the ſun at noon to the northward when he has more than 20 degrees north declination, and to the ſouthward when he has leſs. 4. Such of the inhabitants of the earth as live without the tropics, if in the northern hemiſphere, have the ſun at noon to the ſouthward of them, but to the northward if in the ſouthern hemiſphere. 5. When the ſun is in the zenith of any place, the ſhadow of a man or any upright object falls directly upon the place where they ſtand, and conſequently is inviſible; whence the inhabitants of ſuch places were called *Aſcii*, or without ſhadows: thoſe who live between the tropics, and have the ſun ſometimes to the north and ſometimes to the ſouth of them, have of conſequence their ſhadows projecting north at ſome ſeaſons of the year and ſouth at others; whence they were called *Amphiſcii*, or having two kinds of ſhadows. They who live without the tropics have their noon ſhadows always the ſame way; and are therefore called *Heteroſcii*, that is, having only one kind of ſhadow. If they are in north latitude, the ſhadows are always turned towards the north; and if in the ſouthern hemiſphere, towards the ſouth. When a place is ſo far diſtant from the equator that the days are 24 hours long or longer, the inhabitants were called *Periſcii*, becauſe their ſhadows turn round them.

Principles and Practice.

43 Names from the parallel latitude or diſtance of places.

Names have likewiſe been impoſed upon the inhabitants of different parts of the earth from the parallels of latitude under which they live, and their ſituation with regard to one another. Thus, when two places are ſo near each other that the inhabitants have only one horizon, or at leaſt that there is no perceptible difference between them, the inhabitants were called *Synæci*, that is, near neighbours; the ſeaſons, days, nights, &c. in both places being perfectly alike. Thoſe who lived at diſtant places, but under the ſame parallel, were called *Periæci*, that is, living in the ſame circle. Thoſe who are on the ſame ſide of the equator have the ſeaſons of the year at the ſame time; but if on different ſides, the ſummer ſeaſon of the one is the winter of the other, as is fully explained under the article ASTRONOMY. Some writers, however, by the name of *Periæci*, diſtinguiſh thoſe who live under oppoſite points of the ſame parallel, where the noon of one is the midnight of the other. When two places lie under parallels equally diſtant from the equator, but in oppoſite hemiſpheres, the inhabitants were called *Antæci*. Theſe have a ſimilar increaſe of days and nights, and ſimilar ſeaſons, but in oppoſite months of the year. According to ſome, the Antæci were ſuch as lived under the ſame geographical meridian, and had day and night at the ſame time. If two places are in parallels equally diſtant from the equator, and in oppoſite meridians, the inhabitants were called *Antichthones* with reſpect to one another, that is, living on oppoſite ſides of the earth; or *Antipodes*, that is, having their feet oppoſite to one another. When two perſons are Antipodes, the zenith of the one is the

Principles and Practice.

nadir of the other. They have a like elevation of the pole, but it is of different poles: they have alſo days and nights alike, and ſimilar ſeaſons of the year; but they have oppoſite hours of the day and night, as well as ſeaſons of the year: Thus, when it is mid-day with us, it is midnight with our Antipodes; when it is ſummer with us, it is winter with them, &c.

44 Diviſion of the earth into zones.

From the various appearances of the ſun, and the effects of his light and heat upon different parts of the earth, the diviſion of it into *zones* has ariſen. Theſe are five in number. 1. The torrid zone, lying between the two tropics for a ſpace of 47° of latitude. This is divided into two equal parts by the equator; and the inhabitants have the ſun vertical to them twice a-year, excepting only thoſe who dwell under the tropics, to whom he is vertical only once, as has already been explained. 2. The two temperate zones lie between the polar circles and the tropics, containing a ſpace of 43° of latitude. And, 3. The two frigid zones lie between the polar circles and the poles. In theſe laſt the longeſt day is never below 24 hours, in the temperate zones it is never quite ſo much, and in the torrid zone it has never above 14. The zones are named from the degree of heat they were ſuppoſed to be ſubjected to. The torrid zone was ſuppoſed by the ancients to be uninhabitable by reaſon of its heat; but this is now found to be a miſtake, and many parts of the temperate zones are more intolerable in this reſpect than the torrid zone itſelf. Towards the polar circles, alſo, theſe zones are intolerably cold during the winter ſeaſon. Only a ſmall part of the northern frigid zone, and none of the ſouthern, is inhabited. Some geographers reckoned ſix zones, dividing the torrid zone into two by the equator.

45 Right or left hand explained in geography, &c.

When any parts of the heaven or earth are ſaid to be on the right or left, we are to underſtand the expreſſion differently according to the profeſſion of the perſon who makes uſe of it; becauſe according to that his face is ſuppoſed to be turned towards a certain quarter. A geographer is ſuppoſed to ſtand with his face to the north, becauſe the northern part of the world is beſt known. An aſtronomer looks towards the ſouth, to obſerve the celeſtial bodies as they come to the meridian. The ancient augurs, in obſerving the flight of birds, looked towards the eaſt; while the poets look towards the *Fortunate Iſles*. In books of geography, therefore, by the right hand we muſt underſtand the eaſt; in thoſe of aſtronomy, the weſt; in ſuch as relate to augury, the ſouth; and in the writings of poets, the north.

46 Directions for drawing a meridian line.

Under the article ASTRONOMY, n° 376, *et ſeq.* the method of drawing a meridian line is fully explained; the knowledge of which is abſolutely neceſſary both for geographers and aſtronomers. To what is mentioned there we ſhall only add further, that the time for drawing a line of this kind is when the ſun is nearly at the ſummer ſolſtice; becauſe the difference of declination is then ſcarce perceptible for ſeveral days, and in the few hours requiſite for the operation may be totally diſregarded. The winter ſolſtice would do equally well, were it not that the ſun is then ſo low in the heavens that a difference in the refraction might cauſe a conſiderable error in the reſult. The motion of the luminary above the horizon is likewiſe ſo oblique, that he changes his vertical faſter than his altitude, which is inconvenient in an operation where we are to determine the vertical by the altitude. A clear day muſt be choſen for the purpoſe; and the ground on which the ſhadow falls ought to be white, that the ſhadow may be the better defined. The ſtile ought not to be too high, becauſe then the top of the ſhadow will be indiſtinct; neither ought it to terminate in a point, for the ſame reaſon. Dr Long recommends the top of it to be about an eighth of an inch thick. Having drawn a meridian line upon one plane, we may draw one upon another by the following method: Hang a thread with a plummet exactly over the ſouth end of the meridian line given, and another on the plane on which the meridian line is to be drawn. Let one perſon obſerve at noon the moment when the ſhadow of the firſt thread falls exactly upon the meridian given, and let another obſerver at the ſame time mark two diſtant points in the ſhadow of the ſecond thread: a line drawn through theſe points is the meridian line required. Thus alſo a meridian line may be drawn upon a ſouth wall by marking two points in the ſhadow of a thread hung at a little diſtance from it. If the meridians are near, he that obſerves the ſhadow of the firſt thread may let the other know the moment it falls upon the meridian line by ſaying, *Now*; if far diſtant, it ſhould be done by the motion of the hand, becauſe ſound takes up ſome time in paſſing from one place to another. A quadrant or other aſtronomical inſtrument may now be fixed in the meridian line in ſuch a manner as to be capable of different elevations, in order to obſerve the altitudes of the different celeſtial bodies; the plane of that ſide of the inſtrument on which the degrees are marked being all the while kept in the meridian. The mural arc in the Royal Obſervatory at Greenwich is a wall of black marble; one ſide of which, ſtanding exactly in the plane of the meridian, has a large and accurately divided braſs quadrant fixed to it, moveable round its centre, and with teleſcope ſights. See ASTRONOMY, n° 497. At ſea, where they cannot have a meridian line, the greateſt height of a ſtar or the ſun is taken for the meridian height.

Principles and Practice.

47 Method uſed in drawing the meridian line through France.

Having got a meridian line by either of the methods mentioned under the article ASTRONOMY, it may be prolonged to what length we pleaſe, and the diſtance of it meaſured. The meridian of the royal obſervatory at Paris being found, and an inſtrument with teleſcopic ſights placed vertically therein, the north and ſouth points of the viſible horizon were obſerved through the ſights, and a pillar erected upon the north point; then, by another inſtrument placed horizontally, ſeveral diſtant objects, as ſteeples, &c. were viewed, and the angles which the viſual lines made with the meridian line were obſerved. From the places of theſe new objects, then, others were obſerved; and where natural objects were deficient, they ſet up large poles. Thus ſeveral triangles were formed along the meridian: and in order to meaſure thoſe triangles, a paved way from *Villejuive* to *Juviſy* was made choice of for the fundamental baſe, as lying in a ſtraight line from north to ſouth. For the actual menſuration of this way, two poles were made uſe of, each of them four toiſes in length, and made of two pike-ſtaves joined together at the great ends by a ſcrew. One of the meaſuring poles was firſt laid upon the

Principles and Practice.

ground; the other was joined to it end to end along by a rope ſtretched from north to ſouth: the firſt pole was then taken up and laid down at the end of the ſecond, and ſo on ſucceſſively; and for the greater eaſe in keeping the account, the meaſurer who laid down the ſecond pole had ten little ſtakes given him, one of which he ſtuck into the ground at the end of his pole every time he laid it down; ſo that every ſtake marked eight toiſes; the whole, when ſtuck into the ground, marking 80 toiſes. Thus the length of the road above mentioned was twice meaſured, and found to be 5663 toiſes and 4 feet in going, and 5663 toiſes and 1 foot in returning; ſo that as a greater exactneſs could not be hoped for, 5663 toiſes were pitched upon as the true length of this fundamental baſe. This is repreſented fig. 5. by the line O P; and the calculations of the triangles upon it were made in the following manner. The angle C O P was obſerved from O, one end of the baſe; from the other end the angle O P C; and from the ſtation C the angle O C P: and thus all the angles of the triangle C P O, and the length of one ſide O P, being known, the lengths of the remaining ſides OC and PC were found by calculation. The next ſtep was to obſerve all the angles of the triangle OBC, and from thence, and the known length of the ſide OC, to calculate the other ſide OB and BC. Then all the angles being obſerved, and the ſide BC being known of the triangle ABC, which may be called the firſt or principal triangle of the meridian of the obſervatory, the other ſides AB and AC were found. Then, from one of the ſides now known, and the angles obſerved, all the ſides of the next adjoining triangle CBE were found. Thus they proceeded from one triangle to another to the place where the meridian ended in the ſouth part of France; and there the laſt triangle was terminated by a baſe of the length of 7246 toiſes, which was actually meaſured in order to verify the preceding operations. The meridian line of Paris being prolonged in the manner juſt now deſcribed, the ſituation of ſeveral other places in France was determined by trigonometry, and an accurate map of the country drawn, eſpecially of thoſe parts which lie near the meridian of Paris.

Plate CCXI.

48 To obſerve the tranſits, altitudes, &c. of the heavenly bodies.

Having found a meridian line, the tranſits or paſſages of the heavenly bodies acroſs it may be obſerved by hanging two threads with plummets exactly over it, at a little diſtance from one another, which conſequently will be directly in the plane of the meridian: if you place your eye cloſe to one of the threads in ſuch a manner that you make it cover the other, and both appear as one thread, when a ſtar is behind the threads, it is in the meridian. By the ſame method the ſun may be viewed through a ſmoked glaſs: when the threads paſs through his centre he is in the meridian. But the beſt way of obſerving either the ſun, moon, ſtars, or planets, is through a teleſcope placed in the meridian, with two croſs hairs, one of which is in a vertical, the other in an horizontal poſition. The ſun is in the meridian when the vertical hair paſſes through his centre.

To find the elevation of the pole in any place, take the greateſt and leaſt height of ſome ſtar which never ſets, the middle height between theſe extremes is the elevation of the pole. Or the elevation of the pole may be found by one obſervation of the height of a ſtar in the meridian, if the declination of that ſtar be known; for as the diſtance from the pole is the complement of its diſtance from the equator, this being ſubtracted from the greateſt height of the ſtar, leaves the elevation of the pole deſired. The ſame thing may be done by obſerving the leaſt height of a ſtar, and adding to that the diſtance from the pole: but for obſervations of this kind we ought to chooſe the time when the ſtars are in the zenith, and not pitch upon any who happen to be near the horizon; becauſe the refraction occaſions ſuch errors as are too conſiderable not to affect the obſervations materially.

Principles and Practice.

The height of the equator is found by taking the height of the ſun or a ſtar when we know by an almanack they have no declination; or it may be otherwiſe known by taking the meridian height of the ſun, and adding or ſubtracting the known declination. Having found the height of the equator, we know the elevation of the pole; or, having found the elevation of the pole, we know that of the equator, the one being the complement of the other.

49 Method of taking altitudes by a gnomon.

A method much uſed by the ancients was that of taking the altitudes of the celeſtial bodies by means of a gnomon, or upright pillar erected for this purpoſe. Thus the height of the pole and the ſeaſons of the year might be known by obſerving the length of the meridian ſhadow, which would be greater or leſs according to the altitude of the ſun at that time. The moſt ancient obſervations of this kind were thoſe made by Pytheas in the time of Alexander the Great, at Marſeilles in France, by which he found the meridian length of the ſhadow at the ſummer ſolſtice to be to the height of the gnomon as 213½ to 600; the ſame which Gaſſendus afterwards found it in the year 1636.

The elevation of the pole may be found by means of the gnomon, by finding the meridian height of the ſun; for this being given, we have the elevation of the equator, and conſequently that of the pole. The meridian height of the ſun may be found in the following manner. Let AC, fig. 1. be the gnomon, AB the ſhadow, and CB part of a ray drawn from the centre of the ſun paſſing by the top of the gnomon and terminating the ſhadow at B. Theſe three lines form a right-angled triangle BAC, whereof the two legs AB and AC are given, the number of feet and inches in them being found by actual menſuration. Hence the acute angles may be found in the following manner. Let one leg be radius, and the other will be tangent of the oppoſite angle. Thus, if we make AB radius, AC will be tangent of the oppoſite angle ABC. This tangent is found by the golden rule, as the number of feet, inches, &c. in AB, is to the number of feet, inches, &c. in AC; ſo is the radius to a fourth number, which is the tangent required. This fourth number looked for in the table of tangents gives the meaſure of the angle ABC, which is the meridian height of the ſun required.

Plate CCXI.

50 Inaccuracies of this method.

This method of obſervation, however, is by no means accurate; and Ricciolus takes notice of the following deficiences in the ancient obſervations made in this manner: 1. They did not take into account the ſun's parallax, which makes his apparent altitude ten ſeconds leſs than it would be if the gnomon were placed at the centre of the earth. 2. They neglected refrac-

Principles and Practice.

tion, by which the apparent height of the sun is somewhat increased. 3. They made their calculations as if the shadow were terminated by a ray coming from the sun's centre; whereas it is bounded by one coming from the upper edge of his limb. In many cases, however, these errors are of no moment; but at any rate they may be corrected in the following manner: To the altitude of the sun found by the gnomon, add his parallax of 10″, and take from the sum the semidiameter of the sun at that time, which is about 16′; together with the refraction, which is different at different heights of the sun, and must be had from a table of refractions. Thus the altitude of the sun will be had free of any errors, excepting those unavoidable ones arising from the difficulty in finding the true length of the shadow by reason of the penumbra, which always accompanies it.

51 Gnomons which do not show the altitude by the shadow.

Some gnomons show the altitude of the sun not by the shadow, but by an hole in the top made in a plate of metal inserted there, through which the rays fall upon a level pavement. In gnomons of this kind the centre of the instrument is always exactly under the hole in the metal-plate; and the method of finding the height of the sun is the same as that already described. A gnomon of this kind was made in the year 1576 by Egnatio Dinte in the church of St Petronia at Bologna. Near the top of the south wall of the church he placed a brass plate about three-eighths of an inch thick, in which was cut a circular hole almost exactly an inch in diameter. The plate was set in the wall at an angle of about 45½ deg. the height of the equator in that place. The height of the hole in the plate from the ground is near 66 feet, and the length of the line drawn upon the pavement is 169 feet. This line, however, is not exactly in the meridian, but as near it as the pillars of the church would admit; and on it the rays of the sun, passing through the hole, formed an ellipsis at different distances from the wall, according to the season of the year. Another gnomon of this kind was made in the same church by Dominico Cassini in 1645. He placed the brass-plate through which the rays of the sun were to pass in the roof of the church, and drew a meridian line 120 feet long upon the pavement; which performance was so much approved, that a medal was struck upon the occasion. In like manner Bianchini and Moraldi drew a meridian line upon the pavement of the great hall of the baths of Diocletian, now the church of the Carthusians at Rome.

52 Construction of these gnomons.

To construct gnomons of this kind, place the brass-plate with the hole in it in the south end of the roof of the building; by a thread with a plummet at the end of it let down through the centre of the hole, find the point in the pavement which is exactly under it; this point is the centre of the gnomon: from this centre draw several concentric circles: an hour or two before and after noon mark the points where the northern as also where the southern edge of the sun's picture touches these circles, and there will be several arches, through the middle of which a line drawn from the centre of the gnomon is a meridian line, as will be understood from what has been already said concerning the method of drawing these lines. The meridians just mentioned are usually marked upon long plates of brass, with which the marble pavement is inlaid; there are also drawn upon it lines crossing the meridians at right angles, to show how far the centre of the sun's image reaches at different times of the year: when this at noon is farthest from the centre of the gnomon, the sun is then lowest, and it is the winter solstice: when the same picture is nearest to the centre of the gnomon, the sun is highest, and consequently he is then in his greatest north declination, and it is then the summer solstice.

Principles and Practice.

53 To find the time of the solstice.

The time of the solstice is observed, by marking exactly the distance of the sun's picture from the centre of the gnomon the day before and the day after the solstitical day: if these distances be exactly equal, the meridian heights of the sun are for these two days exactly equal; and then the time of the sun's being in the solstitical point is exactly at noon: if the distance of the sun's picture from the centre of the gnomon be greater the day before the solstice than it is the day after, it shows that the time of the solstice is before noon; and if less, that it is after noon. It is, however, extremely difficult to determine the exact moment of the solstice by this method, or even to approach within some hours of it; for at those times the sun's declination, and consequently his meridian height, alters not above 15″ in a natural day; and therefore an error of more than 15′ in the observation of the sun's meridian height will occasion an error of a whole day in fixing the time of the solstice, an error of one half of 15″ will occasion an error of half a day; and so in proportion.

54 Of the equinox.

The time of the equinox is found by a gnomon in the following manner: On the day of the equinox find the meridian height of the sun and the height of the equator. If these be equal, the equinox is exactly at noon; if the height of the sun be different from that of the equator, then as many minutes as the sun is higher than the equator, so many hours is the moment of the equinox before noon; as many minutes as the sun is lower than the equator, so many hours is the equinox after noon. The reason of this computation is, that at the equinox the declination of the sun alters at the rate of 24 minutes in a natural day, which is at the rate of a minute in an hour; whence it appears that the equinoxes are much more easily observed than the solstices. It is probable that many of the obelisks in Egypt were erected for the purpose of observing the altitude of the sun by the length of the shadow. It is likewise worth observing, that the Spaniards at the conquest of Peru found pillars of curious and costly workmanship, by the meridian shadows of which their *Amautas* or philosophers had by long experience and observation learned to determine the time of the equinoxes: these seasons of the year were celebrated by them with great festivity and rejoicing in honour of the sun, whom they imagined to sit at those times in all his glory upon the throne they had erected for him; and therefore on those days they presented him with rich offerings of gold, silver, jewels, and other valuable gifts; adorning his throne, as they did also the pillars, with fragrant herbs and flowers.

55 Geographical uses of the observations of the heavenly bodies.

The principal uses which geographers have for observing the altitudes of the celestial bodies with such accuracy, are to determine the length of the year, the seasons, but especially the distance of places on the earth, their situation with regard to one another, and the

Principles and Practice.

the dimensions of the whole. An account of the most remarkable attempts for discovering the circumference of the globe has been given in the preceding section. The foundation of the whole is to obtain an exact measure of one degree of the meridian; which being once got, we have only to multiply the number of miles, feet, or any other measure employed, by 360, the number of degrees in the circumference, and the product is that of the whole globe. This being obtained, we may easily determine its superficial and solid contents by the geometrical methods employed in other cases. According to the best calculations which have yet appeared, the dimensions of this globe are as follow.

	English miles.
One minute of a degree contains	$1\frac{9}{80}$
A degree - - -	$69\frac{1}{2}$
The circumference - -	24,930
The diameter - -	$7935\frac{1}{7}$
The semidiameter -	$3967\frac{1}{7}$
The superficial measure	200,000,000

The solid contents two hundred and sixty-six thousand millions of cubic miles.

A second of a degree is no more than $101\frac{1}{2}$ English feet.

In making measurements of this kind, the principal difficulty arises from the want of an absolutely level surface, the length of which may be determined by actual mensuration as the foundation of our calculations. Snellius, as has already been mentioned, had a singular opportunity of this kind by means of a great extent of ice; and similar conveniences might be had on the frozen lakes in the north of Europe, though difficulties would then arise from the great refraction of the atmosphere. It must likewise be considered, that there is always some difference between the apparent level and the true, which in great distances is apt to affect our calculations materially. A truly level surface is the segment of any spherical surface concentric to the surface of the earth: thus the surface of the sea or any large piece of water when at rest forms itself into a true level. A true line of level then is an arc of a great circle, which we suppose to be described upon a truly level surface. The apparent level is a straight line drawn tangent to the true level; whence every point of the apparent level, excepting only that of contact, is somewhat higher than the true level. This difference is easily known after the semidiameter of the earth is known. Thus in fig. 6. let the observer standing at A look through a telescope placed horizontally at the object B; here BAC is a right-angled triangle, in which if AC be made radius, AB will be tangent, and CB secant of the angle ACB. Now, to find this tangent, say, as the number of feet in AC is to the number of feet in AB, the distance of the object; so is AC as radius to AB as tangent. Then having found the tangent AB in the table, we have the secant CB; from which if the radius CG be taken, the remainder GB is the excess of the secant above the radius, or the height of the apparent level above the true. The following table was constructed by Cassini.

A Table showing the Height of the Apparent Level above the True.

If the distance of the object from the place of the spectator be which measured in a great circle upon the earth amounts to the height of the apparent level above the true will be

Principles and Practice.

The uſes of this table are, 1. An arc of a great circle on the earth being given in ſeconds or minutes, to find the length of it in miles or feet. Thus an arc of 8 ſeconds is 812 feet ſix inches and four-tenths of an inch; and thus again an arc of 20′ is 121880 Engliſh feet. 2. An arc of a great circle upon the earth being given in ſeconds or minutes, or in feet or inches, to find the height of the apparent level above the true. In very ſmall arcs this is ſo little, that it may be diſregarded, and is therefore marked only at 5″, and afterwards at every 10″ in the table of ſeconds, and at every ſingle minute in the other. 3. The diſtance of any object which is viewed through ſights placed horizontally being given, the height of it may be found; or converſely, the height of any object being given, the diſtance of it may be found. Thus, if the diſtance of an object whoſe top is in the horizon be 15′ or 91410 feet, the height of that object is 199 feet 4 inches; and thus converſely, if the height of an object whoſe top is in the horizon be 199 feet 4 inches, the diſtance will be 91,410 feet. 4. If the diſtance of an object given be a number of feet which is not in the table, take that which is next to it, and ſay, as the ſquare of the number thus taken is to the ſquare of the number given; ſo is the height of the apparent level above the true, correſponding to the number taken, to the height of the apparent level which correſponds to the number given. Thus, if it be inquired what is the height of the apparent level above the true when the diſtance of the object is 200,000 feet, the neareſt number to this in the table is 201,102, the height of the level correſponding thereto is 965 feet; ſay then, as the ſquare of 201,102 is to the ſquare of 200,000; ſo is 965 to a fourth number by which the apparent level exceeds the height of the true one, at the diſtance of 200,000 feet.

Hitherto we have ſuppoſed the line of level to be a tangent to an arc of a great circle drawn upon the ſurface of the earth; whereas in levelling, the eye is uſually at ſome diſtance above the ſurface, ſuppoſe 4 feet: but this makes no difference in levelling; for as the height of the eye muſt be added to the ſecant CB, fig. 6. becauſe ML is ſuppoſed in levelling to be parallel to HD, there is indeed a difference between the length of AI and BL, but it is quite inſenſible. Another uſe of the table is for levelling, in order to convey water from one place to another. See LEVELLING. We ſhall now proceed to give a ſolution of ſome geographical problems relating to the horizon.

57 Of finding the extent of the horizon.

1. To find the extent of the viſible horizon, the ſemidiameter of the earth and height of the eye being given. Let ADE, fig. 3. be an arc of a great circle upon the earth, C the centre of the earth, B the eye of the obſerver, BD the height of the eye, BA and BE lines drawn from the eye touching the ſurface of the earth at A and E, and terminating the viſible horizon; the length of BA is required. In order to find it, add DB the height of the eye, which ſuppoſe to be 5 feet, to DC the ſemidiameter of the earth, which is 20,949,655 feet, and you have the length of CB 20,949,660 feet; draw CA, and you have a triangle BAC whoſe angle at A is a right one; make the hypothenuſe CB radius, and CA will be the line of the oppoſite angle ABC. Say then, as CB is to CA; ſo is the whole line or radius to the line of the angle ABC.

Principles and Practice.

ABC. This angle being found, its complement ACB is known, and consequently also the arc AD, which may be found in feet or miles by the table: Thus, in the foregoing example, as 20,949,660 is to 20,949,655; so is the radius 1000, &c. to a fourth number, viz. 9,999,993, which number is the fine of an angle of 89° 56′; the angle ABC then is 89° 56′; and therefore its complement ACD is 4′, and the arc DA is 4′; that is, by the table, 24376 feet.

58 Depression of the horizon of the sea.

2. To find the depression of the visible horizon of the sea at a given height of the eye. In fig. 3. if the eye be at B, the sensible horizon is FG, the depression of the horizon of the sea is the angle FBA; which, being the complement of ABC, is equal to ACD, that is, 4′.

59 Extent of the horizon at any height of the eye.

3. To find the extent of the visible horizon at any height of the eye by observation. The semidiameter of the horizon does not sensibly differ from an arch of a great circle upon the earth of the same number of minutes and seconds as the angle of depression is observed to be; and the number of feet contained in that arc may be found in the table: Thus, if the depression of the horizon be 30′, its semidiameter is also 30′; that is, by the table 18,820 feet. Various accounts of the extent of the visible horizon are given by different authors: either because they differ in their accounts of the earth's semidiameter from whence that of the horizon is computed, or in the measures they make use of.

The following table, taken from Cassini, shows the different depressions of the horizon of the sea at different heights of the eye, both by observation and calculation; with the difference betwixt the two occasioned by refraction.

The height of the eye above the surface of the sea.		The depression of the horizon of the sea.	
Feet	Inches	′ ″	
1157	6,9	32 30	by observation
		36 18	by calculation
Difference by refraction		3 48	
775	2,3	27 0	by observation
		29 36	by calculation
Difference by refraction		2 36	
571	11,0	24 0	by observation
		25 25	by calculation
Difference by refraction		1 25	
387	3,4	19 45	by observation
		20 54	by calculation
Difference by refraction		1 9	
288	4,3	15 0	by observation
		17 1	by calculation
Difference by refraction		2 1	
187	0,9	13 0	by observation
		14 41	by calculation
Difference by refraction		1 41	
9	7,3	3 20	by observation
		3 18	by calculation

Here the calculated depression is greater than that by observation in all the cases except the last, which is less by two seconds; but the instrument used by our author would not discover such a small difference. Refraction by raising the objects of vision makes the angle of depression less; but refraction itself is variable, and of consequence the depression and extent of the horizon also. Cassini informs us, that, even in the finest weather, refraction was different at the same hours of different days, and at different hours of the same day. The truth of this position is easily seen by fixing a telescope with cross hairs, so that the weathercock of a distant steeple may be viewed through it: for at different times of the day the weather-cock will sometimes appear in the centre of the object-glass, sometimes above and sometimes below it: the same experiment may also be tried with plain sights. It has long been observed, that the top of a distant hill may at some times, when the refraction is greatest, be seen from a station from which at other times, when refraction is less, it cannot be seen, even when the weather is sufficiently clear.

60 Earth not an exact sphere.

Hitherto we have supposed the circumference of the earth to be exactly circular, or the globe itself to be a perfect sphere; but, from some observations, this appears not to be the case. Some time ago, the French made an observation, showing that a pendulum vibrates slower in proportion as it is brought nearer to the equator: that is, the gravity or celerity of descent of the pendulum, and of all other bodies, is less in countries approaching to the equator than in places near either pole. This excited the curiosity of the celebrated philosophers Huygens and Newton, who thence conjectured that the earth must have some other figure than what was commonly supposed. Sir Isaac Newton afterwards demonstrated that this diminution of weight naturally arises from the earth's rotation round its axis; which, according to the laws of circular motion, repels all heavy bodies from the axis of motion: so that this motion, being swifter at the equator than in parts more remote, the weight of bodies must also be much less there than nearer the poles.—To determine this matter, several mathematicians were by the French king employed to measure a degree on the earth's surface in different parts of the world; and, according to their mensurations, the diameter of the earth from north to south is shorter than that from east to west by 36 miles.

61 Of finding the longitudes and latitudes.

With regard to the method of finding the longitudes and latitudes of particular places, rules have been already laid down under ASTRONOMY, n° 408, and 482, 483. The same thing, however, may be done by other methods. Thus the latitude may be found by observing exactly the meridian altitude of the sun, and knowing his declination for that day, the declination subtracted from the meridian altitude gives the complement of the latitude, and this last subtracted from 90° leaves the latitude required. As to the longitude, Mr Harrison, by his invention of time-pieces which go much more exactly than either clocks or watches could be made to do formerly, hath in a great measure facilitated that. For supposing any person, possessed of one of these time-pieces, to set out on a journey, *e. g.* from London. If he adjusts his time-piece properly before he goes away, he will know the hour

Principles and Practice.

hour at London exactly, let him go where he pleases; and when he hath proceeded so far either eastward or westward, that a difference is perceived betwixt the hours shown by his time-piece, and those on the clocks or watches at the place to which he goes, the distance of that place from London in degrees and minutes of longitude will be known; and if the length of a degree of longitude is known, the real distance between the two places may also be easily found. It is not to be expected, however, that any instrument, with whatever care it may be constructed, can always be depended upon as an exact measurer of time; and therefore frequent corrections of longitudes taken in this manner will be necessary. The method of finding the longitude from the eclipses of Jupiter's satellites appears to be the best of any. Eclipses of the sun, and occultations of the stars by the moon, are also very proper, though they happen but seldom. Eclipses of the moon have also been made use of for this purpose; but it is found impossible to observe either the beginning or end of a lunar eclipse with the accuracy necessary for determining the longitude of any place.—All these different methods agree in this, that they determine the longitude by the difference of time between the observation of the phenomenon in two different places; and of this time, four minutes are to be allowed for every degree of longitude either east or west.

62 Of the different kinds of maps.

After the geographer is thus become acquainted with the longitudes and latitudes of a great number of different places, he may delineate them upon paper, or make a *map*, either of the whole world, or of any particular country with which he is best acquainted. General maps of the world, or of very large tracts, answer the purpose of showing in what manner the different countries of the world lie with respect to each other. They cannot be made of such a size as to admit the delineation of many particular towns or cities, neither indeed is it at all required. Where the whole world is delineated at once, the mind can hardly take in more than the idea of the situations of different kingdoms from one another; the situations of the different cities of each particular kingdom being almost wholly overlooked, and not attended to: and this happens likewise where a very large portion of the globe, as one of the four quarters, is represented on a single map. Besides these, therefore, it is necessary to have particular maps of all the different countries done upon a larger scale, that thus the mind may not be fatigued by endeavouring to comprehend too much at once. The qualifications which maps ought to have, in order to render them complete, are, 1. That they represent the countries exactly of the same shape, and in the same proportions to the eye, that they really have on the earth itself. 2. That the divisions of one country from another be distinctly marked, and readily perceptible, without a disagreeable and tedious search. 3. That the longitudes and latitudes of different places be found exactly on the map, and with little or no trouble.

The foundation of all maps is what is called *the projection of the sphere*, i. e. the delineation of those circles apparently traced out by the sun in the heavens, upon some substance, either plane or spherical, designed to represent the surface of the earth; upon which also are delineated the parallels of latitude, and the meridians, in as great number as the size of the map will admit of without confusion. Principles and Practice.

These delineations upon a spherical surface are very easy: and under the article GLOBE, full directions are given for the construction of the spherical substances upon which maps of the earth and the heavens are usually delineated; and which, when furnished with the rest of their apparatus, are called *terrestrial* and *celestial globes*. The method of drawing the maps for these globes is never followed in any other case; for which reason it is also referred to the article GLOBE. The ordinary kinds of maps are constructed by delineating the circles of the sphere upon a plane surface, according to the rules of perspective. This is properly the projection of the sphere; and is designed to give a view of the terraqueous globe, as it would appear, at some distance, to an eye that could take in the whole extent of it at once.

§ 1. *Of Projections of the Spheres and Maps.*

OF projections there are two kinds, the *orthographic* and *stereographic*; both of which represent the surface of the earth projected upon the plane of one of its great circles.

63 Orthographic projection.

1. The *orthographic* supposes the eye to be placed at an infinite distance in the axis of the circle of projection, while the stereographic supposes it to be only in the pole of that circle. The circles on which the projections are usually made, are, the equator, some of the meridians, or the rational horizon of some particular place. For maps of the world a meridian is generally chosen; and most commonly that one which passes through Ferro, one of the Canary islands, because thus the continents of Europe, Asia, and Africa, are conveniently delineated in one circle, and America in the other.

64 On the plane of meridian

1. To project the sphere orthographically on the plane of any meridian, we have only to consider, that as the eye is supposed to be at an infinite distance, all the rays which come from the disk of the earth are parallel; and consequently all lines drawn from the eye to the disk must be perpendicular to the latter. Let therefore, A B C D, (fig. 1.) represent the plane of one of the meridians. The equator, which cuts all the meridians in the middle, must be represented by an infinite number of points let fall upon the plane of projection, and dividing it exactly in the middle; that is, by the right line B D. The parallels of latitude, being also perpendicular to the plane of the meridian, will be marked out by an infinite number of right lines let fall from their peripheries upon that plane, thus forming the right lines *a b*, *c d*, &c. The meridians will likewise be represented on the disk by an infinite number of right lines let fall perpendicularly from their peripheries upon the plane of projection, and thus will form the elliptic curves A10C A20C, &c. From an inspection of the figure, therefore, it appears, that in this projection both longitudes and latitudes are measured by a line of sines, and both of them decrease prodigiously as we approach the edges of the disk; and hence the countries which lie at a distance from the equator are exceedingly distorted, and it is even impossible to draw them with any degree of accuracy. The orthographic projection on the plane of a meridian, therefore, is never used but for a map of the world. Plate CCIX.

Principles and Practice.

2. On the plane of the equator, the orthographic projection repreſents the meridians as ſtraight lines diverging from a centre, and the parallels of latitude as concentric circles. The latter, however, are by no means to be placed at equal diſtances from each other; for the meridians are to be divided by the line of ſines, as in the laſt; and thus the equatorial parts of the globe are as much diſtorted and confuſed as the polar ones were in the foregoing. This projection, therefore, is ſeldom uſed for a map of the whole world, though it anſwers very well for a repreſentation of the polar regions.

65 On the equator. fig. 2.

66 On any particular horizon, fig. 3.

3. On the horizon of any particular place, except either of the poles, or any point lying directly under the equator, the orthographic projection repreſents both parallels and meridians by ſegments of ellipſes. The figure ſhows a map done on the horizon of Ur of the Chaldees: it is obvious, however, that a conſiderable degree of diſtortion takes place here alſo; though leſs than in the former caſes. Projections of this kind, therefore, are uſed only for the conſtruction of ſolar eclipſes. See ASTRONOMY, ſect. x.

67 Stereographic projection.

II. The *ſtereographic* projection of the ſphere ſuppoſes the eye to be in the pole of the circle of projection. The laws of this projection are,

1. A right circle is projected into a line of half tangents.

2. The repreſentation of a right circle, perpendicularly oppoſed to the eye, will be a circle in the plane of the projection.

3. The repreſentation of a circle placed oblique to the eye, will be a circle in the plane of the projection.

4. If a great circle is to be projected upon the plane of another great circle, its centre will lie in the line of meaſures, diſtant from the centre of the primitive by the tangent of its elevation above the plane of the primitive.

5. If a leſſer circle, whoſe poles lie in the plane of the projection, were to be projected; the centre of its repreſentation would be in the line of meaſures, diſtant from the centre of the primitive, by the ſecant of the leſſer circles diſtance from its pole, and its ſemidiameter or radius be equal to the tangent of that diſtance.

6. If a leſſer circle were to be projected, whoſe poles lie not in the plane of the projection, its diameter in the projection, if it falls on each ſide of the pole of the primitive, will be equal to the ſum of the half tangents of its greateſt and neareſt diſtance from the pole of the primitive, ſet each way from the centre of the primitive in the line of meaſures.

7. If the leſſer circle to be projected fall entirely on one ſide of the pole of the projection, and do not encompaſs it: then will its diameter be equal to the difference of the half tangents of its greateſt and neareſt diſtance from the pole of the primitive, ſet off from the centre of the primitive one; and the ſame way in the line of meaſures.

8. In the ſtereographic projection, the angles made by the circles of the ſurface of the ſphere, are equal to the angles made by their repreſentatives in the plane of their projection.

For a demonſtration of theſe laws, ſee the articles PERSPECTIVE and PROJECTION. The method of delineating general maps of the world will, however, be eaſily underſtood by the following directions.

Principles and Practice.

68 On the plane of a meridian, fig. 6.

1. To delineate a map of the earth upon the plane of a meridian. Draw a circle of any convenient magnitude, as ABCD, to repreſent one half of the earth's diſc; draw two diameters AB, CD, interſecting each other at right angles; AB will then repreſent the equator, and CD that meridian which is directly perpendicular to the plane of projection, C will be the north pole, and D the ſouth pole. Divide the circle into 360 equal parts, repreſenting the degrees of latitude; or into ſmaller parts, if it can admit of ſuch a diviſion, to repreſent minutes. Then, by means of a ſector, divide the equator AB into two lines of ſemitangents EA and EB, which will repreſent the degrees of longitude. Then with the ſecant of 80°, as a radius deſcribe the arch of the circle C *c* D, which repreſents a meridian cutting the plane of projection, at an angle of 80°; with the ſecant of 70°, deſcribe the arch C *d* D, which repreſents a meridian cutting the plane of projection at 70°; and thus proceed with the reſt of the meridians, which are uſually drawn at every 10 degrees longitude, as the parallels are at every 10 degrees latitude. Theſe laſt are to be drawn with the tangents for radii as the meridians are with the ſecants; GH repreſenting the parallel of 10 degrees, with the tangent of 80°, that of 20 with the tangent of 70, &c. The ecliptic AQB is drawn with the tangent of 66.31 for a radius, its greateſt diſtance from the equator being 23.29. This is the moſt common projection for maps of the world, and is that on which the map Plate CCXIV. is delineated. It hath this diſadvantage, however, that neither the degrees of longitude nor latitude continue of the ſame length, even under the ſame parallel; and conſequently the ſhape of the countries is ſomewhat diſtorted: it is alſo exceedingly difficult to find the preciſe degree of longitude or latitude belonging to any place upon maps of this kind, as muſt be evident from an inſpection of the figures.

69 On a particular horizon.

2. On the plane of the horizon. Suppoſe, for inſtance, it is deſired to have London the centre of the map: its latitude we will ſuppoſe to be 51 degrees 32 minutes. Take then the point E (fig. 5.) for London; and from this, as a centre, deſcribe the circle ABCD to repreſent the horizon; which you are then to divide into four quadrants, and each of theſe into 90 degrees. Let the diameter BD be the meridian, B the northern quarter, D the ſouthern; the line of equinoctial eaſt and weſt ſhows the firſt vertical, A the weſt, C the eaſt, or a place of 90 degrees from the zenith in the firſt vertical. All the verticals are repreſented by right lines drawn from the centre E to the ſeveral degrees of the horizon. Divide BD into 180 degrees, as in the former method; the point in EB repreſenting 51 deg. 32 min. of the arch BC, will be the projection of the north pole, which note with the letter P. The point in ED repreſenting 51 deg. 32 min. of the arch DC (reckoning from C towards D), will be the projection of the interſection of the equator and meridian of London; and from this, towards P, write the numbers of the degrees, 1, 2, 3, &c. As alſo towards D, and from B towards P, viz. 51, 52, 53, &c. Then taking the correſponding points of equal degrees, 88, 89, &c. about thoſe, as diameters, deſcribe circles, which will repreſent parallels, or circles of latitude,

Principles and Practice.

titude, with the equator, tropics, and polar circles. For the meridians, firſt deſcribe a circle through the three points A, P, C. This will repreſent the meridian 90 degrees from London. Let its centre be M in BD (continued to the point N, which repreſents the ſouth pole), PN being the diameter: through M draw a parallel to A C, *viz.* FH, continued each way to K and L. Divide the circle P H N F into 360 degrees, and from the point P draw right lines to the ſeveral degrees cutting K F H L: through the ſeveral points of interſection, and the poles P, N, as through three given points, deſcribe circles repreſenting all the meridians. The centres for deſcribing the arches will be in the ſame K L, as being the ſame that are found by the former interſection; but are to be taken with this caution, that for the meridian next B D N towards A, the moſt remote centre towards L be taken for the firſt, the ſecond from this, &c.—The circles of longitude and latitude thus drawn, inſert the places from a table.

Maps of this kind may be uſeful for particular purpoſes: but the irregular length of the degrees, both of longitude and latitude, render them very unfit for repreſenting the countries in their proper ſhape; and the difficulties in finding the particular degrees of longitude and latitude are even greater in this than any other projection, as is evident from the inſpection of fig. 4.

III. Beſides theſe, there may be a variety of other projections, though few of them are applicable to any particular purpoſe. The three following are thoſe moſt generally uſeful, as having each ſome peculiar property which cannot be found in any other but themſelves.

70 Projection in which the earth is ſuppoſed to be conical.

1. If, inſtead of its globular figure, we ſuppoſe the earth to have a conical one, it is plain, that the meridians would be repreſented by ſtraight lines diverging from the apex of the cone, while the parallels are ſhown by concentric circles placed at equal diſtances. This kind of projection is ſhown in Plate CCXIII. fig. 1, 2. It hath this great advantage, that the longitudes and latitudes may be found with the greateſt eaſe by means of a moveable index placed on the centre. The whole earth may alſo be thus repreſented on a ſingle circle: but thus the countries towards the ſouth pole are prodigiouſly augmented in breadth in proportion to their length; for the degrees of longitude conſtantly increaſe the farther we are removed from the pole, while thoſe of latitude ſtill remain the ſame. This apparent error, however, doth not in the leaſt affect the real proportion of the map, or render it more difficult to find the longitudes or latitudes upon it.

Principles and Practice.

71 Mercator's projection, ſuppoſing it a cylinder.

2. Mercator's projection ſuppoſes the earth, inſtead of a globular, to have a cylindrical figure; in conſequence of which, the degrees of longitude become of an equal length throughout the whole ſurface, and are marked out on the map by parallel lines. The circles of latitude alſo are repreſented by lines croſſing the former at right angles, but at unequal diſtances. The farther we remove from the equator, the longer the degrees of latitude become in proportion to thoſe of longitude, and that in no leſs a degree than as the ſecant of an arch to the radius of the circle: that is, if we make one degree of longitude at the equator the radius of a circle; at one degree diſtant from the equator, a degree of latitude will be expreſſed by the ſecant of one degree; at ten degrees diſtance, by the ſecant of ten degrees; and ſo on *. A map of the world, therefore, cannot be delineated upon this projection, without diſtorting the ſhape of the countries in an extraordinary manner. The projection itſelf is, however, very uſeful in navigation, as it ſhows the different bearings with perfect accuracy, which cannot be done upon any other map. See CCXIII. fig. 3.

* See Plate CCXII.

72 Globular projection.

3. The globular projection is an invention of M. de la Hire, and is more uſeful than any of the former for exhibiting the true ſhape of the countries. It may be made in the following manner: Having drawn a circle repreſenting one-half of the earth's diſc, draw two diameters as before, which repreſent the equator and vertical meridian. Divide each of theſe into 180 equal parts for the meaſures of the degrees of longitude and latitude. Then through the two poles, and every tenth diviſion on the equator, draw arches of circles for the meridians; and in like manner through every tenth degree on each ſemicircle draw an arch, which ſhall likewiſe paſs through every tenth diviſion on the meridian for the parallels of latitude.

73 Conſtruction of particular maps.

IV. The conſtruction of maps of particular parts of the earth requires a different operation. Large portions of its ſurface may indeed be drawn on the plane of the meridian, as before directed; but when a ſmall part, as the iſland of Britain, for inſtance, is to be repreſented on a large ſcale, it would be found difficult to draw the arches of ſuch large circles as are neceſſary, and therefore the following method may be adopted. In this caſe, the degrees of longitude and latitude may be both repreſented by ſtraight lines. It is to be remembered, however, that though the degrees of latitude always continue of an equal length, it is not ſo with thoſe of longitude. They muſt neceſſarily decreaſe as we approach the pole. The proportion in which they decreaſe may be found by the line of longitudes on the plane ſcale; or by the following

29	52	48	59	30	90	89	01	05
30	51	96	60	30	00	90	00	00

Suppose, then, it is required to draw the meridians and parallels for a map of Britain. This island is known to lie between 50 and 60 degrees of latitude, and two and seven of longitude. Having therefore chosen the length of your degrees of latitude, you must next proportion your degrees of longitude to it. By the table you find, that in the latitude of 50° the length of a degree of longitude is to one of latitude as 38,57 is to 60; that is, a degree of longitude in latitude 50 is somewhat more than half the length of a degree of latitude. The exact proportion may easily be taken by a diagonal scale; after which, you are to mark out seven or eight of those degrees upon a right line for the length of your intended map. On the extremities of this line raise two perpendiculars, upon which mark out ten degrees of latitude for the height of it. Then, having completed the parallelogram, consult the table for the length of a degree of longitude in lat. 60°, which is found to be very nearly one half a degree of latitude. It will always be proper, however, to draw a vertical meridian exactly in the middle of the parallelogram, to which the meridian on each side may converge; and from this you are to set off the degrees of longitude on each side. Then, having divided the lines bounding your map into as many parts as can conveniently be done, to serve for a scale, you may by their means set off the longitudes and latitudes with much less trouble than where curve lines are used. This method may always be followed where a particular kingdom is to be delineated, and will represent the true figure and situation of the places with tolerable exactness. The particular points of the compass on which the towns lie with respect to one another, or their bearings, cannot be exactly known, except by a globe or Mercator's projection. Their distances, however, may by this means be accurately expressed, and this is the only kind of maps to which a scale of miles can be truly adapted.

Principles and Practice.

§ 2. *Description and Use of the Globes and Armillary Sphere.*

When we have thus discovered, by means of maps, or any other way, the true situation of the different places of the earth with regard to one another, we may easily know every other particular relative to them; as, how far distant they are from us, what hour of the day it is, what season of the year, &c. at any particular place. As each of these problems, however, would require a particular and sometimes troublesome calculation, machines have been invented, by which all the calculations may be saved, and every problem in geography may be solved mechanically, and in the most easy and expeditious manner. These machines are the celestial and terrestrial globes, and the armillary sphere; of which, and the method of using them, we proceed to give a description.

74 The terrestrial globe.

If a map of the world be accurately delineated on a spherical ball, the surface thereof will represent the surface of the earth: for the highest hills are so inconsiderable with respect to the bulk of the earth, that they take off no more from its roundness than grains of sand do from the roundness of a common globe; for the diameter of the earth is 8000 miles in round numbers, and no known hill upon it is much above three miles in perpendicular height.

With regard to what we call *up* and *down*, see the article Gravity.

75 The face of the heavens and of the earth represented in a machine.

To an observer placed any where in the indefinite space, where there is nothing to limit his view, all remote objects appear equally distant from him; and seem to be placed in a vast concave sphere, of which his eye is the centre. The moon is much nearer to us than the sun; some of the planets are sometimes nearer and sometimes farther from us than the sun; others of them never come so near to us as the sun always is; the remotest planet in our system is beyond comparison nearer to us than any of the fixed stars are: and yet all these celestial objects appear equally distant from us. Therefore, if we imagine a large hollow sphere of glass to have as many bright studs fixed to its inside as there are stars visible in the heaven, and these studs to be of different magnitudes, and placed at the same angular distances from each other as the stars are; the sphere will be a true representation of the starry heaven, to an eye supposed to be in its centre, and viewing it all around. And if a small globe, with a map of the earth upon it, be placed on an axis in the centre of this starry sphere, and the sphere be made to turn round on this

Principles and Practice.

axis, it will represent the apparent motion of the heavens round the earth.

If a great circle be so drawn upon this sphere as to divide it into two equal parts or hemispheres, and the plane of the circle be perpendicular to the axis of the sphere, this circle will represent the *equinoctial*, which divides the heaven into two equal parts, called the *northern* and the *southern hemispheres;* and every point of that circle will be equally distant from the *poles*, or ends of the axis in the sphere. That pole which is in the middle of the northern hemisphere, will be called the *north pole of the sphere;* and that which is in the middle of the southern hemisphere, the *south pole*.

If another grand circle be drawn upon the sphere in such a manner as to cut the equinoctial at an angle of $23\frac{1}{2}$ degrees in two opposite points, it will represent the *ecliptic*, or circle of the sun's apparent annual motion; one half of which is on the north side of the equinoctial, and the other half on the south.

If a large stud be made to move eastward in this ecliptic in such a manner as to go quite round it in the time that the sphere is turned round westward 366 times upon its axis, this stud will represent the *sun* changing his place every day a 365th part of the ecliptic, and going round westward the same way as the stars do; but with a motion so much slower than the motion of the stars, that they will make 366 revolutions about the axis of the sphere in the time that the sun makes only 365. During one half of these revolutions, the sun will be on the north side of the equinoctial; during the other half, on the south; and at the end of each half, in the equinoctial.

If we suppose the terrestrial globe in this machine to be about one inch in diameter, and the diameter of the starry sphere to be about five or six feet, a small insect on the globe would see only a very little portion of its surface; but it would see one half of the starry sphere, the convexity of the globe hiding the other half from its view. If the sphere be turned westward round the globe, and the insect could judge of the appearances which arise from that motion, it would see some stars rising to its view in the eastern side of the sphere, whilst others were setting on the western: but as all the stars are fixed to the sphere, the same stars would always rise in the same points of view on the east side, and set in the same points of view on the west side. With the sun it would be otherwise; because the sun is not fixed to any point of the sphere, but moves slowly along an oblique circle in it. And if the insect should look towards the south, and call that point of the globe, where the equinoctial in the sphere seems to cut it on the left side, the east point; and where it cuts the globe on the right side, the west point; the little animal would see the sun rise north of the east, and set north of the west, for $182\frac{1}{2}$ revolutions; after which, for as many more, the sun would rise south of the east, and set south of the west. And in the whole 365 revolutions, the sun would rise only twice in the east point, and set twice in the west. All these appearances would be the same, if the starry sphere stood still (the sun only moving in the ecliptic), and the earthly globe were turned round the axis of the sphere eastward. For, as the insect would be carried round with the globe, he would be quite insensible of its motion, and the sun and stars would appear to move westward.

1. *Description of the Terrestrial Globe.*

Principles and Practice.

76 The terrestrial globe described. Plate CCX. fig. 1.

The equator, ecliptic, and tropics, polar circles, and meridians, are laid down upon the globe in the manner already described. The ecliptic is divided into 12 signs, and each sign into 30 degrees. Each tropic is $23\frac{1}{2}$ degrees from the equator, and each polar circle $23\frac{1}{2}$ degrees from its respective pole. Circles are drawn parallel to the equator, at every 10 degrees distance from it on each side to the poles: these circles are called *parallels of latitude*. On large globes there are circles drawn perpendicularly through every tenth degree of the equator, intersecting each other at the poles: but on globes of or under a foot diameter, they are only drawn through every fifteenth degree of the equator; these circles are generally called *meridians*, sometimes *circles of longitude*, and at other times *hour-circles*.

The globe is hung in a brass-ring (A), called the *brasen meridian*, and turns upon a wire in each pole sunk half its thickness into one side of the meridian ring; by which means that side of the ring divides the globe into two equal parts, called the *eastern* and *western hemispheres;* as the equator divides it into two equal parts, called the *northern* and *southern hemispheres*. The ring is divided into 360 equal parts or degrees, on the side wherein the axis of the globe turns. One half of these degrees are numbered, and reckoned, from the equator to the poles, where they end at 90: their use is to show the latitudes of places. The degrees on the other half of the meridian are numbered from the poles to the equator, where they end at 90: their use is to show how to elevate either the north or south pole above the horizon, according to the latitude of any given place, as it is north or south of the equator.

The brasen meridian is let into two notches made in a broad flat ring called the *wooden horizon*, B, C; the upper surface of which divides the globe into two equal parts, called the *upper* and *lower hemispheres*. One notch is in the north point of the horizon, and the other in the south. On this horizon are several concentric circles, which contain the months and days of the year, the signs and degrees answering to the sun's place for each month and day, and the 32 points of the compass and the circles of amplitude and azimuth.—The graduated side of the brass meridian lies towards the east side of the horizon, and should be generally kept towards the person who works problems by the globes.

There is a small horary circle D, so fixed to the north part of the brasen meridian, that the wire in the north pole of the globe is in the centre of that circle; and on the wire is an index, which goes over all the 24 hours of the circle, as the globe is turned round its axis. Sometimes there are two horary circles, one between each pole of the globe and the brasen meridian.

There is a thin slip of brass, called the *quadrant of altitude*, which is divided into 90 equal parts or degrees, answering exactly to so many degrees of the equator. It is occasionally fixed to the uppermost point of the brasen meridian by a nut and screw. The divisions end at the nut E, and the quadrant is turned round upon it.

There is also applied occasionally to the globe a magnetic needle, freely moving over a circle divided into

Principles and Practice.

into four times 90 degrees; reckoning from the north and south points towards the east and west, and also into the 32 points of the compass. As this needle makes nearly a certain constant angle with the meridian in every place, called the *variation*; therefore this compass being added to the frame, will rectify the position of the meridian of the globe when the variation of the needle is known. Thus at London, the variation of the needle is at this time about 23 degrees northward; therefore, by moving the frame of the globe about till the needle settles itself over the 23d degree, reckoning westward from the north point or *fleur de lis*, we shall have the brass meridian coinciding with the true meridian. The compass is sometimes fixed between the legs underneath the globe.

Principles and Practice.

2. *Description and Use of the Armillary Sphere.*

77 Armillary sphere described. Place CCXI. fig. 4.

The exterior parts of this machine are, a compages of brass rings, which represent the principal circles of the heaven, viz. 1. The equinoctial AA, which is divided into 360 degrees (beginning at its intersection with the ecliptic in Aries), for showing the sun's right ascension in degrees; and also into 24 hours, for showing his right ascension in time. 2. The ecliptic BB, which is divided into 12 signs, and each sign into 30 degrees, and also into the months and days of the year; in such a manner, that the degree or point of the ecliptic in which the sun is, on any given day, stands over that day in the circle of months. 3. The tropic of Cancer CC, touching the ecliptic at the beginning of Cancer in *e*, and the tropic of Capricorn DD, touching the ecliptic at the beginning of Capricorn in *f*; each 23½ degrees from the equinoctial circle. 4. The arctic circle E, and the antarctic circle F, each 23½ degrees from its respective pole at N and S. 5. The equinoctial colure GG, passing through the north and south poles of the heaven at N and S, and through the equinoctial points Aries and Libra, in the ecliptic. 6. The solstitial colure HH, passing through the poles of the heaven, and through the solstitial points Cancer and Capricorn in the ecliptic. Each quarter of the former of these colures is divided into 90 degrees, from the equinoctial to the poles of the world, for showing the declination of the sun, moon, and stars; and each quarter of the latter, from the ecliptic at *e* and *f*, to its poles *b* and *d*, for showing the latitude of the stars.

In the north pole of the ecliptic is a nut *b*, to which is fixed one end of a quadrantal wire, and to the other end a small sun Y, which is carried round the ecliptic BB, by turning the nut: and in the south pole of the ecliptic is a pin *d*, on which is another quadrantal wire, with a small moon Z upon it, which may be moved round by the hand: but there is a particular contrivance for causing the moon to move in an orbit which crosses the ecliptic at an angle of 5½ degrees, in two opposite points called the *moon's nodes*; and also for shifting these points backward in the ecliptic, as the moon's nodes shift in the heaven.

Within these circular rings is a small terrestrial globe I, fixed on an axis KK, which extends from the north and south poles of the globe at *n* and *s*, to those of the celestial sphere at N and S. On this axis is fixed the flat celestial meridian LL, which may be set directly over the meridian of any place on the globe, and then turned round with the globe, so as to keep over the same meridian upon it. This flat meridian is graduated the same way as the brass meridian of a common globe, and its use is much the same. To this globe is fitted the moveable horizon MM, so as to turn upon two strong wires proceeding from its east and west points to the globe, and entering the globe at the opposite points of its equator, which is a moveable brass ring let into the globe in a groove all around its equator. The globe may be turned by hand within this ring, so as to place any given meridian upon it, directly under the celestial meridian LL. The horizon is divided into 360 degrees all around its outermost edge, within which are the points of the compass for showing the amplitude of the sun and moon both in degrees and points. The celestial meridian LL, passes thro' two notches in the north and south points of the horizon, as in a common globe: but here, if the globe be turned round, the horizon and meridian turn with it. At the south pole of the sphere is a circle of 24 hours, fixed to the rings; and on the axis is an index which goes round that circle, if the globe be turned round its axis.

The whole fabric is supported on a pedestal N, and may be elevated or depressed upon the joint O, to any number of degrees from 0 to 90, by means of the arc P, which is fixed in the strong brass arm Q, and slides in the upright piece R, in which is a screw at *r*, to fix it at any proper elevation.

In the box T are two wheels (as in Dr Long's sphere), and two pinions, whose axes come out at V and U; either of which may be turned by the small winch W. When the winch is put upon the axis V, and turned backward, the terrestrial globe, with its horizon and celestial meridian, keep at rest; and the whole sphere of circles turns round from east, by south, to west, carrying the sun Y, and moon Z, round the same way, and causing them to rise above and set below the horizon. But when the winch is put upon the axis U, and turned forward, the sphere with the sun and moon keep at rest; and the earth, with its horizon and meridian, turn round from west, by south, to east; and bring the same points of the horizon to the sun and moon, to which these bodies came when the earth kept at rest and they were carried round it; showing that they rise and set in the same points of the horizon, and at the same times in the hour-circle, whether the motion be in the earth or in the heaven. If the earthly globe be turned, the hour-index goes round its hour-circle; but if the sphere be turned, the hour-circle goes round below the index.

And so, by this construction, the machine is equally fitted to show either the real motion of the earth or the apparent motion of the heaven.

To rectify the sphere for use, first slacken the screw *r* in the upright stem R, and taking hold of the arm Q, move it up or down until the given degree of latitude for any place be at the side of the stem R; and then the axis of the sphere will be properly elevated so as to stand parallel to the axis of the world, if the machine be set north and south by a small compass: this done, count the latitude from the north pole, upon the celestial meridian LL, down towards the north notch of the horizon, and set the horizon to that latitude; then turn the nut *b* until the sun Y comes to the

Principles and Practice

the given day of the year in the ecliptic, and the ſun will be at its proper place for that day: find the place of the moon's aſcending node, and alſo the place of the moon, by an ephemeris, and ſet them right accordingly: laſtly, turn the winch W, until either the ſun comes to the meridian LL, or until the meridian comes to the ſun (according as you want the ſphere or earth to move), and ſet the hour-index to the XII, marked noon, and the whole machine will be rectified. Then turn the winch, and obſerve when the ſun or moon riſe and ſet in the horizon, and the hour-index will ſhow the times thereof for the given day.

As thoſe who underſtand the uſe of the globes will be at no loſs to work many other problems by this ſphere, it is needleſs to enlarge any farther upon it.

3. *Directions for uſing Globes.*

In uſing globes, keep the eaſt ſide of the horizon towards you (unleſs the problem requires the turning of it), which ſide you may know by the word Eaſt upon the horizon; for then you have the graduated ſide of the meridian towards you, the quadrant of altitude before you, and the globe divided exactly into two equal parts, by the graduated ſide of the meridian.

78 Directions for uſing the terreſtrial globe.

In working ſome problems, it will be neceſſary to turn the whole globe and horizon about, that you may look on the weſt ſide thereof; which turning will be apt to jog the ball ſo, as to ſhift away that degree of the globe which was before ſet to the horizon or meridian: to avoid which inconvenience, you may thruſt in the feather end of a quill between the ball of the globe and the brazen meridian; which, without hurting the ball, will keep it from turning in the meridian, whilſt you turn the weſt ſide of the horizon towards you.

Prob. I. *To find the latitude and longitude of any given place upon the globe*—Turn the globe on its axis, until the given place comes exactly under that graduated ſide of the braſen meridian on which the degrees are numbered from the equator; and obſerve what degree of the meridian the place then lies under; which is its latitude, north or ſouth, as the place is north or ſouth of the equator.

The globe remaining in this poſition, the degree of the equator, which is under the braſen meridian, is the longitude of the place, which is eaſt or weſt, as the place lies on the caſt or weſt ſide of the firſt meridian of the globe.—All the Atlantic ocean, and America, is on the weſt ſide of the meridian of London; and the greateſt part of Europe, and of Africa, together with all Aſia, is on the eaſt ſide of the meridian of London, which is reckoned the firſt meridian of the globe by the Britiſh geographers and aſtronomers.

Prob. II. *The longitude and latitude of a place being given, to find that place on the globe.*—Look for the given longitude in the equator (counting it eaſtward or weſtward from the firſt meridian, as it is mentioned to be eaſt or weſt); and bringing the point of longitude in the equator to the braſen meridian, on that ſide which is above the ſouth point of the horizon: then count from the equator, on the braſen meridian, to the degree of the given latitude, towards the north or ſouth pole, according as the latitude is north or ſouth; and under that degree of latitude on the meridian you will have the place required.

Principles and Practice

Prob. III. *To find the difference of longitude, or difference of latitude, between any two given places.*—Bring each of theſe places to the braſen meridian, and ſee what its latitude is: the leſſer latitude ſubtracted from the greater, if both places are on the ſame ſide of the equator, or both latitudes added together if they are on different ſides of it, is the difference of latitude required. And the number of degrees contained between theſe places, reckoned on the equator, when they are brought ſeparately under the braſen meridian, is their difference of longitude, if it be leſs than 180; but if more, let it be ſubtracted from 360, and the remainder is the difference of longitude required. Or,

Having brought one of the places to the braſen meridian, and ſet the hour-index to XII, turn the globe until the other place comes to the braſen meridian; and the number of hours and parts of an hour, paſſed over by the index, will give the longitude in time; which may be eaſily reduced to degrees, by allowing 15 degrees for every hour, and one degree for every four minutes.

N. B. When we ſpeak of bringing any place to the braſen meridian, it is the graduated ſide of the meridian that is meant.

Prob. IV. *Any place being given, to find all thoſe places that have the ſame longitude or latitude with it.*—Bring the given place to the braſen meridian; then all thoſe places which lie under that ſide of the meridian, from pole to pole, have the ſame longitude with the given place. Turn the globe round its axis; and all thoſe places which paſs under the ſame degree of the meridian that the given place does, have the ſame latitude with that place.

Since all latitudes are reckoned from the equator, and all longitudes are reckoned from the firſt meridian, it is evident, that the point of the equator which is cut by the firſt meridian, has neither latitude nor longitude.—The greateſt latitude is 90 degrees, becauſe no place is more than 90 degrees from the equator: And the greateſt longitude is 180 degrees, becauſe no place is more than 180 degrees from the firſt meridian.

Prob. V. *To find the* antœci, periœci, *and* antipodes, *of any given place.*—Bring the given place to the braſen meridian; and having found its latitude, keep the globe in that ſituation, and count the ſame number of degrees of latitude from the equator towards the contrary pole; and where the reckoning ends, you have the *antœci* of the given place upon the globe. Thoſe who live at the equator have no *antœci*.

The globe remaining in the ſame poſition, ſet the hour-index to the upper XII on the horary circle, and turn the globe until the index comes to the lower XII; then the place which lies under the meridian, in the ſame latitude with the given place, is the *periœci* required. Thoſe who live at the poles have no *periœci*.

As the globe now ſtands (with the index at the lower XII), the *antipodes* of the given place will be under the ſame point of the braſen meridian where its *antœci* ſtood before. Every place upon the globe has its *antipodes*.

Prob. VI. *To find the diſtance between any two places*

Principles and Practice.

places on the globe.—Lay the graduated edge of the quadrant of altitude over both the places, and count the number of degrees intercepted between them on the quadrant; then multiply theſe degrees by 60, and the product will give the diſtance in geographical miles: but to find the diſtance in miles, multiply the degrees by 69½, and the product will be the number of miles required. Or, take the diſtance betwixt any two places with a pair of compaſſes, and apply that extent to the equator; the number of degrees, intercepted between the points of the compaſſes, is the diſtance in degrees of a great circle; which may be reduced either to geographical miles, or to Engliſh miles, as above.

Prob. VII. *A place on the globe being given, and its diſtance from any other place; to find all the other places upon the globe which are at the ſame diſtance from the given place.*—Bring the given place to the braſen meridian, and ſcrew the quadrant of altitude to the meridian directly over that place; then keeping the globe in that poſition, turn the quadrant quite round upon it, and the degree of the quadrant that touches the ſecond place will paſs over all the other places which are equally diſtant with it from the given place.

This is the ſame as if one foot of a pair of compaſſes was ſet in the given place, and the other foot extended to the ſecond place, whoſe diſtance is known; for if the compaſſes be then turned round the firſt place as a centre, the moving foot will go over all thoſe places which are at the ſame diſtance with the ſecond from it.

Prob. VIII. *The hour of the day at any place being given, to find all thoſe places where it is noon at that time.*—Bring the given place to the braſen meridian, and ſet the index to the given hour; this done, turn the globe until the index points to the upper XII, and then all the places that lie under the braſen meridian have noon at that time.

N. B. The upper XII always ſtands for noon; and when the bringing of any place to the braſen meridian is mentioned, the ſide of that meridian on which the degrees are reckoned from the equator is meant, unleſs the contrary ſide be mentioned.

Prob. IX. *The hour of the day at any place being given, to find what o'clock it then is at any other place.*—Bring the given place to the braſen meridian, and ſet the index to the given hour; then turn the globe, until the place where the hour is required comes to the meridian, and the index will point out the hour at that place.

Prob. X. *To find the ſun's place in the ecliptic, and his declination, for any given day of the year*—Look on the horizon for the given day, and right againſt it you have the degree of the ſign in which the ſun is (or his place) on that day at noon. Find the ſame degree of that ſign in the ecliptic line upon the globe, and having brought it to the braſen meridian, obſerve what degree of the meridian ſtands over it; for that is the ſun's declination, reckoned from the equator.

Prob. XI. *The day of the month being given, to find all thoſe places of the earth over which the ſun will paſs vertically on that day.*—Find the ſun's place in the ecliptic for the given day, and having brought it to the braſen meridian, obſerve what point of the meridian is over it; then, turning the globe round its axis, all thoſe places which paſs under that point of the meridian are the places required; for as their latitude is equal, in degrees and parts of a degree, to the ſun's declination, the ſun muſt be directly over-head to each of them at its reſpective noon.

Principles and Practice.

Prob. XII. *A place being given in the torrid zone, to find thoſe two days of the year on which the ſun ſhall be vertical to that place.*—Bring the given place to the braſen meridian, and mark the degree of latitude that is exactly over it on the meridian; then turn the globe round its axis, and obſerve the two degrees of the ecliptic which paſs exactly under that degree of latitude: laſtly, find on the wooden horizon the two days of the year in which the ſun is in thoſe degrees of the ecliptic, and they are the days required: for on them, and none elſe, the ſun's declination is equal to the latitude of the given place; and, conſequently, he will then be vertical to it at noon.

Prob. XIII. *To find all thoſe places of the north frigid zone, where the ſun begins to ſhine conſtantly without ſetting, on any given day, from the 21ſt of March to the 23d of September.*—On theſe two days, the ſun is in the equinoctial, and enlightens the globe exactly from pole to pole: therefore, as the earth turns round its axis, which terminates in the poles, every place upon it will go equally through the light and the dark, and ſo make the day and night equal to all places of the earth. But as the ſun declines from the equator, towards either pole, he will ſhine juſt as many degrees round that pole as are equal to his declination from the equator: ſo that no place within that diſtance of the pole will then go through any part of the dark, and conſequently the ſun will not ſet to it. Now, as the ſun's declination is northward from the 21ſt of March to the 23d of September, he muſt conſtantly ſhine round the north pole all that time; and on the day that he is in the northern tropic, he ſhines upon the whole north frigid zone; ſo that no place within the north polar circle goes through any part of the dark on that day. Therefore,

Having brought the ſun's place for the given day to the braſen meridian, and found his declination (by Prob. IX) count as many degrees on the meridian, from the north pole, as are equal to the ſun's declination from the equator, nnd mark that degree from the pole where the reckoning ends; then turning the globe round its axis, obſerve what places in the north frigid zone paſs directly under that mark; for they are the places required.

The like may be done for the ſouth frigid zone, from the 23d of September to the 21ſt of March, during which time the ſun ſhines conſtantly on the ſouth pole.

Prob. XIV. *To find the place over which the ſun is vertical at any hour of a given day.*—Having found the ſun's declination for the given day (by Prob. X.) mark it with a chalk on the braſen meridian: then bring the place where you are (ſuppoſe Edinburgh) to the braſen meridian, and ſet the index to the given hour; which done, turn the globe on its axis, until the index points to XII at noon; and the place on the globe, which is then directly under the point of

the

Principles and Practice.

the ſun's declination marked upon the meridian, has the ſun that moment in the zenith, or directly over head.

Prob. XV. *The day and hour of a lunar eclipſe being given; to find all thoſe places of the earth to which it will be viſible.*—The moon is never eclipſed but when ſhe is full, and ſo directly oppoſite to the ſun, that the earth's ſhadow falls upon her. Therefore, whatever place of the earth the ſun is vertical to at that time, the moon muſt be vertical to the antipodes of that place: ſo that the ſun will be then viſible to one half of the earth, and the moon to the other.

Find the place to which the ſun is vertical at the given hour (by Prob. XIV.) elevate the pole to the latitude of that place, and bring the place to the upper part of the braſen meridian, as in the former problem: then, as the ſun will be viſible to all thoſe parts of the globe which are above the horizon, the moon will be viſible to all thoſe parts which are below it, at the time of her greateſt obſcuration.

Prob. XVI. *To rectify the globe for the latitude, the zenith, and the ſun's place.*—Find the latitude of the place (by Prob. I.) and if the place be in the northern hemiſphere, raiſe the north pole above the north point of the horizon, as many degrees (counted from the pole upon the braſen meridian) as are equal to the latitude of the place. If the place be in the ſouthern hemiſphere, raiſe the ſouth pole above the ſouth point of the horizon as many degrees as are equal to the latitude. Then, turn the globe till the place comes under its latitude on the braſen meridian, and faſten the quadrant of altitude ſo, that the chamfered edge of its nut (which is even with the graduated edge) may be joined to the zenith, or point of latitude. This done, bring the ſun's place in the ecliptic for the given day (found by Prob. X.) to the graduated ſide of the braſen meridian, and ſet the hour-index to XII at noon, which is the uppermoſt XII on the hour-circle; and the globe will be rectified.

Prob. XVII. *The latitude of any place, not exceeding 66½ degrees, and the day of the month, being given; to find the time of the ſun's riſing and ſetting, and conſequently the length of the day and night.*—Having rectified the globe for the latitude, and for the ſun's place on the given day (as directed in the preceding problem), bring the ſun's place in the ecliptic to the eaſtern ſide of the horizon, and the hour-index will ſhow the time of ſun-riſing; then turn the globe on its axis, until the ſun's place comes to the weſtern ſide of the horizon, and the index will ſhow the time of ſun-ſetting.

The hour of ſun-ſetting doubled, gives the length of the day; and the hour of ſun-riſing doubled, gives the length of the night.

Prob. XVIII. *The latitude of any place, and the day of the month, being given; to find when the morning twilight begins, and the evening twilight ends, at that place.*—This problem is often limited: for, when the ſun does not go 18 degrees below the horizon, the twilight continues the whole night; and for ſeveral nights together in ſummer, between 49 and 66½ degrees of latitude; and the nearer to 66½, the greater is the number of theſe nights. But when it does begin and end, the following method will ſhow the time for any given day.

Rectify the globe, and bring the ſun's place in the ecliptic to the eaſtern ſide of the horizon; then mark with a chalk that point of the ecliptic which is in the weſtern ſide of the horizon, it being the point oppoſite to the ſun's place: this done, lay the quadrant of altitude over the ſaid point, and turn the globe eaſtward, keeping the quadrant at the chalk mark, until it is juſt 18 degrees high on the quadrant; and the index will point out the time when the morning twilight begins: for the ſun's place will then be 18 degrees below the eaſtern ſide of the horizon. To find the time when the evening twilight ends, bring the ſun's place to the weſtern ſide of the horizon; and the point oppoſite to it, which was marked with the chalk, will be riſing in the eaſt: then, bring the quadrant over that point, and keeping it thereon, turn the globe weſtward, until the ſaid point be 18 degrees above the horizon on the quadrant, and the index will ſhow the time when the evening twilight ends; the ſun's place being then 18 degrees below the weſtern ſide of the horizon.

Prob. XIX. *To find on what day of the year the ſun begins to ſhine conſtantly, without ſetting, on any given place in the north frigid zone; and how long he continues to do ſo.*—Rectify the globe to the latitude of the place, and turn it about until ſome point of the ecliptic, between Aries and Cancer, coincides with the north point of the horizon where the braſen meridian cuts it; then find, on the wooden horizon, what day of the year the ſun is in that point of the ecliptic; for that is the day on which the ſun begins to ſhine conſtantly on the given place without ſetting. This done, turn the globe, until ſome point of the ecliptic, between Cancer and Libra, coincides with the north point of the horizon, where the braſen meridian cuts it; and find, on the wooden horizon, on what day the ſun is in that point of the ecliptic; which is the day that the ſun leaves off conſtantly ſhining on the ſaid place, and riſes and ſets to it as to other places on the globe. The number of natural days, or complete revolutions of the ſun about the earth, between the two days above found, is the time that the ſun keeps conſtantly above the horizon without ſetting: for all that portion of the ecliptic, which lies between the two points which interſect the horizon in the very north, never ſets below it; and there is juſt as much of the oppoſite part of the ecliptic that never riſes: therefore, the ſun will keep as long conſtantly below the horizon in winter as above it in ſummer.

Prob. XX. *To find in what latitude the ſun ſhines conſtantly without ſetting, for any length of time leſs than 182½ of our days and nights.*—Find a point in the ecliptic half as many degrees from the beginning of Cancer (either toward Aries or Libra) as there are natural days in the time given; and bring that point to the north ſide of the brazen meridian, and which the degrees are numbered from the pole towards the equator: then keep the globe from turning on its axis, and ſlide the meridian up or down until the forefaid point of the ecliptic comes to the north point of the horizon, and then the elevation of the pole will be equal to the latitude required.

Prob. XXI. *The latitude of a place, not exceeding 66½ degrees, and the day of the month, being given; to find the ſun's amplitude or point of the compaſs on which he riſes or ſets.*—Rectify the globe, and bring the ſun's place

Fig. 4.

Fig. 3.

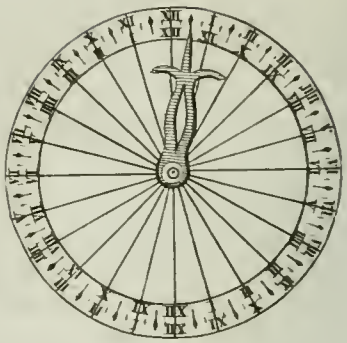

Fig. 1.

Fig. 2.

A. Bell Prin. Wal. Le Sculptor fecit.

Principles and Practice.

place to the eaſtern ſide of the horizon; then obſerve what point of the compaſs on the horizon ſtands right againſt the ſun's place, for that is his amplitude at riſing. This done, turn the globe weſtward, until the ſun's place comes to the weſtern ſide of the horizon, and it will ſhew the point of his amplitude at ſetting. Or, you may count the riſing amplitude in degrees, from the eaſt point of the horizon, to that point where the ſun's place cuts it; and the ſetting amplitude from the weſt point of the horizon, to the ſun's place at ſetting.

Prob. XXII. *The latitude, the ſun's place, and his altitude, being given; to find the hour of the day, and the ſun's azimuth, or number of degrees that he is diſtant from the meridian.*—Rectify the globe, and bring the ſun's place to the given height upon the quadrant of altitude; on the eaſtern ſide of the horizon, if the time be in the forenoon; or the weſtern ſide, if it be in the afternoon: then the index will ſhow the hour; and the number of degrees in the horizon, intercepted between the quadrant of altitude and the ſouth point, will be the ſun's true azimuth at that time.

Prob. XXIII. *The latitude, hour of the day, and the ſun's place, being given; to find the ſun's altitude and azimuth.*—Rectify the globe, and turn it until the index points to the given hour; then lay the quadrant of altitude over the ſun's place in the ecliptic, and the degree of the quadrant cut by the ſun's place is his altitude at that time above the horizon; and the degree of the horizon cut by the quadrant is the ſun's azimuth, reckoned from the ſouth.

Prob. XXIV. *The latitude, the ſun's altitude, and his azimuth, being given; to find his place in the ecliptic, the day of the month, and hour of the day, though they had all been loſt.*—Rectify the globe for the latitude and zenith, and ſet the quadrant of altitude to the given azimuth in the horizon; keeping it there, turn the globe on its axis until the ecliptic cuts the quadrant in the given altitude: that point of the ecliptic which cuts the quadrant there, will be the ſun's place; and the day of the month anſwering thereto, will be found over the like place of the ſun on the wooden horizon. Keep the quadrant of altitude in that poſition; and, having brought the ſun's place to the braſen meridian, and the hour-index to XII at noon, turn back the globe, until the ſun's place cuts the quadrant of altitude again, and the index will ſhow the hour.

Any two points of the ecliptic, which are equidiſtant from the beginning of Cancer or of Capricorn, will have the ſame altitude and azimuth at the ſame hour, though the months be different; and therefore it requires ſome care in this problem, not to miſtake both the month and the day of the month; to avoid which, obſerve, that from the 20th of March to the 21ſt of June, that part of the ecliptic which is between the beginning of Aries and beginning of Cancer is to be uſed; from the 21ſt of June to the 23d of September, between the beginning of Cancer and beginning of Libra; from the 23d of September to the 21ſt of December, between the beginning of Libra and the beginning of Capricorn; and from the 21ſt of December to the 20th of March, between the beginning of Capricorn and beginning of Aries. And as one can never be at a loſs to know in what quarter of the year he takes the ſun's altitude and azimuth, the above caution with regard to the quarters of the ecliptic will keep him right as to the month and day thereof.

Principles and Practice.

Prob. XXV. *To find the length of the longeſt day at any given place.*—If the place be on the north ſide of the equator, find its latitude (by Prob. I.) and elevate the north pole to that latitude; then, bring the beginning of Cancer to the braſen meridian, and ſet the hour-index to XII at noon. But if the given place be on the ſouth ſide of the equator, elevate the ſouth pole to its latitude, and bring the beginning of Capricorn to the braſs meridian, and the hour-index to XII. This done, turn the globe weſtward, until the beginning of Cancer or Capricorn (as the latitude is north or ſouth) comes to the horizon; and the index will then point out the time of ſun-ſetting, for it will have gone over all the afternoon hours, between mid-day and ſun-ſet; which length of time being doubled, will give the whole length of the day from ſun riſing to ſun-ſetting. For, in all latitudes, the ſun riſes as long before mid-day, as he ſets after it.

Prob. XXVI. *To find in what latitude the longeſt day is, of any given length, leſs than 24 hours.*—If the latitude be north, bring the beginning of Cancer to the braſen meridian, and elevate the north pole to about 66½ degrees; but if the latitude be ſouth, bring the beginning of Capricorn to the meridian, and elevate the ſouth pole to about 66½ degrees; becauſe the longeſt day in north latitude is, when the ſun is in the firſt point of Cancer; and in ſouth latitude, when he is in the firſt point of Capricorn. Then ſet the hour-index to XII at noon, and turn the globe weſtward, until the index points at half the number of hours given; which done, keep the globe from turning on its axis, and ſlide the meridian down in the notches, until the aforeſaid point of the ecliptic (viz. Cancer or Capricorn) comes to the horizon; then, the elevation of the pole will be equal to the latitude required.

Prob. XXVII. *The latitude of any place, not exceeding 66½ degrees, being given; to find in what climate the place is.*—Find the length of the longeſt day at the given place, by Prob. XXV. and whatever be the number of hours whereby it exceedeth twelve, double that number, and the ſun will give the climate in which the place is.

Prob. XXVIII. *The latitude, and the day of the month, being given; to find the hour of the day when the ſun ſhines.*—Set the wooden horizon truly level, and the braſen meridian due north and ſouth by a mariner's compaſs; then, having rectified the globe, ſtick a ſmall ſewing-needle into the ſun's place in the ecliptic, perpendicular to that part of the ſurface of the globe; this done, turn the globe on its axis, until the needle comes to the braſen meridian, and ſet the hour-index to XII at noon; then, turn the globe on its axis, until the needle points exactly towards the ſun (which it will do when it caſts no ſhadow on the globe), and the index will ſhow the hour of the day.

4. *The Uſe of the Celeſtial Globe.*

79 How to uſe the celeſtial globe.

Having done for the preſent with the terreſtrial globe, we ſhall proceed to the uſe of the celeſtial; firſt premiſing, that as the equator, ecliptic, tropics, polar

Principles and Practice.

polar circles, horizon, and braſen meridian, are exactly alike on both globes, all the former problems concerning the ſun are ſolved the ſame way by both globes. The method alſo of rectifying the celeſtial globe is the ſame as rectifying the terreſtrial. *N. B.* The ſun's place for any day of the year ſtands directly over that day on the horizon of the celeſtial globe, as it does on that day of the terreſtrial.

80 Latitude and longitude of the ſtars.

The *latitude* and *longitude* of the ſtars, or of all other celeſtial phenomena, are reckoned in a very different manner from the latitude and longitude of places on the earth: for all terreſtrial latitudes are reckoned from the equator; and longitudes from the meridian of ſome remarkable place, as of London by the Britiſh, and of Paris by the French. But the aſtronomers of all nations agree in reckoning the latitudes of the moon, ſtars, planets, and comets, from the ecliptic; and their longitudes from the equinoctial colure, in that ſemicircle of it which cuts the ecliptic at the beginning of Aries; and thence eaſtward, quite round, to the ſame ſemicircle again. Conſequently thoſe ſtars which lie between the equinoctial and the northern half of the ecliptic, have north declination and ſouth latitude; thoſe which lie between the equinoctial and the ſouthern half of the ecliptic, have ſouth declination and north latitude; and all thoſe which lie between the tropics and poles, have their declinations and latitudes of the ſame denomination.

There are ſix great circles on the celeſtial globe, which cut the ecliptic perpendicularly, and meet in two oppoſite points in the polar circles; which points are each ninety degrees from the ecliptic, and are called its poles. Theſe polar points divide thoſe circles into 12 ſemicircles; which cut the ecliptic at the beginnings of the twelve ſigns. They reſemble ſo many meridians on the terreſtrial globe: and as all places which lie under any particular meridian-ſemicircle on that globe have the ſame longitude; ſo all thoſe points of the heaven, through which any of the above ſemicircles are drawn, have the ſame longitude.—And as the greateſt latitudes on the earth are at the north and ſouth poles of the earth, ſo the greateſt latitudes in the heaven are at the north and ſouth poles of the ecliptic.

For the diviſion of the ſtars into conſtellations, &c. ſee ASTRONOMY, n. 403, 406.

PROB. I. *To find the right aſcenſion and declination of the ſun, or any fixed ſtar*—Bring the ſun's place in the ecliptic to the braſen meridian: then that degree in the equinoctial which is cut by the meridian, is the ſun's *right aſcenſion*; and that degree of the meridian which is over the ſun's place, is his *declination*. Bring any fixed ſtar to the meridian, and its right aſcenſion will be cut by the meridian in the equinoctial; and the degree of the meridian that ſtands over it is its declination.

So that right aſcenſion and declination, on the celeſtial globe, are found in the ſame manner as longitude and latitude on the terreſtrial.

PROB. II. *To find the latitude and longitude of any ſtar.*—If the given ſtar be on the north ſide of the ecliptic, place the 90th degree of the quadrant of altitude on the north pole of the ecliptic, where the 12 ſemicircles meet, which divide the ecliptic into the 12 ſigns; but if the ſtar be on the ſouth ſide of the ecliptic, place the 90th degree of the quadrant on the ſouth pole of the ecliptic: keeping the 90th degree of the quadrant on the proper pole, turn the quadrant about, until its graduated edge cuts the ſtar: then the number of degrees in the quadrant, between the ecliptic and the ſtar, is its latitude; and the degree of the ecliptic, cut by the quadrant, is the ſtar's longitude, reckoned according to the ſign in which the quadrant then is.

Principles and Practice.

PROB. III. *To repreſent the face of the ſtarry firmament, as ſeen from any given place of the earth, at any hour of the night.*—Rectify the celeſtial globe for the given latitude, the zenith, and ſun's place in every reſpect, as taught by the XVIth problem for the terreſtrial; and turn it about, until the index points to the given hour: then the upper hemiſphere of the globe will repreſent the viſible half of the heaven for that time; all the ſtars upon the globe being then in ſuch ſituations, as exactly correſpond to thoſe in the heaven. And if the globe be placed duly north and ſouth, by means of a ſmall ſea-compaſs, every ſtar in the globe will point toward the like ſtar in the heaven: by which means, the conſtellations and remarkable ſtars may be eaſily known. All thoſe ſtars which are in the eaſtern ſide of the horizon, are then riſing in the eaſtern ſide of the heaven; all in the weſtern, are ſetting in the weſtern ſide; and all thoſe under the upper part of the braſen meridian, between the ſouth point of the horizon and the north pole, are at their greateſt altitude, if the latitude of the place be north; but if the latitude be ſouth, thoſe ſtars which lie under the upper part of the meridian, between the north point of the horizon and the ſouth pole, are at their greateſt altitude.

PROB. IV. *The latitude of the place, and day of the month, being given; to find the time when any known ſtar will riſe, or be upon the meridian, or ſet.*—Having rectified the globe, turn it about until the given ſtar comes to the eaſtern ſide of the horizon, and the index will ſhow the time of the ſtar's riſing; then turn the globe weſtward, and when the ſtar comes to the braſen meridian, the index will ſhow the time of the ſtar's coming to the meridian of your place; laſtly, turn on, until the ſtar comes to the weſtern ſide of the horizon, and the index will ſhow the time of the ſtar's ſetting. *N. B.* In northern latitudes, thoſe ſtars which are leſs diſtant from the north pole than the quantity of its elevation above the north point of the horizon, never ſet; and thoſe which are leſs diſtant from the ſouth pole than the number of degrees by which it is depreſſed below the horizon, never riſe: and *vice verſa* in ſouthern latitudes.

PROB V. *To find at what time of the year a given ſtar will be upon the meridian, at a given hour of the night.*—Bring the given ſtar to the upper ſemicircle of the braſs meridian, and ſet the index to the given hour; then turn the globe, until the index points to XII at noon, and the upper ſemicircle of the meridian will then cut the ſun's place, anſwering to the day of the year ſought; which day may be eaſily found againſt the like place of the ſun among the ſigns on the wooden horizon.

PROB. VI *The latitude, day of the month, and azimuth of any known ſtar being given; to find the hour of the night.*—Having rectified the globe for the latitude, zenith,

Principles and Practice

zenith, and sun's place, lay the quadrant of altitude to the given degree of azimuth in the horizon: then turn the globe on its axis, until the star comes to the graduated edge of the quadrant; and when it does, the index will point out the hour of the night.

Prob. VII. *The latitude of the place, the day of the month, and altitude of any known star, being given; to find the hour of the night.*—Rectify the globe as in the former problem, guess at the hour of the night, and turn the globe until the index points at the supposed hour: then lay the graduated edge of the quadrant of altitude over the known star; and if the degree of the star's height in the quadrant upon the globe answers exactly to the degree of the star's observed altitude in the heaven, you have guessed exactly: but if the star on the globe is higher or lower than it was observed to be in the heaven, turn the globe backwards or forwards, keeping the edge of the quadrant upon the star, until its centre comes to the observed altitude in the quadrant; and then the index will show the true time of the night.

Prob. VIII. *An easy method for finding the hour of the night by any two known stars, without knowing either their altitude or azimuth; and then of finding both their altitude and azimuth, and thereby the true meridian.*—Tie one end of a thread to a common musket bullet; and having rectified the globe as above, hold the other end of the thread in your hand, and carry it slowly round betwixt your eye and the starry heaven, until you find it cuts any two known stars at once. Then guessing at the hour of the night, turn the globe until the index points to that time in the hour circle; which done, lay the graduated edge of the quadrant over any one of these two stars on the globe which the thread cut in the heaven. If the said edge of the quadrant cuts the other star also, you have guessed the time exactly; but if it does not, turn the globe slowly backwards or forwards, until the quadrant (kept upon either star) cuts them both through their centres: and then the index will point out the exact time of the night; the degree of the horizon, cut by the quadrant, will be the true azimuth of both these stars from the south; and the stars themselves will cut their true altitudes in the quadrant. At which moment, if a common azimuth-compass be so set upon a floor or level pavement, that these stars in the heaven may have the same bearing upon it (allowing for the variation of the needle) as the quadrant of altitude has in the wooden horizon of the globe, a thread extended over the north and south points of that compass will be directly in the plane of the meridian: and if a line be drawn upon the floor or pavement, along the course of the thread, and an upright wire be placed in the southmost end of the line, the shadow of the wire will fall upon that line, when the sun is on the meridian, and shines upon the pavement.

Prob. IX. *To find the place of the moon, or of any planet; and thereby to show the time of its rising, southing, and setting*—See in Parker's or Weaver's ephemeris the geocentric place of the moon or planet in the ecliptic, for the given day of the month; and according to its longitude and latitude, as shown by the ephemeris, mark the same with a chalk upon the globe. Then, having rectified the globe, turn it round its axis westward; and as the said mark comes to the eastern side of the horizon, to the brasen meridian, and to the western side of the horizon, the index will show at what time the planet rises, comes to the meridian, and sets, in the same manner as it would do for a fixed star.

4. *Description of the Modern Improvements applied to Globes.*

81 Improvements on globes.

Globes mounted in the common manner, and with their hour circles fixed on the meridian, although instructive instruments for explaining the first principles of geography and the spherical doctrine of astronomy, yet contain several defects; as they prevent any elevation of the north and south poles near to their axes, or the brass meridian from being quite moveable round in the horizon. They do not show how all the phenomena illustrated by them arise from the motion of the earth; a matter of consequence to beginners: and they are only adapted to the present age; consequently do not serve accurately the purposes of chronology and history, which they might be made to do if the poles whereon they turn were contrived to move in a circle round those of the ecliptic, according to its present obliquity.

82 Mr Senex's contrivance.

The late Mr John Senex F. R. S. invented a contrivance for remedying these defects, by fixing the poles of the diurnal motion to two shoulders or arms of brass at the distance of $23\frac{1}{2}$ deg. from the poles of the ecliptic. These shoulders are strongly fastened at the other end to an iron axis, which passes through the poles of the ecliptic, and is made to move round with a very stiff motion; so that when it is adjusted to any point of the ecliptic which the equator is made to intersect, the diurnal motion of the globe on its axis will not disturb it. When it is to be adjusted for any time, past or future, one of the brasen shoulders is brought under the meridian, and held fast to it with one hand, whilst the globe is turned about with the other; so that the point of the ecliptic which the equator is to intersect may pass under the 0 degree of the brazen meridian; then holding a pencil to that point, and turning the globe about, it will describe the equator according to its position at the time required; and transferring the pencil to $23\frac{1}{2}$ and $66\frac{1}{2}$ degrees on the brasen meridian, the tropics and polar circles will be so described for the same time. By this contrivance, the celestial globe may be so adjusted, as to exhibit not only the rising and setting of the stars in all ages and in all latitudes, but likewise the other phenomena that depend upon the motion of the diurnal axis round the annual axis. Senex's celestial globes, especially the two greatest, of 17 and 28 inches in diameter, have been constructed upon this principle; so that by means of a nut and screw, the pole of the equator is made to revolve about the pole of the ecliptic. Phil. Trans. N° 447. p. 201, 203. or Martyn's Abr. Vol. VIII. p. 217. and N° 493. art. 18. in Phil. Trans. Vol. XLVI. p. 290.

83 Mr Martin's addition to Mr Senex's

To represent the above phenomena in the most natural and easy manner, the late Mr B. Martin applied to Mr Senex's contrivance a moveable, equinoctial, and

Principles and Practice

and ſolſtitial colure; a moveable equinoctial circle, and a moveable ecliptic; all ſo connected together as to repreſent thoſe imaginary circles in the heavens for any age of the world.

84 Mr Harris's improvement.

Mr Joſeph Harris, late aſſay-maſter of the mint, contrived to remedy the former of the defects above mentioned, by placing two horary circles under the meridian, one at each pole; theſe circles are fixed tight between two braſs rollers placed about the axis, ſo that when the globe is turned they are carried round with it, the meridian ſerving as an index to cut the horary divisions. The globe in this ſtate ſerves univerſally and readily for ſolving problems in north and ſouth latitudes, and alſo in places near the equator; whereas in the common conſtruction, the axis and horary circle prevent the braſs meridian from being moveable quite round in the horizon. This globe is alſo adapted for ſhowing how the viciſſitudes of day and night, and the alteration of their lengths, are really occaſioned by the motion of the earth: for this purpoſe, he divided the braſs meridian at one of the poles into months and days, according to the ſun's declination, reckoning from the pole. Therefore, by bringing the day of the month to the horizon, and rectifying the globe according to the time of the day, the horizon will repreſent the circle ſeparating light and darkneſs; and the upper half of the globe, the illuminated hemiſphere, the ſun being in the zenith. Phil. Tranſ. N° 456. p. 321. or Martyn's Abr. Vol. VIII. p. 352.

85 Mr Adam's additions

The late Mr George Adam, mathematical inſtrument maker, has made ſome additional improvements in the conſtruction of the globes. His globes, like others, are ſuſpended at their poles in a ſtrong braſs circle NZÆS (ſee fig. 2. repreſenting the celeſtial), and turn therein upon two iron pins, which form the axis. They have each a thin braſs ſemicircle NHS moveable about theſe poles, with a ſmall, thin, ſliding, circle H thereon; which ſemicircle is divided into two quadrants of 90 degrees each, from the equator to both the poles. On the terreſtrial globe this ſemicircle is a moveable meridian, and its ſmall ſliding circle, which is divided into a few points of the compaſs, is the viſible horizon of any particular place to which it is ſet. On the celeſtial globe this ſemicircle is a moveable circle of declination, and its ſmall annexed circle an artificial ſun or planet. Each globe has a braſs wire TWY placed at the limits of the crepuſculum or twilight; which, together with the globe, is mounted in a wooden frame, ſupported by a neat pillar and claw-feet, with a magnetic needle in a compaſs-box marked M in the figure. On the ſtrong braſs circle of the terreſtrial globe, and about 23½ degrees on each ſide of the north pole, the days of each month are laid down according to the ſun's declination; and this braſs circle is ſo contrived, that the globe may be placed with the north and ſouth poles in the plane of the horizon, and with the ſouth pole elevated above it. The equator on the ſurface of either globe ſerves the purpoſe of the horary circle, by means of a ſemicircular wire placed in the plane of the equator (ÆF), carrying two indices (F); one on the eaſt, the other on the weſt ſide of the ſtrong braſs circle; one of which is occaſionally to be uſed to point out the time upon the equator. In theſe globes, therefore, the indices being ſet to the particular time on the equator, the globes are turned round, and the indices point out the time by remaining fixed; whereas in the globes as generally mounted, the indices move over the horary circles while the globe is moving, and thus point out the change of time. For farther particulars of theſe globes, and the method of uſing them, Mr Adam's Treatiſe on their Conſtruction and Uſe, &c. 1772, may be conſulted.

Principles and Practice.

The additions and alterations above mentioned, made by Mr Adam, may ſave trouble to a practitioner in the performance of a few complex problems, and render the globes more elegant and coſtly; but to a young beginner, the more ſimple the conſtruction of the globes, the better will they be adapted to initiate him into the rationale and practice of the problems in general; and as ſuch, the globes, as improved by the late Mr B. Martin and Mr Wright, deſcribed below, appear to have conſiderably the advantage in ſimplicity, and to obviate ſeveral material defects that attend the conſtruction of the other globes. The chief of the defects in the old globes is, that the horary circle being ſcrewed on the meridian at the north pole, prevents the elevation of the ſouth pole; which is neceſſary for the performance of problems for all latitudes. In Mr Adam's, the ſemicircular wire ÆF preventing the equator being placed exactly in the horizon, or the poles in the zenith, the great diſtance of the ſtrong braſs circle NZÆS from the ſurface of the globe, on account of the braſs ſemicircles, renders the ſolution of problems, which require the uſe of the ſtrong circle, not very eaſy nor accurate.

Plate CCX.

86 Mr Martin's improvement

An eaſy and expeditious method of elevating the ſouth pole of the terreſtrial globe, and by which means the new diſcoveries, tracks, &c. made of late years by Captain Cook and other eminent navigators in the ſouth ſeas, may be clearly ſeen and traced by the eye over all the ſouthern ocean, was made uſe of by Mr B. Martin in the conſtruction of the following improvement.

There is a groove turned out on the back part of the braſs meridian A (fig. 1.); and by unſcrewing the nut of the hour circle D at the north pole, the circle is made to ſlide away to any other part of the meridian, as at G. The meridian is fixed or moveable at pleaſure by a ſcrew paſſing into the groove, through the piece or ſide of the notch in which it moves, on the bottom or nadir point: by properly looſening this ſcrew, the meridian is free to move, and the globe with it, into any required poſition; but at the ſame time, it is confined within the notch of the braſs-piece, and thereby the globe is prevented from falling out of the frame in any poſition thereof whatſoever. The hour-circle being removed, both the north and ſouth poles of the globe may be placed in the horizon, and thereby form a right ſphere, which the uſual mounting of the globes does not admit of.

Alſo by this conſtruction, the ſouth pole may be elevated for all latitudes: for this purpoſe there is an hour-circle about the ſouth pole between the meridian and the globe, which does not obſtruct the ſight of any land, none having been thereabouts diſcovered. Conſequently the globe is thus equally uſeful for the ſo-

Principles and Practice.

solution of all common geographical problems in the southern as in the northern hemisphere, and more extensively so than heretofore.

In this new method of mounting the globe, it may readily be converted into a *tellurian*; for as the globe cannot fall out of the frame, the horizon of the globe may be placed in a perpendicular position: then the sun's place in the ecliptic being brought to the meridian, and its declination found, the pole of the globe must be elevated to that declination; which may be done by means of the degrees cut on the outer edge of the meridian for that purpose. If a lighted candle be placed at a considerable distance, exactly the height of the centre of the globe, and in a line with the meridian, the globe will exhibit all the phenomena of our earth for that day; for in this case the horizon of the globe becomes the solar horizon, and divides the whole into the enlightened and dark hemispheres: therefore upon turning the globe about its axis from west to east, it will clearly appear that all places emerging out of the dark hemisphere into the luminous one, under the western part of the horizon, will see the sun then as rising; when they arrive at the meridian, it will be their noon; and when they descend into the dark hemisphere at the eastern part of the horizon, they will see the sun as setting.

When any place is under the meridian, set the hour-index to XII, and revolve the globe; then you will see the natural motion and position of that place at hours of the day; at what time the sun rises or sets to it; the length of the diurnal and nocturnal arches, or of day and night; at what places the sun does not rise and set at that time; and from whence the vicissitudes of the seasons throughout the year in all latitudes, &c. &c.

To give this experiment the best effect, the candle should be enclosed within a common dark lanthorn, and its light issue through a hole or lens made for that purpose.

On the outer part of the sliding hour-circle, at the north pole, are usually engraved the points of the compass; so that by bringing that circle centrally over any place on the globe, it will appear by inspection only upon what point of the compass any other place bears from it, and that all over the globe.

86 Wright's more simple improvement

This method of the sliding hour-circle is equally applicable to the celestial globe. Mr G. Wright of London has yet farther simplified the construction of the hour-circles, and it is thereby rather less operose than Mr Martin's above mentioned. It consists of the following particulars: There are engraved on the globes two hour-circles, one at each of the poles; which are divided into a double set of 12 hours, as usual in the common brass ones, except that the hours are figured round both to the right and left (see fig. 3.). The hour-hand or index (A) is placed in such a manner under the brass meridian, as to be moveable at pleasure to any required part of the hour-circle, and yet remain there fixed during the revolution of the globe on its axis and is entirely independent of the poles of the globe. In this manner the motion of the globe round its axis, carrying the hour-circle, the fixed index serves to point out the time, the same as in the reverse way by Mr Martin's or other globes.

There is a small advantage by having the hour circle figured both ways, as one hour serves as a complement to XII for the other, and the time of sun rising and setting, and *vice versa*, may be both seen at the same time on the hour circle. In the problems generally to be performed, the inner circle is the circle of reckoning, and the outer one only the complement. Fig. 4. is a representation of the globe, with Mr Wright's improved hour-circle at C.

Principles and Practice.

Mr William Jones, mathematical instrument maker, Holborn, who mounts globes according to the improvements above mentioned of Messrs Martin and Wright, applies a compass of a portable size to the east part of the wooden horizon circle of both globes (see F, fig. 1.), by a dove-tail slider on the lid of the compass-box; which method is found more convenient and ready in the performance of problems, than when fixed underneath the frame at their feet; and as it occasionally slides away from the globes, the compass becomes useful in other situations.

88 Mr Smeaton's improvements.

In order to the performance of the problems which relate to the altitudes and azimuths of celestial objects, Mr Smeaton, F. R. S. has made some improvements applicable to the celestial globe; and to give some idea of the construction, they may be described as follows: Instead of a thin flexible slip of brass, which generally accompanies the globes, called the *quadrant of altitude*, Mr Smeaton substitutes an arch of a circle of the same radius, breadth, and substance, as the brass meridian, divided into degrees, &c. similar to the divisions of that circle, and which, on account of its strength, is not liable to be bent out of the plane of a vertical circle, as usual with the common quadrant put to globes. That end of this circular arch at which the divisions begin, rests on the horizon, being filed off square to fit and rest steadily on it throughout its whole breadth; and the upper end of the arch is firmly attached, by means of an arm, to a vertical socket, in such a manner that when the lower end of the arch rests on the horizon, the lower end of this socket shall rest on the upper edge of the brass meridian, directly over the zenith of the globe. This socket is fitted to and ground with a steel-spindle of the same length, so that it will turn freely on it without shaking; and the steel-spindle has an apparatus attached to its lower end, by which it can be fastened in a vertical position to the brass meridian, with its centre directly over the zenith point of the globe. The spindle being fixed firmly in this position, and the socket which is attached to the circular arch put on to it, and so adjusted that the lower end of the arch just rests on and fits close to the horizon; it is evident that the altitude of any object above the horizon will be shown by the degree which it intersects on this arch, and its azimuth by that end of the arch which rests on the horizon.

Besides this improvement, Mr Smeaton directs to place the index which is usually fixed on one end of the axis to point out the hour, in such a manner that its upper surface may move in the plane of the hour-circle rather than above it, as it usually does. He files off the end of this index to a circular arch, of the same radius with the inner edge of the hour-circle, to which it is to fit very exactly; and a fine line is drawn on its upper surface to determine the time by, instead of the tapering point which is generally

Principles and Practice.

rally uſed. By theſe means half minutes may be diſtinguiſhed, if the hour circle be four inches in diameter. Mr Smeaton alſo deſcribes a contrivance for preventing the meridian from ſhifting after being rectified for the latitude of the place, and while the operator is engaged in adjuſting other parts of the apparatus. But as the purpoſe which this is intended to anſwer appears to be much better performed by the turned groove on the meridian in Mr Martin's contrivance deſcribed above, we ſhall omit the particular deſcription; and for farther explanations and figures of Mr Smeaton's improvements, refer the reader to the Phil. Tranſ. Vol. LXXIX, Part i.

For another improvement made to the celeſtial globe, by Mr Ferguſon, ſee ASTRONOMY, n° 493, and fig. 187 of plate LXXXI.

Moſt of the above problems may alſo be performed by means of accurate maps; but this requires a great deal of calculation, which is often very troubleſome. The Analemma, or Orthographic Projection, delineated on Plate CCXII. will ſolve many of the moſt curious; and with the aſſiſtance of the maps will be almoſt equivalent to a terreſtrial globe. The parallel lines drawn on this figure repreſent the degrees of the ſun's declination from the equator, whether north or ſouth, amounting to $23\frac{1}{2}$ nearly. On theſe lines are marked the months and days which correſpond to ſuch and ſuch declinations. The ſize of the figure does not admit of having every day of the year inſerted; but by making allowance for the intermediate days, in proportion to the reſt, the declination may be gueſſed at with tolerable exactneſs. The elliptical lines are deſigned to ſhow the hours of ſun-riſing or ſun-ſetting before or after ſix o'clock. As 60 minutes make an hour of time, a fourth part of the ſpace between each of the hour-lines will repreſent 15 minutes; which the eye can readily gueſs at, and which is as great exactneſs as can be expected from any mechanical invention, or as is neceſſary to anſwer any common purpoſe. The circles drawn round the centre at the diſtance of $11\frac{1}{4}$ each, ſhow the point of the compaſs on which the ſun riſes and ſets, and on what point the twilight begins and ends.

In order to make uſe of this analemma, it is only neceſſary to conſider, that, when the latitude of the place and the ſun's declination are both north or both ſouth, the ſun riſes before ſix o'clock, between the eaſt and the elevated pole; that is, towards the north, if the latitude and declination are north; or towards the ſouth, if the latitude and declination are ſouth. Let us now ſuppoſe it is required to find the time of the ſun's riſing and ſetting, the length of the days and nights, the time when the twilight begins and ends, and what point of the horizon the ſun riſes and ſets on, for the Lizard point in England, Franckfort in Germany, or Abbeville in France, on the 30th of April. The latitude of theſe places by the maps will be found nearly 50° north. Place the moveable index ſo that its point may touch 50° on the quadrant of north latitude in the figure; then obſerve where its edge cuts the parallel line on which April 30th is wrote. From this reckon the hour-lines towards the centre, and you will find that the parallel-line is cut by the index nearly at the diſtance of one hour and 15 minutes. So the ſun riſes at one hour 15 minutes before ſix, or 45 minutes after four in the morning, and ſets 15 minutes after ſeven in the evening. The length of the day is 14 hours 30 minutes. Obſerve how far the interſection of the edge of the index with the parallel of April 30th is diſtant from any of the concentric circles; which you will find to be a little beyond that marked two points of the compaſs; and this ſhows, that on the 30th of April the ſun riſes two points and ſomewhat more from the eaſt towards the north, or a little to the northward of E. N. E. and ſets a little to the northward of W. N. W. To find the beginning and ending of twilight, take from the graduated arch of the circle $17\frac{1}{2}$ degrees with a pair of compaſſes; move one foot of the compaſſes extended to this diſtance along the parallel for the 30th of April, till the other juſt touches the edge of the index, which muſt ſtill point at 50. The place where the other foot reſts on the parallel of April 30th, then denotes the number of hours before ſix at which the twilight begins. This is ſomewhat more than three hours and an half; which ſhows, that the twilight then begins ſoon after two in the morning, and likewiſe that it begins to appear near five points from the eaſt towards the north. The uſes of this analemma may be varied in a great number of ways; but the example juſt now given will be ſufficient for the ingenious reader.—The ſmall circles on the ſame plate, marked *Iſland*, *Promontory*, &c. are added in order to render the maps more intelligible, by ſhowing how the different ſubjects are commonly delineated on them.

HAVING thus explained the uſe of the globes, and general principles of geography, we muſt refer to the Maps for the ſituation of each particular country, with regard to longitude, latitude, &c. and to the names of the countries as they occur in the order of the alphabet, for the moſt remakable particulars concerning them.

GEOMANCY, GEOMANTIA, a kind of divination, performed by means of a number of little points, or dots, made on paper at random: and conſidering the various lines and figures, which thoſe points preſent; and thence forming a pretended judgment of futurity, and deciding any queſtion propoſed.

The word is formed of the Greek γη, *terra*, "earth;" and μαντια, "divination;" it being the ancient cuſtom to caſt little pebbles on the ground, and thence to form their conjectures; inſtead of the points afterwards made uſe of.

Polydore Virgil defines geomancy a kind of divination performed by means of clefts or chinks made in the ground; and takes the Perſian Magi to have been the inventors thereof.

GEOMETRY

ORIGINALLY ſignified no more than the art of meaſuring the earth, or any diſtances or dimenſions within it: but at preſent it denotes the ſcience of magnitude in general; comprehending the doctrine and relations of whatever is ſuſceptibe of augmentation or diminution, conſidered in that light.

Hence to geometry may be referred the conſideration not only of lines, ſurfaces, and ſolids; but alſo of time, velocity, number, weight, &c.

This ſcience had its riſe among the Egyptians, who were in a manner compelled to invent it, to remedy confuſion which generally happened in their lands, from the inundations of the river Nile, which carried away all boundaries, and effaced all the limits of their poſſeſſions. Thus this invention, which at firſt conſiſted only in meaſuring the lands, that every perſon might have what belonged to him, was called *geometry*, or the art of meaſuring land; and it is probable that the draughts and ſchemes, which they were annually compelled to make, helped them to diſcover many excellent properties of theſe figures; which ſpeculations continued to be gradually improved, and are ſo to this day.

From Egypt geometry paſſed into Greece; where it continued to receive new improvements in the hands of Thales, Pythagoras, Archimedes, Euclid, &c. The Elements of Geometry, written by this laſt in 15 books, are a moſt convincing proof to what perfection this ſcience was carried among the ancients. However, it muſt be acknowledged, that it fell ſhort of modern geometry; the bounds of which, what by the invention of fluxions, and the diſcovery of the almoſt infinite orders of curves, are greatly enlarged.

We may diſtinguiſh the progreſs of geometry into three ages; the firſt of which was in its meridian glory at the time when Euclid's Elements appeared; the ſecond, beginning with Archimedes, reaches to the time of Des Cartes, who, by applying algebra to the elements of geometry, gave a new turn to this ſcience, which has been carried to its utmoſt perfection by Sir Iſaac Newton and Mr Leibnitz.

In treating this uſeful ſubject, we ſhall divide it into two parts; the firſt containing the general principles; and the ſecond, the application of theſe principles to the menſuration of ſurfaces, ſolids, &c.

PART I. GENERAL PRINCIPLES OF GEOMETRY.

Art. 1. A POINT is that which is not made up of parts, or which is of itſelf indiviſible.

2. A line is a length without breadth, as B——

3. The extremities of a line are points; as the extremities of the line AB, are the points A and B, fig. 1.

4. If the line AB be the neareſt diſtance between its extremes A and B, then it is called a *ſtraight line*, as AB; but if it be not the neareſt diſtance, then it is called a *curve line*, as *a b*, fig. 1.

5. A ſurface is that which is conſidered as having only length and breadth, but no thickneſs, as fig. 2.

6. The terms or boundaries of a ſurface are lines.

7. A plain ſurface is that which lies equally between its extremes.

8. The inclination between two lines meeting one another (provided they do not make one continued line), or the opening between them, is called an *angle*; thus the inclination of the line AB to the line CB (fig. 3.) meeting one another at B, or the opening between the two lines AB and CB, is called an *angle*.

9. When the lines forming the angle are right lines, then it is called a *right-lined angle*, as fig. 4; if one of them be right and the other curved, it is called a *mixed angle*, as fig. 5; if both of them be curved, it is called a *curve-lined angle*, as fig. 6.

10. If a right line AB fall upon another DC, (fig 7.) ſo as to incline neither to one ſide nor to the other, but make the angles ABD, ABC, on each ſide equal to one another; then the line AB is ſaid to be *perpendicular* to the line DC, and the two angles are called *right-angles*.

11. An obtuſe angle is that which is greater than a right one, as fig. 8.; and an acute angle, that which is leſs than a right one, as fig. 9.

12. If a right line DC be faſtened at one of its ends C, and the other end D be carried quite round, then the ſpace comprehended is called a *circle*; the curve-line deſcribed by the point D, is called the *periphery* or *circumference* of the circle; the fixed point C is called the *centre* of it; fig. 10.

13. The deſcribing line CD is called the *radius*, viz. any line drawn from the centre to the circumference; whence all radii of the ſame or equal circles are equal.

14. Any line drawn through the centre, and terminated both ways by the circumference, is called a *diameter*, as BD is a diameter of the circle BADE. And the diameter divides the circle and circumference into two equal parts, and is double the radius.

15. The circumference of every circle is ſuppoſed to be divided into 360 equal parts, called *degrees*; and each degree is divided into 60 equal parts, called *minutes*; and each minute into 60 equal parts, called *ſeconds*; and theſe into *thirds*, *fourths*, &c. theſe parts being greater or leſs according as the radius is.

16. Any part of the circumference is called an *arch*, or *arc*; and is called an arc of as many degrees as it contains parts of the 360, into which the circumference was divided: thus if AD be the $\frac{1}{8}$ of the circumference, then the arc AD is an arc of 45 degrees.

17. A line drawn from one end of an arc to the other, is called a *chord*, and is the meaſure of the arc: thus the right line AB is the chord of the arc ADB, fig. 11.

18. Any

General Principles

18. Any part of a circle cut off by a circle, is called a *segment*; thus the ſpace comprehended between the chord AB and circumference ADB (which is cut off by the chord AB) is called a *segment*. Whence it is plain,

1*ſt*, That all chords divide the circle into two ſegments.

2*dly*, The leſs the chord is, the more unequal are the ſegments, and *e contra*.

3*dly*, When the chord is greateſt, viz. when it is a diameter, then the ſegments are equal, viz. each a ſemicircle.

19. Any part of a circle (leſs than a ſemicircle) contained between two radii and an arc, is called a *ſector*; thus the ſpace contained between the two radii, AC, BC, and the arc AB, is called the *ſector*, fig. 12.

20. The right ſine of any arc, is a line drawn perpendicular from one end of the arc, to a diameter drawn through the other end of the ſame arc; thus (fig. 13.) AD is the right ſine of the arc AB, it being a line drawn from A, the one end of the arc AB, perpendicular to CB, a diameter paſſing through B, the other end of the arc AB.

Now the lines ſtanding on the ſame diameter, ſtill increaſe till they come to the centre, and then becoming the radius, it is plain that the radius EC is the greateſt poſſible ſine, and for that reaſon it is called the *whole ſine*.

Since the whole ſine EC muſt be perpendicular to the diameter FB (by def. 20), therefore producing the diameter EG, the two diameters FB, EG, muſt croſs one another at right angles, and ſo the circumference of the circle muſt be divided by them into four parts, EB, BG, GF, and FE, and theſe four parts are equal to one another (by def. 10) and ſo EB a quadrant, or fourth part of the circumference: therefore the radius EC is always the ſine of the quadrant, or fourth part of the circle EB.

Sines are ſaid to be of ſo many degrees, as the arc contains parts of the 360, into which the circumference is ſuppoſed to be divided; ſo the radius being the ſine of a quadrant, or fourth part of the circumference, which contains 90 degrees (the fourth part of 360), therefore the radius muſt be the ſine of 90 degrees.

21. The part of the radius comprehended between the extremity of the right ſine and the lower end of the arc, viz. DB, is called the verſed ſine of the arc AB.

22. If to any point in the circumference, viz. B, there be drawn a diameter FCB, and from the point B, perpendicular to that diameter, there be drawn the line BH; that line is called a *tangent* to the circle in the point B; which tangent can touch the circle only in one point B, elſe if it touched it in more, it would go within it, and ſo not be a tangent but a chord, (by art 17.)

23. The tangent of any arc AB, is a right line drawn perpendicular to a diameter through the one end of the arc B, and terminated by a line CAH, drawn from the centre through the other end A; thus BH is the tangent of the arc AB.

24. And the line which terminates the tangent, viz. CH, is called the ſecant of the arc AB.

25. What an arc wants of a quadrant is called the *complement* of that arc; thus AE, being what the arc AB wants of the quadrant EB, is called the complement of the arc AB.

26. And what an arc wants of a ſemicircle is called the *ſupplement* of that arc; thus ſince AF is what the arc AB wants of the ſemicircle BAF, it is the ſupplement of the arc AB.

27. The ſine, tangent, &c. of the complement of any arc, is called the *co-ſine*, *co-tangent*, &c. of that arc; thus the ſine, tangent, &c. of the arc AE, is called the co-ſine, co-tangent, &c. of the arc AB.

28. The ſine of the ſupplement of an arc is the ſame with the ſine of the arc itſelf; for drawing them according to the definitions, there reſults the ſelf-ſame line.

29. A right lined angle is meaſured by an arc of a circle deſcribed upon the angular point as a centre, comprehended between the two legs that form the angle; thus (fig. 14.) the angle ABD is meaſured by the arc AD of the circle CADE that is deſcribed upon the point B as a centre; and the angle is ſaid to be of as many degrees as the arc is; ſo if the arc AD be 45 degrees, then the angle ABD is ſaid to be an angle of 45 degrees.

Hence the angles are greater or leſs, according as the arc deſcribed about the angular point, and terminated by the two legs, contain a greater or a leſs number of degrees.

30. When one line falls perpendicularly on another, as AB on CD, fig. 15. then the angles are right (by the 10th def.); and deſcribing a circle on the centre B, ſince the angles ABC ABD are equal, their meaſures muſt be ſo too. *i. e.* the arcs AC AD muſt be equal; but the whole CAD is a ſemicircle, ſince CD, a line paſſing through the centre B, is a diameter; therefore each of the parts AC AD is a quadrant, *i. e.* 90 degrees; ſo the meaſure of a right angle is always 90 degrees.

31. If one line AB fall any way upon another, CD, then the ſum of the two angles ABC ABD is always equal to the ſum of two right angles; fig. 16. For on the point B, deſcribing the circle CAD, it is plain, that CAD is a ſemicircle (by the 14th); but CAD is equal to CA and AD the meaſure of the two angles; therefore the ſum of the two angles is equal to a ſemicircle, that is, to two right angles. (by the laſt)

Cor. 1. From whence it is plain, that all the angles which can be made from a point in any line, towards one ſide of the line, are equal to two right angles.

2. And that all the angles which can be made about a point, are equal to four right ones.

32. If one line AC croſs another BD in the point E, then the oppoſite angles are equal, viz. BEA to CED, and BEC equal to AED; fig. 17. For upon the point E, as a centre, deſcribing the circle ABCD, it is plain ABC is a ſemicircle, as alſo BCD (by the 14th); therefore the arc ABC is equal to the arc BCE; and from both taking the common arc BC, there will remain AB equal to CD, *i. e.* the angle BEA equal to the angle CED (by art. 29.) After the ſame manner we may prove, that the angle BEC is equal to the angle AED.

33. Lines which are equally diſtant from one another, are called *parallel lines*; as AB, CD, fig. 18.

34. If

General Principles.

34. If a line GH croſs two parallels AB, CD, (fig. 19.) then the external oppoſite angles are equal, viz. GEB equal to CFH, and AEG equal to HFD. For ſince AB and CD are parallel to one another, they may be conſidered as one broad line, and GH croſsing it; then the vertical or oppoſite angles GEB CFH are equal (by art. 32.), as alſo AEG and HFD by the ſame.

35. If a line GH croſs two parallels AB, CD, then the alternate angles, viz. AEF and EFD, or CFE and FEB, are equal; that is, the angle AEF is equal to the angle EFD, and the angle CFE is equal to the angle FEB, for GEB is equal to AEF (by art. 32.), and CFH is equal to EFD (by the ſame); but GEB is equal to CFH (by the laſt); therefore AEF is equal to EFD. The ſame way we may prove FEB equal to EFC.

36. If a line GH croſs two parallel lines AB, CD, then the external angle GEB is equal to the internal oppoſite one EFD, or GEA equal to CFE. For the angle AEF is equal to the angle EFD (by the laſt); but AEF is equal to GEB (by art. 32.), therefore GEB is equal to EFD. The ſame way we may prove AEG equal to CFE.

37. If a line GH croſs two parallel lines AB, CD, then the ſum of the two internal angles, *viz.* BEF and DFE, or AEF and CFE, are equal to two right angles; for ſince the angle GEB is equal to the angle EFD (by art. 36.), to both add the angle FEB, then GEB and BEF are equal to BEF and DFE; but GEB and BEF are equal to two right angles (by art. 31.), therefore BEF and DFE are alſo equal to two right angles. The ſame way we may prove that AEF and CFE are equal to two right angles.

38. A figure is any part of ſpace bounded by lines or a line. If the bounding lines be ſtraight, it is called a *rectilineal figure*, as fig. 20. if they be curved, it is called a *curvilineal figure*, as fig. 21. and fig. 22.; if they be partly curve lines and partly ſtraight, it is called a *mixt figure*, as fig. 23.

39. The moſt ſimple rectilinear figure is that which is bounded by three right lines, and is called a *triangle*, as fig. 24.

40. Triangles are divided into different kinds, both with reſpect to their ſides and angles: with reſpect to their ſides, they are commonly divided into three kinds, *viz.*

41. A triangle having all its three ſides equal to one another, is called an *equilateral triangle*, as fig. 25.

42. A triangle having two of its ſides equal to one another, and the third ſide not equal to either of them, is called an *Iſoſceles triangle*, as fig. 26.

43. A triangle having none of its ſides equal to one another, is called a *ſcalene triangle*, as fig. 27.

44. Triangles, with reſpect to their angles, are divided into three different kinds, *viz.*

45. A triangle having one of its angles right, is called a *right-angled triangle*, as fig. 28.

46. A triangle having one of its angles obtuſe, or greater than a right angle, is called an *obtuſe-angled triangle*, as fig. 29.

47. Laſtly, a triangle having all its angles acute, is called an *acute-angled-triangle*, as fig. 30.

48. In all right-angled triangles, the ſides comprehending the right angle are called the *legs*, and the ſide oppoſite to the right angle is called the *hypothenuſe*. Thus in the right-angled triangle ABC, fig. 31. (the right angle being at B), the two ſides AB and BC, which comprehended the right angle ABC, are the legs of the triangle; and the ſide AC, which is oppoſite to the right angle ABC, is the hypothenuſe of the right-angled triangle ABC.

General Principles.

49. Both obtuſe and acute angled triangles are in general called *oblique-angled triangles*; in all which any ſide is called the *baſe*, and the other two the *ſides*.

50. The perpendicular height of any triangle is a line drawn from the vertex to the baſe perpendicularly; thus if the triangle ABC (fig. 32.) be propoſed, and BC be made its baſe, then A will be the vertex, *viz.* the angle oppoſite to the baſe; and if from A you draw the line AD perpendicular to BC, then the line AD is the height of the triangle ABC ſtanding on BC as its baſe.

Hence all triangles ſtanding between the ſame parallels have the ſame height, ſince all the perpendiculars are equal by the nature of parallels.

51. A figure bounded by four ſides is called a *quadrilateral* or *quadrangular figure*, as ABDC, fig. 33.

52. Quadrilateral figures, whoſe oppoſite ſides are parallel, are called *parallelograms*. Thus in the quadrilateral figure ABDC, if the ſide AC be parallel to the ſide BD which is oppoſite to it, and AB be parallel to CD, then the figure ABDC is called a *parallelogram*.

53. A parallelogram having all its ſides equal and angles right, is called a *ſquare*, as fig. 34.

54. That which hath only the oppoſite ſides equal and its angles right, is called a *rectangle*, as fig. 35.

55. That which hath equal ſides, but oblique angles, is called a *rhombus*, as fig. 36. and is juſt an inclined ſquare.

56. That which hath only the oppoſite ſides equal and the angles oblique, is called a *rhomboides*, as fig. 37. and may be conceived as an inclined rectangle.

57. When none of the ſides are parallel to another, then the quadrilateral figure is called a *trapezium*.

58. Every other right lined figure, that has more ſides than four, is in general called a *polygon*. And figures are called by particular names according to the number of their ſides, *viz.* one of five ſides is called a *pentagon*, of ſix a *hexagon*, of ſeven a *heptagon*, and ſo on. When the ſides forming the polygon are equal to one another, the figure is called a regular figure or polygon.

59. *In any triangle* ABC (fig. 38.) *one of its legs, as* BC, *being produced towards* D, *the external angle* ACD *is equal to both the internal oppoſite ones taken together, viz. to* ABC *and* BAC. In order to prove this, through C, draw CE parallel to AB; then ſince CE is parallel to AB, and the lines AC and BD croſs them, the angle ECD is equal to ABC (by art. 36.) and the angle ACE equal to CAB (by art 35.); therefore the angles ECD and ECA are equal to the angles ABC and CAB; but the angles ECD and ECA are together equal to the angle ACD; therefore the angle ACD is equal to both the angles ABC and CAB taken together.

Cor. Hence it may be proved, that if two lines AB

General Principles.

and CD (fig. 39.) be croſſed by a third line EF, and the alternate angles AEF and EFD be equal, the lines AB and CD will be parallel; for if they are not parallel, they muſt meet one another on one ſide of the line EF (ſuppoſe at G), and ſo form the triangle EFG, one of whoſe ſides GE being produced at A, the exterior angle AEF muſt (by this article) be equal to the ſum of the two angles EFG and EGF; but, by ſuppoſition, it is equal to the angles EFG alone; therefore the angle AEF muſt be equal to the ſum of the two angles EFG and EGF, and at the ſame time equal to the angle EFG alone, which is abſurd; ſo the lines AB and CD cannot meet, and therefore muſt be parallel.

60. *In any triangle* ABC, *all the three angles taken together are equal to two right angles.* To prove this, you muſt produce BC, one of its legs, to any diſtance, ſuppoſe to D; then by the laſt propoſition, the external angle, ACD, is equal to the ſum of the two internal oppoſite ones CAB and ABC; to both add the angle ACB, then the ſum of the angles ACD and ACB will be equal to the ſum of the angles CAB and CBA and ACB. But the ſum of the angles ACD and ACB is equal to two right ones (by art. 32.), therefore the ſum of the three angles CAB and CBA and ACB, is equal to two right angles; that is, the ſum of the three angles of any triangle ACB is equal to two right angles.

Cor. 1. Hence in any triangle given, if one of its angles be known, the ſum of the other two is alſo known: for ſince (by the laſt) the ſum of all the three is equal to two right angles, or a ſemicircle, it is plain, that taking any one of them from a ſemicircle or 180 degrees, the remainder will be the ſum of the other two. Thus (in the former triangle ABC) if the angle ABC be 40 degrees, by taking 40 from 180 we have 140 degrees; which is the ſum of the two angles BAC, ACB: the converſe of this is alſo plain, *viz.* the ſum of any two angles of a triangle being given, the other angle is alſo known by taking that ſum from 180 degrees.

2. In any right-angled triangle, the two acute angles muſt juſt make up a right one between them; conſequently, any one of the oblique angles being given, we may find the other by ſubtracting the given one from 90 degrees, which is the ſum of both.

61. If in any two triangles, ABC (fig. 40.) DEF (fig. 41.) two legs of the one, *viz.* AB and AC, be equal to two legs of the other, *viz.* to DE and DF, each to each reſpectively, *i. e.* AB to DE and AC to DF; and if the angles included between the equal legs be equal, *viz.* the angle BAC equal to the angle EDF; then the remaining leg of the one ſhall be equal to the remaining leg of the other, *viz.* BC to EF; and the angles oppoſite to equal legs ſhall be equal, *viz* ABC equal to DEF (being oppoſite to the equal legs AC and DF), alſo ACB equal to DFE (which are oppoſite to the equal legs AB and DE). For if the triangle ABC be ſuppoſed to be lifted up and put upon the triangle DEF, and the point A on the point D; it is plain, ſince BA and DE are of equal length, the point E will fall upon the point B; and ſince the angles BAC EDF are equal, the line AC will fall upon the line DF; and they being of equal length, the point C will fall upon the point F; and ſo the line BC will exactly agree with the line EF, and the triangle ABC will in all reſpects be exactly equal to the triangle DEF; and the angle ABC will be equal to the angle DEF, alſo the angle ACB will be equal to the angle DFE.

General Principles.

Cor. 1. After the ſame manner it may be proved, that if in any two triangles ABC, DEF (ſee the preceding figure), two angles ABC and ACB of the one, be equal to two angles DEF and DFE of the other, each to each reſpectively, *viz.* the angle ABC to the angle DEF, and the angle ACB equal to the angle DFE, and the ſides included between theſe angles be alſo equal, *viz.* BC equal to EF, then the remaining angles, and the ſides oppoſite to the equal angles, will alſo be equal each to each reſpectively; *viz.* the angle BAC equal to the angle EDF, the ſide AB equal to DE, and AC equal to DF: for if the triangle ABC be ſuppoſed to be lifted up and laid upon the triangle DEF, the point B being put upon the point E, and the line BC upon the line EF, ſince BC and EF are of equal lengths, the point C will fall upon the point F, and ſince the angle ACB is equal to the angle DFE, the line CA will fall upon the line FD, and by the ſame way of reaſoning the line BA will fall upon the line ED; and therefore the point of interſection of the two lines BA and CA, *viz.* A, will fall upon the point of interſection of the two lines ED and FD, *viz.* D, and conſequently BA will be equal to ED, and AC equal to DF, and the angle BAC equal to the angle EDF.

Cor. 2. It follows likewiſe from this article, that if any triangle ABC (fig. 42.) has two of its ſides AB and AC equal to one another, the angles oppoſite to theſe ſides will alſo be equal, *viz.* the angles ABC equal to the angle ACB. For ſuppoſe the line AD biſecting the angle BAC, or dividing it into two equal angles BAD and CAD, and meeting BC in D, then the line AD will divide the whole triangle BAC into two triangles ABD and DAC; in which BA and AD two ſides of the one, are equal to CA and AD two ſides of the other, each to each reſpectively, and the included angles BAD and DAC are by ſuppoſition equal; therefore (by this article) the angle ABC muſt be equal to the angle ACB.

62. *Any angle, as* BAD (fig. 43.) *at the circumference of a circle* BADE, *is but half the angle* BCD *at the centre ſtanding on the ſame arch* BED. To demonſtrate this, draw through A and the centre C the right line ACE, then the angle ECD is equal to both the angles DAC and ADC (by art. 59.); but ſince AC and CD are equal (being two radii of the ſame circle), the angles ſubtended by them muſt be equal alſo (by *art.* 62. *cor.* 2.), *i. e.* the angle CAD equal to the angle CDA; therefore the ſum of them is double any one of them, *i. e.* DAC and ADC is double of CAD, and therefore ECD is alſo double of DAC: the ſame way it may be proved, that ECB is double of CAB; and therefore the angle BCD is double of the angle BAD, or BAD the half of BCD, which was to be proved.

Cor. 1. Hence an angle at the circumference is meaſured by half the arc it ſubtends; for the angle at the centre (ſtanding on the ſame arc) is meaſured by the whole arc (by art. 29.); but ſince the angle at the centre is double that at the circumference, it is plain the

angle

General Principles.

angle at the circumference must be measured by only half the arc it stands upon.

Cor. 2. Hence all angles, ACB, ADB, AEB, &c. (fig. 44.) at the circumference of a circle, standing on the same chord AB, are equal to one another; for by the last corollary they are all measured by the same arc, *viz.* half the AB which each of them subtends.

Cor. 3. Hence an angle in a segment greater than a semicircle is less than a right angle: thus, if ADB be a segment greater than a semicircle (see the last figure), then the arc AB, on which it stands, must be less than a semicircle, and the half of it less than a quadrant or a right angle; but the angle ADB in the segment is measured by the half of AB, therefore it is less than a right angle.

Cor. 4. An angle in a semicircle is a right angle. For since ABD (fig. 46.) is a semicircle, the arc AED must also be a semicircle: but the angle ABD is measured by half the arc AED, that is, by half a semicircle or quadrant; therefore the angle ABD is a right one.

Cor. 5. Hence an angle in a segment less than a semicircle, as ABD (fig. 45.), is greater than a right angle: for since the arc ABD is less than a semicircle, the arc AED must be greater than a semicircle, and so it is half greater than a quadrant, *i. e.* than the measure of a right angle; therefore the angle ABD, which is measured by half the arc AED, is greater than a right angle.

63. *If from the centre* C *of the circle* ABE (fig. 47.) *there be let fall the perpendicular* CD *on the chord* AB, *then that perpendicular will bisect the chord* AB *in the point* D. To demonstrate this, draw from the centre to the extremities of the chord the two lines CA, CB; then, since the lines CA and CB are equal, the angles CAB, CBA, which they subtend, must be equal also (by *art.* 62 *cor.* 2.), but the perpendicular CD divides the triangle ACB into two right angled triangles ACD and CDB, in which the sum of the angles ACD and CAD in the one is equal to the sum of the angles DCB and CDB in the other, each being equal to a right angle (by *cor.* 2. of *art.* 61.) but CAD is equal to CBD, therefore ACD is equal to BCD. So in the two triangles ACD and BCD, the two legs AC and CD in the one, are equal to the two legs BC and CD in the other, each to each respectively, and the included angles ACD and BCD are equal; therefore the remaining legs AD and BD are equal (by art. 61.), and consequently AB bisected in D.

64. If from the centre C of a circle ABE, there be drawn a perpendicular CD on the chord AB, and produced still it meet the circle in F, then the line CF bisects the arch AB in the point F; for (see the foregoing figure) joining the points A and F, F and B by the straight lines AF, FB, then in the triangles ADF, BDF, AD is equal to DB (by art. 63), and DF common to both; therefore AD and DF, two legs of the triangle ADF, are equal to BD and DF, two legs of the triangle BDF, and the included angles ADF BDF are equal, being both right; therefore (by art. 61.) the remaining legs AF and FB are equal; but in the same circle equal lines are chords of equal arches, therefore the arches AF and FB are equal. So the whole arch AFB is bisected in the point F by the line CF.

Cor. 1. From art. 63. it follows, that any line bisecting a chord at right angles is a diameter; for since (by art. 63.) a line drawn from the centre perpendicular to a chord, bisects that chord at right angles; therefore, conversely, a line bisecting a chord at right angles, must pass through the centre, and consequently be a diameter.

Cor. 2. From the two last articles it follows, that the sine of any arc is the half of the chord of twice the arc; for (see the foregoing scheme) AD is the sine of the arc AF, by the definition of a sine, and AF is half the arc AFB, and AD half the chord AB (by art. 63.); therefore the *corollary* is plain.

65. In any triangle, the half of each side is the sine of the opposite angle; for if a circle be supposed to be drawn through the three angular points A, B, and D of the triangle ABD, fig. 48. then the angle DAB is measured by half the arch BKD (by *cor.* 1. of *art* 62.), but the half of BD, *viz.* BE, is the sine of half the arch BKD, *viz.* the sine of BK (by *cor.* 2. of the last), which is the measure of the angle BAD; therefore the half of BD is the sine of the angle BAD: the same way, it may be proved, that the half of AD is the sine of the angle ABD, and the half of AB is the sine of the angle ADB.

66. The sine, tangent, &c. of any arch is called also the *sine*, *tangent*, &c. of the angle whose measure the arc is: thus, because the arc GD (fig. 49.) is the measure of the angle GCD; and since GH is the sine, DE the tangent, HD the versed sine, CE the secant, also GK the co-sine, BF the co-tangent, and CF the co-secant, &c. of the arch GD; then GH is called the *sine*, DL the *tangent*, &c. of the angle GCD, whose measure is the arch GD.

67. *If two equal and parallel lines*, AB *and* CD (fig. 50.) *be joined by two others*, AC *and* BD; *then these shall also be equal and parallel.* To demonstrate this, join the two opposite angles A and D with the line AD; then it is plain this line AD divides the quadrilateral, ACDB, into two triangles, *viz.* ABD, ACD, in which AB a leg of the one, is equal to DC a leg of the other, by supposition, and AD is common to both triangles; and since AB is parallel to CD, the angle BAD will be equal to the angle ADC (by art. 36.); therefore in the two triangles BA and AD, and the angle BAD, is equal to CD and DA, and the angle ADC; that is, two legs and the included angle in the one is equal to two legs and the included angle in the other; therefore (by art. 61.) BD is equal to AC, and since the angle DAC is equal to the angle ADB, therefore the lines BD AC are parallel (by *cor. art.* 59)

Cor. 1. Hence it is plain, that the quadrilateral ABDC is a parallelogram, since the opposite sides are parallel.

Cor. 2. In any parallelogram the line joining the opposite angles (called the *diagonal*) as AD, divides the figure into two equal parts, since it has been proved that the triangles ABD ACD are equal to one another.

Cor. 3 It follows also, that a triangle ACD on the same base CD, and between the same parallels with a parallelogram ABDC, is the half of that parallelogram.

Cor. 4. Hence it is plain, that the opposite sides of a

General Principles.

parallelogram are equal; for it has been proved, that ABDC being a parallelogram, AB will be equal to CD, and AC equal to BD.

68. All parallelograms on the same or equal bases, and between the same parallels, are equal to one another: that is, if BD and GH (fig. 51.) be equal, and the lines BH and AF be parallel, then the parallelograms ABDC, BDFE, and EFHG, are equal to one another. For AC is equal to EF, each being equal to BD (by *cor.* 4. of 67.) To both add CE, then AE will be equal to CF. So in the two triangles ABE CDF, AB a leg of the one, is equal to CD a leg in the other; and AE is equal to CF, and the angle BAE is equal to the angle DCF (by art. 36.); therefore the two triangles ABE CDF are equal (by art. 61.); and taking the triangle CKE from both, the figure ABKC will be equal to the figure KDFE; to both which add the little triangle KBD, then the parallelogram ABDC will be equal to the parallelogram BDFE. The same way it may be proved, that the parallelogram EFHG is equal to the parallelogram EFDB; so the three parallelograms ABDC, BDFE, and EFHG, will be equal to one another.

Cor. Hence it is plain, that triangles on the same base, and between the same parallels, are equal; since they are the half of the parallelograms on the same base and between the same parallels (by *cor.* 3. of last *art.*)

69. *In any right-angled triangle*, ABC, (fig. 52.) *the square of the hypothenuse* BC, *viz.* BCMH, *is equal to the sum of the squares made on the two sides* AB *and* AC, viz. *to* ABDE *and* ACGF. To demonstrate this, through the point A draw AKL perpendicular to the hypothenuse BC, join AH, AM, DC, and BG; then it is plain that DB is equal to BA (by art. 53.), also BH is equal to BC (by the same); so in the two triangles DBC ABH, the two legs DB and BC in the one are equal to the two legs AB and BH in the other; and the included angles DBC and ABH are also equal; (for DBA is equal to CBH, being both right; to each add ABC, then it is plain that DBC is equal to ABH) therefore the triangles DBC ABH are equal (by art. 61.), but the triangle DBC is half of the square ADBE (by *cor.* 3. of 67.), and the triangle ABH is half the parallelogram BKLH (by the same), therefore half the square ABDE is equal to half the parallelogram BKLH. Consequently the square ABDE is equal to the parallelogram BKLH. The same way it may be proved, that the square ACGF is equal to the parallelogram KCML. So the sum of the squares ABDE and ACGF is equal to the sum of the parallelograms BKLH and KCML, but the sum of these parallelograms is equal to the square BCMH; therefore the sum of the squares on AB and AC is equal to the square on BC.

Cor. 1. Hence in a right-angled triangle, the hypothenuse and one of the legs being given, we may easily find the other, by taking the square of the given leg from the square of the hypothenuse, and the square root of the remainder will be the leg required.

Cor. 2. Hence the legs in a right-angled triangle being given, we may find the hypothenuse, by taking the sum of the squares of the given legs, and extracting the square root of that sum.

70. If upon the line AB (fig. 53.) there be drawn a semicircle ADB, whose centre is C, and on the point C there be raised a perpendicular to the line AB, *viz.* CD; then it is plain the arc DB is a quadrant, or contains 90 degrees; suppose the arc DB to be divided into 9 equal arcs, each of which will contain 10 degrees, then on the point B raising BE perpendicular to the line AB, it will be a tangent to the circle in quadrant, *viz.* B 10, B 20, B 30, B 40, *&c.* you draw the line, tangent, *&c.* (as in the scheme) we shall have the line, tangent, *&c.* to every 10 degrees in the quadrant: and the same way we may have the line, tangent, *&c.* to every single degree in the quadrant, by dividing it into 90 equal parts beginning from B, and drawing the line, tangent, *&c.* to all the arcs beginning at the same point B. By this method they draw the lines of lines, tangents, *&c.* of a certain circle on the scale; for after drawing them on the circle, they take the length of them, and set them off in the lines drawn for that purpose. The same way, by supposing the radius of any number of equal parts, (suppose 1000, or 10,000, *&c.*) it is plain the line, tangent, *&c.* of every arc must consist of some number of these equal parts, and by computing them in parts of the radius, we have tables of lines, tangents, *&c.* to every arc in the quadrant, called *natural lines*, *tangents*, &c. and the logarithms of these give us tables of logarithmic lines, tangents, *&c.* See LOGARITHMS.

71. In any triangle, ABC, (fig. 1.) if one of its sides, as AC, be bisected in E (and consequently AC double of AE), and through E be drawn ED, parallel to BC, and meeting AB in D, then BC will be double of ED, and AB double of AD. Through D draw DF, parallel to AC, meeting BC in F: for since, by construction, DF is parallel to AC, and DE parallel to BC; therefore (by art. 36.) the angle BFD will be equal to the angle BCA, and (by the same article) the angle BCA will be equal to the angle DEA, consequently the angle BFD will be equal to the angle DEA; also (by art. 36.) the angle BDF will be equal to the angle DAE: and since DF is parallel to EC, and DE parallel to FC, the quadrilateral DFCE will be a parallelogram; and therefore (by art. 59. cor. 4.) DF will be equal to EC, which, by construction, is equal to AE; so in the two triangles BDF DAE, the two angles BFD and BDF in the one, are equal to the two angles DEA and DAE in the other, each to each respectively; and the included side DF is equal to the included side AE; therefore (by art. 61. cor. 1.) AD will be equal to DB, and consequently AB double of AD; also (by the same) DE will be equal to BF; but DE is also (by art. 67. cor. 4.) equal to FC; therefore BF and ED together, or BC, will be double of DE. Plate CCXVI.

After the same manner it may be proved, that if in the triangle AKG, (fig. 2.) AE be taken equal to a third part of AK, and through E be drawn ED, parallel to KG, and meeting AG in D; then ED will be equal to a third part of GK, and AD equal to a third part of AG.

Likewise if in any triangle ABC, (fig. 3.) upon the side AB, be taken AE, equal to one fourth, one-fifth, one-sixth, *&c.* of AB, and through E be drawn ED parallel to BC and meeting AC in D, then D will be one-fourth, one-fifth, one-sixth, *&c.* of BC, and AD the like part of AC; and, in general, if in any triangle

angle ABC, there be assumed a point E on one of its sides AB, and through that point be drawn a line ED, parallel to one of its sides BC, and meeting the other side AC in D; then whatever part AE is of AB, the same part will ED be of BC, and AD of AC.

Cor. Hence it follows, that if in any triangle ABC, there be drawn ED, parallel to one of its sides BC, and meeting the other two in the points E and D, then AE : AB :: ED : BC :: AD : AC; that is, AE is to AB, as ED is to BC, and that as AD to AC.

72. If any two triangles ABC, fig. 4. a b c, fig. 5. are similar, or have all the angles of the one equal to all the angles of the other, each to each respectively; that is, the angle CAB equal to the angle c a b, and the angle ABC equal to the angle a b c, and the angle ACB equal to the angle a c b; then the legs opposite to the equal angles are proportioned, *viz.* AB : a b :: AC : a c :: and AB : a b :: BC : b c :: and AC : a c :: BC : b c. On AB of the largest triangle set off AE equal to a b, and through E draw ED parallel to BC, meeting AC in D; then since DE and BC are parallel, and AB crossing them, the angle AED will (by art. 36.) be equal to the angle ABC, which (by supposition) is equal to the angle a b c, also the angle DAE is (by supposition) equal to the angle c a b; so in the two triangles AED, a b c, the two angles DAE AED of the one, are equal to two angles c a b a b c of the other, each to each respectively, and the included side AE is (by construction) equal to the included side a b; therefore, (by art. 61. cor. 1.) AD is equal to a c, and DE equal to c b; but since, in the triangle ABC, there is drawn DE parallel to BC one of its sides, and meeting the two other sides in the points D and E, therefore (by cor. art. 71.) AB : AE :: AC : AD, and AB : AE :: BC : DE, and AC : AD :: BC : DE; and in the three last proportions, instead of the lines AE, DE, and AD, putting in their equals a b, b c, and a c, we shall have AB : a b :: AC : a c, and AB : a b :: BC : b c, and lastly, AC : a c :: BC : b c.

73. The chord, sine, tangent, *&c.* of any arc in one circle, is to the chord, sine, tangent, *&c.* of the same arc in another, as the radius of the one is to the radius of the other, fig. 6. 6. Let ABD a b d be two circles, BD b d two arcs of these circles, equal to one another, or consisting of the same number of degrees; FD f d the tangents, BD b d the chords, BE b e the sines, *&c.* of these two arcs BD b d, and CD c d the radii of the circles; then say, CD : c d :: FD : f d, and CD : c d :: BD : b d, and CD : c d :: BE : b e, *&c.* For since the arcs BD b d are equal, the angles BCD b c d will be equal; and FD f d, being tangents to the points D and d, the angles CDF c d f will be equal, being each a right angle (art. 22.) so in the two triangles CDF c d f, the two angles FCD CDF of the one, being equal to the two angles f c d c d f of the other, each to each, the remaining angle CFD will be equal to the remaining angle c f d (by art 60.); therefore the triangles CFD c f d are similar, and consequently (by art 73.) CD : c d :: FD : f d. In the same manner it may be demonstrated, that CD : c d :: BD : b d, and CD : c d :: BE b e, *&c.*

74. Let ABD (fig. 7.) be a quadrant of a circle described by the raduis CD; BD any arc of it, and BA its complement; BG or CF the sine, CG or BF the cosine; DE the tangent, and CE the secant of that arc BD. Then since the triangles CDE CBG are similar or equiangular, it will be (by art. 72.) DE : EC :: GB : BC, *i. e.* the tangent of any arc, is to the secant of the same, as the sine of it is to the radius. Also since DE : EC :: GB : BC; therefore, by inverting that proportion, we have EC : DE :: BC : GB, *i. e.* the secant is to the tangent, as the radius is to the sine of any arc. General Principles.

Again, since the triangles CDE CGB are similar, therefore (by art. 72.) it will be CD : CE :: CG : CB, *i. e.* as the radius is to the secant of any arc, so is the co-sine of that arc to the radius. And by inverting the proportion we have this, *viz.* as the secant of any arc is to the radius, so is the radius to the co-sine of that arc.

75. In all circles the chord of 60 is always equal in length to the radius. Thus in the circle AEBD, (fig. 8.) if the arc AEB be an arc of 60 degrees, then drawing the chord AB, I say AB shall be equal to the radius CB or AC; for in the triangle ACB, the angle ACB is 60 degrees, being measured by the arc AEB; therefore the sum of the other two angles is 120 degrees, (by *cor.* 1. of 60); but since AC and CB are equal, the two angles CAB, CBA will also be equal; consequently each of them half their sum 120, *viz.* 60 degrees; therefore, all the three angles are equal to one another, consequently all the legs, therefore AB is equal to CB.

Cor. Hence the radius from which the lines on any scale are formed, is the chord of 60 on the line of chords.

Geometrical Problems.

Prob. 1. From a point C (fig. 9.) in a given line AB to raise a perpendicular to that line.

Rule. From the point C take the equal distances CB, CA on each side of it. Then stretch the compasses to any greater distance than CB or CA, and with one foot of them in B, sweep the arc EF with the other; again, with the same opening, and one foot in A, sweep the arc GH with the other, and these two arcs will intersect one another in the point D; then join the given points C and D with the line CD, and that shall be the perpendicular required.

2. To divide a given right line AB (fig. 10.) into two equal parts; that is, to bisect them.

Rule. Take any distance with your compasses that you are sure is greater than half the given line; then setting one foot of them in B, with the other sweep the arc DFG; and with the same distance, and one foot in A, with the other sweep the arc CED; these two arcs will intersect one another in the points CD, which joined by the right line CD will bisect AB in G.

3. From a given point D, (fig. 11.) to let fall a perpendicular on a given line AB.

Rule Set one foot of the compasses in the point D, and extend the other to any greater distance than the least distance between the given point and the line, and with that extent sweep the arc AEB, cutting the line in the two points A and B, then (by the last prob.) bisect the line AB in the point C; lastly, join C and D, and that line CD is the perpendicular required.

General Principles.

4. (Fig. 12.) Upon the end B of a given right line BA, to raiſe a perpendicular.

Rule. Take any extent in your compaſſes, and with one foot in B fix the other in any point C without the given line; then with one point of the compaſſes in C, deſcribe with the other the circle EBD, and through E and C draw the diameter ECD meeting the circle in D; join D and B, and the right line DB is that required; for EBD is a right angle (by *cor.* 4. of 63.)

5. (Fig. 13.) To draw one line parallel to another given line AB, that ſhall be diſtant from one another by any given diſtance D.

Rule. Extend your compaſſes to the given diſtance D; then ſetting one foot of them in any point of the given line (ſuppoſe A,) with the other ſweep the arc FCG; again, at the ſame extent, and one foot in any other point of the given line B, ſweep the arc HDK, and draw the line CD touching them, and that will be parallel to the given line AB, and diſtant from it by the line D as was required.

6. (Fig. 14.) To divide a given line AB into any number of equal parts, ſuppoſe 7.

Rule. From the point A draw any line AD, making an angle with the line AB, then through the point B, draw a line BC parallel to AD; and from A, with any ſmall opening of the compaſſes, ſet off a number of equal parts (on the line AD) leſs by one than the propoſed number (here 6.); then from B ſet off the ſame number of the ſame parts (on the line BC); laſtly, join 1 and 6, 2 and 5, 3 and 4, 4 and 3, 5 and 2, 6 and 1, and theſe lines will cut the given line as required.

7. (Fig. 15.) To quarter a given circle, or to divide it into four equal parts.

Rule. Through the centre C of the given circle, draw a diameter AB, then upon the point C raiſe a perpendicular DCE to the line AB; and theſe two diameters AB and DE ſhall quarter the circle.

8. (Fig. 16.) Through three given points A, B, and D, to draw a circle. *Note*, The three points muſt not lie in the ſame ſtraight line.

Rule. Join A and B, alſo B and D, with the ſtraight lines AB BD; then (by prob. 2.) biſect AB with the line EC, alſo BD with the line FC, which two lines will cut one another in ſome point C; that is the centre of the circle required: then fixing one point of our compaſſes in D, and ſtretching the other to A, deſcribe the circle ABDG, which will paſs through the three points given. The reaſon of this is plain from cor. 1. of art. 64.

9. (Fig. 17.) From the point A of the given line AB, to draw another line (ſuppoſe AC) that ſhall make with AB an angle of any number of degrees, ſuppoſe 45.

Rule. Let the given line AB be produced, then take off your ſcale the length of the chord of 60 degrees, which is equal to the radius of the circle the ſcale was made for (by art. 75.); and ſetting the foot in A, with the other ſweep off the arc BC; then with your compaſſes take from your ſcale the chord of 45 degrees, and ſet off that diſtance from B to C. Laſtly, join A and C, and the line AC is that required. For the angle CAB, which is meaſured by the arc BC, is an angle of 45 degrees, as was required.

10. An angle BAC (fig. 18.) being given, to find how many degrees it contains. General Principles.

Rule. With your compaſſes take the length of your chord of 60 from your ſcale. Then, ſetting one foot of them in A, with the other ſweep the arc BC, which is the arc comprehended between the two legs AB, AC produced if needful. Laſtly, take with your compaſſes the diſtance BC, and applying it to your line of chords on the ſcale, you will find how many degrees the arc BC contains, and conſequently the degrees of the angle BAC which was required.

11. Three lines x, y, and z being given. (fig. 19. 19.) to form a triangle of them; but any two of theſe lines taken together muſt always be greater than the third.

Rule. Make any one of them, as x, the baſe; then with your compaſſes take another of them, as z, and ſetting one foot in one end of the line x, as B, with the other ſweep the arc DE; and taking with your compaſſes the length of the other y, ſet one foot of them in A, the other end of the line x, and with the other ſweep the arc FG, which will cut the other in C; laſtly, join CA and CB, and the triangle CAB is that required.

12. To make a triangle, having one of its legs of any number of equal parts (ſuppoſe 160,) and one of the angles at that leg 50 degrees, and the other 44 degrees.

Rule. Draw an indefinite line ED, (fig. 20.) then take off the line of equal parts with your compaſſes, 160 of them, and ſet them on the indefinite line, as BC; then (by prob. 9.) draw BA, making the angle ABC of 50 degrees, and (by the ſame) draw from C the line AC, making the angle ABC of 44 degrees; which two lines will meet one another in A, and the triangle ABC is that required. See TRIGONOMETRY.

13. Upon a given line AB (fig. 21.) to make a ſquare.

Rule Upon the extremity A of the given line AB, raiſe a perpendicular AC (by prob. 4.); then take AC equal to AB, and with that extent, ſetting one foot of the compaſſes in C, ſweep with the other foot the arc GH; then with the ſame extent, and one foot in B, with the other ſweep the arc EF, which will meet the former in ſome point D; laſtly, join C and D, D and B, and the figure ABDC will be the ſquare required.

14. On a given line AB (fig. 22.) to draw a rhomb that ſhall have one of its angles equal to any number of degrees, ſuppoſe 60 degrees.

Rule. From the point A of the given line AB, draw the line AC, making the angle CAB of 60 degrees, (by prob. 9.) then take AC equal to AB, and with that extent, fixing one foot of the compaſſes in B, with the other deſcribe the arc GH; and at the ſame extent, fixing one foot of the compaſſes in C, with the other deſcribe the arc EF cutting the former in D; laſtly, join CD and DB, and the figure ACDB is that required.

16. Given two lines x and z, of theſe two to make a rectangle.

Rule Draw a line, as AB, (fig. 23. 23.) equal in length to one of the given lines x; and on the extremity A of that line raiſe a perpendicular AC, on

es and gles. which take AC equal to the other line z; then take with your compaſſes the length of the line AB, and at that extent, fixing one foot of them in C, with the other ſweep the arc EF; and alſo taking with your compaſſes the extent of the line AC, fix one foot of them in B, and with the other ſweep the arc GH, which will meet the former in D; laſtly, join CD and BD, and the figure ABDC will be that required.

16. Two lines x and z being given, of theſe to form a rhomboides that ſhall have one of its angles any number of degrees, ſuppoſe 50.

Rule. Draw a line AB (fig. 24. 24.) equal in length to one of the lines, as x; then draw the line AC, making with the former the angle BAC equal to the propoſed, ſuppoſe 50 degrees, and on that line take AC equal to the given line z; then with your compaſſes take the length of AB, and fixing one foot in C, ſweep the arc EF; alſo taking the length of AC, and ſetting one foot in B, with the other ſweep the arc GH, which will cut the former in D; then join CD and DB, ſo the figure ACDB will be that required. Lines and Angles.

PART. II. THE APPLICATION OF THE FOREGOING PRINCIPLES TO THE MENSURATION OF SURFACES, SOLIDS, &c.

CHAP. I. *Of the Menſuration of Lines and Angles.*

A Line or length to be meaſured, whether it be diſtance, height, or depth, is meaſured by a line leſs than it. With us the leaſt meaſure of length is an inch: not that we meaſure no line leſs than it, but becauſe we do not uſe the name of any meaſure below that of an inch; expreſſing leſſer meaſures by the fractions of an inch: and in this treatiſe we uſe decimal fractions as the eaſieſt. Twelve inches make a foot; three feet and an inch make the Scots ell; ſix ells make a fall; forty falls make a furlong; eight furlongs make a mile: ſo that the Scots mile is 1184 paces, accounting every pace to be five feet. Theſe things are according to the ſtatutes of Scotland; notwithſtanding which, the glaziers uſe a foot of only eight inches; and other artiſts for the moſt part uſe an Engliſh foot, on account of the ſeveral ſcales marked on the Engliſh foot-meaſure for their uſe. But the Engliſh foot is ſomewhat leſs than the Scots; ſo that 185 of theſe make 186 of thoſe.

Lines, to the extremities and any intermediate point of which you have eaſy acceſs, are meaſured by applying to them the common meaſure a number of times. But lines, to which you cannot have ſuch acceſs, are meaſured by methods taken from geometry; the chief whereof we ſhall here endeavour to explain. The firſt is by the help of the geometrical ſquare.

"As for the Engliſh meaſures, the yard is 3 feet, or 36 inches. A pole is ſixteen feet and a half, or five yards and a half. The chain, commonly called *Gunter's chain*, is four poles, or 22 yards, that is, 66 feet. An Engliſh ſtatute-mile is fourſcore chains, or 1760 yards, that is, 5280 feet.

"The chain (which is now much in uſe, becauſe it is very convenient for ſurveying) is divided into 100 links, each of which is $7\frac{92}{625}$ of an inch: whence it is eaſy to reduce any number of thoſe links to feet, or any number of feet to links.

"A chain that may have the ſame advantages in ſurveying Scotland, as Gunter's chain has in England, ought to be in length 74 feet, or 24 Scots ells, if no regard is had to the difference of the Scots and Engliſh foot above mentioned. But if regard is had to that difference, the Scots chain ought to conſiſt of $74\frac{3}{5}$ Engliſh feet, or 74 feet 4 inches and $\frac{3}{5}$ths of an inch. This chain being divided into 100 links, each of thoſe links is 8 inches and $\frac{92}{625}$ of an inch. In the following table, the moſt noted meaſures are expreſſed in Engliſh inches and decimals of an inch."

Lines and Angles.

PROPOSITION I.

Plate CCXVII.

PROB. *To describe the structure of the geometrical square.*—The geometrical square is made of any solid matter, as brass or wood, or of any four plain rulers joined together at right angles (as in fig. 1.), where A is the centre, from which hangs a thread with a small weight at the end, so as to be directed always to the centre. Each of the sides BE and DE is divided into an hundred equal parts, or (if the sides be long enough to admit of it) into a thousand parts; C and F at two sights, fixed on the side AD. There is moreover an index GH, which, when there is occasion, is joined to the centre A, in such manner as that it can move round, and remain in any given situation. On this index are two sights perpendicular to the right line going from the centre of the instrument: these are K and L. The side DE of the instrument is called the upright side; E the reclining side.

PROPOSITION II.

FIG. 2. *To measure an accessible height* AB *by the help of a geometrical square, its distance being known.*—Let BR be an horizontal plane, on which there stands perpendicularly any line AB: let BD, the given distance of the observator from the height, be 96 feet: let the height of the observator's eye be supposed 6 feet; and let the instrument, held by a steady hand, or rather leaning on a support, be directed towards the summit A, so that one eye (the other being shut) may see it clearly through the sights; the perpendicular or plumb-line meanwhile hanging free, and touching the surface of the instrument; let now the perpendicular be supposed to cut off on the right side KN 80 equal parts. It is clear that LKN, ACK, are similar triangles; for the angles LKN, ACK are right angles, and therefore equal; moreover, LN and AC are parallel, as being both perpendicular to the horizon; consequently (by art. 60. cor. 1. Part I), the angles KLN, KAC, are equal; wherefore (by art. 60. cor. 2. of Part I), the angles LNK and CAK are likewise equal: so that in the triangles NKL, KAC, (by art. 72. of Part I.) as NK : KL :: KC (i. e. BD) : CA; that is, as 80 to 100, so is 96 feet to CA. Therefore, by the rule of three, CA will be found to be 120 feet; and CB, which is 6 feet, being added, the whole height is 126 feet.

But if the distance of the observator from the height, as BE, be such, that when the instrument is directed as formerly toward the summit A, the perpendicular falls on the angle P, opposite to H, the centre of the instrument, and BE or CG be given of 120 feet; CA will also be 120 feet. For in the triangles HGP, ACG, equiangular, as in the preceding case, as DG : GH :: GC : CA. But PG is equal to GH; therefore GC is likewise equal to CA: that is, CA will be 120 feet, and the whole height 126 feet as before.

Let the distance BF be 300 feet, and the perpendicular or plumb-line cut off 40 equal parts from the reclining side: Now, in this case, the angles QAC, QZI, are equal, and the angles QZI, ZIS, are equal: therefore the angle ZIS is equal to the angle QAC. But the angles ZSI, QCA are equal, being right angles; therefore, in the equiangular triangles ACQ, SZI, it will be, as ZS : SI :: CQ : CA; that is, as 100 to 40, so is 300 to CA. Wherefore, by the rule of three, CA will be found to be of 102 feet. And, by adding the height of the observator, the whole BA will be 126 feet. Note, that the height is greater than the distance, when the perpendicular cuts the right side, and less if it cut the reclined side; and that the height and distance are equal, if the perpendicular fall on the opposite angle.

Lines and Angles.

SCHOLIUM.

If the height of a tower to be measured as above, end in a point (as in fig. 3.), the distance of the observator opposite to it, is not CD, but is to be accounted from the perpendicular to the point A; that is, to CD must be added the half of the thickness of the tower, viz. BD: which must likewise be understood in the following propositions, when the case is similar.

PROPOSITION III.

FIG. 4. *From the height of a tower* AB *given, to find a distance on the horizontal plane* BC, *by the geometrical square.*—Let the instrument be so placed, as that the mark C in the opposite plane may be seen through the sights; and let it be observed how many parts are cut off by the perpendicular. Now, by what hath been already demonstrated, the triangles AEF, ABC, are similar; therefore, it will be as EF to AE, so AB (composed of the height of the tower BG, and of the height of the centre of the instrument A, above the tower BG) to the distance BC. Wherefore, if, by the rule of three, you say, as EF to AE, so is AB to BC, it will be the distance sought.

PROPOSITION IV.

FIG. 5. *To measure any distance at land or sea, by the geometrical square.*—In this operation, the index is to be applied to the instrument, as was shown in the description; and, by the help of a support, the instrument is to be placed horizontally at the point A; then let it be turned till the remote point F, whose distance is to be measured, be seen through the fixed sights; and bringing the index to be parallel with the other side of the instrument, observe by the sights upon it any accessible mark B, at a sensible distance: then carrying the instrument to the point B, let the immoveable sights be directed to the first station A, and the sights of the index to the point F. If the index cut the right side of the square, as in K, in the two triangles BRK, and BAF, which are equiangular, it will be as BR to RK, so BA (the distance of the stations to be measured with a chain) to AF; and the distance AF sought will be found by the rule of three. But if the index cut the reclined side of the square in any point L, where the distance of a more remote point is sought: in the triangles BLS, BAG, the side LS shall be to SB, as BA to AG, the distance sought; which accordingly will be found by the rule of three.

PROPOSITION V.

FIG. 6. *To measure an accessible height by means of a plain mirror.*—Let AB be the height to be measured; let the mirror be placed at C, in the horizontal plane BD, at a known distance BC; let the observer go back to D, till he see the image of the summit in the mirror, at a certain point of it, which he must diligently mark; and let DE be the height of the observator's eye. The triangles ABC and EDC are equiangular; for the angles at D and B are right angles; and ACB, ECD, are equal, being the angles of

Abell Prin. Mat. Sculptor. fecit.

of incidence and reflexion of the ray AC, as is demonſtrated in optics; wherefore the remaining angles at A and E are alſo equal; therefore it will be as CD to DE, ſo CB to BA; that is, as the diſtance of the obſervator from the point of the mirror in the right line betwixt the obſervator and the height, is to the height of the obſervator's eye, ſo is the diſtance of the tower from that point of the mirror to the height of the tower ſought; which therefore will be found by the rule of three.

Note 1. The obſervation will be more exact, if, at the point D, a ſtaff be placed in the ground perpendicularly, over the top of which the obſervator may ſee a point of the glaſs exactly in a line betwixt him and the tower.

Note 2. In place of a mirror may be uſed the ſurface of water contained in a veſſel, which naturally becomes parallel to the horizon.

PROPOSITION VI.

Fig 7. *To meaſure an acceſſible height* AB *by means of two ſtaffs.*—Let there be placed perpendicularly in the ground a longer ſtaff DE, likewiſe a ſhorter one FG, ſo as the obſervator may ſee A, the top of the height to be meaſured, over the ends DF of the two ſtaffs; let FH and DC, parallel to the horizon, meet DE and AB in H and C; then the triangles FHD, DCA, ſhall be equiangular; for the angles at C and H are right ones; likewiſe the angle A is equal to the angle FDH; wherefore the remaining angles DFH, and ADC, are alſo equal: wherefore, as FH, the diſtance of the ſtaffs, to HD, the exceſs of the longer ſtaff above the ſhorter; ſo is DC, the diſtance of the longer ſtaff from the tower, to CA, the exceſs of the height of the tower above the longer ſtaff. And thence CA will be found by the rule of three.

To which if the length DE be added, you will have the whole height of the tower BA.

SCHOLIUM.

Fig. 8. Many other methods may be occaſionally contrived for meaſuring an acceſſible height. For example, from the given length of the ſhadow BD, to find out the height AB, thus: Let there be erected a ſtaff CE perpendicularly, producing the ſhadow EF: The triangles ABD, CEF, are equiangular; for the angles at B and E are right; and the angles ADB and CFE are equal, each being equal to the angle of the ſun's elevation above the horizon: Therefore, as EF, the ſhadow of the ſtaff, to EC, the ſtaff itſelf; ſo BD, the ſhadow of the tower, to BA, the height of the tower. Though the plane on which the ſhadow of the tower falls be not parallel to the horizon, if the ſtaff be erected in the ſame plane, the rule will be the ſame.

PROPOSITION VII.

To meaſure an inacceſſible height by means of two ſtaffs.—Hitherto we have ſuppoſed the height to be acceſſible, or that we can come at the lower end of it; now if, becauſe of ſome impediment, we cannot get to a tower, or if the point whoſe height is to be found out be the ſummit of a hill, ſo that the perpendicular be hid within the hill; if, for want of better inſtruments, ſuch an inacceſſible height is to be meaſured by means of two ſtaffs, let the firſt obſervation be made with the ſtaffs DE and FG, (as in prop. 6.); then the obſervator is to go off in a direct line from the height and firſt ſtation, till he come to the ſecond ſtation; where (fig. 11.) he is to place the longer ſtaff perpendicularly at RN, and the ſhorter ſtaff at KO, ſo that the ſummit A may be ſeen along their tops; that is, ſo that the points KNA may be in the ſame right line. Through the point N, let there be drawn the right line NP parallel to FA: Wherefore in the triangles KNP, KAF, the angles KNP, KAF are equal, alſo the angle AKF is common to both; conſequently the remaining angle KPN is equal to the remaining angle KFA. And therefore, PN : FA :: KP : KF. But the triangles PNL, FAS are ſimilar; therefore, PN : FA :: NL : SA. Therefore (by the 11. 5. Euel.) KP : KF :: NL : SA. Thence, alternately, it will be, as KP (the exceſs of the greater diſtance of the ſhort ſtaff from the long one above its leſſer diſtance from it) to NL, the exceſs of the longer ſtaff above the ſhorter; ſo KF, the diſtance of the two ſtations of the ſhorter ſtaff to SA, the exceſs of the height ſought above the height of the ſhorter ſtaff. Wherefore SA will be found by the rule of three. To which let the height of the ſhorter ſtaff be added, and the ſum will give the whole inacceſſible height BA.

Note 1. In the ſame manner may an inacceſſible height be found by a geometrical ſquare, or by a plain ſpeculum. But we ſhall leave the rules to be found out by the ſtudent, for his own exerciſe.

Note 2. That by the height of the ſtaff we underſtand its height above the ground in which it is fixed.

Note 3. Hence depends the method of uſing other inſtruments invented by geometricians; for example, of the geometrical croſs: and if all things be juſtly weighed, a like rule will ſerve for it as here. But we incline to touch only upon what is moſt material.

PROPOSITION VIII.

Fig. 9. *To meaſure the diſtance* AB, *to one of whoſe extremities we have acceſs, by the help of four ſtaffs.*—Let there be a ſtaff fixed at the point A; then going back at ſome ſenſible diſtance in the ſame right line, let another be fixed in C, ſo as that both the points A and B be covered and hid by the ſtaff C: likewiſe going off in a perpendicular from the right line CB, at the point A (the method of doing which ſhall be ſhown in the following ſcholium), let there be placed another ſtaff at H; and in the right line CKG (perpendicular to the ſame CB, at the point B), and at the point of it K, ſuch that the points K, H, and B may be in the ſame right line, let there be fixed a fourth ſtaff. Let there be drawn, or let there be ſuppoſed to be drawn, a right line GH parallel to CA. The triangles KGH, HAB, will be equiangular; for the angles HAB, KGH are right angles. Alſo the angles ABH, KHG are equal; wherefore, as KG (the exceſs of CK above AH) to GH, or to CA, the diſtance betwixt the firſt and ſecond ſtaff; ſo is AH, the diſtance betwixt the firſt and third ſtaff, to AB the diſtance ſought.

SCHOLIUM.

Fig. 10. To draw on a plane a right line AE perpendicular to CH, from a given point A: take the right lines AB, AD, on each ſide equal; and in the points B and D, let there be fixed ſtakes, to which let there be tied two equal ropes BE, DE, or one having a mark in the middle, and holding in your hand their extremities joined (or the mark in the middle, if it be but one), draw out the ropes on the ground; and then

Lines and Angles.

then where the two ropes meet, or at the mark, when by it the rope is fully ſtretched, let there be placed a third ſtake at E; the right line AE will be perpendicular to CH in the point A (prob. 1. of Part I.). In a manner not unlike to this, may any problems, that are reſolved by the ſquare and compaſſes, be done by ropes and a cord turned round as a radius.

PROPOSITION IX.

Fig. 12. *To meaſure the diſtance* AB, *one of whoſe extremities is acceſſible.*—From the point A, let the right line AC of a known length be made perpendicular to AB (by the preceding ſcholium): likewiſe draw the right line CD perpendicular to CB, meeting the right line AB in D: then as DA : AC :: AC : AB. Wherefore, when DA and AC are given, AB will be found by the rule of three.

SCHOLIUM.

All the preceding operations depend on the equality of ſome angles of triangles, and on the ſimilarity of the triangles ariſing from that equality. And on the ſame principles depend innumerable other operations which a geometrician will find out of himſelf, as is very obvious. However, ſome of theſe operations require ſuch exactneſs in the work, and without it are ſo liable to errors, that, *cæteris paribus*, the following operations, which are performed by a trigonometrical calculation, are to be preferred; yet could we not omit thoſe above, being moſt eaſy in practice, and moſt clear and evident to thoſe who have only the firſt elements of geometry. But if you are provided with inſtruments, the following operations are more to be relied upon. We do not inſiſt on the eaſieſt caſes to thoſe who are ſkilled in plain trigonometry, which is indeed neceſſary to any one who would apply himſelf to practice. See Trigonometry.

PROPOSITION X.

Fig. 13. *To deſcribe the conſtruction and uſe of the geometrical quadrant.*—The geometrical quadrant is the fourth part of a circle divided into 90 degrees, to which two ſights are adapted, with a perpendicular or plumb-line hanging from the centre. The general uſe of it is for inveſtigating angles in a vertical plane, comprehended under right lines going from the centre of the inſtrument, one of which is horizontal, and the other is directed to ſome viſible point. This inſtrument is made of any ſolid matter, as wood, copper, &c.

PROPOSITION XI.

Fig. 14. *To deſcribe and make uſe of the graphometer.*—The graphometer is a ſemicircle made of any hard matter, of wood, for example, or braſs, divided into 180 degrees; ſo fixed on a fulcrum, by means of a braſs ball and ſocket, that it eaſily turns about, and retains any ſituation; two ſights are fixed on its diameter. At the centre there is commonly a magnetical needle in a box. There is likewiſe a moveable ruler, which turns round the centre, and retains any ſituation given it. The uſe of it is to obſerve any angle, whoſe vertex is at the centre of the inſtrument in any plane (though it is moſt commonly horizontal, or nearly ſo), and to find how many degrees it contains.

PROPOSITION XII.

Fig. 15. and 16. *To deſcribe the manner in which angles are meaſured by a quadrant or graphometer.*—Let there be an angle in a vertical plane, comprehended between a line parallel to the horizon HK, and the right line RA, coming from any remarkable point of a tower or hill, or from the ſun, moon, or a ſtar. Suppoſe that this angle RAH is to be meaſured by the quadrant: let the inſtrument be placed in the vertical plane, ſo as that the centre A may be in the angular point; and let the ſights be directed towards the object at R (by the help of the ray coming from it, if it be the ſun or moon, or by the help of the viſual ray, if it is any thing elſe), the degrees and minutes in the arc BC, cut off by the perpendicular, will meaſure the angle RAH required. For, from the make of the quadrant, BAD is a right angle; therefore BAR is likewiſe right, being equal to it. But, becauſe HK is horizontal, and AC perpendicular, HAC will be a right angle; and therefore equal alſo to BAR. From thoſe angles ſubtract the part HAB that is common to both; and there will remain the angle BAC equal to the angle RAH. But the arc BC is the meaſure of the angle BAC; conſequently, it is likewiſe the meaſure of the angle RAH.

Note, That the remaining arc on the quadrant DC is the meaſure of the angle RAZ, comprehended between the foreſaid right line RA and AZ which points to the zenith.

Let it now be required to meaſure the angle ACB (fig. 16.) in any plane, comprehended between the right lines AC and BC, drawn from two points A and B, to the place of ſtation C. Let the graphometer be placed at C, ſupported by its fulcrum (as was ſhown above); and let the immoveable ſights on the ſide of the inſtrument DE be directed towards the point A; and likewiſe (while the inſtrument remains immoveable) let the ſights of the ruler FG (which is moveable about the centre C) be directed to the point B. It is evident that the moveable ruler cuts off an arc DH, which is the meaſure of the angle ACB ſought. Moreover, by the ſame method, the inclination of CE, or of FG, may be obſerved with the meridian line, which is pointed out by the magnetic needle incloſed in the box, and is moveable about the centre of the inſtrument, and the meaſure of this inclination or angle found in degrees.

PROPOSITION XIII.

Fig. 17. *To meaſure an acceſſible height by the geometrical quadrant.*—By the 12th prop. of this Part, let the angle C be found by means of the quadrant. Then in the triangle ABC, right-angled at B (BC being ſuppoſed the horizontal diſtance of the obſervator from the tower), having the angle at C, and the ſide BC, the required height BA will be found by the 3d caſe of plane trigonometry. See Trigonometry.

PROPOSITION XIV.

Fig. 18. *To meaſure an inacceſſible height by the geometrical quadrant.*—Let the angle ACB be obſerved with the quadrant (by the 12th prop. of this Part); then let the obſerver go from C to the ſecond ſtation D, in the right line BCD (provided BCD be a horizontal plane); and after meaſuring this diſtance CD, take the angle ADC likewiſe with the quadrant. Then, in the triangle ACD, there is given the angle ADC, with the angle ACD; becauſe ACB was given before: therefore (by art. 59. of Part I.) the remaining angle CAD is given likewiſe. But the ſide CD is likewiſe

Lines and Angles.

likewise given, being the distance of the station C and D; therefore (by the first case of oblique-angled triangles in trigonometry) the side AC will be found. Wherefore, in the right-angled triangle ABC, all the angles and the hypothenuse AC are given; consequently, by the fourth case of trigonometry, the height sought AB will be found; as also (if you please) the distance of the station C, from AB the perpendicular within the hill or inaccessible height.

PROPOSITION XV.

Fig. 19. *From the top of a given height, to measure the distance* BC.—Let the angle BAC be observed by the 12th prop. of this; wherefore in the triangle ABC, right angled at B, there is given by observation the angle at A; whence (by the 59th art. of Part. I.) there will also be given the angle BCA: moreover the side AB (being the height of the tower) is supposed to be given. Wherefore, by the 3d case of trigonometry, BC, the distance sought, will be found.

PROPOSITION XVI.

Fig. 20. *To measure the distance of two places* A *and* B, *of which one is accessible, by the graphometer.*—Let there be erected at two points A and C, sufficiently distant, two visible signs; then (by the 12th prop. of this Part) let the two angles BAC, BCA, be taken by the graphometer. Let the distance of the stations A and C be measured with a chain. Then the third angle B being known, and the side AC being likewise known; therefore, by the first case of trigonometry, the distance required, AB, will be found.

PROPOSITION XVII.

Fig. 21. *To measure by the graphometer the distance of two places, neither of which is accessible.*—Let two stations C and D be chosen, from each of which the places may be seen whose distance is sought; let the angles ACD, ACB, BCD, and likewise the angles BDC, BDA, CDA, be measured by the graphometer; let the distance of the stations C and D be measured by a chain, or (if it be necessary) by the preceding practice. Now, in the triangle ACD, there are given two angles ACD and ADC; therefore, the third CAD is likewise given; moreover, the side CD is given; therefore, by the first case of trigonometry, the side AD will be found. After the same manner, in the triangle BCD, from all the angles and one side CD given, the side BD is found. Wherefore, in the triangle ADB, from the given sides DA and DB, and the angle ADB contained by them, the side AB (the distance sought) is found by the 4th case of trigonometry of oblique-angled triangles.

PROPOSITION XVIII.

Fig. 22. *It is required by the graphometer and quadrant to measure an accessible height* AB, *placed so on a steep, that one can neither go near it in an horizontal plane, nor recede from it, as we supposed in the solution of the 14th prop.*—Let there be chosen any situation, as C, and another D; where let some mark be erected: let the angles ACD and ADC be found by the graphometer; then the third angle DAC will be known. Let the side CD, the distance of the stations, be measured with a chain, and thence (by trigon.) the side AC will be found. Again, in the triangle ACB, right-angled at B, having found by the quadrant the angle ACB, the other angle CAB is known likewise: but the side AC in the triangle ADC is already known; therefore the height required AB will be found by the 4th case of right-angled triangles. If the height of the tower is wanted, the angle BCF will be found by the quadrant: which being taken from the angle ACB already known, the angle ACF will remain: but the angle FAC was known before; therefore the remaining angle AFC will be known. But the side AC was also known before; therefore, in the triangle AFC, all the angles and one of the sides AC being known, AF, the height of the tower above the hill, will be found by trigonometry.

Lines and Angles.

SCHOLIUM.

It were easy to add many other methods of measuring heights and distances; but if what is above be understood, it will be easy (especially for one that is versed in the elements) to contrive methods for this purpose, according to the occasion: so that there is no need of adding any more of this sort. We shall subjoin here a method by which the diameter of the earth may be found out.

PROPOSITION XIX.

Plate CCXVIII.

Fig. 1. *To find the diameter of the earth from one observation.*—Let there be chosen a high hill AB, near the sea-shore, and let the observator on the top of it, with an exact quadrant divided into minutes and seconds by transverse divisions, and fitted with a telescope in place of the common sights, measure the angle ABE contained under the right line AB, which goes to the centre, and the right line BE drawn to the sea, a tangent to the globe at E; let there be drawn from A perpendicular to BD, the line AF meeting BE in F. Now in the right-angled triangle BAF all the angles are given, also the side AB, the height of the hill; which is to be found by some of the foregoing methods as exactly as possible; and (by trigonometry) the sides BF and AF are found. But by cor. 36th 3. Eucl. AF is equal to FE; therefore BE will be known. Moreover, by 36th 3. Eucl. the rectangle under BA and BD is equal to the square of BE. And thence by 17th 6. Eucl. as AB : BE : : BE : BD. Therefore, since AB and BE are already given, BD will be found by 11th 6. Eucl. or by the rule of three; and subtracting BA, there will remain AD the diameter of the earth sought.

SCHOLIUM.

Many other methods might be proposed for measuring the diameter of the earth. The most exact is that proposed by Mr Picart of the academy of sciences at Paris.

"According to Mr Picart, a degree of the meridian at the latitude of 49° 21′ was 57,060 French toises, each of which contains six feet of the same measure: from which it follows, that if the earth be an exact sphere, the circumference of a great circle of it will be 123,249,600 Paris feet, and the semidiameter of the earth 19,615,800 feet: but the French mathematicians, who of late have examined Mr Picart's operations, assure us, that the degree in that latitude is 57,183 toises. They measured a degree in Lapland, in the latitude of 66° 20′, and found it of 57,438 toises. By comparing these degrees, as well as by the observations on pendulums, and the theory of gravity, it appears that the earth is an oblate spheroid; and (supposing those degrees to be accurately measured) the axis or diameter that passes through the poles will be to the

Lines and Angles.

diameter of the equator as 177 to 178, or the earth will be 22 miles higher at the equator than at the poles. A degree has likewise been measured at the equator, and found to be considerably less than at the latitude of Paris; which confirms the oblate figure of the earth. But an account of this last mensuration has not been published as yet. If the earth was of an uniform density from the surface to the centre, then, according to the theory of gravity, the meridian would be an exact ellipsis, and the axis would be to the diameter of the equator as 230 to 231; and the difference of the semidiameter of the equator and semiaxis about 17 miles."

In what follows, a figure is often to be laid down on paper, like to another figure given; and because this likeness consists in the equality of their angles, and in the sides having the same proportion to each other (by the definitions of the 6th of Euel.) we are now to show what methods practical geometricians use for making on paper an angle equal to a given angle, and how they constitute the sides in the same proportion. For this purpose they make use of a protractor (or, when it is wanting, a line of chords), and of a line of equal parts.

PROPOSITION XX.

Fig. 2. 3. 4. 5. and 6. *To describe the construction and use of the protractor, of the line of chords, and of the line of equal parts.* The protractor is a small semicircle of brass, or such solid matter. The semicircumference is divided into 180 degrees. The use of it is, to draw angles on any plane, as on paper, or to examine the extent of angles already laid down. For this last purpose, let the small point in the centre of the protractor be placed above the angular point, and let the side AB coincide with one of the sides that contain the angle proposed; the number of degrees cut off by the other side, computing on the protractor from B, will show the quantity of the angle that is to be measured.

But if an angle is to be made of a given quantity on a given line, and at a given point of that line, let AB coincide with the given line, and let the centre A of the instrument be applied to that point. Then let there be a mark made at the given number of degrees; and a right line drawn from that mark to the given point, will constitute an angle with the given right line of the quantity required; as is manifest.

This is the most natural and easy method, either for examining the extent of an angle on paper, or for describing on paper an angle of a given quantity.

But when there is scarcity of instruments, or because a line of chords is more easily carried about (being described on a ruler on which there are many other lines besides), practical geometricians frequently make use of it. It is made thus: let the quadrant of a circle be divided into 90 degrees (as in fig. 4.) The line AB is the chord of 90 degrees; the chord of every arc of the quadrant is transferred to this line AB, which is always marked with the number of degrees in the corresponding arc.

Note, That the chord of 60 degrees is equal to the radius, by corol. 15. 4th Euel. If now a given angle EDF is to be measured by the line of chords from the centre D, with the distance DG (the chord of 60 degrees), describe the arc GF; and let the points G and F be marked where this arc intersects the sides of the angle. Then if the distance GF, applied on the line of chords from A to B, gives (for example) 25 degrees, this shall be the measure of the angle proposed.

Lines and Angles.

When an obtuse angle is to be measured with this line, let its complement to a semicircle be measured, and thence it will be known. It were easy to transfer to the diameter of a circle the chords of all arches to the extent of a semicircle; but such are rarely found marked upon rules.

But now, if an angle of a given quantity, suppose of 50 degrees, is to be made at a given point M of the right line KL (fig. 6.) From the centre M, and the distance MN, equal to the chord of 60 degrees, describe the arc QN. Take off an arc NR, whose chord is equal to that of 50 degrees on the line of chords; join the points M and R; and it is plain that MR shall contain an angle of 50 degrees with the line KL proposed.

But sometimes we cannot produce the sides till they be of the length of a chord of 60 degrees on our scale; in which case it is fit to work by a circle of proportions (that is a sector), by which an arc may be made of a given number of degrees to any radius.

The quantities of angles are likewise determined by other lines usually marked upon rules, as the lines of sines, tangents, and secants; but as these methods are not so easy or so proper in this place, we omit them.

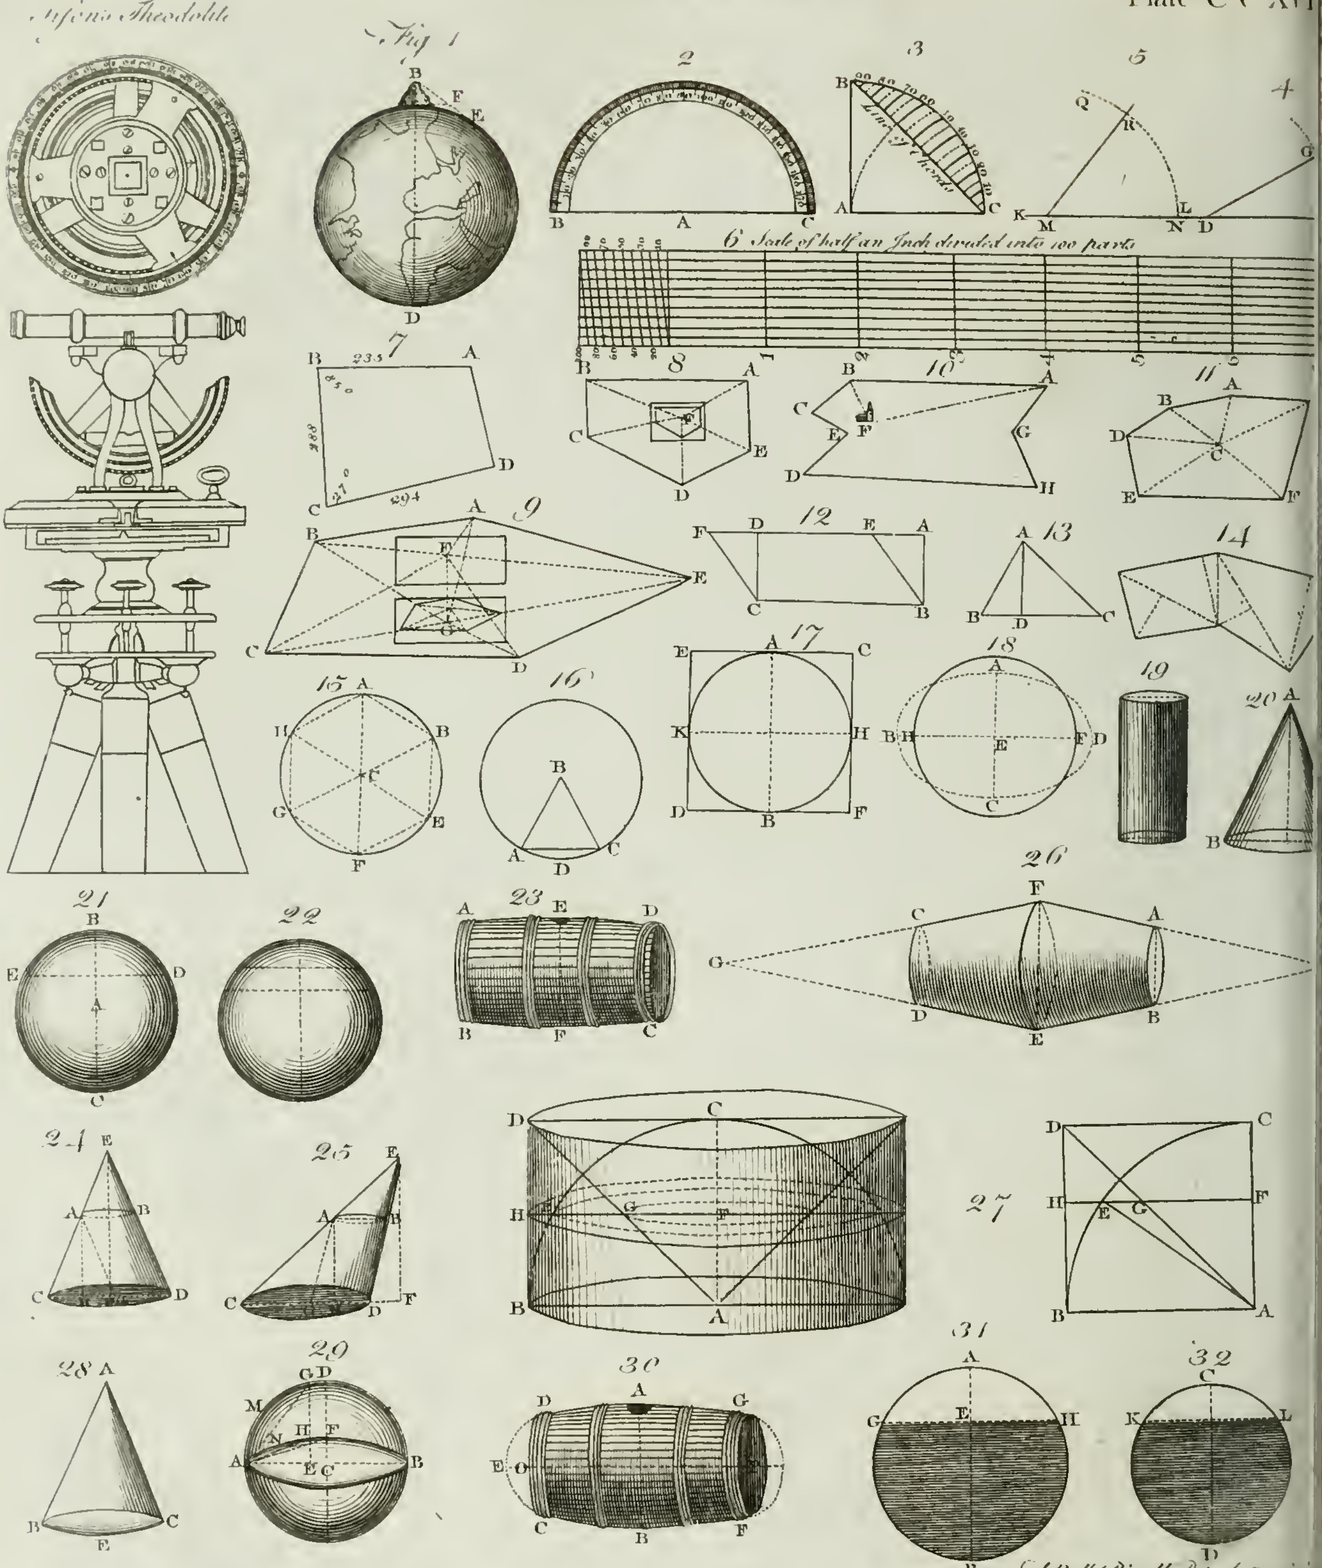
To delineate figures similar or like to others given, besides the equality of the angles, the same proportion is to be preserved among the sides of the figure that is to be delineated, as is among the sides of the figures given. For which purpose, on the rules used by artists, there is a line divided into equal parts, more or less in number, and greater or less in quantity according to the pleasure of the maker.

A foot is divided into inches; and an inch, by means of transverse lines, into 100 equal parts; so that with this scale, any number of inches below 12, with any part of an inch, can be taken by the compasses, providing such part be greater than the 100th part of an inch. And this exactness is very necessary in delineating the plans of houses, and in other cases.

PROPOSITION XXI.

Fig. 7. *To lay down on paper, by the protractor or line of chords, and line of equal parts, a right lined figure like to one given, providing the angles and sides of the figure given be known by observation or mensuration.* For example, suppose that it is known that in a quadrangular figure, one side is of 235 feet, that the angle contained by it and the second side is of 84°, the second side of 288 feet, the angle contained by it and the third side of 72°, and that the third side is 294 feet. These things being given, a figure is to be drawn on paper like to this quadrangular figure. On your paper at a proper point A, let a right line be drawn, upon which take 235 equal parts, as AB. The part representing a foot is taken greater or less, according as you would have your figure greater or less. In the adjoining figure, the 100th part of an inch is taken for a foot. And accordingly an inch divided into 100 parts, and annexed to the figure, is called a scale of 100 feet. Let there be made at the point B (by the preceding proposition) an angle ABC of 85°, and let BC be taken of 288 parts like to the former. Then let the angle BCD be made of 72°, and the side CD

of



A. Bell Prin. Wal. Sculptor fecit

ies and ngles.

of 294 equal parts. Then let the side AD be drawn; and it will complete the figure like to the given. The measures of the angle A and D can be known by the protractor or line of chords, and the side AD by the line of equal parts; which will exactly answer to the corresponding angles and to the side of the primary figure.

After the very same manner, from the sides and angles given which bound any right-lined figure, a figure like to it may be drawn, and the rest of its sides and angles be known.

COROLLARY.

Hence any trigonometrical problem in right-lined triangles may be resolved by delineating the triangle from what is given concerning it, as in this proposition. The unknown sides are examined by a line of equal parts, and the angles by a protractor or line of chords.

PROPOSITION XXII.

The diameter of a circle being given, to find its circumference nearly.—The periphery of any polygon inscribed in the circle is less than the circumference, and the periphery of any polygon described about a circle is greater than the circumference. Whence Archimedes first discovered that the diameter was in proportion to the circumference, as 7 to 22 nearly; which serves for common use. But the moderns have computed the proportion of the diameter to the circumference to greater exactness. Supposing the diameter 100, the periphery will be more than 314, but less than 315. The diameter is more nearly to the circumference, as 113 to 355. But Ludolphus van Cuelen exceeded the labours of all; for by immense study he found, that supposing the diameter

100,000,000,000,000,000,000,000,000,000,000,000,

the periphery will be less than

314,159,265,358,979,323,846,264,338,327,951,

but greater than

314,159,265,358,979,323,846,264,338,327,950;

whence it will be ealy, any part of the circumference being given in degrees and minutes, to assign it in parts of the diameter.

CHAP. II. *Of Surveying and Mensuring of Land.*

HITHERTO we have treated of the measuring of angles and sides, whence it is abundantly easy to lay down a field, a plane, or an entire country; for to this nothing is requisite but the protraction of triangles, and of other plain figures, after having measured their sides and angles. But as this is esteemed an important part of practical geometry, we shall subjoin here an account of it with all possible brevity; suggesting withal, that a surveyor will improve himself more by one day's practice than by a great deal of reading.

PROPOSITION XXIII.

To explain what surveying is, and what instruments Surveyors use.—First, it is necessary that the surveyor view the field that is to be measured, and investigate its sides and angles, by means of an iron chain (having a particular mark at each foot of length, or at any number of feet, as may be most convenient for reducing lines or surfaces to the received measures), and the graphometer described above. Secondly, It is necessary to delineate the field *in plano*, or to form a map of it; that is, to lay down on paper a figure similar to the field; which is done by the protractor (or line of chords) and the line of equal parts. Thirdly, It is necessary to find out the area of the field so surveyed and represented by a map. Of this last we are to treat below. Surveying of Land.

The sides and angles of small fields are surveyed by the help of a plain-table: which is generally of an oblong rectangular figure, and supported by a *fulcrum*, so as to turn every way by means of a ball and socket. It has a moveable frame, which surrounds the board, and serves to keep a clean paper put on the board close and right to it. The sides of the frame facing the paper are divided into equal parts every way. The board hath besides a box with a magnetic needle, and moreover a large index with two sights. On the edge of the frame of the board are marked degrees and minutes, so as to supply the room of a graphometer.

PROPOSITION XXIV.

FIG. 8. *To delineate a field by the help of a plain-table, from one station whence all its angles may be seen and their distances measured by a chain.*—Let the field that is to be laid down be ABCDE. At any convenient place F, let the plain-table be erected; cover it with clean paper, in which let some point near the midde represent the station. Then applying at this place the index with the sights, direct it so as that through the sights some mark may be seen at one of the angles, suppose A; and from the point F, representing the station, draw a faint right line along the side of the index: then, by the help of the chain, let FA the distance of the station from the foresaid angle be measured. Then taking what part you think convenient for a foot or pace from the line of equal parts, set off on the faint line the parts corresponding to the line FA that was measured; and let there be a mark made representing the angle of the field A. Keeping the table immoveable, the same is to be done with the rest of the angles; then right lines joining those marks shall include a figure like to the field, as is evident from 5, 6. Euel.

COROLLARY.

The same thing is done in like manner by the graphometer: for having observed in each of the triangles, AFB, BFC, CFD, &c. the angle at the station F, and having measured the lines from the station to the angles of the field, let similar triangles be protracted on paper (by the 21. prop. of this), having their common vertex in the point of station. All the lines, excepting those which represent the sides of the field, are to be drawn faint or obscure.

Note 1. When a surveyor wants to lay down a field, let him place distinctly in a register all the observations of the angles, and the measures of the sides, until, at time and place convenient, he draw out the figure on paper.

Note 2. The observations made by the help of the graphometer are to be examined: for all the angles about the point F ought to be equal to four right ones. (by cor. 2. art. 30. of Part I.)

PROPOSITION XXV.

FIG. 9. *To lay down a field by means of two stations, from each of which all the angles can be seen, by measuring only the distance of the stations.*—Let the instrument be placed at the station F: and having chosen

Surveying of Land.

a point repreſenting it upon the paper which is laid upon the plain table, let the index be applied at this point, ſo as to be moveable about it. Then let it be directed ſucceſſively to the ſeveral angles of the field: and when any angle is ſeen through the ſights, draw an obſcure line along the ſide of the index. Let the index, with the ſights, be directed after the ſame manner to the ſtation G: on the obſcure line drawn along its ſide, pointing to A, ſet off from the ſcale of equal parts a line correſponding to the meaſured diſtance of the ſtations, and this will determine the point G. Then remove the inſtrument to the ſtation G, and applying the index to the line repreſenting the diſtance of the ſtations, place the inſtrument ſo that the firſt ſtation may be ſeen through the ſights. Then the inſtrument remaining immoveable, let the index be applied to the point repreſenting the ſecond ſtation G, and be ſucceſſively directed by means of its ſights to all the angles of the field, drawing (as before) obſcure lines: and the interſection of the two obſcure lines that were drawn to the ſame angle from the two ſtations will always repreſent that angle on the plan. Care muſt be taken that thoſe lines be not miſtaken for one another. Lines joining thoſe interſections will form a figure on the paper like to the field.

SCHOLIUM.

It will not be difficult to do the ſame by the graphometer, if you keep a diſtinct account of your obſervations of the angles made by the line joining the ſtations, and the lines drawn from the ſtations to the reſpective angles of the field. And this is the moſt common manner of laying down whole countries. The tops of two mountains are taken for two ſtations, and their diſtance is either meaſured by ſome of the methods mentioned above, or is taken according to common repute. The ſights are ſucceſſively directed towards cities, churches, villages, forts, lakes, turnings of rivers, woods, &c.

Note, The diſtance of the ſtations ought to be great enough, with reſpect to the field that is to be meaſured; ſuch ought to be choſen as are not in a line with any angle of the field. And care ought to be taken likewiſe that the angles, for example, FAG, FDG, &c. be neither very acute, nor very obtuſe. Such angles are to be avoided as much as poſſible; and this admonition is found very uſeful in practice.

PROPOSITION XXVI.

FIG. 10. *To lay down any field, however irregular its figure may be, by the help of the graphometer.*—Let ABCEDHG be ſuch a field. Let its angles (in going round it) be obſerved with a graphometer (by the 12. of this) and noted down; let its ſides be meaſured with a chain; and (by what was ſaid on the 21. of this) let a figure like to the given field be protracted on paper. If any mountain is in the circumference, the horizontal line hid under it is to be taken for a ſide, which may be found by two or three obſervations according to ſome of the methods deſcribed above; and its place on the map is to be diſtinguiſhed by a ſhade, that it may be known a mountain is there.

If not only the circumference of the field is to be laid down on the plan, but alſo its contents, as villages, gardens, churches, public roads, we muſt proceed in this manner.

Let there be (for example) a church F, to be laid down in the plan. Let the angles ABF BAF be obſerved and protracted on paper in their proper places, the interſection of the two ſides BF and AF will give the place of the church on the paper: or, more exactly, the lines BF AF being meaſured, let circles be deſcribed from the centres B and A, with parts from the ſcale correſponding to the diſtances BF and AF, and the place of the church will be at their interſection. Surveying of Land.

Note 1. While the angles obſerved by the graphometer are taken down, you muſt be careful to diſtinguiſh the external angles, as E and G, that they may be rightly protracted afterwards on paper.

Note 2. Our obſervations of the angles may be examined by computing if all the internal angles make twice as many right angles, four excepted, as there are ſides of the figure; (for this is demonſtrated by 32, 1. Euc.) But in place of any external angle DEC, its complement to a circle is to be taken.

PROPOSITION XXVII.

FIG. 11. *To lay down a plain field without inſtruments.*—If a ſmall field is to be meaſured, and a map of it to be made, and you are not provided with inſtruments; let it be ſuppoſed to be divided into triangles, by right-lines, as in the figure; and after meaſuring the three ſides of any of the triangles, for example of ABC, let its ſides be laid down from a convenient ſcale on paper, (by the 22. of this.) Again, let the other two ſides BD CD of the triangle CBD be meaſured and protracted on the paper by the ſame ſcale as before. In the ſame manner proceed with the reſt of the triangles of which the field is compoſed, and the map of the field will be perfected; for the three ſides of a triangle determine the triangle; whence each triangle on the paper is ſimilar to its correſpondent triangle in the field, and is ſimilarly ſituated; conſequently the whole figure is like to the whole field.

SCHOLIUM.

If the field be ſmall, and all its angles may be ſeen from one ſtation, it may be very well laid down by the plain-table, (by the 24. of this) If the field be larger, and have the requiſite conditions, and great exactneſs is not expected, it likewiſe may be plotted by means of the plain-table, or by the graphometer (according to the 25. of this); but in fields that are irregular and mountainous, when an exact map is required, we are to make uſe of the graphometer (as in the 26. of this), but rarely of the plain-table.

Having protracted the bounding lines, the particular parts contained within them may be laid down by the proper operations for this purpoſe (delivered in the 26th propoſition; and the method deſcribed in the 27th propoſition may be ſometimes of ſervice); for we may truſt more to the meaſuring of ſides than to the obſerving of angles. We are not to compute four-ſided and many-ſided figures till they are reſolved into triangles: for the ſides do not determine thoſe figures.

In the laying down of cities, or the like, we may make uſe of any of the methods deſcribed above that may be moſt convenient.

The map being finiſhed, it is transferred on clean paper, by putting the firſt ſketch above it, and marking the angles by the point of a ſmall needle. Theſe points being joined by right lines, and the whole illu-

Surveying of Land.

minated by colours proper to each part, and the figure of the mariner's compass being added to distinguish the north and south, with a scale on the margin, the map or plan will be finished and neat.

We have thus briefly and plainly treated of surveying, and shown by what instruments it is performed; having avoided those methods which depend on the magnetic needle, nut only because its direction may vary in different places of a field (the contrary of this at least doth not appear,) but because the quantity of an angle observed by it cannot be exactly known; for an error of two or three degrees can scarcely be avoided in taking angles by it.

As for the remaining part of surveying, whereby the area of a field already laid down on paper is found in acres, roods, or any other superficial measures; this we leave to the following section, which treats of the mensuration of surfaces.

"Besides the instruments described above, a surveyor ought to be provided with an off-set staff equal in length to 10 links of the chain, and divided into 10 equal parts. He ought likewise to have 10 arrows or small straight sticks near two feet long, shod with iron ferrils. When the chain is first opened, it ought to be examined by the off-set staff. In measuring any line, the leader of the chain is to have the 10 arrows at first setting out. When the chain is stretched in the line, and the near end touches the place from which you measure, the leader sticks one of the 10 arrows in the ground, at the far end of the chain. Then the leader leaving the arrow, proceeds with the chain another length; and the chain being stretched in the line, so that the near end touches the first arrow, the leader sticks down another arrow at his end of the chain. The line is preserved straight, if the arrows be always set so as to be in a right line with the place you measure from, and that to which you are going. In this manner they proceed till the leader have no more arrows. At the eleventh chain, the arrows are to be carried to him again, and he is to stick one of them into the ground, at the end of the chain. And the same is to be done at the 21. 31. 41. &c. chains, if there are so many in a right line to be measured. In this manner you can hardly commit an error in numbering the chains, unless of 10 chains at once.

The off-set staff serves for measuring readily the distances of any things proper to be represented in your plan, from the station-line, while you go along. These distances ought to be entered into your field-book, with the corresponding distances from the last station, and proper remarks, that you may be enabled to plot them justly, and be in no danger of mistaking one for another when you extend your plan. The field-book may be conveniently divided into five columns. In the middle column the angles at the several stations taken by the theodolite are to be entered, with the distances from the stations. The distances taken by the off-set staff, on either side of the station-line, are to be entered into columns on either side of the middle column, according to their position with respect to that line. The names and characters of the objects, with proper remarks, may be entered in columns on either side of these last.

"Because, in the place of the graphometer described by your author, surveyors now make use of the theodolite, we shall subjoin a description of Mr Sisson's latest improved theodolite from Mr Gardner's practical surveying improved. See a figure of it in Plate CCXVIII.

"In this instrument, the three staffs, by brass ferrils at top screw into bell-metal joints, that are moveable between brass pillars, fixed in a strong brass plate; in which, round the centre, is fixed a socket with a ball moveable in it, and upon which the four screws press, that set the limb horizontal: Next above is another such plate, through which the said screws pass, and on which, round the centre, is fixed a frustrum of a cone of bell-metal, whose axis (being connected with the centre of the bell) is always perpendicular to the limb, by means of a conical brass ferril fitted to it, whereon is fixed the compass-box; and on it the limb, which is a strong bell-metal ring, whereon are moveable three brass indexes, in whose plate are fixed four brass pillars, that, joining at top, hold the centre pin of the bell-metal double sextant, whose double index is fixed on the centre of the same plate: Within the double sextant is fixed the spirit level, and over it the telescope.

"The compass-box is graved with two diamonds for north and south, and with 20 degrees on both sides of each, that the needle may be set to the variation, and its error also known.

"The limb has two *fleurs de luce* against the diamonds in the box, instead of 180 each, and is curiously divided into whole degrees, and numbered to the left hand at every 10 to twice 180, having three indexes distant 120. (with Nonius's divisions on each for the decimals of a degree), that are moved by a pinion fixed below one of them, without moving the limb; and in another is a screw and spring under, to fix it to any part of the limb. It has also divisions numbered, for taking the quarter girt in inches of round timber at the middle height, when standing 10 feet horizontally distant from its centre; which at 20 must be doubled, and at 30 tripled; to which a shorter index is used, having Nonius's divisions for the decimals of an inch; but an abatement must be made for the bark, if not taken off.

"The double sextant is divided on one side from under its centre (when the spirit-tube and telescope are level) to above 60 degrees each way, and numbered at 10, 20, &c. and the double index (through which it is moveable) shows on the same side the degree and decimal of any altitude or depression to that extent by Nonius's divisions: On the other side are divisions numbered, for taking the upright height of timber, &c. in feet, when distant 10 feet; which at 20 must be doubled, and at 30 tripled; and also the quantities for reducing hypothenusal lines to horizontal. It is moveable by a pinion fixed in the double index.

"The telescope is a little shorter than the diameter of the limb, that a fall may not hurt it; yet it will magnify as much, and show a distant object as perfect as most of triple its length. In its focus are very fine cross wires, whose intersection is in the plane of the double sextant; and this was a whole circle, and turned in a lathe to a true plane, and is fixed at right angles to the limb; so that, whenever the limb is set horizontal (which is readily done by making the spirit-

Surveying of Land.

rit-tube level over two ſcrews, and the like over the other two), the double ſextant and teleſcope are moveable in a vertical plane; and then every angle taken on the limb (though the teleſcope be never ſo much elevated or depreſſed) will be an angle in the plane of the horizon. And this is abſolutely neceſſary in plotting a horizontal plane.

"If the lands to be plotted are hilly, and not in any one plane, the lines meaſured cannot be truly laid down on paper, without being reduced to one plane, which muſt be the horizontal, becauſe angles are taken in that plane.—

"In viewing your objects, if they have much altitude or depreſſion, either write down the degree and decimal ſhown on the double ſextant, or the links ſhown on the back ſide; which laſt ſubtracted from every chain in the ſtation-line, leaves the length in the horizontal plane. But if the degree is taken, the following table will ſhow the quantity.

A Table of the links to be ſubtracted out of every chain in hypothenuſal lines of ſeveral degrees altitude, or depreſſion, for reducing them to horizontal.

Degrees.	Links.	Degrees.	Links.	Degrees.	Links.
4,05	¼	14,07	3	23,074	8
5,73	½	16,26	4	24.495	9
7,02	¾	18,195	5	25,84	10
8,11	1	19,95	6	27,13	11
11,48	2	21,565	7	28,36	12

"Let the firſt ſtation line really meaſure 1107 links, and the angle of altitude or depreſſion be 19°, 95; looking in the table you will find againſt 19°, 95, is 6 links. Now 6 times 11 is 66, which ſubtracted from 1107, leaves 1041, the true length to be laid down in the plan.

It is uſeful in ſurveying, to take the angles, which the bounding lines form, with the magnetic needle, in order to check the angles of the figure, and to plot them conveniently afterwards."

Chap. III. *Of the Surfaces of Bodies.*

The ſmalleſt ſuperficial meaſure with us is a ſquare inch; 144 of which make a ſquare foot. Wrights make uſe of theſe in the meaſuring of deals and planks; but the ſquare foot which the glaziers uſe in meaſuring of glaſs, conſiſts only of 64 ſquare inches. The other meaſures are, firſt, the ell ſquare; ſecondly, the fall, containing 36 ſquare ells; thirdly, the rood, containing 40 falls; fourthly, the acre, containing 4 roods. Slaters, maſons, and pavers, uſe the ell ſquare and the fall; ſurveyors of land uſe the ſquare ell, the fall, the rood, and the acre.

The ſuperficial meaſures of the Engliſh are, firſt, the ſquare foot; ſecondly, the ſquare yard, containing 9 ſquare feet, for their yard contains only 3 feet; thirdly, the pole, containing 30¼ ſquare yards; fourthly, the rood, containing 40 poles; fifthly, the acre, containing 4 roods. And hence it is eaſy to reduce our ſuperficial meaſures to the Engliſh, or theirs to ours.

"In order to find the content of a field, it is moſt convenient to meaſure the lines by the chains deſcribed above, p. 671. that of 22 yards for computing the Engliſh acres, and that of 24 Scots ells for the acres of Scotland. The chain is divided into 100 links, and the ſquare of the chain is 10,000 ſquare links; 10 ſquares of the chain, or 100,000 ſquare links, give an acre. Therefore, if the area be expreſſed by ſquare links, divide by 100,000, or cut off five decimal places, and the quotient ſhall give the area in acres and decimals of an acre. Write the entire acres apart; but multiply the decimals of an acre by 4, and the product ſhall give the remainder of the area in roods and decimals of a rood. Let the entire roods be noted apart after the acres; then multiply the decimals of a rood by 40, and the product ſhall give the remainder of the area in falls or poles. Let the entire falls or poles be then writ after the roods, and multiply the decimals of a fall by 36, if the area is required in the meaſures of Scotland; but multiply the decimals of a pole by 30¼, if the area is required in the meaſures of England, and the product ſhall give the remainder of the area in ſquare ells in the former caſe, but in ſquare yards in the latter. If, in the former caſe, you would reduce the decimals of the ſquare ell to ſquare feet, multiply them by 9.50694; but, in the latter caſe, the decimals of the Engliſh ſquare yard are reduced to ſquare feet, by multiplying them by 9. Surfaces Bodies

"Suppoſe, for example, that the area appears to contain 12.65842 ſquare links of the chain of 24 ells; and that this area is to be expreſſed in acres, roods, falls, &c. of the meaſures of Scotland. Divide the ſquare links by 100,000, and the quotient 12.65842 ſhows the area to contain 12 acres $\frac{65842}{100000}$ of an acre. Multiply the decimal part by 4, and the product 2.63368 gives the remainder in roods and decimals of a rood. Thoſe decimals of the rood being multiplied by 40, the product gives 25.3472 falls. Multiply the decimals of the fall by 36, and the product gives 12.4992 ſquare ells. The decimals of the ſquare ell multiplied by 9.50994 give 4.7458 ſquare feet. Therefore the area propoſed amounts to 12 acres, 2 roods, 25 falls, 12 ſquare ells, and $4\frac{7458}{10000}$ ſquare feet.

"But if the area contains the ſame number of ſquare links of Gunter's chain, and is to be expreſſed by Engliſh meaſures, the acres and roods are computed in the ſame manner as in the former caſe. The poles are computed as the falls. But the decimals of the pole, *viz.* $\frac{3472}{10000}$, are to be multiplied by 30¼ (or 30.25), and the product gives 10.5028 ſquare yards. The decimals of the ſquare yard, multiplied by 9, give 4.5252 ſquare feet; therefore, in this caſe, the area is in Engliſh meaſure 12 acres, 2 roods, 25 poles, 10 ſquare yards, and $4\frac{5252}{10000}$ ſquare feet.

"The Scots acre is to the Engliſh acre, by ſtatute, as 100,000 to 78,694, if we have regard to the difference betwixt the Scots and Engliſh foot above mentioned. But it is cuſtomary in ſome parts of England to have 18.21, &c. feet to a pole, and 160 ſuch poles to an acre; whereas, by the ſtatute, 16½ feet make a pole. In ſuch caſes the acre is greater in the duplicate ratio of the number of feet to a pole.

"They who meaſure land in Scotland by an ell of 37 Engliſh inches, make the acre leſs than the true Scots acre by 593$\frac{6}{10}$ ſquare Engliſh feet, or by about $\frac{1}{37}$ of the acre.

"An huſband land contains 6 acres of ſock and ſcythe-land, that is, of land that may be tilled with a plough, and mown with a ſcythe; 13 acres of arable land

land make an oxgang or oxengate; four oxengate make a pound land of old extent (by a decree of the Exchequer, March 11. 1585), and is called *librata terræ*. A forty-ſhilling land of old extent contains 8 oxgang, or 104 acres.

" The arpent, about Paris, contains 32,400 ſquare Paris feet, and is equal to $2\frac{7}{9}$ Scots roods, or $3\frac{1}{65}$ Engliſh roods.

" The *actus quadratus*, according to Varro, Columella, &c. was a ſquare of 120 Roman feet. The *jugerum* was the double of this. It is to the Scots acre as 10,000 to 20,456, and to the Engliſh acre as 10,000 to 16,097. It was divided (like the *as*) into 12 *unciæ*, and the *uncia* into 24 *ſcrupula*."—This, with the three preceding paragraphs, are taken from an ingenious manuſcript, written by Sir Robert Stewart profeſſor of natural philoſophy. The greateſt part of the table in p. 671. was taken from it likewiſe.

PROPOSITION XXVIII.

Fig. 12. *To find out the area of a rectangular parallelogram* ABCD.—Let the ſide AB, for example, be 5 feet long, and BC (which conſtitutes with BA a right angle at B) be 17 feet. Let 17 be multiplied by 5, and the product 85 will be the number of ſquare feet in the area of the figure ABCD. But if the parallelogram propoſed is not rectangular as BEFC, its baſe BC multiplied into its perpendicular height AB (not into its ſide BE) will give its area. This is evident from art. 68. of Part I.

PROPOSITION XXIX.

Fig. 13. *To find the area of a given triangle.*—Let the triangle BAC be given, whoſe baſe BC is ſuppoſed 9 feet long: let the perpendicular AD be drawn from the angle A oppoſite to the baſe, and let us ſuppoſe AD to be 4 feet. Let the half of the perpendicular be multiplied into the baſe, or the half of the baſe into the perpendicular, or take the half of the product of the whole baſe into the perpendicular, the product gives 18 ſquare feet for the area of the given triangle.

But if only the ſides are given, the perpendicular is found either by protracting the triangle, or by 12th and 13th 2. Eucl. or by trigonometry. But how the area of a triangle may be found from the given ſides only, ſhall be ſhown in the 31ſt propoſition.

PROPOSITION XXX.

Fig. 14. *To find the area of any rectilineal figure.*—If the figure be irregular, let it be reſolved into triangles; and drawing perpendiculars to the baſes in each of them, let the area of each triangle be found by the preceding propoſition, and the ſum of theſe areas will give the area of the figure.

SCHOLIUM 1.

In meaſuring boards, planks, and glaſs, their ſides are to be meaſured by a foot-rule divided into 100 equal parts; and after multiplying the ſides, the decimal fractions are eaſily reduced to leſſer denominations. The menſuration of theſe is eaſy, when they are rectangular parallelograms.

SCHOLIUM 2.

If a field is to be meaſured, let it firſt be plotted on paper, by ſome of the methods above deſcribed, and let the figure ſo laid down be divided into triangles, as was ſhown in the preceding propoſition.

The baſe of any triangle, or the perpendicular upon the baſe, or the diſtance of any two points of the field, is meaſured by applying it to the ſcale according to which the map is drawn.

SCHOLIUM 3.

But if the field given be not in an horizontal plane, but uneven and mountainous, the ſcale gives the horizontal line between any two points, but not their diſtance meaſured on the uneven ſurface of the field. And indeed it would appear, that the horizontal plane is to be accounted the area of an uneven and hilly country. For if ſuch ground is laid out for building on, or for planting with trees, or bearing corn, ſince theſe ſtand perpendicular to the horizon, it is plain, that a mountainous country cannot be conſidered as of greater extent for thoſe uſes than the horizontal plane; nay, perhaps, for nouriſhing of plants, the horizontal plane may be preferable.

If, however, the area of a figure, as it lies regularly on the ſurface of the earth, is to be meaſured, this may be eaſily done by reſolving it into triangles as it lies. The ſum of their areas will be the area ſought; which exceeds the area of the horizontal figure more or leſs, according as the field is more or leſs uneven.

PROPOSITION XXXI.

Fig. 13. *The ſides of a triangle being given, to find the area, without finding the perpendicular.*—Let all the ſides of the triangle be collected into one ſum; from the half of which let the ſides be ſeparately ſubtracted, that three differences may be found betwixt the foreſaid half ſum and each ſide; then let theſe three differences and the half ſum be multiplied into one another, and the ſquare root of the product will give the area of the triangle. For example, let the ſides be 10, 17, 21; the half of their ſum is 24; the three differences betwixt this half ſum and the three ſides, are 14, 7, and 3. The firſt being multiplied by the ſecond, and their product by the third, we have 294 for the product of the differences; which multiplied by the foreſaid half ſum 24, gives 7056; the ſquare root of which 84 is the area of the triangle. The demonſtration of this, for the ſake of brevity, we omit. It is to be found in ſeveral treatiſes, particularly in Clavius's Practical Geometry.

PROPOSITION XXXII.

Fig. 15. *The area of the ordinate figure* ABEFGH *is equal to the product of the half circumference of the polygon, multiplied into the perpendicular drawn from the centre of the circumſcribed circle to the ſide of the polygon.*—For the ordinate figure can be reſolved into as many equal triangles as there are ſides of the figure; and ſince each triangle is equal to the product of half the baſe into the perpendicular, it is evident that the ſum of all the triangles together, that is the polygon, is equal to the product of half the ſum of the baſes (that is the half of the circumference of the polygon) into the common perpendicular height of the triangles drawn from the centre C to one of the ſides; for example, to AB.

PROPOSITION XXXIII.

Fig. 16. *The area of a circle is found by multiplying the half of the periphery into the radius, or the half of the radius into the periphery.* For a circle is not different from an ordinate or regular polygon of an infinite number of ſides, and the common height of the triangles in-

Surfaces of Bodies.

to which the polygon or circle may be fuppofed to be divided is the radius of the circle.

Were it worth while, it were eafy to demonftrate accurately this propofition, by means of the inferibed and circumferibed figures, as is done in the 5th prop. of the treatife of Archimedes concerning the dimenions of the circle.

COROLLARY.

Hence alfo it appears, that the area of the fector ABCD is produced by multiplying the half of the arc into the radius, and likewife that the area of the fegment of the circle ADC is found by fubtracting from the area of the fector the area of the triangle ABC.

PROPOSITION XXXIV.

FIG. 17. *The circle is to the fquare of the diameter as* 11 *to* 14 *nearly.*—For if the diameter AB be fuppofed to be 7, the circumference AHBK will be almoft 22 (by the 22d prop. of this Part), and the area of the fquare DC will be 49: and, by the preceding prop. the area of the circle will be 38½: therefore the fquare DC will be to the inferibed circle as 49 to 38½, or as 98 to 77, that is, as 14 to 11. *Q. E. D.*

If greater exactnefs is required, you may proceed to any degree of accuracy: for the fquare DC is to the inferibed circle, as 1 to $1-\frac{1}{3}+\frac{1}{5}-\frac{1}{7}+\frac{1}{9}-\frac{1}{11}+\frac{1}{13}$, &c. *in infinitum.*

"This feries will be of no fervice for computing the area of the circle accurately, without fome further artifice, becaufe it converges at too flow a rate. The area of the circle will be found exactly enough for moft purpofes, by multiplying the fquare of the diameter by 7854, and dividing by 10,000, or cutting off four decimal places from the product; for the area of the circle is to the circumferibed fquare nearly as 7854 to 10,000."

PROPOSITION XXXV.

FIG. 18. *To find the area of a given ellipfe.*—Let ABCD be an ellipfe, whofe greater diameter is BD, and the leffer AC, bifecting the greater perpendicularly in E. Let a mean proportional HF be found (by 13th 6. Euel.) between AC and BD, and (by the 33d of this) find the area of the circle deferibed on the diameter HF. This area is equal to the area of the ellipfe ABCD. For becaufe, as BD to AC, fo the fquare of BD to the fquare of HF, (by 2. cor. 20th 6. Euel.): but (by the 2d 12. Euel.) as the fquare of BD to the fquare of HF, fo is the circle of the diameter BD to the circle of the diameter HF: therefore as BD to AC, fo is the circle of the diameter BD to the circle of the diameter HF. And (by the 5th prop. of Archimedes of fpheroids) as the greater diameter BD to the leffer AC, fo is the circle of the diameter BD to the ellipfe ABCD. Confequently (by the 11th 5. Euel.) the circle of the diameter BD will have the fame proportion to the circle of the diameter HF, and to the ellipfe ABCD. Therefore (by 9th 5. Euel.) the area of the circle of the diameter HF will be equal to the area of the ellipfe ABCD. *Q. E. D.*

SCHOLIUM.

From this and the two preceding propofitions, a method is derived of finding the area of an ellipfe. There are two ways: 1ft, Say, as one is to the leffer diameter, fo is the greater diameter to a fourth number, (which is found by the rule of three). Then again fay, as 14 to 11, fo is the fourth number found to the area fought. But the fecond way is fhorter. Multiply the leffer diameter into the greater, and the product by 11; then divide the whole product by 14, and the quotient will be the area fought of the ellipfe. For example, Let the greater diameter be 10, and the leffer 7; by multiplying 10 by 7, the product is 70; and multiplying that by 11, it is 770; and dividing 770 by 14, the quotient will be 55, which is the area of the ellipfe fought.

"The area of the ellipfe will be found more accurately, by multiplying the product of the two diameters by 7854."

We fhall add no more about other plain furfaces, whether rectilinear or curvilinear, which feldom occur in practice; but fhall fubjoin fome propofitions about meafuring the furface of folids.

PROPOSITION XXXVI.

To meafure the furface of any prifm.—By the 14th definition of the 11th Euel. a prifm is contained by planes, of which two oppofite fides (commonly called the bafes) are plain rectilineal figures; which are either regular and ordinate, and meafured by prop. 32. of this; or however irregular, and then they are meafured by the 28th prop. The other fides are parallelograms, which are meafured by prop. 28th; and the whole fuperficies of the prifm conffits of the fum of thofe taken altogether.

PROPOSITION XXXVII.

To meafure the fuperficies of any pyramid.—Since its bafis is a rectilineal figure, and the reft of the planes terminating in the top of the pyramid are triangles; thefe meafured feparately, and added together, give the furface of the pyramid required.

PROPOSITION XXXVIII.

To meafure the fuperficies of any regular body.—Thefe bodies are called *regular*, which are bounded by equilateral and equiangular figures. The fuperficies of the tetraedon conffits of four equal and equiangular triangles; the fuperficies of the hexaedron or cube, of fix equal fquares; an octedron, of eight equal equilateral triangles; a dodecaedron, of twelve equal and ordinate pentagons; and the fuperficies of an icofiedron, of twenty equal and equilateral triangles. Therefore it will be eafy to meafure thefe furfaces from what has been already fhown.

In the fame manner we may meafure the fuperficies of a folid contained by any planes.

PROPOSITION XXXIX.

FIG. 19. *To meafure the fuperficies of a cylinder.*—Becaufe a cylinder differs very little from a prifm, whofe oppofite planes or bafes are ordinate figures of an infinite number of fides, it appears that the fuperficies of a cylinder, without the bafis, is equal to an infinite number of parallelograms; the common altitude of all which is the fame with the height of the cylinder, and the bafes of them all differ very little from the periphery of the circle which is the bafe of the cylinder. Therefore this periphery multiplied into the common height, gives the fuperficies of the cylinder, excluding the bafes; which are to be meafured feparately by the 33d propofition.

This propofition concerning the meafure of the furface of the cylinder (excluding its bafis) is evident from this, that when it is conceived to be fpread out,

it

Surfaces of Bodies.

it becomes a parallelogram, whose base is the periphery of the circle of the base of the cylinder stretched into a right line, and whose height is the same with the height of the cylinder.

PROPOSITION XL.

Fig. 20. *To measure the surface of a right cone.*—The surface of a right cone is very little different from the surface of a right pyramid, having an ordinate polygon for its base of an infinite number of sides; the surface of which (excluding the base) is equal to the sum of the triangles. The sum of the bases of these triangles is equal to the periphery of the circle of the base, and the common height of the triangles is the side of the cone AB; wherefore the sum of these triangles is equal to the product of the sum of the bases (i. e. the periphery of the base of the cone) multiplied into the half of the common height, or it is equal to the product of the periphery of the base.

If the area of the base is likewise wanted, it is to be found separately by the 33d prop. If the surface of a cone is supposed to be spread out on a plane, it will become a sector of a circle, whose radius is the side of the cone; and the arc terminating the sector is made from the periphery of the base. Whence, by corol. 33d prop. of this, its dimension may be found.

COROLLARY.

Hence it will be easy to measure the surface of a *frustum* of a cone cut by a plane parallel to the base.

PROPOSITION XLI.

Fig. 21. *To measure the surface of a given sphere.*—Let there be a sphere, whose centre is A, and let the area of its convex surface be required. Archimedes demonstrates (37th prop. 1. book of the sphere and cylinder) that its surface is equal to the area of four great circles of the sphere; that is, let the area of the great circle be multiplied by 4, and the product will give the area of the sphere; or (by the 20th 6. and 2d 12. of Eucl.) the area of the sphere given is equal to the area of a circle whose radius is the right line BC, the diameter of the sphere. Therefore having measured (by 33d prop.) the circle described with the radius BC, this will give the surface of the sphere.

PROPOSITION XLII.

Fig. 22. *To measure the surface of a segment of a sphere.*—Let there be a segment cut off by the plane ED. Archimedes demonstrates (49. and 50. 1. *De Sphæra*) that the surface of this segment, excluding the circular base, is equal to the area of a circle whose radius is the right line BE drawn from the vertex B of the segment to the periphery of the circle DE. Therefore (by the 33d prop.) it is easily measured.

COROLLARY 1.

Hence that part of the surface of a sphere that lieth between two parallel planes is easily measured, by subtracting the surface of the lesser segment from the surface of the greater segment.

COROLLARY 2.

Hence likewise it follows, that the surface of a cylinder, described about a sphere (excluding the basis) is equal to the surface of the sphere, and the parts of the one to the parts of the other, intercepted between planes parallel to the basis of the cylinder.

Gauging.

Chap. IV. *Of solid Figures and their Mensuration, comprehending likewise the Principles of Gauging Vessels of all Figures.*

As in the former part of this treatise we took an inch for the smallest measure in length, and an inch square for the smallest superficial measure; so now, in treating of the mensuration of solids, we take a cubical inch for the smallest solid measure. Of these, 109 make a Scots pint; other liquid measures depend on this, as is generally known.

In dry measures, the firlot, by statute, contains $19\frac{1}{3}$ pints; and on this depend the other dry measures: therefore, if the content of any solid be given in cubical inches, it will be easy to reduce the same to the common liquid or dry measures, and conversely to reduce these to solid inches. The liquid and dry measures, in use among other nations, are known from their writers.

"As to the English liquid measures, by act of parliament 1706, any round vessel commonly called a *cylinder*, having an even bottom, being seven inches in diameter throughout, and six inches deep from the top of the inside to the bottom (which vessel will be found by computation to contain 230,[illegible] cubical inches), or any vessel containing 231 cubical inches, and no more, is deemed to be a lawful wine-gallon. An English pint therefore contains $28\frac{7}{8}$ cubical inches; 2 pints make a quart; 4 quarts a gallon; 18 gallons a roundlet; 3 roundlets and an half, or 63 gallons, make a hogshead; the half of a hogshead is a barrel: 1 hogshead and a third, or 84 gallons, make a puncheon; 1 puncheon and a half, or 2 hogsheads, or 126 gallons, make a pipe or butt; the third part of a pipe, or 42 gallons, make a tierce; 2 pipes, or 3 puncheons, or 4 hogsheads, make a ton of wine. Though the English wine gallon is now fixed at 231 cubical inches, the standard kept in Guildhall being measured, before many persons of distinction, May 25. 1688, it was found to contain only 224 such inches.

"In the English beer-measure, a gallon contains 282 cubical inches; consequently $35\frac{1}{4}$ cubical inches make a pint, 2 pints make a quart, 4 quarts make a gallon, 9 gallons a firkin, 4 firkins a barrel. In ale, 8 gallons make a firkin, and 32 gallons make a barrel. By an act of the first of William and Mary, 34 gallons is the barrel, both for beer and ale, in all places, except within the weekly bill of mortality.

"In Scotland it is known that 4 gills make a mutchkin, 2 mutchkins make a chopin; a pint is two chopins; a quart is two pints; and a gallon is four quarts, or eight pints. The accounts of the cubical inches contained in the Scots pint vary considerably from each other. According to our author, it contains 109 cubical inches. But the standard jugs kept by the dean of guild of Edinburgh (one of which has the year 1555, with the arms of Scotland, and the town of Edinburgh, marked upon it) having been carefully measured several times, and by different persons, the Scots pint, according to those standards, was found to contain about 103,[illegible] cubic inches. The pewterers jugs (by which the vessels in common use are made) are said to contain sometimes betwixt 105 and 106 cubic inches. A cask that was measured by the brewers of Edinburgh, before the commissioners of ex-

 cise,

Gauging.

ciſe in 1707, was found to contain 46⅞ Scots pints; the ſame veſſel contained 18$\frac{1}{16}$ Engliſh ale-gallons. Suppoſing this menſuration to be juſt, the Scots pint will be to the Engliſh ale-gallon as 289 to 750; and if the Engliſh ale-gallons be ſuppoſed to contain 282 cubical inches, the Scots pint will contain 108.664 cubical inches. But it is ſuſpected, on ſeveral grounds, that the experiment was not made with ſufficient care and exactneſs.

"The commiſſioners appointed by authority of parliament to ſettle the meaſures and weights, in their act of Feb. 19. 1618, relate, That having caſed till the Linlithgow firlot with water, they found that it contained 21¼ pints of the juſt Stirling jug and meaſure. They likewiſe ordain that this ſhall be the juſt and only firlot; and add, *That the wideneſs and broadneſs of the which firlet, under and above even over within the buirds, ſhall contain nineteen inches and the ſixth part of an inch, and the deepneſs ſeven inches and a third part of an inch.* According to this act (ſuppoſing their experiment and computation to have been accurate) the pint contained only 99.56 cubical inches; for the content of ſuch a veſſel as is deſcribed in the act, is 2115.85, and this divided by 21¼ gives 99.56. But by the weight of water ſaid to fill this firlot in the ſame act, the meaſure of the pint agrees nearly with the Edinburgh ſtandard above mentioned.

"As for the Engliſh meaſures of corn, the Winchester gallon contains 272¼ cubical inches; 2 gallons make a peck; 4 pecks, or 8 gallons (that is, 2178 cubical inches), make a buſhel; and a quarter is 8 buſhels.

"Our author ſays, that 19½ Scots pints make a firlot. But this does not appear to be agreeable to the ſtatute above mentioned, nor to the ſtandard-jugs. It may be conjectured, that the proportion aſſigned by him has been deduced from ſome experiment of how many pints, according to common uſe, were contained in the firlot. For if we ſuppoſe thoſe pints to have been each of 108.664 cubical inches, according to the experiment made in the 1707 before the commiſſioners of exciſe, deſcribed above; then 19½ ſuch pints will amount to 2118.94, cubical inches; which agrees nearly with 2115.85, the meaſure of the firlot by ſtatute above mentioned. But it is probable, that in this he followed the act 1587, where it is ordained, That the wheat-firlot ſhall contain 19 pints and two joucattes. A wheat-firlot marked with the Linlithgow ſtamps being meaſured, was found to contain about 2211 cubical inches. By the ſtatute of 1618, the barley-firlot was to contain 31 pints of the juſt Stirling-jug.

"A Paris pint is 48 cubical Paris inches, and is nearly equal to an Engliſh wine-quart. The *Boiſſean* contains 664.68099 Paris cubical inches, or 780.36 Engliſh cubical inches.

"The Roman *amphora* was a cubical Roman foot, the *congius* was the eighth part of the *amphora*, the *ſextarius* was one-ſixth of the *congius*. They divided the *ſextarius* like the *as* or *libra*. Of dry meaſures, the *medimnus* was equal to two amphoras, that is, about 1$\frac{1}{15}$ Engliſh legal buſhels; and the *modius* was the third part of the *amphora*."

PROPOSITION XLIII.

To find the ſolid content of a given priſm.—By the 29th prop. let the area of the baſe of the priſm be meaſured, and be multiplied by the height of the priſm, the product will give the ſolid content of the priſm.

PROPOSITION XLIV.

To find the ſolid content of a given pyramid.—The area of the baſe being found (by the 30th prop.), let it be multiplied by the third part of the height of the pyramid, or the third part of the baſe by the height, the product will give the ſolid content, by 17th 12. Euel.

COROLLARY.

If the ſolid content of a *fruſtum* of a pyramid is required, firſt let the ſolid content of the entire pyramid be found; from which ſubtract the ſolid content of the part that is wanting, and the ſolid content of the broken pyramid will remain.

PROPOSITION XLV.

To find the content of a given cylinder.—The area of the baſe being found by prop. 33. if it be a circle, and by prop. 35. if it be an ellipſe (for in both caſes it is a cylinder), multiply it by the height of the cylinder, and the ſolid contents of the cylinder will be produced.

COROLLARY.

Fig. 23. And in this manner may be meaſured the ſolid content of veſſels and caſks not much different from a cylinder, as ABCD. If towards the middle EF it be ſomewhat groſſer, the area of the circle of the baſe being found (by 33d prop.) and added to the area of the middle circle EF, and the half of their ſum (that is, an arithmetical mean between the area of the baſe and the area of the middle circle) taken for the baſe of the veſſel, and multiplied into its height, the ſolid content of the given veſſel will be produced.

Note, That the length of the veſſel, as well as the diameters of the baſe, and of the circle EF, ought to be taken within the ſtaves; for it is the ſolid content within the ſtaves that is ſought.

PROPOSITION XLVI.

To find the ſolid content of a given cone.—Let the area of the baſe (found by prop 33) be multiplied into ⅓ of the height, the product will give the ſolid content of the cone; for by the 10th 12. Euel. a cone is the third part of a cylinder that has the ſame baſe and height.

PROPOSITION XLVII.

Fig. 24. 25. *To find the ſolid content of a* fruſtum *of a cone cut by a plane parallel to the plane of the baſe.*—Firſt, let the height of the entire cone be found, and thence (by the preceding prop.) its ſolid content; from which ſubtract the ſolid content of the cone cut off at the top, there will remain the ſolid content of the *fruſtum* of the cone.

How the content of the entire cone may be found, appears thus: Let ABCD be the *fruſtum* of the cone (either right or ſcalenous, as in the figures 2. and 3.) let the cone ECD be ſuppoſed to be completed; let AG be drawn parallel to DE, and let AH and EF be perpendicular on CD; it will be (by 2d 6. Euel.) as CG : CA :: CD : CE; but (by art. 72. of Part I.) as CA : AH :: CE : EF; conſequently (by 22d 5. Euel.)

as

as CG : AH : : CD : EF; that is, as the exceſs of the diameter of the leſſer baſe is to the height of the *fruſtum*, ſo is the diameter of the greater baſe to the height of the entire cone.

COROLLARY.

Fig. 26. Some caſks whoſe ſtaves are remarkably bended about the middle, and ſtrait towards the ends, may be taken for two portions of cones, without any conſiderable error. Thus ABEF is a *fruſtum* of a right cone, to whoſe baſe EF, on the other ſide, there is another ſimilar *fruſtum* of a cone joined, EDCF. The vertices of theſe cones, if they be ſuppoſed to be completed, will be found at G and H. Whence (by the preceding propoſition) the ſolid content of ſuch veſſels may be found.

PROPOSITION XLVIII.

Fig. 27. A cylinder circumſcribed about a ſphere, that is, having its baſe equal to a great circle of the ſphere, and its height equal to the diameter of the ſphere, is to the ſphere as 3 to 2.

Let ABEC be the quadrant of a circle, and ABDC the circumſcribed ſquare; and likewiſe the triangle ADC; by the revolution of the figure about the right line AC, as axis, a hemiſphere will be generated by the quadrant, a cylinder of the ſame baſe and height by the ſquare, and a cone by the triangle. Let theſe three be cut any how by the plane HF, parallel to the baſe AB; the ſection in the cylinder will be a circle whoſe radius is FH, in the hemiſphere a circle of the radius EF, and in the cone a circle of the radius GF.

By art. 69. of Part I. EA^q, or $HF^q = EF^q$ and FA^q taken together (but $AF^q = FG^q$, becauſe AC=CD); therefore the circle of the radius FH is equal to a circle of the radius EF, together with a circle of the radius GF; and ſince this is true every where, all the circles together deſcribed by the reſpective *radii* HF (that is, the cylinder) are equal to all the circles deſcribed by the reſpective *radii* EF and FG (that is, to the hemiſphere and the cone taken together); but (by the 10th 12. Eucl.) the cone generated by the trinagle DAC is one third part of the cylinder generated by the ſquare BC. Whence it follows, that the hemiſphere generated by the rotation of the quadrant ABEC is equal to the remaining two third parts of the cylinder, and that the whole ſphere is $\frac{2}{3}$ of the double cylinder, circumſcribed about it.

This is that celebrated 39th prop. 1. book of Archimedes of the ſphere and cylinder; in which he determines the proportion of the cylinder to the ſphere inſcribed to be that of 3 to 2.

COROLLARY.

Hence it follows, that the ſphere is equal to a cone whoſe height is equal to the ſemidiameter of the ſphere, having for its baſe a circle equal to the ſuperficies of the ſphere, or to four great circles of the ſphere, or to a circle whoſe radius is equal to the diameter of the ſphere (by prop. 41. of this.) And indeed a ſphere differs very little from the ſum of an infinite number of cones that have their baſes in the ſurface of the ſphere, and their common vertex in the centre of the ſphere; ſo that the ſuperficies of the ſphere (of whoſe dimenſion ſee prop. 41. of this) multiplied into the third part of the ſemidiameter, gives the ſolid content of the ſphere.

PROPOSITION XLIX.

Fig. 28. *To find the ſolid content of a ſector of the ſphere.*—A ſpherical ſector ABC (as appears by the corollary of the preceding prop.) is very little different from an infinite number of cones, having their baſes in the ſuperficies of the ſphere BEC, and their common vertex in the centre. Wherefore the ſpherical ſuperficies BEC being found (by prop. 42. of this), and multiplied into the third part of AB the radius of the ſphere, the product will give the ſolid content of the ſector ABC.

COROLLARY.

It is evident how to find the ſolidity of a ſpherical ſegment leſs than a hemiſpherical, by ſubtracting the cone ABC from the ſector already found. But if the ſpherical ſegment be greater than a hemiſphere, the cone correſponding muſt be added to the ſector, to make the ſegment.

PROPOSITION L.

Fig. 29. *To find the ſolidity of the ſpheroid, and of its ſegments cut by planes perpendicular to the axis.*—

In prop. 44. of this, it is ſhown, that every where EH : EG : : CF : CD; but circles are as the ſquares deſcribed upon their rays, that is, the circle of the radius EH is to the circle of the radius EG, as CF^q to CD^q. And ſince it is ſo every where, all the circles deſcribed with the reſpective rays EH (that is, the ſpheroid made by the rotation of the ſemi-ellipſis AFB around the axis AB) will be to all the circles deſcribed by the reſpective *radii* EG (that is, the ſphere deſcribed by the rotation of the ſemicircle ADB on the axis AB) as FC^q to CD^q; that is, as the ſpheroid to the ſphere on the ſame axis, ſo is the ſquare of the other axis of the generating ellipſe to the ſquare of the axis of the ſphere.

And this holds, whether the ſpheroid be found by a revolution around the greater or leſſer axis.

COROLLARY 1.

Hence it appears, that the half of the ſpheroid, formed by the rotation of the ſpace AHFC around the axis AC, is double of the cone generated by the triangle AFC about the ſame axis; which is the 32d prop. of Archimedes of conoids and ſpheroids.

COROLLARY 2.

Hence, likewiſe, is evident the meaſure of ſegments of the ſpheroid cut by planes perpendicular to the axis. For the ſegment of the ſpheroid made by the rotation of the ſpace ANHE, round the axis AE, is to the ſegment of the ſphere having the ſame axis AC, and made by the rotation of the ſegment of the circle AMGE, as CF^q to CD^q.

But if the meaſure of this ſolid be wanted with leſs labour, by the 34th prop. of Archimedes of conoids and ſpheroids, it will be as BE to AC+EB; ſo is the cone generated by the rotation of the triangle AHE round the axis AE, to the ſegment of the ſphere made by the rotation of the ſpace ANHE round the ſame axis AE; which could eaſily be demonſtrated by the method of indiviſibles.

COROLLARY 3.

Hence it is eaſy to find the ſolid content of the ſegment of a ſphere or ſpheroid intercepted between two parallel planes, perpendicular to the axis. This agrees as well to the oblate as to the oblong ſpheroid; as is obvious.

COROLLARY 4.

Fig. 30. If a cask is to be valued as the middle piece of an oblong spheroid, cut by the two planes DC and FG, at right angles to the axis: first, let the solid content of the half spheroid ABCED be measured by the preceding prop. from which let the solidity of the segment DEC be subtracted, and there will remain the segment ABCD; and this doubled will give the capacity of the cask required.

The following method is generally made use of for finding the solid content of such vessels. The double area of the greatest circle, that is, of that which is described by the diameter AB at the middle of the cask, is added to the area of the circle at the end, that is, of the circle DC or FG (for they are usually equal), and the third part of this sum is taken for a mean base of the cask; which therefore multiplied into the length of the cask OP, gives the content of the vessel required.

Sometimes vessels have other figures, different from those we have mentioned; the easy methods of measuring which may be learned from those who practise this art. What hath already been delivered is sufficient for our purpose.

PROPOSITION LI.

Fig. 31. and 32. *To find how much is contained in a vessel that is in part empty, whose axis is parallel to the horizon.*—Let AGBH be the great circle in the middle of the cask, whose segment GBH is filled with liquor, the segment GAH being empty; the segment GBH is known, if the depth EB be known, and EH a mean proportional between the segments of the diameter AB and EB; which are found by a rod or ruler put into the vessel at the orifice. Let the basis of the cask at a medium be found, which suppose to be the circle CKDL; and let the segment KCL be similar to the segment GAH (which is either found by the rule of three, because as the circle AGBH is to the circle CKDL, so is the segment GAH to the segment KCL; or is found from the tables of segments made by authors); and the product of this segment multiplied by the length of the cask will give the liquid content remaining in the cask.

PROPOSITION LII.

To find the solid content of a regular and ordinate body.—A tetraedon being a pyramid, the solid content is found by the 44th prop. The hexaedron, or cube, being a kind of prism, it is measured by the 43d prop. An octaedron consists of two pyramids of the same square base, and of equal heights; consequently its measure is found by the 44th prop. A dodecaedron consists of 12 pyramids having equal equilateral and equiangular pentagonal bases; and so one of these being measured (by the 44th prop. of this), and multiplied by 12, the product will be equal to the solid content of the dodecaedron. The icosiaedron consists of 20 equal pyramids having triangular bases; the solid content of one of which being found (by the 44th prop.), and multiplied by 20, gives the whole solid. The bases and heights of these pyramids, if you want to proceed more exactly, may be found by trigonometry. See Trigonometry.

PROPOSITION LIII.

To find the solid content of a body however irregular.—Let the given body be immersed into a vessel of water, having the figure of a parallelopipedon or prism, and let it be noted how much the water is raised upon the immersion of the body. For it is plain, that the space which the water fills, after the immersion of the body, exceeds the space filled before its immersion, by a space equal to the solid content of the body, however irregular. But when this excess is of the figure of a parallelopipedon or prism, it is easily measured by the 43d prop. of this, *viz.* by multiplying the area of the base, or mouth of the vessel, into the difference of the elevations of the water before and after immersion: Whence is found the solid content of the body given.

In the same way the solid content of a part of a body may be found, by immersing that part only in water.

There is no necessity to insist here on diminishing or enlarging solid bodies in a given proportion. It will be easy to deduce these things from the 11th and 12th books of Euclid.

"The following rules are subjoined for the ready computation of contents of vessels, and of any solids in the measures in use in Great Britain.

"I. To find the content of a cylindric vessel in English wine gallons, the diameter of the base and altitude of the vessel being given in inches and decimals of an inch.

"Square the number of inches in the diameter of the vessel; multiply this square by the number of inches in the height: then multiply the product by the decimal fraction .0034; and this last product shall give the content in wine-gallons and decimals of such a gallon. To express the rule arithmetically; let D represent the number of inches and decimals of an inch in the diameter of the vessel, and H the decimals of an inch in the height of the vessel; then the content in wine-gallons shall be $DDH \times \frac{3,4}{1000}$, or DDH× .0034. *Ex.* Let the diameter D=51.2 inches, the height H=62.3 inches, then the content shall be 51.2×51.2×62.3×.0034=555.27.332 wine-gallons. This rule follows from prop. 33. and 45. For by the former, the area of the base of the vessel is in square inches DD×.7854; and by the latter, the content of the vessel in solid inches is DDH×.7854; which divided by 231 (the number of cubical inches in a wine-gallon) gives DDH×.0034, the content in wine gallons. But though the charges in the excise are made (by statute) on the supposition that the wine-gallon contains 231 cubical inches; yet it is said, that in sale 224 cubical inches, the content of the standard measured at Guildhall (as was mentioned above), are allowed to be a wine-gallon.

"II. Supposing the English ale-gallon to contain 282 cubical inches, the content of a cylindric vessel is computed in such gallons, by multiplying the square of the diameter of a vessel by its height as formerly, and their product by the decimal fraction .0,027,851: that is, the solid content in ale-gallons is DDH× .0,027,851.

"III. Supposing the Scots pint to contain about 103.4 cubical inches (which is the measure given by the standards at Edinburgh, according to experiments mentioned above), the content of a cylindric vessel is computed in Scots pints, by multiplying the square of the diameter of the vessel by its height, and the product

Gauging. duct of these by the decimal fraction .0076. Or the content of such a vessel in Scots pints is DDH× 0.076.

"Supposing the Winchester bushel to contain 2187 cubical inches, the content of a cylindric vessel is computed in those bushels by multiplying the square of the diameter of the vessel by the height, and the product by the decimal fraction .0,003,606. But the standard bushel having been measured by Mr Everard and others in 1696, it was found to contain only 2145.6 solid inches; and therefore it was enacted in the act for laying a duty upon malt, *That every round bushel, with a plain and even bottom, being* 18½ *inches diameter throughout, and* 8 *inches deep, should be esteemed a legal* Winchester *bushel*. According to this act (ratified in the first year of queen Anne) the legal Winchester bushel contains only 2150.42 solid inches. And the content of a cylindric vessel is computed in such bushels, by multiplying the square of the diameter by the height, and their product by the decimal fraction .0,003,625. Or the content of the vessel in those bushels is DDH×.0,003,625.

"V. Supposing the Scots wheat-firlot to contain 21¼ Scots pints (as is appointed by the statute 1618), and the pint to be conform to the Edinburgh standards above mentioned, the contents of a cylindric vessel in such firlots is computed by multiplying the square of the diameter by the height, and their product by the decimal fraction .00,358. This firlot, in 1426, is appointed to contain 17 pints; in 1457, it was appointed to contain 18 pints; in 1587, it is 19¼ pints; in 1628, it is 21¼ pints: and though this last statute appears to have been founded on wrong computations in several respects, yet this part of that act that relates to the number of pints in the firlot seems to be the least exceptionable; and therefore we suppose the firlot to contain 21¼ pints of the Edinburgh standard, or about 2197 cubical inches; which a little exceeds the Winchester bushel, from which it may have been originally copied.

"VI. Supposing the bear-firlot to contain 31 Scots pints (according to the statute 1618), and the pint conform to the Edinburgh standards, the content of a cylindric vessel in such firlots is found by multiplying the square of the diameter by the height, and this product by .000245.

"When the section of the vessel is not a circle, but an ellipsis, the product of the greatest diameter by the least is to be substituted in those rules for the square of the diameter.

"VII. To compute the content of a vessel that may be considered as a frustum of a cone in any of those measures.

"Let A represent the number of inches in the diameter of the greater base, B the number of inches in the diameter of the lesser base. Compute the square of A, the product of A multiplied by B, and the square of B, and collect these into a sum. Then find the third part of this sum, and substitute it in the preceding rules in the place of the square of the diameter; and proceed in all other respects as before. Thus, for example, the content in wine-gallons in AA×AB×BB×$\frac{1}{3}$×HX.0034.

"Or, to the square of half the sum of the diameters A and B, add one-third part of the square of half their difference, and substitute this sum in the preceding rules for the square of the diameter of the vessel; for the square of $\frac{1}{2}$A×$\frac{1}{2}$B added to $\frac{1}{3}$ of the square of $\frac{1}{2}$A—$\frac{1}{2}$B, gives $\frac{7}{12}$AA×$\frac{1}{6}$AB×$\frac{1}{12}$BB. Gauging.

"VIII. When a vessel is a frustum of a parabolic conoid, measure the diameter of the section at the middle of the height of the frustum; and the content will be precisely the same as of a cylinder of this diameter of the same height with the vessel.

"IX. When a vessel is a frustum of a sphere, if you measure the diameter of the section at the middle of the height of the frustum, then compute the content of a cylinder of this diameter of the same height with the vessel, and from this subtract $\frac{1}{3}$ of the content of a cylinder of the same height on a base whose diameter is equal to its height; the remainder will give the content of the vessel. That is, if D represent the diameter of the middle section, and H the height of the frustum, you are to substitute DD—$\frac{1}{3}$HH for the square of the diameter of the cylindric vessel in the first six rules.

"X. When the vessel is a frustum of a spheroid, if the bases are equal, the content is readily found by the rule in p. 685. In other cases, let the axis of the solid be to the conjugate axis as *n* to 1; let D be the diameter of the middle section of the frustum, H the height or length of the frustum; and substitute in the first six rules DD—$\frac{HH}{3nn}$ for the square of the diameter of the vessel.

"XI. When the vessel is an hyperbolic conoid, let the axis of the solid be to the conjugate axis as *n* to 1, D the diameter of the section at the middle of the frustum, H the height or length: compute DD×$\frac{1}{3n}$×HH, and substitute this sum for the square of the diameter of the cylindric vessel in the first six rules.

"XII. In general, it is usual to measure any round vessel, by distinguishing it into several frustums, and taking the diameter of the section at the middle of each frustum; thence to compute the content of each, as if it was a cylinder of that mean diameter; and to give their sum as the content of the vessel. From the total content, computed in this manner, they subtract successively the numbers which express the circular areas that correspond to those mean diameters, each as often as there are inches in the altitude of the frustum to which it belongs, beginning with the uppermost; and in this manner calculate a table for the vessel, by which it readily appears how much liquor is at any time contained in it, by taking either the dry or wet inches; having regard to the inclination or drip of the vessel when it has any.

"This method of computing the content of a frustum from the diameter of the section at the middle of its height, is exact in that case only when it is a portion of a parabolic conoid; but in such vessels as are in common use, the error is not considerable. When the vessel is a portion of a cone or hyperbolic conoid, the content by this method is found less than the truth; but when it is a portion of a sphere or spheroid, the content computed in this manner exceeds the truth. The difference or error is always the same in the different parts of the same or of similar vessels, when the altitude of the frustum is given. And when the altitudes are different, the error is in the triplicate ratio of

Gauging. of the altitude. If exactneſs be required, the error in meaſuring the fruſtum of a conical veſſel in this manner is $\frac{1}{4}$ of the content of a cone ſimilar to the veſſel, of an altitude equal to the height of the fruſtum. In a ſphere, it is $\frac{1}{7}$ of a cylinder of a diameter and height equal to the fruſtum. In the ſpheroid and hyperbolic conoid, it is the ſame as in a cone generated by the right-angled triangle, contained by the two ſemiaxes of the figure, revolving about that ſide which is the ſemiaxis of the fruſtum.

" In the uſual method of computing a table for a veſſel, by ſubducting from the whole content the number that expreſſes the uppermoſt area as often as there are inches in the uppermoſt fruſtum, and afterwards the numbers for the other areas ſucceſſively; it is obvious, that the contents aſſigned by the table, when a few of the uppermoſt inches are dry, are ſtated a little too high if the veſſel ſtands upon its baſe, but too low when it ſtands on its greater baſe; becauſe, when one inch is dry, for example, it is not the area at the middle of the uppermoſt fruſtum, but rather the area at the middle of the uppermoſt inch, that ought to be ſubducted from the total content, in order to find the content in this caſe.

" XIII. To meaſure round timber: Let the mean circumference be found in feet and decimals of a foot; ſquare it; multiply this ſquare by the decimal .079,577, and the product by the length. *Ex.* Let the mean circumference of a tree be 10 3 feet, and the length 24 feet. Then 10 3×10 3×.079,577×24=202.615, is the number of cubical feet in the tree. The foundation of this rule is, that when the circumference of a circle is 1, the area is .0,795,774,715, and that the areas of circles are as the ſquares of their circumferences.

" But the common way uſed by artificers for meaſuring round timber, differs much from this rule. They call one fourth part of the circumference the *girt*, which is by them reckoned the ſide of a ſquare, whoſe area is equal to the area of the ſection of the tree; therefore they ſquare the *girt*, and then multiply by the length of the tree. According to their method, the tree of the laſt example would be computed at 159.13 cubical feet only.

" How ſquare timber is meaſured, will be eaſily underſtood from the preceding propoſitions. Fifty ſolid feet of hewn timber, and forty of rough timber, make a load.

" XIV. To find the burden of a ſhip, or the number of tons it will carry, the following rule is commonly given. Multiply the length of the keel taken within board, by the breadth of the ſhip within board, taken from the midſhip beam from plank to plank, and the product by the depth of the hold, taken from the plank below the keelſon to the under part of the upper deck plank, and divide the product by 94, the quotient is the content of the tonnage required. This rule, however, cannot be accurate; nor can one rule be ſuppoſed to ſerve for the meaſuring exactly the burden of ſhips of all ſorts. Of this the reader will find more in the Memoirs of the Royal Academy of Sciences at Paris for the year 1721. Gauging

" Our author having ſaid nothing of weights, it may be of uſe to add briefly, that the Engliſh Troy-pound contains 12 ounces, the ounce 20 penny-weight, and the penny-weight 24 grains; that the Averdupois pound contains 16 ounces, the ounce 16 drams, and that 112 pounds is uſually called the hundred weight. It is commonly ſuppoſed, that 14 pounds Averdupois are equal to 17 pounds Troy. According to Mr Everard's experiments, 1 pound Averdupois is equal to 14 ounces 12 penny-weight and 16 grains Troy, that is, to 7000 grains; and an Averdupois ounce is $437\frac{1}{2}$ grains. The Scots Troy-pound (which, by the ſtatute 1718, was to be the ſame with the French) is commonly ſuppoſed equal to $15\frac{3}{4}$ ounces Engliſh Troy, or 7560 grains. By a mean of ſtandards kept by the dean of guild at Edinburgh, it is $7599\frac{3}{17}$ or 7600 grains. They who have meaſured the weights which were ſent from London after the union of the kingdoms to be the ſtandards by which the weights in Scotland ſhould be made, have found the Engliſh Averdupois pound (from a medium of the ſeveral weights) to weigh 7000 grains, the ſame as Mr Everard; according to which, the Scots, Paris, or Amſterdam pound, will be to the pound Averdupois as 38 to 35. The Scots Troy-ſtone contains 16 pounds, the pound 2 marks or 16 ounces, an ounce 16 drops, a drop 36 grains. Twenty Scots ounces make a Tron-pound; but becauſe it is uſual to allow one to the ſcore, the Tron-pound is commonly 21 ounces. Sir John Skene, however, makes the Tron-ſtone to contain only $19\frac{1}{2}$ pounds."

GEO

George. GEORGE I. II. and III. kings of Great Britain.—George I. the ſon of Erneſt Auguſtus, duke of Brunſwick Lunenburgh, and elector of Hanover; ſucceeded to the throne of Great Britain in 1714, in virtue of an act of parliament, paſſed in the latter part of the reign of king William III limiting the ſucceſſion of the crown, after the demiſe of that monarch, and queen Anne (without iſſue), to the princeſs Sophia of Hanover, and the heirs of her body, being Proteſtants.—George II. the only ſon of the former, ſucceeded him in 1727, and enjoyed a long reign of glory; dying amidſt the moſt rapid and extenſive conqueſts in the 77th year of his age. He was ſucceeded by

GEO

his grandſon George III. our preſent ſovereign. For particulars, ſee BRITAIN, n° 374—701. Georg

GEORGE, or *Knights of St GEORGE*, has been the denomination of ſeveral military orders, whereof that of the garter is one of the moſt illuſtrious. See GARTER, and *St GEORGE*, below.

King GEORGE's Iſlands, are two iſlands in the South Sea, lying in W. Long. 144. 56. S. Lat. 14. 28. They were firſt diſcovered by commodore Byron in 1765, and have ſince been viſited by Captain Cook in 1774. Commodore Byron's people had an encounter with the inhabitants, which proved fatal to ſome of the natives; but Captain Cook was more fortunate. A lieutenant

and

George. and two boats well armed were ſent on ſhore by Captain Cook*; and landed without oppoſition. As ſoon as the gentlemen landed, the iſlanders embraced them by touching noſes, a mode of civility uſed in New Zealand, which is 900 leagues diſtant, and the only place beſides this where the cuſtom has been obſerved to prevail. Notwithſtanding this ceremony, however, very little real friendſhip ſeemed to take place on the part of the iſlanders. They crowded about the boats as the people were ſtepping into them, and ſeemed in doubt whether they ſhould detain them or let them go; at laſt, however, not thinking themſelves ſufficiently ſtrong, they ſeemed contented with their departure, and aſſiſted them in puſhing off their boats; but ſome of the moſt turbulent threw ſtones into the water which fell very near them, and all ſeemed to glory that they had as it were driven them off. The Britiſh, however, brought off five dogs of a white colour with fine long hair, with which the iſland ſeemed to be plentifully ſupplied. Theſe they purchaſed with ſmall nails, and ſome ripe bananas which had been brought from the Marqueſas. On this iſland Mr Foreſter found a kind of ſcurvy-graſs, which the natives informed him they were wont to bruiſe and mix with ſhell-fiſh; after which, they threw it into the ſea whenever they perceived a ſhoal of fiſh. This preparation intoxicates them for ſome time; and thus they are caught on the ſurface of the water without any other trouble than that of taking them out. The name of this plant among the natives is *e now*. The largeſt iſland, which they call *Tiookea*, is ſomething of an oval ſhape, and about 10 leagues in circuit; the other iſland, which lies two leagues to the weſtward of Tiookea, is four leagues long from north-eaſt to ſouthweſt, and from five to three miles broad. The ſoil of both is extremely ſcanty; the foundation conſiſts of coral, very little elevated above the ſurface of the water.

GEORGE (St) or *GEORGE of Cappadocia*; a name whereby ſeveral orders, both military and religious, are denominated. It took its riſe from a ſaint or hero famous throughout all the Eaſt, called by the Greeks Μεγαλομάρτυς, q. d. *great martyr*.

On ſome medals of the emperors John and Manuel Comneni, we have the figure of St George armed, holding a ſword or javelin in one hand, and in the other a buckler, with this inſcription; an O, and therein a little P A, and ΓΕ—ΓΙΟC, making Ο ΑΓΙΟΣ ΓΕΩΡΓΙΟΣ, *O holy George*. He is generally repreſented on horſeback, as being ſuppoſed to have frequently engaged in combats in that manner. He is highly venerated throughout Armenia, Muſcovy, and all the countries which adhere to the Greek rite: from the Greek, his worſhip has long ago been received into the Latin church; and England and Portugal have both choſen him for their patron ſaint.

Great difficulties have been raiſed about this ſaint or hero. His very exiſtence has been called in queſtion. Dr Heylin, who wrote firſt and moſt about him, concluded with giving him entirely up, and ſuppoſing him only a ſymbolical device; and Dr Pettingal has turned him into a mere Baſilidian ſymbol of victory. Mr Pegg, in a paper in the Archæologia*, has attempted to reſtore him. And, finally, Mr Gibbon † has ſunk him into an Arian biſhop in the reigns of Conſtantius and Julian.—The biſhop alluded to,

Vol. I. 1.

Hiſt. vol. II. 404.

GEORGE the Cappadocian, was ſo ſurnamed, according to our author, from his parents or education; and was born at Epiphania in Cilicia, in a fuller's ſhop. "From this obſcure and ſervile origin he raiſed himſelf by the talents of a paraſite: and the patrons, whom he aſſiduouſly flattered, procured for their worthleſs dependent a lucrative commiſſion, or contract, to ſupply the army with bacon. His employment was mean: he rendered it infamous. He accumulated wealth by the baſeſt arts of fraud and corruption; but his malverſations were ſo notorious, that George was compelled to eſcape from the purſuits of juſtice. After this diſgrace, in which he appears to have ſaved his fortune at the expence of his honour, he embraced, with real or affected zeal, the profeſſion of Arianiſm. From the love, or the oſtentation, of learning, he collected a valuable library of hiſtory, rhetoric, philoſophy, and theology; and the choice of the prevailing faction promoted George of Cappadocia to the throne of Athanaſius." His conduct in this ſtation is repreſented by our hiſtorian as polluted by cruelty and avarice, and his death conſidered as a juſt puniſhment for the enormities of his life, among which Mr Gibbon ſeems to rank his "enmity to the Gods." George.

The immediate occaſion of his death, however, as narrated by eccleſiaſtical writers, will not probably appear calculated to add any ſtain to his memory. "There was in the city of Alexandria a place in which the heathen prieſts had been uſed to offer human ſacrifices. This place, as being of no uſe, Conſtantius gave to the church of Alexandria, and George the biſhop gave orders for it to be cleared, in order to build a Chriſtian church on the ſpot. In doing this they diſcovered an immenſe ſubterraneous cavern, in which the heathen myſteries had been performed, and in it were many human ſkulls. Theſe, and other things which they found in the place, the Chriſtians brought out and expoſed to public ridicule. The heathens, provoked at this exhibition, ſuddenly took arms, and ruſhing upon the Chriſtians, killed many of them with ſwords, clubs, and ſtones: ſome alſo they ſtrangled, and ſeveral they crucified. On this the Chriſtians proceeded no farther in clearing the temple; but the heathens, purſuing their advantage, ſeized the biſhop as he was in the church, and put him in priſon. The next day they diſpatched him; and then faſtening the body to a camel, he was dragged about the ſtreets all day, and in the evening they burnt him and the camel together. This fate, Sozomen ſays, the biſhop owed in part to his haughtineſs while he was in favour with Conſtantius, and ſome ſay the friends of Athanaſius were concerned in this maſſacre; but he aſcribes it chiefly to the inveteracy of the heathens, whoſe ſuperſtitions he had been very active in aboliſhing.

"This George, the Arian biſhop of Alexandria, was a man of letters, and had a very valuable library, which Julian ordered to be ſeized for his own uſe; and in his orders concerning it, he ſays that many of the books were on philoſophical and rhetorical ſubjects, though many of them related to the doctrine of the impious Galileans (as in his ſneering contemptuous way he always affected to call the Chriſtians). 'Theſe books (ſays he) I could wiſh to have utterly deſtroyed; but leſt books of value ſhould be deſtroyed along with them, let theſe alſo be carefully ſought for.'

George. But Mr Gibbon gives a different turn to the affair of George's murder, as well as relates it with different circumſtances. "The Pagans (ſays he) excited his devout avarice; and the rich temples of Alexandria were either pillaged or inſulted by the haughty prelate, who exclaimed, in a loud and threatening tone, 'How long will theſe ſepulchres be permitted to ſtand?' Under the reign of Conſtantius, he was expelled by the fury, or rather by the juſtice, of the people; and it was not without a violent ſtruggle, that the civil and military powers of the ſtate could reſtore his authority, and gratify his revenge. The meſſenger who proclaimed at Alexandria the acceſſion of Julian, announced the downfall of the archbiſhop. George, with two of his obſequious miniſters, count Diodorus, and Dracontius maſter of the mint, was ignominiouſly dragged in chains to the public priſon. At the end of 24 days, the priſon was forced open by the rage of a ſuperſtitious multitude, impatient of the tedious forms of judicial proceedings. The *enemies of gods* and men expired under their cruel inſults; the lifeleſs bodies of the archbiſhop and his aſſociates were carried in triumph through the ſtreets on the back of a camel; and the inactivity of the Athanaſian party was eſteemed a ſhining example of evangelical patience. The remains of theſe guilty wretches were thrown into the ſea; and the popular leaders of the tumult declared their reſolution to diſappoint the devotion of the Chriſtians, and to intercept the future honours of theſe martyrs, who had been puniſhed, like their predeceſſors, by the enemies of their religion. The fears of the Pagans were juſt, and their precautions ineffectual. The meritorious death of the archbiſhop obliterated the memory of his life. The rival of Athanaſius was dear and ſacred to the Arians, and the ſeeming converſion of theſe ſectaries introduced his worſhip into the boſom of the Catholic church. The odious ſtranger, diſguiſing every circumſtance of time and place, aſſumed the maſk of a martyr, a ſaint, and a Chriſtian hero; and the infamous George of Cappadocia has been transformed into the renowned St George of England, the patron of arms, of chivalry, and of the garter."

Knights of St GEORGE. See GARTER. There have been various other orders under this denomination, moſt of which are now extinct; particularly one founded by the emperor Frederic III. in the year 1470, to guard the frontiers of Bohemia and Hungary againſt the Turks; another, called *St George of Alfama*, founded by the kings of Arragon: another in Auſtria and Carinthia; and another in the republic of Genoa, ſtill ſubſiſting &c.

Religious of St GEORGE. Of theſe there are divers orders and congregations; particularly canons regular of St George in Alga, at Venice, eſtabliſhed by authority of pope Boniface IX. in the year 1404. The foundation of this order was laid by Bartholomew Colonna, who preached, in 1396, at Padua, and ſome other villages in the ſtate of Venice. Pope Pius V. in 1570, gave theſe canons precedence of all other religious. Another congregation of the ſame inſtitute in Sicily, &c.

St GEORGE *del Mina*, the capital of the Dutch ſettlements, on the gold-coaſts of Guinea, ſituated ſeven or eight miles weſt of Cape-coaſt caſtle, the capital of the Britiſh ſettlements there. W. Long. 5°. and N. Lat. 5°. George, Georgia.

St GEORGE, a fort and town of Aſia, in the peninſula on this ſide the Ganges, and on the coaſt of Coromandel, belonging to the Britiſh; it is otherwiſe called *Madraſs*, and by the natives *Chili patam*. It fronts the ſea, and has a ſalt-water river on its back ſide, which hinders the freſh-water ſprings from coming near the town, ſo that they have no good water within a mile of them. In the rainy ſeaſons it is incommoded by inundations; and from April to September, it is ſo ſcorching hot, that if the ſea-breezes did not cool the air, there would be no living there. There are two towns, one of which is called the *White Town*, which is walled round, and has ſeveral bulwarks and baſtions to defend it: it is 400 paces long and 150 broad, and is divided into regular ſtreets. Here are two churches, one for the Proteſtants, and the other for the Papiſts; as alſo a good hoſpital, a town hall, and a priſon for debtors. They are a corporation, and have a mayor and aldermen, with other proper officers. The *Black Town* is inhabited by Gentoos, Mahometans, and Portugueſe and Armenian Chriſtians, and each religion have their temples and churches. This, as well as the White Town, is ruled by the Engliſh governor and his council. The diamond-mines are but a week's journey from this place, which renders them pretty plentiful, but there are no large ones ſince that great diamond was procured by governor Pitt. This colony produces very little of its own growth or manufacture for foreign markets, and the trade is in the hands of the Armenians and Gentoos. The chief things the Britiſh deal in, beſides diamonds, are calicoes, chintz, muſlins, and the like. This colony may conſiſt of 80,000 inhabitants in the towns and villages, and there are generally 400 or 500 Europeans. Their rice is brought by ſea to Gangam and Orixa, their wheat from Surat and Bengal, and their fire-wood from the iſlands of Diu: ſo that an enemy, with a ſuperior force at ſea, may eaſily diſtreſs them. The houſes of the White Town are built with brick, and have lofty rooms and flat roofs; but the Black Town conſiſts chiefly of thatched cottages. The military power is lodged in the governor and council, who are alſo the laſt reſort in civil cauſes. The company have two chaplains, who officiate by turns, and have each 100l. a-year, beſides the advantages of trade. They never attempt to make proſelytes, but leave that to the Popiſh miſſionaries. The ſalaries of the company's writers are very ſmall: but, if they have any fortune of their own, they may make it up by trade; which muſt generally be the caſe, for they commonly grow rich. It was taken by the French in 1746, who reſtored it at the peace of Aix-la-Chapelle.

St GEORGE's, the largeſt of the Bermuda or Summer iſlands. W. Long. 65. 10. N. Lat. 32. 30.

Croſs of St GEORGE, a red one in a field argent, which makes part of the Britiſh ſtandard.

GEORGIA, a country of Aſia, bounded on the north by Circaſſia, on the eaſt by Dagheſtan and Shirvan, on the ſouth by Armenia, and on the weſt by the Euxine or Black Sea; comprehending the greateſt part of the ancient Colchis, Iberia, and Albania. About the etymon of the name of this country, authors are not agreed. The moſt probable opinion

is,

Georgia. is, that it is a corruption by softening of *Kurgia*, from the river Kur; whence also it is supposed that the inhabitants are called by the Persians indifferently *Gurgi* and *Kurgi*; and the country *Kurgistan* and *Gurgistan*: It is divided by a ridge of mountains into eastern and western; the former of which is again subdivided into the kingdoms of Caket, Carduel or Carthuel, and Goguetia; and the latter into the provinces of Abcassia, Mineta, or Imaretta, and Guriel. Another division is into Georgia Proper, Abcassia, and Mingrelia. A third division will be afterwards mentioned.

"Georgia (says Sir George Chardin) is as fertile a country as can be seen; the bread is as good here as in any part of the world; the fruit of an exquisite flavour, and of different sorts; no place in Europe yields better pears and apples, and no place in Asia better pomegranates. The country abounds with cattle, venison, and wild-fowl, of all sorts; the river Kur is well stocked with fish; and the wine is so rich, that the king of Persia has always some of it for his own table. The inhabitants are robust, valiant, and of a jovial temper; great lovers of wine, and esteemed very trusty and faithful; endowed with good natural parts, but, for want of education, very vicious. The women are generally so fair and comely, that the wives and concubines of the king of Persia and his court are for the most part Georgian women. Nature has adorned them with graces no where else to be met with: it is impossible to see them without loving them; they are of a good size, clean limbed, and well-shaped." Another traveller, however, of no mean character, thus expresses himself with respect to the women: "As to the Georgian women, they did not at all surprise us; for we expected to find them perfect beauties. They are, indeed, no way disagreeable; and may be counted beauties, if compared with the Curdes. They have an air of health that is pleasing enough; but, after all, they are neither so handsome nor so well shaped as is reported. Those who live in the towns have nothing extraordinary more than the others; so that I may, I think, venture to contradict the accounts that have been given of them by most travellers."

This country formerly abounded with great cities, as appears not only from its history, but from the ruins of many of them still visible, which show that they must have been very large, opulent, and magnificently built. These were all destroyed by the inundations of northern barbarians from mount Caucasus, as the Alans, Huns, Suevi, and some others, so much noted in history for their strength, courage, and conquests.

The latest division of this country is into nine provinces; five of which are subject to the famous prince Heraclius, forming what is commonly called the kingdom of Georgia; and four are under the dominion of David, composing the kingdom or principality of Imeretia. See IMERETIA.

This whole country is so extremely beautiful, that some fanciful travellers have imagined they had here found the situation of the original garden of Eden. The hills are covered with forests of oak, ash, beech, chesnuts, walnuts, and elms, encircled with vines, growing perfectly wild, but producing vast quantities of grapes. From these is annually made as much wine as is necessary for the yearly consumption; the remainder are left to rot on the vines. Cotton grows spontaneously, as well as the finest European fruit-trees. Rice, wheat, millet, hemp, and flax, are raised on the plains, almost without culture. The valleys afford the finest pasturage in the world; the rivers are full of fish; the mountains abound in minerals, and the climate is delicious; so that nature appears to have lavished on this favoured country every production that can contribute to the happiness of its inhabitants. Georgia.

On the other hand, the rivers of Georgia, being fed by mountain torrents, are at all seasons either too rapid or too shallow for the purposes of navigation: the Black Sea, by which commerce and civilization might be introduced from Europe, has been till very lately in the exclusive possession of the Turks: the trade of Georgia by land is greatly obstructed by the high mountains of Caucasus: and this obstacle is still increased by the swarms of predatory nations, by which those mountains are inhabited.

It is said, that in the 15th century, a king of Georgia divided among his five sons the provinces of Carduel and Caket, Imeretia, Mingrelia, Guriel, and Abkhasia. These petty princes were too jealous to unite for their common defence, and too weak singly to resist a foreign enemy, or even to check the incroachments of their great vassals, who soon became independent. By forming a party among these nobles, the Turks gradually gained possession of all the western provinces, while the Persians occupied the governments of Carduel and Caket. Since that period the many unsuccessful attempts of the Georgians to recover their liberty, have repeatedly produced the devastation of their country. Abbas the Great is said to have carried off in one expedition from the provinces of Carduel and Caket no less than 80,000 families, a number which, probably, exceeds the whole actual population of those provinces. The most horrible cruelties were again exercised on the unhappy people, at the beginning of the present century, by the merciless Nadir; but these were trifling evils, compared with those arising from the internal dissentions of the great barons. This numerous body of men, idle, arrogant, and ferocious, possessed of an unlimited power over the lives and properties of their vassals, having no employment but that of arms, and no hopes of aggrandizing themselves but by the plunder of their rivals, were constantly in a state of warfare; and as their success was various, and the peasants of the vanquished were constantly carried off and sold to the Turks or Persians, every expedition increased the depopulation of the country. At length they invited the neighbouring mountaineers, by the hopes of plunder, to take part in their quarrels; and these dangerous allies, becoming acquainted with the country, and being spectators of the weakness of its inhabitants, soon completed its desolation. A few squalid wretches, half naked, half starved, and driven to despair by the merciless exactions of their landlords, are thinly dispersed over the most beautiful provinces of Georgia. The revolutions of Persia, and the weakness of the Turks, have indeed enabled the princes of the country to recover their independence; but the smallness of their revenue has hitherto disabled them from repressing effectually the tyranny of the nobles, and relieving the burdens of the peasants.

Georgia. The capital of Georgia is Teflis, where prince Heraclius refides (See Teflis.) Of this prince, fo celebrated for his exploits and fucceefs in fhaking off the Ottoman yoke, we have the following account by the late profeffor Guldenftaedt when he travelled into thefe parts in 1770. "Heraclius, or, as he is called, the tzar Iracli, is above 60 years old, of a middle fize, with a long countenance, a dark complexion, large eyes, and a fmall beard. He paffed his youth at the court and in the army of the celebrated Nadir Shah, where he contracted a fondnefs for Perfian cuftoms and manners, which he has introduced into his kingdom. He has feven fons and fix daughters. He is much revered and dreaded by the Perfian khans his neighbours; and is ufually chofen to mediate between them in their difputes with each other. When they are at war, he fupports one of the parties with a few troops, who diffufe a fpirit and courage among the reft, becaufe the Georgian foldiers are efteemed the braveft of thofe parts; and prince Heraclius himfelf is renowned for his courage and military fkill. When on horfeback he has always a pair of loaded piftols at his girdle, and, if the enemy is near, a mufket flung over his fhoulder. In all engagements he is the foremoft to give examples of perfonal bravery; and frequently charges the enemy at the head of his troops with the fabre in his hand. He loves pomp and expence: he has adopted the drefs of Perfia; and regulates his court after the manner of that country. From the example of the Ruffian troops, who were quartered in Georgia during the laft Turkifh war, he has learnt the ufe of plates, knives, and forks, difhes and houfehold-furniture, &c."

The fubjects of Heraclius are eftimated at about 60,000 families; but this, notwithftanding the prefent defolated ftate of the country, is probably an under valuation. The peafants belonging to the queen, and thofe of the patriarch, pay no tax to the prince, and therefore do not appear on the books of the revenue officers. Many fimilar exemptions have likewife been granted by the prince to his fons in-law, and his favourites. Befides, as the impoft on the peafants is not a poll tax, but a tax on hearths, the inhabitants of a village, on the approach of the collectors, frequently carry the furniture of feveral huts into one, and deftroy the remainder, which are afterwards very eafily replaced. It is probable, therefore, that the population of Georgia does not fall fhort of 350,000 fouls. The revenues may be eftimated at about 150,000 roubles, or 26,250l. They confift of, 1. The cuftoms, farmed at 1750l.—2. Rent paid by the farmers of the mint at Teflis, 1750l.—3. The tribute paid by the Khans of Erivan and Ganfha, 7000l.— and, 4. The hearth money levied on the peafants, amounting to 15,750l. The common coins here are the abaffes, of about 15d. value, and a fmall copper coin, ftamped at the mint at Teflis. Befides thefe, a large quantity of gold and filver money is brought into the country from Perfia and Turkey, in exchange for honey, butter, cattle, and blue linens.

The government of Georgia is defpotic; but, were it not for the affiftance of the Ruffian troops, the prince would be frequently unable to carry his decrees into execution. The punifhments in criminal cafes are fhockingly cruel; fortunately they are not frequent, becaufe it is feldom difficult to efcape into fome of the neighbouring countries, and becaufe the prince is more enriched by confifcating the property of the criminal, than by putting him to torture. Judicial combats are confidered as the privilege of nobility, and take place when the caufe is extremely intricate, or when the power and intereft of two claimants are fo equal, that neither can force a decifion of the court in his favour. This mode of trial is called an appeal to the judgment of God. Georgia.

The drefs of the Georgians nearly refembles that of the Coffaks; but men of rank frequently wear the habit of Perfia. They ufually dye their hair, beard, and nails with red. The Georgian women employ the fame colour to ftain the palms of their hands. On their heads they wear a cap or fillet, under which their black hair falls on their forehead: behind, it is braided into feveral treffes. Their eye-brows are painted with black, in fuch a manner as to form one entire line, and their faces are perfectly coated with white and red. Their robe is open to the girdle, fo that they are reduced to conceal the breads with their hands. Their air and manner are extremely voluptuous. Being generally educated in convents, they can all read and write; a qualification which is very unufual among the men, even of the higheft rank. Girls are betrothed as foon as poffible, often at three or four years of age. In the ftreets the women of rank are always veiled, and then it is indecent in any man to accoft them. It is likewife uncivil in converfation to inquire after the wives of any of the company. Thefe, however, are not ancient cuftoms, but are a confequence of the violences committed by the Perfians, under Shah Nadir.

Travellers accufe the Georgians of drunkennefs, fuperftition, cruelty, floth, avarice, and cowardice; vices which are every where common to flaves and tyrants, and are by no means peculiar to the natives of this country. The defcendants of the colonifts, carried off by Shah Abbas, and fettled at Peria, near Ifpahan, and in Mafanderan, have changed their character with their government; and the Georgian troops, employed in Perfia againft the Affghans, were advantageoufly diftinguifhed by their docility, their difcipline, and their courage.

The other inhabitants of Georgia are Tartars, Offi, and Armenians, called in the Georgian language Somakhi. Thefe laft are found all over Georgia, fometimes mixed with the natives, and fometimes in villages of their own. They fpeak among themfelves their own language, but all underftand and can talk the Georgian. Their religion is partly the Armenian, and partly the Roman Catholic. They are the moft oppreffed of the inhabitants, but are ftill diftinguifhed by that inftinctive induftry which every where characterizes the nation.

Befides thefe, there are in Georgia confiderable numbers of Jews, called, in the language of the country, Uria. Some have villages of their own; and others are mixed with the Georgian, Armenian, and Tartar inhabitants, but never with the Offi. They pay a fmall tribute above that of the natives.

Georgia, one of the United States of America, lying between South Carolina and Florida. It extends 120 miles upon the fea-coaft, and 300 miles from

Georgia. from thence to the Apalachian mountains, and its boundaries to the north and south are the rivers Savannah and Alatamaha. The whole coast is bordered with islands; the principal of which are Skidaway, Wassaw, Ossabaw, St Catherines, Sapelo, Frederica, Jekyl, Cumberland, and Amelia.

The settlement of a colony between the rivers Savannah and Alatamaha was meditated in England in 1732, for the accommodation of poor people in Great Britain and Ireland, and for the farther security of Carolina. Private compassion and public spirit conspired to promote the benevolent design. Humane and opulent men suggested a plan of transporting a number of indigent families to this part of America free of expence. For this purpose they applied to the king, George II. and obtained from him letters patent, bearing date June 9. 1732, for legally carrying into execution what they had generously projected. They called the new province *Georgia*, in honour of the king, who encouraged the plan. A corporation, consisting of 21 persons, was constituted by the name of, The Trustees for settling and establishing the colony of Georgia.

In November 1732, 116 settlers embarked for Georgia, to be conveyed thither free of expence, furnished with every thing requisite for building and for cultivating the soil. Mr James Oglethorpe, one of the trustees, and an active promoter of the settlement, embarked as the head and director of these settlers. They arrived at Charlestown early in the next year. Mr Oglethorpe, accompanied by William Bull, shortly after his arrival, visited Georgia; and after surveying the country, marked the spot on which Savannah now stands, as the fittest to begin their settlement. Here they accordingly began and built a small fort; a number of small huts for their defence and accommodation. Such of the settlers as were able to bear arms were embodied, and well appointed with officers, arms, and ammunition. A treaty of friendship was concluded between the settlers and their neighbours the Creek Indians, and every thing wore the aspect of peace and future prosperity. But the fundamental regulations established by the trustees of Georgia were ill adapted to the circumstances and situation of the poor settlers, and of pernicious consequences to the prosperity of the province. Yet although the trustees were greatly mistaken with respect to their plan of settlement, it must be acknowledged their views were generous. Like other distant legislators, who framed their regulations upon principles of speculation, they were liable to many errors and mistakes; and however good their design, their rules were found improper and impracticable. These injudicious regulations and restrictions, the wars in which they were involved with the Spaniards and Indians, and the frequent insurrections among themselves, threw the colony into a state of confusion and wretchedness too great for human nature long to endure. Their oppressed situation was represented to the trustees by repeated complaints; till at length finding that the province languished under their care, and weary with the complaints of the people, they in the year 1752 surrendered their charter to the king, and it was made a royal government. — In the year 1740, the Rev. George Whitefield founded an orphan-house academy in Georgia, about 12 miles from Savannah. Mr Whitefield died at Newbury Port, in New England, in October 1770, in the 56th year of his age, and was buried under the Presbyterian church in that place. From the time Georgia became a royal government in 1752, till the peace of Paris in 1763, she struggled under many difficulties arising from the want of credit, from friends, and the frequent molestations of enemies. The good effects of the peace were sensibly felt in the province of Georgia. From this time it began to flourish under the fatherly care of governor Wright. To form a judgment of the rapid growth of the colony, we need only attend to its exports. In the year 1763, they consisted of 7500 barrels of rice, 9633 pound of indigo, 1250 bushels of Indian corn, which, together with deer and beaver skins, naval stores, provisions, timber, &c, amounted to no more than L. 27,021 sterling. Ten years afterwards, in 1773, they amounted to L. 121,677 sterling. The chief articles of export from this state are rice, tobacco, indigo, sago, lumber of various kinds, naval stores, leather, deer-skins, snake-root, myrtle, bees-wax, corn, live stock, &c. Georgia.

During the late war, Georgia was over-run by the British troops, and the inhabitants were obliged to flee into the neighbouring states for safety. Since the peace, the progress of the population of this state is said to have been astonishingly rapid: though it has been a good deal checked within these few years by the hostile irruptions of the Creek Indians, who continually harass the frontiers of the state. Treaties have been held, and a cessation of hostilities agreed to, between the parties; but all have hitherto proved ineffectual to the accomplishment of a peace.

These Indians inhabit the middle parts of the state, and are the most numerous tribe of Indians of any within the limits of the United States. Their whole number is 17,280, of which 5860 are fighting men. Their principal towns lie in latitude 32° and longitude 11° 20 from Philadelphia. They are settled in a hilly but not mountainous country. The soil is fruitful in a high degree, and well watered, abounding in creeks and rivulets, whence they are called the *Creek Indians*. The Seminolas, a division of the Creek nation, inhabit a level flat country on the Apalachicola and Flint rivers, fertile and well watered. The Chactaws or flat-heads inhabit a very fine and extensive tract of hilly country, with large and fertile plains intervening, between the Alabama and Mississipi rivers, in the western part of this state. This nation have 43 towns and villages, in three divisions, containing 12,123 souls, of which 4041 are fighting men. The Chicasaws are settled on the head branches of the Tombeckbe, Mobile, and Yazoo rivers, in the north west corner of the state. Their country is an extensive plain, tolerably well watered from springs, and of a pretty good soil. They have 7 towns, the central one of which is in latitude 34° 23, and longitude 14° 30 west. The number of souls in this nation have been reckoned at 1725, of which 575 are fighting men.

That part of Georgia which has been laid out in counties is divided into the following, *viz.* Chatham, Effingham, Burke, Richmond, Wilkes, Liberty, Glynn, Camden, Washington, Greene, Franklin; and the chief towns are, Savannah, Ebenezer, Waynesborough and

2 Louisville,

Georgia. Louiſville, Auguſta, Waſhington, Sunbury, Brunſwick, St Patrick's, Golphinton, Greenſburg.—Savannah was formerly the capital, and is ſtill the largeſt town (ſee SAVANNAH). But the preſent ſeat of government in this ſtate is *Auguſta*, ſituated on the ſouthweſt bank of Savannah river, about 134 miles from the ſea, and 117 northweſt of Savannah. The town, which contains not far from 200 houſes, is on a fine large plain; and as it enjoys the beſt ſoil, and the advantage of a central ſituation between the upper and lower counties, is riſing faſt into importance. Louiſville, however, is deſigned as the future ſeat of government in this ſtate. It has lately been laid out on the bank of Ogeechee river, about 70 miles from its mouth, but is not yet built.

Savannah river forms a part of the diviſional line which ſeparates this ſtate from South Carolina. It is formed principally of two branches, by the names of *Tugulo* and *Keowee*, which ſpring from the mountains. Ogeechee river, about 18 miles ſouth of the Savannah, is a ſmaller river, and nearly parallel with it in its courſe. Alatamaha, about 60 miles ſouth of Savannah river, is formed by the junction of the Okonee and Okemulgee branches. It is a noble river, but of difficult entrance. Like the Nile, it diſcharges itſelf by ſeveral mouths into the ſea. Beſides theſe, there is Turtle river, Little Sitilla, Great Sitilla, Crooked river, and St Mary's, which form a part of the ſouthern boundary of the United States. The rivers in the middle and weſtern parts of this ſtate are Apalachiola, which is formed by the Chatahouchee and Flint rivers, Mobile, Paſcagoula, and Pearl rivers. All theſe running ſouthwardly, empty into the Gulf of Mexico.

In the grand convention at Philadelphia in 1787, the inhabitants of this ſtate were reckoned at 90,000, including three-fifths of 20,000 negroes. But from the number of the militia, which has been aſcertained with a conſiderable degree of accuracy, there cannot be at moſt more than half that number. No general character will apply to the inhabitants at large. Collected from different parts of the world, as intereſt, neceſſity, or inclination led them, their character and manners muſt of courſe partake of all the varieties which diſtinguiſh the ſeveral ſtates and kingdoms from whence they came. There is ſo little uniformity, that it is difficult to trace any governing principles among them. An averſion to labour is too predominant, owing in part to the relaxing heat of the climate, and partly to the want of neceſſity to excite induſtry. An open and friendly hoſpitality, particularly to ſtrangers, is an ornamental characteriſtic of a great part of this people.

In regard to religion, politics, and literature, this ſtate is yet in its infancy. In Savannah is an epiſcopal church, a preſbyterian church, a ſynagogue, and a German Lutheran church, ſupplied occaſionally by a German miniſter from Ebenezer, where there is a large convenient ſtone church, and a ſettlement of ſober induſtrious Germans of the Lutheran religion. In Auguſta they have an epiſcopal church. In Midway is a ſociety of Chriſtians eſtabliſhed on the congregational plan. Their anceſtors emigrated in a colony from Dorcheſter, near Boſton, about the year 1700, and ſettled at a place named Dorcheſter, about 20 miles ſouthweſt of Charleſtown, South Carolina. In 1752, for the ſake of a better climate and more land, almoſt the whole ſociety removed and ſettled at Midway. They, as a people, retain in a great meaſure that ſimplicity of manners, that unaffected piety and brotherly love which characterized their anceſtors, the firſt ſettlers of New England. The upper counties are ſupplied pretty generally by baptiſt and methodiſt miniſters; but the greater part of the ſtate is without miniſters of any denomination. Georgia II Gephi

The numerous defects in the late conſtitution of this ſtate, induced the citizens pretty univerſally to petition for a reviſion of it. It was accordingly reviſed, or rather a new one was formed, in the courſe of the year 1789, nearly upon the plan of the conſtitution of the United States, which has lately been adopted by the ſtate.

The charter containing the preſent ſyſtem of education in this ſtate was paſſed in the year 1785. A college, with ample and liberal endowments, is inſtituted in Louiſville, a high and healthy part of the country, near the centre of the ſtate. There is alſo proviſion made for the inſtitution of an academy in each county in the ſtate, to be ſupported from the ſame funds, and conſidered as parts and members of the ſame inſtitution, under the general ſuperintendance and direction of a preſident and board of truſtees, appointed for their literary accompliſhments from the different parts of the ſtate, and inveſted with the cuſtomary powers of corporations. The inſtitution thus compoſed is denominated *the univerſity of Georgia*. The funds for the ſupport of this inſtitution are principally in lands, amounting in the whole to about 50,000 acres, a great part of which is of the beſt quality, and at preſent very valuable. There are alſo nearly L. 6000 ſterling in bonds, houſes, and town lots in the town of Auguſta. Other public property to the amount of L. 1000 in each county has been ſet apart for the purpoſes of building and furniſhing their reſpective academies. The funds originally deſigned for the ſupport of the orphan-houſe, are chiefly in rice plantations and negroes.

GEORGIC, a poetical compoſition upon the ſubject of huſbandry, containing rules thereon, put into a pleaſing dreſs, and ſet off with all the beauties and embelliſhments of poetry. The word is borrowed from the Latin *georgicus*, and that of the Greek γεωργικος, of γη, *terra*, "earth," and εργαζομαι, *opero*, "I work, or labour," of εργον, *opus*, "work." Heſiod and Virgil are the two greateſt maſters in this kind of poetry. The moderns have produced nothing in this kind, except Rapin's book of Gardening; and the celebrated poem intitled Cyder, by Mr Philips, who, if he had enjoyed the advantage of Virgil's language, would have been ſecond to Virgil in a much nearer degree.

Georgium Sidus. See ASTRONOMY, n° 328, &c.

GEPIDÆ, GEPIDES, or GEPIDI (anc. geog.), according to Procopius, were a Gothic people, or a canton or branch of them; ſome of whom, in the migration of the Goths, ſettled in an iſland at the mouth of the Viſtula, which they called *Gepidos* after their own name, which denotes lazy or ſlothful; others in Dacia, calling their ſettlement there *Gepidia*.

GE-

ranites, ranium.

GERANITES, in natural hiſtory, an appellation given to ſuch of the ſemipellucid gems as are marked with a ſpot reſembling a crane's eye.

GERANIUM, CRANES BILL, in botany: A genus of the decandria order, belonging to the monodelphia claſs of plants; and in the natural method ranking under the 34th order, *Gruinales*. Its characters are theſe: the flower hath a permanent empalement, compoſed of five ſmall oval leaves, and five oval or heart-ſhaped petals, ſpreading open, which are in ſome ſpecies equal, and in others the upper two are much larger than the three lower. It has ten ſtamina, alternately longer than each other, but ſhorter than the petals, and terminated by oblong ſummits. In the bottom of the flower is ſituated a five-cornered germen, which is permanent. The flower is ſucceeded by five ſeeds, each being wrapped up in the huſk of the beak, where they are twiſted together at the point, ſo as to form the reſemblance of a ſtork's beak. There are above 80 ſpecies.

The common wild ſorts of this plant, and thoſe alſo which are brought to the curious from the colder climates, are hardy enough, and require little care; but the African ſpecies, and the others from hot countries, which make ſo very beautiful a figure in our green-houſes, require great care in their culture and propagation.

Theſe may be propagated by ſeed, which ſhould be ſown toward the end of March in beds of light earth, and carefully ſhading them from the ſun, and giving them frequent, but gentle waterings, till they are well rooted. The mats with which theſe beds are covered are to be taken off in gentle ſhowers, and always in the hot weather at nights, that the plants may have the benefit of the dew. They ſhould remain about two months in this bed, by which time they will have taken root. Some pots of about ſeven inches wide are then to be filled with light earth, and the plants are to be carefully taken up with as much as poſſible of their own earth about them, and planted ſeverally in the middle of theſe pots; when they are to be ſet in a ſhady place, and watered at times till they have taken root. When they are well-rooted, they ſhould be ſet in a more expoſed place to harden them, and ſhould ſtand out till the middle of October; but when the mornings begin to grow froſty, they muſt be removed into the green-houſe, and then placed as near the windows as poſſible, and the windows ſhould be opened upon them till the weather is very cold. During the winter, they muſt be frequently watered a little at a time, and their dead leaves ſhould be pulled off. They muſt not ſtand under the ſhade of other plants, nor need any artificial heat.

Thoſe who are deſirous that their plants ſhould be large and flower ſoon, ſow the ſeeds on a moderate hot-bed in the ſpring; when they are come up, they ſhould not be drawn weak, and the pots into which they are tranſplanted ſhould be plunged into another moderate hot-bed, ſhading them from the ſun till they have taken root, and gradually inuring them to the open air, into which they ſhould be removed in the beginning of June, and placed in a ſheltered ſituation with other exotic plants.

The ſhrubby African geraniums are commonly propagated by cuttings, which, planted in a ſhady border, in June or July, will take good root in five or ſix weeks; and they may then be taken up and planted in ſeparate pots, placing them in the ſhade till they have taken new root; after which they may be removed into a ſheltered ſituation, and treated as the ſeedling plants.

Geranium ſtands recommended as one of the greateſt vulneraries and abſtergents of the vegetable world, and is highly extolled for its power of ſtopping profluvia of the menſes, and hæmorrhages of all kinds. Experience confirms the truth of this, eſpecially among the poor people in the country; and it were to be wiſhed that the plant could be brought into more eſteem in the ſhops, where at preſent it is diſregarded.

GERAR, or GERARA, (anc. geog.), the ſouth boundary of Canaan near Berſeba; ſituated between Cades and Sur; two deſarts well known, the former facing Egypt, the latter Arabia Petræa.

GERARD (John), a learned Lutheran divine, was profeſſor of divinity, and rector of the academy of Jena, the place of his birth. He wrote, 1. The harmony of the eaſtern languages; 2. A Treatiſe on the Coptic Church; and other works which are eſteemed. He died in 1678.

GERARDE (John), a ſurgeon in London, and the greateſt botaniſt of his time, was many years chief gardener to Lord Burleigh; who was himſelf a great lover of plants, and had the beſt collection of any nobleman in the kingdom, among which were a great number of exotics introduced by Gerarde. In 1597 he publiſhed his *Herbal*, which was printed at the expence of J. Norton, who procured the figures from Francfort. In 1663, Thomas Johnſon, an apothecary, publiſhed an improved edition of Gerarde's book; which met with ſuch approbation by the Univerſity of Oxford, that they conferred on him the degree of doctor of phyſic; and it is ſtill much eſteemed. The deſcriptions in the herbal are plain and familiar; and both theſe authors have laboured more to make their readers underſtand the characters of the plants, than to inform them that they themſelves underſtood Greek and Latin.

GERARDIA, in botany: A genus of the angioſpermia order, belonging to the didynamia claſs of plants; and in the natural method ranking under the 40th order, *Perſonatæ*. The calyx is quinquefid, the corolla bilabiate; the under lip tripartite; the ſide lobes emarginated, and the middle one bipartite; the capſule bilocular and gaping.

GERBIER (Sir Balthazar), a painter of Antwerp, born in the year 1592, diſtinguiſhed himſelf by painting ſmall figures in diſtemper. King Charles I. was ſo pleaſed with his performances, that he invited him to his court, where he obtained the eſteem of the duke of Buckingham, and grew into great favour. He was not only knighted, but ſent to Bruſſels, where he long reſided as agent for the king of Great Britain.

GERFALCON. See FALCO.

GERGESA, (anc. geog.), a Transjordan town, no otherwiſe known than by the *Gergeſeni* of St Matthew; and *Gergeſæi* of Moſes; ſuppoſed to have ſtood in the neighbourhood of Gadara and near the ſea of Tiberias. The *Gergeſæi*, one of the ſeven ancient people of Canaan, leſs frequently mentioned than the reſt, appear to have been leſs conſiderable and more obſcure: their

Gerar || Gergeſa.

name

Gerizim || Germany.

name is from *Girgaſi*, one of Canaan's ſons. See GIRGASHITES.

GERIZIM. See GARIZIM.

GERM, among gardeners. See GERMEN.

GERMAN, in matters of genealogy, ſignifies whole, entire, or own. *Germani, quaſi eadem ſtirpe geniti*; (Feſt.) Hence,

Brother-German, denotes a brother both by the father's and mother's ſide, in contradiſtinction to uterine brothers, &c. who are only ſo by the mother's ſide.

Couſins-German, are thoſe in the firſt or neareſt degree, being the children of brothers or ſiſters.

Among the Romans we have no inſtance of marriage between couſins-german before the time of the emperor Claudius, when they were very frequent.

Theodoſius prohibited them under very ſevere penalties, even fine and proſcription. See CONSANGUINITY.

GERMAN, or *Germanic*, alſo denotes any thing belonging to Germany; as the German empire, German flute, &c.

GERMANDER, in botany. See the article TEUCRIUM.

GERMANICUS CÆSAR, the ſon of Druſus, and paternal nephew to the emperor Tiberius, who adopted him; a renowned general, but ſtill more illuſtrious for his virtues. He took the title of *Germanicus* from his conqueſts in that country; and though he had the moderation to refuſe the empire offered to him by his army, Tiberius, jealous of his ſucceſs, and of the univerſal eſteem he acquired, cauſed him to be poiſoned, A. D. 29, aged 34. He was a protector of learning; and compoſed ſome Greek comedies and Latin poems, ſome of which are ſtill extant.

GERMANY, a very extenſive empire of Europe, but which, in different ages of the world, has had very different limits. Its name, according to the moſt probable conjecture, is derived from the Celtic words *Ghar man*, ſignifying a warlike man, to which their other name, *Allman*, or *Aleman*, likewiſe alludes.

The ancient hiſtory of the Germans is altogether wrapped up in obſcurity; nor do we, for many ages, know any thing more of them than what may be learned from the hiſtory of their wars with the Romans. The firſt time we find them mentioned by the Roman hiſtorians, is about the year 211 B. C. at which time Marcellus ſubdued Inſubria and Liguria, and defeated the Gæſatæ, a German nation ſituated on the banks of the Rhine. From this time hiſtory is ſilent with regard to any of theſe northern nations, till the eruption of the Cimbri and Teutones, who inhabited the moſt northerly parts of Germany. The event of their enterpriſe is related under the articles AMBRONES, CIMBRI, and TEUTONES. We muſt not, however, imagine, becauſe theſe people happened to invade Italy at the ſame time, that therefore their countries were contiguous to one another. The Cimbri and Teutones only, dwelt beyond the Rhine; while the Ambrones inhabited the country between Switzerland and Provence. It is indeed very difficult to fix the limits of the country called *Germany* by the Romans. The ſouthern Germans were intermixed with the Gauls, and the northern ones with the Scythians; and thus the ancient hiſtory of the Germans includes that of the Daeians, Huns, Goths, &c. till the deſtruction of the weſtern Roman empire by them. Ancient Germany, therefore, we may reckon to have included the northern part of France, the Netherlands, Holland, *Germany* ſo called at preſent, Denmark, Pruſſia, Poland, Hungary, part of Turky in Europe, and Muſcovy.

Germany.

1 Limits of ancient Germany.

The Romans divided Germany into two regions; Belgic or Lower Germany, which lay to the ſouthward of the Rhine; and Germany Proper, or High Germany. The firſt lay between the rivers Seine and the Rhine; and in this we find a number of different nations, the moſt remarkable of which were the following.

2 Nations inhabiting Lower Germany.

1. The Ubii, whoſe territory lay between the Rhine and the Moſa or Maeſe, and whoſe capital was the city of Cologne. 2. Next to them were the Tungri, ſuppoſed to be the ſame whom Cæſar calls *Eburones* and *Condruſi*; and whoſe metropolis, then called *Attuatica*, has ſince been named *Tongres*. 3. Higher up from them, and on the other ſide of the Moſelle, were the Treviri, whoſe capital was Auguſta Trevirorum, now *Triers*. 4. Next to them were the Tribocci, Nemetes, and Vangiones. The former dwelt in Alſace, and had Argentoratum, now *Straſburg*, for their capital: the others inhabited the cities of Worms, Spire, and Mentz. 5. The Mediomatrici were ſituated along the Moſelle, about the city of Metz in Lorrain; and above them were ſituated another German nation, named *Raurici*, *Rauraci*, or *Rauriaci*, and who inhabited that part of Helvetia, or Switzerland, about Baſil. To the weſtward and ſouthward of theſe were the Nervii, Sueſſones, Silvanectes, Leuci, Rhemi, Lingones, &c. who inhabited Belgic Gaul.

Between the heads of the Rhine and Danube were ſeated the ancient kingdom of Vindelicia, whoſe capital was called *Auguſta Vindelicorum*, now *Augſburg*. Below it on the banks of the Danube were the kingdoms of Noricum and Pannonia. The firſt of theſe was divided into Noricum *Ripenſe* and *Mediterraneum*. It contained a great part of the provinces of Auſtria, Styria, Carinthia, Tyrol, Bavaria, and ſome others of leſs note. The latter contained the kingdom of Hungary, divided into Upper and Lower; and extending from Illyricum to the Danube, and the mountains Cætii in the neighbourhood of *Vindebona*, now *Vienna*.

3 Nations inhabiting High Germany.

Upper or High Germany lay beyond the Rhine and the Danube. Between the Rhine and the Elbe were the following nations. 1. The Chauci, Upper and Lower; who were divided from each other by the river Viſurges, now the *Weſer*. Their country contained what is now called *Bremen*, *Lunenburg*, *Friezland*, and *Groninghen*. The upper Chauci had the Cheruſci, and the lower the Chamavi on the ſouth-eaſt, and the German Ocean on the north-weſt. 2. The Friſii, upper and lower, were divided from the lower Chauci by the river Amiſia, now the Ems; and from one another by an arm of the Rhine. Their country ſtill retains the name of *Frieſland*, and is divided into eaſt and weſt; but the latter is now diſmembered from Germany, and become one of the Seven United Provinces. 3. Beyond the Iſela, now the *Iſel*, which bounded the country of the Friſii, were ſituated the Bructeri, who inhabited that tract now called *Broecmorland*; and the

Germany. Marſi, about the river Luppe. On the other ſide of that river were the *Uſipii* or *Uſipites*; but theſe were famed for often changing their territories, and therefore found in other places. 4. Next to theſe were the Juones, or inhabitants of Juliers, between the Maeſe and the Rhine. 5. The Catti, another ancient and warlike nation, inhabited Heſſe and Thuringia, from the Hartzian mountains to the Rhine and Weſer; among whom were comprehended the Mattiaci, whoſe capital is by ſome thought to be *Marpurg*, by others *Baden*. 6. Next to theſe were the Seducii bordering upon Suabia; Narifci, or the ancient inhabitants of Northgow, whoſe capital was Nuremberg; and the Marcomanni, whoſe country anciently reached from the Rhine to the head of the Danube, and to the Neckar. The Marcomanni afterwards went and ſettled in Bohemia and Moravia, under their general or king Maroboduus; and ſome of them in Gaul, whence they drove the Boii, who had ſeated themſelves there. 7. On the other ſide of the Danube, and between the Rhine and it, were the Hermunduri, who poſſeſſed the country now called *Miſnia* in Upper Saxony; though ſome make their territories to have extended much farther, and to have reached quite to, or even beyond, the kingdom of Bohemia, once the ſeat of the Boii, whence its name. 8. Beyond them, on the north of the Danube, was another ſeat of the Marcomanni along the river Albis, or Elbe. 9. Next to Bohemia were ſituated the Quadi, whoſe territories extended from the Danube to Moravia, and the northern part of Auſtria. Theſe are comprehended under the ancient name of *Suevi*; part of whom at length forced their way into Spain, and ſettled a kingdom there. 10. Eaſtward of the Quadi were ſituated the Baſtarnæ, and parted from them by the Granna, now *Gran*; a river that falls into the Danube, and by the Carpathian mountains, from them called *Alpes Baſtarnicæ*. The country of the Baſtarnæ indeed made part of the European Sarmatia, and ſo was without the limits of Germany properly ſo called; but we find theſe people ſo often in league with the German nations, and joining them for the deſtruction of the Romans, that we cannot but account them as one people.

Between thoſe nations already taken notice of, ſeated along the other ſide of the Danube and the Hercynian foreſt, were ſeveral others whoſe exact ſituation is uncertain, viz. the Martingi, Burii, Borades, Lygii, or Logiones, and ſome others, who are placed by our geographers along the foreſt above-mentioned, between the Danube and the Viſtula.

On this ſide the Hercynian foreſt, were the famed Rhætii, now *Griſons*, ſeated among the Alps. Their country, which was alſo called *Weſtern Illyricum*, was divided into Rhætia *Prima* or *Propria*, and *Secunda*; and was then of much larger extent, ſpreading itſelf towards Suabia, Bavaria, and Auſtria.

On the other ſide of the Hercynian foreſt, were, 1. The Suevi, who ſpread themſelves from the Viſtula to the river Elbe. 2. The Longobardi, ſo called, according to ſome, on account of their wearing long beards; but, according to others, on account of their conſiſting of two nations, viz. the Bardi and Lingones. Theſe dwelt along the river Elbe, and bordered ſouthward on the Chauci above mentioned. 3. The Burgundi, of whoſe original ſeat we are uncertain. 4. The Semnones; who, about the time of Tiberius, were ſeated on the river Elbe. 5. The Angles, Saxons, and Goths; were probably the deſcendants of the Cimbri; and inhabited the countries of Denmark, along the Baltic ſea, and the peninſula of Scandinavia, containing Norway, Sweden, Lapland, and Finmark. 6. The Vandals were a Gothic nation, who, proceeding from Scandinavia, ſettled in the countries now called *Mecklenburgh* and *Brandenburgh*. 7. Of the ſame race were the Dacians, who ſettled themſelves in the neighbourhood of Palus Mæotis, and extended their territories along the banks of the Danube. Germany.

Theſe were the names of the German nations who performed the moſt remarkable exploits in their wars with the Romans. Beſides theſe, however, we find mention made of the Scordiſci, a Thracian nation, who afterwards ſettled on the banks of the Danube. About the year 113 B. C. they ravaged Macedon, and cut off a whole Roman army ſent againſt them; the general, M. Porcis Cato, grandſon to Cato the cenſor, being the only perſon who had the good fortune to make his eſcape. After this, they ravaged all Theſſaly; and advanced to the coaſts of the Adriatic, into which, becauſe it ſtopped their farther progreſs, they diſcharged a ſhower of darts. By another Roman general, however, they were driven back into their own country with great ſlaughter; and, ſoon after, Metellus ſo weakened them by repeated defeats, that they were incapable, for ſome time, of making any more attempts on the Roman provinces. At laſt, in the conſulſhip of M. Livius Druſus and L. Calpurnius Piſo, the former prevailed on them to paſs the Danube, which thenceforth became the boundary between the Romans and them. Notwithſtanding this, in the time of the Jugurthine war, the Scordiſci repaſſed the Danube on the ice every winter, and being joined by the Triballi a people of Lower Mæſia, and the Daci of Upper Mæſia, penetrated as far as Macedon, committing every where dreadful ravages. So early did theſe northern nations begin to be formidable to the Romans, even when they were moſt renowned for warlike exploits. 4 Wars of the Scordiſci with the Romans.

Till the time of Julius Cæſar, however, we hear nothing more concerning the Germans. About 58 years B. C. he undertook his expedition into Gaul; during which, his aſſiſtance was implored by the Ædui, againſt Arioviſtus, a German prince who oppreſſed them. Cæſar, pleaſed with this opportunity of increaſing his power, invited Arioviſtus to an interview; but this being declined, he next ſent deputies deſiring him to reſtore the hoſtages he had taken from the Ædui, and to bring no more troops over the Rhine into Gaul. To this a haughty anſwer was returned; and a battle ſoon after enſued, in which Arioviſtus was entirely defeated, and with great difficulty made his eſcape. 5 Expedition of Julius Cæſar into Germany.

In 55 B. C. Cæſar having ſubdued the Sueſſones, Bellovaci, Ambiani, Nervii, and other nations of Belgic Gaul, haſtened to oppoſe the Uſipetes and Tencteri. Theſe nations having been driven out of their own country by the Suevi, had croſſed the Rhine with a deſign to ſettle in Gaul. As ſoon as he appeared, the Germans ſent him a deputation, offering to join him provided he would aſſign them lands. Cæſar replied, that there was no room in Gaul for them; but he

Germany. he would desire the Ubii to give them leave to settle among them. Upon this, they desired time to treat with the Ubii; but in the mean time fell upon some Roman squadrons: which so provoked Cæsar, that he immediately marched against them, and, coming unexpectedly upon them, defeated them with great slaughter. They fled in the utmost confusion; but the Romans pursued them to the conflux of the Rhine and the Maese, where the slaughter was renewed with such fury, that almost 400,000 of the Germans perished. After this, Cæsar being resolved to spread the terror of the Roman name through Germany, built a bridge over the Rhine, and entered that country. In this expedition, however, which was his last in Germany, he performed no remarkable exploit. A little before his death, indeed, he had projected the conquest of that as well as of a great many other countries; but his assassination prevented the execution of his designs. Nor is there any thing recorded of the Germans till about 17 B. C. when the Tencteri made an irruption into Gaul, and defeated M. Lollius, proconsul of that province. At last, however, they were repulsed, and forced to retire with great loss beyond the Rhine.

6 Rhæti invade Italy.

Soon after this the Rhæti invaded Italy, where they committed the greatest devastations, putting all the males they met to the sword, without distinction of sex or age: nay, we are told, that when they happened to take women with child, they consulted their augurs to know whether the child was a male or female; and if they pronounced it a male, the mother was immediately massacred. Against these barbarians was sent Drusus, the second son of Livia, a youth of extraordinary valour and great accomplishments. He found means to bring them to a battle; in which the Romans proved victorious, and cut in pieces great numbers of their enemies, with very little loss on their own side. Those who escaped the general slaughter, being joined by the Vindelici, took their rout towards Gaul, with a design to invade that province. But Augustus, upon the first notice of their march, dispatched against them Tiberius with several chosen legions. He was no less successful than Drusus had been; for, having transported his troops over the lake Brigantium, now Constance, he fell unexpectedly on the enemy, gave them a total overthrow, took most of their strong holds, and obliged the whole nation to submit to such terms as he chose to impose upon them.

7 They are subdued, together with the Vindelici and Norici.

Thus were the Vindelici, the Rhæti, and Norici, three of the most barbarous nations in Germany, subdued. Tiberius, to keep the conquered countries in awe, planted two colonies in Vindelicia, and opened from thence a road into Rhætia and Noricum. One of the cities which he built for the defence of his colonies, he called, from his father Drusus, *Drusomagus;* the other by the name of Augustus, *Augusta Vindelicorum;* which cities are now known by the names of *Mimminghen and Augsburg*. He next encountered the Pannonians, who had been subdued by Agrippa, but revolted on hearing the news of that great commander's death, which happened 11 years B. C. Tiberius, however, with the assistance of their neighbours the Scordisci, soon forced them to submit. They delivered up their arms, gave hostages, and put the Romans in possession of all their towns and strong-holds. Tiberius spared their lives; but laid waste their fields, plundered their cities, and sent the best part of their youth into other countries. Germany.

8 And the Pannonians.

In the mean time, Drusus having prevented the Gauls from revolting, which they were ready to do, prepared to oppose the Germans who dwelt beyond the Rhine. They had collected the most numerous and formidable army that had ever been seen in those parts; with which they were advancing towards the Rhine, in order to invade Gaul. Drusus defeated them as they attempted to cross that river; and, pursuing the advantage he had gained, entered the country of the Usipetes, now *Relinchusen*, and from thence advanced against the Sicambri, in the neighbourhood of the Lyppe and Issel. Them he overthrew in a great battle, laid waste their country, burnt most of their cities, and following the course of the Rhine, approached the German ocean, reducing the Frisii and the Chauci between the Ems and the Elbe. In these marches the troops suffered extremely for want of provisions; and Drusus himself was often in great danger of being drowned, as the Romans who attended him were at that time quite unacquainted with the flux and reflux of the ocean.

9 Exploits of Drusus in Germany.

The Roman forces went into east Friesland for their winter-quarters; and next year (10 B. C.) Drusus marched against the Tencteri, whom he easily subdued. Afterwards, passing the Lupias, now the Lyppe, he reduced the Catti and Cherusci, extending his conquests to the banks of the Visurgis or Weser: which he would have passed, had he not been in want of provisions, the enemy having laid waste the country to a considerable distance. As he was retiring, the Germans unexpectedly fell upon him in a narrow passage; and having surrounded the Roman army, cut a great many of them in pieces. But Drusus having animated his men by his example, after a bloody conflict, which lasted the whole day, the Germans were defeated with such slaughter, that the ground was strewed for several miles with dead bodies. Drusus found in their camp a great quantity of iron-chains which they had brought for the Romans; and so great was their confidence, that they had agreed before hand about the division of the booty. The Tencteri were to have the horse, the Cherusci and Sicambri the baggage, and the Usipetes and Catti the captives. After this victory, Drusus built two forts to keep the conquered countries in awe; the one at the confluence of the Lyppe and the Alme, the other in the country of the Catti on the Rhine. On this occasion also he made a famous canal, long after called in honour of him *Fossa Drusiana*, to convey the waters of the Rhine into the Sala or Sale. It extended eight miles; and was very convenient for conveying the Roman troops by water to the countries of the Frisii and Chauci, which was the design of the undertaking.

The following year (9 B. C.), Augustus, bent on subduing the whole of Germany, advanced to the banks of the Rhine, attended by his two sons in-law Tiberius and Drusus. The former he sent against the Daci, who lived up to the south of the Danube; and the latter to complete the conquests he had so successfully begun in the western parts of Germany. The former easily overcame the Daci, and transplanted 40,000 of them into Gaul. The latter, having passed the

Germany. the Rhine, ſubdued all the nations from that river to the Elbe; but having attempted in vain to croſs this laſt, he ſet out for Rome: an end, however, was put to his conqueſts and his life by a violent fever, with which he was ſeized on his return.

After the death of Druſus, Tiberius again over-ran all thoſe countries in which Druſus had ſpent the preceding ſummer; and ſtruck ſome of the northern nations with ſuch terror, that they ſent deputies to ſue for peace. This, however, they could not obtain upon any terms; the emperor declaring that he would not conclude a peace with one, unleſs they all deſired it. But the Catti, or according to ſome the Sicambri, could not by any means be prevailed upon to ſubmit; ſo that the war was ſtill carried on, though in a languid manner, for about 18 years. During this period, ſome of the German nations had quitted their foreſts, and begun to live in a civilized manner under the protection of the Romans; but one Quintilius Varus being ſent to command the Roman forces in that country, ſo provoked the inhabitants by his extortions, that not only thoſe who ſtill held out refuſed to ſubmit, but even the nations that had ſubmitted were ſeized with an eager deſire of throwing off the yoke. Among them was a young nobleman of extraordinary parts and valour, named *Arminius*. He was the ſon of Sigimer, one of the moſt powerful lords among the Catti, had ſerved with great reputation in the Roman armies, and been honoured by Auguſtus with the privileges of a Roman citizen and the title of knight. But the love of his country prevailing over his gratitude, he reſolved to improve the general diſcontent which reigned among his countrymen, to deliver them from the bondage of a foreign dominion. With this view he engaged, underhand, the leading men of all the nations between the Rhine and the Elbe, in a conſpiracy againſt the Romans. In order to put Varus off his guard, he at the ſame time adviſed him to ſhow himſelf to the inhabitants of the more diſtant provinces, adminiſter juſtice among them, and accuſtom them, by his example, to live after the Roman manner, which he ſaid would more effectually ſubdue them than the Roman ſword. As Varus was a man of a peaceable temper, and averſe from military toils, he readily conſented to this inſidious propoſal; and, leaving the neighbourhood of the Rhine, marched into the country of the Cheruſci. Having there ſpent ſome time in hearing cauſes and deciding civil controverſies, Arminius perſuaded him to weaken his army, by ſending out detachments to clear the country of robbers. When this was done, ſome diſtant nations of Germany roſe up in arms by Arminius's directions; while thoſe through which Varus was to paſs in marching againſt them, pretended to be in a ſtate of profound tranquillity, and ready to join the Romans againſt their enemies.

10 Arminius leads the Germans againſt the Romans.

11 Cuts off Varus with his army.

On the firſt news of the revolt, Varus marched againſt the enemy with three legions and ſix cohorts; but being attacked by the Germans as he paſſed thro' a wood, his army was almoſt totally cut off, while he himſelf and moſt of his officers fell by their own hands. Such a terrible overthrow, though it raiſed a general conſternation in Rome, did not, however, diſhearten Auguſtus, or cauſe him to abandon his enterpriſe. About two years after (A. D. 12.), Tiberius and Germanicus were appointed to command in Germany. Germany. The death of Auguſtus, however, which happened ſoon after, prevented Tiberius from going on his expedition; and Germanicus was for ſome time hindered from proceeding in his, by a revolt of the legions, firſt in Pannonia, and then in Germany. About the year 15, Germanicus having brought over the ſoldiers to their duty, laid a bridge croſs the Rhine, over which he marched 12,000 legionaries, 26 cohorts of the allies, and eight alæ (ſquadrons of 300 each) of horſe. With theſe he firſt traverſed the Cœſian foreſt (part of the Hercynian, and thought to lie partly in the duchy of Cleves, and partly in Weſtphalia), and ſome other woods. On his march he was informed that the Marſi were celebrating a feſtival with great mirth and jollity. Upon this he advanced with ſuch expedition, that he ſurpriſed them in the midſt of their debauch; and giving his army full liberty to make what havock they pleaſed, a terrible maſſacre enſued, and the country was deſtroyed with fire and ſword for 50 miles round, without the loſs of a ſingle man on the part of the Romans.—This general maſſacre rouſed the Bructeri, the Tubantes, and the Uſipetes; who, beſetting the paſſes through which the Roman army was to return, fell upon their rear, and put them into ſome diſorder; but the Romans ſoon recovered themſelves, and defeated the Germans with conſiderable loſs. 12 Exploits of Germanicus.

The following year (A. D. 16), Germanicus taking advantage of ſome inteſtine broils which happened among the Catti, entered their country, where he put great numbers to the ſword. Moſt of their youth, however, eſcaped by ſwiming over the Adrana, now the Eder, and attempted to prevent the Romans from laying a bridge over that river: but being diſappointed in this, ſome of them ſubmitted to Germanicus, while the greater part, abandoning their villages, took refuge in the woods; ſo that the Romans, without oppoſition, ſet fire to all their villages, towns, &c. and having laid their capital in aſhes, began their march back to the Rhine.

Germanicus had ſcarce reached his camp, when he received a meſſage from Segeſtes, a German prince, in the intereſt of the Romans, acquainting him that he was beſieged in his camp by Arminius. On this advice, he inſtantly marched againſt the beſiegers; entirely defeated them; and took a great number of priſoners, among whom was Thuſneldis, the wife of Arminius, and daughter of Segeſtes, whom the former had carried off, and married againſt her father's will. Arminius then, more enraged than ever, for the loſs of his wife, whom he tenderly loved, ſtirred up all the neighbouring nations againſt the Romans. Germanicus, however, without being diſmayed by ſuch a formidable confederacy, prepared himſelf to oppoſe the enemy with vigour: but, that he might not be obliged to engage ſuch numerous forces at once, he detached his lieutenant Cæcina, at the head of 40 cohorts, into the territories of the Bructeri; while his cavalry, under the command of Pedo, entered the country of the Friſii. As for Germanicus himſelf, he embarked the remainder of his army, conſiſting of four legions, on a neighbouring lake; and tranſported them by rivers and canals to the place appointed on the river Ems, where the three bodies met. In their

Germany. march they found the ſad remains of the legions conducted by Varus, which they buried with all the ceremony their circumſtances could admit. After this they advanced againſt Arminius, who retired and poſted himſelf advantageouſly cloſe to a wood. The Roman general followed him; and coming up with him, ordered his cavalry to advance and attack the enemy. Arminius, at their firſt approach, pretended to fly; but ſuddenly wheeled about, and giving the ſignal to a body of troops, whom he had concealed in the wood, to ruſh out, obliged the cavalry to give ground. The cohorts then advanced to their relief; but they too were put into diſorder, and would have been puſhed into a moraſs, had not Germanicus himſelf advanced with the reſt of the cavalry to their relief. Arminius did not think it prudent to engage theſe freſh troops, but retired in good order; upon which Germanicus alſo retired towards the Ems. Here he embarked with four legions, ordered Cæcina to reconduct the other four by land, and ſent the cavalry to the ſea-ſide, with orders to march along the ſhore to the Rhine. Tho' Cæcina was to return by roads well known, yet Germanicus adviſed him to paſs, with all poſſible ſpeed, a cauſeway, called the *long bridges*, which led acroſs vaſt marſhes, ſurrounded on all ſides with woods and hills that gently roſe from the plain.

Arminius, however, having got notice of Cæcina's march, arrived at the long bridges before Cæcina, and filled the woods with his men, who, on the approach of the Romans, ruſhed out, and attacked them with great fury. The legions, not able to manage their arms in the deep waters and ſlippery ground, were obliged to yield; and would in all probability have been entirely defeated, had not night put an end to the combat. The Germans, encouraged by their ſucceſs, inſtead of refreſhing themſelves with ſleep, ſpent the whole night in diverting the courſes of the ſprings which roſe in the neighbouring mountains; ſo that, before day, the camp which the Romans had begun was laid under water, and their works were overturned. Cæcina was for ſome time at a loſs what to do; but at laſt reſolved to attack the enemy by day-break, and, having driven them to their woods, to keep them there in a manner beſieged, till the baggage and wounded men ſhould paſs the cauſeway, and get out of the enemy's reach. But when his army was drawn up, the legions poſted on the wings, ſeized with a ſudden panic, deſerted their ſtations, and occupied a field beyond the marſhes. Cæcina thought it adviſable to follow them; but the baggage ſtuck in the mire, as he attempted to croſs the marſhes, which greatly embarraſſed the ſoldiers. Arminius perceiving this, laid hold of the opportunity to begin the attack; and crying out, "This is a ſecond Varus, the ſame fate attends him and his legions," fell on the Romans with inexpreſſible fury. As he had ordered his men to aim chiefly at the horſes, great numbers of them were killed; and the ground becoming ſlippery with their blood and the ſlime of the marſh, the reſt either fell or threw their riders, and, galloping through the ranks, put them in diſorder. Cæcina diſtinguiſhed himſelf in a very eminent manner; but his horſe being killed, he would have been taken priſoner, had not the firſt legion reſcued him. The greedineſs of the enemy, however, ſaved the Romans from utter deſtruction; for juſt as the legions were quite ſpent, and on the point of yielding, the barbarians on a ſudden abandoned them in order to ſeize their baggage. During this reſpite, the Romans ſtruggled out of the marſh, and having gained the dry fields, formed a camp with all poſſible ſpeed, and fortified it in the beſt manner they could. Germany.

The Germans having loſt the opportunity of deſtroying the Romans, contrary to the advice of Arminius, attacked their camp next morning, but were repulſed with great ſlaughter; after which they gave Cæcina no more moleſtation till he reached the banks of the Rhine. Germanicus, in the mean time, having conveyed the legions he had with him down the river Ems into the ocean, in order to return by ſea to the river Rhine, and finding that his veſſels were overloaded, delivered the ſecond and 14th legions to Publius Vitellius, deſiring him to conduct them by land. But this march proved fatal to great numbers of them; who were either buried in the quickſands, or ſwallowed up by the overflowing of the tide, to which they were as yet utter ſtrangers. Thoſe who eſcaped, loſt their arms, utenſils, and proviſions; and paſſed a melancholy night upon an eminence, which they had gained by wading up to the chin. The next morning the land returned with the tide of ebb; when Vitellius, by an haſty march, reached the river Uſingis, by ſome thought to be the Hoerenſter, on which the city of Groningen ſtands. There Germanicus, who had reached that river with his fleet, took the legions again on board, and conveyed them to the mouth of the Rhine, whence they all returned to Cologne, at a time when it was reported they were totally loſt.

This expedition, however, coſt the Romans very dear, and procured very few advantages. Great numbers of men had periſhed; and by far the greateſt part of thoſe who had eſcaped ſo many dangers returned without arms, utenſils, horſes, &c. half naked, lamed, and unfit for ſervice. The next year, however, Germanicus, bent on the entire reduction of Germany, made vaſt preparations for another expedition. Having conſidered the various accidents that had befallen him during the war, he found that the Germans were chiefly indebted for their ſafety to their woods and marſhes, their ſhort ſummers and long winters; and that his troops ſuffered more from their long and tedious marches than from the enemy. For this reaſon he reſolved to enter the country by ſea, hoping by that means to begin the campaign earlier, and ſurpriſe the enemy. Having therefore built with great diſpatch, during the winter, 1000 veſſels of different ſorts, he ordered them early in the ſpring (A. D. 16) to fall down the Rhine, and appointed the iſland of the Batavians for the general rendezvous of his forces. When the fleet was ſailing, he detached Silius one of his lieutenants, with orders to make a ſudden irruption into the country of the Catti; and, in the mean time, he himſelf, upon receiving intelligence that a Roman fort on the Luppias was beſieged, haſtened with ſix legions to its relief. Silius was prevented, by ſudden rains, from doing more than taking ſome ſmall booty, with the wife and daughter of Arpen king of the Catti; neither did thoſe who beſieged the fort wait the arrival of Germanicus. In the mean time; the fleet arriving at the iſland of the Batavians, the

pro-

rmany. provisions and warlike engines were put on board and sent forward; ships were assigned to the legions and allies; and the whole army being embarked, the fleet entered the canal formerly cut by Drusus, and from his name called *Fossa Drusiana*. Hence he sailed prosperously to the mouth of the Ems; where, having landed his troops, he marched directly to the Weser, where he found Arminius encamped on the opposite bank, and determined to dispute his passage. The next day Arminius drew out his troops in order of battle: but Germanicus, not thinking it advisable to attack them, ordered the horse to ford over under the command of his lieutenants Stertinius and Emilius; who, to divide the enemy's forces, crossed the river in two different places. At the same time Cariovalda, the leader of the Batavian auxiliaries, crossed the river where it was most rapid: but, being drawn into an ambuscade, he was killed, together with most of the Batavian nobility; and the rest would have been totally cut off, had not Stertinius and Emilius hastened to their assistance. Germanicus in the mean time passed the river without molestation. A battle soon after ensued; in which the Germans were defeated with so great a slaughter that the ground was covered with arms and dead bodies for more than 10 miles round: and among the spoils taken on this occasion, were found, as formerly, the chains with which the Germans had hoped to bind their captives.

In memory of this signal victory Germanicus raised a mount, upon which he placed as trophies the arms of the enemy, and inscribed underneath the names of the conquered nations. This so provoked the Germans, though already vanquished and determined to abandon their country, that they attacked the Roman army unexpectedly on its march, and put them into some disorder. Being repulsed, they encamped between a river and a large forest surrounded by a marsh except on one side, where it was inclosed by a broad rampart formerly raised by the Angrivarii as a barrier between them and the Cherusci. Here another battle ensued; in which the Germans behaved with great bravery, but in the end were defeated with great slaughter.

After this second defeat, the Angrivarii submitted, and were taken under the protection of the Romans, and Germanicus put an end to the campaign. Some of the legions he sent to their winter-quarters by land, while he himself embarked with the rest on the river Ems, in order to return by sea. The ocean proved at first very calm, and the wind favourable: but all of a sudden a storm arising, the fleet, consisting of 1000 vessels, was dispersed: some of them were swallowed up by the waves; others were dashed in pieces against the rocks, or driven upon remote and inhospitable islands, where the men either perished by famine, or lived upon the flesh of the dead horses with which the shores soon appeared strewed; for, in order to lighten their vessels, and disengage them from the shoals, they had been obliged to throw overboard their horses and beasts of burden, nay, even their arms and baggage. Most of the men, however, were saved, and even great part of the fleet recovered. Some of them were driven upon the coast of Britain; but the petty kings who reigned there generously sent them back.

14 s fleet ersed by torm.

On the news of this misfortune, the Catti, taking new courage, ran to arms; but Caius Silius being detached against them with 30,000 foot and 3000 horse, kept them in awe. Germanicus himself, at the head of a numerous body, made a sudden irruption into the territories of the Marsi, where he recovered one of Varus's eagles, and having laid waste the country, he returned to the frontiers of Germany, and put his troops into winter-quarters; whence he was soon recalled by Tiberius, and never suffered to return into Germany again. Germany.

After the departure of Germanicus, the more northern nations of Germany were no more molested by the Romans. Arminius carried on a long and successful war with Maroboduus king of the Marcomanni, whom he at last expelled, and forced to apply to the Romans for assistance; but, excepting Germanicus, it seems they had at this time no other general capable of opposing Arminius, so that Maroboduus was never restored. After the final departure of the Romans, however, Arminius having attempted to enslave his country, fell by the treachery of his own kindred. The Germans held his memory in great veneration; and Tacitus informs us, that in his time they still celebrated him in their songs. 15 Death of Arminius.

Nothing remarkable occurs in the history of Germany from this time till the reign of the emperor Claudius. A war indeed is said to have been carried on by Lucius Domitius, father to the emperor Nero. But of his exploits we know nothing more than that he penetrated beyond the river Elbe, and led his army farther into the country than any of the Romans had ever done. In the reign of Claudius, however, the German territories were invaded by Cn. Domitius Corbulo, one of the greatest generals of his age. But when he was on the point of forcing them to submit to the Roman yoke, he was recalled by Claudius, who was jealous of the reputation he had acquired.

In the reign of Vespasian, a terrible revolt happened among the Batavians and those German nations who had submitted to the Romans; a particular account of which is given under the article Rome. The revolters were with difficulty subdued; but, in the reign of Domitian, the Dacians invaded the empire, and proved a more terrible enemy than any of the other German nations had been. After several defeats, the emperor was at last obliged to consent to pay an annual tribute to Decebalus king of the Dacians; which continued to the time of Trajan. But this warlike prince refused to pay tribute; alleging, when it was demanded of him, that "he had never been conquered by Decebalus." Upon this the Dacians passed the Danube, and began to commit hostilities in the Roman territories. Trajan, glad of this opportunity to humble an enemy whom he began to fear, drew together a mighty army, and marched with the utmost expedition to the banks of the Danube. As Decebalus was not apprised of his arrival, the emperor passed the river without opposition, and entering Dacia, laid waste the country with fire and sword. At last he was met by Decebalus with a numerous army. A bloody engagement ensued, in which the Dacians were defeated; though the victory cost the Romans dear: the wounded were so numerous, that they wanted linen to bind up their wounds; and to supply the defect, the emperor generously devoted his own wardrobe. After the victory, he pursued Decebalus from 16 The Dacians invade the Roman empire.

place

Germany. place to place, and at last obliged him to consent to a peace on the following terms: 1. That he should surrender the territories which he had unjustly taken from the neighbouring nations. 2. That he should deliver up his arms, his warlike engines, with the artificers who made them, and all the Roman deserters. 3. That for the future he should entertain no deserters, nor take into his service the natives of any country subject to Rome. 4. That he should dismantle all his fortresses, castles, and strong-holds. And, lastly, that he should have the same friends and foes with the people of Rome.

With these hard terms Decebalus was obliged to comply, though sore against his will; and being introduced to Trajan, threw himself on the ground before him, acknowledging himself his vassal: after which the latter, having commanded him to send deputies to the senate for the ratification of the peace, returned to Rome.

This peace was of no long duration. Four years after (A. D. 105), Decebalus, unable to live in servitude as he called it, began, contrary to the late treaty, to raise men, provide arms, entertain deserters, fortify his castles, and invite the neighbouring nations to join him against the Romans as a common enemy. The Scythians hearkened to his solicitations; but the Jazyges, a neighbouring nation, refusing to bear arms against Rome, Decebalus invaded their country. Hereupon Trajan marched against him; but the Dacian, finding himself unable to withstand him by open force, had recourse to treachery, and attempted to get the emperor murdered. His design, however, proved abortive, and Trajan pursued his march into Dacia. That his troops might the more readily pass and repass the Danube, he built a bridge over that river; which by the ancients is styled the most magnificent and wonderful of all his works*. To guard the bridge, he ordered two castles to be built; one on this side the Danube, and the other on the opposite side; and all this was accomplished in the space of one summer. Trajan, however, as the season was now far advanced, did not think it advisable to enter Dacia this year, but contented himself with making the necessary preparations.

* See *Architecture*, n° 139.

17 They are subdued by Trajan.

In the year 106, early in the spring, Trajan set out for Dacia; and having passed the Danube on the bridge he had built, reduced the whole country, and would have taken Decebalus himself had he not put an end to his own life, in order to avoid falling into the hands of his enemies. After his death the kingdom of Dacia was reduced to a Roman province; and several castles were built in it, and garrisons placed in them, to keep the country in awe.

After the death of Trajan, the Roman empire began to decline, and the northern nations to be daily more and more formidable. The province of Dacia indeed was held by the Romans till the reign of Gallienus; but Adrian, who succeeded Trajan, caused the arches of the bridge over the Danube to be broken down, lest the barbarians should make themselves masters of it, and invade the Roman territories. In the time of Marcus Aurelius, the Marcomanni and Quadi invaded the empire, and gave the emperor a terrible overthrow. He continued the war, however, with better success afterwards, and invaded their country in his turn. It was during the course of this war that the Roman army is said to have been saved from destruction by that miraculous event related under the article CHRISTIANS, p. 717. col. 2. Germany.

18 Marcomanni and Quadi formidable to the empire

In the end, the Marcomanni and Quadi were, by repeated defeats, brought to the verge of destruction; insomuch that their country would probably have been reduced to a Roman province, had not Marcus Aurelius been diverted from pursuing his conquests by the revolt of one of his generals. After the death of Marcus Aurelius, the Germanic nations became every day more and more formidable to the Romans. Far from being able to invade and attempt the conquest of these northern countries, the Romans had the greatest difficulty to repress the incursions of their inhabitants. But for a particular account of their various invasions of the Roman empire, and its total destruction by them at last, see the article ROME.

19 Roman empire destroyed by the Heruli

The immediate destroyers of the Roman empire were the Heruli; who, under their leader Odoacer, dethroned Augustulus the last Roman emperor, and proclaimed Odoacer king of Italy. The Heruli were soon expelled by the Ostrogoths; and these in their turn were subdued by Justinian, who re-annexed Italy to the eastern empire. But the popes found means to obtain the temporal as well as spiritual jurisdiction over a considerable part of the country, while the Lombards subdued the rest. These last proved very troublesome to the popes, and at length besieged Adrian I. in his capital. In this distress he applied to Charles the Great king of France; who conquered both Italy and Germany, and was crowned emperor of the west in 800.

20 History of Germany since the time of Charlemagne.

The posterity of Charlemagne inherited the empire of Germany until the year 880; at which time the different princes assumed their original independence, rejected the Carlovinian line, and placed Arnulph king of Bohemia on the throne. Since this time, Germany has ever been considered as an elective monarchy. Princes of different families, according to the prevalence of their interest and arms, have mounted the throne. Of these the most considerable, until the Austrian line acquired the imperial power, were the houses of Saxony, Franconia, and Swabia. The reigns of these emperors contain nothing more remarkable than the contests between them and the popes; for an account of which, see the article ITALY. From hence, in the beginning of the 13th century, arose the factions of the Guelphs and Gibelines, of which the former was attached to the popes, and the latter to the emperor; and both, by their virulence and inveteracy, tended to disquiet the empire for several ages. The emperors too were often at war with the infidels; and sometimes, as happens in all elective kingdoms, with one another, about the succession.

But what more deserves our attention is the progress of government in Germany, which was in some measure opposite to that of the other kingdoms of Europe. When the empire raised by Charlemagne fell asunder, all the different independent princes assumed the right of election; and those now distinguished by the name of *electors* had no peculiar or legal influence in appointing a successor to the imperial throne; they were only the officers of the king's household, his secretary, his steward, chaplain, marshal, or master of his horse,

Germany. horſe, &c. By degrees, however, as they lived near the king's perſon, and had, like all other princes, independent territories belonging to them, they increaſed their influence and authority; and in the reign of Otho III. 984. acquired the ſole right of electing the emperor. Thus, while in the other kingdoms of Europe, the dignity of the great lords, who were all originally allodial or independent barons, was diminiſhed by the power of the king, as in France, and by the influence of the people, as in Great Britain; in Germany, on the other hand, the power of the electors was raiſed upon the ruins of the emperor's ſupremacy, and of the people's juriſdiction. In 1440, Frederic III. duke of Auſtria was elected emperor, and the imperial dignity continued in the male line of that family for 300 years. His ſucceſſor Maximilian married the heireſs of Charles duke of Burgundy; whereby Burgundy and the 17 provinces of the Netherlands were annexed to the houſe of Auſtria. Charles V. grandſon of Maximilian, and heir to the kingdom of Spain, was elected emperor in the year 1519. Under him MEXICO and PERU were conquered by the Spaniards; and in his reign happened the REFORMATION in ſeveral parts of Germany; which, however, was not confirmed by public authority till the year 1648, by the treaty of Weſtphalia, and in the reign of Ferdinand III. The reign of Charles V. was continually diſturbed by his wars with the German princes and the French king Francis I. Though ſucceſsful in the beginning of his reign, his good fortune towards the concluſion of it began to forſake him; which, with other reaſons, occaſioned his abdication of the crown. See CHARLES V.

His brother Ferdinand I. who in 1558 ſucceeded to the throne, proved a moderate prince with regard to religion. He had the addreſs to get his ſon Maximilian declared king of the Romans in his own lifetime, and died in 1564. By his laſt will he ordered, that if either his own male iſſue, or that of his brother Charles, ſhould fail, his Auſtrian eſtates ſhould revert to his ſecond daughter Anne, wife to the elector of Bavaria, and her iſſue. We mention this deſtination, as it gave riſe to the late oppoſition made by the houſe of Bavaria to the pragmatic ſanction, in favour of the empreſs queen of Hungary, on the death of her father Charles VI. The reign of Maximilian II. was diſturbed with internal commotions, and an invaſion from the Turks; but he died in peace in 1576. He was ſucceeded by his ſon Rodolph; who was involved in wars with the Hungarians, and in differences with his brother Matthias, to whom he ceded Hungary and Auſtria in his lifetime. He was ſucceeded in the empire by Matthias; under whom the reformers, who went under the names of *Lutherans* and *Calviniſts*, were ſo much divided among themſelves, as to threaten the empire with a civil war. The ambition of Matthias at laſt tended to reconcile them; but the Bohemians revolted, and threw the imperial commiſſaries out of a window at Prague. This gave riſe to a ruinous war, which laſted 30 years. Matthias thought to have exterminated both parties; but they formed a confederacy, called the *Evangelic League*, which was counterbalanced by a Catholic league.

Matthias dying in 1618, was ſucceeded by his couſin Ferdinand II.; but the Bohemians offered their crown to Frederic the elector Palatine, the moſt powerful Proteſtant prince in Germany, and ſon-in-law to his Britannic majeſty James I. That prince was incautious enough to accept of the crown: but he loſt it, by being entirely defeated by the duke of Bavaria and the imperial generals at the battle of Prague; and he was even deprived of his electorate, the beſt part of which was given to the duke of Bavaria. The Proteſtant princes of Germany, however, had among them at this time many able commanders, who were at the head of armies, and continued the war with wonderful obſtinacy: among them were the margrave of Baden Durlach, Chriſtian duke of Brunſwic, and count Mansfield; the laſt was one of the beſt generals of the age. Chriſtiern IV. king of Denmark declared for them; and Richlieu, the French miniſter, was not fond of ſeeing the houſe of Auſtria aggrandized. The emperor, on the other hand, had excellent generals; and Chriſtiern, having put himſelf at the head of the evangelic league, was defeated by Tilly, an Imperialiſt of great reputation in war. Ferdinand made ſo moderate a uſe of his advantages obtained over the Proteſtants, that they formed a freſh confederacy at Leipſic, of which the celebrated Guſtavus Adolphus king of Sweden was the head. An account of his glorious victories is given under the article SWEDEN. At laſt he was killed at the battle of Lutzen in 1632. But the Proteſtant cauſe did not die with him. He had brought up a ſet of heroes, ſuch as the duke of Saxe Weimer, Torſtenſon, Banier, and others, who ſhook the Auſtrian power; till, under the mediation of Sweden, a general peace was concluded among all the belligerent powers, at Munſter, in the year 1648; which forms the baſis of the preſent political ſyſtem of Europe. Germany.

Ferdinand II. was ſucceeded by his ſon Ferdinand III. This prince died in 1657; and was ſucceeded by the emperor Leopold, a ſevere, unamiable, and not very fortunate prince. He had two great powers to contend with, France on the one ſide, and the Turks on the other; and was a loſer in his war with both. Louis XIV. at that time king of France, was happy in having the two celebrated generals Condé and Turenne in his ſervice. The latter had already diſtinguiſhed himſelf by great exploits againſt the Spaniards; and, on the acceſſion of Leopold, the court of France had taken the opportunity of confirming the treaty of Munſter, and attaching to her intereſt ſeveral of the independent princes of Germany. The tranquillity which now took place, however, was not eſtabliſhed upon any permanent baſis. War with Spain was reſumed in the year 1668; and the great ſucceſſes of Turenne in the Netherlands ſtimulated the ambition of the prince of Condé to attempt the conqueſt of Franche Compte at that time under the protection of the houſe of Auſtria. This was accompliſhed in three weeks: but the rapid ſucceſs of Louis had awakened the jealouſy of his neighbours to ſuch a degree, that a league was formed againſt him by England, Holland, and Sweden; and the French monarch, dreading to enter the liſts with ſuch formidable enemies, conſented to the treaty of Aix-la-Chapelle, by which, among other articles, Franche Compte was reſtored. The flames of war, however, were renewed by the inſatiable ambition of the French monarch; who, having entered.

Germany. ed into an alliance with Charles II. of England, aimed at nothing less than the total overthrow of the Dutch republic. The events of that war are related under the article UNITED PROVINCES: here it is sufficient to observe, that the misfortunes of the Dutch excited the compassion of the emperor and court of Spain, who now openly declared themselves their allies. Turenne was opposed by the prince of Orange in conjunction with the celebrated imperial general Montecuculi, whose artful conduct eluded even the penetration of Turenne, and he sat down suddenly before the city of Bonne. Here he was joined by the prince of Orange, who had likewise found means to elude the vigilance of the French generals. Bonne surrendered in a short time, and several other places in Cologne fell into the hands of the allies; who likewise cut off the communication betwixt France and the United Provinces; so that Louis was soon obliged to recal his armies, and abandon all his conquests with greater rapidity than they had been made. In 1674 he was abandoned by his ally Charles II. of England, and the bishop of Munster and elector of Cologne were compelled to renounce their allegiance to him; but notwithstanding these misfortunes, he continued every where to make head against his enemies, and even meditated new conquests. With a powerful army he again invaded Franche Compte in person, and in six weeks reduced the whole province to his obedience. In Alsace, Turenne defeated the imperial general at Sintzheim, and ravaged the palatinate. Seventy thousand Germans were surprised; a considerable detachment was cut in pieces at Mulhausen; the elector of Brandenburg, who had been entrusted with the chief command, was routed by Turenne near Colmar; a third body met with a similar fate at Turkheim; and the whole German forces were obliged at last to evacuate the province and repass the Rhine.

In consequence of these disasters the Imperial general Montecuculi was recalled to act against Turenne. The military skill of the two commanders seemed to be nearly equal; but before the superiority could be adjudged to either, Turenne was killed by a cannon ball as he was reconnoitring a situation for erecting a battery. By his death the Imperialists obtained a decided superiority. Montecuculi penetrated into Alsace; and the French, under de Lorges nephew to the deceased general, were happy in being able to escape a defeat.

Part of the German army now sat down before Treves, where they were opposed by Marechal Crequi; but the negligence of that general exposed him to such a dreadful defeat, that he was obliged to fly into the city with only four attendants. Here he endeavoured in vain to animate the people to a vigorous defence. The garrison mutinied against his authority; and, when he refused to sign the capitulation they made, delivered him up prisoner to the enemy. Louis in the mean time had taken the field in person against the prince of Orange; but the disastrous state of affairs in Germany induced him to recall the prince of Condé to make head against Montecuculi. In this campaign the prince seemed to have the advantage. He compelled the Germans to raise the sieges of Hagenau and Saverne; and at last to repass the Rhine without having been able to force him to a battle.

This was the last campaign made by these celebrated commanders; both of them now, contented with the fame they had acquired, retiring from the field to spend the remainder of their days in peace. The excellent discipline, however, which the two great French generals had introduced into their armies, still continued to make them very formidable, though it did not always insure them of victory. In Germany, the duke of Lorrain, who had recovered Philipsburgh, was repeatedly defeated by Marechal Crequi, who had been ransomed from his captivity, and become more prudent by his defeat. In Flanders, the prince of Orange was overmatched by the duke of Orleans and Marshal Luxemburg. A peace was at length concluded at Nimeguen in 1679, by which the king of France secured himself Franche Compte with a great many cities in the Netherlands; while the king of Sweden was reinstated in those places of which he had been stripped by the Danes and Germans. This tranquillity, however, was of no long duration. Louis employed every moment in preparations for new conquests; possessed himself of the imperial city of Strasburg by treachery; and dispossessed the Elector Palatine and the elector of Treves of the lordships of Falkemburg, Germansheim, and Valdentz. On the most frivolous pretences he had demanded Alost from the Spaniards; and on their refusal, seized upon Luxemburg. His conduct, in short, was so intolerable, that the prince of Orange, his inveterate enemy, found means to unite the whole empire in a league against him. Spain and Holland became parties in the same cause; and Sweden and Denmark seemed also inclined to accede to the general confederacy. Notwithstanding this formidable combination, however, Louis seemed still to have the advantage. He made himself master of the cities of Philipsburgh, Manheim, Frankendal, Spires, Worms, and Oppenheim; the fruitful country of the palatinate was ravaged in a dreadful manner; the towns were reduced to ashes; and the people, driven from their habitations, were every where left to perish through the inclemency of the weather and want of provisions. By this cruelty his enemies were rather exasperated than vanquished: the Imperialists, under the conduct of the duke of Lorrain, resumed their courage, and put a stop to the French conquests. At length all parties, weary of a destructive war, consented to the treaty of Ryswick in 1697. By this treaty Louis gave up to the empire, Fribourg, Brisac, Kheil, and Philipsburg: he consented also to destroy the fortifications of Strasburg. Fort Louis and Traerbach, the works of which had exhausted the skill of the great Vauban, with Lorrain, Treves, and the Palatinate, were resigned to their respective princes; insomuch that the terms to which the French monarch now consented, after so many victories, were such as could scarce have been expected under the pressure of the greatest misfortunes. The views of Louis, however, in consenting to this apparently humiliating treaty, were beyond the views of ordinary politicians. The health of the king of Spain was in such a declining way, that his death appeared to be at hand; and Louis now resolved to renew his pretensions to that kingdom, which he had formerly by treaty solemnly renounced. His designs in this respect could not be concealed from the vigilance of

William

Germany. William III. of Britain; of which Louis being sensible, and knowing that the emperor had claims of the same nature on Spain, he thought proper to enter into a very extraordinary treaty with William. This was no less than the partition of the whole Spanish dominions, which were now to be distributed in the following manner. To the young prince of Bavaria were to be assigned Spain and the East Indies; the dauphin, son to Louis, was to have Naples, Sicily, and the province of Guipuscoa; while the Archduke Charles, son to the Emperor Leopold, was to have only the duchy of Milan. By this scandalous treaty the indignation of Charles was roused, so that he bequeathed the whole of his dominions to the prince of Bavaria. This scheme, however, was disconcerted by the sudden death of the prince; upon which a new treaty of partition was concluded between Louis and William. By this the kingdom of Spain, together with the East India territories, were to be bestowed on the Archduke Charles, and the duchy of Milan upon the duke of Lorrain. The last moments of the Spanish monarch were disturbed by the intrigues of the rival houses of Austria and Bourbon; but the haughtiness of the Austrian ministers so disgusted those of Spain, that they prevailed upon their dying monarch to make a new will. By this the whole of his dominions were bequeathed to Philip duke of Anjou, grandson to the king of France; and Louis, prompted by his natural ambition, accepted the kingdom bequeathed to his grandson, excusing himself to his allies in the best manner he could for departing from his engagements with them. For this, however, he was made to pay dear. His insatiable ambition and his former successes had alarmed all Europe. The Emperor, the Dutch, and the king of England, entered into a new confederacy against him; and a bloody war ensued, which threatened to overthrow the French monarchy entirely. While this war (of which an account is given under the article BRITAIN) was carried on with such success, the Emperor Leopold died in the year 1705.

He was succeeded by his son Joseph, who put the electors of Cologne and Bavaria to the ban of the empire; but being ill served by Prince Louis of Baden general of the empire, the French partly recovered their affairs, notwithstanding their repeated defeats. The duke of Marlborough had not all the success he expected or deserved. Joseph himself was suspected of a design to subvert the Germanic liberties; and it was plain by his conduct, that he expected England should take the labouring oar in the war, which was to be entirely carried on for his benefit. The English were disgusted at his slowness and selfishness: but he died in 1711, before he had reduced the Hungarians; and leaving no male issue, he was succeeded in the empire by his brother Charles VI. whom the allies were endeavouring to place on the throne of Spain, in opposition to Philip duke of Anjou, grandson to Louis XIV.

When the peace of Utrecht took place in 1713, Charles at first made a show as if he would continue the war; but found himself unable, now that he was forsaken by the English. He therefore was obliged to conclude a peace with France at Baden in 1714, that he might attend the progress of the Turks in Hungary; where they received a total defeat from Prince Eugene at the battle of Peterwaradin. They received another of equal importance from the same general in 1717, before Belgrade, which fell into the hands of the Imperialists; and next year the peace of Passarowitz, between them and the Turks, was concluded. Charles employed every minute of his leisure in making arrangements for increasing and preserving his hereditary dominions in Italy and the Mediterranean. Happily for him, the crown of Britain devolved to the house of Hanover; an event which gave him a very decisive weight in Europe, by the connections between George I. and II. and the empire. Charles was sensible of this; and carried matters with so high a hand, that, about the years 1724 and 1725, a breach ensued between him and George I. and so unsteady was the system of affairs all over Europe at that time, that the capital powers often changed their old alliances, and concluded new ones contradictory to their interest. Without entering into particulars, it is sufficient to observe, that the safety of Hanover, and its aggrandizement, was the main object of the British court; as that of the emperor was the establishment of the pragmatic sanction in favour of his daughter the (late empress-queen), he having no male issue. Mutual concessions upon those great points restored a good understanding between George II. and the emperor Charles; and the elector of Saxony, flattered with the view of gaining the throne of Poland, relinquished the great claims he had upon the Austrian succession. Germany.

The emperor, after this, had very bad success in a war he entered into with the Turks, which he had undertaken chiefly to indemnify himself for the great sacrifices he had made in Italy to the princes of the house of Bourbon. Prince Eugene was then dead, and he had no general to supply his place. The system of France, however, under cardinal Fleury, happened at that time to be pacific; and she obtained for him, from the Turks, a better peace than he had reason to expect. Charles, to keep the German and other powers easy, had, before his death, given his eldest daughter, the late empress-queen, in marriage to the duke of Lorrain, a prince who could bring no accession of power to the Austrian family.

Charles died in 1740; and was no sooner in the grave, than all he had so long laboured for must have been overthrown, had it not been for the firmness of George II. The young king of Prussia entered and conquered Silesia, which he said had been wrongfully dismembered from his family. The king of Spain and the elector of Bavaria set up claims directly incompatible with the pragmatic sanction, and in this they were joined by France; though all those powers had solemnly guaranteed it. The imperial throne, after a considerable vacancy, was filled up by the elector of Bavaria, who took the title of *Charles VII.* in January 1742. The French poured their armies into Bohemia, where they took Prague; and the queen of Hungary, to take off the weight of Prussia, was forced to cede to that prince the most valuable part of the duchy of Silesia by a formal treaty.

Her youth, her beauty, and sufferings, and the noble fortitude with which she bore them, touched the hearts of the Hungarians, into whose arms she threw herself and her little son; and though they had been always remarkable for their disaffection to the

Germany. houſe of Auſtria, they declared unanimouſly in her favour. Her generals drove the French out of Bohemia; and George II. at the head of an Engliſh and Hanoverian army, gained the battle of Dettingen, in 1743. Charles VII. was at this time miſerable on the imperial throne, and would have given the queen of Hungary almoſt her own terms; but ſhe haughtily and impoliticaly rejected all accommodation, though adviſed to it by his Britannic majeſty, her beſt and indeed only friend. This obſtinacy gave a colour for the king of Pruſſia to invade Bohemia, under pretence of ſupporting the imperial dignity; but though he took Prague, and ſubdued the greateſt part of the kingdom, he was not ſupported by the French; upon which he abandoned all his conqueſts, and retired into Sileſia. This event confirmed the obſtinacy of the queen of Hungary; who came to an accommodation with the emperor, that ſhe might recover Sileſia. Soon after, his Imperial majeſty, in the beginning of the year 1745, died; and the duke of Lorrain, then grand duke of Tuſcany, conſort to the queen of Hungary, after ſurmounting ſome difficulties, was choſen emperor.

The bad ſucceſs of the allies againſt the French and Bavarians in the Low Countries, and the loſs of the battle of Fontenoy, retarded the operations of the empreſs-queen againſt his Pruſſian majeſty. The latter beat the emperor's brother, Prince Charles of Lorrain, who had before driven the Pruſſians out of Bohemia; and the conduct of the empreſs-queen was ſuch, that his Britannic majeſty thought proper to guarantee to him the poſſeſſion of Sileſia, as ceded by treaty. Soon after, his Pruſſian majeſty pretended that he had diſcovered a ſecret convention which had been entered into between the empreſs queen, the empreſs of Ruſſia, and the king of Poland as elector of Saxony, to ſtrip him of his dominions, and to divide them among themſelves. Upon this his Pruſſian majeſty, very ſuddenly, drove the king of Poland out of Saxony, defeated his troops, and took poſſeſſion of Dreſden; which he held till a treaty was made under the mediation of his Britannic majeſty, by which the king of Pruſſia acknowledged the duke of Lorrain, great duke of Tuſcany, for emperor. The war, however, continued in the Low Countries, not only to the diſavantage, but to the diſcredit, of the Auſtrians and Dutch, till it was finiſhed by the treaty of Aix-la-Chapelle, in April 1748. By that treaty Sileſia was once more guaranteed to the king of Pruſſia. It was not long before that monarch's jealouſies were renewed and verified; and the empreſs of Ruſſia's views falling in with thoſe of the empreſs-queen and the king of Poland, who were unnaturally ſupported by France in their new ſchemes, a freſh war was kindled in the empire. The king of Pruſſia declared againſt the admiſſion of the Ruſſians into Germany, and his Britannic majeſty againſt that of the French. Upon thoſe two principles all former differences between theſe monarchs were forgotten, and the Britiſh parliament agreed to pay an annual ſubſidy of 670,000l. to his Pruſſian majeſty during the continuance of the war.

The flames of war now broke out in Germany with greater fury and more deſtructive violence than ever. The armies of his Pruſſian majeſty, like an irreſiſtible torrent, burſt in Saxony; totally defeated the imperial general Brown at the battle of Lowoſitz; forced the Saxons to lay down their arms, though almoſt impregnably fortified at Pirna; and the elector of Saxony fled to his regal dominions in Poland. After this, his Pruſſian majeſty was put to the ban of the empire; and the French poured, by one quarter, their armies, as the Ruſſians did by another, into the empire. The conduct of his Pruſſian majeſty on this occaſion is the moſt amazing that is to be met with in hiſtory; for a particular account of which, ſee the article Prussia. Germany.

At laſt, however, the taking of Colberg by the Ruſſians, and of Schweidnitz by the Auſtrians, was on the point of completing his ruin, when his moſt formidable enemy, the empreſs of Ruſſia, died, January 5th 1762; George II. his only ally, had died on the 25th of October 1760.

The deaths of thoſe illuſtrious perſonages were followed by great conſequences. The Britiſh miniſtry of George III. fought to finiſh the war with honour, and the new emperor of Ruſſia recalled his armies. His Pruſſian majeſty was, notwithſtanding, ſo very much reduced by his loſſes, that the empreſs-queen, probably, would have completed his deſtruction, had it not been for the wiſe backwardneſs of other German princes, not to annihilate the houſe of Brandenburg. At firſt the empreſs-queen rejected all terms propoſed to her, and ordered 30,000 men to be added to her armies. The viſible backwardneſs of her generals to execute her orders, and new ſucceſſes obtained by his Pruſſian majeſty, at laſt prevailed on her to agree to an armiſtice, which was ſoon followed by the treaty of Hubertſburgh, which ſecured to his Pruſſian majeſty the poſſeſſion of Sileſia. Upon the death of the emperor her huſband, in 1765, her ſon Joſeph, who had been crowned king of the Romans in 1764, ſucceeded him in the empire.

This prince ſhowed an active and reſtleſs diſpoſition, much inclined to extend his territories by conqueſt, and to make reformations in the internal policy of his dominions, yet without taking any proper methods for accompliſhing his purpoſes. Hence he was almoſt always diſappointed; inſomuch that he wrote for himſelf the following epitaph: "Here lies Joſeph, unfortunate in all his undertakings." In the year 1788, a war commenced betwixt him and the king of Pruſſia; in which, notwithſtanding the impetuous valour of that monarch, Joſeph acted with ſuch caution that his adverſary could gain no advantage over him; and an accommodation took place without any remarkable exploit on either ſide. In 1781 he took the opportunity of the quarrel betwixt Britain and the United Provinces, to deprive the latter of the barrier towns which had been ſecured to them by the treaty of Utrecht. Theſe indeed had frequently been of great uſe to the Houſe of Auſtria in its ſtate of weakneſs; but Joſeph, conſcious of his own ſtrength, looked upon it as derogatory to his honour to allow ſo many of his cities to remain in the hands of foreigners, and to be garriſoned at his expence. As at that time the Dutch were unable to reſiſt, the Imperial orders for evacuating the barrier towns were inſtantly complied with; nor did the court of France, though then in friendſhip with Holland, make any offer to interpoſe. Encouraged by this ſucceſs, Joſeph next demanded the free

Germany. navigation of the Scheldt; but as this would evidently have been very detrimental to the commercial intereſts of Holland, a flat refuſal was given to his requiſitions. In this the emperor was much diſappointed; having flattered himſelf that the Hollanders, intimidated by his power, would yield the navigation of the river as eaſily as they had done the barrier. Great preparations were made by the emperor, which the Dutch, on their part, ſeemed determined to reſiſt. But while the emperor appeared ſo much ſet upon this acquiſition, he ſuddenly abandoned the project entirely, and entered into a new ſcheme of exchanging the Netherlands for the duchy of Bavaria. This was oppoſed by the king of Pruſſia; and by the interference of the court of France, the emperor found himſelf at laſt obliged alſo to abandon his other ſcheme of obtaining the navigation of the Scheldt. A treaty of peace was concluded, under the guarantee of his moſt Chriſtian majeſty. The principal articles were, that the States acknowledged the emperor's ſovereignty over the Scheldt from Antwerp to the limits of Seſtingen; they agreed to demoliſh certain forts, and to pay a conſiderable ſum of money in lieu of ſome claims which the emperor had on Maeſtright, and by way of indemnification for laying part of his territories under water.

The treaty with the Dutch was no ſooner concluded than a quarrel with the Turks took place, which terminated in an open war. It does not appear that the emperor had at this time any real provocation, but ſeems to have acted merely in conſequence of his engagements with Ruſſia to reduce the dominions of the Grand Signor. All theſe foreign engagements, however, did not in the leaſt retard the progreſs of reformation which the emperor carried on throughout his dominions with a rapidity ſcarcely to be matched, and which at laſt produced the revolt of the Auſtrian Netherlands. In the courſe of his labours in this way a complete code of laws was compiled. Theſe were at firſt greatly commended for their humanity, as excluding almoſt entirely every ſpecies of capital puniſhment; yet, when narrowly conſidered, the commutations were found to be ſo exceedingly ſevere, that the moſt cruel death would, comparatively ſpeaking, have been an act of mercy. Even for ſmaller crimes the puniſhments were ſevere beyond meaſure; but the greateſt fault of all was, that the modes of trial were very defective, and the puniſhments ſo arbitrary, that the moſt perfect and innocent character lay at the mercy of a tyrannical judge. The innovations in eccleſiaſtical matters were, however, moſt offenſive to his ſubjects in the Netherlands. Among the many changes introduced into this department, the following were ſome of the moſt remarkable. 1. An abridgment of divine ſervice. 2. A total ſuppreſſion of vocal performers in choirs. 3. The introduction of the vernacular language inſtead of the Latin in adminiſtering the ſacraments. 4. The prohibition of chanting hymns in private houſes. 5. The ſuppreſſion of a great number of religious houſes, and the reduction of the number of the clergy. 6. The total abolition of the papal ſupremacy throughout the Imperial dominions. The ſame ſpirit of innovation diſplayed itſelf even in the moſt minute matters. Many favours were beſtowed upon the Jews; and in 1786 the emperor wrote with his own hand to the different handicraft and trading corporations in Vienna, requeſting that their youth might be received as apprentices in that city. Severe laws againſt gaming were enacted and put in execution with equal rigour. Heavy reſtrictions were alſo laid on all the ſocieties of free maſons in Germany, while thoſe in the Netherlands were totally ſuppreſſed. Germany.

The great number of innovations in religious matters were highly reſented by the inhabitants of the Netherlands, who have always been remarkable for their attachment to the Romiſh religion in its moſt ſuperſtitious form. Indeed the alterations in the civil conſtitution were ſo great, that even thoſe who were leaſt bigotted in this reſpect began to fear that their liberties were in danger, and an univerſal diſſatisfaction was excited. The emperor behaved at firſt in a very haughty manner, refuſed to yield the ſmalleſt point to the ſolicitations of his ſubjects. Finding, however, that a general revolt was about to take place, and being unable at that time, on account of the Turkiſh war, to ſpare ſuch a force as would be neceſſary to reduce the provinces to obedience, he thought proper, in the autumn of 1787, to promiſe a reſtoration of their ancient conſtitution and privileges. His promiſes, however, were found to be ſo deluſive, and his conduct was ſo arbitrary and capricious, that in the end of the year 1789 the States of all the provinces in the Auſtrian Netherlands came to a reſolution of entirely throwing off the yoke. Articles of a federal union were drawn up, and a new republic was formed under the title of the *Belgic Provinces*. The ſituation of the emperor's affairs at that time did not allow him to take the meaſures neceſſary for preventing this revolt; to which perhaps his ill ſtate of health alſo contributed. About the beginning of February 1790 his diſtemper increaſed to ſuch a degree as to be thought dangerous; and continuing daily to grow worſe, he ſunk under it on the 20th of the ſame month, in the 40th year of his age, and 26th of his reign.

The leaders of the Auſtrian revolution, however, ſoon became ſo diſagreeable to their countrymen, that they were obliged to fly; and the congreſs, which had been eſtabliſhed as the ſupreme legiſlative body, behaved with ſuch tyranny, that they became generally deteſted. Mean time, the late emperor was ſucceeded by his brother Peter Leopold Joſeph grand duke of Tuſcany; under whoſe adminiſtration matters have taken a more favourable turn. By his wiſdom, moderation, and humanity, he has already in a great meaſure retrieved the bad conſequences of his predeceſſor's conduct, having made peace with the Ottomans, and regained the allegiance of the Netherlands; and upon the whole ſeems to be actuated not more by a ſenſe of his own rights, than by a regard to the rights and happineſs of his ſubjects.

At preſent, Germany is bounded, on the north, by the Baltic Sea, Denmark, and the German Ocean; on the eaſt, by Pruſſia, Hungary, and Poland; and on the weſt, by the Low Countries, Lorraine, and Franche Compte: ſo that it now comprehends the Palatinate, of Cologne, Triers, and Liege, which formerly belonged to the Gauls; and is diſmembered of Frieſland, Groningen, and Overyſſel, which are now incorporated with the Low Countries.

Since the time of Charles the Great, this country

Germany has been divided into High and Low Germany. The first comprehends the Palatinate of the Rhine, Franconia, Suabia, Bavaria, Bohemia, Moravia, Auſtria, Carinthia, Carniola, Stiria, the Swiſs, and the Griſons. The provinces of Low Germany are, the Low Country of the Rhine, Triers, Cologne, Mentz, Weſtphalia, Heſſe, Brunſwic, Miſnia, Luſatia, High Saxony upon the Elbe, Low Saxony upon the Elbe, Mecklenburg, Lunenburg, Brandenburg, and Pomerania.

21 Situation, extent, &c. of Germany.

22 Conſtitution of the empire.

Monarchy was firſt eſtabliſhed in Germany by Clodovick: after him Charlemagne extended his power and his dominions; and ſo great had the empire become, that during his reign, and that of his ſon, government was adminiſtered in the provinces by perſons veſted with power for that purpoſe under the title of *Dukes*. In the diſtricts of theſe provinces, juſtice was diſtributed by a comes or count, which officer was in German called *Graf*. But from their courts lay an appeal to that of the emperor, before a preſident ſtyled *Comes Palatinus*, that is, "count Palatine, or of the palace," in German denominated *Pfalzgraf*. The frontiers or marches were governed by a marquis, ſtyled by the Germans *Markgraf*, ſimilar to our lord warden. Generally the centre of the empire was ruled by an officer, who poſſeſſed a ſimilar power, but a greater extent of dominion, than the Grave, under the title of *Landgrave*. Towns and caſtles, which were occaſionally honoured with the reſidence of the emperor, were governed by a Burggraf. It may be remarked, however, that the ſignification of the above mentioned titles, and the extent of power which they conferred upon the perſons honoured with them, differ according to the ſucceſſive ages and the gradual developement of the German conſtitution.

By reaſon of family broils in the Imperial houſe, and civil wars in the dominions, the dignity of the ſovereign was depreſſed, and a new form in the government raiſed up. The dukes exalted themſelves above the power of the emperor, and ſecured for their ſons a ſucceſſion to their greatneſs; while the intereſt of the ſovereign, in order to ſtrengthen the bond of perſonal attachment, ratified to others and their deſcendants that ſway which had been formerly delegated and dependant on his will. Hence aroſe the modern conſtitution of diſtinct principalities, acknowledging one head in the perſon of an emperor. But ſhortly after the election of Conrade duke of Franconia to the throne, this new-gained authority of the princes became doubtful. However, after moſt violent diſturbances and confuſions, the regulations yielded to by Albert II. and his ſucceſſors, particularly by Frederick III. laid the foundation of the German conſtitution: but the power and form of which were afterwards improved by Maximilian. Before Charles V. mounted the throne, on the death of Maximilian, the electors formed a bulwark againſt the Imperial power, by an inſtrument called the *capitulation*; to which articles of government he and all emperors elected ſince have ſworn previous to their inveſtiture with imperial dignity.

23 Of the electors.

When the German monarchy received an elective form, the right of election was not limited to the great officers of ſtate, for other princes participated of this privilege. But the empire being governed by four dukes, the princes under their authority, in order to court their favour, gave to them the diſpoſal of their votes, and of thoſe of their vaſſals. The three archbiſhops alſo, who were neceſſarily preſent at the coronation, obtained the electoral dignity. However, beſide this origin of the modern electors, the high ſtations about court procured their poſſeſſors an influence over other members, and their general reſidence there gave them a ſolid advantage in their conſtant and early preſence at the diet of election. For in times of turbulence ſeveral emperors were elected, when princes had not an opportunity to attend. And hence ſprung up a ſanction to that right, which the high officers of the houſhold had aſſumed, of electing without any conſultation of the other members of the empire. Pope Gregory X. too, either conceiving that they did poſſeſs, or willing that they ſhould acquire, this right, exhorted them in a bull to terminate the troubles of Germany by electing an emperor. And ſince that period they have been held as the ſole electors. But the poſſeſſion of this high power was ſtrengthened by a league amongſt themſelves called the *electoral union*, which received additional confirmation from the emperor Louis of Bavaria, and was formally and fully ratified by that famous conſtitution of Charles IV. termed the *golden bull*; according to which, the territories and the high offices by which the electoral dignity is conveyed, muſt deſcend according to the right of primogeniture, and are indiviſible.

The golden bull declares the following number and titles of the electors: The archbiſhop of Mentz as great chancellor of the German empire; the elector of Cologne as great chancellor of the empire in Italy; the elector of Triers as great chancellor of the empire in Gaul and Arles; the king of Bohemia as cupbearer; the count Palatine as high ſteward; the duke of Saxony as grand marſhal; the margrave of Brandenburgh as grand chamberlain. The number originally was ſeven, but the emperor Leopold created the duke of Lunenburg, anceſtor to our preſent Britiſh ſovereign, an elector; to whom the poſt of arch-treaſurer was afterwards given; and thus Hanover forms the eighth electorate. But this number cannot be increaſed by the emperor without a previous election by the electors themſelves; who, thus capable of electing and of being elected, may ſtyle themſelves *Coimperantes*; and they exerciſe part of the imperial authority, if a vacancy of the throne happen. But when or before this occurs, the election of the emperor is proceeded to after the following manner: The elector of Mentz, before the lapſe of a month after the death of the emperor, ſummons, as great chancellor of the empire, the reſt of the electors to attend on ſome fixed day within the ſpace of three months from the date of the ſummons. The electors generally ſend their ambaſſadors to the place of election, which is held at Frankfort on the Mayne; but ſaving the right of the city of Frankfort, it may be held elſewhere.

24 Election of the emperor.

When the diet of electors is aſſembled, they proceed to compoſe the capitulation, to which the emperor when elected is to ſwear. The capitulation being adjuſted, the elector of Mentz appoints a day for the election. When this day arrives, the gates of the city are ſhut, and the keys delivered to the elector of Mentz. The electors or their ambaſſadors, proteſtants excepted, repair in great pomp to maſs; and after its celebration

ermany. bration they take a folemn oath to chooſe, unbiaſſed and uninfluenced, the perſon that appears moſt proper for the imperial dignity. After this they repair to the ſacriſty, where the elector of Mentz firſt aſks, if there be any impediment known againſt their proceeding at preſent to an election? and next he obtains a promiſe, that the perſon elected by the majority ſhall be received as emperor. The declarations of the electoral ambaſſadors, in reſpect to theſe two points, are recorded by two notaries of the empire. Then all witneſſes withdraw; and the elector of Mentz collecting the ſuffrages, which are *viva voce*, and giving his own laſt, the witneſſes are recalled, and he declares the perſon whom the electors have choſen. But the election is not complete, nor is the new emperor proclaimed, until the capitulation be ſworn to either by himſelf or by his ambaſſadors if he be abſent. From this time he is ſtyled king of the Romans until the coronation takes place; which ceremony confers the title of emperor. According to the golden bull, it ſhould be celebrated at Aix-la-Chapelle, out of reſpect to Charlemagne, who reſided there; but ſaving the right to Aix-la-Chapelle, it may take place elſewhere. The coronation is performed by the archbiſhop of Mentz or elector of Cologne. And when he is ſeated on his throne, the duke of Saxony delivers into his hand the ſword of Charles the Great, with which he makes ſome knights of the holy Roman empire, and is alſo obliged to confer that honour upon ſuch others as are nominated by the reſpective electors. When he proceeds to dinner in the great hall, he is ſeated at a table elevated two ſteps higher than that of the electors, and is ſerved by counts of the empire. The electors, each of whom has alſo his table, are attended by the gentlemen of their reſpective courts. Theſe electors, who aſſiſt perſonally at the ceremony, ſit and eat at their own tables; but thoſe who are repreſented by ambaſſadors have only their tables covered out of form with plates, at which the ambaſſadors do not ſit.

For the benefit of the empire during the reign of an emperor, his preſumptive ſucceſſor may be elected king of the Romans. But this election confers at firſt a mere title; for by an expreſs article in his capitulation, the king of the Romans ſwears not to interfere with the government during the life of the emperor; but on his deceaſe, the coronation confirms him emperor without a ſecond election.

Should there not be a king of the Romans, and the throne become vacant, the government is adminiſtered by vicars of the empire, who are the electors Palatine and of Saxony, as count palatine and arch-marſhal of the empire. Each has his diſtrict and tribunal of the vicariate; and by the golden bull it is eſtabliſhed, that all acts of the vicars are valid; but they are all fully confirmed by the emperor; which confirmation, by an article of his capitulation, he is bound to give.

There are alſo vicars of the emperor. Theſe offices are conſtituted by a delegation of the imperial power from the emperor to any prince of the empire, when he is unable to execute his authority himſelf. But theſe vicars ſtand accountable to the emperor; their acts may be annulled and their offices revoked, all dependant on the will of the emperor, and determinable at his pleaſure.

When the race of Charlemagne ceaſed to govern in Germany, the princes and ſtates aſſociated to continue the empire; and that its majeſty might be viſible, and its laws enforced, they agreed to chooſe an emperor. From this emperor all electors and princes except thoſe before 1582 receive inveſtiture of their dominions; counts and free cities from the Aulic council. But this inveſtiture is no more than a ſign of ſubmiſſion to the majeſty of the empire, which is depoſited in the emperor. For as the conſtituted members of the empire are dependent on that collective union from which they derive protection, they therefore ſhow this dependence on the emperor, becauſe he repreſents the majeſty of that union or of the empire; but in all other reſpects they are independent and free. Germany.

Theſe princes or ſovereigns may even wage war with the prince wearing the imperial crown, as poſſeſſed of other titles and dominions unconnected with his imperial ſtation. Nor can the ſovereignty of any member be affected ſo long as he remains loyal to the empire; which loyalty conſtitutes his duty, and ſecures him its protection. But ſhould he be guilty of any violation againſt the emperor, as head of the empire, ſuch a crime would commit him to the puniſhment of its laws, and he would be put under the ban. For this crime would be againſt that collective body of ſovereigns whoſe union conſtitutes the empire; and therefore any violation of that union is juſtly puniſhed with deprivation of theſe territories which render ſuch ſovereigns members of the empire. Nor can this puniſhment of the ban derogate from the dignity of thoſe princes who derive their ſovereignty from this conſtitution, and whoſe ſubjection is an act of their own conſent. However, no member of the empire can at preſent be put under the ban without being firſt heard, and without the concurrence of the electors, princes, and ſtates, being previouſly obtained.

25
Powers of the emperor.

The emperor is endowed with many privileges, and his power partly appears in the exerciſe of his reſerved rights, or the peculiar prerogatives annexed to the imperial dignity. He grants to princes the inveſtiture of their dominions; but to this he is bound as the laws direct. He confers titles, but promiſes that they ſhall be beſtowed only on ſuch perſons as will maintain their dignity, and can ſupport their rank. Beſide, he can give merely the title; for the power or privilege of prince or count can be obtained only from their reſpective bodies. But in ſome inſtances, even titles are of high importance. For the deſcendants of a prince are incapable of ſucceſſion, if their mother be of inferior rank to their father; but the conferring of a title ennobles her and removes the bar, if the collateral line conſents.

The emperor can alſo make cities, found univerſities, grant the privilege of fairs, &c. He can alſo diſpenſe with the tedious terms of minority, and empower princes to aſſume at an earlier age the government of their own dominions. He decides all rank and precedency, and has a power of *primæ preces*, that is, of granting for once in every chapter of the empire a vacant ſeat. But he is not above the law; for electors have not only choſen but depoſed emperors. However, the influence of the capitulation is to prevent ſuch rigorous proceedings: but ſhould the capitulation be violated, the college of electors might proceed to remonſtrance; and if theſe remonſtrances ſhould

be

Germany. be without effect, in conjunction with the diet, they might reſort to more forcible remedies.

26 Diet of the empire.

The diet is that aſſembly of the ſtates in which the legiſlative power of the empire reſides; and is compoſed of the electors, princes, prelates, counts, and free cities of the empire. It has ſat ſince 1663, and is held uſually at Ratiſbon. The emperor, when preſent, preſides in perſon; when abſent, by his commiſſary, whoſe communication of propoſals from the emperor to the aſſembly is called the *commiſſorial decree*. The elector of Mentz, as chancellor of the empire, is director of the diet; and to his chancery are all things addreſſed that are to be ſubmitted to the empire; the reading of which by his ſecretary to the ſecretaries of the other miniſters at the diet is denominated *per dictaturam*, and conſtitutes the form of tranſmitting papers or memorials to the dictature of the empire.—The diet is compoſed of three diſtinct colleges, each of which has its particular director. The firſt college is that of electors; of which the archbiſhop of Mentz is director as firſt elector. The ſecond college is that of princes. It conſiſts of princes, archbiſhops, and biſhops; and of prelates, abbots, and counts, who are not conſidered as princes. Each prince ſpiritual and temporal has a vote, but prelates and counts vote by benches. The prelates are divided into two benches, the counts into four; and each bench has only one vote. The archduke of Auſtria and the archbiſhop of Saltzburg are alternately directors of the college of princes. The third college is that of the free cities of the empire; the director of which is the miniſter of the city in which the diet happens to ſit.

In all theſe colleges, the ſentiments of the majority are concluſive, except in reſpect of fundamental laws, which affect the whole empire, or ſuch matters as relate to religion. In theſe they muſt be unanimous.

Where religion is intereſted, the proceedings are alſo different. The colleges are then conſidered as conſiſting of two bodies, the evangelic and the catholic; and if any religious point be propoſed, it muſt meet not only the unanimous concurrence of the propoſing body, but muſt have the majority of the other to eſtabliſh it. This diſtinction aroſe from a conjunction called the *evangelic body*; which was formed by the Proteſtant ſtates and princes to guard the Proteſtant intereſt in Germany, by watching over the laws for the ſecurity of their religion, and, in caſe of violation, by obtaining redreſs from the imperial throne. For in any part of the empire, as in the palatinate, where the count is a Papiſt and the ſubjects are Proteſtants, ſhould oppreſſions ariſe, application would be made to the evangelic body through the director. The elector of Saxony is director of the evangelic body, though he is a Papiſt: but therefore his repreſentations in favour of the Proteſtants have more force; and beſide, ſhould he abuſe an office which inveſts him with conſiderable weight and influence, he could be inſtantly deprived of it.

The firſt two colleges are ſtyled ſuperior, and in effect conſtitute the diet: for all points that come before the diet, are generally firſt deliberated in the college of electors, and paſs from that to the college of princes; in which, if any objection ariſe, a free conference takes place between the directors of each college. And ſhould they, in conſequence of this free conference, concur, they invite the third college to accede to their joint opinion; which invitation is generally complied with: but ſhould this college return a refuſal, the opinion of the other two colleges is in ſome few caſes engroſſed in the chancery, and delivered to the emperor's commiſſary as the opinion of the empire. The opinion of the third college is merely mentioned at the cloſe. However, though the ſuperior colleges do in effect conſtitute the diet; yet the received maxim is, that no two colleges conſtitute a majority, that is, the majority of voices at the diet; nor can the emperor confirm the opinion of two colleges as an opinion of the diet. By the peace of Weſtphalia, a deciſive vote was recognized as a right of the imperial cities, which the two ſuperior colleges ſhould not infringe upon; their vote being, by the fundamental law, of equal weight with that of the electors and princes. Germa

After a meaſure is approved of by the colleges, it is ſubmitted to his Imperial majeſty to receive his negative or confirmation. Should he approve the point, it is publiſhed in his name as the reſolution of the empire, which ſtates are exhorted to obey, and tribunals deſired to conſider as ſuch.

The diet not only makes and explains laws, but decides ambiguous caſes. It muſt alſo be conſulted before war is made; appoints the field-marſhal who is to command the army, and aſſigns him his council of war. The diet alſo enters into and makes alliances, but uſually empowers the emperor to negociate them; and foreign ſtates have their ambaſſadors at the diet, but the diet ſends no miniſters to foreign courts.

2 Adminiſtration of juſtice

In the origin of the empire, juſtice was adminiſtered in the diſtricts of the provinces by counts, and appeals lay from their courts to that of the emperor before the count palatine. But as civil broils ſhook the power of the emperor, they interrupted alſo the courſe of juſtice. The conſequent inconveniences cauſed ſeveral ſolicitations to be preferred from the ſtates to different emperors for the eſtabliſhment of a court of juſtice, which ſhould take cognizance of great as well as ſmall cauſes. And at length ſuch a court was erected by Maximilian I. under the title of the *Imperial Chamber at Worms*, in the year 1495; but was removed to Spires in 1533, and to Wetzlar in 1696, where it is now held. The members of this court are a judge of the chamber and 25 aſſeſſors, partly Proteſtants partly Papiſts. The preſident is appointed by the emperor, the aſſeſſors by the ſtates. The court receives appeals from inferior juriſdictions, and decides dubious titles; and all cauſes before it between prince and prince, or princes and private perſons, are adjudged according to the laws of the reſpective parties, or according to the Imperial law. This tribunal is under the inſpection of viſitors appointed by the ſtates; and, during their viſitation, the ſentences of the court are ſubject to reviſion. Appeals lie afterward alſo from the judgment of the viſitors to that of the diet.

Aulic council.

The emperors, finding themſelves deprived of many of their powers, wiſhed to raiſe their prerogatives by forming a tribunal, of which they ſhould name the judges, and before whom cauſes in the laſt reſort ſhould come. But Maximilian foreſaw, in reſpect to the new tribunal, that though a conſciouſneſs of its importance made the ſtates ſtruggle for its erection, the expences of its eſtabliſhment would make them neglect its

its support; and the event bore witness to his sagacity. But when, through the omissions and negligence of the states, there happened to be a cessation in the distribution of justice by the Imperial chamber, he revived his court of the count Palatinate or Aulic council. And in order to gain the quiet acquiescence of the states, under the mask of a partition of power, and of generous moderation, he desired them to add eight to the number of assessors, and the salaries of all should be discharged by him. The states swallowed the bait, but soon perceived that they had lost part of their liberty.

The emperor, by keeping the tribunal always open, by filling its seats with men of first-rate talents, and by having its sentences duly and speedily executed, drew all causes before it. The states remonstrated, declaring, that the Imperial chamber ought to be not only the supreme, but sole tribunal of that kind. The emperor answered, that he had erected the Imperial chamber in consequence of their solicitations; but as they had not supplied the tribunal with judges, he provided for that deficiency by a constant administration of justice in the establishment of another.

The Aulic council now subsists with equal authority, each receiving appeals from inferior jurisdictions; but neither appealing to the other, as the *dernier resort* from both must be had to the diet. However, to the Aulic council belong the reserved rights of the emperor; and to the Imperial chamber also are annexed peculiar powers. The Imperial chamber subsists during a vacancy of the throne under the authority of the vicars of the empire; whereas the Aulic council does not exist until appointed by the succeeding emperor.

The Aulic council consists of a president, vice-president, and seventeen assessors, of whom six are Protestants. The vice-chancellor of the empire is also intitled to a seat; and all decrees issuing from the council pass through his hands to those who are to execute them. This tribunal obtains for the emperor, through the appeals from the courts of other princes, a new authority beside that which he possesses from his reserved rights; but electors and some princes, as those of Hanover, Austria, Brunswick, Swedish Pomerania, Hesse, are free from this dependence on the emperor, to whose Aulic council their subjects cannot appeal; nor can it take cognizance of ecclesiastical or criminal causes, both of which appertain to territorial justice; which we shall presently consider when we have surveyed the executive instrument of Imperial justice.

The division of the empire into circles is a regulation coeval with the establishment of the Imperial chamber by Maximilian, in order to strengthen the arm of justice with vigour to enforce its decrees. The original division was into six circles, which are called the *ancient circles*; and are Bavaria Franconia, Suabia, Lower Saxony, the Upper Rhine, and Westphalia: but the powerful princes, who at first declined bringing their dominions under the form of circles, were led by a political finesse of the emperors to adopt the regulation, and increase the number to ten, by forming the four new circles of Austria, Burgundy, the electorate circle, and Upper Saxony.

Over these circles preside directors, to whom the tribunals of justice commit the execution of their decrees. The six old circles have two directors each, the four new have one each. The office of director is permanent and hereditary, as it belongs always to the first prince in the circle, upon whom it confers high authority; for all the decrees of the Imperial chamber and Aulic council are of no avail unless the director will execute them. Germany.

The directors of the circles are not only instruments of war but of peace: for in case of an Imperial war, they are to collect the troops of the circle; and if any state or prince of their respective circles suffer violation from others, they are to yield protection and enforce the peace; or should there be any tumultuous uprisings of the people, the suppression of such belongs to them.

The emperor is the executive instrument of the whole empire; the directors are such of the constitutive parts called circles. The prosperity and security of which being at stake, the directors, as presidents, must hold frequent diets in their respective circles, in order to consult on and adopt salutary measures for their safety and welfare: but as the interests of those near to us are generally so intimately blended with our own, that the good of either cannot be pursued without the mutual concurrence of both, there arise negociations on particular points between the diets of different circles, which are therefore styled *confederate circles*; and these negociations being more frequent amongst the circles of the Upper and Lower Rhine, or Westphalia, they are denominated the *corresponding circles*.

29 Powers of the German princes.

Every prince is sovereign in his own country; and may enter into alliances, and pursue by all political measures his own private interest, as other sovereigns do; for if even an Imperial war be declared, he may remain neuter if the safety of the empire be not at stake.

Each state or sovereign appoints in general three colleges for its government. The first is the *geheimderath*, or privy-council; the second is the *regierung*, or regency; the third the *renthcammer*, or chamber of finances. Each of these has a president; and a member of the first college is always president of the second.—The geheimderath represents the prince, and superintends the other two. The regierung regulates limits of territories, holds conferences with other princes, and is in most countries a court of justice: however, in some states there is also a court of justice called *justitz departement*. And besides the right of conferences assigned to the regierung by the sovereign when there are disputes between princes, there is also an *austrage*, or abitration, appointed in order to decide them. Attention must be paid to this privilege of princes, who must be called on to appoint an austrage before resort be had to the Imperial tribunal, but to which there still lies an appeal from the judgment of the austrage. The renthcammer attends to the regulation of domains and estates, to the territorial revenues, and management of the taxes.

Every sovereign or prince is arbitrary in laws of policy, but not of revenue; for no new tax or impost can be laid on his country without the consent of the nobles and subjects. For this purpose, on the *land tag*, or day on which his subjects are to be convened, which is once in the period of four or five years, and at no other time can he assemble them, he calls together

Germany.

ther the nobles and commiſſaries or deputies of the towns of his dominions. The nobles uſually attend in perſon, but may ſend repreſentatives. To this aſſembly the prince propoſes the taxes, &c. and a majority of voices diſpoſes of the meaſures.

Villages, though conſiderable, ſend no deputies to this aſſembly; becauſe they are either already repreſented by their reſpective lords, or becauſe they rank too low, being in a ſtate of vaſſalage when compared to towns: for their inhabitants muſt mend highways, and can be impreſſed as ſoldiers; from both of which inhabitants of towns are exempt.

On the land tag, the reſpective quotas alſo of each place are fixed, in order to diſcharge the princes contingent in caſe of an Imperial war.

30 Military force and annual revenue.

There is no fixed ſtanding army of the empire; but the various ſtates furniſh their quotas purſuant to the agreement of 1681, when called upon by the diet in caſe of war, viz.

	Foot.	Horſe.
Upper Saxony	2707	1321
Lower Saxony	2707	1321
Weſtphalia	2707	1321
Upper Rhine	2853	491
Lower Rhine	2707	600
Burgundy	2707	1321
Franconia	1902	980
Auſtria	5507	2521
Bavaria	1494	800
Swabia	2707	1321
Total	27,998	11,997

The whole number of forces in the ſervice of the ſeveral German princes have been ſtated at half a million; others calculate, that the eccleſiaſtical princes can furniſh 74,500 men, the temporal princes 379,000, and the emperor 90,000, as head of the houſe of Auſtria. Total 543,500.

The revenue accruing to the emperor as ſuch in time of peace, is very trifling, only about 20,000 crowns, being the contributions of a few imperial towns; but in caſe of war, extraordinary aids, called *Roman months*, laid on by the diet, are contributed by the different circles at the following rate for raiſing 1½ million of florins, viz.

	Florins.	Xtr.
Upper Saxony	156,360	15
Lower Saxony	156,360	15
Weſtphalia	156,360	15
Upper Rhine	101,411	30
Lower Rhine	105,654	5
Burgundy	156,360	15
Franconia	113,481	25
Auſtria	306,390	20
Bavaria	91,261	5
Swabia	156,360	15
Total	1,499,999	40

The actual revenue of all Germany has been calculated at nearly L. 18.000,000 ſterling, or 100 million of dollars.

31 Productions and commerce.

From the great extent of the empire, every variety of ſoil is to be met with; but it is upon the whole more fertile than otherwiſe. The middle parts are moſt productive in corn and cattle; the ſouthern abound with excellent wines and fruits. The northern parts, from their coldneſs, are rather unfavourable to vegetation; however, agriculture throughout improves exceedingly. Their mines, though early explored, ſtill continue great ſources of wealth. They produce, excepting tin, almoſt every mineral. Of quickſilver, one mine alone is computed to yield 50,000 pounds weight a-year. They furniſh the fineſt ſort of clay for porcelain, and have excellent and extenſive ſalt-works.

Germa

From the central ſituation of Germany, its commerce with the reſt of Europe is very extenſive. Its minerals are decidedly the firſt native articles for trade; after which its medicinal waters, ſalt, hemp, flax, linen, ſilk, wines, fruits, corn, cattle, ſtuffs, cloths, timber, porcelain, wrought iron and ſteel, drugs, oil, and colours, are the principal. The artizans furniſhed by the revocation of the edict of Nantz, enable Germany on longer to ſtand in need of the wrought ſilks of other countries. Great commercial fairs ſtill exiſt in Germany, and it is conſidered upon the whole that the balance of trade is in its favour.

32 Character of the ancient Germans.

With regard to the character of the ancient Germans, they are deſcribed to us by the Greek and Roman writers as reſembling the Gauls; and differing from other nations by the largeneſs of their ſtature, ruddy complexion, blue eyes, and yellow buſhy hair, haughty and threatening looks, ſtrong conſtitutions, and being proof againſt hunger, cold, and all kinds of hardſhip.

Their native diſpoſition diſplayed itſelf chiefly in their martial genius, and in their ſingular fidelity. The former of theſe they did indeed carry to ſuch an exceſs as came little ſhort of downright ferocity; but, as to the latter, they not only valued themſelves highly upon it, but were greatly eſteemed by other nations for it; inſomuch that Auguſtus, and ſeveral of his ſucceſſors, committed the guard of their perſons to them, and almoſt all other nations either courted their friendſhip and alliance, or hired them as auxiliaries: though it muſt be owned, at the ſame time, that their extreme love of liberty, and their hatred of tyranny and oppreſſion, have often hurried them to treachery and murder, eſpecially when they have thought themſelves ill uſed by thoſe who hired them; for in all ſuch caſes they were eaſily ſtirred up, and extremely vindictive. In other caſes, Tacitus tells us, they were noble, magnanimous, and beneficent, without ambition to aggrandize their dominions, or invading thoſe from whom they received no injury; rather chooſing to employ their ſtrength and valour defenſively than offenſively; to preſerve their own, than to ravage their neighbours.

Their friendſhip and intercourſe was rather a compound of honeſt bluntneſs and hoſpitality, than of wit, humour, or gallantry. All ſtrangers were ſure to meet with a kind reception from them to the utmoſt of their ability: even thoſe who were not in a capacity to entertain them, made it a piece of duty to introduce them to thoſe who could; and nothing was looked upon as more ſcandalous and deteſtable, than to refuſe them either the one or the other. They do not ſeem, indeed, to have had a taſte for grand and elegant entertainments; they affected in every thing, in their houſes, furniture, diet, &c. rather plainneſs and ſimplicity, than ſumptuouſneſs and luxury. If they learned of the Romans and Gauls the uſe of money, it was rather becauſe they found it more convenient than

Germany. than their ancient way of bartering one commodity for another; and then they preferred thoſe ancient coins which had been ſtamped during the times of the Roman liberty, eſpecially ſuch as were either milled or cut in the rims, becauſe they could not be ſo eaſily cheated in them as in ſome others, which were frequently nothing but copper or iron plated over with ſilver. This laſt metal they likewiſe preferred before gold, not becauſe it made a greater ſhow, but becauſe it was more convenient for buying and ſelling: And as they became in time more feared by, or more uſeful to, the Romans; ſo they learned how to draw enough of it from them to ſupply their whole country, beſides what flowed to them from other nations.

As they deſpiſed ſuperfluities in other caſes, ſo they did alſo in the connubial way: every man was contented with one wife, except ſome few of their nobles, who allowed themſelves a plurality, more for ſhow than pleaſure; and both were ſo faithful to each other, and chaſte, true, and diſintereſted, in their conjugal affections, that Tacitus prefers their manners in this reſpect to thoſe of the Romans. The men fought not dowries from their wives, but beſtowed them upon them. Their youth, in thoſe cold climes, did not begin ſo ſoon to feel the warmth of love as they do in hotter ones: it was a common rule with them not to marry young; and thoſe were moſt eſteemed who continued longeſt in celibacy, becauſe they looked upon it as an effectual means to make them grow tall and ſtrong; and to marry, or be concerned with a woman, before they were full 20 years old, was accounted ſhameful wantonneſs. The women ſhared with their huſbands not only the care of their family, and the education of their children, but even the hardſhips of war. They attended them in the field, cooked their victuals for them, dreſſed their wounds, ſtirred them up to fight manfully againſt their enemies, and ſometimes have by their courage and bravery recovered a victory when it was upon the point of being ſnatched from them. In a word, they looked upon ſuch conſtant attendance on them, not as a ſervitude, like the Roman dames, but as a duty and an honour. But what appears to have been ſtill an harder fate upon the ancient German dames was, that their great Odinus excluded all thoſe from his *valhalla*, or paradiſe, who did not, by ſome violent death, follow their deceaſed huſbands thither. Yet notwithſtanding their having been anciently in ſuch high repute for their wiſdom and ſuppoſed ſpirit of prophecy, and their continuing ſuch faithful and tender helpmates to their huſbands, they ſunk in time ſo low in their eſteem, that, according to the old Saxon law, he that hurt or killed a woman was to pay but half the fine that he ſhould have done if he had hurt or killed a man.

33 Their funerals. There is ſcarcely any one thing in which the Germans, though ſo nearly allied in moſt of their other cuſtoms to the Gauls, were yet more oppoſite to them than in their funerals. Thoſe of the latter were performed with great pomp and profuſion; thoſe of the former were done with the ſame plainneſs and ſimplicity which they obſerved in all other things: the only grandeur they affected in them was, to burn the bodies of their great men with ſome peculiar kinds of wood; but then the funeral pile was neither adorned with the clothes and other fine furniture of the deceaſed, nor perfumed Germany. with fragrant herbs and gums: each man's armour, that is, his ſword, ſhield, and ſpear, were flung into it, and ſometimes his riding-horſe. The Danes, indeed, flung into the funeral pile of a prince, gold, ſilver, and other precious things, which the chief mourners, who walked in a gloomy guiſe round the fire, exhorted the byſtanders to fling liberally into it in honour of the deceaſed. They afterwards depoſited their aſhes in urns, like the Gauls, Romans, and other nations; as it plainly appears, from the vaſt numbers which have been dug up all over the country, as well as from the ſundry diſſertations which have been written upon them by ſeveral learned moderns of that nation. One thing we may obſerve, in general, that, whatever ſacrifices they offered for their dead, whatever preſents they made to them at their funerals, and whatever other ſuperſtitious rites they might perform at them, all was done in conſequence of thoſe excellent notions which their ancient religion had taught them, the immortality of the ſoul, and the bliſs or miſery of a future life.

34 Their belief of a future ſtate. It is impoſſible, indeed, as they did not commit any thing to writing till very lately, and as none of the ancient writers have given us any account of it, to gueſs how ſoon the belief of their great Odin, and his paradiſe, was received among them. It may, for aught we know, have been older than the times of Tacitus, and he have known nothing of it, by reaſon of their ſcrupulous care in concealing their religion from ſtrangers: but as they conveyed their doctrines to poſterity by ſongs and poems, and moſt of the northern poets tell us that they have drawn their intelligence from thoſe very poems which were ſtill preſerved among them; we may rightly enough ſuppoſe, that whatever doctrines are contained in them, were formerly profeſſed by the generality of the nation, eſpecially ſince we find their ancient practice ſo exactly conformable to it. Thus, ſince the ſureſt road to this paradiſe was, to excel in martial deeds, and to die intrepidly in the field of battle; and ſince none were excluded from it but baſe cowards, and betrayers of their country; it is natural to think, that the ſignal and exceſſive bravery of the Germans flowed from this ancient belief of theirs: and, if their females were ſo brave and faithful, as not only to ſhare with their huſbands all the dangers and fatigues of war, but at length to follow them, by a voluntary death, into the other world; it can hardly be attributed to any thing elſe but a ſtrong perſuaſion of their being admitted to live with them in that place of bliſs. This belief, therefore, whether received originally from the old Celtes, or afterwards taught them by the ſince deified Odin, ſeems, from their general practice, to have been univerſally received by all the Germans, though they might differ one from another in their notions of that future life.

The notion of a future happineſs obtained by martial exploits, eſpecially by dying ſword in hand, made them bewail the fate of thoſe who lived to an old age, as diſhonourable here, and hopeleſs hereafter: upon which account, they had a barbarous way of ſending them into the other world, willing or not willing. And this cuſtom laſted ſeveral ages after their receiving Chriſtianity, eſpecially among the Pruſſians and Venidi; the former of whom, it ſeems, diſpatched by a

Germany. quick death, not only their children, the ſick, ſervants, &c. but even their parents, and ſometimes themſelves: and among the latter we have inſtances of this horrid parricide being practiſed even in the beginning of the 14th century. All that need be added is, that, if thoſe perſons, thus ſuppoſed to have lived long enough, either deſired to be put to death, or at leaſt ſeemed cheerfully to ſubmit to what they knew they could not avoid, their exit was commonly preceded with a faſt, and their funeral with a feaſt; but if they endeavoured to ſhun it, as it ſometimes happened, both ceremonies were performed with the deepeſt mourning. In the former, they rejoiced at their deliverance, and being admitted into bliſs; in the latter, they bewailed their cowardly excluding themſelves from it. Much the ſame thing was done towards thoſe wives who betrayed a backwardneſs to follow their dead huſbands.

35 Remarkable for drinking to exceſs.

We muſt likewiſe obſerve, that, in theſe funerals, as well as in all their other feaſts, they were famed for drinking to exceſs; and one may ſay of them, above all the other deſcendants of the ancient Celtes, that their hoſpitality, banquets, &c. conſiſted much more in the quantity of ſtrong liquors, than in the elegance of eating. Beer and ſtreng mead, which were their natural drink, were looked upon as the chief promoters of health, ſtrength, fertility, and bravery; upon which account, they made no ſcruple to indulge themſelves to the utmoſt in them, not only in their feaſts, and eſpecially before an engagement, but even in their common meals.

36 Character of the modern Germans.

The modern Germans in their perſons are tall and ſtrong built. The ladies have generally fine complexions; and ſome of them, eſpecially in Saxony, have all the delicacy of features and ſhape that are ſo bewitching in a certain iſland of Europe.

Both men and women affect rich dreſſes, which in faſhion are the ſame as in France and England; but the better ſort of men are exceſſively fond of gold and ſilver lace, eſpecially if they are in the army. The ladies at the principal courts differ not much in their dreſs from the French and Engliſh, only they are not ſo exceſſively fond of paint as the former. At ſome courts they appear in rich furs; and all of them are loaded with jewels, if they can obtain them. The female part of the burghers families, in many German towns, dreſs in a very different manner, and ſome of them inconceivably fantaſtic, as may be ſeen in many prints publiſhed in books of Travels; but in this reſpect they are gradually reforming, and many of them make quite a different appearance in their dreſs from what they did 30 or 40 years ago. As to the peaſantry and labourers, they dreſs as in other parts of Europe, according to their employments, conveniency, and opulence. In Weſtphalia, and moſt other parts of Germany, they ſleep between two feather-beds, or rather the upper one of down, with ſheets ſtitched to them, which by uſe becomes a very comfortable practice. The moſt unhappy part of the Germans are the tenants of little needy princes, who ſqueeze them to keep up their own grandeur; but, in general the circumſtances of the common people are far preferable to thoſe of the French.

The Germans are naturally a frank, honeſt, hoſpitable people, free from artifice and diſguiſe. The higher orders are ridiculouſly proud of titles, anceſtry, and ſhow. The Germans, in general, are thought to want animation, as their perſons promiſe more vigour and activity than they commonly exert even in the field of battle. But when commanded by able generals, eſpecially the Italians, ſuch as Montecuculi and prince Eugene, they have done great things, both againſt the Turks and the French. The Imperial arms have ſeldom made any remarkable figure againſt either of thoſe two nations, or againſt the Swedes or Spaniards, when commanded by German generals. This poſſibly might be owing to the arbitrary obſtinacy of the court of Vienna; for in the two laſt wars the Auſtrians exhibited prodigies of military valour and genius. Germany

Induſtry, application, and perſeverance, are the great characteriſtics of the German nation, eſpecially the mechanical part of it. Their works of art would be incredible were they not viſible, eſpecially in watch and clock making, jewellery, turnery, ſculpture, drawing, painting, and certain kinds of architecture. The Germans have been charged with intemperance in eating and drinking; and perhaps not unjuſtly, owing to the vaſt plenty of their country in wine and proviſions of every kind. But thoſe practices ſeem now to be wearing out. At the greateſt tables, though the gueſts drink pretty freely during dinner, yet the repaſt is commonly finiſhed by coffee after three or four public toaſts have been drank. But no people have more feaſting at marriages, funerals, and birthdays.

The German nobility are generally men of ſo much honour, that a ſharper in ſother countries, eſpecially in England, meets with more credit if he pretends to be a German, than of any other nation.

The merchants and tradeſmen are very civil and obliging. All the ſons of noblemen inherit their fathers titles, which greatly perplexes the heralds and genealogiſts of that country. This perhaps is one of the reaſons why the German huſbands are not quite ſo complaiſant as they ought otherwiſe to be to their ladies, who are not intitled to any pre-eminence at the table; nor indeed do they ſeem to affect it, being far from either ambition or loquacity, though they are ſaid to be ſomewhat too fond of gaming. From what has been premiſed, it may eaſily be conceived, that many of the German nobility, having no other hereditary eſtate than a high-ſounding title, eaſily enter into their armies, and thoſe of other ſovereigns. Their fondneſs for title is attended with many other inconveniences. Their princes think that the cultivation of their lands though it may treble their revenue, is below their attention; and that, as they are a ſpecies of beings ſuperior to labourers of every kind, they would demean themſelves in being concerned in the improvement of their grounds.

37 Amuſements.

The domeſtic diverſions of the Germans are the ſame as in England; billiards, cards, dice, fencing, dancing, and the like. In ſummer, people of faſhion repair to places of public reſort, and drink the waters. As to their field-diverſions, beſides their favourite one of hunting, they have bull and bear beating, and the like. The inhabitants of Vienna live luxuriouſly, a great part of their time being ſpent in feaſting and carouſing; and in winter, when the ſeveral branches of the Danube are frozen over, and the ground covered with

Germany || Germination

with snow, the ladies take their recreations in sledges of different shapes, such as griffins, tygers, swans, scollop-shells, &c. Here the lady sits, dressed in velvet lined with rich furs, and adorned with laces and jewels, having on her head a velvet cap; and the sledge is drawn by one horse, stag, or other creature, set off with plumes of feathers, ribbons, and bells. As this diversion is taken chiefly in the night-time, servants ride before the sledge with torches, and a gentleman sitting on the sledge behind guides the horse.

38 Religion and learning.

The Reformation first spread in Germany to most advantage; and since the religious peace of 1555, there have been established the Roman Catholic, prevailing mostly in the south; the Lutheran in the north; and the Calvinist, called also the *Reformed*, near the Rhine. Civil wars considerably deranged this settlement: it was, however, established by the celebrated peace of Westphalia, that the religion of the Seven States should remain as in 1624. The Romish superior clergy consist of 8 archbishops, 40 bishops, and many abbots. The Protestant clergy are governed by consistories under the sovereign of each state. The *Corpus Catholicorum* is under the direction of the archbishop, elector of Mentz; and the *Corpus Evangelicorum*, or Protestants, under the elector of Saxony; who have the care of the public concerns of their respective bodies.

Literature is at present in a very advanced state throughout almost all Germany, but particularly in the Protestant states. It is but about half a century since the German language has been purified and cultivated; since which various works of taste and elegance, as well as superior productions in the different walks of science, have appeared in it.—There are 38 universities in Germany; 19 Protestant, 17 Catholic, and 2 which partake of both; besides a number of literary societies and academic institutions: and education in general is particularly attended to even in the very lowest ranks.

GERMEN, the seed-bud; defined by Linnæus to be the base of the pistillum, which contains the rudiments of the seed; and, in progress of vegetation, swells and becomes the seed-vessel.

In assimilating the vegetable and animal kingdoms, Linnæus denominates the seed-bud the *ovarium* or *uterus* of plants; and affirms its existence to be chiefly at the time of the dispersion of the male-dust by the antheræ; as, after its impregnation, it becomes a seed-vessel. See Botany.

Germen, by Pliny and the ancient botanists, is used to signify a bud containing the rudiments of the leaves. See Gemma.

GERMINATION, among botanists, comprehends the precise time which the seeds take to rise after they have been committed to the soil.—The different species of seeds are longer or shorter in rising according to the degree of heat which is proper to each. Millet, wheat, and several of the grasses, rise in one day; blite, spinach, beans, mustard, kidney-beans, turnips, and rocket, in three days; lettuce and dill, in four; cucumber, gourd, melon, and cress, in five; radish and beet, in six; barley, in seven; orach, in eight; purslane, in nine; cabbage, in ten; hyssop, in thirty; parsley, in forty or fifty days; peach, almond, walnut, chesnut, pæony, horned-poppy, hypecoum, and ranunculus falcatus, in one year; rose-bush, cornel-tree, hawthorn, medlar, and hazel-nut, in two. The seeds of some species of orchis, and of some liliaceous plants, never rise at all. Of seeds, some require to be sowed almost as soon as they are ripe, otherwise they will not sprout or germinate. Of this kind are the seeds of coffee and fraxinella. Others, particularly those of the pea-bloom flowers, preserve their germinating faculty for a series of years.—Mr Adanson asserts, that the sensitive plant retains that virtue for 30 or 40 years. Germination || Geropogon.

Air and water are the agents of germination. The humidity of the air alone makes several seeds to rise that are exposed to it. Seeds too are observed to rise in water, without the intervention of earth; but water without air is insufficient.—Mr Homberg's experiments on this head are decisive. He put several seeds under the exhausted receiver of an air-pump, with a view to establish something certain on the causes of germination. Some of them did not rise at all; and the greatest part of those which did, made very weak and feeble productions. Thus it is for want of air that seeds which are buried at a very great depth in the earth, either thrive but indifferently, or do not rise at all. They frequently preserve, however, their germinating virtue for many years within the bowels of the earth; and it is not unusual, upon a piece of ground being newly dug to a considerable depth, to observe it soon after covered with several plants, which had not been seen there in the memory of man. Were this precaution frequently repeated, it would doubtless be the means of recovering certain species of plants which are regarded as lost; or which perhaps, never coming to the knowledge of botanists, might hence appear the result of a new creation. Some seeds require a greater quantity of air than others. Thus purslane, which does not rise till after lettuce in the free air, rises before it *in vacuo*; and both prosper but little, or perish altogether, while cresses vegetate as freely as in the open air.

GERONTES, in antiquity, a kind of judges, or magistrates, in ancient Sparta, answering to what the Areopagites were at Athens. See Areopagus.

The word is formed of the Greek γέρων, which signifies "old man." Whence also the words *gerontic*, something belonging to an old man; and *Geronicon*, a famous book among the modern Greeks, containing the lives of the ancient monks. The senate of gerontes was called *gerusia*, that is, assembly or council of old men.

The gerontes were originally instituted by Lycurgus: their number, according to some, was 28; and, according to others, 32. They governed in conjunction with the king, whose authority they were intended to balance, and to watch over the interests of the people. Polybius defines their office in few words, when he says, *per ipsos, & cum ipsis omnia administrari.* None were to be admitted into this office under 60 years of age, and they held it for life. They were succeeded by the ephori.

GEROPOGON, in botany: A genus of the polygamia æqualis order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Compositæ*. The receptacle is paleaceous, with the points of the palæ sharp or bristly; the calyx is simple; the seeds of the disc have a feathered pappus; those of the radius have a pappus of five awns.

Gerretz
||
Gefner.

GERRETZ. See REMBRANDT.

GERVAISE, (or GERVASE), of Tilbury, a famous Engliſh writer of the 13th century; thus named from his being born at Tilbury on the Thames. He was nephew to Henry II. king of England; and was in great credit with Otho IV. emperor of Germany, to whom he dedicated a Deſcription of the World, and a Chronicle. He alſo compoſed a Hiſtory of England, that of the Holy Land, and other works.

GERUND, in grammar, a verbal noun of the neuter gender, partaking of the nature of a participle, declinable only in the ſingular number, through all the caſes except the vocative; as nom. *amandum*, gen. *amandi*, dat. *amando*, accuſ. *amandum*, abl. *amando*. The word is formed of the Latin *gerundivus*, and that from the verb *gerere*, "to bear."

The *gerund*, expreſſes not only the *time*, but alſo the *manner*, of an action; as, "he fell in running poſt."—It differs from the participle, in that it expreſſes the *time*, which the participle does not; and from the tenſe properly ſo called, in that it expreſſes the *manner*, which the tenſe does not. See GRAMMAR.

GERUNDA, (anc. geog.), a town of the Auſetani, in the Hither Spain, on the ſouth or right ſide of the river Sambroca. *Gerundenſes*, the people. Now *Gironne* in Catalonia, on the Ter. E. Long. 2. 35. Lat. 42.

GESNER (Conrad), a celebrated phyſician and naturaliſt, was born at Zurich in 1516. Having finiſhed his ſtudies in France, he travelled into Italy, and taught medicine and philoſophy in his own country with extraordinary reputation. He was acquainted with the languages; and excelled ſo much in natural hiſtory, that he was ſurnamed the *Pliny of Germany*. He died in 1564, leaving many works behind him; the principal of which are, 1. A hiſtory of animals, plants, and foſſils; 2. *Bibliotheca Univerſalis*. A Greek and Latin lexicon. This author is by Boerhaave emphatically ſtyled *Monſtrum Eruditionis*, a prodigy of learning. Thoſe indeed (as Mr Coxe obſerves in his Letters on Switzerland) "who are converſant with the works of this great ſcholar and naturaliſt, cannot repreſs their wonder and admiration at the amplitude of his knowledge in every ſpecies of erudition, and the variety of his diſcoveries in natural hiſtory, which was his peculiar delight. Their wonder and admiration is ſtill further augmented, when they conſider the groſs ignorance of the age which he helped to enlighten, and the ſcanty ſuccours he poſſeſſed to aid him in thus extending the bounds of knowledge; that he compoſed his works, and made thoſe diſcoveries which would have done honour to the moſt enlightened period, under the complicated evils of poverty, ſickneſs, and domeſtic uneaſineſs."

GESNER (Solomon), the celebrated author of the Death of Abel and many other admired works in the German language, was born at Zurich in the year 1730. In his early years he ſhowed very few ſigns of ſuperior abilities; and his progreſs in the rudiments of education was ſo ſlow, that his maſter gave him up as incapable of any greater attainments than writing and the four firſt rules of arithmetic. Upon this he was placed under a clergyman in the neighbourhood, a relation of his father's, and who ſhowed himſelf better acquainted with the art of diſcovering the natural inclinations of his pupils. This gentleman often carried young Geſner with him into the fields, where he made him obſerve the beauties of nature; and finding that he took great pleaſure in ſuch leſſons, and ſeemed to liſten to them with peculiar attention, he occaſionally repeated ſome of the moſt ſtriking paſſages of the ancient authors, who have written on theſe ſubjects, in the moſt agreeable and pleaſing manner. By this ingenious artifice, the mind of young Geſner began to open, and its powers to expand; and it is, perhaps, owing to this circumſtance, that he became ſo fond of the language of Virgil and Theocritus. When he arrived at a proper age to think of purſuing ſome line of buſineſs, Mr Geſner made choice of that of a bookſeller, which was the profeſſion of his father, and in ſome meaſure of his family. Of five houſes at Zurich in the printing and bookſelling buſineſs, two were occupied by Geſners: one belonged to two brothers of that name; and the other, that in which our poet had a ſhare, was known by the firm of *Orel, Geſner, and Company*. It was known alſo by the extent of its correſpondence, and by the choice and elegance of the works which it gave to the public. Geſner.

Though Mr Geſner was a bookſeller, he did not, however, damp his genius by ſubmitting to the drudgery of buſineſs. He indulged himſelf freely in purſuing his favourite object, and his partners never envied him that time which he devoted to meditation and to ſtudy. In 1752, he made a tour through Germany, not ſo much for the purpoſe of extending his commerce, as to ſee and be acquainted with thoſe authors who have done honour to their country. The following circumſtance, which occurred during this tour, deſerves to be mentioned, as it is ſtrikingly characteriſtic of that timidity which often accompanies true genius. When Mr Geſner was at Berlin, he was admitted into a literary ſociety, of which Gleim and Leſſing were members. Each of the authors who compoſed it uſed to read in turn ſome piece of their own compoſition, and Mr Geſner was very deſirous of ſubmitting to theſe able critics a ſmall work, which was his firſt attempt; but it was far from reſembling thoſe poets, whom Horace, and other ſatyriſts have ridiculed, and who ſtun every one they meet by reciting their verſes before them. As each of the members had done reading, Geſner was obſerved to move his hand with a kind of tremor towards his pocket, and to draw it back again without the manuſcript which he ought to have produced. Having not as yet publiſhed anything, none of the company could gueſs the cauſe of a motion which his modeſty prevented him from explaining. The work which he had not the courage to ſhow, was his ſmall poem, intitled *Night*, which he publiſhed on his return to Zurich in 1753. It was conſidered as an original, of which no model is to be found among the moderns; but in the opinion of the author, it was only a piece of imaginary painting, or, to uſe an expreſſion of his own, in one of his letters to Mr Huber who has tranſlated his works, "A caricature compoſed in the moments of folly or intoxication." In this little poem he has introduced a ſhort epiſode on the origin of the glow-worm, containing a poetical explanation of this natural phoſphorus, which has all the beauty of Ovid's Metamorphoſes without their prolixity.

Gefner. lixity. The ſucceſs of this eſſay emboldened the too timid muſe of our young bookſeller, and he publiſhed a paſtoral romance, called *Daphnis*, in three cantos. The applauſe that was deſervedly beſtowed upon this performance induced the author to publiſh, ſome time after, his Idylls and ſome other rural poems in imitation of thoſe of Theocritus. Paſtoral poetry, which at this time was little known in Germany but by tranſlations from foreign poets, began to find many partiſans, and to be preferred to every other kind. Deſirous, therefore, of tracing out a new path for himſelf, our poet thought that he could not do a more acceptable ſervice to his countrymen, than to paint the felicity of innocence and rural life, and the tender emotions of love and gratitude. The only author worthy of notice who had preceded Mr Geſner in this career, was Mr Roſt of Leipſick, whoſe paſtoral poems appeared for the firſt time in 1744. This writer poliſhed the language of the German ſhepherds; he had addreſs enough to unite ſpirit and ſimplicity in a kind of writing which appears inſipid without the former, and which becomes unnatural and diſguſting if it is too abundant. He ſometimes throws a delicate veil over thoſe images which are deficient in decency, but it is to be regretted that it is often too ſlight. Such was the antagoniſt againſt whom Geſner had to contend. Our poet, however, purſued a different courſe. Inſtead of placing, like Roſt, his ſcenes in modern times, he goes back with Theocritus to the golden age, that happy age which we are fond of reviewing when our paſſions are calm, and when freed from thoſe anxious cares which hurry us beyond ourſelves, we contemplate amidſt tranquillity the beauties and fertility of the country. The characters of Geſner's Idylls, therefore, are taken from thoſe ſocieties which exiſt no longer but in the remembrance or rather the imagination. His ſhepherds are fathers, children, and huſbands, who bluſh not at theſe titles ſo dear to nature, and to whom generoſity, beneficence, and reſpect for the Deity, are ſentiments no leſs familiar than love. Theſe Idylls were the principal and favourite object of his purſuit, and that part of his works which acquired him the greateſt reputation, eſpecially among his countrymen. His death of Abel, which is well known, was publiſhed for the firſt time in 1758. It is written, like the reſt of his pieces, in poetical proſe; and was ſo much ſought after, that it went through no leſs than three editions in the ſpace of a year, without ſpeaking of the ſpurious ones which appeared in Holland, at Berlin, and in France. The French edition was followed by ſeveral others. One came out in Italian; another in the Dutch language; a fourth in the Daniſh; and, laſtly, two in Engliſh, one of them in proſe and the other in verſe. Among the pieces which Mr Geſner publiſhed after the Death of Abel, was his Firſt Navigator, a poem in three cantos, which many people in Germany conſider as his maſterpiece. He made an attempt alſo in the paſtoral drama, but not with the ſame ſucceſs as in other kinds of rural poetry. He produced likewiſe, in the ſame ſtyle, Evander and Alcimne, in three acts; and Eraſtus, a ſmall piece of one act, which was repreſented with ſome applauſe in ſeveral ſocieties, both at Leipſick and Vienna.

But though poetry was Geſner's darling purſuit, and though he enriched the literature of his country with works which will render his name immortal, he did not confine himſelf to one manner of imitating nature; he in turns took up the pencil and the pen, and his active genius equally directed them both. In his infancy he had received a few leſſons in drawing, and he had afterwards purſued this ſtudy, but without any intention of becoming an artiſt. At the age of thirty, he felt that violent deſire, which may be conſidered as the voice of genius; and this was in ſome meaſure excited by the ſight of a beautiful collection formed by Mr Heidegger, whoſe daughter he had married. To pleaſe his father-in-law, he ſtudied this treaſure, compoſed principally of the beſt pieces of the Flemiſh ſchool; and to this new taſte he had almoſt ſacrificed every other. Mr Geſner at firſt ventured only to delineate ſome decorations for the frontiſpieces of curious books printed in his office; but by little and little, he had the courage to make other attempts. In 1765, he publiſhed 10 landſcapes etched and engraved by himſelf, and dedicated them to his friend Mr Watelet. Mr Geſner owed him this mark of reſpect for the care which he took to ornament with beautiful vignettes Mr Huber's tranſlation of his Idylls. Twelve other pieces appeared in 1769; and after theſe attempts, Mr Geſner executed ornaments for many works which came from his preſſes, among which were his own works, a German tranſlation of Swift, and ſeveral others. Geſner.

Were we to judge from Mr Geſner's enthuſiaſm for his favourite purſuits, and from the time and attention which he beſtowed upon them, we ſhould be apt to conclude, that he found little leiſure for diſcharging his duty as a citizen. The contrary, however, was the caſe, for he paſſed almoſt the half of his life in the firſt employments of the ſtate. In 1765 he was called to the grand council, in 1767 to the leſſer. In 1768 he was appointed bailiff of Kilibach, that of the four guards in 1776, and in 1781 ſuperintendant of waters, which office in 1787 was continued to him for ſix years. In all theſe ſtations Mr Geſner diſcharged his duty with the moſt ſcrupulous fidelity; and died of a paralytical diſorder, lamented by his countrymen and by thoſe who had the pleaſure of his acquaintance, on the 2d of March 1788, at the age of 56.

As a paſtoral poet, Geſner undoubtedly is intitled to a very diſtinguiſhed rank; and we may juſtly ſay, that if he has been equalled by any, he has been excelled by none. It is commonly believed, that paſtoral poetry is very limited and confined; but thoſe who read the works of Geſner will be convinced, that it is ſuſceptible of much variety when treated of by the hand of a maſter. His paſtoral romance of Daphnis is not inferior in natural ſimplicity to the celebrated work of Longus; but it ſurpaſſes it far in variety of images and incident. Eraſtus and Evander are inſtructive and intereſting poems, on account of the contraſt between the world and nature which reigns throughout them; and his Firſt Navigator unites the mildeſt philoſophy to all the ſplendor and imagery of fairy-land. If we analyſe his dramatic poems, we ſhall find in them intereſting fictions, characters well delineated, and ſituations replete with novelty. His language is that of the Graces, and the chaſteſt ears might liſten to the love which he has created. If he has ſometimes the humour of Sterne and Fontaine, it is without their

Gefner il Geſture.

licentiouſneſs. The ſevereſt taſte can find in his writings no lacuna to ſupply, no phraſe deſerving reprehenſion, nor could a more ingenious choice of expreſſions be ſubſtituted in the room of thoſe which he has adopted.—Geſner's character, as a man, appears to be no leſs amiable. In whatever point of view we conſider him, whether as a huſband, a father, a friend, a magiſtrate, or a citizen, his virtues are equally conſpicuous. He was naturally of a melancholy turn, but he was no enemy to rational and well-timed mirth; while the mildneſs and affability of his temper rendered his company always engaging, and endeared him to thoſe who had the pleaſure of his acquaintance. Poſſeſſed of that nobleneſs of ſentiment, united with great modeſty, which is the uſual attendant of true genius, he was ſimple in his external appearance, as well as in his converſation. His language was lively and animated; but his reſerve before ſtrangers reſembled timidity, and it was only in the preſence of thoſe with whom he was acquainted, that his real character appeared in its full luſtre.

Mr Geſner's reputation and virtues were known even to the remoteſt parts of Europe. The empreſs of Ruſſia Catharine II. preſented him with a gold medal as a mark of her eſteem. Strangers of all nations gave him no leſs flattering teſtimonies of their admiration; and travellers thought they had ſeen only the half of Switzerland, if they had not been in the company of Geſner, or procured ſome of his landſcapes or drawings. In this laſt way he had acquired ſo much reputation, that he was ranked among the beſt artiſts of Germany; and Mr Fueſlin, his countryman, who was himſelf a painter, in the preface to the third volume of the new edition which he publiſhed of his 'Hiſtorical eſſay on the painters, engravers, architects, and ſculptors, who have done honour to Switzerland,' gives a diſtinguiſhed place to Mr Geſner, though then living.

GESNERIA, in botany: A genus of the angioſpermia order, belonging to the didynamia claſs of plants; and in the natural method ranking under the 40th order, *Perſonatæ*. The calyx is quinqueſid, and placed on the germen; the corolla incurvated and then recurvated; the capſule inferior and bilocular.

GESSORIACUM (anc. geog.), a port and ſtation for ſhips of the Morini in Belgica. In Cæſar's time, according to Dio, there was no town; but Florus ſpeaks of it as one: and the Geſoriacenſes Muri are mentioned by Eumenius in his Panegyric. The author of Tabula Theodoſiana, commonly called *Peutinger's map*, ſays expreſsly, that Geſſoriacum was in his time called *Bononia*. Now *Boulogne* in Picardy. E. Long. 1. 30. N. Lat. 50. 40.

GESTATION, among phyſicians. See PREGNANCY.

GESTRICIA, a province of Sweden, bounded by Helſingia on the north, by the Bothnic gulph on the eaſt, by Upland on the ſouth, and by Dalecarlia on the weſt.

GESTURE, a motion of the body, intended to ſignify ſome idea or paſſion of the mind. It conſiſts principally in the action of the hands and face; and may be defined, a ſuitable conformity of the motions of the countenance, and of ſeveral parts of the body, in ſpeaking to the ſubject matter of the diſcourſe. See DECLAMATION, and ORATORY, n° 130, 131.

Geta il Geum.

GETA (SEPTIMIUS), a ſon of the emperor Severus, brother to Caracalla. In the eighth year of his age, he was moved with compaſſion at the fate of ſome of the partizans of Niger and Albinus who were to be executed, and his father ſtruck with his humanity retracted the ſentence. After Severus's death, he reigned at Rome conjointly with his brother; but Caracalla, who envied his virtues and was jealous of his popularity, ordered him to be poiſoned; and when this could not be effected, he murdered him in the arms of his mother Julia, who in the attempt of defending the fatal blows from his body received a wound in her arm, from the hand of her ſon, A. D. 212. Geta had not yet reached the 23d year of his age, and the Romans had reaſon to lament the death of ſo virtuous a prince, while they groaned under the cruelties and oppreſſion of Caracalla.

GETHIN (Lady Grace), an Engliſh lady of uncommon parts, was the daughter of Sir George Norton of Abbots-Leigh in Somerſetſhire, and born in the year 1676. She had all the advantages of a liberal education; and became the wife of Sir Richard Gethin, of Gethin-Grott in Ireland. She was miſtreſs of great accompliſhments, natural and acquired, but did not live long enough to diſplay them to the world; for ſhe died in the 21ſt year of her age. She was buried in Weſtminſter-abbey, where a beautiful monument with an inſcription is erected over her; and, for perpetuating her memory, proviſion was made for a ſermon to be preached in Weſtminſter-abbey, yearly, on Aſh-Wedneſday for ever. She wrote, and left behind her, in looſe papers, a work which, ſoon after her death, was methodized, and publiſhed under the title of "*Reliquiæ Gethinianæ;* or, Some remains of the moſt ingenious and excellent lady, Grace lady Gethin, lately deceaſed. Being a collection of choice diſcourſes, pleaſant apophthegms, and witty ſentences. Written by her, for the moſt part, by way of eſſay, and at ſpare hours." Lond. 1700, 4to; with her picture before it.

GETHSEMANE (anc. geog.), a village in the mount of Olives, whither Jeſus Chriſt ſometimes retreated in the night-time. It was in a garden belonging to this village that he ſuffered the agony in which he ſweated drops of blood; and here he was arreſted by Judas and the reſt who were conducted by this traitor. The place is by Maundrel deſcribed as an even plot of ground, not above 57 yards ſquare, lying between the foot of Mount Olivet and the brook Cedron.

GETHYLLIS, in botany: A genus of the monogynia order, belonging to the dodecandria claſs of plants; and in the natural method ranking under the ninth order, *Spathaceæ*. The corolla is ſix-cleft, and the ſtamina are in ſix different directions; the capſule is trilocular.

GEUM, AVENS, or *Herb-Bennet:* A genus of the polygamia order, belonging to the icoſandria claſs of plants; and in the natural method ranking under the 35th order, *Senticoſæ*. The calyx is cleft into ten parts; there are five petals, and each of the ſeeds has a jointed awn. There are five ſpecies; of which the moſt remarkable are, 1. The urbanum, with thick fibrous roots of an aromatic taſte, rough, ſerrated leaves, and upright, round, hairy ſtalks terminated by large yellow

Ghent, Ghoſt.

yellow flowers, ſucceeded by globular fruit. 2. The rivale, with a very thick, fleſhy, and fibrous root, hairy leaves, and upright ſtalks, 10 or 12 inches high, terminated by purple flowers nodding on one ſide. Of this there are varieties with red and with yellow flowers.—Both theſe are natives of Britain, and are eaſily propagated either by the root or ſeed. The roots of the firſt, gathered in the ſpring before the ſtem comes up, and infuſed in ale, give it a pleaſant flavour, and prevent its growing ſour. Infuſed in wine, they have a ſtomachic virtue. The taſte is mildly auſtere and aromatic, eſpecially when the plant grows in warm dry ſituations; but in moiſt ſhady places, it hath little virtue Cows, goats, ſheep, and ſwine, eat the plant; horſes are not fond of it.—The powdered root of the ſecond ſpecies will cure tertian agues, and is daily uſed for that purpoſe by the Canadians. Sheep and goats eat the plant; cows, horſes, and ſwine, are not fond of it.

GHENT, a city of the Auſtrian Netherlands, capital of the province of Flanders. It is ſeated on four navigable rivers, the Scheld, the Lys, the Lieve, and the Moere, which run through it, and divide it into canals. Theſe form 26 little iſles, over which there are 300 bridges: among which there is one remarkable for a ſtatue of braſs of a young man who was obliged to cut off his father's head; but as he was going to ſtrike, the blade flew into the air, and the hilt remained in his hand, upon which they were both pardoned. There is a picture of the whole tranſaction in the town-houſe. Ghent is ſurrounded with walls and other fortifications, and is tolerably ſtrong for a place of its circumference. But all the ground within the walls is not built upon. The ſtreets are large and well paved, the market-places ſpacious, and the houſes built with brick. But the Friday's market-place is the largeſt, and is remarkable for the ſtatue of Charles V. which ſtands upon a pedeſtal in the imperial habit. That of Cortere is remarkable for a fine walk under ſeveral rows of trees. In 1737 a fine opera-houſe was built here, and a guard-houſe for the garriſon. Near the town is a very high tower, with a handſome clock and chimes. The great bell weighs 11,000 pounds.

This town is famous for the pacification ſigned here, in 1526, for ſettling the tranquillity of the Seventeen Provinces, which was afterwards confirmed by the king of Spain. It was taken by Louis XIV. in 1678, who afterwards reſtored it. The French took poſſeſſion of it again after the death of Charles II. of Spain. In 1706, it was taken by the duke of Marlborough; and by the French in 1708; but it was retaken the ſame year. Laſt of all, the French took it by ſurpriſe after the battle of Fontenoy; but at the peace of Aix-la-Chapelle it was rendered back. This is the birth-place of John of Gaunt. It is very well ſeated for trade, on account of its rivers and canals. It carries on a great commerce in corn; and has linen, woollen, and ſilk manufactures. The number of inhabitants is about 70,000. E. Long. 4. 0. N. Lat. 51. 24.

GHOST, an apparition, or ſpirit of a perſon deceaſed.

The ancients ſuppoſed every man to be poſſeſſed of three different ghoſts, which after the diſſolution of the human body were differently diſpoſed of. Theſe three ghoſts are diſtinguiſhed by the names of *Manes*, *Spiritus*, *Umbra*. The *manes*, they fancied, went down into the infernal regions; the *ſpiritus* aſcended to the ſkies; and the *umbra* hovered about the tomb, as being unwilling to quit its old connections. Thus Dido (Virg. Æn. iv. 384.) threatens Æneas after death that ſhe will haunt him with her umbra, whilſt her manes rejoice in his torments below. This idea of a threefold ſoul is very clearly expreſſed in theſe lines, which have been attributed to Ovid. Ghoſt.

Bis duo ſunt homini: MANES, CARO, SPIRITUS, UMBRA:
Quatuor iſta loci bis duo ſuſcipiunt
Terra tegit CARNEM, *tumulum circumvolat* UMBRA,
Orcus habet MANES, SPIRITUS *aſtra petit.*

The moſt ſtriking outlines of the popular ſuperſtitions reſpecting ghoſts among us, are thus humorouſly collected by Captain Groſe in his Provincial Gloſſary: "A ghoſt is ſuppoſed to be the ſpirit of a perſon deceaſed, who is either commiſſioned to return for ſome eſpecial errand, ſuch as the diſcovery of a murder, to procure reſtitution of lands or money unjuſtly with-held from an orphan or widow—or, having committed ſome injuſtice whilſt living, cannot reſt till that is redreſſed. Sometimes the occaſion of ſpirits reviſiting this world, is to inform their heir in what ſecret place, or private drawer in an old trunk, they had hidden the title-deeds of the eſtate; or where, in troubleſome times, they buried their money or plate. Some ghoſts of murdered perſons, whoſe bodies have been ſecretly buried, cannot be at eaſe till their bones have been taken up, and depoſited in conſecrated ground with all the rites of Chriſtian burial.

"Sometimes ghoſts appear in conſequence of an agreement made, whilſt living, with ſome particular friend, that he who firſt died ſhould appear to the ſurvivor.

"Glanvil tells us of the ghoſt of a perſon who had lived but a diſorderly kind of life, for which it was condemned to wander up and down the earth, in the company of evil ſpirits, till the day of judgment.

"In moſt of the relations of ghoſts, they are ſuppoſed to be mere aerial beings, without ſubſtance, and that they can paſs through walls and other ſolid bodies at pleaſure. A particular inſtance of this is given, in relation the 27th, in Glanvil's collection, where one David Hunter, neat-herd to the biſhop of Down and Connor, was for a long time haunted by the apparition of an old woman, whom he was by a ſecret impulſe obliged to follow whenever ſhe appeared, which he ſays he did for a conſiderable time, even if in bed with his wife: and becauſe his wife could not hold him in his bed, ſhe would go too, and walk after him till day, though ſhe ſaw nothing; but his little dog was ſo well acquainted with the apparition, that he would follow it as well as his maſter. If a tree ſtood in her walk, he obſerved her always to go through it. Notwithſtanding this ſeeming immateriality, this very ghoſt was not without ſome ſubſtance; for, having performed her errand, ſhe deſired Hunter to lift her from the ground; in the doing of which, he ſays, ſhe felt juſt like a bag of feathers. We ſometimes alſo read of ghoſts ſtriking violent blows; and that, if not made way for, they overturn all impediments, like a furious whirlwind. Glanvil mentions an inſtance of this, in relation 17th, of a Dutch lieutenant who had the faculty of ſeeing ghoſts; and who, being prevented making

Ghoſt. king way for one which he mentioned to ſome friends as coming towards them, was, with his companions, violently thrown down, and ſorely bruiſed. We further learn, by relation 16th, that the hand of a ghoſt is 'as cold as a clod.'

"The uſual time at which ghoſts make their appearance is midnight, and ſeldom before it is dark; though ſome audacious ſpirits have been ſaid to appear even by day-light: but of this there are few inſtances, and thoſe moſtly ghoſts who have been laid, perhaps in the Red Sea (of which more hereafter), and whoſe times of confinement were expired: theſe, like felons confined to the lighters, are ſaid to return more troubleſome and daring than before. No ghoſts can appear on Chriſtmas eve; this Shakeſpeare has put into the mouth of one of his characters in Hamlet.

"Ghoſts commonly appear in the ſame dreſs they uſually wore whilſt living, though they are ſometimes clothed all in white; but that is chiefly the churchyard ghoſts, who have no particular buſineſs, but ſeem to appear *pro bono publico*, or to ſcare drunken ruſtics from tumbling over their graves.

"I cannot learn that ghoſts carry tapers in their hands, as they are ſometimes depicted, though the room in which they appear, if without fire or candle, is frequently ſaid to be as light as day. Dragging chains is not the faſhion of Engliſh ghoſts; chains and black veſtments being chiefly the accoutrements of foreign ſpectres ſeen in arbitrary governments: dead or alive, Engliſh ſpirits are free. One inſtance, however, of an Engliſh ghoſt dreſſed in black, is found in the celebrated ballad of William and Margaret, in the following lines:

> And clay-cold was her lily hand,
> That held her *ſable* ſorrow'd

This, however, may be conſidered as a poetical licence, uſed in all likelihood for the ſake of the oppoſition of *lily* to *ſable*.

"If, during the time of an apparition, there is a lighted candle in the room, it will burn extremely blue: this is ſo univerſally acknowledged, that many eminent philoſophers have buſied themſelves in accounting for it, without once doubting the truth of the fact. Dogs too have the faculty of ſeeing ſpirits, as is inſtanced in David Hunter's relation above quoted; but in that caſe they uſually ſhow ſigns of terror, by whining and creeping to their maſter for protection: and it is generally ſuppoſed that they often ſee things of this nature when their owner cannot; there being ſome perſons, particularly thoſe born on a Chriſtmas eve, who cannot ſee ſpirits.

"The coming of a ſpirit is announced ſome time before its appearance, by a variety of loud and dreadful noiſes; ſometimes rattling in the old hall like a coach and ſix, and rumbling up and down the ſtaircaſe like the trundling of bowls or cannon balls. At length the door flies open, and the ſpectre ſtalks ſlowly up to the bed's foot, and opening the curtains, looks ſtedfaſtly at the perſon in bed by whom it is ſeen; a ghoſt being very rarely viſible to more than one perſon, although there are ſeveral in company. It is here neceſſary to obſerve, that it has been univerſally found by experience, as well as affirmed by diverſe apparitions themſelves, that a ghoſt has not the power to ſpeak till it has been firſt ſpoken to; ſo that, notwithſtanding the urgency of the buſineſs on which it may come, every thing muſt ſtand ſtill till the perſon viſited can find ſufficient courage to ſpeak to it: an event that ſometimes does not take place for many years. It has not been found that female ghoſts are more loquacious than thoſe of the male ſex, both being equally reſtrained by this law. Ghoſt.

"The mode of addreſſing a ghoſt is by commanding it, in the name of the Three Perſons of the Trinity, to tell you who it is, and what is its buſineſs: this it may be neceſſary to repeat three times; after which it will, in a low and hollow voice, declare its ſatisfaction at being ſpoken to, and deſire the party addreſſing it not to be afraid, for it will do him no harm. This being premiſed, it commonly enters into its narrative; which being completed, and its requeſt or commands given, with injunctions that they be immediately executed, it vaniſhes away, frequently in a flaſh of light; in which caſe, ſome ghoſts have been ſo conſiderate as to deſire the party to whom they appeared to ſhut their eyes: ſometimes its departure is attended with delightful muſic. During the narration of its buſineſs, a ghoſt muſt by no means be interrupted by queſtions of any kind; ſo doing is extremely dangerous: if any doubts ariſe, they muſt be ſtated after the ſpirit has done its tale. Queſtions reſpecting its ſtate, or the ſtate of any of their former acquaintance, are offenſive, and not often anſwered; ſpirits perhaps being reſtrained from divulging the ſecrets of their priſon houſe. Occaſionally ſpirits will even condeſcend to talk on common occurrences, as is inſtanced by Glanvil in the apparition of Major George Sydenham to Captain William Dyke, relation 10th, wherein the major reproved the captain for ſuffering a ſword he had given him to grow ruſty; ſaying, 'Captain, captain, this ſword did not uſe to be kept after this manner when it was mine.' This attention to the ſtate of arms, was a remnant of the major's profeſſional duty when living.

"It is ſomewhat remarkable that ghoſts do not go about their buſineſs like the perſons of this world. In caſes of murder, a ghoſt, inſtead of going to the next juſtice of the peace, and laying its information, or to the neareſt relation of the perſon murdered, appears to ſome poor labourer who knows none of the parties, draws the curtains of ſome decrepit nurſe or almswoman, or hovers about the place where his body is depoſited. The ſame circuitous mode is purſued with reſpect to redreſſing injured orphans or widows; when it ſeems as if the ſhorteſt and moſt certain way would be, to go to the perſon guilty of the injuſtice, and haunt him continually till he be terrified into a reſtitution. Nor are the pointing out loſt writings generally managed in a more ſummary way; the ghoſt commonly applying to a third perſon, ignorant of the whole affair, and a ſtranger to all concerned. But it is preſumptuous to ſcrutinize too far into theſe matters: ghoſts have undoubtedly forms and cuſtoms peculiar to themſelves.

"If, after the firſt appearance, the perſons employed neglect, or are prevented from, performing the meſſage or buſineſs committed to their management, the ghoſt appears continually to them, at firſt with a diſcontented, next an angry, and at length with a furious, countenance, threatening to tear them in pieces if the matter

Ghoſt, Giagh.

matter is not forthwith executed; ſometimes terrifying them, as in Glanvil's relation 26th, by appearing in many formidable ſhapes, and ſometimes even ſtriking them a violent blow. Of blows given by ghoſts there are many inſtances, and ſome wherein they have been followed with an incurable lameneſs.

"It ſhould have been obſerved, that ghoſts, in delivering their commiſſions, in order to enſure belief, communicate to the perſons employed ſome ſecret, known only to the parties concerned and themſelves, the relation of which always produces the effect intended. The buſineſs being completed, ghoſts appear with a cheerful countenance, ſaying they ſhall now be at reſt, and will never more diſturb any one; and, thanking their agents, by way of reward communicate to them ſomething relative to themſelves, which they will never reveal.

"Sometimes ghoſts appear, and diſturb a houſe, without deigning to give any reaſon for ſo doing: with theſe, the ſhorteſt and only way is to exorciſe, and eject them; or, as the vulgar term is, lay them. For this purpoſe there muſt be two or three clergymen, and the ceremony muſt be performed in Latin: a language that ſtrikes the moſt audacious ghoſt with terror. A ghoſt may be laid for any term leſs than an 100 years, and in any place or body, full or empty; as, a ſolid oak—the pommel of a ſword—a barrel of beer, if a yeoman or ſimple gentleman—or a pipe of wine, if an eſquire or a juſtice. But of all places the moſt common, and what a ghoſt leaſt likes, is the Red Sea; it being related, in many inſtances, that ghoſts have moſt earneſtly beſought the exorciſts not to confine them in that place. It is nevertheleſs conſidered as an indiſputable fact, that there are an infinite number laid there, perhaps from its being a ſafer priſon than any other nearer at hand; though neither hiſtory nor tradition gives us any inſtance of ghoſts eſcaping or returning from this kind of tranſportation before their time.

"Another ſpecies of human apparition may be here noticed, though it does not come under the ſtrict deſcription of a ghoſt. Theſe are the exact figures and reſemblances of perſons then living, often ſeen not only by their friends at a diſtance, but many times by themſelves; of which there are ſeveral inſtances in Aubery's Miſcellanies: one of Sir Richard Napier, a phyſician of London, who being on the road from Bedfordſhire to viſit a friend in Berkſhire, ſaw at an inn his own apparition lying on his bed as a dead corpſe; he nevertheleſs went forward, and died in a ſhort time: another of Lady Diana Rich, daughter of the Earl of Holland, who met her own apparition walking in a garden at Kenſington, and died a month after of the ſmall pox. Theſe apparitions are called *fetches*; in Cumberland, *ſwarths*; and in Scotland, *wraiths*: they moſt commonly appear to diſtant friends and relations, at the very inſtant preceding the death of the perſon whoſe figure they put on. Sometimes, as in the inſtances above mentioned, there is a greater interval between the appearance and death." For a philoſophical inquiry into the ſubject of apparitions in general, ſee the article SPECTRE.

GIAGH, in chronology, a cycle of 12 years; in uſe among the Turks and Cathayans.

Each year of the giagh bears a name of ſome animal: the firſt that of a mouſe; the ſecond that of a bullock; the third of a lynx or leopard; the fourth of a hare; the fifth of a crocodile; the ſixth of a ſerpent; the ſeventh of a horſe; the eighth of a ſheep; the ninth of a monkey; the tenth of a hen; the eleventh of a dog; and the twelfth of a hog.

Giallolino, Giant.

They alſo divide the day into 12 parts, which they call *giaghs*, and diſtinguiſh them by the name of ſome animals. Each giagh contains two of our hours, and is divided into eight kehs, as many as there are quarters in our hours.

GIALLOLINO, in natural hiſtory, a fine yellow pigment much uſed under the name of NAPLES YELLOW.

GIANT, a perſon of extraordinary bulk and ſtature.

The Romances of all ages have furniſhed us with ſo many extravagant accounts of giants of incredible bulk and ſtrength, that the exiſtence of ſuch people is now generally diſbelieved. It is commonly thought, that the ſtature of man hath been the ſame in all ages; and ſome have even pretended to *demonſtrate* the impoſſibility of the exiſtence of giants mathematically. Of theſe our countryman M'Laurin hath been the moſt explicit. "In general (ſays he) it will eaſily appear, that the efforts tending to deſtroy the coheſion of beams ariſing from their own gravity only, increaſe in the quadruplicate ratio of their lengths; but that the oppoſite efforts tending to preſerve their coheſion, increaſe only in the triplicate proportion of the ſame lengths. From which it follows, that the greater beams muſt be in greater danger of breaking than the leſſer ſimilar ones; and that though a leſſer beam may be firm and ſecure, yet a greater ſimilar one may be made ſo long, that it will neceſſarily break by its own weight. Hence Galileo juſtly concludes, that what appears very firm, and ſucceeds very well in models, may be very weak and infirm, or even fall to pieces by its own weight, when it comes to be executed in large dimenſions according to the model. From the ſame principle he argues, that there are neceſſary limits in the operations of nature and art, which they cannot ſurpaſs in magnitude. Were trees of a very enormous ſize, their branches would fall by their own weight. Large animals have not ſtrength in proportion to their ſize; and if there were any land-animals much larger than thoſe we know, they could hardly move, and would be perpetually ſubject to the moſt dangerous accidents. As to the animals of the ſea, indeed, the caſe is different; for the gravity of the water in a great meaſure ſuſtains thoſe animals; and in fact theſe are known ſometimes to be vaſtly larger than the greateſt land-animals. Nor does it avail againſt this doctrine to tell us, that bones have ſometimes been found which were ſuppoſed to have belonged to giants of immenſe ſize; ſuch as the ſkeletons mentioned by Strabo and Pliny, the former of which was 60 cubits high, and the latter 46: for naturaliſts have concluded on juſt grounds, that in ſome caſes theſe bones had belonged to elephants; and that the larger ones were bones of whales, which had been brought to the places where they were found by the revolutions of nature that have happened in paſt times. Though it muſt be owned, that there appears no reaſon why there may not have been men who have exceeded by ſome feet in height the talleſt we have ſeen."

It will eaſily be ſeen, that arguments of this kind

Giant. can never be concluſive; becauſe, along with an increaſe of ſtature in any animal, we muſt always ſuppoſe a proportional increaſe in the coheſion of the parts of its body. Large works ſometimes fail when conſtructed on the plan of models, becauſe the coheſion of the materials whereof the model is made, and of the large work, are the ſame; but a difference in this reſpect will produce a very remarkable difference in the ultimate reſult. Thus, ſuppoſe a model is made of fir-wood, the model may be firm and ſtrong enough; but a large work made alſo of fir, when executed according to the plan of the model, may be ſo weak that it will fall to pieces with its own weight. If, however, we make uſe of iron for the large work inſtead of fir, the whole will be ſufficiently ſtrong, even though made exactly according to the plan of the model. The like may be ſaid with regard to large and ſmall animals. If we could find an animal whoſe bones exceeded in hardneſs and ſtrength the bones of other animals as much as iron exceeds fir, ſuch an animal might be of a monſtrous ſize, and yet be exceedingly ſtrong. In like manner, if we ſuppoſe the fleſh and bones of a giant to be greatly ſuperior in hardneſs and ſtrength to the bones of other men, the great ſize of his body will be no objection at all to his ſtrength. The whole of the matter therefore concerning the exiſtence of giants muſt reſt on the credibility of the accounts we have from thoſe who pretend to have ſeen them, and not on any arguments drawn *à priori*.

In the ſcripture we are told of *giants*, who were produced from the marriages of the *ſons of God* with the *daughters of men**. This paſſage indeed has been differently interpreted, ſo as to render it doubtful whether the word tranſlated *giants* does there imply any extraordinary ſtature. In other parts of ſcripture, however, giants, with their dimenſions, are mentioned in ſuch a manner that we cannot poſſibly doubt; as in the caſe of Og king of Baſhan, and Goliath. In a memoir read before the Academy of Sciences at Rouen, M. Le Cat gives the following account of giants that are ſaid to have exiſted in different ages.

* See *Antediluvians*, p. 66. col. 1.

"Profane hiſtorians have given ſeven feet of height to Hercules their firſt hero; and in our days we have ſeen men eight feet high. The giant who was ſhown in Rouen in 1735, meaſured eight feet ſome inches. The emperor Maximin was of that ſize; Shenkius and Platerus, phyſicians of the laſt century, ſaw ſeveral of that ſtature; and Goropius ſaw a girl who was ten feet high.—The body of Oreſtes, according to the Greeks, was eleven feet and a half; the giant Galbara, brought from Arabia to Rome under Claudius Cæſar, was near ten feet; and the bones of Secondilla and Puſio, keepers of the gardens of Salluſt, were but ſix inches ſhorter. Funnam, a Scotſman, who lived in the time of Eugene II. king of Scotland, meaſured eleven feet and a half: and Jacob le Maire, in his voyage to the ſtraits of Magellan, reports, that on the 17th of December 1615, they found at Port Deſire ſeveral graves covered with ſtones; and having the curioſity to remove the ſtones, they diſcovered human ſkeletons of ten and eleven feet long. The chevalier Scory, in his voyage to the peak of Teneriffe, ſays, that they found in one of the ſepulchre caverns of that mountain the head of a Guanche which had 80 teeth, and that the body was not leſs than 15 feet long. The giant Ferragus, ſlain by Orlando nephew of Charlemagne, was 18 feet high. Rioland, a celebrated anatomiſt, who wrote in 1614, ſays, that ſome years before there was to be ſeen in the ſuburbs of St Germain the tomb of the giant Iſoret, who was 20 feet high. In Rouen, in 1509, in digging in the ditches near the Dominicans, they found a ſtone-tomb containing a ſkeleton whoſe ſkull held a buſhel of corn, and whoſe ſhin-bone reached up to the girdle of the talleſt man there, being about four feet long, and conſequently the body muſt have been 17 or 18 feet high. Upon the tomb was a plate of copper, whereon was engraved, "In this tomb lies the noble and puiſſant lord, the chevalier Ricon de Vallemont, and his bones." Platerus, a famous phyſician, declares, that he ſaw at Lucerne the true human bones of a ſubject which muſt have been at leaſt 19 feet high. Valence in Dauphiné boaſts of poſſeſſing the bones of the giant Bucart, tyrant of the Vivarais, who was ſlain by an arrow by the count De Cabillon his vaſſal. The Dominicans had a part of the ſhin-bone, with the articulation of the knee, and his figure painted in freſco, with an inſcription, ſhowing that this giant was 22 feet and a half high, and that his bones were found in 1705, near the banks of the Morderi, a little river at the foot of the mountain of Cruſſol, upon which (tradition ſays) the giant dwelt.

Giant.

"January 11. 1613, ſome maſons digging near the ruins of a caſtle in Dauphiné, in a field which (by tradition) had long been called *the giant's field*, at the depth of 18 feet diſcovered a brick-tomb 30 feet long, 12 feet wide, and 8 feet high; on which was a grey ſtone, with the words *Theutobochus Rex* cut thereon. When the tomb was opened, they found a human ſkeleton entire, 25 feet and a half long, 10 feet wide acroſs the ſhoulders, and five feet deep from the breaſt-bone to the back. His teeth were about the ſize each of an ox's foot, and his ſhin-bone meaſured four feet.—Near Mazarino, in Sicily, in 1516, was found a giant 30 feet high; his head was the ſize of an hogſhead, and each of his teeth weighed five ounces. Near Palermo, in the valley of Mazara, in Sicily, a ſkeleton of a giant 30 feet long was found, in the year 1548; and another of 33 feet high, in 1550: and many curious perſons have preſerved ſeveral of theſe gigántic bones.

"The Athenians found near their city two famous ſkeletons, one of 34 and the other of 36 feet high.

"At Totu, in Bohemia, in 758, was found a ſkeleton, the head of which could ſcarce be encompaſſed by the arms of two men together, and whoſe legs, which they ſtill keep in the caſtle of that city, were 26 feet long. The ſkull of the giant found in Macedonia, September 1691, held 210 pounds of corn.

"The celebrated Sir Hans Sloane, who treated this matter very learnedly, does not doubt theſe facts; but thinks the bones were thoſe of elephants, whales, or other enormous animals.

"Elephants bones may be ſhown for thoſe of giants; but they can never impoſe on connoiſſeurs. Whales, which, by their immenſe bulk, are more proper to be ſubſtituted for the largeſt giants, have neither arms nor legs; and the head of that animal hath not the leaſt reſemblance to that of a man. If it be true, therefore, that a great number of the gigantic bones which we have mentioned have been ſeen by anatomiſts, and

by

Giant. by them have been reputed real human bones, the exiſtence of giants is proved."

With regard to the credibility of all or any of theſe accounts, it is difficult to determine any thing. If, in any caſtle of Bohemia, the bones of a man's leg 26 feet in length are preſerved, we have indeed a deciſive proof of the exiſtence of a giant, in compariſon of whom moſt others would be but pigmies. Nor indeed could theſe bones be ſuppoſed to belong to an elephant; for an elephant itſelf would be but a dwarf in compariſon of ſuch an enormous monſter. But if theſe bones were really kept in any part of Bohemia, it ſeems ſtrange that they have not been frequently viſited, and particular deſcriptions of them given by the learned who have travelled into that country. It is certain, however, that there have been nations of men conſiderably exceeding the common ſtature. Thus, all the Roman hiſtorians inform us, that the Gauls and Germans exceeded the Italians in ſize; and it appears that the Italians in thoſe days were of much the ſame ſtature with the people of the preſent age. Among theſe northern nations, it is alſo probable, that there would be as great differences in ſtature as there are among the preſent race of men. If that can be allowed, we may eaſily believe that ſome of theſe barbarians might be called *giants*, without any great impropriety. Of this ſuperiority of ſize, indeed, the hiſtorian Florus gives a notable inſtance in Teutobochus, above mentioned, king of the Teutones: who being defeated and taken priſoner by Marius, was carried in triumph before him at Rome, when his head reached above the trophies that were carried in the ſame proceſſion.

But whether theſe accounts are credited or not, we are very certain, that the ſtature of the human body is by no means abſolutely fixed. We are ourſelves a kind of giants in compariſon of the Laplander; nor are theſe the moſt diminutive people to be found upon the earth. The abbe la Chappe, in his journey into Siberia in order to obſerve the laſt tranſit of Venus, paſſed through a village inhabited by people called *Wotiacks*, neither men nor women of whom were above four feet high. The accounts of the Patagonians alſo, which cannot be entirely diſcredited, render it very probable, that ſomewhere in South America there is a race of people very conſiderably exceeding the common ſize of mankind, and conſequently that we cannot altogether diſcredit the relations of giants handed down to us by ancient authors; though what degree of credit we ought to give them, is not eaſy to be determined. See PATAGONIA.

Rebel GIANTS, in ancient mythology, were the ſons of Cœlus and Terra. According to Heſiod, they ſprang from the blood of the wound which Cœlus received from his ſon Saturn, and Hyginus calls them ſons of Tartarus and Terra. They are repreſented as men of uncommon ſtature, with ſtrength proportioned to their gigantic ſize. Some of them, as Cottus, Briareus, and Gyges, had each 50 heads and 100 arms, and ſerpents inſtead of legs. They were of a terrible aſpect, their hair hung looſe about their ſhoulders, and their beard was ſuffered to grow unmoleſted. Pallene and its neighbourhood was the place of their reſidence. The defeat of the Titans, to whom they were nearly related, incenſed them againſt Jupiter, and they all conſpired to dethrone him. Accordingly they reared Mount Oſſa upon Pelion, and Olympus upon Oſſa; and from thence attacked the gods with huge rocks, ſome of which fell into the ſea and became iſlands, and others fell on the earth and formed mountains. Jupiter ſummoned a council of the gods; when being informed that it was neceſſary to obtain the aſſiſtance of ſome mortal, he by the advice of Pallas called up his ſon Hercules; and with the aid of this hero he exterminated the giants Enceladus, Polybotes, Alcyon, Porphyrion, the two ſons of Alœus, Ephialtus, Othus, Eurytus, Clytius, Tythyus, Pallas, Hippolitus, Agrius, Thoon, and Typhon, the laſt of whom it was more difficult to vanquiſh than all the others. Jupiter having thus gained a complete victory, caſt the rebels down to Tartarus, where they were to receive the full puniſhment of their enormous crimes: according to the accounts of ſome of the poets, he buried them alive under Mount Etna and different iſlands.

Giants-Cauſeway.

GIANTS-Cauſeway, a vaſt collection of Baſaltic pillars in the county of Antrim in Ireland. See the article BASALTES.

The principal or grand cauſeway (for there are ſeveral leſs conſiderable and ſcattered fragments of ſimilar workmanſhip) conſiſts of a moſt irregular arrangement of many hundred thouſands of columns of a black kind of rock, hard as marble: almoſt all of them are of a pentagonal figure, but ſo cloſely and compactly ſituated on their ſides, though perfectly diſtinct from top to bottom, that ſcarce any thing can be introduced between them. The columns are of an unequal height and breadth; ſome of the higheſt, viſible above the ſurface of the ſtrand, and at the foot of the impending angular precipice, may be about 20 feet; they do not exceed this height, at leaſt none of the principal arrangement. How deep they are fixed in the ſtrand, was never yet diſcovered. This grand arrangement extends nearly 200 yards, viſible at low water; how far beyond is uncertain: from its declining appearance, however, at low water, it is probable it does not extend under water to a diſtance any thing equal to what is ſeen above. The breadth of the principal cauſeway, which runs out in one continued range of columns, is, in general, from 20 to 30 feet; at one place or two it may be nearly 40 for a few yards. In this account are excluded the broken and ſcattered pieces of the ſame kind of conſtruction, that are detached from the ſides of the grand cauſeway, as they do not appear to have ever been contiguous to the principal arrangement, though they have frequently been taken into the width; which has been the cauſe of ſuch wild and diſſimilar repreſentations of this cauſeway, which different accounts have exhibited. The higheſt part of this cauſeway is the narroweſt, at the very foot of the impending cliff from whence the whole projects, where, for four or five yards, it is not above ten or fifteen feet wide. The columns of this narrow part incline from a perpendicular a little to the weſtward, and form a ſlope on their tops, by the very unequal height of the columns on the two ſides, by which an aſcent is made at the foot of the cliff, from the head of one column to the next above, *gradatim*, to the top of the great cauſeway, which, at the diſtance of half a dozen yards from the cliff, obtains a perpendicular poſition, and lowering in its general

Giants-Cauſeway.

height, widens to about 20 or between 20 and 30 feet, and for 100 yards nearly is always above water. The tops of the columns for this length being nearly of an equal height, they form a grand and ſingular parade, that may be eaſily walked on, rather inclining to the water's edge. But from high-water mark, as it is perpetually waſhed by the beating ſurges on every return of the tide, the platform lowers conſiderably, and becomes more and more uneven, ſo as not to be walked on but with the greateſt care. At the diſtance of 150 yards from the cliff, it turns a little to the eaſt for 20 or 30 yards, and then ſinks into the ſea. The figure of theſe columns is almoſt unexceptionably pentagonal, or compoſed of five ſides; there are but very few of any other figure introduced: ſome few there are of three, four, and ſix ſides, but the generality of them are five-ſided, and the ſpectator muſt look very nicely to find any of a different conſtruction: yet what is very extraordinary, and particularly curious, there are not two columns in ten thouſand to be found, that either have their ſides equal among themſelves, or whoſe figures are alike. Nor is the compoſition of theſe columns or pillars leſs deſerving the attention of the curious ſpectator. They are not of one ſolid ſtone in an upright poſition; but compoſed of ſeveral ſhort lengths, curiouſly joined, not with flat ſurfaces, but articulated into each other like ball and ſocket, or like the joints in the vertebræ of ſome of the larger kind of fiſh, the one end at the joint having a cavity, into which the convex end of the oppoſite is exactly fitted. This is not viſible, but by diſjoining the two ſtones. The depth of the concavity or convexity is generally about three or four inches. And what is ſtill farther remarkable of the joint, the convexity, and the correſpondent concavity, is not conformed to the external angular figure of the column, but exactly round, and as large as the ſize or diameter of the column will admit; and conſequently as the angles of theſe columns are in general extremely unequal, the circular edges of the joint are ſeldom coincident with more than two or three ſides of the pentagonal, and from the edge of the circular part of the joint to the exterior ſides and angles they are quite plain. It is ſtill farther very remarkable, likewiſe, that the articulations of theſe joints are frequently inverted; in ſome the concavity is upwards, in others the reverſe. This occaſions that variety and mixture of concavities and convexities on the tops of the columns, which is obſervable throughout the platform of this cauſeway, yet without any diſcoverable deſign or regularity with reſpect to the number of either. The length alſo of theſe particular ſtones, from joint to joint, is various: in general, they are from 18 to 24 inches long; and, for the moſt part, longer toward the bottom of the columns than nearer the top, and the articulation of the joints ſomething deeper. The ſize or diameter likewiſe of the columns is as different as their length and figure; in general, they are from 15 to 20 inches in diameter. There are really no traces of uniformity or deſign diſcovered throughout the whole combination, except in the form of the joint, which is invariably by an articulation of the convex into the concave of the piece next above or below it; nor are there any traces of a finiſhing in any part, either in height, length, or breadth, of this curious cauſeway. If there is here and there a ſmooth top to any of the columns above water, there are others juſt by, of equal height, that are more or leſs convex or concave, which ſhow them to have been joined to pieces that have been waſhed or by other means taken off. And undoubtedly thoſe parts that are always above water have, from time to time, been made as even as might be; and the remaining ſurfaces of the joints muſt naturally have been worn ſmoother by the conſtant friction of weather and walking, than where the ſea, at every tide, is beating upon it and continually removing ſome of the upper ſtones and expoſing freſh joints. And farther, as theſe columns preſerve their diameters from top to bottom, in all the exterior ones, which have two or three ſides expoſed to view, the ſame may with reaſon be inferred of the interior columns whoſe tops only are viſible. Yet what is very extraordinary, and equally curious, in this phenomenon, is, that notwithſtanding the univerſal diſſimilitude of the columns, both as to their figure and diameter, and though perfectly diſtinct from top to bottom, yet is the whole arrangement ſo cloſely combined at all points, that hardly a knife can be introduced between them either on the ſides or angles. And it is really a moſt curious piece of entertainment to examine the cloſe contexture and nice inſertion of ſuch an infinite variety of angular figures as are exhibited on the ſurface of this grand parade. From the infinite diſſimilarity of the figure of theſe columns, this will appear a moſt ſurpriſing circumſtance to the curious ſpectator; and would incline him to believe it a work of human art, were it not, on the other hand, inconceivable that the wit or invention of man ſhould conſtruct and combine ſuch an infinite number of columns, which ſhould have a general apparent likeneſs, and yet be ſo univerſally diſſimilar in their figure, as that, from the minuteſt examination, not two in ten or twenty thouſand ſhould be found, whoſe angles and ſides are equal among themſelves, or of the one column to thoſe of the other. That it is the work of nature, there can be no doubt to an attentive ſpectator, who carefully ſurveys the general form and ſituation, with the infinitely various figuration of the ſeveral parts of this cauſeway. There are no traces of regularity or deſign in the outlines of this curious phenomenon; which, including the broken and detached pieces of the ſame kind of workmanſhip, are extremely ſcattered and confuſed, and, whatever they might originally, do not at preſent appear to have any connection with the grand or principal cauſeway, as to any ſuppoſable deſign or uſe in its firſt conſtruction, and as little deſign can be inferred from the figure or ſituation of the ſeveral conſtituent parts. The whole exhibition is, indeed, extremely confuſed, diſuniform, and deſtitute of every appearance of uſe or deſign in its original conſtruction. But what, beyond diſpute, determines its original to have been from nature, is, that the very cliffs, at a great diſtance from the cauſeway, eſpecially in the bay to the eaſtward, exhibit at many places the ſame kind of columns, figured and jointed in all reſpects like thoſe of the grand cauſeway: ſome of them are ſeen near to the top of the cliff, which in general, in theſe bays to the eaſt and weſt of the cauſeway, is near 300 feet in height; others again are ſeen about midway, and at different elevations from the ſtrand. A very conſiderable

Giant's causeway 1 Gibbous.

siderable expoſure of them is ſeen in the very bottom of the bay to the eaſtward, near a hundred roods from the cauſeway, where the earth has evidently fallen away from them upon the ſtrand, and exhibits a moſt curious arrangement of many of theſe pentagonal columns, in a perpendicular poſition, ſupporting, in appearance, a cliff of different ſtrata of earth, clay, rock, &c. to the height of 150 feet or more, above. Some of theſe columns are between 30 and 40 feet high, from the top of the ſloping bank below them; and, being longeſt in the middle of the arrangement, ſhortening on either hand in view, they have obtained the appellation of *organs*, from a rude likeneſs in this particular to the exterior or frontal tubes of that inſtrument; and as there are few broken pieces on the ſtrand near it, it is probable that the outſide range of columns that now appears is really the original exterior line, to the ſeaward, of this collection. But how far they extend internally into the bowels of the incumbent cliff, is unknown. The very ſubſtance, indeed, of that part of the cliff which projects to a point, between the two bays on the eaſt and weſt of the cauſeway, ſeems compoſed of this kind of materials; for beſides the many pieces that are ſeen on the ſides of the cliff that circulate to the bottom of the bays, particularly the eaſtern ſide, there is, at the very point of the cliff, and juſt above the narrow and higheſt part of the cauſeway, a long collection of them ſeen, whoſe heads or tops juſt appearing without the ſloping bank, plainly ſhow them to be in an oblique poſition, and about half-way between the perpendicular and horizontal. The heads of theſe, likewiſe, are of mixed ſurfaces, convex and concave, and the columns evidently appear to have been removed from their original upright, to their preſent inclining or oblique poſition, by the ſinking or falling of the cliff.

GIBBET, or GIBET, a machine in manner of a gallows, whereon notorious criminals, after execution, are hung in irons or chains, as ſpectacles *in terrorem*. See GALLOWS.—The word in French, *gibet*, properly denotes what we call gallows: it is ſuppoſed to come originally from the Arabic *gibel*, "mount or elevation of ground;" by reaſon *gibets* are uſually placed on hills or eminences.

GIBBOUS, a term in medicine, denoting any protuberance or convexity of the body, as a perſon hunched or hump backed.

Infants are much more ſubject to gibboſity than adults, and it oftener proceeds from external than internal cauſes. A fall, blow, or the like, frequently thus diſtorts the tender bones of infants. When it proceeds from an internal cauſe, it is generally from a relaxation of the ligaments that ſuſtain the ſpine, or a caries of its vertebræ; though the ſpine may be inflected forward, and the vertebræ thrown out by a too ſtrong and repeated action of the abdominal muſcles. This, if not timely redreſſed, grows up and fixes as the bones harden, till in adults it is totally irretrievable: but when the diſorder is recent, and the perſon young, there are hopes of a cure. The common method is by a machine of paſteboard, wood, or ſteel, which is made to preſs principally on the gibbous part; and this by long wearing may ſet all right. The ſurgeons, however, have a different inſtrument, which they call a *croſs*, much more efficacious, though not quite ſo convenient in the wearing. By the uſe of this, the parts are always prevented from growing any worſe, and are often cured. During the application of theſe aſſiſtances, the parts ſhould be at times rubbed with hungary-water, ſpirit of lavender, or the like, and defended with a ſtrengthening plaſter.

Gibbous || Gibeon.

GIBBOUS, in aſtronomy, a term uſed in reference to the enlightened parts of the moon, whilſt ſhe is moving from the firſt quarter to the full, and from the full to the laſt quarter: for all that time the dark part appears horned or falcated; and the light one hunched out, convex, or gibbous.

GIBEAH, a city in the tribe of Benjamin, lying north of Jeruſalem about 20 or 30 furlongs, and built upon a hill as its name imports.—This city gave birth to Saul, the firſt king of Iſrael, for which reaſon it is frequently called Gibeah of Saul, or Gibeah the native country of Saul.

GIBELINS, or GIBELLINS, a famous faction in Italy, oppoſite to another called the GUELPHS.

Thoſe two factions ravaged and laid waſte Italy for a long ſeries of years; ſo that the hiſtory of that country, for the ſpace of two centuries, is no more than a detail of their mutual violences and ſlaughters. The Gibelins ſtood for the emperor againſt the pope: but concerning their origin and the reaſon of their names we have but a very obſcure account. According to the generality of authors, they roſe about the year 1240, upon the emperor Frederick II.'s being excommunicated by the pope Gregory IX. Other writers maintain, that the two factions aroſe ten years before, though ſtill under the ſame pope and emperor. But the moſt probable opinion is that of Maimbourg, who ſays, that the two factions of Guelphs and Gibelins aroſe from a quarrel between two ancient and illuſtrious houſes on the confines of Germany, that of the Henries of Gibeling, and that of the Guelphs of Adorf.

GIBEON, a city ſeated on an eminence about 40 furlongs from Jeruſalem northward, and not far from the city of Gibeah. See GEBA.

This was the capital city of the Gibeonites, who took the advantage of Joſhua's oath, and of that which the elders of Iſrael likewiſe ſwore to them, upon an artificial repreſentation which they made of their belonging to a very remote country, and their deſire of making an alliance with the Hebrews. Joſhua (ix. 3, 4, *& ſeq.*) and the elders inconſiderately entered into a league with theſe people; but ſoon diſcovered their miſtake. Upon this, ſending for the Gibeonites, they reproached them with their fraud; and without revoking the promiſe which they had made to them, of giving them their lives, they condemned them to carry wood and water to the tabernacle of the Lord, as ſlaves and captives taken in war; in which ſtate of ſervitude they remained till the ruin and entire diſperſion of the Jewiſh nation.

The Gibeonites were deſcended from the Hivites, the old inhabitants of that country; and poſſeſſed four cities, whereof Gibeon was the capital. The cities were Cephira, Beeroth, Kirjathjearim, and Gibeon, Joſh. ix. 17. Theſe cities were afterwards given to the tribe of Benjamin, except Kirjathjearim, which fell to the tribe of Judah. The Gibeonites continued ever after ſubject to thoſe burdens which Joſhua had impoſed on them, and were very faithful to the Iſraelites.

Giblets, Gibraltar.

GIBLETS, the offals or entrails of a goose; including the heart and liver, with the feet, gizzard, &c. The word is supposed to be formed of *gobiets;* from the French *gobeau*, "mouthful."—Giblets make a considerable article in cookery: they boil giblets, stew giblets, make ragous of giblets, giblet-pies, &c.

GIBRALTAR, a famous promontory, or rather peninsula, of Spain, lying in N. Lat. 35. 50. W. Long. 5. 35. To the ancients it was known by the name of *Calpe*, and was also called one of the *Pillars of Hercules;* by the Arabians it is called *Gebel Tarek*, that is, "the mount of Tarek," from *Tarek*, the name of the Saracen general who conquered Spain in the beginning of the eighth century. The whole is an immense rock, rising perpendicularly about 440 yards, measuring from north to south about two English miles, but not above one in breadth from east to west.—The town lies along the bay on the west side of the mountain on a decline; by which, generally speaking, the rains pass through it, and keep it clean. The old town was considerably larger than the new, which at present consists of between 400 and 500 houses. Many of the streets are narrow and irregular: the buildings are of different materials; some of natural stone out of the quarries, some of a factitious or artificial stone, and a few of brick. The people are supplied with fresh provisions chiefly from the coast of Barbary, with fruit, roots, and vegetables of all sorts from thence, or from their own gardens. Besides what is properly called the town, there are several spacious and commodious public edifices erected; such as barracks for the soldiers, with apartments for their officers, magazines of different kinds, storehouses for provisions, &c. The inhabitants, exclusive of the British subjects dependent on the garrison, or who reside there from other motives, consist of some Spaniards, a few Portuguese, a considerable number of Genoese, and about as many Jews; making in the whole, according to Dr Campbell, between two and three thousand, without reckoning the garrison; though some make them much fewer. The town may be said to have two ports; the first lying to the north, and is proper only for small vessels; the other is very commodious for large vessels, and has a fine stone quay. The bay is very beautiful and capacious, being in breadth about five miles, and in length eight or nine, with several small rivers running into it. It is very advantageous to the place. There is no ground to be found in the middle of it at 100 fathoms depth, so that a squadron may lie there in great safety; the breezes from it are very refreshing; and it contributes likewise to the subsistence of the inhabitants, by supplying them with plenty of fish.

The strait of Gibraltar, through which the ocean passes into the Mediterranean, thereby dividing Europe from Africa, runs from west to east about 13 leagues. In this strait there are three remarkable promonteries or capes on the Spanish side, and as many opposite to them on the Barbary side. The first of these, on the side of Spain, is cape Trefalgar, opposite to which is cape Spartel; and in the neighbourhood of this stood the fortress of Tangier, once in the possession of the British. The next on the Spanish side is Tarifa; and over against it lies Malabata, near the town of Alcaffar, where the straits are about five leagues broad. Lastly, Gibraltar, facing the mountain of Abyla, near the fortress and town of Ceuta, which make the eastern entry of the straits. Gibraltar

This important fortress seems to have been first particularly noticed as a place of consequence in the year 712. At that time the general of the calipn Al Walid landed with an army of 12,000 men on the isthmus between Mons Calpe and the continent; and that he might secure an intercourse with Africa, ordered a castle to be built on the face of that hill. Part of the building still remains; and, from an inscription discovered above the principal gate, appears to have been finished in 725. It continued in the possession of the Saracens till the beginning of the 14th century, when it was recovered by Ferdinand king of Castile. In 1333, however, it was obliged to surrender to the son of the emperor of Fez, who came to the assistance of the Moorish king of Granada. An attempt was made upon it in 1349 by Alonzo king of Castile; but when the fortress had been reduced to the last extremity, a pestilential fever broke out in the Spanish camp, which carried off the king himself, with great part of his army; after which the enterprise was abandoned. 1 Fortress first erected by the Saracens. 2 Various revolutions.

The fortress continued in the possession of the Saracen descendants of the prince of Fez until the year 1410, when it was taken possession of by Joseph III. king of Granada. A design of attacking it was formed by Henry de Gusman in 1435; but the enterprise having miscarried through his imprudence, he was defeated and slain. However, it was at length taken after a gallant defence by his son John de Gusman in 1462; since which time it has remained in the hands of the Christians. In 1540, it was surprised and pillaged by Piali Hamet, one of Barbarossa's corsairs; but the pirates having fallen in with some Sicilian galleys, were by them defeated, and all either killed or taken.

In the reign of Charles V. the fortifications of Gibraltar were modernised, and such additions made as to render them almost impregnable. It was taken by the English, however, in the reign of queen Anne, and since that time has remained in their possession; and probably will always do so, unless ceded by treaty, as it appears altogether impossible to reduce it by any force of artillery let it be ever so great. In the year 1704, in consequence of the resolution adopted by the court of Britain to assist the archduke Charles in his pretensions to the Spanish crown, Sir George Rooke was sent with a powerful fleet into the Mediterranean. His orders being limited, nothing of consequence was done for some time, until at last an attempt on Gibraltar was resolved upon; not so much on account of the importance of the conquest, as to prevent any reflections against the admiral for inactivity. On the 21st of July that year, 1800 troops were landed upon the isthmus under the command of the prince of Hesse Darmstadt; and on the refusal of the governor to surrender, preparations were made for attacking the place. Early in the morning of the 23d, a cannonade was begun from the fleet, and kept up so briskly, that in five or six hours the Spaniards were driven from many of their guns, especially at the new mole-head. The admiral perceiving, that by gaining this part of the fortification, the reduction of the rest would be facilitated, ordered out some armed boats to take possession of it. On their approach the Spaniards sprung a 3 Its fortifications improved and strengthened. 4 Taken by Sir George Rooke in 1704.

Gibraltar.

mine, which demoliſhed part of the works, killed two lieutenants and 40 private ſoldiers, wounding about 60 more. Notwithſtanding this diſaſter, the aſſailants kept poſſeſſion of the work, and took a ſmall baſtion, now the eight-gun battery, half way between the mole and the town. On this the governor thought proper to capitulate, and the prince of Heſſe took poſſeſſion of the gates on the 24th. The garriſon, conſiſting at moſt of 150 men, marched out with the honours of war; and the Spaniards who choſe to remain were allowed the ſame privileges they had enjoyed under the reign of Charles II. The works were found very ſtrong, and the place well provided with ammunition and military ſtores.

This conqueſt was atchieved with the loſs of about 60 killed and 216 wounded on the part of the Engliſh. The prince of Heſſe remained governor; and 18 men of war were left at Liſbon under the command of Sir John Leake, to ſuccour the garriſon if there ſhould be occaſion. The loſs of ſuch an important fortreſs, however, having alarmed both the courts of Madrid and Paris, orders were ſent to the marquis de Villadarias, a Spaniſh grandee, to lay ſiege to it, in which he was to be aſſiſted by a naval force from Toulon. The prince immediately applied to Sir John Leake for aſſiſtance; but before the latter had time to comply with his requeſt, a French fleet arrived, and debarked ſix battalions to the aſſiſtance of the Spaniards; after which they proceeded to the weſtward, leaving only ſix frigates in the bay. The trenches were opened on the 11th of October, about which time Sir John arrived with 20 ſail of Engliſh and Dutch ſhips; but hearing that the French were about to attack him with a ſuperior force, he judged it proper to return and refit. Having very prudently left orders at Liſbon to make preparations for this purpoſe in his abſence, he was enabled to accompliſh the work with ſuch expedition, that on the 29th of the ſame month, he returned, and ſurpriſed in the bay three frigates, a fire-ſhip, two Engliſh prizes, a tartan, and a ſtore-ſhip. After this exploit he landed ſome reinforcements, ſupplied the garriſon with ſix months proviſion and ammunition; at the ſame time detaching on ſhore a body of 500 ſailors to aſſiſt in repairing the breaches which had been made by the enemy's fire.

Thus the Spaniards were diſappointed in their hopes of ſucceſs from an attack which had been projected that very night, and for which purpoſe 200 boats had been collected. Still, however, they did not deſpair; and ſuppoſing that the garriſon would be off their guard and ſecure on account of the vicinity of their fleet, they formed the raſh deſign of attempting to ſurpriſe the place though the Britiſh admiral was ſtill before it. In this mad attempt 500 volunteers aſſociated, taking the ſacrament never to return unleſs they accompliſhed their purpoſe. They were conducted by a goat herd to the ſouth ſide of the rock near the cave-guard, at that time called *the paſs of beuſt-trees*. This they mounted, and lodged themſelves the firſt night in the Cave of St Michael: the next they ſcaled Charles V.'s Wall; ſurpriſed and maſſacred the guard at Middle-hill; where afterwards, by ropes and ladders, ſeveral hundreds of the party deſigned to ſupport them were hauled up; but being diſcovered, they were attacked by a ſtrong party of grenadiers, and all of them at laſt either killed or taken. Theſe brave adventurers were to have been ſupported by a body of French troops, and ſome feints were propoſed to draw off the attention of the garriſon; but, through the diſagreement of the commanding officers, theſe propoſals were not put in execution, and thus the volunteers were left to their fate.

8 They are all killed or taken.

Notwithſtanding theſe misfortunes the Spaniards ſtill continued the ſiege, and fitted out a ſtrong ſquadron from Cadiz, with a deſign to intercept the convoys of proviſions which might be ſent to the garriſon; flattering themſelves at the ſame time, that, on the arrival of their fleet, Sir John would be obliged to retire, and the garriſon of conſequence to ſurrender to their united attacks. They continued their fire therefore with additional fury, diſmounted many of the cannon, and did eſſential injury to the works in ſeveral different places. The prince of Heſſe, however, was by no means deficient in his endeavours to diſappoint their expectations. As it was probable that an attempt might be made to ſtorm the curtain, a cuvette was dug in the ditch which was filled by the tide, and a double row of paliſades placed parallel to the works. The chambers of the mine under the glacis were loaded, and all means taken to defeat ſuch an attempt; but on a ſudden the Spaniards ſeemed to have altered their deſign, and threatened an attack on the lines which the garriſon had on the declivity of the hill to flank the glacis, and overlook their advanced works. While affairs remained in this ſituation, part of the ſuccours they had long expected arrived in the bay, December 7. 1704, and in two days after, the remainder came in with near 2000 men, along with a proportionable quantity of ammunition and proviſions. Theſe had failed from Cape Sparrel under convoy of four frigates; but were in imminent danger of falling into the hands of the enemy, whoſe fleet they miſtook for their own; however they eſcaped by the fortunate circumſtance of being becalmed, ſo that they could not get up to them.

9 The ſiege ſtill continued.

10 The garriſon reinforced.

Sir John Leake having thus powerfully reinforced the garriſon, thought his preſence in the bay no longer neceſſary, and therefore ſet ſail for Liſbon, where he arrived about the end of the year. In the beginning of January 1705 the Spaniards were reinforced by a conſiderable body of infantry, and on the 11th of the month made an attack on the extremity of the King's Lines, but were repulſed. The attack was renewed next day with 600 grenadiers, French and Walloons, ſupported by 1000 Spaniards under lieutenant-general Fuy. They diſpoſed themſelves in ſuch a manner as ſhowed an intention to ſtorm a breach which had been made in the Round Tower at the extremity of the King's Lines, and another in the entrenchment on the hill. The retrenchment which covered the latter breach, with part of the entrenchment joining the precipice of the rock, was defended at night by a captain, three ſubalterns, and 90 men; but it was cuſtomary for the captain to withdraw, with two ſubalterns and 60 men, at day-break. The Round Tower was defended by 180 men, commanded by a lieutenant colonel. The marquis, by deſerters from the garriſon, had obtained intelligence of the ſtrength of theſe poſts, and planned his attack accordingly. The de-

11 Vigorous attack by the Spaniards.

Gibraltar. detachment for the upper breach mounted the rock at midnight, and concealed themſelves in the clifts until the captain had withdrawn; after which, advancing to the point of the entrenchment, they threw grenades on the ſubaltern and his party, ſo that they were obliged to leave the place. At the ſame time 300 men ſtormed the Round Tower, where lieutenant-colonel Bar made a vigorous defence, though the enemy, having paſſed the breach above, annoyed them on the flanks with great ſtones and grenades. Obſerving, however, the Spaniards marching down to cut off his retreat from the town, he retired; and, by getting over the parapet of the King's Lines, deſcended into the covered way, where the Engliſh guards were poſted. Thus the garriſon were alarmed; all the regiments were aſſembled at their proper poſts; and captain Fiſher endeavoured to ſtop the progreſs of the enemy with 17 men, but they were repulſed, and himſelf taken priſoner. At laſt, however, the Tower was retaken by lieutenant-colonel Moncal at the head of 400 or 500 men, after it had been in the poſſeſſion of the enemy upwards of an hour.

12 They are repulſed

The garriſon were now farther reinforced by ſix companies of Dutch troops and 200 Engliſh ſoldiers, together with ſome proviſions and ſtores. The aſſailants, however, were ſtill determined to go on. The marquis de Villadarias was ſuperſeded by the Mariſchal Teſſe a Frenchman, with whom Admiral Pointis was deſired to co-operate in blocking up the place. The Mariſchal therefore joined the army with four freſh battalions, beſides eight companies which had been ſent before; the ordnance, which had been greatly injured by conſtant uſe, was exchanged for others, and the works, as they then ſtood, put into the beſt repair. On the part of the Engliſh a reinforcement was ordered under the command of Sir Thomas Dilkes and Sir John Hardy, to join Admiral Leake at Liſbon; which junction being effected, the whole fleet, conſiſting of 28 Engliſh, 4 Dutch, and 8 Portugueſe men of war, having on board two battalions of land forces, ſet ſail from Liſbon. Happily for the beſieged, however, the inceſſant rains and ſtorms about this time had retarded the operations of the land-forces, and greatly diſtreſſed the fleet of the enemy. Eight ſhips of the latter were forced from their anchors by the ſtrong weſterly wind, and obliged to drive aloft. At this critical period Sir John Leake, with the allied fleet, entered the ſtraits. On his approach the few remaining French ſhips put out to ſea; and the Britiſh admiral diſcovering five ſail making out of the bay, and a gun fired at them from the garriſon, immediately gave chace. Three French men of war were taken, and the admiral's ſhip and another driven on ſhore, where they were burnt. The reſt, on hearing the report of the guns, had made the beſt of their way to Toulon.

13 The ſiege carried on with freſh ardour.

14 The French fleet diſperſed by a ſtorm.

The garriſon was now ſo well ſupplied, that Mariſchal Teſſe withdrew his troops from the trenches, and formed a blockade, drawing an intrenchment acroſs the iſthmus to prevent the garriſon from ravaging the country. The prince of Heſſe remained for ſome time in the place, where he repaired the batteries, and made ſome additions to the fortifications; after which he joined the arch-duke Charles at Liſbon. As the latter, however, was reſolved to try his fortune with the Earl of Peterborough in Valencia and Catalonia, the prince was ſent back to Gibraltar to prepare part of the garriſon for embarkation, and ſoon after was followed by the whole fleet. Major General Ramos was now appointed governor of Gibraltar, in which only two new battalions were left, as nothing was to be feared from the enemy. The new governor, however, brought with him 400 men for the greater ſecurity of the place; but ſoon reſigned his government to Colonel Roger Elliot, during whoſe time Gibraltar was made a free port by a ſpecial order from the queen. Gibraltar

15 The ſiege turned into a blockade, and at laſt raiſed.

Colonel Elliot was ſucceeded by colonel Congreve before the year 1714, and he by Colonel Cotton a ſhort time after. In 1720 the Spaniards ſeem to have threatened another attack. Ceuta, a Spaniſh fortreſs in Barbary, had been for many years beſieged by the Moors; and a powerful armament, commanded by the marquis de Lada, was now aſſembled in Gibraltar-bay, under pretence of relieving the African fortreſs, but with a ſecret deſign of firſt ſurpriſing Gibraltar; for which purpoſe they had provided ſcaling ladders, &c. The armament, however, had not been fitted out with ſuch ſecrecy, but that the Britiſh miniſtry had intelligence of it. On this they ſent orders to colonel Kane, governor of Minorca, to embark with part of his garriſon for Gibraltar under convoy of the fleet in the Mediterranean. On his arrival he found the place in a critical ſituation. The garriſon conſiſted only of three weak battalions under major Hetherington, beſides whom there was only one other field-officer, major Batteroux, in the place, and no more than 14 days proviſions remaining. The poſture of affairs, however, was altered by the arrival of colonel Kane with 500 men with proviſions and ammunition; which reinforcement, together with the ſpirited behaviour of the Britiſh commodore, induced the Spaniſh commander to abandon his deſign, though he remained of opinion that the fortreſs might then have been carried by a general aſſault.

16 A new attack threatened by the Spaniards in 1720.

17 The deſign given up.

Notwithſtanding this diſappointment, the Spaniards continued to keep a watchful eye over Gibraltar; and, in the latter end of the year 1726, aſſembled an army in the neighbourhood of Algeſiras, encamping, on the 20th of January following, on the plain below St Roch, and erecting a battery on the beach to protect their camp. Though admiral Hopſon was then at anchor in the bay of Gibraltar, yet, as he had received no intelligence of the actual commencement of hoſtilities between Britain and Spain, he was obliged to allow the boats of the latter to paſs with proviſions, arms, and ammunition, between Algeſiras and the camp, at the ſame time that colonel now brigadier Kane, who had been a ſecond time ſent from Minorca, lay under ſimilar embarraſſments. The operations of the Spaniards, however, ſeemed ſo evidently to tend towards an attack, that the governor thought proper to order ſuch of that nation as were in the town to leave it, and to forbid their galleys to anchor under his guns (A).

18 Another attempt in 1726.

The count de Las Torres commanded the Spaniſh forces

(A) At this time the fortifications of Gibraltar were conſiderably different from what they had been in 1705. Several

Gibraltar. forces, amounting to near 20,000 men; and soon after forming his camp, he advanced within reach of the garrison. The brigadier then desired him to keep out of his reach, otherwise he should do his utmost to force him; but to this the Spanish commander replied, that, as the garrison could command no more than they had power to maintain, he should obey his Catholic majesty's orders, and incroach as far as possible. Hostilities, however, were not commenced until the 10th of February 1727, when the Spaniards, having brought materials for batteries to the old wind-mill on the neutral ground, it was determined in a council of war, that the Spanish general had commenced hostilities by incroaching so far on the liberties of the garrison. Still, however, the governor sent to the count to know the reason of breaking ground before the garrison; but received for answer, that "he was in his master's territories, and was not answerable to any other person for his conduct." On this the governor opened the batteries of the Old Mole and those of Willis upon the Spanish workmen; however, they persisted in carrying on their operations, and at night marched a party down to the Devil's Tower, where they immediately broke ground, and began a communication with their other works. The governor was now informed by some deserters, that the enemy were forming a mine in a cave under Willis's Battery, with a design to blow it up: but the plot being thus happily discovered, a party was immediately stationed to cut off the communication. On the 22d of February the Spaniards opened on the garrison with 17 pieces of cannon besides mortars; and the day following brigadier Kane left Gibraltar to send a reinforcement from Minorca. On the 3d of March the enemy opened a new battery of 22 guns on the Old Mole, and on the 8th another of 15 guns, bearing also upon the same Mole, the guns of which had annoyed the western flank of their approaches.

All this time the garrison had kept up a constant and well directed fire from the batteries which bore upon the works of the enemy; but the ordnance in general being old, were frequently bursting; by which they suffered more than from the fire of the besiegers. The latter were also greatly distressed by the fleet under admiral Hopson and Sir Charles Wager, who, since the beginning of the siege, had intercepted their homebound ships, and at the same time greatly benefited the garrison by bringing the prizes into the bay. Finding the Spaniards, however, obstinately bent on their enterprise, they formed a design, on the second of April, to bombard Algesiras, from whence the besieged were supplied with various articles of ammunition; but the fleet happening to be becalmed, the design was afterwards unaccountably abandoned; and on the arrival of a reinforcement from Minorca, they sailed to the westward, leaving the garrison to defend themselves the best way they could.

The enemy continued to augment their batteries, and erect new ones, until they amounted at last to 60 cannon besides mortars; and, on the 3d of May, the governor received intelligence that a general assault was intended; to repel which he took every proper precaution. The enemy, however, still added to their approaches, and considerable reinforcements were received by both parties. Hostilities, however, ceased on the 12th, when news arrived that the preliminaries of a general peace were signed; since which time to the year 1779 no farther attempts were made on Gibraltar. In the course of these two sieges the loss of the Spaniards was very considerable; that of 1705 costing them not less than 10,000 men, including those who died of sickness; and in that of 1727 their loss was computed at near 3000, besides casualties, which could not be ascertained. That of the garrison amounted in 1705 to 400; and in 1727 to 300; a very small number, considering that during the siege 70 cannon and 30 mortars burst on the batteries.

Gibraltar. 19 Cessation of hostilities. 20 Great loss of the Spaniards in their attempts.

The hostile manifesto presented by the Spanish ambassador to the court of London at the commencement of the late war, was soon followed by an interruption of communication betwixt Spain and the fortress of Gibraltar. No direct intention of attacking or distressing it, however, was manifested till the 16th of July, when the port was completely blocked up by a squadron of two 74 gun ships, several frigates, galleys, &c. Ten days after they began to form a camp on the plain below St Roch, three miles from the fortress. The garrison at this time consisted of 5382 men, including officers, with a company of engineers and artificers; but the greatest expectations were formed from the abilities and valour of general Elliot the governor. As soon as the breaking off the communication with Spain indicated approaching hostilities, the governor took every precaution that could be suggested by military wisdom; but though informed of the rupture betwixt the two courts having actually taken place, and though he beheld the hostile operations of the enemy, no means were used to interrupt them till the 12th of September, when the batteries of Green's Lodge, Willis, and Queen Charlotte, were opened for a few hours, with a view to disturb the workmen.

21 Gibraltar blocked up in 1779. 22 Hostilities commenced by the garrison.

From this time to the beginning of the year 1780 the enemy continued the blockade both by sea and land, but without doing any damage to the works or garrison; and it was not until the 12th of January that a single person was wounded. This happened to be a woman, who, passing near one of the houses, was slightly hurt by a shot from the enemy. In the mean time, however, the usual supplies of provisions being cut off, the garrison began to feel all the horrors of famine. All the necessaries of life were very scarce, and to be procured only at exorbitant prices. Veal, mutton, and beef, sold from half a crown to four shillings per pound; fresh pork from two to three shillings; salted beef and pork fifteen pence; fowls eighteen shillings per couple; ducks a guinea; fire-wood, five shillings per hundred weight; a pint of milk and water fifteen pence; a small cabbage cost five shillings, and a small bunch of outer leaves five pence; Irish butter half a crown per pound; candles as much; and eggs sixpence each. As the rock, however, is almost surrounded

23 A woman first wounded in the fortress. 24 Excessive dearness of provisions.

Several works were erected on the heights above the lines called *Willis's Batteries*; the Prince's Lines were extended to the extremity of the rock, and an inundation was formed out of the morass in front of the grand battery.

Gibraltar. rounded by the ſea, it was natural to ſuppoſe, that in ſuch a ſcarcity of other proviſions great benefit would have been derived from the ocean; but the fiſhermen, being all foreigners, and under no regulation, took advantage of the preſent ſcarcity of proviſions in the garriſon to exact a moſt exorbitant price for the fiſh they ſupplied. Gibraltar.

25 The Spaniſh fleet defeated and their admiral taken by Rodney.

Had matters remained long in this ſtate, it is plain that the fortreſs, however ſtrong, muſt have fallen into the hands of the enemy. They were, however, effectually relieved in conſequence of the victory gained by admiral Rodney over the Spaniſh fleet commanded by Don Juan de Langara. The former had been furniſhed with a ſtrong ſquadron, in order to relieve this important fortreſs; with which having ſet ſail, he in a few days fell in with a Spaniſh fleet of 16 tranſports bound from Bilboa to Cadiz, and laden with proviſions and naval ſtores, conveyed by a man of war of 64 guns, four frigates, and two armed veſſels. Of theſe only a ſingle tranſport eſcaped, the reſt being all captured on the 8th of January 1780; and the loſs of them, at the ſame time that it promiſed to be very ſerviceable to the garriſon, was equally detrimental to the enemy, who were now in great want both of proviſions and materials for their ſhipping.

This advantage was ſoon after followed by a much greater. On the 16th of the ſame month a Spaniſh ſquadron of 11 ſail of the line was diſcovered off Cape St Vincent; and the Britiſh admiral having taken the proper methods to come up with them as quickly as poſſible, an engagement took place about four in the afternoon. At this time the headmoſt ſhips of the Britiſh line cloſed in with the neareſt of the enemy, and in half an hour one of the Spaniards, mounting 70 guns, and having on board 600 men, blew up, and all on board periſhed. In two hours more another Spaniſh ſhip of the line was taken; notwithſtanding which the fight continued with great vigour till two in the morning, when the headmoſt ſhip of the enemy ſtruck to the Sandwich; after which the firing ceaſed. The weather throughout the night was ſo tempeſtuous that it was with the utmoſt difficulty the Britiſh could take poſſeſſion of thoſe ſhips which ſurrendered. Theſe were ſix in number, but two of them drove aſhore and were loſt, only four being brought ſafe into Gibraltar. Theſe were the admiral's ſhip of 80 guns and 700 men, with three others of 70 guns and 600 men. The engagement, however, happened ſo near the ſhore, and the Britiſh were ſo eager in ſecuring the lee-gage to prevent the enemy's eſcape, that Admiral Rodney's ſhip, together with ſome of the largeſt in the fleet, were in great danger of running on the ſhoals of St Lucar; nor could they be got into deep water again without much labour and the exertion of great naval ſkill. It was the opinion of all who were preſent in the action, that had this engagement happened in the day-time, or had the weather been leſs boiſterous, not one of the Spaniſh ſhips could have eſcaped; and even as it was, thoſe which got off were ſo eſſentially damaged as to be unfit for ſervice.

26 The garriſon relieved and reinforced.

The news of this important victory arrived at Gibraltar on the evening of the day after it was fought; and in two days more the garriſon was completely relieved by the arrival of the fleet and convoy, at the ſame time that they were farther reinforced by a regiment of Highlanders, conſiſting of 1051 men, officers included. An opportunity was alſo taken of ſending away with the fleet all the invalids and women in the garriſon; with whom they ſet ſail on the 10th of February, leaving in the bay only the Edgar and Panther ſhips of the line, with two frigates. Gibraltar.

On the departure of the Britiſh fleet the blockade was immediately reſumed; and notwithſtanding the ample ſupplies lately received, the garriſon ſoon began again to experience the inconveniency of wanting freſh proviſions. It had hitherto received theſe in abundance from the coaſt of Barbary; but an unaccountable alteration had now taken place, ſo that the friendſhip of the emperor of Morocco was transferred from Great Britain to Spain in a manner totally unprecedented. His partiality towards the latter was the more ſurpriſing, as Britain had given no provocation, and the enmity between Spain and Morocco ſeemed to be in a manner conſtitutional, and founded upon ſuch cauſes as could never ceaſe to operate. Thus, however, the garriſon became daily more and more diſtreſſed, from being obliged to make conſtant uſe of their ſalt proviſions, and even this with the ſtricteſt economy. The induſtry and reſolution of the Britiſh ſeamen and officers, indeed, ſometimes overcame all obſtacles, ſo that they found means to procure the neceſſary refreſhments; though in ſo doing they were certainly expoſed to the utmoſt danger from the enemy. At the ſame time the defence of the garriſon was ſo vigorous, that while it continued to be ſupplied even in this ſcanty manner, the Spaniards began to loſe all hope of reducing it; for which reaſon they formed a project of burning all the Britiſh ſhipping in the bay. The night appointed for putting this ſcheme in execution was the 6th of June 1780, when ten fire-ſhips, favoured by an uncommon darkneſs, ſtood over from the Spaniſh to the Britiſh ſide of the bay. Their deſign was to ſet fire to the ſtorehouſes neareſt to the water ſide, as well as to the ſhipping there; but having been too precipitate in firing their ſhips, and being received alſo by a very heavy cannonade, the attempt was fruſtrated. On this occaſion the ſkill and intrepidity of the Britiſh ſeamen was eminently diſplayed. Having manned their boats, they grappled the fireſhips already in flames; and, notwithſtanding their dreadful appearance and the danger of their exploding, towed them clear of the veſſels under the walls, and extinguiſhed them.

27 The garriſon again reduced to ſtraits.

28 Unſucceſsful attempt to burn the Britiſh ſhipping.

The failure of this project was a grievous diſappointment to Don Barcelo the Spaniſh admiral, who lay ready with his ſquadron to intercept the Britiſh veſſels that might attempt to eſcape; at the ſame time that the batteries on their lines were in readineſs to bombard the town, if the fire-ſhips had ſucceeded in cauſing any conflagration on ſhore. The failure of the preſent attempt, however, was ſoon followed by other diſaſters. As ſoon as they had, with great labour, puſhed forward their new works, and conſtructed new batteries, they were certainly deſtroyed by the beſieged; and their mortification on theſe occaſions was the greater, as it was uſual for the governor to allow them to complete their works before he commenced his deſtructive operations. Thus the labour of many days was often loſt in a few hours, and afterwards was to be reſumed with as little proſpect of ſucceſs as before.

29 Spaniſh works deſtroyed.

Gibraltar.

fore. The garriſon were now conſiderably annoyed by the Spaniſh gun-boats, to which indeed the ſhipping were equally expoſed with themſelves. Theſe were veſſels from 30 to 40 tons burden, conſtructed ſo that they lay low in the water, which rendered them difficult to be aimed at. They had 15 oars on a ſide, carried 40 or 50 men, with a 26 pounder on the prow; and, from the facility of managing them, two were deemed, in calm weather, to be a match for a frigate of moderate ſize. All their efforts, however, could ſtill do no more than to reduce the garriſon to great ſtraits for want of proviſions; and to this dreadful inconvenience the Britiſh ſubmitted with the greateſt cheerfulneſs. From the time of Admiral Rodney's departure in the month of February 1780 to the month of October, almoſt the only proviſions in the garriſon were ſuch as tended to produce the ſcurvy; which accordingly raged in ſuch a manner as to threaten the moſt fatal conſequences. An antidote, however, was happily procured by the capture of a Daniſh dogger from Malaga laden with lemons and oranges, which the governor immediately purchaſed for the uſe of the garriſon, and diſtributed among them. "At this time (ſays Captain Drinkwater) the ſcurvy had made dreadful ravages in our hoſpitals, and more were daily confined; many, however, unwilling to yield to its firſt attacks, perſevered in their duty to the more advanced ſtages. It was therefore not uncommon, at this period, to ſee men, who, ſome months before, were hale, and capable of enduring any fatigue, ſupporting themſelves to their poſts upon crutches, and even with that aſſiſtance ſcarcely able to move along. The moſt fatal conſequences in ſhort were to be apprehended to the garriſon from this terrible diſorder, when this Dane was happily directed to our relief." According to Mr Cairncroſs, an eminent ſurgeon, who was preſent during this ſiege, "the ſcurvy, which now raged in Gibraltar, differed in no reſpect from that diſeaſe uſually contracted by ſailors in long ſea-voyages; and of which the immediate cauſe ſeemed to be the ſubſiſting for a length of time upon ſalted proviſions only, without a ſufficient quantity of vegetables or other acceſcent foods. The circumſtances related in the voyage of that celebrated circumnavigator Lord Anſon, of conſolidated fractures diſuniting, and the calloſity of the bone being perfectly diſſolved, occurred frequently in our hoſpitals, and old ſores and wounds opened anew from the nature of the diſorder. Various antiſcorbutics were uſed without ſucceſs, ſuch as acid of vitriol, ſour crout, extract of malt, eſſence of ſpruce, &c.; but the only ſpecifics were freſh lemons and oranges given liberally; or, when they could not be procured, the preſerved juice in ſuch quantities, from one to four ounces per day, as the patient could bear. Whilſt the lemons were found, from one to three were adminiſtred each day as circumſtances directed. The juice given to thoſe in the moſt malignant ſtate was ſometimes diluted with ſugar, wine, or ſpirits; but the convaleſcents took it without dilution. Women and children were equally affected, nor were the officers exempted from this dreadful diſorder. It became almoſt general at the commencement of the winter ſeaſon, owing to the cold and moiſture; and in the beginning of ſpring when vegetables were ſcarce. The juice was preſerved by adding to 60 gallons of expreſſed liquor about five or ten gallons of brandy, which kept it in ſo wholeſome a ſtate, that ſeveral caſks were opened in good condition at the cloſe of the ſiege. The old juice, however, was not ſo ſpeedily efficacious as the fruit, though by perſevering longer in its uſe it ſeldom failed."

Gibraltar.

30 The garriſon annoyed by the Spaniſh gun-boats.

31 The ſcurvy rages in the garriſon.

32 Cairncroſs's account of it.

33 Method of preſerving lemon juice.

Till this month the allowance of ſalt proviſions had continued undiminiſhed; but now it was judged neceſſary to reduce the allowance of bread and meat, and to make ſome other regulations in order to enforce the ſtricteſt economy with regard to food. Every thing of this kind that could be practiſed, however, ſeemed inſufficient to preſerve the garriſon from abſolute want. In the beginning of the year 1781 proviſions became exceedingly ſcarce, by reaſon of the almoſt total expenditure of what was contained in the public ſtores, and the vigilance of the enemy's cruizers. About the middle of February the town bakers left off work for want of flour; and many of the poorer ſort wanted bread. The price of freſh proviſions again roſe to a moſt enormous height. Small pigs ſold at two guineas; turkeys at three; geeſe at 30 ſhillings; fowls and ducks at 10 ſhillings; damaged biſcuit a ſhilling the pound; peaſe 18d.; and all other neceſſaries in proportion; at the ſame time the ſcarcity of fuel was ſuch, that it was ſometimes ſcarcely procurable in quantity ſufficient to dreſs the victuals.

34 The garriſon diſtreſſed for want of proviſions.

The garriſon had hitherto derived aſſiſtance occaſionally from the gardens on the neutral ground, tho' vaſt quantities of vegetables had been removed thence by the enemy. Towards the end of the month of October 1780, however, the Spaniards determined to expel the Britiſh from the gardens entirely; and this they accompliſhed in ſpite of all that could be done to prevent them. From this time the reſources with regard to vegetables depended entirely upon the attention paid to cultivation; which, happily for the garriſon, was attended with ſuch ſucceſs, eſpecially during the winter months, that the produce came at laſt to be nearly equal to the demands. At laſt, on the 12th of April 1781, ſupplies were brought by the Britiſh fleet under admirals Darby, Digby, and Roſs, though they could not be got in without great difficulty. The gun-boats already mentioned were now much increaſed in number and ſtrength of conſtruction; infeſting the bay in ſuch a manner as greatly to interrupt the debarkation of the ſtores. As no veſſels of the ſame kind had been prepared to oppoſe them, they could ſcarce be prevented from effecting their purpoſe of burning the ſtore ſhips. With this view they had approached them every morning in hazy weather to the number of between 20 and 30, ſeveral of them carrying mortar-pieces; and as they uſed both ſails and oars, they eluded all purſuit, by withdrawing on the riſe of any breeze. To keep off theſe troubleſome gueſts ſeveral ſtout frigates were obliged to ſtation themſelves along the bay for the protection of the ſhipping; but even this did not prevent them from continuing their moleſtation; and notwithſtanding the vigilance and activity of the Britiſh ſailors, it was ſeldom that they could come near enough to do them any damage. In ſpite of all their endeavours, however, the garriſon was effectually relieved; an exploit which ſo exceedingly irritated the court of Spain, that they determined to exert the utmoſt force of the kingdom rather than fail in

35 The garriſon entirely deprived of the uſe of the neutral ground.

36 Supplied by the Britiſh fleet.

37 The Spaniards reſolve to exert themſelves to the utmoſt.

Gibraltar. in the execution of their favourite project. The works before the town were therefore carried on with more vigour than ever, and the moſt tremendous preparations made to cauſe the obſtinate garriſon feel the reſentment of an exaſperated enemy. Their batteries were now mounted with guns of the heavieſt metal, and with mortar-pieces of the largeſt ſize; the number of the former augmented to near 200, and of the latter to upwards of 80. For three weeks this prodigious artillery continued to pour forth an almoſt inceſſant ſhower of ſhot and ſhells, inſomuch that, in the time juſt mentioned, they had conſumed 100,000 lb. of gunpowder, and thrown into the town four or five thouſand ſhot or ſhells every 24 hours.

38 The town entirely deſtroyed.

By ſuch an immenſe bombardment the town was almoſt totally laid in ruins. The inhabitants, computed at more than 3000 in number, experienced every difficulty that could ariſe from the deſtruction of their habitations: ſeveral of them were killed, and all forced to leave the town, and take ſhelter under tents with what accommodation could be provided for them in ſuch ſcenes of horror and confuſion. Numbers took the opportunity of retiring with the fleet; while many that remained were now reduced from a ſtate of opulence to the greateſt diſtreſs. The conduct of Governor Elliot was very humane and compaſſionate to ſuch as were obliged to ſtay; allowing them a free paſſage to England, and ſupplying them with proviſions for the voyage. Gibraltar.

During this bombardment, not only the greateſt part of the effects belonging to the inhabitants were deſtroyed, but the fortifications were in many places greatly injured; and the worſt was, that the remainder were deſtroyed by the ſoldiers, who had arrived at ſuch a pitch of licentiouſneſs, that they neither regarded nor would obey their officers. They were incited to this deſtructive ſcheme by the avarice of ſome of the inhabitants who had hoarded up and concealed a quantity of neceſſary articles, in order to procure an advanced price. They now, therefore, kept no bounds in diſſipation, waſte, and extravagance; a remarkable inſtance of which is given by Captain Drinkwater, in their roaſting a pig by a fire made of cinnamon. To put a ſtop to theſe atrocious proceedings, rigorous meaſures were of neceſſity adopted; and it was intimated, that any ſoldier convicted of being drunk or aſleep upon his poſt, or found marauding, ſhould be immediately executed. The loſs of human lives during this dreadful bombardment was leſs than could have been expected; but many remarkable circumſtances are taken notice of by Captain Drinkwater, ſome of which are related in the note (A).

39 Diſorderly behaviour of the ſoldiers.

(B) Two boys belonging to the artificer company were endowed with ſuch wonderful ſtrength of viſion, that they could ſee the ſhot of the enemy in the air almoſt as ſoon as it came from the mouth of the gun; and were therefore conſtantly placed upon ſome part of the works to give notice to the ſoldiers of the approaching danger. During the time of the hotteſt fire, however, the men were ſo habituated to the fall of ſhells and ſhot around them, that they contracted an inſenſibility of danger, and almoſt required to be cautioned by their officers to avoid the explоſion of a ſhell when lying with the fuſee burning at their feet. In conſequence of this inattention, they frequently neglected the advice of the boys above mentioned, and their neglect could not but be productive of fatal effects. An inſtance of this happened on the Princeſs Amelia's battery, where a ſhot thus diſregarded came through one of the capped embraſures, carried off one of the legs from three ſoldiers, and wounded a fourth in both. In other caſes, in which the perſons themſelves have obſerved the ſhot or ſhells coming towards them, they have been faſcinated by its appearance, and unable to move from the ſpot, as ſmall birds are ſaid to be by the rattle-ſnake. "This ſudden arreſt of the faculties (ſays our author) was nothing uncommon: ſeveral inſtances occurred to my own obſervation, where men, totally free, have had their ſenſes ſo engaged by a ſhell in its deſcent, that though ſenſible of their danger, even ſo far as to cry for aſſiſtance, they have been immoveably fixed to the place. But what is more remarkable, theſe men have ſo inſtantaneouſly recovered themſelves on its fall to the ground, as to remove to a place of ſafety before the ſhell burſt." In this manner Lieutenant Lowe of the 12th regiment was faſcinated by a ſhot which he ſaw coming, but had not power to remove from the place before it fell upon him and took off his leg.

Where theſe ſhells burſt they produced inſtant and certain deſtruction, mangling in the moſt dreadful manner. The following are ſome inſtances. A matroſs had the misfortune of breaking his thigh by ſome accident; and being a man of great ſpirit, could ſcarce bear the confinement neceſſary for its reunion. In conſequence of this he went abroad too ſoon, and thus unfortunately broke the bone a ſecond time. Being now confined to bed, a ſhell happened to fall into the room where he was, and, rebounding, lodged itſelf directly upon him. The convaleſcents and ſick inſtantly ſummoned all their ſtrength, and crawled out of the room, while the poor matroſs lay below the ſhell, kept down by its weight, and utterly unable to ſtir. In a few ſeconds it burſt, and took off both his legs, and ſcorched him in a dreadful manner. He ſurvived the explоſion, was ſenſible to the laſt moment, and died regretting that he had not been killed on the batteries. The caſe of a ſoldier of the 73d regiment ſhows that even in the moſt dangerous caſes we ſhould never deſpair of recovery while life remains. This unfortunate man had been knocked down by the wind of a ſhell, which, inſtantly burſting, killed his companion, and mangled himſelf in a ſhocking manner. His ſkull was dreadfully fractured, his left arm broken in two places, one of his legs ſhattered, the ſkin and muſcles torn off from part of his right hand, the middle finger broken to pieces, and his whole body moſt ſeverely bruiſed and marked with gunpowder. He preſented ſo horrid an object to the ſurgeons, that they had not the leaſt hopes of ſaving his life, and were at a loſs what part to attend to firſt. He was that evening trepanned; a few days afterwards his leg was amputated, and other wounds and fractures were dreſſed. Being poſſeſſed of a moſt excellent conſtitution, nature performed wonders in his favour, and in 11 weeks his cure was completely effected. On the 18th of September a ſhell from the lines fell into a houſe where the town-major captain Burke, with majors

Mercier

braltar. By the beginning of June 1781, the enemy had relaxed conſiderably in their firing, ſeldom exceeding 600 ſhot in a day; and continued gradually to diminiſh this number ſo remarkably, that towards the end of Auguſt they ſeldom fired in the day, and only diſcharged ſix or ſeven, and ſometimes not above three, ſhot in the night. The batteries at land, however, were ſucceeded by the gun-boats; which renewed their attacks every day, keeping the garriſon in continual alarm, and never failing to do more or leſs execution. To reſtrain them, therefore, a battery of guns capable of throwing their ſhot to a great diſtance was erected as near as poſſible to the enemy; and as it reached their very camp, it was determined to open it upon them as often as the gun-boats made their attacks; which being ſoon perceived, they thought it prudent to deſiſt in ſome meaſure from that mode of hoſtility. They continued ſtill, however, to improve their works, and for this purpoſe employed the beſt engineers both of France and Spain; ſo that by the latter part of November 1781, they had them brought to ſuch a ſtate of perfection as filled both kingdoms with the moſt ſanguine expectations of ſucceſs. Governor Elliot, however, far from being diſmayed at theſe formidable bulwarks, ſuffered them to proceed without moleſtation to the end of their ſcheme, that he might as in a moment deſtroy the labour of ſo many months, and thus render the diſappointment the greater. In the night of the 27th of November, a choſen party of 2000 men was detached, in order to deſtroy the enemies works and batteries; and their ſucceſs was equal to their moſt ſanguine expectation. They marched out in great order and ſilence about two o'clock in the morning, under the command of brigadier-general Roſs; after which they proceeded with the ſame circumſpection, but with the utmoſt celerity, to the enemy's works, which they ſtormed and overthrew with aſtoniſhing rapidity. The Spaniards were inſtantly thrown into confuſion, and fled on every ſide; the guns and mortars on the batteries were all ſpiked up; and the artillery-men, artificers, and ſailors, exerted themſelves ſo vigorouſly, that in the ſpace of an hour the magazines were blown up, the ſtore-houſes of arms, ammunition, and military implements of every kind, and all the works that had been conſtructed, were ſet on fire, and totally conſumed; the whole damage done on this occaſion being eſtimated at upwards of two millions ſterling. Gibraltar.

40 e works he ene- brought he ut- ſt per- ion.

41 ey are irely de- yed.

For ſeveral days after this diſaſter the Spaniards continued inactive, without even making any attempt to extinguiſh their batteries, which ſtill continued in flames; but in the beginning of December, as if ſuddenly arouſed from their reverie, upwards of 1000 men were ſet to work in order to prepare a great number of faſcines, from whence it was concluded that they deſigned to repair their works. In this they proceeded with their uſual perſeverence and diligence; but as the former methods of attack had conſtantly failed, it was evident, that if the place could be reduced at all, it muſt be by ſome means hitherto unattempted; and for the reduction of this ſingle fortreſs, the Spaniſh monarch, after the conqueſt of Minorca, determined to employ the whole ſtrength of his empire. Among the various projects formed at this time, that of the chevalier D'Arcon, a French engineer of diſtinction, proved the moſt acceptable to the court of Spain; and though the expence attending it was immenſe, this ſeemed in the preſent circumſtances to be but a matter of ſmall conſideration. His plan was to conſtruct ſuch floating batteries as might neither be liable to be ſunk nor ſet on fire. With this view their bottoms were made of the thickeſt timber, and their ſides of wood and cork long ſoaked in water, with a layer of wet-ſand betwixt them. Their thickneſs was ſuch, that they were impenetrable to cannon-ſhot; and to prevent the effects of red-hot balls, a number of pipes were contrived to carry water through every part of the veſſel, and pumps ſufficient to furniſh

42 Floating batteries invented by the chevalier D'Arcon.

Mercier and Vignoles of the 39th regiment were ſitting. It took off major Burke's thigh; afterwards fell through the floor into the cellar: there it burſt, and forced the flooring with the unfortunate major up to the ceiling. When aſſiſtance came, they found him almoſt buried in the ruins of the room. He was inſtantly conveyed to the hoſpital, where he died ſoon after the wounded part had been amputated. Majors Mercier and Vignoles had time to eſcape before the ſhell burſt; nevertheleſs they were ſlightly wounded by the ſplinters, as were a ſerjeant and his daughter, who happened to be in the cellar when the ſhell entered.

The following are related as inſtances of very extraordinary eſcapes from the deſtructive power of theſe engines, and which indeed it ſeems difficult to account for.—A corporal had the muzzle of his firelock cloſed, and the barrel twiſted like a French horn, by a ſhell, without any injury to his perſon. A ſhell happened to fall into a tent where two ſoldiers were aſleep, without awakening them by its fall. A ſerjeant in an adjacent tent heard it, and ran near 40 yards to a place of ſafety, when he recollected the ſituation of his comrades. Thinking the ſhell had fallen blind, he returned and awakened them; both immediately roſe, but continued by the place, debating on the narrow eſcape they had had, when the ſhell exploded, and forced them with great violence againſt a garden wall, but "miraculouſly" did no further miſchief than deſtroying every thing in the tent. On the new year's day of 1782, an officer of artillery obſerved a ſhell falling towards the place where he ſtood, and got behind a traverſe for protection. This he had ſcarcely done, when the ſhell fell into the traverſe, and inſtantly entangled him in the rubbiſh: one of the guard, named *Martin*, obſerving his diſtreſs, generouſly riſked his own life in defence of his officer, and ran to extricate him: but finding his own efforts ineffectual, called for aſſiſtance; when another of the guard joining him, they relieved the officer from his ſituation; and almoſt the ſame inſtant the ſhell burſt, and levelled the traverſe with the ground. Martin was afterwards promoted, and rewarded by the governor; who at the ſame time told him, that "he ſhould equally have noticed him for attending to his comrade." A ſhell happening to fall into the room where enſign Mackenzie of the 73d regiment was ſitting, carried away part of his chair, and fell into the room below, where it burſt, lifting him and the chair from the floor without further injury.

Gibraltar.

niſh a conſtant ſupply for the purpoſe. The people at the batteries were ſheltered from the bombs by a rope-netting made ſloping, that they might roll off, and ſpread with wet ſkins to prevent fire. Ten of theſe batteries were conſtructed out of the hulls of large veſſels, ſome of 50 or 60 guns, cut down for that purpoſe, and carrying from 10 to 28 guns each, with about half as many in reſerve in caſe of accidents. Each gun was ſerved by 36 artillery-men; and theſe floating batteries were to be ſeconded by 80 large boats carrying guns and mortars of heavy metal; a great number of ſhips of force and frigates, with ſome hundreds of ſmall craft, were to accompany them with troops, for the inſtant execution of what might be judged neceſſary. On this occaſion upwards of 1000 pieces of artillery and 80,000 barrels of gun-powder were provided. A body of 12,000 of the beſt troops of France were now added to the Spaniſh army before the place; the body of engineers was the beſt that both kingdoms could produce; and numbers of volunteers, of the beſt families in both, attended the ſiege. Numbers of military gentlemen alſo came from every part of Europe to be witneſſes of what paſſed at this celebrated ſiege, which was now compared to the moſt famous recorded in hiſtory. The conducting of it was committed to the duke de Crillon, who had diſtinguiſhed himſelf by the conqueſt of Minorca. Two princes of the blood royal of France, the count of Artois brother to the king, and the duke of Bourbon his couſin, came to be witneſſes of this extraordinary enterprize. Theſe behaved with the greateſt politeneſs both to the governor and garriſon. The count of Artois tranſmitted a packet of letters for various individuals in the garriſon, which had been intercepted and carried to Madrid, and which he requeſted that he might be the means of conveying to thoſe for whom they were deſigned. Both he and the duke of Bourbon ſignified to General Elliot the high regard they had for his perſon and character; and the duke de Crillon himſelf took this opportunity of expreſſing the ſame ſentiments, and to intreat him to accept of ſome refreſhments. General Elliot returned a polite anſwer, but accepted of the preſent with reluctance, and requeſted him for the future not to confer any favours of that kind upon him.

Such a prodigious armament raiſed the confidence of the beſiegers ſo high, that they looked upon the conqueſt of the place as an abſolute certainty. They began to be impatient at the delays which aroſe in bringing matters to the utmoſt point of perfection; and the commander in chief was thought by far too modeſt, when he ſaid, that the garriſon might hold out for a fortnight. "It appeared (ſays Captain Drinkwater) that they meant, previous to their final efforts, to ſtrike if poſſible a terror through their opponents, by diſplaying an armament more powerful than had probably ever been brought before any fortreſs. Forty-ſeven ſail of the line, including three inferior two deckers; ten battering ſhips, deemed perfect in deſign, and eſteemed invincible, carrying 212 guns; innumerable frigates, xebeques, bomb ketches, cutters, gun and mortar boats, and ſmaller craft for diſembarking men, were aſſembled in the bay. On the land ſide were moſt ſtupendous and ſtrong batteries and works, mounting 200 pieces of heavy ordnance, and protected by an army of near 40,000 men, commanded by a victorious and active general, and animated by the immediate preſence of two princes of the blood royal of France, with other dignified perſonages, and many of their own nobility. In their certainty of ſucceſs, however, the enemy ſeemed entirely to have overlooked the nature of that force which was oppoſed to them; for though the garriſon ſcarcely conſiſted of more than 7000 effective men, including the marine brigade, they forgot that they were now veterans in this ſervice, had long been habituated to the effects of artillery, and were by degrees prepared for the arduous conflict that awaited them. We were at the ſame time commanded by officers of approved courage, prudence, and activity; eminent for all the accompliſhments of their profeſſion, and in whom we had unbounded confidence. Our ſpirits too were not a little elevated by the ſucceſs attending the firing of red-hot ſhot (c), which in this attack we hoped would enable us to bring our labours to a concluſion, and relieve us from the tedious cruelty of a vexatious blockade."

43 Prodigious armament brought before the fortreſs.

As a prelude to the dreadful ſtorm which was about to be poured forth on this devoted garriſon, the enemy, on the 9th of September 1782, opened a battery of 64 of their largeſt cannon, which was ſhortly accompanied with a terrible fire from other batteries, and a great number of mortars. On this and the following day an attack was made upon the batteries erected on Europa Point (ſo called from being the moſt ſoutherly point of the continent of Europe), which at that time were entirely under the management of captain Curtis of the Brilliant frigate, who had diſtinguiſhed himſelf during the ſiege, and now commanded a brigade of ſeamen by whom the batteries were ſerved. By theſe the fire of the Spaniards was ſo warmly returned, that they not only could make no impreſſion, but were forced to retire, after having received ſo much damage, that two of their principal ſhips were obliged to withdraw to the bay of Algeſiras, oppoſite to Gibraltar, in order to refit. On the 12th the enemy made preparations for the enſuing day, which was allotted for their grand and deciſive attack. Accordingly, on the morning of the 13th, the ten floating batteries came forward, under the command of Don Buenventura de Moreno, a Spaniſh officer of great gallantry, and who had ſignalized himſelf at the taking of Minorca. Before ten o'clock they had all got into their proper ſtations, anchoring in a line about a thouſand yards diſtant from the ſhore. As ſoon as they were properly arranged, they began a heavy cannonade, and were ſeconded by all the cannon and mortars in the enemy's lines and approaches, at the ſame time that the garriſon opened all its batteries both with hot and cold ſhot from the guns, and ſhells from the howitzers and mortars. This terrible fire continued on both ſides without intermiſſion until noon; when that

44 Deciſive attack on 13th of September, 1782.

(c) This was ſuggeſted by lieutenant-governor Boyd, and had been attended with remarkable ſucceſs, September 8th, when the enemy's advanced works were almoſt deſtroyed by it.

Gibraltar. that of the Spaniards began to ſlacken, and the fire of the garriſon to obtain a ſuperiority. About two o'clock the principal battering ſhip commanded by Don Moreno was obſerved to emit ſmoke as if on fire, and ſome men were ſeen buſy upon the roof ſearching from whence it proceeded. The fire from the garriſon was now kept up without the leaſt diſcontinuance or diminution, while that from the floating batteries was perceived ſenſibly to decreaſe; ſo that about ſeven in the evening they fired but few guns, and that only at intervals. At midnight the admiral's ſhip was plainly ſeen to burn, and an hour after was completely in flames. Eight more of theſe batteries took fire ſucceſſively; and on the ſignals of diſtreſs made by them, the multitude of feluccas, launches, and boats, with which they were ſurrounded, all came to their aſſiſtance, and began to take the men out of the burning veſſels. Captain Curtis, who lay ready with the gun-boats to take advantage of any favourable circumſtance, came upon them at two in the morning, and forming a line on the enemy's flank, advanced upon them with ſuch order and expedition as to throw them into immediate confuſion. At this ſudden and unexpected attack they were ſo aſtoniſhed and diſconcerted, that they fled precipitately with all their boats, totally abandoning their floating batteries to be burnt, and all who were in them to periſh in the flames. This would undoubtedly have been their fate, had not captain Curtis extricated them from the fire at the imminent danger of his own life and that of his men. In this work he was ſo eager, that while his boat was along ſide of one of the largeſt batteries, it blew up, and the fragments of the wreck ſpreading all around to a vaſt diſtance, ſome heavy pieces of timber fell into his boat and pierced through its bottom, killing one man and wounding ſeveral others. He eſcaped with difficulty out of this boat, which was ſunk, as well as another, by the ſame accident. The floating batteries were every one conſumed: and the violence with which they exploded was ſuch, that doors and windows at a great diſtance on ſhore were burſt open. About 400 people were ſaved from them; many of whom were picked up floating on rafts and pieces of timber. Indeed the blowing up of the batteries as the flames reached their powder-rooms, and the diſcharge of the guns in ſucceſſion as the metal became heated by the fire, rendered any attempt to ſave them very dangerous.

This terrible cataſtrophe took place in ſight of the combined fleets of France and Spain. It had been propoſed that they ſhould co-operate upon this important occaſion, by attacking the garriſon at Europa Point, and ſuch places as appeared moſt expoſed to an attempt by ſea. This, it was afterwards ſaid, muſt have occaſioned a material diverſion of the garriſon's force, and, by dividing it, have weakened conſiderably the vigorous means of defence uſed in thoſe parts which were actually attacked. The reaſon aſſigned for this inactivity was the want of wind.

Though this terrible repulſe effectually convinced the Spaniards that Gibraltar could not be taken by force, ſome hope ſtill remained, that, without any further exertions on their part, the garriſon would be obliged to ſurrender from want of ammunition and proviſions. With this view they continued to blockade it cloſely, and to cut off all communication, flattering themſelves that Britain would not be able to collect a naval force ſufficient to drive their fleet from the bay before the fortreſs was reduced to extremity; and this, they imagined, muſt be the caſe in a few days. Such diligence, however, had been uſed on the part of the Britiſh, that a fleet was already aſſembled at Portſmouth, conſiſting of 35 ſail of the line, in excellent condition, and filled with the beſt officers and ſailors in Europe. The command was given to Lord Howe, who was accompanied in the expedition by admirals Barrington, Milbank, Hood, Sir Richard Hughes, and commodore Hotham, all of them men eminent in their profeſſion. At the ſame time alſo it fortunately happened, that a large Britiſh fleet of merchantmen had juſt arrived in ſafety from the Baltic; and that a Dutch ſquadron, which had been cruizing on their own coaſts, not being able to penetrate ſouthwards in order to join the French, had retired into port, and given up the intention of effecting any junction for that ſeaſon.

At this time the Britiſh nation was in the utmoſt anxiety about the fate of Gibraltar. The progreſs of the ſhips was delayed by contrary winds, and it was not until they had gained the ſouthern coaſt of Portugal that they received information of the defeat of the enemy's attempt on the 13th of September. On the 11th of October Lord Howe entered the Straits, and ſeveral of the ſtoreſhips deſtined for Gibraltar came ſafe to anchor under the cannon of the fort without any moleſtation from the enemy. The combined fleet in the mean time had been much damaged by a ſtorm; two ſhips of the line were driven aſhore near Algeſiras; two more were driven out of the bay into the Mediterranean; others loſt their maſts, and moſt of them ſuffered conſiderably. One in particular, a ſhip of 70 guns, was carried by the ſtorm acroſs the bay, and ran aground under the works of Gibraltar, where ſhe was taken by the garriſon, with her whole complement of men, conſiſting of 700. Notwithſtanding the endeavours of the enemy to deſtroy her, ſhe was ſafely got off, and properly repaired. The combined fleet, however, put to ſea on the 13th, with a view to prevent the remaining ſtoreſhips that had overſhot the bay to the eaſt from making good their entrance into it; and at the ſame time to rejoin the two ſhips that had been ſeparated from the main body by the ſtorm. Having the advantage of the wind, they bore down upon the Britiſh fleet, which drew up in order of battle to receive them; but notwithſtanding their ſuperiority, they declined coming to an engagement. On the wind becoming more favourable next day, Lord Howe took the opportunity to bring in the ſtoreſhips that were in company; and the day following the remainder were conveyed to Gibraltar. the troops for the reinforcement of the garriſon were landed, with a large ſupply of powder and ample proviſion in every other reſpect. As they returned through the ſtraits they were threatened with an engagement by the combined fleets; but though the latter had a ſuperiority of 12 ſhips of the line, they kept at a wary diſtance. Some firing indeed took place, but it was attended with little effect on either ſide.

48 The garriſon finally relieved.

This laſt relief proved entirely deciſive; for though the blockade continued till news arrived of the preliminaries of peace being ſigned, in the beginning of February 1783, no other attack was made. The news of the

Gibraltar, Gibson.

the pacification were received with the utmoſt joy by the Spaniards. Mutual civilities paſſed between the commanders in chief, and the Duke de Crillon paid many handſome compliments to the governor and garriſon for their noble defence; declaring that he had exerted himſelf to the utmoſt of his abilities, and though he had not proved ſucceſsful, yet he was happy in having his ſovereign's approbation of his conduct.

The poſſeſſion of Gibraltar is eſteemed of very great conſequence to Britain. It not only gives us the command of the Straits, and their navigation; but affords refreſhment and accommodation to our fleets in time of war, and to our merchantment at all times; which, to a maritime power, is of very great advantage. From its ſituation, it divides both the kingdoms of France and Spain; that is, it hinders a ready communication by ſea between the different parts of theſe kingdoms. This, of courſe, hinders the conjunction of the fleets and ſquadrons with each other, or at leaſt renders it ſo difficult as to be a perpetual check upon theſe ambitious powers. It awes alſo the piratical ſtates of Barbary, and in like manner the emperor of Morocco; inſomuch, that our commerce is more ſafe than that of any other European power, which gives us great advantages in point of freight. It is otherwiſe highly favourable to our trade in the Mediterranean and Levant. It procures us the reſpect of the Italian and other powers; who, though far diſtant from Britain, muſt conſider this as an inſtance of her power to hurt or aſſiſt them. It alſo ſaves us the expence of ſquadrons and convoys, upon any diſputes or diſturbances that may happen among thoſe powers, and which would otherwiſe be neceſſary for the protection of our navigation.

GIBSON (Richard), an Engliſh painter, commonly called the *Dwarf*, was originally page to a lady at Mortlake; who, obſerving that his genius led him to painting, had the generoſity to get him inſtructed in the rudiments of that art. He devoted himſelf to Sir Peter Lely's manner, and copied his pictures to admiration, eſpecially his portraits: his paintings in water-colours were alſo eſteemed. He was in great favour with Charles I. who made him his page of the back-ſtairs; and he had the honour to inſtruct in drawing queen Mary and queen Anne when they were princeſſes. He married one Mrs Anne Shepherd, who was alſo a dwarf; on which occaſion king Charles I. honoured their marriage with his preſence, and gave away the bride. Mr Waller wrote a poem on this occaſion, intitled "The marriage of the Dwarfs;" in which are theſe lines:

"Deſign or chance makes others wive,
"But nature did this match contrive;
"Eve might as well have Adam fled,
"As ſhe deny'd her little bed
"To him, for whom heav'n ſeem'd to frame
"And meaſure out this only dame."

Mr Fenton, in his notes on this poem, obſerves that he had ſeen this couple painted by Sir Peter Lely; and that they were of an equal ſtature, each being three feet ten inches high. However, they had nine children, five of whom arrived at maturity; theſe well proportioned, and of the uſual ſtandard of mankind. But what nature denied this couple in ſtature, ſhe gave them in length of days: for Mr Gibſon died in the 75th year of his age; and his wife, having ſurvived him almoſt 20 years, died in 1709, aged 89.

Gibson (Dr Edmund), biſhop of London, was born in Weſtmoreland, in 1669. He applied himſelf early and vigorouſly to learning, and diſplayed his knowledge in ſeveral writings and tranſlations, which recommended him to the patronage of archbiſhop Tenniſon. He was appointed domeſtic chaplain to his Grace; and we ſoon after find him rector of Lambeth, and archdeacon of Surry. Becoming thus a member of the convocation, he engaged in a controverſy, which was carried on with great warmth by the members of both houſes, and defended his patron's rights, as preſident, in eleven pamphlets; he then formed and completed his more comprehenſive ſcheme of the legal duties and rights of the Engliſh clergy, which was at length publiſhed under the title of *Codex Juris Eccleſiaſtici Anglicani*, in folio. Archbiſhop Tenniſon dying in 1715, and Dr Wake biſhop of Lincoln being made archbiſhop of Canterbury, Dr Gibſon ſucceeded the latter in the ſee of Lincoln, and in 1720 was promoted to the biſhoprick of London. He now not only governed his dioceſe with the moſt exact regularity, but by his great care promoted the ſpiritual affairs of the church of England colonies in the Weſt Indies. He was extremely jealous of the leaſt of the privileges belonging to the church; and therefore, though he approved of the toleration of the Proteſtant Diſſenters, he continually guarded againſt all the attempts made to procure a repeal of the corporation and teſt acts; in particular, his oppoſition to thoſe licentious aſſemblies called *maſquerades*, gave great umbrage at court, and effectually excluded him from all further favours. He ſpent the latter part of his life in writing and printing paſtoral letters, viſitation-charges, occaſional ſermons, and tracts againſt the prevailing immoralities of the age. His paſtoral letters are juſtly eſteemed as the moſt maſterly productions againſt infidelity and enthuſiaſm. His moſt celebrated work, the *Codex*, has been already mentioned. His other publications are, 1. An edition of Drummond's *Polemo-Middiana*, and James V. of Scotland's *Cantilena Ruſtica*, with notes. 2. The *Chronicon Saxonicum*, with a Latin tranſlation, and notes. 3. *Reliquiæ Spelmannianæ*, the poſthumous works of Sir Henry Spelman, relating to the laws and antiquities of England. 4. An edition of *Quintilian de Arte Oratoria*, with notes. 5. An Engliſh tranſlation of Camden's *Britannia*, with additions, two volumes folio: and, 6. A number of ſmall pieces, that have been collected together and printed in three volumes folio.—His intenſe application to ſtudy impaired his health; notwithſtanding which, he attained the age of 79. He expired in September 1748, after an epiſcopate of near 33 years.—With regard to biſhop Gibſon's private life and character, he was in every reſpect a perfect economiſt. His abilities were ſo well adapted to diſcharge the duties of his ſacred function, that, during the incapacity of archbiſhop Wake, the tranſaction of eccleſiaſtical affairs was committed to the biſhop of London. He was a true friend to the eſtabliſhed church and government, and as great an enemy to perſecution. He was uſually conſulted by the moſt learned and exalted perſonages in church and ſtate, and the great-

Gideon
Giggle wick

greateſt deference was paid to his judgment. He poſſeſſed the ſocial virtues in an eminent degree; his beneficence was very extenſive; and had ſuch generoſity, that he freely gave two thouſand five hundred pounds, left him by Dr Crow, who was once his chaplain, to Crow's own relations, who were very poor.

GIDEON the ſon of Joaſh, of the tribe of Manaſſeh. He dwelt in the city of Ophrah; and had a very extraordinary call to deliver the Iſraelites from the oppreſſion of the Midianites, to which they had become ſubject after the death of Barak and Deborah. Having effected their deliverance by ſupernatural aid, he was choſen judge of Iſrael in the year of the world 2759, and died in 2768. (See Judges, Chap. vi, vii, & viii.

GIFT, *Donum*, in law, is a conveyance which paſſeth either lands or goods: and is of a larger extent than a grant, being applied to things moveable and immoveable; yet as to things immoveable, when taken ſtrictly, it is applicable only to lands and tenements given in tail; but *gift* and *grant* are too often confounded.

New-Year's Gifts, preſents made on new-year's day, as a token of the giver's good-will, as well as by way of preſage of a happy year.

This practice is very ancient, the origin of it among the Romans being referred to Tatius king of the Sabines, who reigned at Rome conjointly with Romulus, and who having conſidered as a good omen a preſent of ſome ſprigs of vervain gathered in a wood conſecrated to Strenia the goddeſs of ſtrength, which he received on the firſt day of the new year, authoriſed this cuſtom afterwards, and gave to theſe preſents the name of Strenæ. However this may be, the Romans on that day celebrated a feſtival in honour of Janus, and paid their reſpects at the ſame time to Juno; but they did not paſs it in idleneſs, leſt they ſhould become indolent during the reſt of the year. They ſent preſents to one another of figs, dates, honey, &c. to ſhow their friends that they wiſhed them a happy and agreeable life. Clients, that is to ſay thoſe who were under the protection of the great, carried preſents of this kind to their patrons, adding to them a ſmall piece of ſilver. Under Auguſtus, the ſenate, the knights, and the people, preſented ſuch gifts to him, and in his abſence depoſited them in the Capitol. Of the ſucceeding princes ſome adopted this cuſtom, and others aboliſhed it, but it always continued among the people. The early Chriſtians condemned it, becauſe it appeared to be a relique of Paganiſm, and a ſpecies of ſuperſtition; but when it began to have no other object than that of being a mark of veneration and eſteem, the church ceaſed to diſapprove of it.

GIGG, Giga, or Jig, in muſic and dancing, a gay, briſk, ſprightly compoſition, and yet in full meaſure, as well as the allemand, which is more ſerious. Menage takes the word to ariſe from the Italian *giga*, a muſical inſtrument mentioned by Dante. Others ſuppoſe it to be derived from the Teutonic *gieg*, or *ghiighe*, "a fiddle." This is a favourite air in moſt nations of Europe: its characteriſtic is duple time, marked $\frac{6}{4}$, or $\frac{12}{8}$: it conſiſts of two ſtrains, without any determinate number of bars.

GIGGLEWICK, a town in the Weſt Riding of Yorkſhire, half a mile from Settle, ſtands on the river Ribble; where, at the foot of a mountain, is a ſpring, the moſt noted in England for ebbing and flowing ſometimes thrice in an hour, and the water ſubſides three quarters of a yard at the reflux, though the ſea is 30 miles off. At this town is an eminent free grammar ſchool; and in the neighbourhood are dug up flags, ſlate, and ſtone, with a good lime-kiln.

Gilan || Gilbert.

GILAN, or Ghilan, a conſiderable province of Aſia in Perſia, lying on the ſide of the Caſpian ſea, and to the S. W. of it. It is ſuppoſed to be the Hyrcania of the ancients. It is very agreeably ſituated, having the ſea on one ſide and high mountains on the other; and there is no entering in but through narrow paſſes, which may eaſily be defended. The ſides of the mountains are covered with many ſorts of fruit-trees, and in the higheſt parts of them there are deer, bears, wolves, leopards, and tygers; which laſt the Perſians have a method of taming, and hunt with them as we do with dogs. Gilan is one of the moſt fruitful provinces of all Perſia; and produces abundance of ſilk, oil, wine, rice, and tobacco, beſides excellent fruits. The inhabitants are brave, and of a better complexion than the other Indians, and the women are accounted extremely handſome. Reſht is the capital town.

GIHON, (anc. geog.) one of the rivers of Paradiſe; according to Wells, the eaſtern branch of the Euphrates, into which it divides after its conjunction with the Tigris.

GILBERT, or Gilberd, (William), a phyſician, was born at Colcheſter in the year 1540, the eldeſt ſon of the recorder of that borough. Having ſpent ſome time in both univerſities, he went abroad; and at his return ſettled in London, where he practiſed with conſiderable reputation. He became a member of the college of phyſicians, and phyſician in ordinary to Queen Elizabeth, who, we are told, gave him a penſion to encourage him in his ſtudies. From his epitaph it appears that he was alſo phyſician to King James I. He died in the year 1603, aged 63; and was buried in Trinity-church in Colcheſter, where a handſome monument was erected to his memory. His books, globes, inſtruments, and foſſils, he bequeathed to the college of phyſicians, and his picture to the ſchool-gallery at Oxford. He wrote, 1. *De magnete, magneticeſque corporibus, et de magno magnete tellure, phyſiologia nova*; London 1600, folio. 2. *De mundo noſtro ſublunari, philoſophia nova*; Amſterdam 1651, 4to. He was alſo the inventor of two mathematical inſtruments for finding the latitude at ſea without the help of ſuon, moon, or ſtars A deſcription of theſe inſtruments was afterwards publiſhed by Thomas Blondeville in his *Theoriques of the planets*.

Gilbert (Sir Humphrey), a brave officer and ſkilful navigator, was born about the year 1539, in Devonſhire, of an ancient and honourable family. Though a ſecond ſon, he inherited a conſiderable fortune from his father. He was educated at Eaton, and afterwards at Oxford; where probably he did not continue long, as he hath eſcaped the induſtrious Anthony Wood. It ſeems he was intended to finiſh his ſtudies in the Temple; but being introduced at court by his aunt Mrs Catherine Aſhley, then in the queen's ſervice, he was diverted from the ſtudy of the law, and commenced ſoldier. Having diſtinguiſhed him-

Gilbert
Gilboa.

ſelf in ſeveral military expeditions, particularly that to Newhaven in 1563, he was ſent over to Ireland to aſſiſt in ſuppreſſing a rebellion; where, for his ſignal ſervices, he was made commander in chief and governor of Munſter, and knighted by the lord deputy, Sir Henry Sidney, on the firſt day of the year 1570. He returned ſoon after to England, where he married a rich heireſs. Nevertheleſs, in 1572, he ſailed with a ſquadron of nine ſhips to reinforce Colonel Morgan, who at that time meditated the recovery of Fluſhing. Probably on his return to England he reſumed his coſmographical ſtudies, to which he was naturally inclined: for, in the year 1576, he publiſhed his book on the north-weſt paſſage to the Eaſt Indies; and as Martin Frobiſher ſailed the ſame year, probably it was in conſequence of this treatiſe. In 1578, he obtained from the queen a very ample patent, empowering him to diſcover and poſſeſs in North America any lands then unſettled. He ſailed to Newfoundland, but ſoon returned to England without ſucceſs: nevertheleſs, in 1583, he embarked a ſecond time with five ſhips, the largeſt of which put back on account of a contagious diſtemper on board. Our general landed on Newfoundland on the third of Auguſt, and on the fifth took poſſeſſion of the harbour of St John's. By virtue of his patent, he granted leaſes to ſeveral people; but though none of them remained there at that time, they ſettled afterwards in conſequence of theſe leaſes: ſo that Sir Humphrey deſerves to be remembered as the real founder of the vaſt American empire. On the 20th of Auguſt he put to ſea again, on board a ſmall ſloop; which on the 29th foundered in a hard gale of wind. Thus periſhed Sir Humphry Gilbert; a man of quick parts, a brave ſoldier, a good mathematician, a ſkilful navigator, and of a very enterpriſing genius. We learn alſo, that he was remarkable for his eloquence, being much admired for his patriotic ſpeeches both in the Engliſh and Iriſh parliaments. He wrote "A diſcourſe to prove a paſſage by the north-weſt to Cathaia and the Eaſt Indies, printed Lond. 1576." This treatiſe, which is a maſterly performance, is preſerved in Hakluyt's collection of voyages, vol. iii. p. 11. The ſtyle is ſuperior to moſt, if not to all, the writers of that age; and ſhows the author to have been a man of conſiderable reading. He mentions, at the cloſe of this work, another treatiſe on navigation, which he intended to publiſh: it is probably loſt.

GILBERTINES, an order of religious, thus called from St Gilbert of Sempringham, in the county of Lincoln, who founded the ſame about the year 1148: the monks of which obſerved the rule of St Auguſtine; and were accounted canons: and the nuns that of St Benedict.

The founder of this order erected a double monaſtery, or rather two different ones, contiguous to each other, the one for men, the other for women, but parted by a very high wall.

St Gilbert himſelf founded 13 monaſteries of this order, viz. four for men alone, and nine for men and women together, which had in them 700 brethren and 1500 ſiſters. At the diſſolution there were about 25 houſes of this order in England and Wales.

GILBOA, (anc. geog.), mountains of Samaria, ſtretching out from weſt to eaſt, on the confines of the half tribe of Manaſſeh, and of the tribe of Iſſachar; and to the ſouth part of the valley of Jezreel, beginning weſtward at the city of Jezreel, ſituated at the foot of theſe mountains, reaching almoſt quite to the Jordan, lying at the diſtance of ſix miles from Scythopolis. Famous for the death of Saul and his ſon Jonathan, and the defeat of the Iſraelites by the Philiſtines.

Gilchriſt
Gildas.

GILCHRIST (Dr Ebenezer), an eminent Scots phyſician, was born at Dumfries in 1707. He began the ſtudy of medicine at Edinburgh, which he afterwards proſecuted at London and Paris. He obtained the degree of doctor of medicine from the univerſity of Rheims; and in the year 1732 he returned to the place of his nativity, where he afterwards conſtantly reſided, and continued the practice of medicine till his death. It may with juſtice be ſaid, that few phyſicians of the preſent century have exerciſed their profeſſion in a manner more reſpectable or ſucceſsful than Dr Gilchriſt; and few have contributed more to the improvement of the healing art. Having engaged in buſineſs in an early period of life, his attention was wholly devoted to obſervation. Endowed by nature with a judgment acute and ſolid, with a genius active and inventive, he ſoon diſtinguiſhed himſelf by departing, in various important particulars, from eſtabliſhed but unſucceſsful modes of practice. Several of the improvements which he introduced have procured him great and deſerved reputation, both at home and abroad. His practice, in ordinary caſes, was allowed to be judicious, and placed him high in the confidence and eſteem of the inhabitants of that part of the country where he lived. But his uſefulneſs was not confined to his own neighbourhood. On many occaſions he was conſulted by letter from the moſt diſtant parts of the country. In different collections are to be found ſeveral of his performances, which prove that he had ſomething new and uſeful to offer upon every ſubject to which he applied himſelf. But thoſe writings which do him the greateſt honour, are two long diſſertations on Nervous Fevers, in the Medical Eſſays and Obſervations publiſhed by a Society in Edinburgh; and a treatiſe on the uſe of Sea-voyages in medicine, which firſt made its appearance in the year 1757, and was afterwards re-printed in 1771. By means of the former, the attention of phyſicians was firſt turned to a ſpecies of fever which is now found to prevail univerſally in this country; and the liberal uſe of wine, which he was the firſt among the moderns to recommend, has ſince been adopted in theſe fevers by the moſt judicious phyſicians of the preſent age, and has probably contributed not a little to the ſucceſs of their practice. His treatiſe on Sea-voyages points out in a manner ſo clear, and ſo much on the ſure footing of experience, their utility in various diſtempers, particularly in conſumptions, that there is now a proſpect of our being able to employ a remedy in this untractable diſeaſe much more efficacious than any hitherto in uſe. Dr Gilchriſt died in 1774.

GILD, or GUILD. See GUILD.

GILDAS (ſurnamed *the Wiſe*), was born in Wales in the year 511. Where he was educated is uncertain; but it appears from his own writings that he was a monk. Some writers ſay that he went over to Ireland; others, that he viſited France and Italy. They agree however in aſſerting, that after his return to

Eng-

Gilding. England he became a celebrated and moſt aſſiduous preacher of the goſpel. Du Pin ſays he founded a monaſtery at Venetia in Britain. Gildas is the only Britiſh author of the ſixth century whoſe works are printed; they are therefore valuable on account of their antiquity, and as containing the only information we have concerning the times of which he wrote. His Hiſtory of Britain is, however, a very flimſy performance, and his ſtyle obſcure and inelegant.

GILDING, the art of ſpreading or covering a thing over with gold, either in leaf or liquid. The art of gilding was not unknown among the ancients, though it never arrived among them at the perfection to which the moderns have carried it. Pliny aſſures us, that the firſt gilding ſeen at Rome was after the deſtruction of Carthage, under the cenſorſhip of Lucius Mummius, when they began to gild the ceilings of their temples and palaces; the Capitol being the firſt place on which this enrichment was beſtowed. But he adds, that luxury advanced on them ſo haſtily, that in a little time you might ſee all, even private and poor perſons, gild the very walls, vaults, &c. of their houſes.

1 Gilding when firſt introduced at Rome.

We need not doubt but they had the ſame method with us, of beating gold, and reducing it into leaves; though it ſhould ſeem they did not carry it to the ſame height, if it be true which Pliny relates, that they only made 750 leaves of four fingers ſquare out of a whole ounce. Indeed he adds, that they could make more; that the thickeſt were called *bracteæ Præneſtinæ*, by reaſon of a ſtatue of the goddeſs Fortune at Præneſte gilt with ſuch leaves; and that the thinner ſort were called *bracteæ queſtoriæ*.

The modern gilders do alſo make uſe of gold leaves of divers thicknеſſes; but there are ſome ſo fine, that a thouſand do not weigh above four or five drachms. The thickeſt are uſed for gilding on iron and other metals; and the thinneſt on wood. But we have another advantage over the ancients in the manner of uſing or applying the gold: the ſecret of painting in oil, diſcovered of late ages, furniſhes us with means of gilding works that ſhall endure all the injuries of time and weather, which to the ancients was impracticable. They had no way to lay the gold on bodies that would not endure the fire but with whites of eggs or ſize, neither of which will endure the water; ſo that they could only gild ſuch places as were ſheltered from the moiſture of the weather.

2 Ancient Gilding inferior to the modern.

The Greeks called the compoſition on which they applied their gilding on wood *leucophæum* or *leucophorum*; which is deſcribed as a ſort of glutinous compound earth, ſerving in all probability to make the gold ſtick and bear poliſhing. But the particulars of this earth, its colour, ingredients, &c. the antiquaries and naturaliſts are not agreed upon.

The luſtre and beauty of gold have occaſioned ſeveral inquiries and diſcoveries concerning the different methods of applying it to different ſubſtances. Hence the art of gilding is very extenſive, and contains many particular operations and various management.

3 Falſe gilding with laquer or Dutch-leaf.

A colour of gold is given by painting and by varniſhes, without employing gold; but this is a falſe kind of gilding. Thus a very fine golden colour is given to braſs and to ſilver, by applying upon theſe metals a gold-coloured varniſh, which, being tranſparent, ſhows all the brilliancy of the metals beneath. Many ornaments of braſs are varniſhed in this manner, which is called *gold laquering*, to diſtinguiſh them from thoſe which are really gilt. Silver-leaves thus varniſhed are put upon leather, which is then called *gilt leather*. See LAQUER. Gilding.

Amongſt the falſe gilding may alſo be reckoned thoſe which are made with thin leaves of copper or braſs, called *Dutch-leaf*. In this manner are made all the kinds of what is called *gilt paper*.

In the true guilding, gold is applied to the ſurface of bodies. The gold intended for this purpoſe ought in general to be beat into thin leaves, or otherwiſe divided into very fine parts.

4 Gilding with ſize.

As metals cannot adhere well merely by contact to any but to other metallic ſubſtances, when gold is to be applied to the ſurface of ſome unmetallic body, that ſurface muſt be previouſly covered with ſome gluey and tenacious ſubſtance, by which the gold ſhall be made to adhere. Theſe ſubſtances are in general called *ſizes*. Some of theſe are made of vegetable and animal glues, and others of oily, gluey, and drying matters. Upon them the leaves of gold are applied, and preſſed down with a little cotton or a hare's foot; and when the whole is dry, the work is to be finiſhed and poliſhed with a hard inſtrument, called a *dog's tooth*, to give luſtre.

5 With oil.

When the work is required to be capable of reſiſting rain or moiſture, it ought to be previouſly covered with a compoſition of drying oil and yellow ochre ground together; otherwiſe a water-ſize may be uſed, which is prepared by boiling cuttings of parchment or white leather in water, and by mixing with this ſome chalk or whiting: ſeveral layers of this ſize muſt be laid upon the wood, and over theſe a layer of the ſame ſize mixed with yellow ochre. Laſtly, another mixture, called *gold ſize*, is to be applied above theſe; upon which the gold-leaves are to be fixed. This gold ſize, the uſe of which is to make the gold-leaf capable of being burniſhed, is compoſed of tobacco-pipe clay, ground with ſome ruddle or black lead, and tempered with a little tallow or oil of olives. The edges of glaſſes may be guilt by applying firſt a very thin coat of varniſh, upon which the gold-leaf is to be fixed; and when the varniſh is hardened, may be burniſhed. This varniſh is prepared by boiling powdered amber with linſeed oil in a braſs veſſel to which a valve is fitted, and by diluting the above ſolution with four or five times its quantity of oil of turpentine; and that it may dry ſooner, it may be ground with ſome white lead.

6 Of gilding metals.

The method of applying gold upon metals is entirely different. The ſurface of the metal to be gilt is firſt to be cleaned; and then leaves are to be applied to it, which, by means of rubbing with a poliſhed bloodſtone, and a certain degree of heat, are made to adhere perfectly well. In this manner ſilver-leaf is fixed and burniſhed upon braſs in the making of what is called *French plate*, and ſometimes alſo gold-leaf is burniſhed upon copper and upon iron.

Gold is applied to metals in ſeveral other manners. One of theſe is by previouſly forming the gold into a paſte or amalgam with mercury. In order to obtain a ſmall amalgam of gold and mercury, the gold is firſt to be reduced into thin plates or grains, which are heated red-hot, and thrown into mercury previouſly

Gilding

heated, till it begins to ſmoke. Upon ſtirring the mercury with an iron rod, the gold totally diſappears. The proportion of mercury to gold is generally as ſix or eight to one.

With this amalgam the ſurface of the metal to be gilded is to be covered; then a ſufficient heat is to be applied to evaporate the mercury; and the gold is laſtly to be burniſhed with a blood-ſtone.

This method of gilding by amalgamation is chiefly uſed for gilding copper, or an allay of copper, with a ſmall portion of zinc, which more readily receives the amalgam; and is alſo preferable for its colour, which more reſembles that of gold than the colour of copper. When the metal to be gilt is wrought or chaſed, it ought to be previouſly covered with quickſilver before the amalgam is applied, that this may be eaſier ſpread: but when the ſurface of the metal is plain, the amalgam may be applied directly to it. The quickſilver or amalgam is made to adhere to the metal by means of a little aquafortis, which is rubbed on the metallic ſurface at the ſame time, by which this ſurface is cleanſed from any ruſt or tarniſh which might prevent the union or adheſion of the metals. But the uſe of the nitrous acid in this operation is not, as is generally ſuppoſed, confined merely to cleanſe the ſurface of the metal to be gilt from any ruſt or tarniſh it may have acquired; but it alſo greatly facilitates the application of the amalgam to the ſurface of that metal, probably in the following manner: It firſt diſſolves part of the mercury of the amalgam; and when this ſolution is applied to the copper, this latter metal having a ſtronger diſpoſition to unite with the nitrous acid than the mercury has, precipitates the mercury upon its ſurface, in the ſame manner as a poliſhed piece of iron precipitates upon its ſurface copper from a ſolution of blue vitriol. When the metal to be gilt is thus covered over with a thin precipitated coat of mercury, it readily receives the amalgam. In this ſolution and precipitation of mercury, the principal uſe of the nitrous acid in the proceſs of gilding appears to conſiſt. The amalgam being equally ſpread over the ſurface of the metal to be gilt by means of a bruſh, the mercury is then to be evaporated by a heat juſt ſufficient for that purpoſe; for if it be too great, part of the gold may alſo be expelled, and part of it will run together, and leave ſome of the ſurface of the metal bare: while the mercury is evaporating, the piece is to be from time to time taken from the fire, that it may be examined, that the amalgam may be ſpread more equally by means of a bruſh, that any defective parts of it may be again covered, and that the heat may not be too ſuddenly applied to it: when the mercury is evaporated, which is known by the ſurface being entirely become of a dull yellow colour, the metal muſt then undergo other operations, by which the fine gold colour is given to it. Firſt, the gilded piece of metal is rubbed with a ſcratch-bruſh (which is a bruſh compoſed of braſs wire) till its ſurface is made ſmooth; then it is covered over with a compoſition called *gilding wax*, and is again expoſed to the fire till the wax be burnt off. This wax is compoſed of bees-wax, ſometimes mixed with ſome of the following ſubſtances; red ochre, verdegriſe, copper-ſcales, alum, vitriols, borax: but according to Dr Lewis, the ſaline ſubſtances alone are ſufficient, without any wax. By this operation the colour of the gilding is heightened; and this effect ſeems to be produced by a perfect diſſipation of ſome mercury remaining after the former operation. This diſſipation is well effected by this equable application of heat. The gilt ſurface is then covered over with a ſaline compoſition, conſiſting of nitre, alum, or other vitriolic ſalt, ground together, and mixed up into a paſte with water or urine. The piece of metal thus covered is expoſed to a certain degree of heat, and then quenched in water. By this method its colour is further improved, and brought nearer to that of gold. This effect ſeems to be produced by the acid of nitre (which is diſengaged by the vitriolic acid of the alum or other vitriolic ſalt during the expoſure to heat) acting upon any particles of copper which may happen to lie on the gilded ſurface. Laſtly, ſome artiſts think that they give an additional luſtre to their gilt-work by dipping it in a liquor prepared by boiling ſome yellow materials, as ſulphur, orpiment, or turmeric. The only advantage of this operation is, that a part of the yellow matter, as the ſulphur or turmeric, remains in ſome of the hollows of the carved work, in which the gilding is apt to be more imperfect, and to which it gives a rich and ſolid appearance.

7 Uſe of the nitrous acid in gilding.

Iron cannot be gilt by amalgamation, unleſs, as it is ſaid, it be previouſly coated with copper by dipping in a ſolution of blue vitriol. Iron may alſo receive a golden coat from a ſaturated ſolution of gold in aqua-regia, mixed with ſpirit of wine, the iron having a greater affinity with the acid, from which it therefore precipitates the gold. Whether any of theſe two methods be applicable to uſe, is uncertain: but the method commonly employed of fixing gold upon iron is that above mentioned, of burniſhing gold-leaf upon this metal when heated ſo as to become blue; and the operation will be more perfect if the ſurface has been previouſly ſcratched or graved.

Another method is mentioned by authors of gilding upon metals, and alſo upon earthen ware, and upon glaſs; which is, to fuſe gold with regulus of antimony, to pulveriſe the maſs which is ſufficiently brittle to admit that operation, to ſpread this powder upon the piece to be gilt, and expoſe it to ſuch a fire that the regulus may be evaporated, while the gold remains fixed. The inconveniences of this method, according to Dr Lewis, are, that the powder does not adhere to the piece, and cannot be equally ſpread; that part of the gold is diſſipated along with the regulus; that glaſs is fuſible with the heat neceſſary for the evaporation of regulus of antimony; and that copper is liable to be corroded by the regulus, and to have its ſurface rendered uneven.

8 Improvements by Dr Lewis.

On the ſubject of gilding by amalgamation Dr Lewis has the following remarks. "There are two principal inconveniences in this buſineſs: One, that the workmen are expoſed to the fumes of the mercury, and generally, ſooner or later, have their health greatly impaired by them: the other, the loſs of the mercury; for tho' part of it is ſaid to be detained in cavities made in the chimney for that purpoſe, yet the greateſt part of it is loſt. From ſome trials I have made, it appeared that both theſe inconveniences, particularly the firſt and moſt conſiderable one, might in good meaſure be avoided, by means of a furnace of a due conſtruction. If the communication of a furnace with its chimney, inſtead

Phil. Com. of Arts.

Gilding. stead of being over the fire, is made under the grate, the ash-pit door, or other apertures beneath the grate, closed, and the mouth of the furnace left open; the current of air, which otherwise would have entered beneath, enters now at the top, and, passing down thro' the grate to the chimney, carries with it completely both the vapour of the fuel and the fumes of such matters as are placed upon it: the back part of the furnace should be raised a little higher above the fire than the fore part, and an iron plate laid over it, that the air may enter only at the front, where the workman stands, who will be thus effectually secured from the fumes, and from being incommoded by the heat, and at the same time have full liberty of introducing, inspecting and removing the work. If such a furnace is made of strong forged (not milled) iron plate, it will be sufficiently durable: the upper end of the chimney may reach above a foot and a half higher than the level of the fire: over this is to be placed a larger tube, leaving an interval of an inch or more all round between it and the chimney, and reaching to the height of 10 or 12 feet, the higher the better. The external air, passing up between the chimney and the outer pipe, prevents the latter from being much heated, so that the mercurial fumes will condense against its sides into running quicksilver, which, falling down to the bottom, is there catched in a hollow rim, formed by turning inwards a portion of the lower part, and conveyed, by a pipe at one side, into a proper receiver.

9 du ...'s me- ...od of rai ...g gold fi- ...ures.

"Mr Hellot communicates, in the Memoirs of the French Academy for the year 1745, a method of making raised figures of gold on works of gold or silver, found among the papers of M. du Fay, and of which M. du Fay himself had seen several trials. Fine gold in powder, such as results from the parting of gold and silver by aquafortis, is directed to be laid in a heap on a levigating stone, a cavity made in the middle of the heap, and half its weight of pure mercury put into the cavity; some of the fetid spirit obtained from garlic root by distillation in a retort, is then to be added, and the whole immediately mingled and ground with a muller till the mixture is reduced into an uniform grey powder. The powder is to be ground with lemon juice to the consistence of paint, and applied on the piece previously well cleaned and rubbed over with the same acid juice: the figures drawn with it may be raised to any degree by repeating the application. The piece is exposed to a gentle fire till the mercury is evaporated so as to leave the gold yellow, which is then to be pressed down, and rubbed with the finger and a little sand, which makes it appear solid and brilliant: after this it may be cut and embellished. The author observes, that being of a spongy texture, it is more advisable to cut it with a chissel than to raise it with a graver; that it has an imperfection of being always pale; and that it would be a desirable thing to find means of giving it colour, as by this method ornaments might be made of exquisite beauty and with great facility. As the paleness appears to proceed from a part of the mercury retained by the gold, I apprehend it might be remedied by the prudent application of a little warm aquafortis, which, dissolving the mercury from the exterior part, would give at least a superficial high colour: if the piece is silver, it must be defended from the aquafortis by covering it with wax. Instruments or ornaments of gold, stained by mercury, where the gold is connected with substances incapable of bearing fire, may be restored to their colour by the same means. Gilding.

10 Another method.

"The foregoing process is given entirely on the authority of the French writer. I have had no experience of it myself, but have seen very elegant figures of gold raised upon silver, on the same principle, by a different procedure. Some cinnabar was ground, not with the distilled spirit, but with the expressed juice of garlick, a fluid remarkably tenacious. This mixture was spread all over the polished silver; and when the first layer was dry, a second, and after this a third, was applied. Over these were spread as many layers of another mixture, composed chiefly of asphaltum and linseed oil boiled down to a due consistence. The whole being dried with a gentle heat on a kind of wire-grate, the figures were traced and cut down to the silver so as to make its surface rough: the incisions were filled with an amalgam of gold, raised to different heights in different parts according to the nature of the design; after which a gentle fire, at the same time that it evaporated the mercury, destroyed the tenacity of the gummy juice, so that the coating, which served to confine the amalgam, and as a guide in the application of it, was now easily got off. The gold was then pressed down and embellished as in the former method; and had this advantage, that the surface of the silver under it having been made rough, it adhered more firmly, so as not to be in danger of coming off, as M. du Fay says the gold applied in his way sometimes did. The artist, however, found the process so troublesome, that though he purchased the receipt for a considerable sum, he has laid the practice aside."

Finally, some metals, particularly silver, may be gilt in the following manner:

11 Easy method of gilding silver.

Let gold be dissolved in aqua-regia. In this solution pieces of linen are to be dipt, and burnt to black ashes. These ashes being rubbed on the surface of the silver by means of a wet linen rag, apply the particles of gold which they contain, and which by this method adhere very well. The remaining part of the ashes is to be washed off; and the surface of the silver, which in this state does not seem to be gilt, is to be burnished with a blood-stone, till it acquire a fine colour of gold. This method of gilding is very easy, and consumes a very small quantity of gold. Most gilt ornaments upon fans, snuff-boxes, and other toys of much show and little value, are nothing but silver gilt in this manner.

Gold may also be applied to glass, porcelain, and other vitrified matters. As the surface of these matters is very smooth, and consequently is capable of a very perfect contact with gold leaves, these leaves adhere to them with some force, although they are not of metallic nature. This gilding is so much more perfect, as the gold is more exactly applied to the surface of the glass. The pieces are then to be exposed to a certain degree of heat, and burnished slightly to give them lustre.

12 Method of gilding glass.

A more substantial gilding is fixed upon glass, enamel, and porcelain, by applying to these substances powder of gold mixed with a solution of gum arabic, or with some essential oil, and a small quantity of borax; after which a sufficient heat is to be applied to soften the glass and the gold, which is then to be burnished. With this mixture any figures may be drawn.

The

Gilead || Gill.

The powders for this purpose may be made, 1. By grinding gold-leaf with honey, which is afterwards to be washed away with water. 2. By distilling to dryness a solution of gold in aqua-regia. 3. By evaporating the mercury from an amalgam of gold, taking care to stir well the mass near the end of the process. 4. By precipitating gold from its solution in aqua-regia by applying to it a solution of green vitriol in water, or some copper, and perhaps some other metallic substances.

GILEAD, the son of Machir, and grandson of Manasseh, had his inheritance allotted him in the mountains of Gilead, from whence he took his name. The mountains of Gilead were part of that ridge which runs from mount Lebanon southward, on the east of the Holy Land; gave their name to the whole country which lies on the east of the sea of Galilee, and included the mountainous region called in the New Testament *Trachonitis*. Jeremiah (xxii. 6.) seems to say, that Gilead begins from mount Libanus. 'Thou art Gilead unto me, and the head of Lebanon.' Jacob, at his return from Mesopotamia, came in six days to the mountains of Gilead (Gen. xxxi. 21, &c.) where this patriarch, with Laban his father-in-law, raised a heap of stones, in memory of their agreement and covenant, and called it *Galeed*, i. e. "an heap of witnesses," and which Laban called *Jegar-sahadutha*. These mountains were covered with a sort of trees abounding with gum, called the *balm of Gilead*, which the scripture commends much. (Jer. viii. 21. xlvi. 11. li. 8.) The merchants who bought Joseph came from Gilead, and were carrying balm into Egypt. (Gen. xxxvii. 25.)

The Gileadites being invaded by the Ammonites, &c. chose Jephthah for their general, who vanquished all their enemies.

Balm of GILEAD. See AMYRIS.

GILGAL (anc. geog.), a place between Jericho and Jordan, noted for the first encampment of the Israelites on this side Jordan, about a mile from Jericho. It sometimes also denotes Galilee, (Joshua xii. 23.)

GILL (John), D. D. a Protestant dissenting minister of the Baptist denomination, and the son of Edward and Elizabeth Gill, was born at Kettering in Northamptonshire, November 23. 1697. At a very early period of life, his father, who was a deacon of the Baptist church at Kettering, discovered in him an uncommon capacity for learning; and his ability for literary pursuits was afterwards evidenced by such rapid progress in whatever became the object of tuition, that it was found necessary to remove him from the school in which his striking talents were first manifested, and to place him in one more favourable to his improvement. He was therefore sent to a grammar school in the neighbourhood; where he very soon surpassed those boys who were much his seniors in age and as pupils. At this school he continued till he arrived at his 11th year; where, besides going through the common school-books, he read most of the Latin classics, and made very considerable proficiency in the Greek language.

Mr Gill's celebrity as a scholar, and his strong attachment to books, were soon observed by the neighbouring clergy, who frequently met and conversed with him at a bookseller's shop, to which he at every opportunity resorted for the purpose of reading; and indeed such was his application to books, that it became a proverbial saying among the common people, "Such a thing is as certain, as that John Gill is in the bookseller's shop." Gill.

He left the grammar school, however, early in life. This was occasioned by the imperious conduct of his master, who insisted that the children of dissenting parents should, with other scholars that belonged to the establishment, attend him to church on week days during the performance of divine service. The dissenters considered this requisition as a stretch of power to which his engagements with them gave no claim; and as it was virtually making conformity a test by which his pupils were to expect the benefits of tuition, they resented his conduct; and the children of those parents that were in affluent circumstances were removed to seminaries where the same advantages might be obtained without being subject to the impositions of clerical bigotry. But as the parents of Mr Gill had it not in their power to confer on him the same privilege, the same steps could not be taken to facilitate his advancement in learning. To pave the way, however, for the completion of his studies, efforts were made by several ministers, of different denominations, to get him upon one or other of the funds in London. For this purpose, specimens of his progress in the different branches of literature were transmitted to the metropolis: in answer to which it was objected, "that he was too young, and that should he continue, as it might be expected he would, to make such rapid advances in his studies, he would go through the common circle before he could be capable of taking care of himself, or of being employed in any public service." But these formidable objections were of no weight with our young scholar: his love of learning was unconquerable. Insuperable difficulties, it is true, obstructed the way in which literary eminence is usually acquired; but these difficulties could neither repress his ardent desire of knowledge, nor damp the zeal and application that had marked his former studies. For though his time was daily devoted to the business of his father; yet he had so far improved the hours of leisure, as to be able, before he arrived at his 19th year, to read all the Greek and Latin authors that fell in his way. He studied logic, rhetoric, moral and natural philosophy; and learnt the Hebrew language, so as to read it with ease, without any other assistance than Buxtorf's grammar and lexicon.

Neither the pursuit of learning, however, nor the other necessary avocations incumbent on Mr Gill, could eradicate those religious impressions received in early life. On November 1. 1716, he made a public profession of his faith before the Baptist church at Kettering, and was baptized the same day by Mr Thomas Wallis. Of this church Mr Gill had not been long a member before he was called to the work of the ministry: soon after which, he removed to Higham-Ferrers, with a view to pursue his studies under the direction of Mr Davis; but his stay at this place was soon interrupted by an invitation from London in 1719, to preach to the Baptist church in Horsleydown, over which he was the same year, being the 22d of his age, ordained pastor; which office he sustained upwards of 51 years.

Mr Gill had not been long in London before rabbinical

Gill. binical learning, of which he had before conſiderable knowledge, became an object of purſuit. To facilitate his progreſs through the intricacies of this labyrinth, he contracted an acquaintance with one of the moſt learned Jewiſh rabbies. He read the Targums, the Talmuds, the Rabbot; their ancient commentaries, the book Zohar, and whatever elſe of this kind he was able to procure. Of the Oriental languages he made himſelf a complete maſter: in ſhort, there was no branch of knowledge that could either enlarge or enrich biblical learning, which, however difficult, was not attempted and attained: and it may be truly aſſerted, that in this line he had but few equals, and that the annals of literature do not exhibit a character by whom he was excelled.

In 1748 Mr Gill publiſhed a commentary on the New Teſtament in three vols folio. The immenſe reading and learning diſcoverable in this arduous work, attracted the attention of the Mariſchal College and Univerſity of Aberdeen; and procured for him, without either his ſolicitation or his knowledge, a diploma, creating him Doctor in divinity. This intelligence was communicated to the Doctor in the moſt handſome terms by the profeſſors Oſborn and Pollock; who declared, "that on account of his knowledge of the ſcriptures, of the Oriental languages, and of Jewiſh antiquities, of his learned defence of the ſcriptures againſt Deiſts and Infidels, and the reputation gained by his other works; the univerſity had, without his privity, unanimouſly agreed to confer on him the degree of Doctor in divinity."

Dr Gill's ſentiments, as a divine, were throughout Calviniſtic: "And perhaps no man (ſays the Reverend Mr Toplady, a miniſter in the church of England) ſince the days of Auſtin, has written ſo largely in defence of the ſyſtem of grace; and certainly no man has treated that momentous ſubject in all its branches, more cloſely, judiciouſly, and ſucceſsfully. What was ſaid of Edward the black prince, that he never fought a battle which he did not win; what has been remarked of the great Duke of Marlborough, that he never undertook a ſiege which he did not carry; may be juſtly accommodated to our great philoſopher and divine; who, ſo far as the diſtinguiſhing doctrines of the goſpel are concerned, never beſieged an error which he did not force from its ſtrongholds, nor ever encountered an adverſary whom he did not baffle and ſubdue. His learning and labours, if exceedable, were exceeded only by the invariable ſanctity of his life and converſation. From his childhood to his entrance on the miniſtry, and from his entrance on the miniſtry to the moment of his diſſolution, not one of his moſt inveterate oppoſers was ever able to charge him with the leaſt ſhadow of immorality. Himſelf, no leſs than his writings, demonſtrated that the doctrine of grace does not lead to licentiouſneſs. Thoſe who had the honour and happineſs of being admitted into the number of his friends, can go ſtill farther in their teſtimony. They know that his moral demeanor was more than blameleſs: it was from firſt to laſt conſiſtently exemplary. And indeed an undeviating conſiſtency, both in his views of evangelical truths, and in his obedience as a ſervant of God, was one of thoſe qualities by which his caſt of character was eminently marked. He was in every reſpect a burning and a ſhining light: Burning with love to God, to truth, and to ſouls; ſhining as an example to believers, in word, in faith, in purity, a pattern of good works, and a model of all holy converſation and godlineſs; and while true religion and ſound learning have a ſingle friend remaining in the Britiſh empire, the works and name of Gill will be precious and revered."

Gill || Gillingham.

He died at Camberwell, October 14. 1771, aged 73 years 10 months and 10 days. In 1718 the Doctor married Mrs Elizabeth Negus; by whom he had many children, two of whom only ſurvived him. Mrs Gill died in 1764.

His works are, A Commentary on the Old and New Teſtament, in 9 vols folio. A Body of Divinity in 3 vols quarto. The Cauſe of God and Truth, 4 vols octavo. A Treatiſe concerning the Prophecies of the Old Teſtament reſpecting the Meſſiah. A Diſſertation on the antiquity of the Hebrew Language, Letters, Vowel-Points, and Accents. Sermons on the Canticles, folio; beſides a great number of ſermons and controverſial pieces on different ſubjects.

Gill, a meaſure of capacity, containing a quarter of an Engliſh pint.

GILLS, or Branchiæ of fiſhes. See *Comparative Anatomy*, n° 160.

GILLINGHAM, a pariſh in the county of Dorſetſhire, on the river Stour, near the foreſt of its own name; where, *anno* 1016, king Edmund Ironſide vanquiſhed the Danes. It is one of the largeſt pariſhes in the county, being 41 miles in circuit, containing 64,000 acres. It lies on the borders of Wilts and Somerſet, 4 miles N. W. of Shaftſbury. It has a manufacture of linen, but the chief produce is grazing and the dairies. Near it are the traces of an ancient reſidence of Norman or Saxon kings, 320 feet long and 240 broad, ſurrounded by a rampart of earth. Henry I. reſided here, and king John repaired it at the expence of the county. Edward I. ſpent his Chriſtmas here in 1270; but the whole of the materials are removed, and the foundation of the houſe only can be traced, which was in the form of the letter L, in length 180 feet by 80 broad, and the foot of the letter 48 by 40. The area of the houſe containing 168,000 ſquare feet. It ſtood half a mile from the church, on the road to Shaftſon, encompaſſed by a moat, now dry, in ſome places 9 feet deep and 20 broad. The rampart appears to have been 30 feet thick. Here is a free ſchool, a large old building, and a workhouſe, as well as two ſtone bridges. In 1694 it received damage of near 4000l. by a fire. Near it is Gillingham foreſt, four miles long and one mile broad. The church is a large ancient fabrick.

Gillingham, a pariſh of Kent, three miles below Chatham, and on the ſame ſide of the Medway. Part of Chatham-dock is in this pariſh; and here is a caſtle well furniſhed with guns that commands the river, there being no leſs than 170 embrazures for cannon; which would ſtop the progreſs of any enemy that ſhould happen to make way by Sheerneſs-fort, before they could reach Chatham. Here are alſo copperas works. At this place 600 Norman gentlemen, who came over in the retinue of the two princes Alfred and Edward, were all barbarouſly murdered by earl Godwin. It was in remote times the property of the archbiſhop of Canterbury,

Gilolo, Gilpin

Canterbury, who had here an elegant palace, the old hall of which is now converted to a barn: it is built principally of flint, but the windows are filled up with brick. Near it are the remains of the chapel, &c. and a great part of the whole of its original outer walls may be traced.

GILOLO, a large island of the Pacific Ocean, lying between 1° S. Lat. and 2° N. Lat. and between 125° and 128° E. Long. It belongs to the Dutch; but does not produce any of the fine spices, tho' it lies in the neighbourhood of the spice-islands. The natives are fierce and cruel savages.

GILPIN (Bernard), rector of Houghton, distinguished by his extraordinary piety and hospitality, was descended from an ancient and honourable family in Westmoreland, and born in 1517. As he was bred in the Catholic religion, so he for some time defended it against the reformers, and at Oxford held a disputation with Hooper afterward bishop of Worcester and martyr for the Protestant faith; but was staggered in another disputation with Peter Martyr, and began seriously to examine the contested points by the best authorities. Thus, being presented to the vicarage of Norton in the diocese of Durham, he soon resigned it, and went abroad to consult eminent professors on both sides; and after three years absence returned a little before the death of queen Mary, satisfied in the general doctrines of the reformation. He was kindly received by his uncle Dr Tonstall, bishop of Durham; who soon after gave him the archdeaconry of Durham, to which the rectory of Essington was annexed. When repairing to his parish, though the persecution was then at its height, he boldly preached against the vices, errors, and corruptions of the times, especially in the clergy, on which a charge consisting of 13 articles was drawn up against him, and presented in form to the bishop. But Dr Tonstall found a method of dismissing the cause in such a manner as to protect his nephew, without endangering himself, and soon after presented him to the rich living of Houghton le Spring. He was a second time accused to the bishop, and again protected; when his enemies, enraged at this second defeat, laid their complaint before Dr Bonner, bishop of London; who immediately gave orders to apprehend him. Upon which Mr Gilpin bravely prepared for martyrdom; and ordering his house-steward to provide him a long garment that he might make a decent appearance at the stake, set out for London. Luckily, however, he broke his leg on the journey; which protracted his arrival until the news of the queen's death freed him from all further apprehensions. Being immediately set at liberty, he returned to Houghton, where he was received by his parishioners with the sincerest joy.

Upon the deprivation of the Popish bishops, he was offered the see of Carlisle, which he declined; and confining his attention to his rectory, discharged all the duties of his function in the most exemplary manner. To the greatest humanity and courtesy, he added an unwearied application to the instruction of those under his care. He was not satisfied with the advice he gave in public, but used to instruct in private; and brought his parishioners to come to him with their doubts and difficulties. He had a most engaging manner towards those whom he thought well-disposed: nay, his very reproof was so conducted, that it seldom gave offence; the becoming gentleness with which it was urged, made it always appear the effect of friendship. Thus, with unceasing assiduity, did he employ himself in admonishing the vicious, and encouraging the well-intentioned; by which means, in a few years, he made a greater change in his neighbourhood than could well have been imagined. A remarkable instance, what reformation a single man may effect, when he hath it earnestly at heart!

Gilpin

But his hopes were not so much in the present generation, as in the succeeding. It was an easier task, he found, to prevent vice, than to correct it; to form the young to virtue, than to amend the bad habits of the old. He employed much of his time, therefore, in endeavouring to improve the minds of the younger part of his parish; suffering none to grow up in an ignorance of their duty; but pressing it as the wisest part to mix religion with their labour, and amidst the cares of this life to have a constant eye upon the next. He attended to every thing which might be of service to his parishioners. He was very assiduous in preventing all law-suits among them. His hall is said to have been often thronged with people, who came to him about their differences. He was not indeed much acquainted with law; but he could decide equitably, and that satisfied: nor could his sovereign's commission have given him more weight than his own character gave him.

His hospitable manner of living was the admiration of the whole country. He spent in his family every fortnight 40 bushels of corn, 20 bushels of malt, and a whole ox; besides a proportionable quantity of other kinds of provision. Strangers and travellers found a cheerful reception. All were welcome that came; and even their beasts had so much care taken of them, that it was humorously said, "If a horse was turned loose in any part of the country, it would immediately make its way to the rector of Houghton's."

Every Sunday, from Michaelmas till Easter, was a sort of public day with him. During this season he expected to see all his parishioners and their families. For their reception, he had three tables well covered: the first was for gentlemen, the second for husbandmen and farmers, and the third for day-labourers. This piece of hospitality he never omitted, even when losses, or a scarcity of provision, made its continuance rather difficult to him. He thought it his duty, and that was a deciding motive. Even when he was absent from home, no alteration was made in his family-expences; the poor were fed as usual, and his neighbours entertained.

But notwithstanding all this painful industry, and the large scope it had in so extended a parish, Mr Gilpin thought the sphere of his benevolence yet too confined. It grieved him extremely to see every where, in the parishes around him, so great a degree of ignorance and superstition, occasioned by the shameful neglect of the pastoral care in the clergy of those parts. These bad consequences induced him to supply, as far as he could, what was wanting in others. For this purpose, every year he used regularly to visit the most neglected parishes in Northumberland, Yorkshire, Cheshire, Westmoreland, and Cumberland; and that his own parish in the mean time might not suffer, he

Gilpin.

he was at the expence of a conſtant aſſiſtant. In each place he ſtaid two or three days; and his method was, to call the people about him, and lay before them, in as plain a way as poſſible, the danger of leading wicked or even careleſs lives; explaining to them the nature of true religion; inſtructing them in the duties they owed to God, their neighbour, and themſelves: and ſhowing them how greatly a moral and religious conduct would contribute to their preſent as well as future happineſs.

As Mr Gilpin had all the warmth of an enthuſiaſt, though under the direction of a very calm and ſober judgment, he never wanted an audience, even in the wildeſt parts; where he rouſed many to a ſenſe of religion, who had contracted the moſt inveterate habits of inattention to every thing of a ſerious nature. And wherever he came, he uſed to viſit all the gaols and places of confinement; few in the kingdom having at that time any appointed miniſter. And by his labours, and affectionate manner of behaving, he is ſaid to have reformed many very abandoned perſons in thoſe places. He would employ his intereſt likewiſe for ſuch criminals whoſe caſes he thought attended with any hard circumſtances, and often procured pardons for them.

There is a tract of country upon the border of Northumberland, called *Readſ-dale* and *Tine-dale*, of all barbarous places in the north, at that time the moſt barbarous. Before the Union, this place was called the *debateable land*, as ſubject by turns to England and Scotland, and the common theatre where the two nations were continually acting their bloody ſcenes. It was inhabited by a kind of deſperate banditti, rendered fierce and active by conſtant alarms: they lived by theft, uſed to plunder on both ſides of the barrier; and what they plundered on one, they expoſed to ſale on the other; by that means eſcaping juſtice. And in this dreadful country, where no man would even travel that could help it, Mr Gilpin never failed to ſpend ſome part of every year.

He generally choſe the Chriſtian holidays for his journey, becauſe he found the people at that ſeaſon moſt diſengaged, and moſt eaſily aſſembled. He had ſet places for preaching, which were as regularly attended as the aſſize-towns of a circuit. If he came where there was a church, he made uſe of it: if not, of barns, or any other large building; where great crowds of people were ſure to attend him, ſome for his inſtructions, and others for his charity.—This was a very difficult and laborious employment. The country was ſo poor, that what proviſion he could get, extreme hunger only could make palatable. The inclemency of the weather, and the badneſs of the roads through a mountainous country, and at that ſeaſon covered with ſnow, expoſed him likewiſe often to great hardſhips. Sometimes he was overtaken by the night, the country being in many places deſolate for ſeveral miles together, and obliged to lodge out in the cold. At ſuch times, we are told, he would make his ſervant ride about with his horſes, whilſt himſelf on foot uſed as much exerciſe as his age and the fatigues of the preceding day would permit. All this he cheerfully underwent; eſteeming ſuch ſervices well compenſated by the advantages which he hoped might accrue from them to his uninſtructed fellow-creatures.

The diſintereſted pains he took among theſe barbarous people, and the good offices he was always ready to do them, drew from them the warmeſt and ſincereſt expreſſions of gratitude. Indeed, he was little leſs than adored among them, and might have brought the whole country almoſt to what he pleaſed. One inſtance that is related, ſhows how greatly he was revered. By the careleſſneſs of his ſervants, his horſes were one day ſtolen. The news was quickly propagated, and every one expreſſed the higheſt indignation at the fact. The thief was rejoicing over his prize, when, by the report of the country, he found whoſe horſes he had taken. Terrified at what he had done, he inſtantly came trembling back, confeſſed the fact, returned the horſes, and declared he believed the devil would have ſeized him directly, had he carried them off knowing them to have been Mr Gilpin's.

Gilpin.

We have already taken notice of Mr Gilpin's uncommonly generous and hoſpitable manner of living. The value of his rectory was about 400 l. a-year: an income, indeed, at that time very conſiderable, but yet in appearance very unproportionate to the generous things he did: indeed, he could not have done them, unleſs his frugality had been equal to his generoſity. His friends, therefore, could not but wonder to find him, amidſt his many great and continual expences, entertain the deſign of building and endowing a grammar-ſchool: a deſign, however, which his exact economy ſoon enabled him to accompliſh, though the expence of it amounted to upwards of 500 l. His ſchool was no ſooner opened, than it began to flouriſh; and there was ſo great a reſort of young people to it, that in a little time the town was not able to accommodate them. He put himſelf, therefore, to the inconvenience of fitting up a part of his own houſe for that purpoſe, where he ſeldom had fewer than 20 or 30 children. Some of theſe were the ſons of perſons of diſtinction, whom he boarded at eaſy rates: but the greater part were poor children, whom he not only educated, but clothed and maintained: he was at the expence likewiſe of boarding in the town many other poor children. He uſed to bring ſeveral every year from the different parts where he preached, particularly Readſ-dale and Tine-dale; which places he was at great pains in civilizing, and contributed not a little towards rooting out that barbariſm which every year prevailed leſs among them.

As to his ſchool, he not only placed able maſters in it, whom he procured from Oxford, but himſelf likewiſe conſtantly inſpected it. And, that encouragement might quicken the application of his boys, he always took particular notice of the moſt forward: he would call them *his own ſcholars*, and would ſend for them often into his ſtudy, and there inſtruct them himſelf. One method uſed by him to fill his ſchool was a little ſingular. Whenever he met a poor boy upon the road, he would make trial of his capacity by a few queſtions; and if he found it ſuch as pleaſed him, he would provide for his education. And beſides thoſe whom he ſent from his own ſchool to the univerſities, and there wholly maintained, he would likewiſe give to others, who were in circumſtances to do ſomething for themſelves, what farther aſſiſtance they needed. By which means he induced many parents to allow their children a liberal education, who otherwiſe would not have done

Gilpin. it. And Mr Gilpin did not think it enough to afford the means only of an academical education to these young people, but endeavoured to make it as beneficial to them as he could. He still considered himself as their proper guardian; and seemed to think himself bound to the public for their being made useful members of it, as far as it lay in his power to make them so. With this view he held a punctual correspondence with their tutors; and made the youths themselves frequently write to him, and give him an account of their studies. So solicitous indeed was he about them, knowing the many temptations to which their age and situation exposed them, that once every other year he generally made a journey to the universities to inspect their behaviour. And this uncommon care was not unrewarded; for many of his scholars became ornaments to the church, and exemplary instances of piety.

To the account that hath been already given of Mr Gilpin's hospitality and benevolence, the following particulars may be added. Every Thursday throughout the year, a very large quantity of meat was dressed wholly for the poor; and every day they had what quantity of broth they wanted. Twenty-four of the poorest were his constant pensioners. Four times in the year a dinner was provided for them; when they received from his steward a certain quantity of corn, and a sum of money: and at Christmas they had always an ox divided among them.

Whenever he heard of any in distress, whether of his own parish or any other, he was sure to relieve them. In his walks abroad, he would frequently bring home with him poor people, and send them away clothed as well as fed. He took great pains to inform himself of the circumstances of his neighbours, that the modesty of the sufferer might not prevent his relief. But the money best laid out was, in his opinion, that which encouraged industry. It was one of his greatest pleasures to make up the losses of his laborious neighbours, and prevent their sinking under them. If a poor man had lost a beast, he would send him another in his room: or if any farmer had had a bad year, he would make him an abatement in his tythes.—Thus, as far as he was able, he took the misfortunes of his parish upon himself; and, like a true shepherd, exposed himself for his flock. But of all kinds of industrious poor, he was most forward to assist those who had large families: such never failed to meet with his bounty, when they wanted to settle their children in the world.

In the distant parishes where he preached, as well as in his own neighbourhood, his generosity and benevolence were continually showing themselves; particularly in the desolate parts of Northumberland. "When he began his journey," says an old manuscript life of him; "he would have 10 pounds in his purse; and, at his coming home, he would be 20 nobles in debt, which he would always pay within a fortnight after."—In the gaols he visited, he was not only careful to give the prisoners proper instructions, but used to purchase for them likewise what necessaries they wanted.

Even upon the public road, he never let slip an opportunity of doing good. He has often been known to take off his cloak, and give it to an half-naked traveller: and when he has had scarce money enough in his pocket to provide himself a dinner, yet would he give away part of that little, or the whole, if he found any who seemed to stand in need of it.—Of this benevolent temper, the following instance is preserved. One day returning home, he saw in a field several people crowding together; and judging something more than ordinary had happened, he rode up, and found that one of the horses in a team had suddenly dropped down, which they were endeavouring to raise; but in vain, for the horse was dead. The owner of it seemed much dejected with his misfortune; and declaring how grievous a loss it would be to him, Mr Gilpin bade him not be disheartened: "I'll let you have (says he), honest man, that horse of mine," and pointed to his servant's.—"Ah! master (replied the countryman), my pocket will not reach such a beast as that." "Come, come (said Mr Gilpin), take him, take him; and when I demand my money, then thou shalt pay me." Gilthead ‖ Gingiro.

This worthy and excellent divine, who merited and obtained the glorious titles of *the Father of the Poor*, and *the Apostle of the North*, died in 1583, in the 66th year of his age.

GILTHEAD, in ichthyology. See SPARUS.

GIN. See GENEVA.

GIN, in mechanics, a machine for driving piles, fitted with a windlass and winches at each end, where eight or nine men heave, and round which a rope is reeved that goes over the wheel at the top: one end of this rope is seized to an iron-monkey, that hooks to a beetle of different weights, according to the piles they are to drive, being from eight to thirteen hundred weight; and when hove up to a cross-piece, near the wheel, it unhooks the monkey, and lets the beetle fall on the upper end of the pile, and forces the same into the ground: then the monkey's own weight overhauls the windlass, in order for its being hooked again to the beetle.

GINGER, the root of a species of amomum. See AMOMUM.

GINGIDIUM, in botany: A genus of the digynia order, belonging to the pentandria class of plants. The calyx is an involucrum, with about six linear leaves; the corolla consists of five oval-lanceolated petals; the stamina are five filaments; the antheræ roundish; the pericarpium an ovato-truncated fruit, with eight striæ; there are two striated seeds, in some places plane, and in others convex.

GINGIRO, or ZINDERO, a small territory of Africa to the south of Abyssinia; being separated from it by the river Zebee, by which it is also almost entirely surrounded. This river is extremely large, having more water than the Nile, and being much more rapid; so that, during the rainy season, it would be altogether impassable, were it not for the large rocks which are in its channel. The extreme difficulty which occurs in passing this river, however, is the means of preserving the kingdom of Gingiro, which would otherwise be conquered in a single season by the Galla.

The most remarkable particular with regard to this kingdom is, that the sovereign is a professed votary of the devil. "This superstition (says Mr Bruce) reaches down all the western side of the continent on the Atlantic ocean, in the countries of Congo, Angola, and Benin. In spite of the firmest foundation in true philo-

Gingiro || Gilglymus

philoſophy, a traveller, who decides from the information and inveſtigation of facts, will find it very difficult to treat theſe appearances as abſolute fictions, or as owing to the ſuperiority of cunning of one man in over-reaching another. For my own part, I confeſs, I am equally at a loſs to aſſign reaſons for diſbelieving the fiction on which their pretenſions to ſome preternatural information are founded, as to account for them by the operation of ordinary courſes."

In this kingdom every thing is conducted, or pretended to be conducted, by magic; and all thoſe ſlaves, which in other African countries are ſold to Europeans, are here ſacrificed to the devil, human blood being a neceſſary part in all their accurſed ſolemnities. "How far (ſays Mr Bruce) this reaches to the ſouthward, I do not know; but I look upon this to be the geographical bounds of the reign of the devil on the north ſide of the equator in the peninſula of Africa."

With regard to this country, very little farther is known than ſome of the cuſtoms of the people tranſiently picked up by the Jeſuit miſſionaries in Abyſſinia. From them we learn, that the kingdom is hereditary in one family, though it does not regularly deſcend to the eldeſt ſon, the king being choſen by the nobles; in which they reſemble their neighbours the Abyſſinians. When the king dies, his body is wrapped in a fine cloth, and a cow is killed. The body ſo wrapped up is next incloſed in the cow's ſkin; and all the princes of the royal family fly and hide themſelves in the buſhes, while thoſe who are intruſted with the election enter the thickets, beating about every where as if for game. At laſt a bird of prey, called in their language *liber*, appears, and hovers over the perſon deſtined to be king; crying and making a great noiſe without quitting his ſtation. By this means the perſon deſtined to be elected is found out, ſurrounded, as is reported, by lions, tigers, panthers, and other wild beaſts; all which are ſuppoſed to be brought by the power of magic or of the devil.—After the king is found, he flies upon thoſe who came in queſt of him with great fury, killing and wounding as many as he can reach, until at laſt he is dragged to the throne whether he will or not. One particular family have the privilege of conducting him to the throne; and if they ſhould not happen to find him at firſt, they have a right to take him out of the hands of thoſe who did ſo; and thus another battle enſues before the vacant throne can be filled. Laſtly, before he enters his palace, two men muſt be killed; one at the foot of a tree by which the houſe is ſupported; and the other at the threſhold of the door, which is beſmeared with the blood of the victim. It is the particular privilege of one family to afford theſe victims; and ſo far are they from ſeeking to avoid this fate, that they glory in the occaſion, and willingly offer themſelves to meet it. This laſt particular, Mr Bruce ſays he had in Abyſſinia from people coming from Gingiro.

GINGIVÆ, the gums. See Gums.

GINGLYMUS, in anatomy, one of the ſpecies of articulation. It is that jointure of the bones where each bone mutually receives the other; ſo that each bone both receives and is received. See Anatomy, n° 2.

GINKGO, the maden-hair-tree. See Mauritia. Ginkgo || Giotto.

GINORA, in botany: A genus of the monogynia order, belonging to the dodecandria claſs of plants; and in the natural method ranking with thoſe of which the order is doubtful. The calyx is cleft into ſix parts; the petals ſix; the capſule unilocular, quadrivalved, coloured, and polyſpermous.

GINSENG. See Panax.

GIOIA (Flavio), of Amalfi, in the kingdom of Naples, the celebrated mathematician; who, from his knowledge of the magnetic powers, invented the mariner's compaſs, by which the navigation of the Europeans was extended to the moſt diſtant regions of the globe: before this invention, navigation was confined to coaſting. The king of Naples being a younger branch of the royal family of France, he marked the north point with a fleur de lis, in compliment to that country. It is ſaid the Chineſe knew the compaſs long before; be this as it may, the Europeans are indebted to Gioia for this invaluable diſcovery. He flouriſhed A. D. 1300.

GIORDANO (Luca.) See Jordano.

GIORGIONE, ſo called from his comely aſpect, was an illuſtrious Venetian painter, born in 1478. He received his firſt inſtructions from Giovanni Bellino; but ſtudying afterwards the works of Leonardo da Vinci, he ſoon ſurpaſſed them both, being the firſt among the Lombards who found out the admirable effects of ſtrong lights and ſhadows. Titian became his rival in this art; and was ſo careful in copying the life, that he excelled Giorgione in diſcovering the delicacies of nature, by tempering the boldneſs of his colouring. The moſt valuable piece of Giorgione in oil is that of Chriſt carrying his croſs, now in the church of San Rovo in Venice; where it is held in great veneration. He died of the plague young, in 1511.

GIOSEPPINO, an eminent painter, ſo called by way of contraction from *Gioſeppe d' Arpino* the town of Naples where he was born in 1560. Being carried to Rome very young, and employed by painters then at work in the Vatican to grind their colours, he ſoon made himſelf maſter of the elements of deſign, and by degrees grew very famous. His wit and humour gained him the favour of popes and cardinals, who found him buſineſs in plenty. Gregory XIII. ſhowed him great reſpect; and Louis XIII. of France made him a knight of the order of St Michael. By the force of a happy genius he acquired a light and agreeable manner of deſigning; though it is remarked by De Piles, that he degenerated into a ſtyle which neither partook of true nature nor of the antique. His battles in the Capitol are the moſt eſteemed of all his pieces. He died at Rome in 1640.

GIOTTO, an ingenious painter, ſculptor, and architect of Florence, born in 1276. He was the diſciple of Cimabue; but far ſuperior to his maſter in the air of his heads, the attitude of his figures, and in the tone of his colouring; but could not expreſs livelineſs in the eyes, tenderneſs in the fleſh, or ſtrength in the muſcles of his naked figures. He was principally admired for his works in moſaic; the beſt of which is over the grand entrance of St Peter's church at Rome.

Giraffe || Girdle.

The obſervation of Alberti on that piece is, that in the ſhip of Giotto, the expreſſion of fright and amazement of the diſciples at ſeeing St Peter walk upon the water is ſo excellent, that each of them exhibits ſome characteriſtic ſign of his terror. His death happened in 1336, and the city of Florence honoured his memory with a ſtatue of marble over his tomb.

GIRAFFE, in zoology. See CERVUS.

GIRALD (Barry), or *Giraldus Cambrenſis*. See BARRY.

GIRALDI (Lilio Gregorio), an ingenious critic, and one of the moſt learned men that modern Italy has produced, was born at Ferrara in 1479. He was at Rome when it was plundered by the emperor Charles V.; and having thus loſt all he had, and being tormented by the gout, he ſtruggled through life with ill fortune and ill health. He wrote, nevertheleſs, 17 performances, which were collected and publiſhed at Baſil in 2 vols folio in 1580, and at Leyden in 1696. Authors of the firſt rank have beſtowed the higheſt eulogies on Giraldus; particularly Caſaubon and Thuanus.

GIRALDI (John Baptiſt Cintio), an Italian poet of the ſame family with the foregoing Lilio, was born in 1504. He was ſecretary to the duke of Ferrara, and afterwards became profeſſor of rhetoric at Pavia. He died in 1573. His works, which conſiſt chiefly of tragedies, were collected and publiſhed at Venice by his ſon Celſo Giraldi, in 1583; and ſome ſcruple not to rank him among the beſt tragic writers Italy has produced.

GIRARDON (Francis), a celebrated French architect and ſculptor, born at Troyes in 1627. Louis XIV. being informed of his great talents, ſent him to Rome with a penſion of 1000 crowns. At his return into France, he laboured for the royal palaces, and the gardens of Verſailles and Trianon; where there are many of his works executed in bronze and in marble, from the deſigns of Charles le Brun. The mauſoleum of cardinal de Richelieu, in the Sorbonne, and the equeſtrian ſtatue of Louis XIV. at the Place de Vendome, where the ſtatue and horſe are caſt in one piece, paſs for his moſt excellent performances. Girardon was profeſſor, rector, and chancellor, of the Academy of Painting and Sculpture; and had the poſt of inſpector-general of all the works done in ſculpture. He died in 1715.

GIRDERS, in architecture, the largeſt pieces of timber in a floor. Their ends are uſually faſtened into the ſummers, or breſt-ſummers; and the joiſts are framed in at one end to the girders.

By the ſtatute for rebuilding London, no girder is to lie leſs than ten inches into the wall, and their ends to be always laid in loam, &c.

GIRDLE (*Cingulus* or *Zona*), a belt or band of leather or other matter, tied about the reins to keep that part more firm and tight.

It was anciently the cuſtom for bankrupts and other inſolvent debtors to put off and ſurrender their girdle in open court. The reaſon of this was, that our anceſtors uſed to carry all their neceſſary utenſils, as purſe, keys, &c. tied to the girdle; whence the girdle became a ſymbol of the eſtate. Hiſtory relates, that the widow of Philip I. duke of Burgundy, renounced her right of ſucceſſion by putting off her girdle upon the duke's tomb. Girgaſhites, Girgenti.

The Romans always wore a girdle to tuck up the tunica when they had occaſion to do any things: this cuſtom was ſo general, that ſuch as went without girdles, and let their gowns hang looſe, were reputed idle, diſſolute, perſons.

Maidens or *Virgins* GIRDLE. It was the cuſtom among the Greeks and Romans for the huſband to untie his bride's girdle. Homer, lib. xi. of his Odyſſey, calls the girdle παρθενιην ζωνην, *maid's girdle*. Feſtus relates, that it was made of ſheep's wool, and that the huſband untied it in bed: he adds, that it was tied in the Herculanean knot; and that the huſband unlooſed it, as a happy preſage of his having as many children as Hercules, who at his death left ſeventy behind him.

The poets attribute to Venus a particular kind of girdle called *ceſtus*, to which they annexed a faculty of inſpiring the paſſion of love.

GIRGASHITES, or GERGESENES, an ancient people of the land of Canaan, whoſe habitation was beyond the ſea of Tiberias, where we find ſome footſteps of their name in the city of *Gergeſa*, upon the lake of Tiberias. The Jewiſh doctors inform us, that when Joſhua firſt came into the land of Canaan, the Girgaſhites took a reſolution rather to forſake their country than ſubmit to the Hebrews, and accordingly retired into Africa. Nevertheleſs, it is certain that a good number of them ſtaid behind, ſince Joſhua (xxiv. 11.) informs us that he ſubdued the Girgaſhites, and they whom he overcame were certainly on this ſide Jordan.

GIRGENTI, a town of Sicily, which occupies part of the ſite of the ancient *Agrigentum*. It has only one ſtreet fit for carriages. It is inhabited by 15,000 perſons; but has no remarkable buildings or works of art that deſerve mention: the only antiquities to be ſeen were a Latin inſcription of the time of the Antonines, as is pretended, relative to ſome aſſociation between Agrigentum and Lilybæum; and a piece of ancient maſonry in the foundations of a church pretended to be the remains of a temple of Jupiter. At ſome diſtance, on the old ground in the vale, ſtands the cathedral, a clumſy building patched up by barbarous architects with various diſcordant parts. This church is enriched with no works of modern painters or ſculptors that claim any title to praiſe, but the baptiſmal font is made out of an ancient ſarcophagus faced with very beautiful baſſo relievos. This ſee is the richeſt in Sicily, but has the character of being leſs enlightened and poliſhed than the reſt of the iſland. Among the curioſities belonging to the cathedral is an Etruſcan vaſe of rare ſize and preſervation. There are alſo ſome golden pateras of extreme rarity. The monaſtery of San Nicolo ſtands on a little eminence in the centre of the old city, admirably ſituated. The range of hills towards the ſouth eaſt ſinks gradually, ſo as to admit a noble reach of ſea and of plain, terminated on each ſide by thick groves of fruit-trees. Above appear the remains of ancient grandeur, wonderfully contraſted with the humble ſtraw cottages built at their feet. In the orchard of this convent is a ſquare building with pilaſters, which is ſuppoſed to have been part of the palace of the Roman prætor.

Gironne
ll
Giula.

Girgenti has the convenience of a port; for which, however, it is leſs indebted to its natural ſituation than to the recent aſſiſtance of art. The harbour is formed by means of a pier carried out in three ſides of an octagon, with a battery at the head; the light-houſe is to be erected on the cliffs onſhore, as there is no poſſibility of raiſing it high enough on the mole without danger of ſinking. The work is admirable as to ſtrength and neatneſs, but the intention of creating a ſafe and complete haven has not been fully anſwered; the Scirocco commands it entirely, and drives in great quantities of ſand, which it is feared will in time choak up the port; even now ſhips of burden find it difficult to get in, but the Caricatore is conſiderable, and the magazines in the rocks along the ſhore are very ſpacious.

GIRONNE, or Gironny, in heraldry, a coat of arms divided into girons, or triangular figures, meeting in the centre of the ſhield, and alternately colour and metal.

GISCO, ſon of Himileo the Carthaginian general, was baniſhed from Carthage by the influence of his enemies. Being afterwards recalled, he was made general in Sicily againſt the Corinthians, about 309 years before the Chriſtian era, and by his ſucceſs and intrepidity he obliged the enemies of his country to ſue for peace. See Carthage.

GISBOROUGH, a town of England, in the Weſt Riding of Yorkſhire, on the road from Whitby to Durham, 224 miles from London, and 4 miles from the mouth of the Tees, where is a bay and harbour for ſhips. It had formerly an abbey, which was once the common burial-place of the nobility of theſe parts, and its church by the ruins ſeems to have been equal to the beſt cathedrals in England. The ſoil, beſides its fertility in paſture and a conſtant verdure adorned with plenty of field-flowers almoſt all the year, has earths of ſundry colours, ſome iron, and mines of alum, which were firſt diſcovered in the reign of king James I. and have been ſince very much improved. Sir Paul Pindar, who firſt farmed them, paid rents to the king 12,500l. to the Earl Muſgrave 1640l. and to Sir William Penniman 600l. and had moreover 800 men by ſea and land in conſtant pay; yet he was a conſiderable gainer, becauſe there was then ſcarce any other to be had, and the price was 26l. a ton: but now there are ſeveral other alum-works in this county, which have taken a great part of the trade from hence; ſo that the works here have for ſome years lain neglected.

GITTITH, a Hebrew word occurring frequently in the Pſalms, and generally tranſlated *wine preſſes*. The conjectures of interpreters are various concerning this word. Some think it ſignifies a ſort of muſical inſtrument; others, that the pſalms with this title were ſung after the vintage; laſtly, others, that the hymns of this kind were invented in the city of Gath. Calmet is rather of opinion, that it was given to the claſs of young women or ſongſtreſſes of Gath to be ſung by them; Pſal. viii. 1. lxxxi. 1. lxxxiv. 1. Dr Hammond thinks that the pſalms with this title were all ſet to the ſame tune, and made on Goliah the Gittite.

GIULA, a ſtrong town of Upper Hungary, on the frontiers of Tranſilvania. It was taken by the Turks in 1566, and retaken by the Imperialiſts in 1695. It is ſeated on the river Kereſbian, in E. Long. 21. 1. N. Lat. 46. 25.

Giuſtandel
Glaciers

GIUSTANDEL, a large and ſtrong town of Turkey in Europe, and in Macedonia, with a Greek archbiſhop's ſee. It is ſeated near the lake Ochrida, in E. Long. 20. 50. N. Lat. 41. 10.

GLACIERS, a name given to ſome very extenſive fields of ice among the Alps.—Mr Coxe obſerves of theſe mountains in general, that they are compoſed of many parallel chains, the higheſt of which occupy the centre, and the others gradually diminiſh in proportion as we recede from thence. The central chain appears covered with pointed rocks; all parts of which, that are not abſolutely perpendicular, lie hid under perpetual ſnow and ice even in ſummer. On each ſide of this ridge are fertile and cultivated valleys, interſperſed with numerous villages, and watered by numerous ſtreams. The elevated peaks of the central chain are covered with ſnow: but their declivities, excepting thoſe that are extremely ſteep, have all a covering of ice as well as ſnow; the intermediate parts being filled with vaſt fields of ice, terminating in the cultivated valleys above mentioned. The ſame phenomena, though on a ſmaller ſcale, occur in thoſe chains that are at a diſtance from the principal one: In thoſe which are moſt remote, no ice, and ſcarcely any ſnow, is obſerved, unleſs upon ſome of the moſt elevated ſummits; and the mountains diminiſhing in height and ruggedneſs, appear covered with verdure, until at laſt they terminate in ſmall hills and plains.

Thus the glaciers may be divided into two ſorts; one occupying the deep valleys ſituated in the boſom of the Alps, and diſtinguiſhed by the name of Ice-valleys; the others are thoſe which clothe the declivities and ſides of the mountains. Theſe two kinds of glaciers are diſtinguiſhed by Mr Coxe into the upper and lower glaciers.

The lower glaciers are by far the moſt conſiderable; ſome of them extending ſeveral leagues in length. They do not communicate with each other, as has been generally ſuppoſed, few of them being parallel to the central chain; but, ſtretching moſtly in a tranſverſe direction, are bordered at the higher extremity by inacceſſible rocks, and at the lower extending into the cultivated valleys. The thickneſs of the ice varies in different parts. In the glacier des Bois, which extends more than 15 miles in length, and upwards of three in breadth, M. Sauſſure found it generally from 80 to 100 feet; but he was credibly informed that in ſome places it was not leſs than 600 feet, and even more. Theſe vaſt maſſes of ice uſually reſt on an inclined plain; where, being puſhed forward by their own weight, and but weakly ſupported by the rugged rocks beneath them, they are interſected by large crevices, and have an appearance of walls, pyramids, &c. according to the poſition of the eye in viewing them. In thoſe parts, however, where they lie upon even ground, or ſuch as has only a gentle inclination, the ſurface of the ice is nearly uniform, the crevices being few and narrow, and the glacier being croſſed by travellers on foot without any difficulty. The ſurface of the ice is rough and granulated, ſo that people may walk upon it excepting ſuch places as have a ſteep deſcent. It is opaque, full of ſmall bubbles about the ſize of a pea, very porous, and greatly reſembles a mixture of ſnow and water congeal-

ed.

Glaciers. ed. A vaſt quantity of ſtones and earth falls down from the mountains upon the glaciers, and are by them thrown off on each ſide according to the deſcent of the ice, as will be afterwards explained. The place on which theſe reſt is more hard and elevated than the reſt of the ice, and is very difficult to walk upon; the earth is likewiſe laid upon them in ſuch regular heaps, that it appears to have been done by art. This collection of earth and ſtones is termed by the natives the *Moraine*.

Mr Coxe, who viſited the glacier des Bois, informs us, that the appearance of it at a diſtance was ſo tremendous, that it ſeemed impracticable to croſs it. Numerous and broad chaſms interſected it in every direction; but entering upon it, the company found that courage and activity were only required to accompliſh the taſk. They had large nails in their ſhoes and ſpiked ſticks; which on this occaſion were found to be particularly ſerviceable. Having paſſed the Moraine, and deſcended upon the glacier itſelf, they found the ice ſoftened by a warm wind which rendered it leſs ſlippery than uſual. Having walked acroſs it for about a quarter of an hour, they came again to the Moraine, along which they continued their journey for half an hour, and then entered upon the great body of the glacier. "Here (ſays Mr Coxe) it was curious to obſerve the numerous little rills produced by the collection of drops occaſioned by the thawing of the ice on the upper part of the glacier: theſe little rills hollow out ſmall channels, and, torrent-like, precipitate themſelves into the chaſms with a violent noiſe, increaſing the body of waters formed by the melting of the interior ſurface, and finding an outlet under the immenſe arch of ice in the valley of Chamouni, from which the Arveron ruſhes." As our traveller proceeded on his journey, he was ſurprized by the noiſe of a large fragment of rock which had detached itſelf from one of the higheſt needles, and bounded from one precipice to another with great rapidity; but before it reached the plain, it was almoſt reduced to duſt. "Having proceeded about an hour (ſays he), we were aſtoniſhed with a view more magnificent than imagination can conceive: hitherto the glaciers had ſcarcely anſwered my expectations, but now they far ſurpaſſed them. Nature had clad herſelf in all her terrors. Before us was a valley of ice 20 miles in extent, bounded by a circular glacier of pure unbroken ſnow, named Takul, which leads directly to the foot of Mont Blanc, and is ſurrounded by large conical rocks, terminating in ſharp points like the towers of an ancient fortification; to the right roſe a range of magnificent peaks, their intervals filled with glaciers; and far above the reſt, the magnificent ſummit of Mont Blanc, his higheſt point obſcured with clouds. He appeared of ſuch immenſe magnitude, that, at his preſence, the circumjacent mountains, however gigantic, ſeemed to ſhrink before him, and *hide their diminiſhed heads*. In half an hour we arrived at the Moraine, which forms a boundary of the valley, croſſed it, and proceeded upon a body of ice about three quarters of a mile broad. Here the ice was more even and free from chaſms than in the great valley. We then paſſed a ſecond moraine, and beyond that another maſs of ice to a third moraine: deſcending from thence we came upon the laſt ridge of ice, broader conſiderably than the two former, and full of large chaſms: it is ſeparated from the rock only by a very narrow moraine. Theſe moraines contain great quantities of cryſtal." Glacie

They continued to aſcend the valley of ice, the ſcene conſtantly increaſing in magnificence and horror; and having walked about five miles on the ice, they arrived at laſt at the foot of the eminence named *Couvercle*, where they were obliged to quit the ice. The doing this was extremely dangerous, and at one place very tremendous. It was a bulging ſmooth rock, with a precipice of conſiderable depth terminated by a vaſt crevice in the ice, which ſeemed to ſtop all further progreſs: a ſmall hollow in the middle, however, afforded room for one foot; and having fixed this, they ſprung over to the other ſide, being helped and directed by the guides who went over firſt. Having gained the top of the Couvercle, they had a view of three of the glaciers, viz. that of *Talefre* to the left, *l'Echaut* in front, and *Takul* on the right; all uniting in that great one called the *Glacier de Bois*. The Couvercle itſelf is a moſt extraordinary rock, having the appearance of a large irregular building with many ſides; the ſubſtance of which is granite. Having reached the top, they were ſurprized with a thunder-ſtorm, from whence they took ſhelter under an impending rock. The view was exceedingly magnificent; the glaciers appearing like a rugged expanſe of frozen ſea bounded by gigantic rocks, and terminated by Mount Blanc. A ſingle rock appeared of a triangular figure, covered with Alpine plants; and which, by reaſon of its contraſt with the rugged and ſnowy mountains in the neighbourhood, has obtained the name of the *Garden*.—During this, as well as other excurſions among the Alps, Mr Coxe had occaſion to obſerve that the colour of the ſky was of a much deeper blue than in the lower regions.

The upper glaciers may be ſubdivided into thoſe which cover the ſummits, and thoſe which extend along the ſides of the Alps. Thoſe on the very ſummit, however, though they have the appearance of ice, are not ſo in reality, but conſiſt entirely of ſnow hardened by the extreme cold. M. Sauſſure found that which covered the top of Mount Blanc to be penetrable, though with difficulty, by a ſtick; but below this hard cruſt was a ſoft ſnow without coherence. The ſides are covered with a mixture of ice and ſnow; by reaſon of the ſuperior power of the ſummer ſun to diſſolve the ſnow, which afterwards congeals into hard ice.

Several conjectures have been made concerning the formation of theſe extraordinary bodies of ice. Mr Coxe agrees with M. Gruner in opinion, that they are produced by the continual diſſolution of the ſnow in ſummer, and its congelation by the ſucceeding froſts. Hence, on the ſummits of the mountains where the ſun has very little power, the glacier is ſoft, and contains no ice: as we deſcend the mountains the conſiſtence becomes firmer, becauſe there is a conſiderable mixture of ſnow-water, the congelation of which augments the hardneſs; and in the valleys, the glacier is hardeſt of all, becauſe the portion of water is there much ſuperior to that of the ſnow. Hence it ſeems plain that the glaciers derive their origin from the melting of the ſnow on the upper parts of the mountains, and the congelation of the water as it advances: and to this cauſe M. Sauſſure adds the quantity of ſnow which often rolls down into the valleys and congeals along with the water juſt mentioned.

Another

laciers. Another queſtion concerning the glaciers naturally occurs, namely, Whether they are to be conſidered as in a ſtate of increaſe or diminution? Mr Coxe is of opinion, that they occaſionally increaſe and decreaſe; in proof of which he addduces the following obſervation. "The borders of the glacier of Montanvert are moſtly ſkirted with trees: towards its baſe a vaſt arch of ice riſes to near 100 feet in height; under which the river Arveron ruſhes with conſiderable force, and in a large body of water. As we approached the ice, we paſſed through a wood of firs: thoſe trees which ſtand at a little diſtance from the arch are about 80 feet high, and are undoubtedly of a very great age. Between theſe and the glacier the trees are of a later growth; as is evident from their texture and inferior ſize. Others, ſtill ſmaller, have been overturned and enveloped in the ice: there ſeems to be a kind of regular gradation in the age of theſe ſeveral trees, from the largeſt which are ſtanding, to the ſmalleſt that lie proſtrate."—Hence our author concludes, that the glacier once extended as far as the row of ſmall firs; but that, upon its gradual diſſolution, a number of trees ſhot up on the ſpot it had occupied; ſince which time the ice has again advanced, and overturned the laſt grown trees before they had attained to any conſiderable height.—This he thinks alſo confirmed by the following fact.—"Large ſtones of granite are uſually found at a ſmall diſtance from the extremities of the glacier. Theſe ſtones have certainly fallen from the mountains upon the ice; have been carried on in its progreſs; and have tumbled into the plain upon the diſſolution or ſinking of the ice which ſupported them. Theſe ſtones, which the natives call *Moraine*, form a kind of border towards the foot of the valley of ice, and have been puſhed forward by the glacier in its advances: they extend even to the place occupied by the larger pines."

In oppoſition to thoſe who maintain that there is a conſtant accumulation of ice and ſnow in the Alpine regions, our author makes the following remarks. 1. Between the years 1776 and 1785 the glacier of Grindelevald had diminiſhed to ſuch a degree, that the ſpot which its extremity occupied in the former year, was at leaſt 400 paces from that occupied by it in the latter. 2. In the year 1785 the Murailles de Glace, which in 1776 he had deſcribed as forming the border of the glacier of Boſſon, no longer exiſted; and young trees had ſhot up in the parts which were then covered by the glacier of Montanvert. Still, however, it may be urged, that theſe changes only take place in the valleys where the power of the ſun is conſiderable; and that from thence we cannot form any adequate idea of what paſſes in the more elevated regions, where in all probability more ſnow falls than can be diſſolved. In ſupport of this opinion, it is alleged, that the cold produced by the maſs of ice already formed ought to augment it ſtill more; and that, within the memory of the preſent generation, many places have been covered with ice which were not ſo before. To theſe arguments, however, Mr Coxe replies, that the cauſes, which diminiſh the ice in the upper regions, are no leſs powerful than the cold which tends to augment it. Theſe are, 1. Rain or ſleet; which falling upon the lower glaciers, thaw the ice, increaſe the rills on its ſurface, excavate channels, and in many ways tend to diminiſh its quantity. 2. Evaporation, which takes place even from the ſurface of the ice itſelf, acts ſtill more powerfully; and its action is not confined to any particular ſeaſon. 3. The falling of the ſnow and ice; both that which comes gradually from the clouds, and which deſcends from the mountains in great maſſes, called by the natives *avalanches*. When theſe laſt fall down into milder regions, though ſometimes they may reſiſt the influence of the ſun and form ice-valleys, yet they generally diſſolve. They are moſt common in the upper glaciers, though ſometimes they deſcend upon the lower, while the gradual deſcent of ſnow from the clouds, which chiefly takes place in the lower, contributes very much to leſſen the maſs. 4. All the lower glaciers or valleys of ice reſt on an inclined plane, are hollow, and undermined by torrents which are conſtantly flowing from the upper glaciers, as well as from their own lowermoſt ſurface. Their foundation being thus conſtantly diminiſhing, the lower glaciers are carried imperceptibly forward into the cultivated fields, where an end is neceſſarily put to their progreſs by the heat of the ſun. Hence we may ſee the reaſon of that ſtrange phenomenon taken notice of by Mr Coxe, that with one hand he could touch ripe corn, and with the other ſolid ice. This deſcent of the glacier is demonſtrable from the trees overturned by it, and the morain always obſerved at the bottom of the lower glaciers. 5. The heat of the ſun is an evident cauſe of the diminution of the glaciers. To this Mr Coxe adds another cauſe leſs generally known, viz. the warm winds which blow by night as well as by day both in the upper and lower glaciers. "Theſe warm winds (ſays he) are during ſummer ſo common in thoſe parts, that I never croſſed a glacier without feeling in ſome particular poſitions a warmth ſimilar to the air of a hot-bath." 6. Another cauſe is the mean temperature of the earth itſelf; which, where it is not expoſed to the piercing cold of the atmoſphere, is found to have a temperature always above the freezing point. As the vaſt thickneſs of the ſuperincumbent ice, therefore, is in the preſent caſe abundantly ſufficient to prevent the acceſs of the atmoſphere, it is plain that the lower ſurface of it muſt, by being in contact with the earth, continually decay. With regard to the other argument drawn from the known increaſe of the ice in ſome places, Mr Coxe does not deny it; but inſiſts, that there is no continual increaſe of the whole, but that if it increaſes in ſome places, it diminiſhes in others; and his opinion in this reſpect was confirmed by thoſe who frequent the mountains.

Glaciers ‖ Gladiators.

GLACIS, in building, an eaſy inſenſible ſlope or declivity.

The deſcent of the glacis is leſs ſteep than that of the talus. In gardening, a deſcent ſometimes begins in talus, and ends in glacis.

The glacis of the corniche, is an eaſy imperceptible ſlope in the cymatium, to promote the deſcent and draining off the rain-water.

GLACIS, in fortification, that maſs of earth which ſerves as a parapet to the covered way, ſloping eaſily towards the champaign or field.

GLADE, in gardening and agriculture, an opening and light paſſage made through a wood, by lopping off the branches of trees along that way.

GLADIATORS, in antiquity, perſons who fought, generally

Gladiators. generally in the arena at Rome, for the entertainment of the people.

The gladiators were uſually ſlaves, and fought out of neceſſity; though ſometimes freemen made profeſſion thereof, like our prize-fighters, for a livelihood.

The Romans borrowed this cruel diverſion from the Aſiatics: ſome ſuppoſe that there was policy in the practice, the frequent combats of gladiators tending to accuſtom the people to deſpiſe dangers and death.

The origin of ſuch combats ſeems to be as follows. From the earlieſt times with which we have any acquaintance in profane hiſtory, it had been the cuſtom to ſacrifice captives, or priſoners of war, to the manes of the great men who had died in the engagement: thus Achilles, in the Iliad, lib. xxiii. ſacrificcs twelve young Trojans to the manes of Patroclus; and in Virgil, lib. xi. ver. 81. Æncas ſends captives to Evander, to be ſacrificed at the funeral of his ſon Pallas.

In courſe of time they came alſo to ſacrifice ſlaves at the funerals of all perſons of condition: this was even eſteemed a neceſſary part of the ceremony; but as it would have appeared barbarous to have maſſacred them like beaſts, they were appointed to fight with each other, and endeavour to ſave their own lives by killing their adverſary. This ſeemed ſomewhat leſs inhuman, becauſe there was a poſſibility of avoiding death, by an exertion of ſkill and courage.

This occaſioned the profeſſion of gladiator to become an art: hence aroſe maſters of the art, and men learned to fight and exerciſe it. Theſe maſters, whom the Latins called *laniſtæ*, bought them ſlaves to be trained up to this cruel trade, whom they afterwards ſold to ſuch as had occaſion to preſent the people with ſo horrible a ſhow.

Theſe exhibitions were at firſt performed near the ſepulchre of the deceaſed, or about the funeral pile; but were afterwards removed to the circus and amphitheatres, and became ordinary amuſements.

The firſt ſhow of gladiators, called *munus gladiatorum*, was exhibited at Rome, according to Valerius Maximus, by M. and D. Brutus, upon the death of their father, in the year of the city 490. On this occaſion there were probably only three pair of gladiators. In 537, the three ſons of M. Æmilius Lepidus the augur, who had been three times conſul, entertained the people with the cruel pleaſure of ſeeing 22 gladiators fight in the forum. In 547, the firſt Africanus diverted his army at New Carthage with a ſhow of gladiators, which he exhibited in honour of his father and uncle, who had begun the reduction of Spain. In proceſs of time, the Romans became ſo fond of theſe bloody entertainments, that not only the heir of any great and rich citizen lately deceaſed, but all the principal magiſtrates, preſented the people with ſhows of this nature, to procure their affection. The ædiles, pretors, conſuls, and, above all, the candidates for offices, made their court to the people, by entertaining them frequently with theſe fights: and the prieſts were ſometimes the exhibitors of the barbarous ſhows; for we meet with the *ludi pontificales* in Suetonius, Auguſt. cap. 44. and with the *ludi ſacerdotales*, in Pliny, Epiſt. lib. vii. As for the emperors, it was ſo much their intereſt to ingratiate themſelves with the populace, that they obliged them with combats of gladiators almoſt upon all occaſions; and as theſe increaſed, the number of combatants increaſed likewiſe. Accordingly, Julius Cæſar, in his ædileſhip, diverted the people with 320 couple. Titus exhibited a ſhow of gladiators, wild beaſts, and repreſentations of ſea-fights, which laſted 100 days; and Trajan continued a ſolemnity of this nature for 123 days; during which time he brought out 1000 pair of gladiators. Before this time, under the republic, the number of gladiators was ſo great, that when the conſpiracy of Catiline broke out, the ſenate ordered them to be diſperſed into the garriſon and ſecured, leſt they ſhould have joined the diſaffected party. See *Gladiator's War*. Gladiato

Theſe ſports were become ſo common, and their conſequences in a variety of reſpects ſo dangerous, that Cicero preferred a law that no perſon ſhould exhibit a ſhow of gladiators within two years before he appeared candidate for any office. Julius Cæſar ordered, that only a certain number of men of this profeſſion ſhould be in Rome at a time; Auguſtus decreed, that only two ſhows of gladiators ſhould be preſented in a year, and never above ſixty couple of combatants in a ſhow; and Tiberius provided by an order of ſenate, that no perſon ſhould have the privilege of gratifying the people with ſuch a ſolemnity unleſs he was worth 400,000 ſeſterces. They were alſo conſiderably regulated by Nerva.

The emperor Claudius reſtrained them to certain occaſions: but he ſoon afterwards annulled what he decreed, and private perſons began to exhibit them at pleaſure as uſual; and ſome carried the brutal ſatisfaction ſo far as to have them at their ordinary feaſts. And not ſlaves only, but other perſons, would hire themſelves to this infamous office.

The maſter of the gladiators made them all firſt ſwear that they would fight to death; and if they failed, they were put to death either by fire or ſwords, clubs, whips, or the like.

It was a crime for the wretches to complain when they were wounded, or to aſk for death or ſeek to avoid it when overcome; but it was uſual for the emperor or the people to grant them life when they gave no ſigns of fear, but waited the fatal ſtroke with courage and intrepidity: Auguſtus even decreed that it ſhould always be granted them.

From ſlaves and freedmen the inhuman ſport at length ſpread to people of rank and condition; ſo that Auguſtus was obliged to iſſue a public edict that none of the ſenatorian order ſhould become gladiators; and ſoon after he laid the ſame reſtraint on the knights: nevertheleſs Nero is related to have brought upwards of 400 hundred ſenators and 600 Roman knights upon the arena; though Lipſius takes both theſe numbers to be falſified, and not without reaſon reduces them to 40 ſenators and 60 knights: yet Domitian, that other monſter of cruelty, refined upon Nero, exhibiting combats of women in the night-time.

Conſtantine the Great is ſaid to have firſt prohibited the combats of gladiators in the Eaſt. At leaſt he forbad thoſe who were condemned to death for their crimes to be employed; there being an order ſtill extant to the *præfectus prætorii* rather to ſend them to work in the mines in lieu thereof: it is dated at Berytus in Phœnicia the 1ſt of October 325.

The emperor Honorius forbad them at Rome on occaſion of the death of Telemachus, who coming out

Gladiator. of the East into Rome at the time of one of these spectacles, went down into the arena, and used all his endeavours to prevent the gladiators from continuing the sport; upon which the spectators of that carnage, fired with anger, stoned him to death. It must be observed, however, that the practice was not entirely abolished in the West before Theodoric king of the Ostrogoths. Honorius, on the occasion first mentioned, had prohibited them; but the prohibition does not seem to have been executed. Theodoric, in the year 500, abolished them finally.

Some time before the day of combat, the person who presented the people with the shows gave them notice thereof by programmas or bills, containing the names of the gladiators, and the marks whereby they were to be distinguished: for each had his several badge; which was most commonly a peacock's feather, as appears from the scholiast of Juvenal on the 158th verse of the third satire, and Turnebus Adverss. lib. ii. cap. 8. They also gave notice how long the shows would last, and how many couples of gladiators there were; and it even appears, from the 52d verse of the seventh satire of the second book of Horace, that they sometimes made representations of these things in painting, as is practised among us by those who have any thing to show at fairs.

The day being come, they began the entertainment by bringing two kinds of weapons; the first were staves or wooden files, called *rudes*; and the second were effective weapons, as swords, poniards, &c. The first were called *arma lusoria*, or *exercitoria*; the second *decretoria*, as being given by decree or sentence of the prætor, or of him at whose expence the spectacle was exhibited. They began to fence or skirmish with the first, which was to be the prelude to the battle; and from these, when well warmed, they advanced to the second at the sound of the trumpets, with which they fought naked. Then they were said *vertere arma*. The terms of striking were *petere & repetere*; of avoiding a blow, *exire*; and when one of the combatants received a remarkable wound, his adversary or the people cried out, *Habet*, or *Hoc habet*. The first part of the engagement was called *ventilare, præludere*; and the second, *dimicare ad certum*, or *verss armis pugnare*: and some authors think, with much probability, that it is to these two kinds of combat that St Paul alludes in the passage 1 Cor. ix. 26, 27. "I fight, not as one that beateth the air; but I keep my body, and bring it into subjection."

If the vanquished surrendered his arms, it was not in the victor's power to grant him life: it was the people during the time of the republic, and the prince or people during the time of the empire, that were alone empowered to grant the boon. The reward of the conqueror was a branch of palm-tree, and a sum of money, probably collected among the spectators: sometimes they gave him his congé, or dismissed him by putting one of the wooden files or *rudis* in his hand; and sometimes they even gave him his freedom, putting the pileus on his head. The sign or indication, whereby the spectators showed that they granted the favour, was *premere pollicem*, which M. Dacier takes to be a clenching of the fingers of both hands between one another, and so holding the two thumbs upright close together; and, when they would have the combat finished and the vanquished slain, *verterunt pollicem*, they bent back the thumb; which we learn from Juvenal, Sat. iii. ver. 36. The gladiators challenged or defied each other, by showing the little finger; and, by extending this, or some other, during the combat, they owned themselves vanquished, and begged mercy from the people: *Victi ostensum digiti veniam a populo postulabant*, says the old scholiast on Persius. Gladiator, Gladiolus.

There were various kinds of gladiators, distinguished by their weapons, manner, and time of fighting, &c. as, The *andabatæ*, mentioned under Andabatæ. The *catervarii*, who always fought in troops or companies, number against number; or, according to others, who fought promiscuously, without any certain order. The *dimachæ*, who fought armed with two poniards or swords, or with sword and dagger. The *essedarii*, who fought in cars. The *fiscales*, or *Cæsariani*, who belonged to the emperor's company; and who, being more robust and dexterous than the rest, were frequently called for; and therefore named also *postulatitii*. Several other kinds are mentioned in the ancient authors.

Gladiators War (bellum Gladiatorium or *Spartacum)*, called also the *servile war*, was a war which the Romans sustained about the year of their city 680. Spartacus, Crinus, and Oenomaus, having escaped, with other gladiators to the number of seventy-four, out of the place where they had been kept at Capua, gathered together a body of slaves, put themselves at their head, rendered themselves masters of all Campania, and gained several victories over the Roman prætors. At length they were defeated in the year 682, at the extremity of Italy; having, in vain, attempted to pass over into Sicily.

This war proved very formidable to the Romans. Crassus was not able to finish it: the great Pompey was forced to be sent as general.

The Dying Gladiator, a most valuable monument of ancient sculpture, which is now preserved in the palace of Chighi. This man, when he had received the mortal stroke, is particularly careful *ut procumbat honeste*, that he might fall honourably. He is seated in a reclining posture on the ground, and has just strength sufficient to support himself on his right arm: and in his expiring moments it is plainly seen, that he does not abandon himself to grief and dejection; but is solicitous to maintain that firmness of aspect which the gladiators valued themselves on preserving in this season of distress, and that attitude which they had learnt of the masters of defence. He fears not death, nor seems to betray any tokens of fear by his countenance, nor to shed one tear: *quis mediocris gladiator ingemuit, quis vultum mutavit unquam, quis non modo flevit, verum etiam decubuit turpiter*, says Cicero, in that part of his Tusculan where he is describing the astonishing firmness of those persons. We see, in this instance, notwithstanding his remaining strength, that he has but a moment to live; and we view him with attention, that we may see him expire and fall: thus the ancients knew how to animate marble, and to give it almost every expression of life.

GLADIOLUS, Corn-flag: A genus of the monogynia

Glair, Glamorganſhire.

monogynia order, belonging to the triandria claſs of plants; and in the natural method ranking under the ſixth order, *Enſatæ*. The corolla is ſexpartite, and ringent; the ſtamina aſcending and bending upwards. There are 10 ſpecies, of which the moſt remarkable is the communis, or common gladiolus. This hath a round, compreſſed, tuberous root; long ſword-ſhaped leaves; an erect flower-ſtalk, two or three feet high; the top garniſhed with ſeveral pretty large flowers of a red or white colour, having each ſix petals. They appear in May and June, and are ſucceeded by plenty of ſeed in Auguſt. The plants are very hardy, and will thrive in any ſoil or ſituation. They are propagated by offsets from the roots.

GLAIR of eggs, is the ſame as the white of eggs, and is uſed as a varniſh for preſerving paintings. For this purpoſe it is beat to an unctuous conſiſtence, and commonly mixed with a little brandy or ſpirit of wine, to make it work more freely, and with a lump of ſugar to give it body and prevent its cracking: and then ſpread over the picture or painting with a bruſh.

GLAMORGANSHIRE, a county of South Wales, ſaid to have derived its name from a contraction of the Welſh words *Gwald Morgan*, or "the county of Morgan," and ſuppoſed to have been thus called from a prince of this part of the country, ſaid to have been killed 800 years before the birth of our Saviour: but ſome other writers derive the name from the word *Mor*, which in the Britiſh tongue ſignifies the *ſea*; this being a maritime county. It is bounded on the ſouth, and part of the weſt, by Briſtol channel; on the north-weſt, by Caermarthenſhire; on the north, by Brecknockſhire; and on the eaſt, by Monmouthſhire. It extends 48 miles in length from eaſt to weſt, 27 in breadth from north to ſouth, and is 116 in circumference. It is divided into 10 hundreds, in which are one city, 7 market-towns, 118 pariſhes, about 10,000 houſes, and 58,000 inhabitants. It is in the dioceſe of Llandaff. This county, in the time of the Romans, was part of the diſtrict inhabited by the Silures, and had ſeveral Roman ſtations. Thus Boverton, a few miles to the ſouth of Cowbridge, is ſuppoſed to be the Bovium of Antoninus; Neath to be his Nidum; and Loghor, to the weſt of Swanſey, to be his Leucarum. The principal rivers of this county are the Rhymny, the Taff, the Ogmore, the Avon, the Cledaugh, and the Tave. The air, in the ſouth part, towards the ſea, is temperate and healthful; but the northern part, which is mountainous, is cold and piercing, full of thick woods, extremely barren, and thin of inhabitants. The mountains, however, ſerve to feed herds of cattle, and ſend forth ſtreams which add greatly to the fertility of the other parts of the county: they have likewiſe coal and lead-ore. The ſouth part is ſo remarkably fertile, pleaſant, and populous, that it is generally ſtyled the garden of Wales; but it has no manufacture. This county was formerly full of caſtles, moſt of which are now fallen to decay. It has many ſmall harbours on the coaſt for exporting coals and proviſions. Of the former it ſends large quantities both to England and Ireland; but of the latter, to England almoſt ſolely, eſpecially butter. It ſends two members to parliament, one for the ſhire, and one for the borough of Cardiff the capital.

GLAMOUR, or GLAMER, an old term of popular ſuperſtition in Scotland, denoting a kind of magical miſt believed to be raiſed by ſorcerers, and which deluded their ſpectators with viſions of things which had no real exiſtence, altered the appearance of thoſe which really did exiſt, &c.—The eaſtern nations have a ſimilar ſuperſtition, as we may learn from the Arabian Nights Entertainments and other works of Oriental fiction.

GLAND, in anatomy. See ANATOMY, n° 128.

GLANDERS. See FARRIERY, § xvi.

GLANDORE, a town of Ireland, ſituated in the county of Cork and province of Munſter, near the harbour of that name.

GLANDORE-Harbour, ſituated two leagues weſt of the Galley-head in the county of Cork, province of Munſter, N. Lat. 51. 22. W. Lon. 8. 56. Between this harbour and Roſs the coaſt continues high and bold, with only two ſmall coves; that to the eaſt called *Millcove*, and that to the weſt *Cowcove*. This harbour lies three miles weſt of Roſs; and though ſmall, is an exceeding good one; near it is a caſtle of the ſame name, and on the upper-end is a deep and dangerous glin, called the *Leap*. Glandore gives title of earl to the family of Croſbie.

GLANDORP (Matthias), a learned phyſician, born in 1595, at Cologn, in which town his father was a ſurgeon. After receiving a doctor's degree at Padua, and viſiting the principal towns of Italy, he ſettled at Bremen in 1618, where he practiſed phyſic and ſurgery with ſo much ſucceſs, that he was made phyſician to the republic and to the archbiſhop. He publiſhed at Bremen, *Speculum chirurgorum*, *Methodus medendæ paronychiæ*, *Tractatus de polypo narium affectu graviſſimo*, and *Gazophylacium polypuſium fontiviſſimo*; which four pieces were collected and publiſhed, with his life prefixed, at London, in 4to, 1729. Glandorp died young; and it muſt ſuggeſt a high opinion of his abilities, that, notwithſtanding the great improvements in all branches of ſcience, his works ſhould be deemed worthy a republication 100 years after his death.

GLANDULÆ *Renales*. See ANATOMY, n° 100.

GLANS, in anatomy, the tip or button of the penis, or that part covered with the prepuce, called alſo *balanus*. See ANATOMY, p. 739, col. 1.

GLANS is alſo uſed to denote the tip or extremity of the clitoris, from its reſemblance, both in form and uſe, to that of the penis. See ANATOMY, p. 739, col. 2.

GLANVIL (Joſeph), a learned and ingenious, but fanciful and credulous writer in the 17th century, was born at Plymouth in 1636, and bred at Oxford. He became a great admirer of Mr Baxter, and a zealous perſon for a commonwealth. After the reſtoration, he publiſhed *The vanity of dogmatizing*; was choſen a fellow of the Royal Society; and, taking orders in 1662, was preſented to the vicarage of Frome-Selwood in Somerſetſhire. This ſame year he publiſhed his *Lux Orientalis*; in 1665, his *Sceſſis Scientifica*; and in the year following, *Some philoſophical conſiderations touching the being of witches and witchcraft*, and other pieces on the ſame ſubject. In 1660, he publiſhed *Plus ultra*; or, *The progreſs and advancement of knowledge ſince the days of Ariſtotle*. He likewiſe publiſhed

A

Glaris, Glaſgow.

A ſeaſonable recommendation and defence of reaſon; and *Philoſophia Pia*, or *A diſcourſe of the religious temper and tendencies of the experimental philoſophy*. In 1678 he was made a prebendary of Worceſter, and died in 1680.

GLARIS, one of the cantons of Swiſſerland, is bounded on the eaſt, partly by the Griſons, and partly by the territory of Sargans; on the north, by the bailiwick of Gaſter, and by the lake Wahleſtatt; on the eaſt, by the canton of Schwits; and on the ſouth, by part of the canton of Uri, and part of the league of the Griſons. It is a mountainous country, being entirely within the Alps.

GLARIS, a town of Swiſſerland, capital of the canton of the ſame name, is ſeated in a plain, at the foot of high craggy mountains. The ſtreets are large, and the houſes kept in good repair. It has ſome public buildings; among which are two churches, one in the middle of the town, and the other without upon an eminence. On this eminence there is a cavern, with groteſque figures formed by the water that drops therein. The general aſſemblies of the country are held here on the firſt Sundays in May, where all the males above the age of ſixteen are obliged to appear. Both the Calviniſts and the Roman Catholics are tolerated in this town, and they have divine ſervice by turns in the ſame church. It is ſeated on the river Lint, E. Long. 9. 13. N. Lat. 47. 6.

GLASGOW, a large city of Lanerkſhire or Clydeſdale in Scotland, ſituated in W. Long. 4. 30. N. Lat. 55. 50.

Concerning the foundation of this city we have no authentic records. The word in the Gaelic language ſignifies a *gray ſmith*; from whence it has been inferred, that ſome ſpot in the moſt ancient part of the city was originally the reſidence of ſome blackſmith who had become eminent in his profeſſion, ſo that the place went by his name.

1 Biſhopric of Glaſgow, when founded.

In the year 560, a biſhopric is ſaid to have been founded here by Saint Mungo, or Kentigern, ſuppoſed to be the ſon of Thamates, daughter of Loth king of the Picts; but in what ſtate the town at that time was, is altogether uncertain. Moſt probably the prieſts and diſciples who attended St Kentigern would contribute conſiderably towards its advancement: the aged and infirm, who were unfit for the purpoſes of war, or ſuch as were religiouſly inclined, would come and ſettle round the habitation of the holy man, in order to have the benefit of his prayers; and as a number of miracles were ſaid to have been wrought at his tomb, the ſame cauſes would ſtill contribute to the increaſe of the town.

Hiſtory has not informed us of the name of the prince who founded and endowed the biſhopric of Glaſgow in favour of St Kentigern. But from an abſtract of the life of Kentigern (contained in Mr Innes's Critical Eſſay on the Ancient Inhabitants of Scotland), which was written in the 12th century, we learn, that the ſaint being ill uſed by Marken or Marcus, one of the kings of the Britons, retired into Wales. On the invitation of Ruderic, however, one of Marken's ſucceſſors, he returned to Glaſgow, and enjoyed the ſee till 601, when he died. He was buried in the church of Glaſgow, where his monument is ſtill to be ſeen; and we find him marked among the ſaints in the Roman kalendar, January 13. 578. Glaſgow.

The immediate ſucceſſors of Kentigern were Baldrede and Conwal. The firſt eſtabliſhed a religious houſe at Inchinnan; the ſecond went into Lothian to preach to the Saxons; and both of them are ranked as ſaints in the Roman kalendar, Baldrede on the 6th of March 608, and Conwal on the 18th of May 612. From this time, however, till the 1115, we have no diſtinct accounts concerning the city or biſhopric of Glaſgow. We find then, that David I. king of Scotland made an attempt to retrieve the people from a ſtate of groſs barbarity into which they were fallen, and reſtored to the church thoſe lands of which ſhe had been robbed. The only account we have of the tranſactions with regard to Glaſgow, during that period, is in the inquiſition made by David concerning the church-lands of Glaſgow, and is as follows. "This church, by the divine appointment, admitted St Kentigern into the biſhopric, who furniſhed large draughts of knowledge to thoſe thirſting after heavenly things, &c. But a fraudulent deſtroyer, employing his common wiles, brought in, after a long ſeries of time, unaccountable ſcandals into the Cumbrian church. For after St Kentigern and many of his ſucceſſors were removed to heaven, various diſturbances every where ariſing, not only deſtroyed the church and her poſſeſſions, but, waſting the whole country, drove the inhabitants into exile. Theſe good men being deſtroyed, various tribes of different nations flocking in from ſeveral quarters, poſſeſſed the foreſaid deſerted country; but being of different origins, and varying from each other in their language and cuſtoms, and not eaſily agreeing among themſelves, they followed the manners of the Gentiles, rather than thoſe of the true faith. The inhabitants of which unhappy and abandoned country, though living like brutes, the Lord, who chooſes that none ſhould periſh, vouchſafed to viſit in mercy," &c.

2 Barbarity of the people in the time of David I.

From the year 1116 to the reformation, the records of the biſhopric are tolerably complete. The moſt remarkable particulars furniſhed by them are the following.

In 1136, John Achaius, choſen biſhop of Glaſgow by David I. built and adorned a part of the cathedral, which he ſolemnly conſecrated on the 9th of July. The king was preſent at the ceremony; and beſtowed on the church the lands of Perdeyk, now Patrick. This prelate alſo divided the dioceſe into the two archdeanries of Glaſgow and Teviotdale; and eſtabliſhed the offices of dean, ſubdean, chancellor, treaſurer, ſacriſt, chantor, and ſucceſſor; and ſettled a prebendary upon each of them, out of the donatives he received from the king.

In 1174, Joceline, abbot of Melroſe, was elected biſhop, and conſecrated by Eſkilus, biſhop of Lunden in Denmark, the Pope's legate for that kingdom, on the 1ſt of June 1175. He rebuilt the cathedral, or rather made an addition to the church already built by John Achaius. He alſo procured a charter from William king of Scotland, erecting Glaſgow into a royal borough, and likewiſe a charter for a fair to be held there annually for eight days.

3 Glaſgow erected into a royal borough.

In 1335, John Lindſay, biſhop of Glaſgow, was

Glaſgow. killed in an engagement at ſea with the Engliſh, as he was returning home from Flanders. His ſucceſſor, William Rae, built the ſtone bridge over the Clyde. In the time of Matthew Glendoning, who was elected biſhop in 1387, the great ſpire of the church, which had been built only of wood, was conſumed by lightning. The biſhop intended to have built another of ſtone; but was prevented by death, in 1408, from accompliſhing his purpoſe. His ſucceſſor, William Lauder, laid the foundation of the veſtry of the cathedral, and built the great tower of ſtone as far as the firſt battlement. The great tower of the epiſcopal palace was founded about the year 1437, on which biſhop Cameron expended a great deal of money.

4 Glaſgow erected into a regality, and the univerſity founded.

In 1447, William Turnbull, a ſon of the family of Bedrule in Roxburgh-ſhire, was choſen biſhop. He obtained from king James II. in 1450, a charter erecting the town and the patrimony of the biſhops into a regality. He alſo procured a bull from pope Nicholas V. for erecting an univerſity within the city, which he endowed, and on which he alſo beſtowed many privileges. He died in 1454, leaving behind him a moſt excellent character. The eſtabliſhment of the college contributed more than any thing that had been formerly done towards the enlargement of the town. Before this time the town ſeems to have been inconſiderable. Mr Gibſon * is of opinion, that the number of its inhabitants did not exceed 1500. But though the eſtabliſhment of the univerſity greatly increaſed the number of inhabitants, it in fact deſtroyed the freedom of the town. Biſhop Turnbull ſeems to have made a point of it with king James II. that the city of Glaſgow, with the biſhops foreſt, ſhould be erected into a regality in his favour; which was accordingly done at the time above-mentioned; and this at once took away all power from the citizens, and transferred it to the biſhop. As the powers of the biſhop, however, were reckoned by Turnbull inſufficient to convey to the members of the univerſity all that freedom which he wiſhed to beſtow upon them, he therefore obtained from the king a great many privileges for them; and afterwards he himſelf, with the conſent of his chapter, granted them many more.

* *Hiſt. of Glaſgow*, P. 74.

5 Which deſtroys the freedom of the city.

6 Population of Glaſgow increaſed by the univerſity.

The good effects of the eſtabliſhment of the college were very ſoon obvious in Glaſgow. The number of inhabitants increaſed exceedingly; the high ſtreet, from the convent of the Black friars, to where the croſs is now placed, was very ſoon filled up; the ancient road which led to the common being too far diſtant for the conveniency of the new inhabitants, the Gallows-gate began to be built. Soon after, the collegiate church of the bleſſed Mary (now the Tron-church) being founded by the citizens, occaſioned the Trongate ſtreet to be carried to the weſtward as far as the church. The reſt of the city increaſed gradually towards the bridge, by the building of the Salt-market ſtreet. The borough-roads, and the cattle that grazed on the commons, were now found inſufficient to maintain the increaſed number of inhabitants; for which reaſon a greater degree of attention than formerly was paid to the fiſhing in the river. Many poor people ſubſiſted themſelves by this occupation; they were incorporated into a ſociety; and in order that they might be at hand to proſecute their buſineſs, they built a conſiderable part of the ſtreet now called the *Bridge gate*, but at that time *Fiſhers-gate*. Glaſgow.

Notwithſtanding all this, however, the city of Glaſgow did not for a long time attain the rank among the other towns of Scotland which it holds at preſent. In 1556, it held only the 11th place among them, as appears by queen Mary's taxation. The introduction of the reformed religion proved for ſome time prejudicial to the opulence of the city. The money which had formerly been expended among the citizens by the biſhop and his clergy, was now diverted into other channels: the advantages reſulting from the univerſity were alſo for a time loſt; for as the reformers generally deſpiſed human learning, the college was in a manner deſerted.

7 Great part of the town deſtroyed by a fire.

In the time of the civil wars, Glaſgow ſuffered ſeverely. To the miſchiefs attending inteſtine diſcord, were added a peſtilence and famine; and to complete their misfortunes, a violent fire broke out in June 1652, which deſtroyed the greateſt part of the Saltmarket, Trongate, and High-ſtreet. The fronts of the houſes at that time were moſtly of wood, ſo that they became an eaſy prey to the flames. The fire continued with great violence for the ſpace of 18 hours; by which a great many of the inhabitants were ruined, the habitations of almoſt 1000 families being totally deſtroyed. On this account collections were made thro' different parts of the country; and to prevent ſuch accidents for the future, the fronts were built with free ſtone, which abounds in the neighbourhood.

By the charter given to biſhop Turnbull in 1450, the citizens had been deprived of the power of electing their own magiſtrates, which was thenceforth exerciſed by the biſhop; which, however, was not done without ſome reſiſtance on the part of the inhabitants. After the reformation was introduced into Scotland, we find this power exerciſed by the citizens, the biſhop, the earl of Lenox, and others. The idea that the town was a biſhop's borough, and not a royal free borough, gave occaſion to this unſettled manner of appointing the magiſtracy; and though, in 1633, they were declared to be a royal free borough by the parliament, yet their freedom of election was afterwards diſturbed by the privy-council, by Cromwell, and the duke of York. But on the 4th of June 1690, the town was declared free by a charter of William and Mary; and in confirmation of this charter it was inſerted in the act of parliament, dated June 14th the ſame year, that they ſhould have power to elect their own magiſtrates as fully and freely, in all reſpects, as the city of Edinburgh or any other royal borough within the kingdom; which freedom of election ſtill continues.

8 Glaſgow declared free by William and Mary.

By the aſſeſſment of the boroughs in 1695, we find the city of Glaſgow reckoned the ſecond in Scotland in point of wealth, which place it ſtill continues to hold. To account for this great increaſe of wealth, we muſt obſerve, that for a long time, even before the reſtoration of Charles II. the inhabitants of Glaſgow had been in poſſeſſion of the ſale both of raw and refined ſugars for the greateſt part of Scotland; they had a privilege of diſtilling ſpirits from their molaſſes, free of all duty and exciſe; the herring fiſhery was alſo carried on to what was at that time thought a very conſiderable extent; they were the only people in Scotland who made

9 Great increaſe of its wealth.

ſoap;

Glaſgow

ſoap; and they ſent annually ſome hides, linen, &c to Briſtol, from whence they brought back in exchange, a little tobacco, ſugar, and goods of the manufacture of England, with which they ſupplied a conſiderable part of the kingdom. From the year 1707, however, in which the union between Scotland and England took place, we may date the proſperity of Glaſgow. By the union, the American trade was laid open to the inhabitants: and ſo ſenſible were they of their advantageous ſituation, that they began almoſt inſtantly to proſecute that commerce; an aſſiduous application to which, ever ſince, hath greatly contributed to raiſe the city to the pitch of affluence and ſplendor which it at preſent enjoys. The city was now greatly enlarged; and as the community were ſenſible of the inconvenience that attended the want of a ſufficiency of water in the river for carrying on their commerce, they reſolved to have a port of their own nigher the mouth of the river. At firſt, they thought of making their harbour at Dumbarton: but as this is a royal borough, the magiſtrates oppoſed it; becauſe they thought that the influx of ſailors and others, occaſioned by the harbour, would be ſo great, that a ſcarcity of proviſions would be occaſioned. The magiſtrates and town-council of Glaſgow, therefore, purchaſed ſome lands on the ſouth ſide of the river Clyde for this purpoſe; and ſo expeditious were they in making their harbour, and rearing their town, that in 1710 a bailie was appointed for the government of Port-Glaſgow. It is now a very conſiderable pariſh, and lies 21 miles nigher the mouth of Clyde than Glaſgow.

10 ection of ort-Glaſ- w.

In 1725, Mr Campbell, the member of parliament for Glaſgow, having given his vote for having the malt-tax extended over Scotland, a riot enſued among the lower claſs of people. In this diſturbance, Mr Campbell's furniture was deſtroyed, and ſome exciſemen were maltreated for attempting to take an account of the malt. General Wade, who commanded the forces in Scotland, had ſent two companies of ſoldiers, under the command of captain Buſhel, to prevent any diſturbance of this kind. Captain Buſhel drew up his men in the ſtreet, where the multitude pelted them with ſtones. He firſt endeavoured to diſperſe the mob by firing with powder only: but this expedient failing, he ordered his men to load their pieces with ball; and, without the ſanction of the civil authority, commanded them to fire four different ways at once. By this diſcharge about 20 perſons were killed and wounded; which enraged the multitude to ſuch a degree, that having procured ſome arms, they purſued Buſhel and his men to the caſtle of Dumbarton, about 14 miles diſtant. General Wade being informed of this tranſaction, aſſembled a body of forces, and being accompanied by Duncan Forbes, lord advocate, took poſſeſſion of the town: the magiſtrates were apprehended and carried priſoners to Edinburgh; but on an examination before the lords, their innocence clearly appeared, upon which they were immediately diſmiſſed. Buſhell was tried for murder, convicted, and condemned; but, inſtead of ſuffering the penalties of law, he was indulged with a pardon, and promoted in the ſervice. Mr Campbell petitioned the Houſe of Commons for an indemnification of his loſſes: a bill was paſſed in his favour; and this, together with ſome other expences incurred in the affair, coſt the town 9000 l. Sterling. Glaſgow.

11 ſturbance out the iſe-bill.

During the time of the rebellion in 1745, the citizens of Glaſgow gave proof of their attachment to revolution principles, by raiſing two battalions, of 600 men each, for the ſervice of government. This piece of loyalty, however, had like to have coſt them dear. The rebels, in their journey ſouth, took a reſolution to plunder and burn the city: which would probably have been done, had not Mr Cameron of Lochiel threatened, in that caſe, to withdraw his clan. A heavy contribution, however, was laid on. The city was compelled to pay 5000 l. in money, and 500 l. in goods; and on the return of the rebels from England, they were obliged to furniſh them with 12,000 linen ſhirts, 6000 cloth coats, 6000 pairs of ſhoes, 6000 pairs of hoſe, and 6000 bonnets. Theſe goods, with the money formerly paid them, the expence of raiſing and ſubſiſting the two city-battalions, and the charge of maintaining the rebel army in free quarters for ten days, coſt the community about 14,000 l. ſterling; 10,000 l. of which they recovered in 1749, by an application to parliament.

12 Change of manners and method of living.

About the year 1750, a very conſiderable change took place in the manner of living among the inhabitants of Glaſgow. Till this time, an attentive induſtry, and a frugality bordering upon parſimony, had been their general characteriſtic; the ſeverity of the ancient manners prevailed in its full vigour: But now, when an extenſive commerce and increaſed manufactures had produced wealth, the ideas of the people were enlarged, and ſchemes of trade and improvement were adopted which people would formerly have been denominated madmen if they had undertaken; a new ſtyle was introduced in living, dreſs, building, and furniture; wheel-carriages were ſet up, public places of entertainment were frequented, and an aſſembly-room, ball-room, and playhouſe, were built by ſubſcription; and from this time we may date all the improvements that have taken place, not only in Glaſgow, but all over the weſt of Scotland. The beſt method, however, of eſtimating the growing improvement of any town, is by the frequency of their applications for aſſiſtance to parliament; we ſhall therefore enumerate the acts of parliament which have been paſſed in favour of the city of Glaſgow ſince the year 1750. In 1753, an act paſſed for repairing ſeveral roads leading into the city of Glaſgow.—In 1756, an act for erecting and ſupporting a light-houſe in the iſland of Little Cumray, at the mouth of the Clyde, and for rendering the navigation of the frith and river more ſafe and commodious.—In 1759, an act for improving the navigation of the river Clyde to the city of Glaſgow, and for building a new bridge acroſs the river.—In 1767, the people of Glaſgow having propoſed to make a ſmall cut or canal from the frith of Forth to that of Clyde, for the conveniency of their trade to the eaſtern ſide of the iſland, ſeveral gentlemen at Edinburgh, and throughout different parts of the kingdom, propoſed that this canal ſhould be executed upon a much larger ſcale than what had been originally projected. An act was accordingly obtained, and the canal executed in the manner deſcribed under the

13 Acts of Parliament in favour of the city.

Glaſgow. the article CANAL.—In 1770, another act was obtained for improving the navigation of the river, building the bridge, &c. being an amendment of the former act for theſe purpoſes.—In 1771, an act for making and widening a paſſage from the Salt-market to St Andrew's church; for enlarging and completing the church-yard of that church, and likewiſe for building a convenient exchange or ſquare in the city; alſo for amending and explaining the former act relative to the navigation of the Clyde.—An act for making and maintaining a navigable canal and waggon-way from the collieries in the pariſhes of Old and New Monkland, to the city of Glaſgow. This laſt canal, which was undertaken with a view to reduce the price of coals, has not been attended with the deſired effect; but the other improvements have been productive of very great advantages.

14 Deſcription of the city.

The moſt ancient part of the city ſtands on a riſing ground. The foundation of the cathedral is 104 feet higher than the bed of the river; and the deſcent from the high ground reaches to about 100 yards below the college. The reſt of the city is built chiefly upon a plain, bounded ſouthward by the Clyde, and northward by a gentle ridge of hills lying in a parallel direction with that river. Theſe grounds till lately conſiſted of gardens and fields; but are now covering with buildings, in conſequence of the increaſing wealth and population of the city. The ſtreets are all clean and well paved; and ſeveral of them interſecting one another at right angles, produce a very agreeable effect. The four principal ſtreets, croſſing one another in that manner, divide the city nearly into four equal parts; and the different views of them from the croſs, or centre of interſection, have an air of great magnificence. The houſes, conſiſting of four or five floors in height, are built of hewn ſtone, generally in an exceeding good taſte, and many of them elegant. The moſt remarkable public buildings are,

15 Of the cathedral.

1. *The Cathedral* or *High Church*, is a magnificent building, and its ſituation greatly to its advantage, as it ſtands higher than any part of the city. It has been intended to form a croſs, though the traverſe part has never been finiſhed. The great tower is founded upon four large maſſy pillars, each of them about 30 feet in circumference. The tower itſelf is 25½ feet ſquare within; and is furrounded by a balluſtrade, within which riſes an octangular ſpire terminated by a fane. The tower upon the weſt end is upon the ſame level, but appears not to have been finiſhed, though it is covered over with lead. In this tower is a very large bell 11 feet four inches in diameter. The principal entry was from the weſt; the gate 11 feet broad at the baſe, and 17 feet in height. The weſt end of the choir is now appropriated for a place of divine worſhip; and is divided from the remaining part by a ſtone partition, which is incloſed by another ſtone-wall parting it from the nave. It is impoſſible to form an adequate idea of the awful ſolemnity of the place occaſioned by the loftineſs of the roof and the range of pillars by which the whole is ſupported.

The nave of the church riſes four ſteps higher than the choir; and on the weſt ſide ſtood the organ-loft, formerly ornamented with a variety of figures, but now defaced. The pillars here are done in a better taſte than thoſe in the choir, and their capitals are ornamented with fruits. The arched roof of the altar is ſupported by five pillars, over which was a fine terrace walk, and above it a large window of curious workmanſhip, but now ſhut up. On the north ſide of the altar is the veſtry, being a cube of 28 feet, the roof arched and vaulted at top, and ſupported by one pillar in the centre of the houſe. Arched pillars from every angle terminate in the grand pillar, which is 19 feet high. The lower part of the ſouth croſs is made uſe of as a burying place for the clergy of the city; and is by much the fineſt piece of workmanſhip in the whole building. It is 55 feet long, 28 broad, and 15 high; arched and vaulted at top, and ſupported by a middle range of pillars, with their capitals highly ornamented; correſponding to which are columns adjoining to the walls, which as they riſe, ſpring into ſemi-arches, and are every where met at acute angles by their oppoſites, and are ornamented with carvings at the cloſing and croſſing of the lines. At the eaſt end of the choir you deſcend by flights of ſteps upon each ſide into paſſages which, in former times, were the principal entries to the burying vault which is immediately under the nave. It is now made uſe of as a pariſh church for the barony of Glaſgow; and is full of pillars, ſome of them very maſſy, which ſupport the arched roof: but it is a very uncomfortable place for devotion. The ſpace under the altar and veſtry, though now made uſe of as a burying-place by the heritors of the barony, was formerly, according to tradition, employed for keeping of the relics; and indeed, from the beautiful manner in which this place is finiſhed, one would imagine that it had not been deſtined for common uſe. Here is ſhown the monument of St Mungo, or Kentigern, with his figure lying in a cumbent poſture. Glaſgow.

The whole length of the cathedral within the walls is 284 feet, its breadth 65; the height of the choir, from the floor to the canopy, 90 feet; the height of the nave, 85 feet; the height of the middle tower, 220 feet. This fabric was begun by John Achaius in 1123, and conſecrated in 1136; and continued by ſucceeding biſhops till ſuch time as it was finiſhed in the manner in which it ſtands at preſent. The wealth of the ſee of Glaſgow, however, was not ſufficient for ſo great an undertaking, ſo that they were obliged to have recourſe to all the churches of Scotland for aſſiſtance in it.

This venerable edifice was in danger of falling a victim to the frenzy of fanaticiſm in 1579; and owed its preſervation to the ſpirit and good ſenſe of the tradeſmen, who, upon hearing the beat of drum for collecting the workmen appointed to demoliſh it, flew to arms, and declared that the firſt man who pulled down a ſingle ſtone ſhould that moment be buried under it.

Near the cathedral are the ruins of the biſhop's palace or caſtle, incloſed with a wall of hewn ſtone by archbiſhop James Beaton; the great tower built by archbiſhop Cameron in 1426.

2. *St Andrew's Church* was begun by the community in 1739, and finiſhed in 1756. It is the fineſt piece of modern architecture in the city; and is built after the model of St Martin's in the Fields, London, whoſe architect was the famous Gibbs. The length of 16 St Andrew's church.

Glaſg w. the church is 104 feet, and its breadth 66. It has a fine arched roof, well ornamented with figures in ſtucco, and ſuſtained by ſtone-columns of the Corinthian order. Correſpondent to the model, it has a place for the altar on the eaſt, in which is a very ancient Venetian window; but the altar-place being ſeated, makes this end appear to no great advantage. The fronts of the galleries and the pulpit are done in mahogany in a very elegant manner. The ſpire by no means correſponds with the reſt of the building; and, inſtead of being an ornament, diſgraces this beautiful fabric. Its height is 170 feet.

Beſides the cathedral (which contains three congregations) and St Andrew's church, there is a number of others, as the College-church, Ram's-horn, Tron, Wynd, &c. together with an Engliſh chapel, Highland church, ſeveral ſeceding meeting-houſes, and others for ſectaries of various denominations.

17 The college. 3. *The College.* The front of this building extends along the eaſt ſide of the high ſtreet, and is upwards of 330 feet long. The gate at the entrance is decorated with ruſtics, and over it are the king's arms. The building conſiſts of two principal courts or ſquares. The firſt is 88 feet long and 44 broad. The weſt ſide is elevated upon ſtone pillars, on which are placed pilaſters ſupporting the Doric entablature, and ornamented with arches forming a piazza. Above theſe is the public hall; the aſcent to which is by a double flight of ſteps incloſed by a handſome ſtone balluſtrade, upon the right of which is placed a lion, and on the left an unicorn, cut in free ſtone. The ſpire ſtands on the eaſt ſide, is 135 feet high, and has a very good clock. Under this is the gateway into the inner and largeſt court, which is 103 feet long and 79 broad. Over the entry, in a niche, is a ſtatue of Mr Zacharias Boyd, who was a benefactor to the univerſity. On the eaſt ſide of the court is a narrow paſſage leading into a handſome terrace walk, gravelled, 122 feet long by 64 feet broad. This walk is incloſed to the eaſt by an iron palliſade, in the centre of which is a gate leading into the garden. This laſt conſiſts of ſeven acres of ground, laid out in walks for the recreation of the ſtudents; and there is alſo a botanic garden. On the ſouth ſide of the walk ſtands the library; a very neat edifice, well conſtructed for the purpoſe intended, and containing a very valuable collection of books. Underneath are preſerved in caſes all the Roman inſcriptions found on Graham's Dike, together with altars and other antiquities collected from different parts of Scotland.—Adjoining, there is an obſervatory, well furniſhed with aſtronomical inſtruments. The college alſo poſſeſſes, by bequeſt, the late Dr Hunter's famous anatomical preparations, library, and muſeum: And in the department of natural philoſophy, it is furniſhed with an apparatus which is univerſally acknowledged to be the moſt extenſive and uſeful in Britain, and which owes its perfection to the liberality and unremitting labour of Mr Anderſon the preſent profeſſor of that ſcience.

18 Town houſe, &c. 4. *The Tolbooth*, or *Town-Houſe*, is a magnificent and extremely elegant building. The front is adorned with a range of Ionic pilaſters; and is elevated on ſtrong ruſticated pillars with arches, forming a piazza for merchants and others to ſhelter themſelves from the weather when met upon buſineſs. One of the apartments was the aſſembly-hall; a neat room, 47 feet long, and 24 in breadth and height, finiſhed in a good taſte, though too ſmall for the city. The town-hall is a very ſpacious and loſty apartment, 52 feet long by 27 broad, and 24 in height. It is finiſhed in a very grand manner: the ceiling is divided into different compartments well ornamented. In it are full-length portraits of king James VI. and VII. Charles I. and II. William and Mary, queen Anne, king George I. II. and III. and Archibald duke of Argyle in his juſticiary robes. The two laſt are by Ramſay. Oppoſite to the front of this building is the exchange-walk, which is well paved with free ſtone, and incloſed from the ſtreet by ſtone pillars. In the middle of this area is an equeſtrian ſtatue of king William III. placed upon a lofty pedeſtal, and ſurrounded with an iron rail.—In 1781, the exchange under the piazzas was greatly enlarged, by taking down the lower part of the town-hall and aſſembly-room; and at the ſame time, by a tontine ſcheme entered into by the inhabitants, a moſt elegant coffee-room was added, with a ſuite of buildings adjoining for the purpoſes of a tavern and hotel, aſſembly-room, and offices for notaries and underwriters. The aſſembly-room, however, being found to be ſtill too ſmall, a ſubſcription of above L. 5000 has been raiſed by a ſimilar plan of a tontine for building a new one, which is propoſed to be erected in the north corner of one of the new ſtreets which join Ingram-ſtreet to Argyle-ſtreet. Glaſgow.

19 Guild-hall. 5. *The Guild-Hall* or *Merchant's Houſe.* This building is ſituated upon the ſouth ſide of Bridgegate ſtreet; and is in length 82 feet, in breadth 31. The great hall, which is the whole length and breadth of the building, is ſo capacious, that it is better adapted for the reception of great and numerous aſſemblies than any other in the city. This houſe is adorned with a very elegant ſpire 200 feet high.

20 Town's hoſpital. 6. *The Town's Hoſpital* is a very neat building, conſiſting of two wings and a large front: the length 156 feet, the breadth of the centre 30 feet, and the depth of the wings 68 feet. Behind the building is an infirmary 127 feet long by 25 feet broad, the aſcent to which is by a flight of ſteps. The lower part of this building is appointed for the reception of lunatics. The area between the buildings is large, which, with the agreeable open ſituation of the hoſpital on the river, muſt conduce to the health of the inhabitants.

21 Grammar ſchool. 7. *The Grammar School* is ſituated on the new taken in grounds to the north-weſt of the town, and was built in 1787. It is a very handſome building, containing a large hall, and ſix airy commodious teaching rooms. In this ſchool there are four claſſes, the courſe being four years: each claſs is carried on the whole four years by the ſame maſter; ſo that, there being no rector, each maſter is head of the ſchool one year in rotation. It is under the direction of a committee of the town council; who aſſiſted by the profeſſors, clergy, and other perſons of learning, frequently viſit it during the ſeſſion; and at an annual examination, prizes of books are diſtributed to the ſcholars according to their reſpective merits. The preſent number of ſcholars is above 300.—The building is not yet entirely finiſhed; and the rooms which are not occupied by the Latin claſſes are intended for teaching writing, arithmetic, drawing, &c.

22 New Bridge. 8. *The New Bridge* is built in an elegant manner. It

Glaſgow

It is 32 feet wide; with a commodious foot-way for paſſengers, five feet broad on each ſide, raiſed above the road made for carriages, and paved with free ſtone. This bridge is about 500 feet in length; and conſiſts of ſeven arches, the faces of which are wrought in ruſtic, with a ſtrong block cornice above. The arches ſpring but a little way above low-water mark; which, though it renders the bridge ſtronger than if they ſprung from taller piers, diminiſhes its beauty. Between every arch there is a ſmall circular one: theſe break the force of the water when the river riſes to a flood, and add to the ſtrength of the whole. The parapet-wall or breaſt-work is cut out in the Chineſe taſte; and the two ends are finiſhed off with a ſweep. This bridge was begun in 1768, and finiſhed in 1772.

23 Markets, &c.

9. *The Markets in King's Street* are juſtly admired, as being the completeſt of their kind in Britain. They are placed on both ſides of the ſtreet. That on the eaſt ſide, appropriated entirely for butcher-meat, is 112 feet in length, and 67 in breadth. In the centre is a ſpacious gateway, decorated on each ſide with coupled Ionic columns, ſet upon their pedeſtals, and ſupporting an angular pediment. At the north end is a very neat hall belonging to the incorporation of butchers, the front ornamented with ruſtics and a pediment. The markets upon the weſt ſide of the ſtreet conſiſt of three courts, ſet apart for fiſh, mutton, and cheeſe. The whole of the front is 173 feet, the breadth 46 feet; in the centre of which, as on the oppoſite ſide, is a very ſpacious gateway of the Dorick order, ſupporting a pediment. This is the entry to the mutton-market. Each of the other two has a well-proportioned arch faced with ruſticks for their entrance. All theſe markets are well paved with free-ſtone; have walks all round them; and are covered over for ſhelter by roofs ſtanding upon ſtone piers, under which the different commodities are expoſed to ſale. They have likewiſe pump-wells within, for cleanſing away all the filth; which render the markets always ſweet and agreeable. Theſe markets were erected in 1754.

10. *The Herb-Market* is neat and commodious; and the principal entry is decorated with columns. It is ſituated in the Candleriggs, and is laid out in the ſame manner with the markets in King's-ſtreet.

24 Guard-houſe.

11. *The Guard-Houſe* is a very handſome building, with a piazza formed by arches, and columns of the Ionic order ſet upon their pedeſtals. It was originally ſituated on the Highſtreet, at the corner of the Candleriggs ſtreet: but has lately been carried near half way up the Candleriggs, where it occupies the ground on which the weigh-houſe formerly ſtood, and is made larger and more commodious than it was before. An excellent new weigh houſe has been erected at the head of the Candleriggs: And at the foot of the Candleriggs, or corner next the Highſtreet, where the Guard-houſe was formerly ſituated, a ſuperb new hotel has been built, containing 75 fire-rooms.

The moſt remarkable public charities in Glaſgow are,

25 Public charities.

1. *Muirhead's* or *St Nicholas's Hoſpital*. This was originally appointed to ſubſiſt 12 old men and a chaplain: but its revenues have, from ſome unknown cauſes, been loſt; ſo that no more of them now remains than the paltry ſum of 139l. 2s. 5d. Scots money, 128l. of which is annually divided among four old men, at the rate of 2l. 13s. 4d. each.

Glaſgow.

2. *Hutcheſon's Hoſpital*, was founded and endowed in 1639 by George Hutcheſon of Lamb-hill notary-public, and Mr Thomas Hutcheſon his brother who was bred a preacher, for the maintenance of old men and orphans. The funds of this hoſpital were increaſed by James Blair merchant in Glaſgow in 1710, and by ſubſequent donations. From the ſale of ſome of their lands which lay convenient for building, and the riſe of the reſt, the income is now above L. 1400, which is diſtributed in penſions to old people from L. 3 to L. 20, and in educating about 50 children.

3. *The Merchants Houſe* likewiſe diſtributes in penſions and other charities about L. 800 yearly.

4. *The Town's Hoſpital*, above deſcribed, was opened for the reception of the poor on the 15th of November 1733. The funds whence this hoſpital is ſubſiſted are, the general ſeſſion, the town-council, the trades houſe and merchants houſe, the intereſt of money belonging to their funds, which are ſums that have been mortified for the uſe of the houſe. Theſe ſupplies, however, are found inſufficient to defray the expences of the houſe; for which reaſon an aſſeſſment is annually made upon the inhabitants in the following manner. The magiſtrates nominate 12, 14, or ſometimes more gentlemen of known integrity and character, who have a liſt laid before them of all the inhabitants in town. This liſt they divide into 16 or 18 columns. Each of theſe columns contains the names of ſuch inhabitants as carry on trade to a certain extent, or are ſuppoſed to be well able to pay the ſum affixed to the particular column in which their names are inſerted. If it is neceſſary to raiſe 500l. for inſtance, then each name, in every ſeparate column, is valued at as much as the fortunes of the perſons in each particular column are ſuppoſed to be. If 1000l. or more is to be raiſed, it is only continuing a proportional increaſe through the whole of the columns. The higheſt ſum that ever was thus raiſed, was 12s. 6d. upon every thouſand pounds that each perſon was ſuppoſed to be worth. The number of people maintained in this hoſpital are about 620.

5. *Wilſon's Charity* for the education of boys, was founded by George Wilſon, who in 1778 left 3000l. for that purpoſe. This fund is now conſiderably increaſed, and gives education and clothing to 48 boys, who each continues four years, ſo that 12 are admitted annually.

Beſides theſe, there are many public ſchools for the education of children; as well as many inſtitutions of private ſocieties for the purpoſe of relieving the indigent and inſtructing youth, ſuch as *Graham's Society*, *Buchanan's Society*, the *Highland Society*, &c. Theſe laſt put annually 20 boys apprentices to trades, and during the firſt three years give them clothing and education.

26 Members of the univerſity.

The univerſity of Glaſgow owes its origin, as we have already obſerved, to biſhop Turnbull. The inſtitution conſiſted at firſt of a rector, a dean of faculty, a principal who taught theology, and three profeſſors of philoſophy; and, ſoon after this, the civil and canon laws were taught by ſome clergymen. From the time of its eſtabliſhment in 1450 to the reformation in 1560, the college was chiefly frequented by thoſe who were intended for the church; its members were all eccleſiaſtics, and its principal ſupport was derived from the church. The reformation brought the univerſity to the

Glaſgow. the verge of deſtruction: maſters, ſtudents, and ſervants, all forſook it. The magiſtrates were ſo ſenſible of the loſs which the community had ſuſtained by this deſertion, that they endeavoured to reſtore it in 1572, by beſtowing upon it conſiderable funds, and preſcribing a ſet of regulations for its management. Theſe, however, proved inſufficient; for which reaſon king James VI. erected it anew, by a charter called the *Nova Erectio*, in 1577, and beſtowed upon it the teinds of the pariſh of Govan. The perſons who were to compoſe the new univerſity were, a principal, three profeſſors of philoſophy, four ſtudents burſars, one œconomus, a principal's ſervant, a janitor, and cook.

Since the year 1577, the funds of the univerſity have been conſiderably increaſed by the bounty of kings and the donations of private perſons. The profeſſors have therefore alſo been increaſed; ſo that at preſent the univerſity of Glaſgow conſiſts of a chancellor, rector, dean of faculty, principal, and 14 profeſſors (ſix of them in the gift of the crown), together with burſars, &c. The archbiſhop of Glaſgow was formerly chancellor of the univerſity *ex officio*; at preſent, the chancellor is choſen by the rector, dean of faculty, principal, and maſters.

The chancellor, as being the head of the univerſity, is the fountain of honour, and in his name are all academical degrees beſtowed. The office of rector is to exerciſe that academical juriſdiction in diſputes among the ſtudents themſelves, or between the ſtudents and citizens, which is beſtowed upon the greater part of the univerſities in Europe. He is choſen annually in the *comitia*; that is, in a meeting in which all the ſtudents, as well as the other members of the univerſity, have a voice. Immediately after his admiſſion, he has been in uſe to chooſe certain perſons as his aſſeſſors and counſellors in his capacity of judge: and, in former periods, it was cuſtomary to name the miniſters of Glaſgow, or any other gentlemen who had no connection with the univerſity; but, for a great while paſt, the rector has conſtantly named the dean of faculty, the principal, and maſters, for his aſſeſſors; and he has always been, and ſtill is, in the daily practice of judging in the cauſes belonging to him, with the advice of his aſſeſſors. Beſides theſe powers as judge, the rector ſummons and preſides in the meetings of the univerſity for the election of his ſucceſſor; and he is likewiſe in uſe to call meetings of the profeſſors for drawing up addreſſes to the king, electing a member to the general aſſembly, and other buſineſs of the like kind.

The dean of faculty has, for his province, the giving directions with regard to the courſe of ſtudies; the judging, together with the rector, principal, and profeſſors, of the qualifications of thoſe who deſire to be created maſters of arts, doctors of divinity, &c.; and he preſides in meetings which are called by him for theſe purpoſes. He is choſen annually by the rector, principal, and maſters.

The principal and maſters, independent of the rector and dean, compoſe a meeting in which the principal preſides; and as they are the perſons for whoſe behoof chiefly the revenue of the college was eſtabliſhed, the adminiſtration of that revenue is therefore committed to them. The revenue ariſes from the teinds of the pariſh of Govan, granted by king James VI. in 1557; from the teinds of the pariſhes of Renfrew and Kilbride, granted by the ſame monarch in 1617, and confirmed by king Charles I. on the 28th of June 1630; from the teinds of the pariſhes of Calder, Old and New Monkland, conveyed to them by a charter from Charles II. in 1670; from a tack of the archbiſhoprick; and from ſeveral donations conferred by private perſons. Glaſgow.

The college of Glaſgow, for a very conſiderable time after its erection, followed the mode of public teaching which is common even to this day in Oxford and Cambridge, and in many other univerſities throughout Europe; that is, each profeſſor gave a few lectures every year, *gratis*, upon the particular ſcience which he profeſſed: but, in place of this, the profeſſors have, for a great while paſt, adopted the mode of private teaching; that is, they lecture and examine two hours every day during the ſeſſion, viz. from the 10th of October to the 10th of June; a method which comes much cheaper to the ſtudent, as he has it in his power, if he is attentive, to acquire his education without being under the neceſſity of employing a tutor. They have alſo private claſſes, in which they teach one hour *per* day. The number of ſtudents who have attended this college for ſeveral years paſt, has been upwards of 500 each ſeaſon.

27
Hiſtory of the trade of Glaſgow.

The trade of Glaſgow is ſaid to have been firſt promoted by one Mr William Elphinſtone in 1420. This trade was moſt probably the curing and exporting of ſalmon; but the firſt authentic document concerning Glaſgow as a trading city is in 1546. Complaints having been made by Henry VIII. king of England, that ſeveral Engliſh ſhips had been taken and robbed by veſſels belonging to Scotland, an order of council was iſſued, diſcharging ſuch captures for the future; and among other places made mention of in this order is the city of Glaſgow. The trade which at that time they carried on could not be great. It probably conſiſted of a few ſmall veſſels to France loaded with pickled ſalmon; as this fiſhery was, even then, carried on to a conſiderable extent, by Glaſgow, Renfrew, and Dumbarton. Between the year 1630 and 1660, a very great degree of attention ſeems to have been paid to inland commerce by the inhabitants of Glaſgow. Principal Baillie informs us, that the increaſe of Glaſgow ariſing from this commerce was exceedingly great. The exportation of ſalmon and of herrings were alſo continued and increaſed. In the war between Britain and Holland during the reign of Charles II. a privateer was fitted out in Clyde to cruiſe againſt the Dutch. She was called the *Lion of Glaſgow*, Robert M'Allan commander; and carried five pieces of cannon, and 60 hands.

A ſpirit of commerce appears to have ariſen among the inhabitants of Glaſgow between the year 1660 and 1707. The citizens who diſtinguiſhed themſelves moſt during this period were Walter Gibſon and John Anderſon. Gibſon cured and packed in one year 300 laſts of herrings, which he ſent to St Martin's in France on board of a Dutch veſſel, called the *St Agate*, of 450 tons burthen; his returns were brandy and ſalt. He was the firſt who imported iron from Stockholm into Clyde. Anderſon is ſaid to have been the firſt who imported white-wines.

Whatever their trade was at this time, it could not be conſiderable: the ports to which they were

Glaſgow. obliged to trade lay all to the eaſtward: the circumnavigation of the iſland would therefore prove an almoſt unſurmountable bar to the commerce of Glaſgow; and of conſequence the people on the eaſt coaſt would be poſſeſſed of almoſt all the commerce of Scotland. The union with England opened a field for commerce for which the ſituation of Glaſgow, ſo convenient in reſpect to the Atlantic, was highly advantageous. Since that time the commerce of the eaſt coaſt has declined, and that of the weſt increaſed to an amazing degree. No ſooner was the treaty of union ſigned, than the inhabitants of Glaſgow began to proſecute the trade to Virginia and Maryland; they chartered veſſels from Whitehaven, ſent out cargoes of goods, and brought back tobacco in return. The method in which they at firſt proceeded in this trade, was certainly a very prudent one. A ſupercargo went out with every veſſel. He bartered his goods for tobacco, until ſuch time as he had either ſold off his goods, or procured as much tobacco as was ſufficient to load his veſſel. He then immediately ſet out on his return; and if any of his goods remained unſold, he brought them home with him. While they continued to trade in this way, they were of great advantage to the country, by the quantity of manufactures which they exported; their own wealth began to increaſe; they purchaſed ſhips of their own; and, in 1718, the firſt veſſel of the property of Glaſgow croſſed the Atlantic. Their imports of tobacco were now conſiderable, and Glaſgow began to be looked upon as a conſiderable port; the tobacco trade at the ports of Briſtol, Liverpool, and Whitehaven, was obſerved to dwindle away; the people of Glaſgow began to ſend tobacco to theſe places, and to underſell the Engliſh even in their own ports. Thus the jealouſy of the latter was ſoon excited, and they took every method in their power to deſtroy the trade of Glaſgow. The people of Briſtol preſented remonſtrances to the commiſſioners of the cuſtoms at London againſt the trade of Glaſgow, in 1717. To theſe remonſtrances the merchants of Glaſgow ſent ſuch anſwers to the commiſſioners as convinced them that the complaints of the Briſtol merchants were without foundation. But in 1721, a moſt formidable confederacy was entered into by almoſt all the tobacco-merchants in South Britain againſt the trade of Glaſgow. Thoſe of London, Liverpool, and Whitehaven, preſented ſeverally to the Lords of the Treaſury, petitions, arraigning the Glaſgow merchants of frauds in the tobacco trade. To theſe petitions the Glaſgow people gave in replies; and the Lords of the Treaſury, after a full and impartial hearing, were pleaſed to diſmiſs the cauſe with the following ſentence: "That the complaints of the merchants of London, Liverpool, and Whitehaven, were groundleſs; and that they proceeded from a ſpirit of envy, and not from a regard to the intereſt of trade, or of the king's revenue."

But the efforts of theſe gentlemen did not ſtop here. They brought their complaints into the Houſe of Commons. Commiſſioners were ſent to Glaſgow in 1722, who gave in their reports to the houſe in 1723. The merchants ſent up diſtinct and explicit anſwers to theſe reports; but ſuch was the intereſt of their adverſaries, that theſe anſwers were diſregarded. New officers were appointed at the ports of Greenock and Port-Glaſgow, whoſe private inſtructions ſeem to have been, to ruin the trade if poſſible, by putting all imaginable hardſhips upon it. Hence it languiſhed till the year 1735; but after that time it began to revive, tho' even after its revival it was carried on but ſlowly for a conſiderable ſpace of time. Glaſgow.

At laſt, however, the active and enterpriſing ſpirit of the merchants, ſeconding the natural advantages of their ſituation, prevailed over all oppoſition; and the American trade continued to flouriſh and increaſe until the year 1775, inſomuch that the importation of tobacco into Clyde that year from the provinces of Virginia, Maryland, and Carolina, amounted to 57,143 hogsheads. But ſince the breach with America, this trade has now fallen greatly off, and very large ſums are ſaid to remain due to the merchants from that quarter of the world.

28 Manufactures of Glaſgow.

With regard to the manufactures of Glaſgow, Mr Gibſon is of opinion that the commerce to America firſt ſuggeſted the idea of introducing them, in any conſiderable degree at leaſt. The firſt attempts in this way were about the year 1725, and their increaſe for ſome time was very ſlow, nor did they begin to be conſiderable till great encouragement was given by the legiſlature to the linen manufacture in Scotland. The firſt cauſes of the ſucceſs of this manufacture were the act of parliament in 1748, whereby the wearing of French cambrics was prohibited under ſevere penalties; that of 1751, allowing weavers in flax or hemp to ſettle and exerciſe their trades any where in Scotland free from all corporation-dues; and the bounty of three-halfpence per yard on all linens exported at and under 18d. per yard. Since that time a ſpirit of manufacture has been excited among the inhabitants of Glaſgow; and great variety of goods, and in very great quantity, have been manufactured. Checks, linen, and linen and cotton, are manufactured to a great extent. Printed linens and cottons were begun to be manufactured in 1738; but they only made garments till 1754, when handkerchiefs were firſt printed.

Incles were firſt made here about the year 1732. The engine-looms uſed at that time were ſo inconvenient, and took up ſo much time in making the goods, that the Dutch, who were the only people poſſeſſed of the large incle-looms, were almoſt ſolely in poſſeſſion of this manufacture. Mr Hervey, who began this branch in Glaſgow, was ſo ſenſible of the diſadvantages under which it laboured, that he went over to Holland; and in ſpite of the care and attention which the Dutch took to conceal their methods of manufacturing, he brought over with him from Haerlem two of their looms, and one of their workmen. This Dutchman remained ſome years in Glaſgow; but on ſome diſguſt he went to Manchester, and inſtructed the people there in the method of carrying on the manufacture.

In 1757, carpets were begun to be made, and are now carried on to a conſiderable extent. Hunters cloths, Engliſh blankets, and other goods of the ſame kind, are alſo made.

Beſides theſe, a great variety of articles are manufactured at Glaſgow, of which our limits will not permit us to enter into a detail, ſuch as ſoap, refining of ſugar, iron-mongery, braſs, jewellery, glaſs both common and white, pottery, &c. Types for printing are made in this city by Dr Wilſon and Sons, equal,

Glaſgow. if not ſuperior, in beauty to any others in Britain. Printing of books was firſt begun here by George Anderſon about the year 1638. But there was no good printing in Glaſgow till the year 1735, when Robert Urie printed ſeveral books in a very elegant manner. The higheſt perfection, however, to which printing hath yet been carried in this place, or perhaps in any other, was by the late Robert and Andrew Foulis, (who began in the year 1740); as the many correct and ſplendid editions of books printed by them in different languages ſufficiently teſtify. Some of their claſſics, it is ſaid, are held in ſuch high eſteem abroad, as to ſell nearly at the price of ancient MSS. The ſame gentlemen alſo eſtabliſhed an academy of painting; but the wealth of Scotland being unequal to the undertaking, it has been ſince given up.

Since the ſtagnation of the American trade, already noticed, the merchants of Glaſgow have turned their attention more to manufactures, which have of late, eſpecially that of cottons and muſlins, increaſed in a very rapid degree, and bid fair for putting the city in a more flouriſhing condition than ever it was before. The manufacturing-houſes, the influx of people for carrying on the manufactures, the means and encouragement which theſe afford to population, and the wealth thence derived by individuals as well as accruing to the community, have all tended lately to increaſe, and are daily increaſing, the extent of the city and the elegance of the buildings. Beſides various improvements in the old ſtreets, ſeveral handſome new ones as well as new ſquares have been added. The ſite of theſe new buildings is the tract of riſing ground already mentioned as the north boundary of the town previous to its late extenſion. The weſtern part of it, which is perfectly level, is occupied by a ſpacious ſquare, denominated *George's Square*; two ſides of which are built and inhabited, and a third begun. The graſs plot in the middle is incloſed with a handſome iron railing. The ſquare is deficient in regularity; the houſes on the weſt ſide being a ſtory higher than thoſe of the eaſt; but in other reſpects it is very neat. To the eaſt of this ſquare are ſeveral new ſtreets laid out and paved, and ſome of them almoſt completely built on. The principal, though as yet the moſt incomplete of thoſe ſtreets, is Ingram Street, which runs from eaſt to weſt. From this the others begin; ſome of them being carried northward up the hill, others going ſouthward and joining the main ſtreet of the town. One of the fineſt of theſe croſs ſtreets is Hutcheſon Street.

29 The river, &c. The ſouth boundary of the city was mentioned to be the Clyde. Over this river there are two bridges. One of them, the Old Bridge, built about 400 years ago by archbiſhop Rae, but ſince repaired and partly rebuilt, conſiſts of eight arches; and connects the ſuburbs of Gorbals, ſituated on the oppoſite ſide of the river, with the city. The other is the New Bridge, deſcribed above.—On the banks of the river, eaſtward, is the Green; a ſpot appropriated to the uſe of the inhabitants, with conveniences for waſhing and drying linens, and with agreeable and extenſive walks for recreation.

On the ſame or ſouth ſide of the town, weſtward, is the Broomie-law, where the quay is ſituated. Till within theſe few years, the river here and for ſeveral miles diſtance, was ſo ſhallow and ſo obſtructed by ſhoals, as to admit only of ſmall craft from Greenock, Port-Glaſgow, and the Highlands: but of late it has been cleared and deepened ſo as to admit veſſels of conſiderable burden; and it is intended to make the depth as nearly equal as poſſible to that of the canal, in order that the veſſels from Ireland and the weſt coaſt may not be induced excluſively to aſcend the weſt end of the canal and deliver their goods at Canal-baſon, but may come up Clyde and unload at the Broomie-law. Glaſgow, Glaſs.

30 Government, revenue, &c. of the city. The government of the city of Glaſgow is veſted in a provoſt and three bailies, a dean of guild, deacon-conveener, and a treaſurer, with a common council of 13 merchants and 12 mechanics. The provoſt and two of the bailies muſt, by the ſet of the borough, be elected from the merchant rank, and the other bailie from the trades rank, *i. e.* the mechanics. The provoſt is, from courteſy and cuſtom, ſtyled *lord provoſt*. He is properly lord of the police of the city, preſident of the community, and is *ex officio* a juſtice of the peace for both the borough and county.

31 Number of inhabitants. The revenue of the town ariſes from a duty upon all grain and meal brought into the city (which tax is denominated *the ladles*); from the rents of lands and houſes the property of the community; from an impoſt of two pennies Scots upon every Scots pint of ale or beer brewed, inbrought, or ſold, within the city; from certain dues payable out of the markets; from the rents of the ſeats in churches; from the dues of cranage at the quay, at the weigh-houſe, &c. As to the tonnage on the river, the pontage of the bridge, and ſtatute-work; theſe, making no part of the city revenue, are kept ſeparate and diſtinct under the management of commiſſioners appointed by act of parliament.

About the time of the union, the number of inhabitants in Glaſgow was reckoned about 14,000. In 1765, when a new diviſion of the pariſhes took place, they were eſtimated at 28,000. In 1785, when an accurate ſurvey was made, the number was about 36,000; beſides the ſuburbs, containing the Calton, Gorbals, and Anderſton, reckoned about 1000. Since that time many new buildings, as above noticed, have been erected, and the city has become conſiderably more populous, but no exact eſtimate has been made; though it is generally thought that the number of inhabitants cannot at preſent be computed at much leſs than 50,000.

GLASS, a tranſparent, brittle, factitious body, produced from ſand melted in a ſtrong fire with fixed alkaline ſalts, lead, ſlags, &c. till the whole becomes perfectly clear and fine. The word is formed of the Latin *glaſtum*, a plant called by the Greeks *iſatis*, by the Romans *vitrum*, by the ancient Britons *guadum*, and by the Engliſh *woad*. We find frequent mention of this plant in ancient writers, particularly Cæſar, Vitruvius, Pliny, &c. who relate, that the ancient Britons painted or dyed their bodies with glaſtum, guadum, vitrum, &c. i. e. with the blue colour procured from this plant. And hence, the factitious matter we are ſpeaking of came to be called *glaſs*; as having always ſomewhat of this bluiſhneſs in it.

I. History of glaſs-making. At what time the art of glaſs-making was firſt invented, is altogether uncertain. Some imagine it to have

Glaſs. have been invented before the flood: but of this we have no direct proof, though there is no improbability in the ſuppoſition; for we know, that it is almoſt impoſſible to excite a very violent fire, ſuch as is neceſſary in metallurgic operations, without vitrifying part of the bricks or ſtones wherewith the furnace is built. This indeed might furniſh the firſt hints of glaſs-making; tho' it is alſo very probable, that ſuch imperfect vitrifications would be obſerved a long time before people thought of making any uſe of them.

Neri traces the antiquity of glaſs as far back as the time of Job. That writer, ſpeaking of the value of wiſdom, chap. xxviii. verſe 17. ſays, that gold and *cryſtal* cannot equal it. But this word, which Neri will have to ſignify factitious glaſs, is capable of a great many different interpretations, and properly ſignifies only whatever is beautiful or tranſparent. Dr Merret will have the art to be as ancient as that of pottery or the making of bricks, for the reaſons already given, viz. that by all vehement heat, ſome imperfect vitrifications are produced. Of this kind undoubtedly was the foſſile glaſs mentioned by Ferant. Imperator. to have been found under-ground where great fires had been. But it is evident, that ſuch imperfect vitrifications might have paſſed unnoticed for ages; and conſequently we have no reaſon to conclude from thence, that the art of glaſs-making is of ſuch high antiquity.

The Egyptians boaſt, that this art was taught them by their great Hermes. Ariſtophanes, Ariſtotle, Alexander, Aphrodiſeus, Lucretius, and St John the divine, put it out of all doubt that glaſs was uſed in their days. Pliny relates, that it was firſt diſcovered accidentally in Syria, at the mouth of the river Belus, by certain merchants driven thither by a ſtorm at ſea; who being obliged to continue there, and dreſs their victuals by making a fire on the ground, where there was great plenty of the herb kali; that plant, burning to aſhes, its ſalts mixed and incorporated with the ſand, or ſtones fit for vitrification, and thus produced glaſs; and that, this accident being known, the people of Sidon in that neighbourhood eſſayed the work, and brought glaſs into uſe; ſince which time the art has been continually improving. Be this as it will, however, the firſt glaſs-houſes mentioned in hiſtory were erected in the city of Tyre, and here was the only ſtaple of the manufacture for many ages. The ſand which lay on the ſhore for about half a mile round the mouth of the river Belus was peculiarly adapted to the making of glaſs, as being neat and glittering; and the wide range of the Tyrian commerce gave an ample vent for the productions of the furnace.

Mr Nixon, in his obſervations on a plate of glaſs, found at Herculaneum, which was deſtroyed A. D. 80, on which occaſion Pliny loſt his life, offers ſeveral probable conjectures, as to the uſes to which ſuch plates might be applied. Such plates, he ſuppoſes, might ſerve for *ſpecula*, or looking-glaſſes; for Pliny, in ſpeaking of Sidon, adds, *ſiquidem etiam ſpecula excogitaverat:* the reflection of images from theſe ancient ſpecula being effected by beſmearing them behind, or tinging them through with ſome dark colour. Another uſe in which they might be employed, was for adorning the walls of their apartments, by way of wainſcot, to which Pliny is ſuppoſed to refer by his *vitreæ cameræ*, lib. xxxvi. cap. 25. § 64. Mr Nixon farther conjectures, that theſe glaſs plates might be uſed for windows, as well as the lamina of lapis *ſpecularis* and *phengites*, which were improvements in luxury mentioned by Seneca, and introduced in his time, Ep. xc. However, there is no poſitive authority relating to the uſage of glaſs-windows earlier than the cloſe of the third century: *Manifeſtius eſt* (ſays Lactantius *), *mentem eſſe, quæ per oculos ea quæ ſunt oppoſita, tranſpiciat, quaſi per feneſtras lucente vitro aut ſpeculari lapide obductas.* Glaſs.

* *De opif. Dei*, cap. 8.

The firſt time we hear of glaſs made among the Romans was in the reign of Tiberius, when Pliny relates that an artiſt had his houſe demoliſhed for making glaſs malleable, or rather flexible; though Petronius Arbiter, and ſome others, aſſure us, that the emperor ordered the artiſt to be beheaded for his invention.

It appears, however, that before the conqueſt of Britain by the Romans, glaſs-houſes had been erected in this iſland, as well as in Gaul, Spain, and Italy. Hence, in many parts of the country are to be found annulets of glaſs, having a narrow perforation and thick rim, denominated by the remaining Britons *gleinen naidreedh*, or *glaſs adders*, and which were probably in former times uſed as amulets by the druids †. It can ſcarcely be queſtioned that the Britons were ſufficiently well verſed in the manufacture of glaſs, to form out of it many more uſeful inſtruments than the glaſs-beads. Hiſtory indeed aſſures us, that they did manufacture a conſiderable quantity of glaſs veſſels. Theſe, like their annulets, were moſt probably green, blue, yellow, or black, and many of them curiouſly ſtreaked with other colours. The proceſs in the manufacture would be nearly the ſame with that of the Gauls or Spainards. The ſand of their ſhores being reduced to a ſufficient degree of fineneſs by art, was mixed with three-fourths of its weight of their nitre (much the ſame with our kelp), and both were melted together. The metal was then poured into other veſſels, where it was left to harden into a maſs, and afterwards replaced in the furnace, where it became tranſparent in the boiling, and was afterwards figured by blowing, or modelling in the lath, into ſuch veſſels as they wanted.

† See *Anguinum*, *Ovum*.

It is not probable that the arrival of the Romans would improve the glaſs manufacture among the Britons. The taſte of the Romans at that time was juſt the reverſe of that of the inhabitants of this iſland. The former preferred ſilver and gold to glaſs for the compoſition of their drinking veſſels. They made indeed great improvements in their own at Rome, during the government of Nero. The veſſels then formed of this metal rivalled the bowls of porcelain in their dearneſs, and equalled the cups of cryſtal in their tranſparency. But theſe were by far too coſtly for common uſe; and therefore, in all probability, were never attempted in Britain. The glaſs commonly made uſe of by the Romans was of a quality greatly inferior; and, from the fragments which have been diſcovered at the ſtations or towns of either, appear to have conſiſted of a thick, ſometimes white, but moſtly blue green, metal.

According to venerable Bede, artificers ſkilled in making *glaſs* for windows were brought over into England in the year 674, by abbot Benedict, who were employed in glazing the church and monaſtery of Weremouth. According to others, they were firſt brought

over

Glaſs. over by Wilfrid, biſhop of Worceſter, about the ſame time. Till this time the art of making ſuch *glaſs* was unknown in Britain; though *glaſs* windows did not begin to be common before the year 1180: till this period they were very ſcarce in private houſes, and conſidered as a kind of luxury, and as marks of great magnificence. Italy had them firſt, next France, from whence they came into England.

Venice, for many years, excelled all Europe in the fineneſs of its *glaſſes*; and in the thirteenth century, the Venetians were the only people that had the ſecret of making cryſtal looking *glaſſes*. The great *glaſs*-works were at Muran, or Murano, a village near the city, which furniſhed all Europe with the fineſt and largeſt *glaſſes*.

The *glaſs* manufacture was firſt begun in England in 1557: the finer ſort was made in the place called Crutched Friars, in London; the fine flint *glaſs*, little inferior to that of Venice, was firſt made in the Savoy-houſe, in the Strand, London. This manufacture appears to have been much improved in 1635, when it was carried on with ſea-coal or pit-coal inſtead of wood, and a monopoly was granted to Sir Robert Manſell, who was allowed to import the fine Venetian flint *glaſſes* for drinking, the art of making which was not brought to perfection before the reign of William III. But the firſt *glaſs* plates, for looking-*glaſſes* and coach windows, were made, 1673, at Lambeth, by the encouragement of the duke of Buckingham; who, in 1670, introduced of the manufacture of fine *glaſs* into England, by means of Venetian artiſts, with amazing ſucceſs. So that within a century paſt, the French and Engliſh have not only come up to, but even ſurpaſſed the Venetians, and we are now no longer ſupplied from abroad.

The French made a conſiderable improvement in the art of *glaſs*, by the invention of a method to caſt very large plates, till then unknown, and ſcarce practiſed yet by any but themſelves and the Engliſh. That court applied itſelf with a laudable induſtry to cultivate and improve the *glaſs* manufacture. A company of *glaſs*-men was eſtabliſhed by letters patent; and it was provided by an arret, not only that the working in *glaſs* ſhould not derogate any thing from nobility, but even that none but nobles ſhould be allowed to work therein.

An extenſive manufactory of this elegant and valuable branch of commerce was firſt eſtabliſhed in Lancaſhire, about the year 1773, through the ſpirited exertions of a very reſpectable body of proprietors, who were incorporated by an act of parliament. From thoſe various difficulties conſtantly attendant upon new undertakings, when they have to contend with powerful foreign eſtabliſhments, it was for ſome time conſiderably embarraſſed; but Government, of late, having taken off ſome reſtrictions that bore hard upon it, and made ſome judicious regulations relative to the mode of levying the exciſe duty, it now bids fair to rival, if not ſurpaſs, the moſt celebrated continental manufactures, both with reſpect to the quality, brilliancy, and ſize of its productions.

2 Theory of vitrification uncertain.

With regard to the theory of vitrification, we are almoſt totally in the dark. In general, it ſeems to be that ſtate in which ſolid bodies are, by the vehement action of fire, fitted for being diſſipated or carried off in vapour. In all vitrifications there is a plentiful evaporation; and if any ſolid ſubſtance is carried off in vapour by the intenſe heat of a burning ſpeculum, a vitrification is always obſerved previouſly to take place. The difference, then, between the ſtate of fuſion and vitrification of a ſolid body we may conceive to be, that in the former the element of fire acts upon the parts of the ſolid in ſuch a manner as only to disjoin them, and render the ſubſtance fluid; but in vitrification the fire not only disjoins the particles, but combines with them in a latent ſtate into a third ſubſtance; which, having now as much fire as it can contain, can receive no further change from that element except being carried off in vapour. Glaſs.

But though we are unable to effect this change upon ſolid bodies without a very violent heat, it is otherwiſe in the natural proceſſes. By what we call *cryſtallization*, nature produces more perfect glaſſes than we can make with our furnaces. Theſe are called *precious ſtones*; but in all trials they diſcover the eſſential properties of glaſs, and not of ſtones. The moſt diſtinguiſhing property of glaſs is its reſiſting the force of fire, ſo that this element cannot calcine or change it as it does other bodies, but can only melt it, and then carry it off in vapours. To this laſt all the precious ſtones are ſubject. The diamond (the hardeſt and moſt ponderous of them all) is diſſipable in a leſs degree of heat than what would diſſipate common glaſs. Nor can it be any objection to this idea, that ſome kinds of glaſs are capable of being converted into a kind of porcelain by a long-continued cementation with certain materials. This change happens only to thoſe kinds of glaſs which are made of alkaline ſalt and ſand; and Dr Lewis hath ſhown that this change is produced by the diſſipation of the ſaline principle, which is the leaſt fixed of the two. Glaſs, therefore, we may ſtill conſider as a ſubſtance upon which the fire has no other effect than either to melt or diſſipate it in vapour.

The other properties of glaſs are very remarkable, ſome of which follow.

3 Remarkable properties of glaſs.

1. It is one of the moſt elaſtic bodies in nature. If the force with which glaſs balls ſtrike each other be reckoned 16, that wherewith they recede by virtue of their elaſticity will be nearly 15.

2. When glaſs is ſuddenly cooled, it becomes exceedingly brittle; and this brittleneſs is ſometimes attended with very ſurpriſing phenomena. Hollow bells made of annealed glaſs, with a ſmall hole in them, will fly to pieces by the heat of the hand only, if the hole by which the internal and external air communicate be ſtopped with a finger. Lately, however, ſome veſſels made of ſuch annealed glaſs have been diſcovered, which have the remarkable property of reſiſting very hard ſtrokes given from without, though they ſhiver to pieces by the ſhocks received from the fall of very light and minute bodies dropped into their cavities. Theſe glaſſes may be made of any ſhape; all that needs be obſerved in making them is, that their bottom be thicker than their ſides. The thicker the bottom is, the eaſier do the glaſſes break. One whoſe bottom is three fingers breadth in thickneſs, flies with as much eaſe at leaſt as the thineſt glaſs. Some of theſe veſſels have been tried with ſtrokes of a mallet ſufficient to drive a nail into wood tolerably hard, and have held good without breaking. They have alſo

4 Surpriſing fragility of annealed glaſs.

Glaſs. reſiſted the ſhock of ſeveral heavy bodies let fall into their cavities, from the height of two or three feet; as muſket-balls, pieces of iron, or other metal, pyrites, jaſper, wood, bone, &c. But this is not ſurpriſing, as other glaſſes of the ſame ſhape and ſize will do the ſame: but the wonder is, that taking a ſhiver of flint of the ſize of a ſmall pea, and letting it fall into the glaſs only from the height of three inches, in about two ſeconds the glaſs flies, and ſometimes at the very moment of the ſhock; nay, a bit of flint no larger than a grain, dropped into ſeveral glaſſes ſucceſſively, though it did not immediately break them, yet when ſet by, they all flew in leſs than three quarters of an hour. Some other bodies produce the ſame effect with flint; as ſapphire, diamond, porcelain, hard tempered ſteel; alſo marbles ſuch as boys play with, and likewiſe pearls.

Theſe experiments were made before the Royal Society; and ſucceeded equally when the glaſſes were held in the hand, when they were reſted on a pillow, put in water, or filled with water. It is alſo remarkable, that the glaſſes broke upon having their bottoms ſlightly rubbed with the finger, though ſome of them did not fly till half an hour after the rubbing. If the glaſſes are every where extremely thin, they do not break in theſe circumſtances.

5 Attempts to account for it.

Some have pretended to account for theſe phenomena, by ſaying, that the bodies dropped into the veſſels cauſe a concuſſion which is ſtronger than the coheſive force of the glaſs, and conſequently that a rupture muſt enſue. But why does not a ball of iron, gold, ſilver, or copper, which are perhaps a thouſand times heavier than the flint, produce the ſame effect? It is becauſe they are not elaſtic. But ſurely iron is more elaſtic than the end of one's finger.—Mr Euler has endeavoured to account for theſe appearances from his principles of percuſſion. He thinks that this experiment entirely overthrows the opinion of thoſe who meaſure the force of percuſſion by the *vis viva*, or abſolute apparent ſtrength of the ſtroke. According to his principles, the great hardneſs and angular figure of the flint, which makes the ſpace of contact with the glaſs extremely ſmall, ought to cauſe an impreſſion on the glaſs vaſtly greater than lead, or any other metal; and this may account for the flint's breaking the veſſel, though the bullet, even falling from a conſiderable height, does no damage.—Hollow cups made of green bottle-glaſs, ſome of them three inches thick at the bottom, were inſtantly broken by a ſhiver of flint, weighing about two grains, though they had reſiſted the ſhock of a muſket-ball from the height of three feet.

That Mr Euler's theory cannot be concluſive more than the other, muſt appear evident from a very ſlight conſideration. It is not by angular bodies alone that the glaſſes are broken. The marbles with which children play are round, and yet they have the ſame effect with the angular flint. Beſides, if it was the mere force of percuſſion which broke the glaſſes, undoubtedly the fracture would always take place at the very inſtant of the ſtroke; but we have ſeen, that this did not happen ſometimes till a very conſiderable ſpace of time had elapſed. It is evident, therefore, that this effect is occaſioned by the putting in motion ſome ſubtile fluid with which the ſubſtance of the glaſs is filled; and that the motions of this fluid, when once excited in a particular part of the glaſs, ſoon propagate themſelves through the whole or greateſt part of it, by which means the coheſive power becomes at laſt too weak to reſiſt them. There can be little doubt that the fluid juſt now mentioned is that of electricity. It is known to exiſt in glaſs in very great quantity; and it alſo is known to be capable of breaking glaſſes, even when annealed with the greateſt care, if put into too violent a motion. Probably the cooling of glaſs haſtily may make it more electric than is conſiſtent with its coheſive power, ſo that it is broken by the leaſt increaſe of motion in the electric fluid by friction or otherwiſe. This is evidently the caſe when it is broken by rubbing with the finger; but why it ſhould alſo break by the mere contact of flint and the other bodies above mentioned, has not yet been ſatisfactorily accounted for.

Glaſs.

6 Rotation of glaſs-tubes before a fire.

A moſt remarkable phenomenon alſo is produced in glaſs tubes placed in certain circumſtances. When theſe are laid before a fire in an horizontal poſition, having their extremities properly ſupported, they acquire a rotatory motion round their axis, and alſo a progreſſive motion towards the fire, even when their ſupports are declining from the fire, ſo that the tubes will move a little way up hill towards the fire. When the progreſſive motion of the tubes towards the fire is ſtopped by any obſtacle, their rotation ſtill continues. When the tubes are placed in a nearly upright poſture, leaning to the right hand, the motion will be from eaſt to weſt; but if they lean to the left hand, their motion will be from weſt to eaſt; and the nearer they are placed to the perfectly upright poſture, the leſs will the motion be either way.

If the tube is placed horizontally on a glaſs plane, the fragment, for inſtance, of coach window-glaſs, inſtead of moving towards the fire, it will move from it, and about its axis in a contrary direction to what it had done before; nay, it will recede from the fire, and move a little up-hill when the plane inclines towards the fire.—Theſe experiments are recorded in the Philoſophical Tranſactions *. They ſucceeded beſt with tubes about 20 or 22 inches long, which had in each end a pretty ſtrong pin fixed in cork for an axis.

* N° 476. § 1.

7 Attempts to account for it.

The reaſon given for theſe phenomena, is the ſwelling of the tubes towards the fire by the heat, which is known to expand all bodies. For, ſay the adopters of this hypotheſis, granting the exiſtence of ſuch a ſwelling, gravity muſt pull the tube down when ſupported near its extremities; and a freſh part being expoſed to the fire, it muſt alſo ſwell out and fall down, and ſo on.—But, without going farther in the explanation of this hypotheſis, it may be here remarked, that the fundamental principle on which it proceeds is falſe: for though fire indeed makes bodies expand, it does not increaſe them in weight; and therefore the ſides of the tube, though one of them is expanded by the fire, muſt ſtill remain *in equilibrio*; and hence we muſt conclude, that the cauſes of theſe phenomena remain yet to be diſcovered.

4. Glaſs is leſs dilatable by heat than metalline ſubſtances, and ſolid glaſs-ſticks are leſs dilatable than tubes. This was firſt diſcovered by Col. Roy, in making experiments in order to reduce barometers to a greater degree of exactneſs than hath hitherto been found

Phil. Tran. vol. lxvii. p. 663.

Glaſs.

found practicable; and ſince his experiments were made, one of the tubes 18 inches long, being compared with a ſolid glaſs-rod of the ſame length, the former was found by a pyrometer to expand four times as much as the other, in a heat approaching to that of boiling oil.—On account of the general quality which glaſs has of expanding leſs than metal, M. de Luc recommends it to be uſed in pendulums: and he ſays it has alſo this good quality, that its expanſions are always equable, and proportioned to the degrees of heat; a quality which is not be found in any other ſubſtance yet known.

Ibid. ol. lxviii. 474.

5. Glaſs appears to be more fit for the condenſation of vapours than metallic ſubſtances. An open glaſs filled with water, in the ſummer-time, will gather drops of water on the outſide, juſt as far as the water in the inſide reaches; and a perſon's breath blown on it, manifeſtly moiſtens it. Glaſs alſo becomes moiſt with dew, when metals do not. See Dew.

6. A drinking glaſs partly filled with water, and rubbed on the brim with a wet finger, yields muſical notes, higher or lower as the glaſs is more or leſs full; and will make the liquor friſk and leap. See Harmonica.

7. Glaſs is poſſeſſed of very great electrical virtues. See Electricity, *paſſim*.

8 aterials glaſs.

Materials for Making of Glass. The materials whereof glaſs is made, we have already mentioned to be ſalt and ſand or ſtones.

ee *Sal-*

1. The ſalt here uſed is procured from a ſort of aſhes brought from the Levant, called *polverine*, or *rochetta*; which aſhes are thoſe of a ſort of water-plant called *kali**, cut down in ſummer, dried in the ſun, and burnt in heaps, either on the ground, or on iron grates; the aſhes falling into a pit, grow into a hard maſs, or ſtone, fit for uſe. It may alſo be procured from common kelp, or the aſhes of the *fucus veſiculoſus*. See Kelp, and Fucus.

To extract the ſalt, theſe aſhes, or polverine, are powdered and ſifted, then put into boiling water, and there kept till one third of the water be conſumed; the whole being ſtirred up from time to time, that the aſhes may incorporate with the fluid, and all its ſalts be extracted: then the veſſel is filled up with new water, and boiled over again, till one half be conſumed; what remains is a ſort of ley, ſtrongly impregnated with ſalt. This ley, boiled over again in freſh coppers, thickens in about 24 hours, and ſhoots its ſalt; which is to be ladled out, as it ſhoots, into earthen pans, and thence into wooden vats to drain and dry. This done, it is groſsly pounded, and thus put in a ſort of oven, called *calcar*, to dry. It may be added, that there are other plants, beſides kali and fucus, which yield a ſalt fit for glaſs: ſuch are the common way-thiſtle, bramble, hops, wormwood, woad, tobacco, fern, and the whole leguminous tribe, as peaſe, beans, &c.

Pearl-aſhes form a leading flux in the manufacture of glaſs, and moſtly ſupply the place of the Levant-aſhes, the barillas of Spain, and many other kinds, which were formerly brought here for making both glaſs and ſoap. See *Pearl-Aſhes*.

There are other fluxes uſed for different kinds of glaſs, and for various purpoſes, as calcined lead, nitre, ſea-ſalt, borax, arſenic, ſmiths clinkers, and wood-aſhes, containing the earth and lixiviate ſalts as produced by incineration. With regard to theſe ſeveral fluxes, we may obſerve, in general, that the more calx of lead, or other metallic earth, enters into the compoſition of any glaſs, ſo much the more fuſible, ſoft, coloured, and denſe this glaſs is, and reciprocally. Glaſs.

The colours given to glaſs by calxes of lead, are ſhades of yellow: on the other hand, glaſſes that contain only ſaline fluxes partake of the properties of ſalts; they are leſs heavy, leſs denſe, harder, whiter, more brilliant, and more brittle than the former; and glaſſes containing both ſaline and metallic fluxes do alſo partake of the properties of both theſe ſubſtances. Glaſſes too ſaline are eaſily ſuſceptible of alteration by the action of air and water; eſpecially thoſe in which alkalis prevail; and theſe are alſo liable to be injured by acids. Thoſe that contain too much borax and arſenic, though at firſt they appear very beautiful, quickly tarniſh and become opake when expoſed to air. By attending to theſe properties of different fluxes, phlogiſtic or ſaline, the artiſt may know how to adjuſt the proportions of theſe to ſand, or powdered flints, for the various kinds of glaſs. See the article Vitrification.

2. The ſand or ſtone, called by the artiſts *tarſo*, is the ſecond ingredient in glaſs, and that which gives it the body and firmneſs. Theſe ſtones, Agricola obſerves, muſt be ſuch as will fuſe; and of theſe ſuch as are white and tranſparent are beſt; ſo that cryſtal challenges the precedency of all others.

At Venice they chiefly uſe a ſort of pebble, found in the river Teſino, reſembling white marble, and called *cuogolo*. Indeed Ant. Neri aſſures us, that all ſtones which will ſtrike fire with ſteel, are fit to vitrify: but Dr Morret ſhows, that there are ſome exceptions from this rule. Flints are admirable; and when calcined, powdered, and ſearced, make a pure white cryſtalline metal: but the expence of preparing them makes the maſters of our glaſs-houſes ſparing of their uſe. Where proper ſtones cannot be ſo conveniently had, ſand is uſed. The beſt for this purpoſe is that which is white, ſmall, and ſhining; examined by the microſcope, it appears to be ſmall fragments of rock cryſtal. For green glaſs, that which is of a ſoft texture, and more gritty; it is to be well waſhed, which is all the preparation it needs. Our glaſs-houſes are furniſhed with white ſand for their cryſtal glaſſes from Lynn in Norfolk and Maidſtone in Kent, and with the coarſer for green glaſs from Woolwich.

Some mention a third ingredient in glaſs, viz. manganeſe, a kind of pſeudo-loadſtone, dug up in Germany, Italy, and even in Mendip hills in Somerſetſhire. But the proportion hereof to the reſt is very inconſiderable; beſide, that it is not uſed in all glaſs. Its office is to purge off the natural greeniſh colour, and give it ſome other tincture required.

For this purpoſe it ſhould be choſen of a deep colour, and free from ſpecks of a metalline appearance, or a lighter caſt; manganeſe requires to be well calcined in a hot furnace, and then to undergo a thorough levigation. The effect of manganeſe in deſtroying the colours of glaſs, and hence called the ſoap of glaſs, is accounted for by M. Montamy, in his *Traité des Couleurs pour la Peinture en Email*, in the following manner: the

Glaſs. the manganeſe deſtroys the green, olive, and blue colours of glaſs, by adding to them a purple tinge, and by the mixture producing a blackiſh brown colour; and as blackneſs is cauſed merely by an abſorption of the rays of light, the blackiſh tinge given to the glaſs by the mixture of colours, prevents the reflection of ſo many rays, and thus renders the glaſs leſs coloured than before. But the black produced by this ſubſtance ſuggeſts an obvious reaſon for uſing it very ſparingly in thoſe compoſitions of glaſs which are required to be very tranſparent. Nitre or ſaltpetre is alſo uſed with the ſame intention; for by deſtroying in a certain degree the phlogiſton which gives a ſtrong tinge of yellow to glaſs prepared with lead as a flux, it ſerves to free it from this coloured tinge; and in ſaline glaſſes, nitre is requiſite in a ſmaller proportion to render them ſufficiently tranſparent, as in the caſe of looking-glaſs and other kinds of plates.

Kinds of Glass. The manufactured glaſs now in uſe may be divided into three general kinds; white tranſparent glaſs, coloured glaſs, and common green or bottle glaſs. Of the firſt kind there is a great variety; as the flint glaſs, as it is called with us, and the German cryſtal glaſs, which are applied to the ſame uſes; the glaſs for plates for mirrors or looking-glaſſes; the glaſs for windows and other lights; and the glaſs for phials and ſmall veſſels. And theſe again differ in the ſubſtances employed as fluxes in forming them, as well as in the coarſeneſs or fineneſs of ſuch as are uſed for their body. The flint and cryſtal, mirror and beſt window glaſs, not only require ſuch purity in the fluxes, as may render it practicable to free the glaſs perfectly from all colour; but for the ſame reaſon likewiſe, either the white Lynn ſand, calcined flints, or white pebbles, ſhould be uſed. The others do not demand the ſame nicety in the choice of the materials; though the ſecond kind of window glaſs, and the beſt kind of phial, will not be ſo clear as they ought, if either too brown ſand, or impure ſalts, be ſuffered to enter into their compoſition.

Of coloured glaſs there is a great variety of ſorts, differing in their colour or other properties according to the occaſions for which they are wanted. The differences in the latter kind depend on the accidental preparation and management of the artiſts by whom they are manufactured, as will be afterwards explained.

Furnace for the Making of Glass. In this manufacture there are three ſorts of furnaces; one called *calcar* is for the frit; the ſecond is for working the glaſs; the third ſerves to anneal the glaſs, and is called the *leer*. See Plate CCXX.

The calcar reſembles an oven ten feet long, ſeven feet broad, and two deep: the fuel, which in Britain is ſea-coal, is put into a trench on one ſide of the furnace; and the flame reverberating from the roof upon the frit calcines it. The glaſs-furnace, or working-furnace, is round, of three yards diameter, and two high; or thus proportioned. It is divided into three parts, each of which is vaulted. The lower part is properly called the *crown*, and is made in that form. Its uſe is to keep a briſk fire, which is never put out. The mouth is called the *bocca*. There are ſeveral holes in the arch of this crown, through which the flame paſſes into the ſecond vault or partition, and reverberates into the pots filled with the ingredients above-mentioned. Round the inſides are eight or more pots placed, and piling pots on them. The number of pots is always double that of the boccas or mouths, or of the number of workmen, that each may have one pot refined to work out of, and another for metal to refine in while he works out of the other. Through the working holes the metal is taken out of the pots, and the pots are put into the furnace; and theſe holes are ſtopped with moveable covers made of lute and brick, to ſcreen the workmens eyes from the ſcorching flames. On each ſide of the bocca or mouth is a bocarella or little hole, out of which coloured glaſs or finer metal is taken from the piling pot. Above this oven there is the third oven or *leer*, about five or ſix yards long, where the veſſels or glaſs are annealed or cooled: this part conſiſts of a tower, beſides the leer, into which the flame aſcends from the furnace. The tower has two mouths, through which the glaſſes are put in with a fork, and ſet on the floor or bottom: but they are drawn out on iron pans, called *frames*, through the leer, to cool by degrees; ſo that they are quite cold by the time they reach the mouth of the leer, which enters the faroſel or room where the glaſſes are to be ſtowed. Glaſs.

But the green glaſs-furnace is ſquare; and at each angle it has an arch for annealing or cooling glaſſes. The metal is wrought on two oppoſite ſides, and on the other two they have their colours, into which are made linnet holes for the fire to come from the furnace to bake the frit, and to diſcharge the ſmoke. Fires are made in the arches to anneal the work, ſo that the whole proceſs is done in one furnace.

Theſe furnaces muſt not be of brick, but of hard ſandy ſtones. In France, they build the outſide of brick; and the inner part, to bear the fire, is made of a ſort of fuller's earth, or tobacco-pipe clay, of which earth they alſo make their melting-pots. In Britain the pots are made of Sturbridge clay.

Mr Blancourt obſerves, that the worſt and roughеſt work in this art is the changing the pots when they are worn out or cracked. In this caſe, the great working hole muſt be uncovered; the faulty pot muſt be taken out with iron hooks and forks, and a new one muſt be ſpeedily put in its place, through the flames, by the hands only. For this work, the man guards himſelf with a garment made of ſkins, in the ſhape of a pantaloon, that covers him all but his eyes, and is made as wet as poſſible: the eyes are defended with a proper ſort of glaſs.

Inſtruments for Making of Glass. The inſtruments made uſe of in this work, may be reduced to theſe that follow. A blowing-pipe, made of iron, about two feet and a half long, with a wooden handle. An iron rod to take up the glaſs after it is blown, and to cut off the former. Sciſſars to cut the glaſs when it comes off from the firſt hollow iron. Shears to cut and ſhape great glaſſes, &c. An iron-ladle, with the end of the handle caſed with wood, to take the metal out of the refining pot, to put it into the workmens pots. A ſmall iron-ladle, caſed in the ſame manner, to ſkim the alkalic ſalt that ſwims at top. Shovels, one like a peel, to take up the great glaſſes; another, like a fire-ſhovel, to feed the furnace with coals. A hooked iron fork, to ſtir the matter in the pots. An

Compoſitions for White and Cryſtal GLASS. 1. To make *cryſtal glaſs*, take of the whiteſt tarſo, pounded ſmall, and ſearced as fine as flour, 200 pounds; of the ſalt of polverine 130 pounds; mix them together, and put them into the furnace called the *calcar*, firſt heating it. For an hour keep a moderate fire, and keep ſtirring the materials with a proper rake, that they may incorporate and calcine together; then increaſe the fire for five hours; after which take out the matter; which being now ſufficiently calcined, is called *frit*. From the calcar put the frit in a dry place, and cover it up from the duſt for three or four months. Now to make the glaſs or cryſtal: take of this cryſtal frit, called alſo *bollito;* ſet it in pots in the furnace, adding to it a due quantity of magneſia or manganeſe: when the two are fuſed, caſt the fluor into fair water, to clear it of the ſalt called *ſandiver;* which would otherwiſe make the cryſtal obſcure and cloudy. This lotion muſt be repeated again and again, as often as needful, till the cryſtal be fully purged; or this ſcum may be taken off by means of proper ladles. Then ſet it to boil four, five, or ſix days; which done, ſee whether it have manganeſe enough; and if it be yet greeniſh, add more manganeſe, at diſcretion, by little and little at a time, taking care not to overdoſe it, becauſe the manganeſe inclines it to a blackiſh hue. Then let the metal clarify, till it becomes of a clear and ſhining colour; which done, it is fit to be blown or formed into veſſels at pleaſure.

2. *Flint glaſs*, as it is called by us, is of the ſame general kind with that which in other places is called cryſtal glaſs. It has this name from being originally made with calcined flints, before the uſe of the white ſand was underſtood; and retains the name, though no flints are now uſed in the compoſition of it. This flint glaſs differs from the other, in having lead for its flux, and white ſand for its body; whereas the fluxes uſed for the cryſtal glaſs are ſalts or arſenic, and the body conſiſts of calcined flints or white river pebbles, tarſo, or ſuch ſtones. To the white ſand and lead a proper proportion of nitre is added, to burn away the phlogiſton of the lead, and alſo a ſmall quantity of magneſia; and in ſome works they uſe a proportional quantity of arſenic to aid the fluxing ingredients. The moſt perfect kind of flint glaſs may be made by fuſing with a very ſtrong fire 120 pounds of the white ſand, 50 pounds of red lead, 40 pounds of the beſt pearl-aſhes, 20 pounds of nitre, and five ounces of magneſia. Another compoſition of flint glaſs, which is ſaid to come nearer to the kind now made, is the following: 120 pounds of ſand, 54 pounds of the beſt pearl-aſhes, 36 pounds of red-lead, 12 pounds of nitre, and 6 ounces of magneſia. To either of theſe a pound or two of arſenic may be added, to increaſe the flux of the compoſition. A cheaper compoſition of flint glaſs may be made with 120 pounds of white ſand, 35 pounds of the beſt pearl-aſhes, 40 pounds of red-lead, 13 pounds of nitre, 6 pounds of arſenic, and 4 ounces of magneſia; or inſtead of the arſenic may be ſubſtituted 15 pounds of common ſalt; but this will be more brittle than the other. The cheapeſt compoſition for the worſt kind of flint glaſs conſiſts of 120 pounds of white ſand, 30 pounds of red-lead, 20 pounds of the beſt pearl-aſhes, 10 pounds of nitre, 15 pounds of common ſalt, and ſix pounds of arſenic. The beſt German cryſtal glaſs is made of 120 pounds of calcined flints or white ſand, 70 pounds of the beſt pearl-aſhes, 10 pounds of ſaltpetre, half a pound of arſenic, and five ounces of magneſia. And a cheaper compoſition is formed of 120 pounds of calcined flints or white ſand, 46 pounds of pearl-aſhes, 7 pounds of nitre, 6 pounds of arſenic, and 5 ounces of magneſia. Glaſs

A glaſs much harder than any prepared in the common way, may be made by means of borax in the following method: Take four ounces of borax, and an ounce of fine ſand; reduce both to a ſubtile powder, and melt them together in a large cloſe crucible ſet in a wind furnace, keeping up a ſtrong fire for half an hour; then take out the crucible, and when cold break it, and there will be found at the bottom a pure hard glaſs capable of cutting common glaſs like a diamond. This experiment, duly varied, ſays Dr Shaw, may lead to ſeveral uſeful improvements in the arts of glaſs, enamels, and factitious gems, and ſhows an expeditious method of making glaſs, without any fixed alkali, which has been generally thought an eſſential ingredient in glaſs, and it is not yet known whether calcined cryſtal or other ſubſtances being added to this ſalt inſtead of ſand, it might not make a glaſs approaching to the nature of a diamond.

There are three principal kinds of glaſſes, diſtinguiſhed by the form or manner of working them; viz. I. *Round glaſs*, as thoſe of our veſſels, phials, drinking-glaſſes, &c. II. *Table* or *window-glaſs*, of which there are divers kinds; viz. crown-glaſs, jealous-glaſs, &c. III. *Plate-glaſs*, or *mirror-glaſs*.

I. *Working or Blowing Round* GLASS. The working furnace, we have obſerved, is round, and has ſix boccas or apertures: at one of theſe called the *great bocca*, the furnace is heated, and the pots of frit are at this ſet in the furnace; two other ſmaller holes, called *bocarellas*, ſerve to lade or take out the melted metal, at the end of an iron, to work the glaſs. At the other holes they put in pots of fuſible ingredients, to be prepared, and at laſt emptied into the lading-pot.

There are ſix pots in each furnace, all made of tobacco-pipe clay, proper to ſuſtain not only the heat of the fire, but alſo the effect of the polverine, which penetrates every thing elſe. There are only two of theſe pots that work: the reſt ſerve to prepare the matter for them. The fire of the furnace is made and kept up with dry hard wood, caſt in without intermiſſion at ſix apertures.

When the matter contained in the two pots is ſufficiently vitrified, they proceed to blow or faſhion it. For this purpoſe the workman dips his blowing pipe into the melting-pot; and by turning it about, the metal ſticks to the iron more firmly than turpentine. This he repeats four times, at each time rolling the end of his inſtrument, with the hot metal thereon, on a piece of plate-iron; over which is a veſſel of water which helps to cool, and ſo to conſolidate and to diſpoſe that matter to bind more firmly with what is to be taken next out of the melting pot. But after he has dipt a fourth time, and the workman perceives there is metal enough on the pipe, he claps his mouth immediately to the other end of it, and blows gently

Glaſs. through the iron tube, till the metal lengthens like a bladder about a foot. Then he rolls it on a marble ſtone a little while to poliſh it; and blows a ſecond time, by which he brings it to the ſhape of a globe of about 18 or 20 inches diameter. Every time he blows into the pipe, he removes it quickly to his cheek; otherwiſe he would be in danger, by often blowing, of drawing the flame into his mouth: and this globe may be flattened by returning it to the fire; and brought into any form by ſtamp-irons, which are always ready. When the glaſs is thus blown, it is cut off at the collet or neck; which is the narrow part that ſtuck to the iron. The method of performing this is as follows: the pipe is reſted on an iron bar, cloſe by the collet; then a drop of cold water being laid on the collet, it will crack about a quarter of an inch, which, with a ſlight blow or cut of the ſhears, will immediately ſeparate the collet.

After this is done, the operator dips the iron rod into the melting-pot, by which he extracts as much metal as ſerves to attract the glaſs he has made, to which he now fixes this rod at the bottom of his work, oppoſite to the opening made by the breaking of the collet. In this poſition the glaſs is carried to the great bocca or mouth of the oven, to be heated and ſcalded; by which means it is again put into ſuch a ſoft ſtate, that, by the help of an iron inſtrument, it can be pierced, opened, and widened, without breaking. But the veſſel is not finiſhed till it is returned to the great bocca; where being again heated thoroughly, and turned quickly about with a circular motion, it will open to any ſize, by the means of the heat and motion.

If there remain any ſuperfluities, they are cut off with the ſhears; for till the glaſs is cool, it remains in a ſoft flexible ſtate. It is therefore taken from the bocca, and carried to an earthen bench, covered with brands, which are coals extinguiſhed, keeping it turning; becauſe that motion prevents any ſettling, and preſerves an evenneſs in the face of the glaſs, where, as it cools, it comes to its conſiſtency; being firſt cleared from the iron rod by a ſlight ſtroke by the hand of the workman.

If the veſſel conceived in the workman's mind, and whoſe body is already made, requires a foot, or a handle, or any other member or decoration, he makes them ſeparately; and now eſſays to join them with the help of hot metal, which he takes out of the pots with his iron-rod: but the glaſs is not brought to its true hardneſs till it has paſſed the leer or annealing oven, deſcribed before.

II. *Working or Blowing of Window or Table* Glass. The method of working round glaſs, or veſſels of any ſort, is in every particular applicable to the working of window or table glaſs, till the blowing iron has been dipt the fourth time. But then inſtead of rounding it, the workman blows, and ſo manages the metal upon the iron plate, that it extends two or or three feet in the form of a cylinder. This cylinder is put again to the fire, and blown a ſecond time, and is thus repeated till it is extended to the dimenſions required, the ſide to which the pipe is fixed diminiſhing gradually till it ends in a pyramidal form; ſo that, to bring both ends nearly to the ſame diameter, while the glaſs is thus flexible, he adds a little hot metal to the end oppoſite the pipe, and draws it out with a pair of iron pincers, and immediately cuts off the ſame end with the help of a little cold water, as before. Glaſs.

The cylinder being now open at one end, is carried back to the bocca; and there, by the help of cold water, it is cut about eight or ten inches from the iron pipe or rod; and the whole length at another place, by which alſo it is cut off from the iron rod. Then it is heated gradually on an earthen table, by which it opens in length; while the workman, with an iron tool, alternately lowers and raiſes the two halves of the cylinder; which at laſt will open like a ſheet of paper, and fall into the ſame flat form in which it ſerves for uſe; in which it is preſerved by heating it over again, cooling it on a table of copper, and hardening it 24 hours in the annealing furnace, to which it is carried upon forks. In this furnace an hundred tables of glaſs may lie at a time, without injury to each other, by ſeparating them into tens, with an iron ſhiver between, which diminiſhes the weight by dividing it, and keeps the tables flat and even.

Of window or table glaſs there are various ſorts, made in different places, for the uſe of building. Thoſe moſt known among us are given us by the author of the Builder's Dictionary, as follows:

1. *Crown*, of which, ſays Neri, there are two kinds, diſtinguiſhed by the places where they are wrought; viz. Ratcliff crown glaſs, which is the beſt and cleareſt, and was firſt made at the Bear-garden, on the Bankſide, Southwark, but ſince at Ratcliff: of this there are 24 tables to the caſe, the tables being of a circular form, about three feet ſix inches in diameter. The other kind, or Lambeth crown glaſs, is of a darker colour than the former, and more inclining to green.

The beſt window or crown glaſs is made of white ſand 60 pounds, of purified pearl aſhes 30 pounds, of ſaltpetre 15 pounds, of borax one pound, and of arſenic half a pound. If the glaſs ſhould prove yellow, magneſia muſt be added. A cheaper compoſition for window glaſs conſiſts of 60 pounds of white ſand, 25 pounds of unpurified pearl aſhes, 10 pounds of common ſalt, 5 pounds of nitre, 2 pounds of arſenic, and one ounce and a half of magneſia. The common or green window glaſs is compoſed of 60 pounds of white ſand, 30 pounds of unpurified pearl aſhes, 10 pounds of common ſalt, 2 pounds of arſenic, and two ounces of magneſia. But a cheaper compoſition for this purpoſe conſiſts of 120 pounds of the cheapeſt white ſand, 30 pounds of unpurified pearl-aſhes, 60 pounds of wood aſhes, well burnt and ſifted, 20 pounds of common ſalt, and 5 pounds of arſenic.

2. *French glaſs*, called alſo *Normandy glaſs*, and formerly *Lorraine glaſs*, becauſe made in thoſe provinces. At preſent it is made wholly in the nine glaſs-works; five whereof are in the foreſt of Lyons, four in the county of Eu; the laſt at Beaumont near Rouen. It is of a thinner kind than our crown glaſs; and when laid on a piece of white paper, appears of a dirtyiſh green colour. There are but 25 tables of this to the caſe.

3. *German glaſs*, is of two kinds, the *white* and the *green*: the firſt is of a whitiſh colour, but is ſubject to thoſe ſmall curved ſtreaks obſerved in our Newcaſtle glaſs, though free from the ſpots and blemiſhes thereof. The green, beſides its colour, is liable to the ſame ſtreaks

Glaſs. ſtreaks as the white; but both of them are ſtraighter and leſs warped than our Newcaſtle glaſs.

4. *Dutch glaſs* is not much unlike our Newcaſtle glaſs either in colour or price. It is frequently much warped like that, and the tables are but ſmall.

5. *Newcaſtle glaſs* is that moſt uſed in England. It is of an aſh-colour, and much ſubject to ſpecks, ſtreaks, and other blemiſhes; and beſides is frequently warped. Leybourn ſays, there are 45 tables to the caſe, each containing five ſuperficial feet: ſome ſay there are but 35 tables, and ſix feet in each table.

6. *Phial glaſs* is a kind betwixt the flint glaſs and the common bottle or green glaſs. The beſt kind may be prepared with 120 pounds of white ſand, 50 pounds of unpurified pearl-aſhes, 10 pounds of common ſalt, 5 pounds of arſenic, and 5 ounces of magneſia. The compoſition for green or common phial glaſs conſiſts of 120 pounds of the cheapeſt white ſand, 80 pounds of wood aſhes well burnt and ſifted, 20 pounds of pearl-aſhes, 15 pounds of common ſalt, and 1 pound of arſenic.

The common bottle or green is formed of ſand of any kind fluxed by the aſhes of burnt wood, or of any parts of vegetables; to which may be added the *ſcoriæ* or clinkers of forges. When the ſofteſt ſand is uſed, 200 pounds of wood aſhes will ſuffice for 100 pounds of ſand, which are to be ground and mixed together. The compoſition with the clinkers conſiſts of 170 pounds of wood-aſhes, 100 pounds of ſand, and 50 pounds of clinkers or *ſcoriæ*, which are to be ground and mixed together. If the clinkers cannot be ground, they muſt be broke into ſmall pieces, and mixed with the other matter without any grinding.

III. *Working of Plate or Mirror* GLASS. 1. The materials of which this glaſs is made are much the ſame thoſe of other works of glaſs, viz. an alkali as ſalt and ſand.

The ſalt, however, ſhould not be that extracted from polverine or the aſhes of the Syrian kali, but that from BARILLA, growing about Alicant in Spain. It is very rare that we can have the barilla pure; the Spaniards in burning the herb make a practice of mixing another herb along with it, which alters its quality; or of adding ſand to it to increaſe the weight, which is eaſily diſcovered if the addition be only made after the boiling of the aſhes, but next to impoſſible if made in the boiling. It is from this adulteration that thoſe threads and other defects in plate glaſs ariſe. To prepare the ſalt, they clean it well of all foreign matters; pound or grind it with a kind of mill, and finally ſift it pretty fine.

Pearl-aſhes, properly purified, will furniſh the alkali ſalt requiſite for this purpoſe; but it will be neceſſary to add borax or common ſalt, in order to facilitate the fuſion, and prevent the glaſs from ſtiffening in that degree of heat in which it is to be wrought into plates. For purifying the pearl-aſhes, diſſolve them in four times their weight of boiling water, in a pot of caſt iron, always kept clean from ruſt. Let the ſolution be removed into a clean tub, and remain there 24 hours or longer. Having decanted the clear part of the fluid from the dregs or ſediment, put it again in the iron pot, and evaporate the water till the ſalts are left perfectly dry. Preſerve them in ſtone-jars, well ſecured from air and moiſture.

Pearl-aſhes may alſo be purified in the higheſt degree, ſo as to be proper for the manufacture of the moſt tranſparent glaſs, by pulverizing three pounds of the beſt pearl-aſhes with ſix ounces of ſaltpetre in a glaſs or marble mortar, till they are well mixed; and then putting part of the mixture into a large crucible, and expoſing it in a furnace to a ſtrong heat. When this is red-hot, throw in the reſt gradually; and when the whole is red hot, pour it out on a moiſtened ſtone or marble, and put it into an earthen or clean iron pot, with ten pints of water; heat it over the fire till the ſalts be entirely melted; let it then ſtand to cool, and filter it through paper in a pewter cullender. When it is filtered, put the fluid again into the pot, and evaporate the ſalt to dryneſs, which will then be as white as ſnow; the nitre having burnt all the phlogiſtic matter that remained in the pearl-aſhes after their former calcination. Glaſs.

As to the ſand, it is to be ſifted and waſhed till ſuch time as the water come off very clear; and when it is well dried again, they mix it with the ſalt, paſſing the mixture through another ſieve. This done, they lay them in the annealing furnace for about two hours; in which time the matter becomes very light and white: in this ſtate they are called *frit* or *fritta;* and are to be laid up in a dry clean place, to give them time to incorporate: they lie here for at leaſt a year.

When they would employ this frit, they lay it for ſome hours in the furnace, adding to ſome the fragments or ſhards of old and ill made glaſſes; taking care firſt to calcine the ſhards by heating them red-hot in the furnace, and thus caſting them into cold water. To the mixture muſt likewiſe be added manganeſe, to promote the fuſion and purification.

The beſt compoſition for looking-glaſs plates conſiſts of 60 pounds of white ſand cleanſed, 25 pounds of purified pearl-aſhes, 15 pounds of ſaltpetre, and 7 pounds of borax. If a yellow tinge ſhould affect the glaſs, a ſmall proportion of magneſia, mixed with an equal quantity of arſenic, ſhould be added. An ounce of the magneſia may be firſt tried; and if this proves inſufficient, the quantity ſhould be increaſed.

A cheaper compoſition for looking-glaſs plate conſiſts of 60 pounds of the white-ſand, 20 pounds of pearl-aſhes, 10 pounds of common ſalt, 7 pounds of nitre, 2 pounds of arſenic, and 1 pound of borax. The matter of which the glaſſes are made at the famous manufacture of St Gobin in France, is a compoſition of ſolder and of a very white ſand, which are carefully cleaned of all heterogeneous bodies; afterwards waſhed for ſeveral times, and dried ſo as to be pulverized in a mill, conſiſting of many peſtles, which are moved by horſes. When this is done, the ſand is ſifted through ſilk ſieves and dried.

The matter thus far prepared is equally fit for plate-glaſs, to be formed either for blowing or by caſting.

The largeſt glaſſes at St Gobin are run; the middle-ſized and ſmall ones are blown.

2. *Blowing the plates.* The workhouſes, furnaces, &c. uſed in the making of this kind of plate-glaſs, are the ſame, except that they are ſmaller, and that the carquaiſſes are diſpoſed in a large covered gallery, over againſt the furnace, as thoſe in the following article, to which the reader is referred.

Glaſs. After the materials are vitrified by the heat of the fire, and the glaſs is ſufficiently refined, the workman dips in his blowing-iron, ſix feet long, and two inches in diameter, ſharpened at the end which is put in the mouth, and widened at the other, that the matter may adhere to it. By this means he takes up a ſmall ball of matter, which ſticks to the end of the tube by conſtantly turning it. He then blows into the tube, that the air may ſwell the annexed ball; and carrying it over a bucket of water, which is placed on a ſupport at the height of about four feet, he ſprinkles the end of the tube to which the matter adheres, with water, ſtill turning it, that by this cooling the matter may coaleſce with the tube, and be fit for ſuſtaining a greater weight. He dips the tube again into the ſame pot, and proceeds as before; and dipping it in the pot a third time, he takes it out, loaded with matter, in the ſhape of a pear, about ten inches in diameter, and a foot long, and cools it at the bucket; at the ſame time blowing into the tube, and with the aſſiſtance of a labourer, giving it a balancing motion, he cauſes the matter to lengthen; which, by repeating this operation ſeveral times, aſſumes the form of a cylinder, terminating like a ball at the bottom, and in a point at the top. The aſſiſtant is then placed on a ſtool three feet and a half high; and on this ſtool there are two upright pieces of timber, with a croſs beam of the ſame, for ſupporting the glaſs and tube, which are kept in an oblique poſition by the aſſiſtant, that the maſter workman may with a punchion ſet in a wooden handle, and with a mallet make a hole in the maſs: this hole is drilled at the centre of the ball that terminates the cylinder, and is about an inch in diameter. When the glaſs is pierced, the defects of it are perceived; if it is tolerably perfect, the workman lays the tube horizontally on a little iron treſſel, placed on the ſupport of the aperture of the furnace. Having expoſed it to the heat for about half a quarter of an hour, he takes it away, and with a pair of long and broad ſhears, extremely ſharp at the end, widens the glaſs, by inſinuating the ſhears into the hole made with the punchion, whilſt the aſſiſtant, mounted on the ſtool, turns it round, till at laſt the opening is ſo large as to make a perfect cylinder at bottom. When this is done, the workman lays his glaſs upon the treſſels at the mouth of the furnace to heat it: he then gives it to his aſſiſtant on the ſtool, and with large ſhears cuts the maſs of matter up to half its height. There is at the mouth of the furnace an iron tool called *pontil*, which is now heating, that it may unite and coaleſce with the glaſs juſt cut, and perform the office which the tube did before it was ſeparated from the glaſs. This pontil is a piece of iron ſix feet long, and in the form of a cane or tube, having at the end of it a ſmall iron bar, a foot long, laid equally upon the long one, and making with it a T. This little bar is full of the matter of the glaſs, about four inches thick. This red-hot pontil is preſented to the diameter of the glaſs, which coaleſces immediately with the matter round the pontil, ſo as to ſupport the glaſs for the following operation. When this is done, they ſeparate the tube from the glaſs, by ſtriking a few blows with a chiſſel upon the end of the tube which has been cooled; ſo that the glaſs breaks directly, and makes this ſeparation, the tube being diſcharged of the glaſs now adhering to the pontil. They next preſent to the furnace the pontil of the glaſs, laying it on the treſſel to heat, and redden the end of that glaſs, that the workman may open it with his ſhears, as he has already opened one end of it, to complete the cylinder; the aſſiſtant holding it on his ſtool as before. For the laſt time, they put the pontil on the treſſel, that the glaſs may become red-hot, and the workman cuts it quite open with his ſhears, right over-againſt the forementioned cut; this he does as before, taking care that both cuts are in the ſame line. In the mean time, the man who looks after the carquaiſſes comes to receive the glaſs upon an iron ſhovel two feet and a half long without the handle, and two feet wide, with a ſmall border of an inch and a half to the right and left, and towards the handle of the ſhovel. Upon this the glaſs is laid, flattening it a little with a ſmall ſtick a foot and a half long, ſo that the cut of the glaſs is turned upwards. They ſeparate the glaſs from the pontil, by ſtriking a few gentle blows between the two with a chiſſel. The glaſs is then removed to the mouth of the hot carquaiſſe, where it becomes red-hot gradually; the workman, with an iron tool ſix feet long, and widened at the end in form of a club at cards four inches long, and two inches wide on each ſide, very flat, and not half an inch thick, gradually lifts up the cut part of the glaſs to unfold it out of its form of a flattened cylinder, and render it ſmooth, by turning it down upon the hearth of the carquaiſſe. The tool already deſcribed being inſinuated within the cylinder, performs this operation by being puſhed hard againſt all the parts of the glaſs. When the glaſs is thus made quite ſmooth, it is puſhed to the bottom of the carquaiſſe or annealing furnace with a ſmall iron raker, and ranged there with a little iron hook. When the carquaiſſe is full, it is ſtopped and cemented as in the caſe of run glaſſes, and the glaſs remains there for a fortnight to be annealed; after which time they are taken out to be poliſhed. A workman can make but one glaſs in an hour, and he works and reſts for ſix hours alternately.

Such was the method formerly made uſe of for blowing plate-glaſs, looking-glaſſes, &c; but the workmen, by this method, could never exceed 50 inches in length, and a proportional breadth, becauſe what were larger were always found to warp, which prevented them from reflecting the objects regularly, and wanted ſubſtance to bear the neceſſary grinding. Theſe imperfections have been remedied by the following invention of the Sieur Abraham Thevart, in France, about the year 1688.

3. *Caſting or Running of Large Mirror-Glass Plates.* The furnace is of a very large dimenſion, environed with ſeveral ovens, or annealing furnaces, called *carquaiſſes*, beſides others for making of frit and calcining old pieces of glaſs. This furnace, before it is fit to run glaſs, coſts 3500l. It ſeldom laſts above three years, and even in that time it muſt be refitted every ſix months. It takes ſix months to rebuild it, and three months to refit it. The melting pots are as big as large hogſheads, and contain about 2000 weight of metal. If one of them burſts in the furnace, the loſs of the matter and time amounts to 250l. The materials in theſe pots are the ſame as deſcribed before. When the furnace is red hot, theſe materials are put in at three different

Plate CCXX.

Glaſs. times, becauſe that helps the fuſion; and in 24 hours they are vitrified, refined, ſettled, and fit for caſting. A is the bocca, or mouth of the furnace; B is the ciſtern that conveys the liquid glaſs it receives out of the melting-pots in the furnace to the caſting table. Theſe ciſterns are filled in the furnace, and remain therein ſix hours after they are filled; and then are hooked out by the means of a large iron chain, guided by a pully, placed upon a carriage with four wheels marked C, by two men. This carriage has no middle piece; ſo that when it has brought the ciſtern to the caſting-table D, they ſlip off the bottom of the ciſtern, and out ruſhes a torrent of flaming matter upon the table: this matter is confined to certain dimenſions by the iron rulers EE, which are moveable, retain the fluid matter, and determine the width of the glaſs; while a man, with the roller F reſting on the edge of the iron rulers, reduceth it as it cools to an equal thickneſs, which is done in the ſpace of a minute. This table is ſupported on a wooden frame, with truſtles for the convenience of moving to the annealing furnace; into which, ſtrewed with ſand, the new plate is ſhoved, where it will harden in about 10 days.

What is moſt ſurpriſing throughout the whole of this operation, is the quickneſs and addreſs wherewith ſuch maſſy ciſterns, filled with a flaming matter, are taken out of the furnace, conveyed to the table, and poured therein, the glaſs ſpread, &c. The whole is inconceivable to ſuch as have not been eye-witneſſes of that ſurpriſing manufacture.

As faſt as the ciſterns are emptied, they carry them back to the furnace and take freſh ones, which they empty as before. This they continue to do ſo long as there are any full ciſterns; laying as many plates in each carquaiſſe as it will hold, and ſtopping them up with doors of baked earth, and every chink with cement, as ſoon as they are full, to let them anneal, and cool again, which requires about 14 days.

The firſt running being diſpatched, they prepare another, by filling the ciſterns anew from the matter in the pots; and after the ſecond, a third; and even a fourth time, till the melting-pots are quite empty.

The ciſterns at each running ſhould remain at leaſt ſix hours in the furnace to whiten; and when the firſt annealing furnace is full, the caſting-table is to be carried to another. It need not here be obſerved, that the carquaiſſes, or annealing furnaces, muſt firſt have been heated to the degree proper for them. It may be obſerved, that the oven-full, or the quantity of matter commonly prepared, ſupplies the running of 18 glaſſes, which is performed in 18 hours, being an hour for each glaſs. The workmen work ſix hours, and are then relieved by others.

When the pots are emptied, they take them out, as well as the ciſterns, to ſcrape off what glaſs remains, which otherwiſe would grow green by continuance of fire, and ſpoil the glaſſes. They are not filled again in leſs than 36 hours, ſo that they put the matter into the furnace, and begin to run it every 54 hours.

The manner of heating the large furnaces is very ſingular: the two tiſors, or perſons employed for that purpoſe, in their ſhirts, run ſwiftly round the furnace without making the leaſt ſtop: as they run along, they take two billets, or pieces of wood, which are cut for the purpoſe; theſe they throw into the firſt tiſſart; and continuing their courſe, do the ſame for the ſecond. This they hold without interruption for ſix hours ſucceſſively; after which they are relieved by others, &c. It is ſurpriſing that two ſuch ſmall pieces of wood, and which are conſumed in an inſtant, ſhould keep the furnace to the proper degree of heat; which is ſuch, that a large bar of iron, laid at one of the mouths of the furnace, becomes red-hot in leſs than half a minute. Glaſs.

The glaſs, when taken out of the melting-furnace, needs nothing farther but to be ground, poliſhed, and foliated.

4. *Grinding and Poliſhing of Plate-Glass.* Glaſs is made tranſparent by fire; but it receives its luſtre by the ſkill and labour of the grinder and poliſher; the former of whom takes it rough out of the hands of the maker.

In order to grind plate-glaſs, they lay it horizontally upon a flat ſtone table made of a very fine-grained free-ſtone; and for its greater ſecurity they plaiſter it down with lime or ſtucco; for otherwiſe the force of the workmen, or the motion of the wheel with which they grind it, would move it about.

This ſtone table is ſupported by a ſtrong frame A, made of wood, with a ledge quite round its edges, riſing about two inches higher than the glaſs. Upon this glaſs to be ground is laid another rough glaſs not above half ſo big, and ſo looſe as to ſlide upon it; but cemented to a wooden plank, to guard it from the injury it muſt otherwiſe receive from the ſcraping of the wheel to which this plank is faſtened; and from the weights laid upon it to promote the grinding or triture of the glaſſes. The whole is covered with a wheel B, made of hard light wood, about ſix inches in diameter, by pulling of which backwards and forwards alternately, and ſometimes turning it round, the workmen, who always ſtand oppoſite to each other, produce a conſtant attrition between the two glaſſes, and bring them to what degree of ſmoothneſs they pleaſe, by firſt pouring in water and coarſe ſand; after that, a finer ſort of ſand, as the work advanceth, till at laſt they muſt pour in the powder of ſmalt. As the upper or incumbent glaſs poliſhes and grows ſmoother, it muſt be taken away, and another from time to time put in its place. Plate CCXX.

This engine is called a *mill* by the artiſts, and is uſed only in the largeſt-ſized glaſſes; for in the grinding of the leſſer glaſſes, they are content to work without a wheel, and to have only four wooden handles faſtened to the four corners of the ſtone which loads the upper plank, by which they work it about.

When the grinder has done his part, who finds it very difficult to bring the glaſs to an exact plainneſs, it is turned over to the poliſher; who, with the fine powder of tripoli ſtone or emery, brings it to a perfect evenneſs and luſtre. The inſtrument made uſe of in this branch is a board, *c c*, furniſhed with a felt, and a ſmall roller, which the workman moves by means of a double handle at both ends. The artiſt, in working this roller, is aſſiſted with a wooden hoop or ſpring to the end of which it is fixed: for the ſpring, by conſtantly bringing the roller back to the ſame points, facilitates the action of the workman's arm.

Colouring of Glass. That the colours given to glaſs may have their full beauty, it muſt be obſerved, that every

Glaſs. every pot when new, and firſt uſed, leaves a foulneſs in the glaſs from its own earthy parts; ſo that a coloured glaſs made in a new pot can never be bright or perfectly fine. For this reaſon, the larger of theſe, when new, may be glazed with white glaſs; but the ſecond time of uſing the pots loſe this foulneſs. The glazing may be done by reducing the glaſs to powder, and moiſtening the inſide of the pot with water; while it is yet moiſt, put in ſome of the powdered glaſs, and ſhake it about, till the whole inner ſurface of the pot be covered by as much as will adhere to it, in conſequence of the moiſture. Throw out the redundant part of the powdered glaſs; and the pot being dry, ſet it in a furnace ſufficiently hot to vitrify the glaſs adhering to it, and let it continue there ſome time; after which, care muſt be taken to let it cool gradually. Thoſe pots which have ſerved for one colour muſt not be uſed for another; for the remainder of the old matter will ſpoil the colour of the new. The colours muſt be very carefully calcined to a proper degree; for if they are calcined either too much or too little, they never do well; the proper proportion, as to quantity, muſt alſo carefully be regarded, and the furnaces muſt be fed with dry hard wood. And all the proceſſes ſucceed much the better if the colour be uſed dividedly, that is, a part of it in the frit, and the reſt in the melted metal.

A hard glaſs, proper for receiving colours, may be prepared by pulveriſing 12 pounds of the beſt ſand, cleanſed by waſhing in a glaſs or flint mortar, and mixing ſeven pounds of pearl-aſhes, or any fixed alkaline ſalt, purified with nitre, one pound of ſalt-petre, and half a pound of borax, and pounding them together. A glaſs leſs hard may be prepared of twelve pounds of white ſand cleanſed, ſeven pounds of pearl-aſhes purified with ſaltpetre, one pound of nitre, half a pound of borax, and four ounces of arſenic, prepared as before.

Amethyſt coloured. See *Purple* below, and the article AMETHYST.

Balas-colour. Put into a pot cryſtal frit, thrice waſhed in water; tinge this with manganeſe, prepared into a clear purple; to this add *alumen cativum*, ſifted fine, in ſmall quantities, and at ſeveral times: this will make the glaſs grow yellowiſh, and a little reddiſh, but not blackiſh, and always diſſipates the manganeſe. The laſt time you add manganeſe give no more of the *alumen cativum*, unleſs the colour be too full. Thus will the glaſs be exactly of the colour of the balas-ruby. See *Ruby* GLASS.

The common black colour. The glaſs makers take old broken glaſs of different colours, grind it to powder, and add to it, by different parcels, a ſufficient quantity of a mixture of two parts zaffar and one part manganeſe: when well purified, they work it into veſſels, &c.

Glaſs beads are coloured with manganeſe only.

Black velvet colour. To give this deep and fine colour to glaſs, take of cryſtalline and pulverine frit, of each 20 pounds; of calx of lead and tin four pounds; ſet all together in a pot in the furnace, well heated; when the glaſs is formed and pure, take ſteel well calcined and powdered, ſcales of iron that fly off from the ſmith's anvil, of each an equal quantity; powder and mix them well; then put ſix ounces of this powder to the above deſcribed metal while in fuſion; mix the whole thoroughly together, and let them all boil ſtrongly together; then let it ſtand in fuſion 12 hours to purify, and after this work it. It will be a moſt elegant velvet black. Glaſs.

There is another way of doing this, which alſo produces a very fair black. It is this: take a hundred weight of rochetta frit, add to this two pounds of tartar and ſix pounds of manganeſe, both in fine powder; mix them well, and put them to the metal while in fuſion, at different times, in ſeveral parcels; let it ſtand in fuſion after this for four days, and then work it.

A glaſs perfectly black may alſo be formed to ten pounds of either of the compoſitions for hard glaſs above deſcribed, one ounce of zaffer, ſix drams of manganeſe, and an equal quantity of iron ſtrongly calcined.

Blue colour. A full blue may be made by adding ſix drams of zaffer and two drams of manganeſe to ten pounds of either of the compoſitions for hard glaſs, deſcribed above. For a very cool or pure blue glaſs, half an ounce of calcined copper may be uſed inſtead of the manganeſe, and the proportion of zaffer diminiſhed by one half. Glaſs reſembling ſapphire may be made with ten pounds of either of the compoſitions for hard glaſs, three drams and one ſcruple of zaffer, and one dram of the *calx caſſii*, or precipitation of gold by tin; or inſtead of this latter ingredient, two drams and two ſcruples of manganeſe. Or a ſapphire-coloured glaſs may be made by mixing with any quantity of the hard glaſs one eighth of its weight of ſmalt. For a beautiful blue glaſs produced from the calx of regulus of cobalt, ſee CHEMISTRY, n° 1299.

Venetian brown, with gold ſpangles, commonly called the *philoſopher's ſtone*, may be prepared in the following manner: take of the ſecond compoſition for hard glaſs above deſcribed, and of the compoſition for paſte, of each five pounds, and of highly calcined iron an ounce; mix them well, and fuſe them till the iron be perfectly vitrified, and has tinged the glaſs of a deep tranſparent yellow brown colour. Powder this glaſs, and add to it two pounds of powdered glaſs of antimony; grind them together, and thus mix them well. Take part of this mixture, and rub into it 80 or 100 leaves of the counterfeit leaf gold called *Dutch gold*; and when the parts of the gold ſeem ſufficiently divided, mix the powder containing it with the other part of the glaſs. Fuſe the whole with a moderate heat till the powder run into a vitreous maſs, fit to be wrought into any of the figures or veſſels into which it is uſually formed; but avoid a perfect liquefaction, becauſe that in a ſhort time deſtroys the equal diffuſion of the ſpangles, and vitrifies, at leaſt in part, the matter of which they are compoſed; converting the whole into a kind of tranſparent olive-coloured glaſs. This kind of glaſs is uſed for a great variety of toys and ornaments with us, who at preſent procure it from the Venetians.

Chalcedony. A mixture of ſeveral ingredients with the common matter of glaſs, will make it repreſent the ſemi-opake gems, the jaſpers, agates, chalcedonies, &c. The way of making theſe ſeems to be the ſame with the method of making marbled paper, by ſeveral colours diſſolved in ſeveral liquors, which are ſuch as

Glaſs. will not readily mix with one another when put into water, before they are caſt upon the paper which is to be coloured. There are ſeveral ways of making theſe variouſly coloured glaſſes, but the beſt is the following.

Diſſolve four ounces of fine leaf ſilver in a glaſs veſſel in ſtrong aquafortis; ſtop up the veſſel, and ſet it aſide.—In another veſſel, diſſolve five ounces of quickſilver in a pound of aquafortis, and ſet this aſide.—In another glaſs veſſel, diſſolve in a pound of aquafortis three ounces of fine ſilver, firſt calcined in this manner: amalgamate the ſilver with mercury, mix the amalgagam with twice its weight of common ſalt well purified, put the mixture in an open fire in a crucible, that the mercury may fly off, and the ſilver be left in form of powder. Mix this powder with an equal quantity of common ſalt well purified, and calcine this for ſix hours in a ſtrong fire; when cold, waſh off the ſalt by repeated boilings in common water, and then put the ſilver into the aquafortis. Set this ſolution alſo aſide.—In another veſſel, diſſolve in a pound of aquafortis three ounces of ſal ammoniac; pour off the ſolution, and diſſolve in it a quarter of an ounce of gold. Set this alſo aſide.—In another veſſel, diſſolve three ounces of ſal ammoniac in a pound of aquafortis; then put into the ſolution cinnabar, crocus martis, ultramarine, and ferretto of Spain, of each half an ounce. Set this alſo aſide.—In another veſſel, diſſolve in a pound of aquafortis three ounces of ſal ammoniac; then put into it crocus martis made with vinegar, calcined tin, zaffer, and cinnabar, of each half an ounce; let each of theſe be powdered very fine, and put gently into the aquafortis. Set this alſo aſide.—In another veſſel, diſſolve three ounces of ſal ammoniac in a pound of aquafortis, and add to it braſs calcined with brimſtone, braſs thrice calcined, manganeſe, and ſcales of iron which fall from the ſmith's anvil, of each half an ounce; let each be well powdered, and put gently into the veſſel. Then ſet this alſo aſide.—In another veſſel, diſſolve two ounces of ſal ammoniac in a pound of aquafortis, and put to it verdigreaſe an ounce, red lead, crude antimony, and the caput mortuum of vitriol, of each half an ounce; put theſe well powdered leiſurely into the veſſel, and ſet this alſo aſide.—In another veſſel, diſſolve two ounces of ſal ammoniac in a pound of aquafortis, and add orpiment, white arſenic, painters lake, of each half an ounce.

Keep the above nine veſſels in a moderate heat for 15 days, ſhaking them well at times. After this pour all the matters from theſe veſſels into one large veſſel, well luted at its bottom; let this ſtand ſix days, ſhaking it at times; and then ſet it in a very gentle heat, and evaporate all the liquor, and there will remain a powder of a purpliſh green.

When this is to be wrought, put into a pot very clear metal, made of broken cryſtalline and white glaſs that has been uſed; for with the virgin-frit, or ſuch as has never been wrought, the chalcedony can never be made, as the colours do not ſtick to it, but are conſumed by the frit. To every pot of 20 pounds of this metal put two or three ounces of this powder at three ſeveral times; incorporate the powder well with the glaſs; and let it remain an hour between each time of putting in the powders. After all are in, let it ſtand 24 hours; then let the glaſs be well mixed, and take an aſſay of it, which will be found of a yellowiſh blue; return this many times into the furnace; when it begins to grow cold, it will ſhow many waves of different colours very beautifuly. Then take tartar eight ounces, ſoot of the chimney two ounces, crocus martis made with brimſtone, half an ounce; let theſe be well powdered and mixed, and put them by degrees into the glaſs at ſix times, waiting a little while between each putting in. When the whole is put in, let the glaſs boil and ſettle for 24 hours; then make a little glaſs body of it; which put in the furnace many times, and ſee if the glaſs be enough, and whether it have on the outſide veins of blue, green, red, yellow, and other colours, and have, beſide theſe veins, waves like thoſe of the chalcedonies, jaſpers, and oriental agates, and if the body kept within looks as red as fire. Glaſs.

When it is found to anſwer thus, it is perfect, and may be worked into toys and veſſels, which will always be beautifully variegated: theſe muſt be well annealed, which adds much to the beauty of their veins. Maſſes of this may be poliſhed at the lapidary's wheel as natural ſtones, and appear very beautiful. If in the working the matter grow tranſparent, the work muſt be ſtopped, and more tartar, ſoot, and crocus martis muſt be put to it, which will give it again the neceſſary body and opacity, without which it does not ſhow the colours well.

Chryſolite colour may be made of ten pounds of either of the compoſitions for hard glaſs deſcribed above, and ſix drams of calcined iron.

Red cornelian colour may be formed by adding one pound of glaſs of antimony, two ounces of the calcined vitriol called *ſcarlet ochre*, and one dram of manganeſe or magneſia, to two pounds of either of the compoſitions for hard glaſs. The glaſs of antimony and magneſia are firſt fuſed with the other glaſs, and then powdered and ground with the ſcarlet ochre: the whole mixture is afterwards fuſed with a gentle heat till all the ingredients are incorporated. A glaſs reſembling the white cornelian may be made of two pounds of either of the compoſitions for hard glaſs, and two drams of yellow ochre well waſhed, and one ounce of calcined bones: grind them together, and fuſe them with a gentle heat.

Emerald colour. See *Green* below.

Garnet colour. To give this colour to glaſs, the workmen take the following method. They take equal quantities of cryſtal and rochetta frit, and to every hundred weight of this mixture they add a pound of manganeſe and an ounce of prepared zaffer: theſe are to be powdered ſeparately, then mixed and added by degrees to the frit while in the furnace. Great care is to be taken to mix the manganeſe and zaffer very perfectly; and when the matter has ſtood 24 hours in fuſion, it may be worked.

Glaſs of this kind may be made by adding one pound of glaſs of antimony, one dram of manganeſe, and the ſame quantity of the precipitate of gold by tin, to two pounds of either of the compoſitions for hard glaſs; or the precipitate of gold may be omitted, if the quantities of the glaſs of antimony and manganeſe be doubled.

Gold colour. This colour may be produced by taking ten pounds of either of the compoſitions for hard glaſs,

Glafs. glafs, omiting the faltpetre; and for every pound adding an ounce of calcined borax, or, if this quantity doth not render the glafs fufficiently fufible, two ounces; ten ounces of red tartar of the deepeft colour; two ounces of magnefia; and two drams of charcoal of fallow, or any other foft kind. Precipitates of filver baked on glafs will ftain it yellow, and likewife give a yellow colour on being mixed and melted with 40 or 50 times their weight of vitreous compofitions: the precipitate from aquafortis by fixed alkali feems to anfwer beft. Yellow glaffes may alfo be obtained with certain preparations of iron, particularly with Pruffian blue. But Dr Lewis obferves, that the colour does not conftantly fucceed, nor approach to the high colour of gold, with filver or with iron. The neareft imitations of gold which he has been able to produce have been effected with antimony and lead. Equal parts of the glafs of antimony, of flint calcined and powdered, and of minium, formed a glafs of a high yellow; and with two parts of glafs of antimony, two of minium, and three of powdered flint, the colour approached ftill more to that of gold. The laft compofition exhibited a multitude of fmall fparkles interfperfed throughout its whole fubftance, which gave it a beautiful appearance in the mafs, but were really imperfections, owing to air-bubbles.

Neri directs, for a gold-yellow colour, one part of red tartar and the fame quantity of manganefe, to be mixed with a hundred parts of frit. But Kunckel obferves, that thefe proportions are faulty; that one part, or one and a quarter, of manganefe, is fufficient for a hundred of frit; but that fix parts of tartar are hardly enough, unlefs the tartar is of a dark red colour, almoft blackifh; and that he found it expedient to add to the tartar about a fourth of its weight of powdered charcoal. He adds, that the glafs fwells up very much in melting, and that it muft be left unftirred, and worked as it ftands in fufion. Mr Samuel More, in repeating and varying this procefs in order to render the colour more perfect, found that the manganefe is entirely unceffential to the gold colour; and that the tartar is no otherwife of ufe than in virtue of the coaly matter to which it is in part reduced by the fire, the phlogifton or inflammable part of the coal appearing in feveral experiments to be the direct tinging fubftance. Mr Pot alfo obferves, that common coals give a yellow colour to glafs; that different coaly matters differ in their tinging power; that caput mortuum of foot and lamp-black anfwer better than common charcoal; and that the fparkling coal, which remains in the retort after the rectification of the thick empyreumatic animal oils, is one of the moft active of thefe preparations. This preparation, he fays, powdered, and then burnt again a little in a clofe veffel, is excellent for tinging glafs, and gives yellow, brown, reddifh, or blackifh colours, according to its quantity; but the frit muft not be very hard of fufion, for in this cafe the ftrong fire will deftroy the colouring fubftance before the glafs melts: and he has found the following compofitions to be nearly the beft; viz. fand two parts, alkali three parts; or fand two, alkali three, calcined borax one; or fand two, alkali two, calcined borax one: and though faltpetre is hardly ufed at all, or very fparingly, for yellow glaffes, as it too much volatilizes the colouring fubftance; yet here for the moft part a certain proportion of it, eafily determined by trial, is very neceffary; for without it the concentrated colouring matter is apt to make the glafs too dark, and even of an opake pitchy blacknefs. It does not certainly appear that there is any material diverfity in the effects of different coals, the difference being probably owing to the different quantities of the inflammable matter which they contain; fo that a little more fhall be required of one kind than of another for producing the fame degree of colour in the glafs. Nor does the foftnefs or fufibility of the frit appear to be in any refpect neceffary. Glafs.

Gold-coloured fpangles may be diffufed through the fubftance of glafs, by mixing the yellow tales with powdered glafs, and bringing the mixture into fufion.

Green. This colour may be imparted to glafs by adding three ounces of copper precipitated from aquafortis, and two drams of precipitated iron to nine pounds of either of the compofitions for hard glafs. The fineft method of giving this beautiful colour to glafs is this: Take five pounds of cryftalline metal that has been paffed feveral times through water, and the fame quantity of the common white metal of polverine, four pounds of common polverine frit, and three pounds of red lead; mix the red-lead well with the frit, and then put all into a pot in a furnace. In a few hours the whole mafs will be well purified: then caft the whole into water, and feparate and take out the lead; then return the metal into the pot, and let it ftand a day longer in fufion; then put in the powder of the refiduum of the vitriol of copper, and a very little crocus martis, there will be produced a moft lively and elegant green, fcarce inferior to that of the oriental emerald. There are many ways of giving a green to glafs, but all are greatly inferior to this.—To make a *fea-green*, the fineft cryftalline glafs only muft be ufed, and no manganefe muft be added at firft to the metal. The cryftal frit muft be melted thus alone; and the falt, which fwims like oil on its top, muft be taken off with an iron ladle very carefully. Then to a pot of twenty pound of this metal add fix ounces of calcined brafs, and a fourth part of the quantity of powdered zaffer: this powder muft be well mixed, and put into the glafs at three times; it will make the metal fwell at firft, and all muft be thoroughly mixed in the pot. After it has ftood in fufion three hours, take out a little for a proof: if it be too pale, add more of the powder. Twenty-four hours after the mixing the powder the whole will be ready to work; but muft be well ftirred together from the bottom, left the colour fhould be deepeft there, and the metal at the top lefs coloured, or even quite colourlefs. Some ufe for this purpofe half cryftal frit and half rochetta frit, but the colour is much the fineft when all cryftal frit is ufed.

Lapis lazuli colour. See *Lapis Lazuli.*

Opal colour. See Opal.

Purple of a deep and bright colour may be produced by adding to ten pounds of either of the compofitions for hard glafs, above defcribed, fix drams of zaffer and one dram of gold precipitated by tin; or to the fame quantity of either compofition one ounce of manganefe and half an ounce of zaffer. The colour of amethyft may be imitated in this way.

Red. A blood-red glafs may be made in the following

Glafs. lowing manner: Put fix pounds of glafs of lead, and ten pounds of common glafs, into a pot glazed with white glafs. When the whole is boiled and refined, add by fmall quantities, and at fmall diftances of time, copper calcined to a rednefs as much as on repeated proofs is found fufficient: then add tartar in powder by fmall quantities at a time, till the glafs is become as red as blood; and continue adding one or other of the ingredients till the colour is quite perfect.

Ruby. The way to give the true fine red of the ruby, with a fair tranfparence, to glafs, is as follows: Calcine in earthen veffels gold diffolved in aqua-regia; the menftruum being evaporated by diftillation, more aqua regia added, and the abftraction repeated five or fix times, till it becomes a red powder. This operation will require many days in a hot furnace. When the powder is of a proper colour, take it out: and when it is to be ufed, melt the fineft cryftal glafs, and purify it by often caiting it into water; and then add, by fmall quantities, enough of this red powder to give it the true colour of a ruby, with an elegant and perfect tranfparence.

The procefs of tinging glafs and enamels by preparations of gold was firft attempted about the beginning of the laft century. Libavius, in one of his tracts intitled *Alchymia*, printed in 1606, conjectures that the colour of the ruby proceeds from gold, and that gold diffolved and brought to rednefs might be made to communicate a like colour to factitious gems and glafs. On this principle Neri, in his Art of Glafs, dated in 1611, gives the procefs above recited. Glauber in 1648 publifhed a method of producing a red colour by gold, in a matter which is of the vitreous kind, though not perfect glafs. For this purpofe he ground powdered flint or fand with four times its weight of fixed alkaline falt: this mixture melts in a moderately ftrong fire, and when cold looks like glafs, but expofed to the air runs into a liquid ftate. On adding this liquor to folution of gold in aqua-regia, the gold and flint precipitate together in form of a yellow powder, which by calcination becomes purple. By mixing this powder with three or four times its weight of the alkaline folution of flint, drying the mixture, and melting it in a ftrong fire for an hour, a mafs is obtained of a tranfparent ruby colour, and of a vitreous appearance; which nevertheleis is foluble in water, or by the moifture of the air, on account of the redundance of the falt. The honourable Mr Boyle, in a work publifhed in 1680, mentions an experiment in which a like colour was introduced into glafs without fufion; for having kept a mixture of gold and mercury in digeftion for fome months, the fire was at laft immoderately increafed, fo that the glafs burft with a violent explofion; and the lower part of the glafs was found tinged throughout of a tranfparent red colour, hardly to be equalled by that of rubies.

About the fame time Caffius is faid to have difcovered the precipitation of gold by tin, and that glafs might be tinged of a ruby colour by melting it with this precipitate; though he does not appear, fays Dr Lewis, from his treatife *De Auro*, to have been the difcoverer of either. He defcribes the preparation of the precipitate and its ufe; but gives no account of the manner of employing it, only that he fays one dram of gold duly prepared will tinge ten pounds of glafs. Glafs.

Commerce of Arts, p. 171, 621, &c.

This procefs was foon after brought to perfection by Kunckel; who fays, that one part of the precipitate is fufficient to give a ruby colour to 1280 parts of glafs, and a fenfible rednefs to upwards of 1900 parts; but that the fuccefs is by no means conftant. Kunckel alfo mentions a purple-gold powder, refembling that of Neri; which he obtained by infpiffating folution of gold to dryneis; abftracting from it frefh aqua-regia three or four times, till the matter appears like oil; then precipitating with ftrong alkaline ley, and waihing the precipitate with water. By diffolving this powder in fpirit of falt and precipitating again, it becomes, he fays, extremely fair; and in this ftate he directs it to be mixed with a due proportion of Venice glafs.

Orfchal, in a treatife intitled *Sol fine Veile*, gives the following procefs for producing a very fine ruby. He directs the purple precipitate made by tin to be ground with fix times its quantity of Venice glafs into a very fine powder, and this compound to be very carefully mingled with the frit or vitreous compofition to be tinged. His frit confifts of equal parts of borax, nitre, and fixed alkaline falt, and four times as much calcined flint as of each of the falts; but he gives no directions as to the proportion of the gold precipitate or mode of fufion. Hellot defcribes a preparation, which, mixed with Venice glafs, was found to give a beautiful purple enamel. This preparation confifts of equal parts of folution of gold and of folution of zinc in aqua-regia mixed together, with the addition of a volatile falt prepared from fal ammoniac by quicklime, in fufficient quantity to precipitate the two metals. The precipitate is then gradually heated till it acquires a violet colour. However, though a purple or red colour, approaching to that of ruby, may, by the methods above recited, be baked on glafs or enamels, and introduced into the mafs by fufion, the way of equally diffufing fuch a colour through a quantity of fluid glafs is ftill, fays Dr Lewis, a fecret. The following procefs for making the ruby glafs was communicated to Dr Lewis by an artift, who afcribed it to Kunckel. The gold is directed to be diffolved in a mixture of one part of fpirit of falt and three of aquafortis, and the tin in a mixture of one part of the former of thefe acids with two of the latter. The folution of gold being properly diluted with water, the folution of tin is added, and the mixture left to ftand till the purple matter has fettled to the bottom. The colourlefs liquor is then poured off, and the purple fediment, while moift and not very thick, is thoroughly mixed with powdered flint or fand. This mixture is well ground with powdered nitre, tartar, borax, and arfenic, and the compound melted with a fuitable fire. The proportions of the ingredients are 2560 parts of fand, 384 of nitre, 240 of tartar, 240 of borax, 28 of arfenic, 5 of tin, and 5 of gold.

Topaz colour. Glafs refembling this ftone may be made by pulverizing ten pounds of either of the compofitions for hard glafs with an equal quantity of the gold-coloured glafs, and fufing them together.

White opake and *femitranfparent* glafs may be made of ten pounds of either of the compofitions for hard glafs and one pound of well calcined horn, ivory, or bone;

Glafs. or an opake whitenefs may be given to glafs by adding one pound of very white arfenic to ten pounds of flint glafs. Let them be well powdered and mixed by grinding them together, and then fufed with a moderate heat till they are thoroughly incorporated. A glafs of this kind is made in large quantities at a manufacture near London; and ufed not only for different kinds of veffels, but as a white ground for enamel in dial-plates and fnuff-boxes, which do not require finifhing with much fire, becaufe it becomes very white and fufible with a moderate heat. Glafs.

Yellow. See *Gold colour* above.

Painting in GLASS. The ancient manner of painting in glafs was very fimple: it confifted in the mere arrangement of pieces of glafs of different colours in fome fort of fymmetry, and conftituted what is now called *Mofaic work*. See MOSAIC.

In procefs of time they came to attempt more regular deligns, and alfo to repreient figures heightened with all their fhades: yet they proceeded no farther than the contours of the figures in black with water-colours, and hatching the draperies after the fame manner on glaffes of the colour of the object they deligned to paint. For the carnation, they ufed glafs of a bright red colour; and upon this they drew the principal lineaments of the face, &c. with black.

At length, the tafte for this fort of painting improving conliderably, and the art being found applicable to the adorning of churches, bafilics, &c. they found out means of incorporating the colours in the glafs itfelf, by heating them in the fire to a proper degree; having firft laid on the colours. A French painter at Marfeilles is faid to have given the firft notion of this improvement, upon going to Rome under the pontificate of Julius II.; but Albert Durer and Lucas of Leyden were the firft that carried it to any height.

This art, however, has frequently met with much interruption, and fometimes been almoft totally loft; of which Mr Walpole gives us the following account, in his Anecdotes of Painting in England.

"The firft interruption given to it was by the reformation, which banifhed the art out of churches; yet it was in fome meafure kept up in the efcutcheons of the nobility and gentry in the windows of their feats. Towards the end of queen Elizabeth's reign it was omitted even there; yet the practice did not entirely ceafe. The chapel of our Lady at Warwick was ornamented anew by Robert Dudley earl of Leiceiter, and his counteis, and the cipher of the glafs painter's name yet remains, with the date 1574: and in fome of the chapels at Oxford the art again appears, dating itfelf in 1622, by the hand of no contemptible maiter.

"I could fupply even this gap of 48 years by many dates on Flemifh glafs: but nobody ever fuppofed that the fecret was loft fo early as the reign of James I. and that it has not perifhed fince will be evident from the following feries, reaching to the prefent hour.

"The portraits in the windows of the library at All Souls, Oxford. In the chapel at Queen's College there are twelve windows dated 1518. P. C. a cipher on the painted glafs in the chapel at Warwick, 1574. The windows at Wadham-college: the drawing pretty good, and the colours fine, by Bernard Van Linge, 1622. In the chapel at Lincoln's Inn, a window, with the name Bernard, 1623. This was probably the preceding Van Linge. In the church of St Leonard, Shoreditch, two windows by Baptifta Sutton, 1634. The windows in the chapel at Univerfity-college, Hen. Giles *pinxit*, 1687. At Chrift-church, Ifaac Oliver, aged 84, 1700. Window in Merton-chapel, William Price, 1700. Windows at Queen's New-college, and Maunlin, by William Price, the fon, now living, whofe colours are fine, whofe drawing is good, and whofe tafte in ornaments and mofaic is far fuperior to any of his predeceffors; is equal to the antique, to the good Italian maiters, and only furpaffed by his own fingular modefty. G'afs.

"It may not be unwelcome to the curious reader to fee fome anecdotes of the revival of tafte for painted glafs in England. Price, as we have faid, was the only painter in that ftyle for many years in England. Afterwards one Rowell, a plumber at Reading, did fome things, particularly for the late Henry earl of Pembroke; but Rowell's colours foon vanifhed. At laft he found out a very durable and beautiful red; but he died in a year or two, and the fecret with him. A man at Birmingham began the fame art in 1756 or 1757, and fitted up a window for Lord Lyttelton, in the church of Hagely; but foon broke. A little after him, one Peckitt at York began the fame bufinefs, and has made good proficiency. A few lovers of that art collected fome difperfed panes from ancient buildings, particularly the late Lord Cobham, who erected a Gothic temple at Stowe, and filled it with arms of the old nobility, &c. About the year 1753, one Afciotti, an Italian, who had married a Flemifh woman, brought a parcel of painted glafs from Flanders, and fold it for a few guineas to the honourable Mr Bateman, of Old Windfor. Upon that I fent Afciotti again to Flanders, who brought me 450 pieces, for which, including the expence of his journey, I paid him 36 guineas. His wife made more journeys for the fame purpofe; and fold her cargoes to one Palmer, a glazier in St Martin's-lane, who immediately raifed the price to one, two, or five guineas for a fingle piece, and fitted up entire windows with them, and with mofaics of plain glafs of different colours. In 1761, Paterfon, an auctioneer at Eflex-houfe in the Strand, exhibited the two firft auctions of painted glafs, imported in like manner from Flanders. All this manufacture confifted in rounds of fcripture-ftories, ftained in black and yellow, or in fmall figures of black and white; birds and flowers in colours, and Flemifh coats of arms."

The colours ufed in painting or ftaining of glafs are very different from thofe ufed in painting either in water or oil colours.

For black, take fcales of iron, one ounce; fcales of copper, one ounce; jet, half an ounce: reduce them to powder, and mix them. For blue, take powder of blue, one pound; fal nitre, half a pound; mix them and grind them well together. For carnation, take red chalk, eight ounces; iron fcales, and litharge of filver, of each two ounces; gum arabic, half an ounce; diffolve in water; grind all together for half an hour as ftiff as you can; then put it in a glafs and ftir it well, and let it ftand to fettle fourteen days. For green, take red lead, one pound; fcales of copper, one pound; and flint, five pounds: divide them into three parts; and add to them as much fal nitre;

put

Glaſs. put them into a crucible, and melt them with a ſtrong fire; and when it is cold, powder it, and grind it on a porphyry. For gold colour, take ſilver, an ounce; antimony, half an ounce; melt them in a crucible; then pound the maſs to powder, and grind it on a copper plate; add to it yellow ochre, or brick-duſt calcined again, fifteen ounces; and grind them well together with water. For purple, take minium, one pound; brown ſtone, one pound; white flint, five pounds: divide them into three parts, and add to them as much ſal nitre as one of the parts; calcine, melt, and grind it as you did the green. For red, take jet, four ounces; litharge of ſilver, two ounces; red chalk, one ounce; powder them fine, and mix them. For white, take jet, two parts; white flint, ground on a glaſs very fine, one part; mix them. For yellow, take Spaniſh brown, ten parts; leaf-ſilver, one part; antimony, half a part; put all into a crucible, and calcine them well.

In the windows of ancient churches, &c. there are to be ſeen the moſt beautiful and vivid colours imaginable, which far exceed any of thoſe uſed by the moderns, not ſo much becauſe the ſecret of making thoſe colours is entirely loſt, as that the moderns will not go to the charge of them, nor be at the neceſſary pains, by reaſon that this ſort of painting is not now ſo much in eſteem as formerly. Thoſe beautiful works which were made in the glaſs-houſes were of two kinds.

In ſome, the colour was diffuſed through the whole ſubſtance of the glaſs. In others, which were the more common, the colour was only on one ſide, ſcarce penetrating within the ſubſtance above one-third of a line; though this was more or leſs according to the nature of the colour, the yellow being always found to enter the deepeſt. Theſe laſt, though not ſo ſtrong and beautiful as the former, were of more advantage to the workmen, by reaſon that on the ſame glaſs, though already coloured, they could ſhow other kinds of colours where there was occaſion to embroider draperies, enrich them with foliages, or repreſent other ornaments of gold, ſilver, &c.

In order to this, they made uſe of emery, grinding or wearing down the ſurface of the glaſs till ſuch time as they were got through the colour to the clear glaſs. This done, they applied the proper colours on the other ſide of the glaſs. By theſe means, the new colours were hindered from running and mixing with the former, when they expoſed the glaſſes to the fire, as will appear hereafter.

When indeed the ornaments were to appear white, the glaſs was only bated of its colour with emery, without tinging the place with any colour at all; and this was the manner by which they wrought their lights and heightenings on all kinds of colour.

The firſt thing to be done, in order to paint or ſtain glaſs, in the modern way, is to deſign, and even colour the whole ſubject on paper. Then they chooſe ſuch pieces of glaſs as are clear, even, and ſmooth, and proper to receive the ſeveral parts; and proceed to diſtribute the deſign itſelf, or papers it is drawn on, into pieces ſuitable to thoſe of the glaſs; always taking care that the glaſſes may join in the contours of the figures and the folds of the draperies; that the carnations, and other finer parts, may not be impaired by the lead with which the pieces are to be joined together. The diſtribution being made, they mark all the glaſſes as well as papers, that they may be known again: which done, applying every part of the deſign upon the glaſs intended for it, they copy or tranſfer the deſign upon this glaſs with the black colour diluted in gum-water, by tracing and following all the lines and ſtrokes as they appear through the glaſs with the point of a pencil. Glaſs.

When theſe ſtrokes are well dried, which will happen in about two days, the work being only in black and white, they give a ſlight waſh over with urine, gum arabic, and a little black; and repeat it ſeveral times, according as the ſhades are deſired to be heightened; with this precaution, never to apply a new waſh till the former is ſufficiently dried.

This done, the lights and riſings are given by rubbing off the colour in the reſpective places with a wooden point, or the handle of the pencil.

As to the other colours above mentioned, they are uſed with gum-water, much as in painting in miniature; taking care to apply them lightly, for fear of effacing the outlines of the deſign; or even, for the greater ſecurity, to apply them on the other ſide; eſpecially yellow, which is very pernicious to the other colours, by blending therewith. And here too, as in pieces of black and white, particular regard muſt always be had not to lay colour on colour, or lay on a new lay, till ſuch time as the former are well dried.

It may be added, that the yellow is the only colour that penetrates through the glaſs, and incorporates therewith by the fire; the reſt, and particularly the blue, which is very difficult to uſe, remaining on the ſurface, or at leaſt entering very little. When the painting of all the pieces is finiſhed, they are carried to the furnace or oven to anneal or bake the colours.

The furnace here uſed is ſmall, built of brick, from 18 to 30 inches ſquare. At ſix inches from the bottom is an aperture to put in the fuel and maintain the fire. Over this aperture is a grate made of three ſquare bars of iron, which traverſe the furnace, and divide it into two parts. Two inches above this partition is another little aperture, through which they take out pieces to examine how the coction goes forward. On the grate is placed a ſquare earthen pan, ſix or ſeven inches deep, and five or ſix inches leſs every way than the perimeter of the furnace. On the one ſide hereof is a little aperture, through which to make trials, placed directly oppoſite to that of the furnaces deſtined for the ſame end. In this pan are the pieces of glaſs to be placed in the following manner: Firſt, the bottom of the pan is covered with three ſtrata or layers of quicklime pulveriſed; thoſe ſtrata being ſeparated by two others of old broken glaſs, the deſign whereof is to ſecure the painted glaſs from the too intenſe heat of the fire. This done, the glaſſes are laid horizontally on the laſt or uppermoſt layer of lime.

The firſt row of glaſs they cover over with a layer of the ſame powder an inch deep; and over this they lay another range of glaſſes, and thus alternately till the pan is quite full; taking care that the whole heap always end with a layer of the lime-powder.

The pan being thus prepared, they cover up the

Glaſs. furnace with tiles, on a ſquare table of earthen ware, cloſely luted all round; only leaving five little apertures, one at each corner, and another in the middle, to ſerve as chimneys. Things thus diſpoſed, there remains nothing but to give the fire to the work. The fire for the firſt two hours muſt be very moderate, and muſt be increaſed in proportion as the coction advances, for the ſpace of ten or twelve hours; in which time it is uſually completed. At laſt the fire, which at firſt was charcoal, is to be of dry wood, ſo that the flame covers the whole pan, and even iſſues out at the chimneys. Glaſs.

During the laſt hours, they make eſſays, from time to time, by taking out pieces laid for the purpoſe through the little aperture of the furnace and pan, to ſee whether the yellow be perfect, and the other colours in good order. When the annealing is thought ſufficient, they proceed with great haſte to extinguiſh the fire, which otherwiſe would ſoon burn the colours, and break the glaſſes.

Glass-Balls, which are circular or otherwiſe ſhaped hollow veſſels of glaſs, may be coloured within, ſo as to imitate the ſemipellucid gems. The method of doing it is this: make a ſtrong ſolution of ichthyocolla, or iſinglaſs, in common water, by boiling; pour a quantity of this while warm into the hollow of a white glaſs veſſel; ſhake it thoroughly about, that all the ſides may be wetted, and then pour off the reſt of the moiſture. Immediately after this, throw in red-lead, ſhake it and turn it about, throw it into many places with a tube, and the moiſture will make it ſtick and run in waves and pretty figures. Then throw in ſome of the painter's blue ſmalt, and make it run in waves in the ball as the red-lead; then do the ſame with verdegris, next with orpiment, then with red lake, all well ground; always caſting in the colours in different places, and turning the glaſs, that the moiſture within may run them into the waves. Then take fine plaſter of Paris, and put a quantity of it into the ball; ſhake it alſo nimbly about; this will every where ſtick firmly to the glaſs, and give it a ſtrong inner coat, keeping all the colours on very fairly and ſtrongly. Theſe are ſet on frames of carved wood, and much eſteemed as ornaments in many places..

Glass of Lead, a glaſs made with the addition of a large quantity of lead, of great uſe in the art of making counterfeit gems. The method of making it is this: Put a large quantity of lead into a potter's kiln, and keep it in a ſtate of fuſion with a moderate fire, till it is calcined to a grey looſe powder; then ſpread it in the kiln, and give it a greater heat, continually ſtirring it to keep it from running into lumps; continue this ſeveral hours, till the powder become of a fair yellow; then take it out, and ſift it fine: this is called *calcined lead*. Take of this calcined lead 15 pounds, and cryſtalline or other frit 12 pounds; mix theſe as well as poſſible together; put them into a pot, and ſet them in the furnace for ten hours; then caſt the whole, which will be now perfectly melted, into water; ſeparate the looſe lead from it, and return the metal into the pot; and after ſtanding in fuſion 12 hours more, it will be fit to work. It is very tender and brittle, and muſt be worked with great care, taking it ſlowly out of the pot, and continually wetting the marble it is wrought upon. Glaſs.

It is well known that ceruſs or white lead, minium, litharge, and all the other preparations and calces of lead, are eaſily fuſed by a moderate fire, and formed into a tranſparent glaſs of a deep yellow colour. But this glaſs is ſo penetrating and powerful a flux, that it is neceſſary to give it a greater conſiſtence, in order to render it fit for uſe. With this view, two parts of calx of lead, e. g. minium, and one part of ſand or powdered flints, may be put into a crucible of refractory clay, and baked into a compact body. Let this crucible, well cloſed with a luted lid, be placed in a melting furnace, and gradually heated for an hour or an hour and a half; and afterwards let the heat be increaſed ſo as to obtain a complete fuſion, and continued in that ſtate for the ſame time: let the crucible remain to cool in the furnace; and when it is broken, a very tranſparent yellow-coloured glaſs will be found in it. Some add nitre and common ſalt to the above mixture, becauſe theſe ſalts promote the fuſion and the more equal diſtribution of the ſand. This glaſs of lead has a conſiderable ſpecific gravity, and its loweſt part is always the heavieſt. It is an important flux in the aſſays of ores to facilitate their ſcorifications.

Glaſs of lead is capable of all the colours of the gems in very great perfection. The methods of giving them are theſe: for green, take polverine frit 20 pounds, lead calcined 16 pounds; ſift both the powders very fine; then melt them into a glaſs, ſeparating the unmixed lead, by plunging the maſs in water; after this return it into the pot, and add braſs thrice calcined ſix ounces, and one penny-weight of crocus martis made with vinegar; put this in at ſix different times, always carefully mixing it together; let it finally ſettle an hour, then mix it together, and take a proof of it; when the colour is right, let it ſtand eight hours, and then work it. If inſtead of the calcined braſs the ſame quantity of the caput mortuum of the vitriolum veneris be uſed, the green is yet much finer.

For topaz-colour, take cryſtal frit 15 pounds, calcined lead 12 pounds; mix them well together, by ſifting the powders through a fine ſieve; then ſet them in a furnace not too hot, and ſeparate the ſuperfluous unmixed lead, by caſting the whole into water; repeat this twice: then add half gold yellow glaſs, and let them incorporate and purify, and they will be of the true and exact colour of the oriental topazes.

For ſea-green, take cryſtal frit 16 pounds, calcined lead 10 pounds; mix and ſift them together, and ſet them in a pot in a furnace; in 12 hours the whole will be melted; then caſt it into water, and ſeparate it from the looſe lead; put them into the furnace again for eight hours; then ſeparate the looſe lead by waſhing a ſecond time, and return it to the pot for eight hours more.

Muſcovy Glass. See Mica.

Painting on Glaſs by means of Prints. See *Back-painting*.

Glass-Porcelain, the name given by many to a modern invention of imitating the china-ware with glaſs.

The

Glaſs. The method given by Mr Reaumur, who was the firſt that carried the attempt to any degree of perfection, is ſhortly this: The glaſs-veſſels to be converted into porcelain are to be put into a large earthen veſſel, ſuch as the common fine earthen diſhes are baked in, or into ſufficiently large crucibles; the veſſels are to be filled with a mixture of fine white ſand, and of fine gypſum or plaſter-ſtone burnt into what is called plaſter of Paris, and all the interſtices are to be filled up with the ſame powder, ſo that the glaſs veſſels may no where touch either one another, or the ſides of the veſſel they are baked in. The veſſel is to be then covered down and luted, and the fire does the reſt of the work; for this is only to be put into a common potter's furnace, and when it has ſtood there the uſual time of the baking the other veſſels, it is to be taken out, and the whole contents will be found no longer glaſs, but converted into a white opake ſubſtance, which is a very elegent porcelain, and has almoſt the properties of that of China.

The powder which has ſerved once will do again as well as freſh, and that for a great many times: nay, it ſeems ever ſo often. The cauſe of this transformation, ſays Macquer, is probably that the vitriolic acid of the gypſum quits its baſis of calcareous earth, and unites with the alkaline ſalt and ſaline earth of the glaſs, with which it forms a kind of ſalt or ſelenites, different from the calcareous ſelenites, by the interpoſition of which matter the glaſs acquires the qualities of porcelain. See further on this ſubject the article Chemistry, n° 591—594.

Glass-Pots, the veſſels in the glaſs trade uſed for melting the glaſs. Thoſe for the white glaſs works are made of a tobacco-pipe clay, brought from the Iſle of Wight, which is firſt well waſhed, then calcined, and afterwards ground to a fine powder in a mill; which being mixt with water, is then trod with the bare feet till it is of a proper conſiſtence to mould with the hands into the proper ſhape of the veſſels. When theſe are thus made, they are afterwards annealed over the furnace. Thoſe for the green glaſs work are made of the nonſuch, and another ſort of clay from Staffordſhire; they make theſe ſo large as to hold three or four hundred weight of metal. And beſides theſe, they have a ſmall ſort called piling-pots, which they ſet upon the larger, and which contain a finer and more nice metal fit for the niceſt works.

The clay that is uſed for this purpoſe ſhould be of the pureſt and moſt refractory kind, and well cleanſed from all ſandy, ferruginous, and pyritous matters; and to this it will be proper to add ground crucibles, white ſand, calcined flints duly levigated, or a certain proportion of the ſame clay baked, and pounded not very finely. The quantity of baked clay that ought to be mixed with the crude clay, to prevent the pots from cracking when dried, or expoſed to a great heat, is not abſolutely determined, but depends on the quality of the crude clay, which is more or leſs fat. M. D'Antic, in a memoir on this ſubject, propoſes the following method of aſcertaining it: the burnt and crude clay, being mixed in different proportions, ſhould be formed into cakes, one inch thick, and four inches long and wide. Let theſe cakes be ſlowly dried, and expoſed to a violent heat, till they become as hard and as much contracted as poſſible, and in this ſtate be examined; and the cake, he ſays, which has ſuffered a diminution of its bulk equal only to an eighteenth part, is made of the beſt proportions. He obſerves, in general, that moſt clays require that the proportion of the burnt ſhould be to the freſh as four to five. Glaſs.

Tin-Glass, the ſame with Biſmuth. See the article Bismuth; alſo Chemistry, N 1250.

Veſſels of Glass uſed in Chemical Experiments. See Chemistry, n° 556.

Glasses are diſtinguiſhed, with regard to their form, uſe, &c. into various kinds, as, drinking glaſſes, optical-glaſſes, looking-glaſſes, burning-glaſſes, &c.

Drinking-Glasses, are ſimple veſſels of common glaſs or cryſtal, uſually made in form of an inverted cone.

Each glaſs conſiſts of three parts, viz. the calyx or bowl, the bottom, and the foot; which are all wrought or blown ſeparately.

Nothing can be more dexterous and expeditious than the manner wherein theſe parts are all blown; two of them opened, and all three joined together. An idea is only to be had thereof, by ſeeing them actually at work.

The glaſſes chiefly uſed in England are made of the aſhes of fern; cryſtal glaſſes being leſs frequent in uſe. The exceeding brittleneſs of this commodity, notwithſtanding the eaſy rate of each glaſs, renders the conſumption thereof very conſiderable. For the method of gilding the edges of drinking-glaſſes, ſee *Gilding on Enamel and Glaſs*.

Optical-Glasses. See Optics.

The improvements hitherto made in teleſcopes by means of combining lenſes made of different kinds of glaſs, though very great, are yet by no means adequate to the expectations that might reaſonably be formed if opticians could fall on any method of obtaining pieces of glaſs ſufficiently large for purſuing the advantages of Mr Dollond's diſcovery. Unfortunately, however, though the board of longitude have offered a conſiderable reward for bringing this art to the requiſite perfection, no attempt of any conſequence has hitherto been made. Mr Keir is of opinion, that the accompliſhment of this is by no means an eaſy taſk; as it requires not only a competent knowledge of the properties of glaſs fitteſt for the purpoſe (the faults not being evident to common inſpection), but a conſiderable degree of chemical knowledge is alſo neceſſary in order to invent a compoſition by which theſe faults may be avoided; and laſtly, a kind of dexterity in the execution of the work, which can only be acquired by practice. Our author, however, thinks, that if the ſubject were more generally underſtood, and the difficulties more fully pointed out, for which purpoſe he makes the following remarks, the end might be more eaſily accompliſhed.

1. The rays of light paſſing through a glaſs lens or priſm, or through any other medium of unequal thickneſs, are refracted; but not in an equal manner, the blue, violet, &c. being more refracted than the red.

2. Hence it happens, that the rays of light, when refracted by a common lens, do not all unite in one focus, but in reality form as many different foci as there are colours; and hence ariſe the priſmatic colours, or iriſes, which appear towards the borders of the image formed by the common convex lenſes, and which render the viſion extremely indiſtinct.

3. The indiſtinctneſs of viſion produced by this cauſe, which

Glaſs. which is ſenſible in teleſcopes of a ſmall aperture, increaſes in ſo great a proportion, viz as the cubes of the diameters, that it ſeemed impoſſible to increaſe the power of dioptric teleſcopes greatly, without extending them to a very inconvenient length, unleſs this confuſion of colours could be corrected. Glaſs.

4 It was known that different tranſparent bodies poſſeſſed different degrees of refractive power; and, until Mr Dollond diſcovered the contrary, it was ſuppoſed, that the refractions of the coloured rays were always in a determinate ratio to one another. On this ſuppoſition it ſeemed impoſſible to correct the faults of refracting teleſcopes: for it was ſuppoſed, that if the diſperſion of light produced by a convex lens were counteracted by another lens or medium of a concave form, the refraction would be totally deſtroyed; and this indeed would be the caſe, if the two mediums were made of the ſame matter; and from ſome experiments made by Sir Iſaac Newton, this was ſuppoſed to be actually the caſe in all ſubſtances whatever.

5. From conſidering that the eyes of animals are formed of mediums of different colours, it occurred firſt to Mr David Gregory, the celebrated profeſſor of aſtronomy at Oxford, and then to Mr Euler, that, by a combination of mediums which had different refractive powers, it might be poſſible to remedy the imperfections of dioptric teleſcopes. It does not, however, appear, that either of theſe gentlemen underſtood the true principle on which theſe phenomena depend. Mr Euler executed his idea by forming a compound object lens from two glaſs lenſes with water interpoſed, but his attempt was not attended with ſucceſs. Mr Dollond, however, was led by ſome arguments adduced by Mr Klingeſternia, to repeat one of Sir Iſaac Newton's experiments, and which had induced even that great philoſopher himſelf to ſuppoſe that the improvement afterwards executed by Mr Dollond was impoſſible. This experiment was made by Sir Iſaac Newton, by placing a glaſs priſm within a priſmatic veſſel filled with water, in ſuch a manner that the rays of light which were refracted by the glaſs priſm ſhould paſs through and be refracted in a contrary direction by the water priſm. In this manner the refraction of the light was entirely deſtroyed. But when Mr Dollond repeated the experiment, he found, that, contrary to his own expectations, when the angles of the two priſms were ſo proportioned that they counteracted each other's mean refraction, then colours appeared; and on the other hand, when they were ſo proportioned that the diſperſion of the coloured rays was counteracted, the mean refraction ſtill ſubſiſted; which evidently proved, that the mean refractive and diſperſive powers of glaſs and water were not proportional to one another.

6. To apply this to the propoſed improvement, Mr Dollond examined ſeveral kinds of glaſs. Crown-glaſs was found to poſſeſs the ſmalleſt diſperſive power in proportion to its refraction; while flint-glaſs poſſeſſed the greateſt diſperſive power in proportion to its refraction, which was alſo very great. On comparing theſe two exactly together, he found, that a wedge of white flint glaſs whoſe angle was about 25 degrees, and another of crown-glaſs whoſe angle was 29 degrees, refracted very nearly alike. He found alſo, that, when the wedges were ground to ſuch angles, the refraction produced by the flint-glaſs was to that produced by the crown-glaſs nearly as two to three, the refracted light was then free from colour. On meaſuring the general refracting powers of theſe two glaſſes, he found, that in flint-glaſs, the ſine of incidence of the rays was to the ſine of mean refraction as 1 to 1.583; and that, in crown-glaſs, the ſine of incidence was to the ſine of mean refraction as 1 to 1.53.

The methods of determining the different refractive powers of glaſs are given under the article Optics. Here we ſhall only obſerve, that two kinds of glaſs are neceſſary for the conſtruction of achromatic teleſcopes; one of which ſhall poſſeſs as ſmall, and the other as great, diſperſive powers, relative to their mean refracting powers, as can be procured. The difference of glaſſes in this reſpect depends on the quality of the ingredients employed in their compoſition. Crown-glaſs, which is compoſed of ſand melted by means of the aſhes of ſea-weeds, barilla, or kelp, both which fluxes are known to conſiſt of vegetable earth, alkali, and neutral ſalt, is found to give the ſmalleſt diſperſive power. Plate glaſs, which conſiſts of ſand melted by means of fixed vegetable alkali, with little or no vegetable earth, gives a greater diſperſive power; but both theſe give much leſs than flint glaſs, which conſiſts of ſand melted by means of minium and fixed alkali. It appears, therefore, that the diſperſion of the rays is greateſt when minium, or probably other metallic calces, are made uſe of; and that alkalies give a greater power of diſperſion than vegetable or other earths. Mr Zieher of Peterſburgh, however, informs us that he has made a kind of glaſs, much ſuperior in this reſpect to flint glaſs; but it does not as yet appear whether it be more fit for optical purpoſes than that commonly made uſe of. There ſeems no difficulty in augmenting the diſperſive power, as that is found to depend on the quantity of minium or other flux: but thus we unfortunately increaſe alſo the capital fault to which flint glaſs and all compoſitions of that kind are ſubject; namely, the being ſubject to veins or ſmall threads running through it. By theſe, even when ſo ſmall as to be imperceptible to the naked eye, the rays which fall on them are diverted from their proper direction, and thereby render the images confuſed. This is owing to the greater denſity of the veins, as appears by their image being received on white paper, when the glaſs is held between the paper and the ſun or a candle, at a proper diſtance. The rays of light being then made to converge by the ſuperior denſity of the veins, their images will appear as bright lines bordered with obſcure edges on the paper. Flint-glaſs is ſo much ſubject to this kind of imperfection, that it is with difficulty the opticians can pick out pieces of the ſize commonly uſed from a large quantity of the glaſs. It is farther to be regretted, that the minium which produces the greateſt diſperſive power, is likewiſe the very ſubſtance which renders flint glaſs much more ſubject to theſe imperfections than any other. The reaſon is, that the ſand and earthy matters mix uniformly in fuſion; and, having not only a conſiderable degree of affinity towards each other, but alſo being not much different from each other, they are not apt to ſeparate. On the other hand, when ſuch an heavy ſubſtance as minium is added to theſe earthy ſubſtances, though it has a pretty ſtrong tendency to unite with the earthy ſubſtances, it has none with the fixed alkali, which

Glaſs. is another ingredient in this glaſs. Hence ſome parts of the glaſs will contain more metallic matter than the reſt; particularly that near the buttom of the pot, which is ſo full of large veins as to be applied only to the making of wares of little value. The veins in this caſe are formed by the deſcent of the minium to the bottom, which in its paſſage forms threads or veins by dragging other parts of the glaſs along with them.

The correction of this fault appears therefore to be very difficult. M. Macquer informs us, that he had in vain tried to remove it by very long fuſion and a fierce fire; which indeed others have found by experience not to correct, but to augment the evil. Mr Keir is of opinion that ſome new compoſition muſt be diſcovered, which, along with a ſufficient refractive power, ſhould poſſeſs a greater uniformity of texture; but he is likewiſe of opinion, that ſcarce any alteration in this reſpect could be made without injuring the colour of the glaſs. For optical purpoſes, however, our author does not think that an alteration in the colour of the ingredients would be very detrimental. "I am convinced (ſays he), that glaſſes ſenſibly tinged with colour, might tranſmit as much or more light than the beſt flint-glaſs. For the colourleſs appearance of flint-glaſs is an optical deception. The minium gives it a conſiderable tinge of yellow, and the alkali inclines it to a bluiſh caſt, beſides the colour ariſing from a greater or leſs impurity of the materials; ſo that the glaſs would actually be very ſenſibly coloured, unleſs by the addition of manganeſe, which is known to give a purpliſh red. Thus the other tinges are counteracted, but not effaced or deſtroyed as has been frequently imagined. By the mixture of the three principal colours, red, yellow, and blue, more or leſs exactly counterpoiſed, a certain dark ſhade is introduced, in which, as not any one of the colours predominates, no coloured tinge appears, but the effect is merely a diminution of the tranſparency of the glaſs, which, however, is too ſmall for ordinary obſervation." Mr Keir is even of opinion, that a certain tinge of yellow would in many caſes be of ſervice, becauſe it would exclude ſome of the blue rays, which being moſt refrangible are moſt injurious to the diſtinctneſs of viſion.

Very conſiderable difficulties, however, muſt ariſe in attempting improvements of this kind; as the experiments muſt all be tried on a very large ſcale. This is not only attended with a very heavy expence in itſelf on account of the quantity of materials employed, but from the heavy duty of exciſe which is rigorouſly exacted whether the glaſs be manufactured into ſaleable articles or not. It is obſerved in the manufacture of every kind of glaſs, that the glaſs in the middle of the area or tranſverſe ſection of a pot is much purer and freer from veins and other imperfections than the part which is near the ſides, and that the glaſs at the bottom is the worſt of all. Conſequently it is chiefly in large pots, ſuch as are uſed in manufactures, that there is a probability of ſucceſs. Very fine and beautiful glaſſes, called *paſte* and *artificial gems*, may be made in ſmaller pots or crucibles; but this glaſs is ſuffered to cool and ſubſide in the veſſel, by which means the contiguous parts are more uniform in their texture than can be expected in a piece of glaſs taken out of the pot while hot in the common way, by making it adhere and twiſt round an iron rod or pipe. But although the method of allowing the glaſs to cool in the pots is very advantageous for the purpoſes of the jeweller, it is by no means applicable to thoſe of the optician. Glaſs cooled in that gradual manner, ſuffers ſome degree of cryſtallization or peculiar arrangement of its parts; the conſequence of which is, that the rays of light undergo certain refractions independent on the form of the glaſs, which greatly affect the diſtinctneſs of viſion in teleſcopes. Glaſs, Glaſtonbury.

GLASTONBURY, a town of Somerſetſhire in England; ſeated in W. Long. 2. 40 N Lat. 51. 15. —It is noted for a famous abbey, ſome magnificent ruins of which are ſtill remaining; but they are every day diminiſhing for the ſake of the ſtones. However, the curious ſtructure called *the Abbot's kitchen* is ſtill pretty entire, and is of a very unuſual contrivance. The monks pretend that it was the reſidence of Joſeph of Arimathea, and of St Patrick; but for this aſſertion they produce no good authority. The king of the Weſt Saxons erected a church here, which he and the ſucceeding kings enriched to ſuch a degree, that the abbot lived like a prince, had the title of *lord*, and ſat among the barons in parliament; and no perſon, not even a biſhop or prince, durſt ſet foot on the iſle of Avalon, in which the abbey ſtands, without his leave. The revenue of the abbey was above 40,000l *per ann.* beſides ſeven parks well ſtocked with deer. The laſt abbot (Richard Whiting), who had 100 monks, and 300 domeſtics, was hanged in his pontificals, with two of his monks, on the Tor, a high hill in the neighbourhood, for refuſing to take the oath of ſupremacy to Henry VIII. and ſurrender his abbey when required. Edgar and many other Saxon kings were buried here; and, as ſome will have it, Arthur the Britiſh king. Every cottage here has part of a pillar, a door, or a window of this fabric; of which there ſtill remain the ruins of the choir, the middle tower, and chapels. The walls that remain of the abbey are overgrown with ivy, and the aſpect of the whole is both melancholy and venerable. Here are two pariſh churches. This town, while under the protection of its abbots, was a parliamentary borough, but it loſt that and its privilege of a corporation; the latter of which was, however, reſtored by queen Anne, who granted it a new charter for a mayor and burgeſſes. The only manufactory here is ſtockings, but the chief ſupport of the place is the reſort of people to ſee the ruins of the abbey. The George inn here was formerly called the *Abbot's Inn*; becauſe it was a receptacle for the ſtrollers that came in pilgrimage to the abbey. At a little diſtance from the old church and facing the monk's church-yard are two remarkable pyramids, with inſcriptions, that are in characters unintelligible, and an image in biſhops veſtments.—The ſtory of the Glaſtonbury thorn, and of its budding always upon Chriſtmas-day, is well known: however, that circumſtance is falſe; though if the win-

ter

Glatz || Glaux.

ter is mild, it always buds about the latter end of December, but later if the weather is ſevere.

GLATZ, a handſome and ſtrong town of Bohemia, and capital of a county of the ſame name. It is ſeated on the river Neiſſe; and has ſtrong fortifications, with a caſtle built upon a mountain. The county was ceded to the king of Pruſſia by the queen of Hungary in 1742; and is about 45 miles in length, and 25 in breadth. It has mines of pit-coal, ſilver, and iron; good quarries, plenty of cattle, and fine ſprings of mineral water. The town is ſituated in E. Long. 15. 16. N. Lat. 50. 25.

GLAUBER (John Rhodolphus), a celebrated German chemiſt, who flouriſhed about the year 1646. He wrote a great number of different treatiſes on chemiſtry, ſome of which have been tranſlated into Latin and French. All his works have been collected into one volume, intitled, *Glauberus concentratus*, which has been tranſlated into Engliſh, and was printed at London, in folio, in 1689.

Glauber's Salts. See Chemistry *Index*.

GLAUCOMA, in medicine and ſurgery, the name of a diſeaſe in the eye, wherein the cryſtalline humour is turned of a bluiſh or greeniſh colour, and its tranſparency hereby diminiſhed.—The word comes from γλαυκος, *cæſius*, "ſea green, ſky-coloured, or greyiſh."

Thoſe in whom this diſorder is forming, diſcover it hence, that all objects appear to them as thro' a cloud or miſt; when entirely formed, the viſual rays are all intercepted, and nothing is ſeen at all.

It is reckoned incurable, when inveterate, and in aged perſons: and even under other circumſtances, is very difficult of cure, externals proving of little ſervice.

The internals beſt ſuited to it, are thoſe uſed in the gutta ſerena. Jul. Cæſar Claudinus, Conſul. 74. gives a remedy for the glaucoma.

The glaucoma is uſually diſtinguiſhed from the cataract or ſuffuſion, in this, that in the cataract the whiteneſs appears in the pupil, very near the cornea; but it ſhows deeper in the glaucoma.

Some late French authors, however, maintain the cataract and glaucoma to be one and the ſame diſeaſe. According to them, the cataract is not a film, or pellicle, formed before the pupil, as had always been imagined; but an inſpiſſation or induration of the humour itſelf, whereby its tranſparency is prevented; which brings the cataract to the glaucoma. According to Mr Sharp, the glaucoma of the ancient Greeks is the preſent cataract; but M. St Yves ſays it is a cataract accompanied with a gutta ſerena. See Surgery.

GLAUCUS, a marine god, or deity of the ſea. There are a great many fabulous accounts of this divinity: but the poetical hiſtory of him is, that before his deification, he was a fiſherman of the town of Anthedon, who having one day taken a conſiderable number of fiſhes, which he laid upon the bank, on a ſudden perceived, that theſe fiſhes, having touched a kind of herb that grew on the ſhore, received new ſtrength, and leaped again into the ſea; upon the ſight of which extraordinary accident, he was tempted to taſte of the herb himſelf, and preſently leaped into the ſea after them, where he was metamorphoſed into a Triton, and became one of the ſea-gods.

GLAUX, in botany: A genus of the monogynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 17th order, *Calycanthemæ*. The calyx is monophyllous; there is no corolla: the capſule is unilocular, quinquevalved, and pentaſpermous. Glazier, Glazing.

GLAZIER, an artificer who works in glaſs.—The principal part of a glazier's buſineſs conſiſts in fitting panes of glaſs to the ſaſhes and window-frames of houſes, pictures, &c. and in cleaning the ſame.

GLAZING, the cruſting over earthen ware by a vitreous ſubſtance, the baſis of which is lead. See *Glass of Lead*.

The workers of common earthen ware, however, are not at the trouble of thus previouſly making a pure glaſs of lead. Their uſual compoſition for glazing their ware is formed of white ſand 40 pounds, of red lead 20 pounds, of pearl-aſhes 20 pounds, and of common ſalt 12 pounds. Powder the ſand by grinding it, and then add it to the other ingredients and grind them together: after which calcine them for ſome time with a moderate heat, and when the mixture is cold, pound it to powder; and when wanted for uſe temper it with water. The proportion of theſe ingredients may be occaſionally varied The ware, after being turned on the wheel and dried in the open air, is covered over with the above compoſition by means of a bruſh; and when ſet in the furnace the violent heat ſoon reduces it to a perfect glaſs, covering the whole internal and external ſurface of the veſſel.

We may obſerve, however, in general, that lead ought to be excluded from the compoſition of glazings, and other fluxes ſubſtituted in its ſtead. A tranſparent glazing may be prepared without lead by calcining 40 pounds of white ſand, 25 pounds of pearl-aſhes, and 15 pounds of common ſalt; and proceeding as before: and a more perfect tranſparent glazing may be made of ſand 40 pounds, of woood-aſhes perfectly burnt 50 pounds, of pearl-aſhes 10 pounds, and of common ſalt 12 pounds. The following recipes are taken for the moſt part from Kunckel, who ſays, that they are the true glazings uſed at Delft and other Dutch manufactories.

Black is made of eight parts of red-lead, iron-filings three, copper-aſhes three, and zaffer two meaſures. This when melted will make a brown-black; and if you want it blacker, add more zaffer to it.

Blue is thus prepared: Take lead-aſhes or red-lead one pound, clear-ſand or powdered flints two pounds, common ſalt two pounds, white calcined tartar one pound, Venice or other glaſs half a pound, zaffer half a pound; mix them well together and melt them for ſeveral times, quenching them always in cold water. If you would have it fine and good, it will be proper to put the mixture into a glaſs furnace for a day or two.

Another blue glazing may be formed of one pound of tartar, a quarter of a pound of red-lead, half an ounce of zaffer, and a quarter of a pound of powdered flints, which are to be fuſed and managed as in the laſt recipe. Or, take two pounds of calcined lead and tin, add five pounds of common ſalt, five pounds of powdered flints, and of zaffer, tartar, and Venetian glaſs, each one pound. Calcine and fuſe the mixture as before. Or, again, take of red-lead one part, of ſand three parts, and of zaffer one part. For a violet blue

Glaſs. glazing, take four ounces of tartar, two ounces of red-lead, five ounces of powdered flints, and half a dram of manganeſe.

Brown is made of red lead and flints of each 14 parts, and of manganeſe two parts fuſed; or of red-lead 12 parts, and manganeſe one part fuſed. A brown glazing, to be laid on a white ground, may be made of manganeſe two parts, and of red-lead and white-glaſs of each one part, twice fuſed.

Fleſh-coloured is made of 12 parts of lead aſhes, and one of white-glaſs.

Gold-coloured. Take of litharge three parts, of ſand or calcined flint one part; pound and mix theſe very well together, then run them into a yellow glaſs with a ſtrong fire. Pound this glaſs, and grind it into a ſubtile powder, which moiſten with a well ſaturated ſolution of ſilver; make it into a paſte, which put into a crucible, and cover it with a cover. Give at firſt a gentle degree of fire; then increaſe it, and continue it till you have a glaſs, which will be green. Pound this glaſs again, and grind it to a fine powder; moiſten this powder with ſome beer, ſo that by means of an hair pencil you may apply it upon the veſſels or any piece of earthen ware. The veſſels that are painted or covered over with this glazing muſt be firſt well heated, then put under a muffle; and as ſoon as the glaſs runs, you muſt ſmoak them, by holding them over burning vegetables, and take out the veſſels. Mr Heinſius of Peterſburgh, who ſent this receipt to the Royal Society, uſes the words *affiare debes fumum*, which is rendered *ſmoak them*, in the Tranſactions. Phil. Tranſ. N. 465. § 6.

Kunckel gives ſeveral preparations for a gold-coloured yellow glazing. This may be produced by fuſing a mixture of three parts of red-lead, two parts of antimony, and one part of ſaffron of Mars; by again melting the powdered maſs, and repeating the operation four times, or by fuſing four or five times a compoſition of red lead and antimony of each an ounce, and of ſcales of iron half an ounce; or by calcining and fuſing together eight parts of red-lead, ſix parts of flints, one part of yellow ochre, one part of antimony, and one part of white glaſs. A tranſparent gold-coloured glazing may be obtained by twice fuſing red-lead and white-flints, of each 12 parts, and of filings of iron one part.

Green may be prepared of eight parts of litharge or red-lead, eight parts of Venice glaſs, four parts of braſs-duſt or filings of copper; or of ten parts of litharge, twelve of flint or pebble, and one of *æs uſtum* or copper-aſhes.—A fine green glazing may be produced by fuſing one part of the Bohemian granate, one part of filings of copper, one part of red-lead, and one part of Venetian glaſs; or by fuſing one part of white glaſs, the ſame quantity of red-lead, and alſo of filings of copper; powdering the maſs, and adding one part of Bohemian granate to two parts of this powder. A fine green may be obtained by mixing and grinding together any of the yellow glazings with equal quantities of the blue glazings; and all the ſhades and teints of green will be had by varying the proportion of the one to the other, and by the choice of the kind of yellow and blue.

Sea-green is made of five pounds of lead-aſhes, one pound of tin-aſhes, three pounds of flint, three quarters of a pound of ſalt, half a pound of tartar, and half a pound of copper-duſt. Glaſs.

Iron-colour is prepared of 15 parts of lead-aſhes or red lead, 14 of white-ſand or flints, and five of calcined copper. This mixture is to be calcined and fuſed

Liver-colour is prepared of 12 parts of litharge, eight of ſalt, ſix of pebble or flint, and one of manganeſe.

Purple-brown conſiſts of lead-aſhes 15 parts, clean ſand or powdered flints 18 parts, manganeſe one part, and white glaſs 15 meaſures, to which ſome add one meaſure of zaffer.

Red is made of antimony three pounds, litharge or red lead three, and ruſt of iron one; grind them to a fine powder. Or, take two pounds of antimony, three of red-lead, and one of calcined ſaffron of Mars, and proceed as before.

White. The white glazing for common ware is made of 40 pounds of clear ſand, 75 pounds of litharge or lead-aſhes, 26 of pot-aſhes, and 10 pounds of ſalt: theſe are three times melted into a cake, quenching it each time in clear cold water. Or it may be made of 50 pounds of clean ſand, 70 of lead-aſhes, 30 of wood-aſhes, and 12 of ſalt.

For a fine white: Take two pounds of lead and one of tin; calcine them to aſhes: of this take two parts, calcined flint, white ſand, or broken white glaſs, one part, and ſalt one part; mix them well together and melt them into a cake for uſe. The trouble of calcining the tin and lead may be prevented by procuring them in a proper ſtate.

A very fine white glazing may be obtained by calcining two parts of lead and one part of tin; and taking one part of this maſs, and of flints and common ſalt of each one part, and fuſing the mixture.

A white glazing may be alſo prepared by mixing 100 pounds of maſticot, 60 pounds of red lead, 20 pounds of calcined tin or putty, and 10 pounds of common ſalt, and calcining and powdering the mixture ſeveral times.

Yellow is prepared of red-lead three pounds; calcined antimony and tin of each two pounds; or, according to ſome, of equal quantities of the three ingredients. Theſe muſt be melted into a cake, then ground fine; and this operation repeated ſeveral times: or it may be made of 15 parts of lead-ore, three parts of litharge of ſilver, and 15 parts of ſand.—A fine yellow glazing may be procured by mixing five parts of red-lead, two parts of powdered brick, one part of ſand, one part of the white glazings, and two parts of antimony, calcining the mixture and then fuſing it. Or, take four parts of white-glaſs, one part of antimony, three parts of red-lead, and one part of iron-ſcales, and fuſe the mixture; or fuſe 16 parts of flints, one part of iron-filings, and 24 parts of litharge. A light yellow glazing may be produced with ten parts of red-lead, three parts of antimony, and three of glaſs, and two parts of calcined tin. See *Gold-colour*, above.—A *citron yellow* is made of ſix parts of red-lead, ſeven parts of fine red brick-duſt, and two parts of antimony. This mixture muſt be calcined day and night for the ſpace of four days, in the aſh-hole of a glaſs-houſe furnace, and at laſt urged to fuſion.

Glead || Gleditſia.

ware, &c. ſee the articles *Delft-Ware*, Porcelain, and Pottery.

The Romans had a method of glazing their earthen veſſels, which in many reſpects appears to have been ſuperior to ours. The common brown glazing eaſily ſcales off, cracks, and in a ſhort time becomes diſagreeable to the eye. Beſides, it is very eaſily deſtroyed by acids; nor can veſſels glazed in this manner be even employed to hold water, without part of it oozing through their pores. Lead is alſo very deſtructive to the human body; and if acids are unwarily put into veſſels glazed with lead, the liquors will receive a very dangerous impregnation from the metal. The Roman glazing, which is yet to be ſeen upon urns dug up in ſeveral places, appears to have been made of ſome kind of varniſh; and Pliny gives us a hint that it was made of bitumen. He tells us that it never loſt its beauty, and that at length it became cuſtomary to glaze our ſtatues in this manner. As this varniſh ſunk deep into the ſubſtance of the ware, it was not ſubject to thoſe cracks and flaws which diſfigure our veſſels; and as it was not liable to be corroded by acids, it could not be ſubject to any of the accidents which may enſue from the uſe of veſſels glazed with lead.

GLEAD, or Glade, a name uſed in the northern parts of the kingdom for the kite. See Falco.

GLEAM is popularly uſed for a ray or beam of light. Among falconers a hawk is ſaid to gleam when ſhe caſts or throws up filth from the gorge.

GLEANING, the act of gathering or picking up the ears of corn left behind after the field has been reaped and the crop carried home. By the cuſtoms of ſome countries, particularly thoſe of Melun and Eſtampes, all farmers and others are forbid, either by themſelves or ſervants, to put any cattle into the fields, or prevent the gleaning in any manner whatever for the ſpace of 24 hours after the carrying off the corn, under penalty of confiſcation.

GLEBE, among miners, ſignifies a piece of earth in which is contained ſome mineral ore.

Glebe, in law, the land belonging to a pariſh-church beſides the tithes.

GLECHOMA, Ground-ivy: A genus of the gymnoſpermia order, belonging to the didynamia claſs of plants; and in the natural method ranking under the 42d order, *Verticillatæ*. Each pair of the antheræ come together in the form of a croſs; the calyx is quinqueſid. There are three ſpecies; the moſt remarkable of which is the hederacea, or common ground-ivy, which is ſo well known that it requires no deſcription. Many virtues were formerly attributed to this plant, which it is now found not to be poſſeſſed of. Some, however, it has. The leaves are thrown into the vat with ale to clarify it and give it a flavour. Ale thus prepared is often drank as an antiſcorbutic. The expreſſed juice mixed with a little wine, and applied morning and evening, deſtroys the white ſpecks upon horſes eyes. The plants that grow near it do not flouriſh. It is ſaid to be hurtful to horſes if they eat much of it. Sheep eat it, horſes are not fond of it; cows, goats, and ſwine, refuſe it.

GLEDITSIA, triple-thorned acacia, or *Honey-locuſt*: A genus of the dioecia order, belonging to the polygamia claſs of plants; and in the natural method ranking under the 33d order, *Lomentaceæ*. The hermaphrodite calyx is quadriſid; the corolla tetrapetalous; the ſtamina ſix, one piſtil and legumen. The male calyx is triphyllous; the corolla tripetalous, with ſix ſtamina. The female calyx is pentaphyllous; the corollo pentapetalous; one piſtil and legumen. There are two ſpecies. Gleditſia.

1. The triacanthos, a native of Virginia and Penſylvania, is of an upright growth, and its trunk is guarded by thorns of three or four inches in length in a remarkable manner. Theſe thorns have alſo others coming out of their ſides at nearly right angles: Their colour is red. The branches are ſmooth, and of a white colour. Theſe are likewiſe armed with red thorns, that are proportionally ſmaller: they are of ſeveral directions, and at the ends of the branches often ſtand ſingle. The young ſhoots of the preceding ſummer are perfectly ſmooth, of a reddiſh green, and retain their leaves often until the middle of November. Although there is a peculiar oddity in the nature and poſition of the ſpines, yet the leaves conſtitute the greateſt beauty of theſe trees: they are doubly pinnated, and of a delightful ſhining green. The pinnated leaves, that form the duplication, do not always ſtand oppoſite by pairs on the middle rib; the pinnæ of which they are compoſed are ſmall and numerous; no leſs than 10 or 11 pair belong to each of them; and as no leſs than four or five pair of ſmall leaves are arranged along the middle rib, the whole compound leaf conſiſts often of more than 200 pinnæ of this fine green colour: They ſit cloſe, and ſpread open in fine weather; though during bad weather they will droop, and their upper ſurfaces nearly join, as if in a ſleeping ſtate. The flowers are produced from the ſides of the young branches in July: They are a greeniſh catkin, and make little ſhow; though many are ſucceeded by pods, that have a wonderful effect; for theſe are exceedingly large, more than a foot, ſometimes a foot and a half in length, and two inches in breadth, and of a nut-brown colour when ripe; ſo that the effect they occaſion, when hanging on the ſides of the branches, may eaſily be gueſſed.—There is a variety of this ſpecies, with fewer thorns, ſmaller leaves, and oval pods. It has nearly the reſemblance of the other; though the thorns being not ſo frequent, and the pods being ſmaller, each containing only one ſeed, this ſort loſes that ſingular effect which the other produces by them.

Theſe trees are eaſily propagated. We receive the ſeeds from America in the ſpring, which keep well in the pods, and are for the moſt part good. They generally arrive in February; and, as ſoon as poſſible after, they ſhould be ſown in a well-ſheltered warm border of light ſandy earth. If no border is to be found that is naturally ſo, it may be improved by applying drift ſand, and making it fine. The ſeeds ſhould be ſown about half an inch deep; and they will for the moſt part come up the firſt ſpring. If the ſummer ſhould prove dry, they muſt be conſtantly watered; and if ſhade could be afforded them in the heat of the day, they would make ſtronger plants by the autumn. A careful attention to this article is peculiarly requiſite; for as the ends of the branches are often killed, if the young plant has not made ſome progreſs, it will be liable to be wholly deſtroyed by the

Gleet, Glendalagh.

the winter's froſt, without protection: And this renders the ſowing the ſeeds in a warm border, under an hedge, in a well-ſheltered place neceſſary; for there theſe ſhrubs will endure our winters, even when ſeedlings, and ſo will require no farther trouble; nay, though the tops ſhould be nipped, they will ſhoot out again lower, and will ſoon overcome it. It will be proper to let them remain two years in the ſeed-bed before they are planted out in the nurſery. The ſpring is the beſt time for the work. Their diſtances ſhould be one foot by two; the rows ſhould be dug between every winter; and, being weeded in ſummer. here they may remain, with no other particular care, until they are ſet out to remain. Theſe trees are late in the ſpring before they exhibit their leaves, but keep ſhooting long in the autumn.

2. The other ſpecies is the inermis, the ſtem of which is unarmed or without thorns. It is a native of South America, and in this country requires to be kept in a ſtove.

GLEET, in medicine, the flux of a thin limpid humour from the urethra. See the Index ſubjoined to MEDICINE.

GLENDALAGH, otherwiſe called *the Seven Churches*, anciently a celebrated town of Ireland, ſituated five miles north weſt of Rothdrum, in the county of Wicklow, and province of Leinſter. The name ſignifies "the valley of the two lakes." In this valley, ſurrounded by high and almoſt inacceſſible mountains, St Kevin or Cavan, called alſo *St Coemgene*, about the middle of the 6th century, founded a monaſtery, which in a ſhort time from the ſanctity of its founder was much reſorted to, and at length became a biſhoprick and a religious city. St Kevin died 3d June 618, aged 120; and on that day annually numbers of perſons flock to the Seven Churches to celebrate the feſtival of that venerated ſaint. During the middle ages the city of Glendalagh, called by Hoveden *Epiſcopatus Biſlagnienſis*, was held in great eſteem, and received ſeveral valuable donations and privileges, its epiſcopal juriſdiction extending to the walls of Dublin.—About the middle of the 12th century, on ſome account or other, it was much neglected by the clergy; and became, inſtead of a holy city, a den of thieves. wherefore Cardinal Papiro, in 1214, united it to the ſee of Dublin, which union was confirmed by king John. The O'Tools, chiefs of Firthuathal, however, by the aſſiſtance of the Pope, continued long after this period to elect biſhops and abbots to Glendalagh, though they had neither revenues or authority, beyond the diſtrict of Tuathal, which was the weſtern part of the county of Wicklow; in conſequence of which the city was ſuffered to decay, and had become nearly a deſart, in 1497, when Dennis White, the laſt titular biſhop, ſurrendered his right in the cathedral church of St Patrick, Dublin From the ruins of this ancient city ſtill remaining, it appears to have been a place of conſequence, and to have contained ſeven churches and religious houſes; ſmall indeed, but built in a neat elegant ſtyle, in imitation of the Greek architecture: the cathedral, the walls of which are yet ſtanding, was dedicated to St Peter and St Paul. South of the cathedral ſtands a ſmall church roofed with ſtone, nearly entire; and in ſeveral parts of the valley are a number of ſtone croſſes, ſome of which are curiouſly carved, but without any inſcriptions. In the north-weſt corner of the cemetery belonging to the cathedral ſtands a round tower, 95 feet high, and 15 in diameter; and in the cemetery of a ſmall church, on the ſouth ſide of the river, near the great lake, called the *Rheſeart church*, are ſome tombs, with Iriſh inſcriptions, belonging to the O'Tools. In a perpendicular projecting rock on the ſouth ſide of the great lake, 30 yards above the ſurface of the water, is the celebrated bed of St Kevin, hewn out of the rock, exceedingly difficult of acceſs and terrible in proſpect. Amongſt the ruins have been diſcovered a number of ſtones, curiouſly carved, and containing inſcriptions in the Latin, Greek, and Iriſh languages. As this city was in a valley, ſurrounded on all ſides, except the eaſt, by high, barren, and inacceſſible mountains, the artificial roads leading thereto are by no means the leaſt curious part of the remains; the principal is that leading into the county of Kildare through Glendaſon. This road for near two miles is yet perfect, compoſed of ſtones placed on their edges, making a firm and durable pavement, about 10 feet broad. At a ſmall diſtance from St Kevin's bed. on the ſame ſide of the mountain, are to be ſeen the ruins of a ſmall ſtone building called *Saint Kevin's cell*.

Glenoides || Gliſſon.

GLENOIDES, the name of two cavities, or ſmall depreſſions, in the inferior part of the firſt vertebra of the neck.

GLICAS, or GLYCAS, (Michael), a Greek hiſtorian about the middle of the 15th century, lived in Sicily, and wrote Annals of what paſſed from the creation of the world to the death of Alexis Comnenus, in 1118. Leunclavius added to it a fifth part, which carries it down to the taking of Conſtantinople. Glicas was alſo the author of ſeveral uſeful and curious letters

GLIMMER, or GLIST. See MICA.

GLINUS, in botany: A genus of the pentagynia order, belonging to the decandria claſs of plants; and in the natural method ranking under the 22d claſs, *Caryophyllei*. The calyx is pentaphyllous; there is no corolla; the nectarium is compoſed of bifid briſtles; the capſule is quinqueangular, quinquelocular, quinquevalved and polyſpermous.

GLIRES, the name of Linnæus's fourth order of mammalia See ZOOLOGY.

GLISSON (Francis), a learned Engliſh phyſician in the 17th century, was educated at Cambridge, and was made regius profeſſor of that univerſity. In 1634 he was admitted a fellow of the college of phyſicians in London. During the civil wars, he practiſed phyſic at Colcheſter, and afterwards ſettled in London. He greatly improved phyſic by his anatomical diſſections and obſervations, and made ſeveral new diſcoveries of ſingular uſe towards eſtabliſhing a rational practice He wrote, 1. *De rachitide*, &c. 2. *De lymphæductis nuper repertis*; with the *Anatomica prolegomena*, & *Anatomia hepatis*. 3. *De naturæ ſubſtantia energetica; ſeu de vita vitæ naturæ, ejuſque tribus primis facultatibus*, &c. quarto. 4. *Tractatus de ventriculo & inteſtinis*, &c. The world is obliged to him for the *capſula communis*, or *vagina portæ*.

Glister || Globe.

GLISTER, in surgery. See CLYSTER.

GLOBBA, in botany: A genus of the monogynia order, belonging to the monandria class of plants. The corolla is equal and trifid; the calyx trifid above; the capsule trilocular, with many seeds.

GLOBE, in geometry, a round or spherical body more usually called a *sphere*. See SPHERE.

GLOBE, is more particularly used for an artificial sphere of metal, plaster, paper, or other matter; on whose convex surface is drawn a map, or representation either of the earth or heavens, with the several circles conceived thereon. See GEOGRAPHY.

Globes are of two kinds, *terrestrial* and *celestial;* each of very considerable use, the one in astronomy, and the other in geography, for performing many of the operations thereof in an easy obvious manner, so as to be conceived without any knowledge of the mathematical grounds of those arts.

The fundamental parts, common to both globes, are an axis, representing that of the world; and a spherical shell. or cover, which makes the body of the globe, on the external surface of which the representation is drawn. See AXIS, POLE, &c.

Globes, we have observed, are made of different materials, viz. silver, brass, paper, plaster, &c. Those commonly used are of plaster and paper: The construction whereof is as follows:

Construction of GLOBES.—A wooden axis is provided, somewhat less than the intended diameter of the globe; and into the extremes hereof two iron wires are driven for poles: this axis is to be the beam, or basis of the whole structure.

On the axis are applied two spherical or rather hemispherical caps, formed on a kind of wooden mould or block.—These caps consist of pasteboard, or paper, laid one lay after another, on the mould, to the thickness of a crown-piece; after which, having stood to dry and embody, making an incision along the middle, the two caps thus parted are slipped off the mould.

They remain now to be applied on the poles of the axis, as before they were on those of the mould: and to fix them in their new place, the two edges are sewed together with pack-thread, &c.

The rudiments of the globe thus laid, they proceed to strengthen and make it smooth and regular. In order to this, the two poles are hasped in a metalline semicircle of the size intended; and a kind of plaster, made of whiting, water, and glue, heated, melted, and incorporated together, is daubed all over the paper-surface. In proportion as the plaster is applied, the ball is turned round in the semicircle, the edge whereof pares off whatever is superfluous and beyond the due dimension, leaving the rest adhering in places that are short of it. After such application of plaster, the ball stands to dry; which done, it is put again in the semicircle, and fresh matter applied: thus they continue alternately to apply the composition, and dry it, till such time as the ball every where accurately touches the semicircle; in which state it is perfectly smooth, regular, firm, &c.

The ball thus finished, it remains to paste the map or description thereon: in order to this, the map is projected in several gores, or gussets; all which join accurately on the spherical surface, and cover the whole ball. To direct the application of these gores, lines are drawn by a semicircle on the surface of the ball, dividing it into a number of equal parts corresponding to those of the gores, and subdividing those again answerably to the lines and divisions of the gores. Globe.

The papers thus pasted on, there remains nothing but to colour and illuminate the globe; and to varnish it, the better to resist dust, moisture, &c.—The globe itself thus finished, they hang it in a brass meridian, with an hour-circle, and a quadrant of altitude; and thus fit it into a wood horizon.

To describe the gores, or gussets, for the globes. In Chambers's Dictionary, the following method is directed.

"1. From the given diameter of the globe, find a right line AB, fig. 1. equal to the circumference of a great circle, and divide it into twelve equal parts. Plate CCXXI.

2. Through the several points of division, 1, 2, 3, 4, &c. with the interval of ten of them, describe arches mutually intersecting each other in D and E; these figures or pieces duly pasted or joined together will make the whole surface of the globe.

3. Divide each part of the right line AB into 30 equal parts, so that the whole line AB, representing the periphery of the equator, may be divided into 360 degrees.

4. From the poles D and E, fig. 2. with the interval of $23\frac{1}{2}$ deg. describe arches *a b;* these will be twelfth-parts of the polar circles.

5. After the like manner, from the same poles D and E, with the interval of $66\frac{1}{2}$ deg. reckoned from the equator, describe arches *c d;* these will be twelfth-parts of the tropics.

6. Through the degree of the equator *e*, corresponding to the right ascension of any given star, and the poles D and E, draw an arch of a circle; and taking in the compasses the complement of the declination from the pole D, describe an arch intersecting it in *i*: this point *i* will be the place of that star.

7. All the stars of a constellation being thus laid down, the figure of the constellation is to be drawn according to Bayer, Hevelius, or Flamstead.

8. Lastly, after the same manner are the declinations and right ascensions of each degree of the ecliptic *d g* to be determined.

9. The surface of the globe thus projected on a plane is to be engraven on copper, to save the trouble of doing this over again for each globe.

10. A ball, in the mean time, is to be prepared of paper, plaster, &c. as before directed, and of the intended diameter of the globe; on this, by means of a semicircle and style, is the equator to be drawn; and through every 30th degree a meridian. The ball thus divided into twelve parts, corresponding to the segments before projected, the latter are to be cut from the printed paper, and pasted on the ball.

11. Nothing now remains but to hang the globe as before in a brasen meridian and wooden horison; to which may be added a quadrant of altitude made of brass, and divided in the same manner as the ecliptic and equator.

If the declinations and right ascensions of the stars be not given, but the longitudes and latitudes in lieu thereof, the surface of the globe is to be projected after the same manner as before; except that, in this case,

Globe. ease, D and E, fig. 2. are the poles of the ecliptic, and *f h* the ecliptic itself; and that the polar circles and tropics, with the equator *g d*, and the parallels thereof, are to be determined from their declinations.

M. De La Lande, in his *Astronomie* 1771, *Tom.* 3. *p.* 736, relates the following methods. "To construct celestial and terrestrial globes, gores must be engraved, which are a kind of projection, or inclosure of the globe (fig. 3.) similar to what is now to be explained. The length PC of the axis of this curve is equal to a quarter of the circumference of the globe; the intervals of the parallels on the axis PC are all equal, the radii of the circles KDI which represent the parallels are equal to the cotangents of the latitudes, and the arches of each, as DI, are nearly equal to the number of the degrees of the breadth of the gore (which is usually 30°) multiplied by the sine of the latitude: thus, there will be found no intricacy in tracing them; but the difficulty proceeds from the variation found in the trial of the gores when pasting them on the globe, and of the quantity that must be taken from the paper, less on the sides than in the middle; (because the sides are longer) to apply it exactly to the space that it should cover.

"The method used among workmen to delineate the gores, and which is described by Mr Bion (*Usage des Globes*, *Tome* 3.) and by Mr Robert de Vaugendy in the 7th volume of the *Encyclopèdie* is little geometrical, but yet is sufficient in practice. Draw on the paper a line AC, equal to the chord of 15°, to make the half breadth of the gore; and a perpendicular PC, equal to three times the chord of 30°, to make the half length: for these papers, the dimensions of which will be equal to the chords, become equal to the arcs themselves when they are pasted on the globe. Divide the height CP into 9 parts, if the parallels are to be drawn in every 10°; divide also the quadrant BE into 9 equal parts through each division point of the quadrant as G; and through the corresponding point D of the right line CP draw the perpendiculars HGF and DF, the meeting of which in F gives one of the points of the curve BEP, which will terminate the circumference of the gore. When a sufficient number of points are thus found, trace the outline PIB with a curved rule. By this construction are given the gore breadths, which are on the globe, in the ratio of the cosines of the latitudes; supposing these breadths taken perpendicular to CD, which is not very exact, but it is impossible to prescribe a rigid operation sufficient to make a plane which shall cover a curved surface, and that on a right line AB shall make lines PA, PC, PB, equal among themselves, as they ought to be on the globe. To describe the circle KDI which is at 30° from the equator: there must be taken above D a point which shall be distant from it the value of the tangent of 60°, taken out either from the tables, or on a circle equal to the circumference of the globe to be traced; this point will serve as a centre for the parallel DI, which should pass through the point D, for it is supposed equal to that of a cone circumscribing the globe, and which would touch at the point D.

"The meridians may be traced to every 10 degrees, by dividing each parallel, as KI, into three parts at the points L and M, and drawing from the pole P, through all these division points, curves, which represent the intermediate meridians between PA and PB, (as BR and ST, fig. 4.). The ecliptic AQ may be described by means of the known declination from different points of the equator that may be found in a table; for 10°, it is 3° 58′; for 20°, 7° 50′ = BQ; for 30°, 11° 29′, &c."

Globe || Globule.

It is observed in general, that the paper on which charts are printed, such as the *colombier*, shortens itself $\frac{1}{12}$ part or a line in six inches upon an average, when it is dried after printing; this inconvenience must therefore be corrected in the engraving of the gores: if notwithstanding that, the gores are found too short, it must be remedied by taking from the surface of the ball a little of the white with which it is covered; thereby making the dimensions suitable to the gore as it was printed. But what is singular is, that in drawing the gore, moistened with the paste to apply on the globe, the axis GH lengthens, and the side AK shortens, in such a manner, that neither the length of the side ACK nor that of the axis GEH of the gore are exactly equal to the quarter of the circumference of the globe, when compared to the figure on the copper, or to the numbered sides shown in fig. 4. Mr Bonne having made several experiments on the dimensions that gores take after they had been parted ready to apply to the globe, and particularly with the paper named *jesus* that he made use of for a globe of one foot in diameter, found that it was necessary to give to the gores, on the copper, the dimensions shown in fig. 4. Supposing that the radius of the globe contained 720 parts, the half breadth of the gore is AG = 188$\frac{1}{10}$, the distance AC for the parallel of 10 degrees taken on the right line LM is 128.1, the small deviation from the parallel of 10 degrees in the middle of the gore ED is 4, the line ABN is right, the radius of the parallel of 10° or of the circle CEF is 4083, and so of the others as marked in the figure. The small circular cap which is placed under H, has its radius 253 instead of 247, which it would have if the sine of 20° had been the radius of it.

For the uses, &c. of the globes, see Geography and Astronomy, with the Plates there referred to.

Globe-Animal. See Animalcule, n° 29.

Globe-Fish. See Ostracion.

GLOBULARIA, Globular blue daisy: A genus of the monogynia order, belonging to the tetrandria class of plants; and in the natural method ranking under the 48th order, *Aggregatæ*. The common calyx is imbricated; the proper one tubulated inferior; the upper lip of the florets bipartite, the under one tripartite; the receptacle paleaceous. There are several species; but only one is commonly to be met with in our gardens, viz. the vulgaris, or common blue daisy. It hath broad thick radical leaves three parted at the ends, upright stalks from about six to 10 or 12 inches high garnished with spear-shaped leaves, and the top crowned by a globular head of fine blue flowers composed of many florets in one cup. It flowers in June, and makes a good appearance; but thrives best in a moist shady situation. It is propagated by parting the roots in September.

GLOBULE, a diminutive of globe, frequently used by physicians in speaking of the red particles of the blood. See Blood.

GLO-

Glocester. GLOCESTER, the capital of Glocesterſhire in England, 101 miles from London. It is an ancient city; and by Antoninus is called *Clevum*, or *Glevum*, which Cambden thinks was formed from the Britiſh *Caer Glowe*, ſignifying "a fair city." It was one of the 28 cities built by the Britons before the arrival of the Romans. By the Romans it was made one of their colonies, and in the eighth century it was eſteemed one of the nobleſt cities in the kingdom. It has ſuffered conſiderably by fire at different periods. It ſtands upon a hill; and from the middle of the city, where the four principal ſtreets meet, there is a deſcent every way, which makes it not only clean and healthy, but adds to the beauty of the place. Forging of iron ſeems to have been its manufactory ſo early as the time of William the Conqueror. King Henry VIII. made it the ſee of a biſhop, with a dean and ſix prebends. Its caſtle, which was erected in the time of William the Conqueror, is very much decayed: part of it is leaſed out by the crown; and the reſt ſerves for a priſon, one of the beſt in England. In its cathedral, which is an ancient but magnificent fabric, and has a tower reckoned one of the moſt curious pieces of architecture in England, are the tombs of Robert duke of Normandy, ſon to William the Conqueror, and of Edward II. and there is a whiſpering-place like to that of St Paul's at London. In the chapter-houſe lies Strongbow who conquered Ireland. There are 12 chapels in it, with the arms and monuments of many great perſons. King John made it a borough to be governed by two bailiffs. Henry III. who was crowned here, made it a corporation. By its preſent charter from Charles I. it is governed by a ſteward, who is generally a nobleman; a mayor; a recorder; 12 aldermen, out of whom the mayor is choſen; a town-clerk; 2 ſheriffs, choſen yearly out of 26 common councilmen; a ſword bearer; and four ſerjeants at mace. Here are 12 incorporated trading companies, whoſe maſters attend the mayor on all public occaſions, &c. Beſides the cathedral, there are five pariſh churches in this city; which is likewiſe well provided with hoſpitals, particularly an infirmary upon the plan of thoſe at London, Wincheſter, Bath, &c. Here is a good ſtone-bridge over the river Severn, with a quay, wharf, and cuſtomhouſe; but moſt of its buſineſs is engroſſed by Briſtol. King Edward I. held a parliament here in 1272, wherein ſome good laws were made, now called the *Statutes of Glocester*; and he erected a gate on the ſouth ſide of the abbey, ſtill called by his name, though almoſt demoliſhed in the civil wars. King Richard II. alſo held a parliament here: and king Richard III. in conſideration of his having (before his acceſſion to the crown) borne the title of *Duke of Glocester*, added the two adjacent hundreds of Dudſton and King's Barton to it, gave it his ſword and cap of maintenance, and made it a county of itſelf by the name of the *county of the city of Glocester*. But after the reſtoration the hundreds were taken away by act of parliament, and the walls pulled down; becauſe the city ſhut the gates againſt Charles I. when he beſieged it in 1643; by which, though the ſiege was raiſed by the earl of Eſſex, it had ſuffered 20,000 l. damage, having 241 houſes deſtroyed, which reduced it ſo much that it has ſcarce recovered its former ſize and grandeur. Before that time it had 11 pariſh churches, but ſix of them were then demoliſhed. Here are abundance of croſſes, and ſtatues of the Engliſh kings, ſome of whom kept their Chriſtmas here; ſeveral market-houſes ſupported with pillars; and large remains of monaſteries, which were once ſo numerous, that it gave occaſion to the monkiſh proverb, *As ſure as God is in Glocester*. Here is a barley market; and a hall for the aſſizes, called the *Booth hall*. Its chief manufacture is pins. In this branch it is aſtoniſhing the number of people who are employed, there being at leaſt 14 or 15 different proceſſes. Under the bridge is a water engine to ſupply the town, and it is ſerved with it alſo from Robin Hood's well, to which is a fine walk from the city. Camden ſays, that the famous Roman way, called *Ermin-ſtreet*, which begins at St David's in Pembrokeſhire, and reaches to Southampton, paſſes through this city. Sudmead in the neighbourhood is noted for horſe-races. The markets here are on Wedneſday and Sunday; and fairs April 5th, July 5th, September 28th, and November 28th. the latter chiefly for fat hogs. Here is a charity-ſchool for above 80 children, of whom above 70 are alſo cloathed; and a well endowed blue-coat ſchool. The city ſends two members to parliament. The duke of Glocester is next brother to George III.

Glocesterſhire.

GLOCESTERSHIRE, a county of England, is bounded on the weſt by Monmouthſhire and Herefordſhire, on the north by Worceſterſhire, on the eaſt by Oxfordſhire and Warwickſhire, and on the ſouth by Wiltſhire and part of Somerſetſhire. It is ſixty miles in length, twenty ſix in breadth, and one hundred and ſixty in circumference; containing 1,100,000 acres, 26,760 houſes, 162,560 inhabitants, 290 pariſhes, 140 are impropriations, 1229 villages, 2 cities, and 28 market-towns. It ſends only 8 members to parliament, 6 for three towns, viz. Glocester, Tewkeſbury, and Cirenceſter; and 2 for the county. Its manufactures are woollen cloths of various kinds, mens hats, leather, pens, paper, bar iron, edge-tools, nails, wire, tinned-plates, braſs, &c.: and of the principal articles of commerce of the county, it exports cheeſe 8000 tons; bacon, grain, cyder, 5000l. worth; perry, fiſh, 40,01. worth, &c. It lies in the dioceſe that takes its name from the captital, and in the Oxford circuit. The air of the county is very wholeſome, but the face of it is very different in different parts: for the eaſtern part is hilly, and is called *Cotteſwold*; the weſtern woody, and called the *Foreſt of Dean*; and the reſt is a fruitful valley, through which runs the river Severn. This river is in ſome places between two and three miles broad; and its courſe through the country, including its windings, is not leſs than ſeventy miles. The tide of flood, called the *Boar*, riſes very high, and is very impetuous. It is remarkable, that the greateſt tides are one year at the full moon, and the other at the new; one year the night-tides, and the next the day. This river affords a noble conveyance for goods and merchandiſe of all ſorts to and from the county; but it is watered by ſeveral others, as the Wye, the Avon, the Iſis, the Leden, the Frome, the Stroud, and Windruſh, beſides leſſer ſtreams, all abounding with fiſh, the Severn in particular with ſalmon, conger-eels, and lampreys. The ſoil is in general very fertile, though pretty much diverſified, yielding plenty of corn, paſture, fruit, and wood. In the hilly part

Glocester-shire || Glogaw.

part of the county, or Cottefwold, the air is fharper than in the lowlands; and the foil, though not fo fit for grain, produces excellent paſture for ſheep; ſo that of the four hundred thouſand that are computed to be kept in the county, the greater part are fed here. Of theſe ſheep the wool is exceeding fine; and hence it is that this ſhire is ſo eminent for its manufacture of cloth, of which fifty thouſand pieces are ſaid to have been made yearly, before the practice of clandeſtinely exporting Engliſh wool became ſo common. In the vale, or lower part of the county, through which the Severn paſſes, the air and ſoil are very different from thoſe of the Cotteſwold: for the former is much warmer, and the latter richer, yielding the moſt luxuriant paſtures; in conſequence of which, numerous herds of black cattle are kept, and great quantities of that excellent cheeſe, for which it is ſo much celebrated, made in it. The remaining part of the county, called the *Foreſt of Dean*, was formerly almoſt entirely over-run with wood, and extended 20 miles in length and 10 in breadth. It was then a neſt of robbers, eſpecially towards the Severn; but now it contains many towns and villages, conſiſting chiefly of miners, employed in the coal-pits, or in digging for or forging iron-ore, with both which the foreſt abounds. Theſe miners have their particular laws, cuſtoms, courts, and judges; and the king, as in all royal foreſts has a ſwain mote for the preſervation of the vert and veniſon. This foreſt was anciently, and is ſtill noted for its oaks, which thrive here ſurpriſingly; but as there is a prodigious conſumption of wood in the forges, it is continually dwindling away. A navigable canal is made from Stroud to Framilode, forming a junction between the Severn and Thames. Its chalybeat ſprings are: St Anthony's well, in Abbenhall pariſh; at Barrow and Maredon, in Bodington pariſh; at Aſh Church, near Tewkeſbury; at Dumbleton, near Winchcomb; at Eaſington, near Durſley; and at Cheltenham. Its ancient fortifications attributed to the Romans, Saxons, or Danes, are at Abſton and Wick, and at Dointon, Dixton, Addleſthorp, Knole, Over Upton, Hanham, Bodington, and Bourton on the Water.

GLOCHIDION, in botany: A genus of the ſyngeneſia order, belonging to the monoecia claſs of plants. There is no calyx; the corolla conſiſts of ſix egg-ſhaped concave petals; the ſtamina are three very ſmall inconſpicuous filaments; the antheræ cylindric and erect; the female flowers have no calyx; the corolla is parted into ſix; the pericarpium is a depreſſed roundiſh capſule with ſix cells; the ſeeds are roundiſh and ſolitary.

GLOGAW, a ſtrong and conſiderable town of Germany, in Sileſia, and capital of a duchy of the ſame name. It is not very large, but is well fortified on the ſide of Poland. It has a handſome caſtle, with a tower, in which ſeveral counſellors were condemned by Duke John, in 1498, to periſh with hunger. Beſides the Papiſts, there are a great number of Proteſtants and Jews. It was taken by aſſault, by the king of Pruſſia, in 1741, and the garriſon made priſoners. After the peace in 1742, the king of Pruſſia ſettled the ſupreme court of juſtice here, it being, next to Breſlaw, the moſt populous place in Sileſia. It is ſeated on the river Oder, in E. Long. 15. 13. N. Lat. 51. 40.

GLOGAW *the* LESS, a town of Sileſia, in the duchy of Opelen, now in poſſeſſion of the king of Pruſſia. It is two miles S. E. of great Glogaw, and 45 N. W. of Breſlaw. E. Lon. 16. 15. N. Lat. 51. 38.

Glogaw || Glory.

GLORIA PATRI, among eccleſiaſtical writers. See DOXOLOGY.

GLORIOSA, SUPERB LILY: A genus of the monogynia order, belonging to the hexandria claſs of plants; and in the natural method ranking under the 11th order, *Sarmentaceæ*. The corolla is hexapetalous, undulated, and reflected; the ſtyle oblique. There is but one ſpecies, a native of Malabar. It hath a thick, fleſhy, tuberous root, ſending forth from its centre declinated round ſtalks growing eight or ten feet long, and garniſhed with very long narrow leaves running out into a point, terminated by a long tendril. From the upper part of the ſtalks proceed large flame-coloured drooping flowers, conſiſting of ſix widely ſpreading reflexed petals. It flowers in June and July; and is of admirable beauty, whence its name of *Glorioſa*, or Superb Lily.—This plant being a native of a very warm climate, requires the protection of a hot-houſe in this country. The flower-ſtalks ſhoot forth in March or April; which being long and trailing, muſt have tall ſticks placed for their ſupport. The plants are propagated by offſets, which are produced in tolerable plenty, and may be ſeparated any time after the ſtalks decay, or in ſpring before new ones ariſe.

GLORY, renown or celebrity. The love of renown, or deſire of fame and reputation, appears to be one of the principal ſprings of action in human ſociety. Glory therefore is not to be contemned, as ſome of the ancient philoſophers affected to teach: but it imports us to regulate our purſuit after it by the dictates of reaſon; and if the public approbation will not follow us in that courſe, we muſt leave her behind. We ought to have our judgements well inſtructed as to what actions are truly glorious; and to remember, that in every important enterpriſe, as Seneca obſerves, *Recte facti feciſſe merces eſt; officii fructus, ipſum officium eſt*: "The reward of a thing well done, is to have done it; the fruit of a good office is the office itſelf." Thoſe who by other methods ſcatter their names into many mouths, ſhow they rather hunt after a great reputation than a good one, and their reward is oftener infamy than fame.

Men generally, and almoſt inſtinctively, affix glory only to ſuch actions as have been produced by an innate deſire for public good; and we meaſure it by that degree of influence which any thing done has upon the common happineſs.

If the actions of the hero conduct ſooneſt to glory and with the greateſt ſplendor, and if the victorious general is ſo great after a ſignal engagement; it is becauſe the ſervice he has done is for the moment, and for all; and becauſe we think, without reflecting, that he has ſaved our habitations, our wealth, and our children, and every thing that attaches us to life. If the man of ſcience, who in his ſtudy has diſcovered and calculated the motions of the heavenly bodies, who in his alembics has unveiled ſome of the ſecrets of nature, or who has exhibited to mankind a new art, riſes to fame with leſs noiſe; it is becauſe the utility which he procures is more widely diffuſed, and is often of leſs

Glory. less service to the present than to succeeding generations.

The consequences, therefore, of these two advantages are as opposite as the causes are different; and while the benefits procured by the warrior appear to have no more influence, and while his glory becomes obscure, that of a celebrated writer or inventor still increases, and is more and more enlarged. His works every day bring back his name to that age which uses them, and thus still add to his celebrity and fame.

This posthumous fame indeed has been decried by some writers. In particular, the author of the *Religion of Nature delineated* has treated it as highly irrational and absurd. "In reality (says he) the man is not known ever the more to posterity, because his name is transmitted to them: He doth not live, because his name does. When it is said, Julius Cæsar subdued Gaul, conquered Pompey, &c. it is the same thing as to say, the conqueror of Pompey was Julius Cæsar; i. e. Cæsar and the conqueror of Pompey is the same thing; Cæsar is as much known by one designation as by the other. The amount then is only this, that the conqueror of Pompey conquered Pompey; or somebody conquered Pompey; or rather, since Pompey is as little known now as Cæsar, somebody conquered somebody. Such a poor business is this boasted immortality! and such is the thing called glory among us! To discerning men this fame is mere air, and what they despise if not shun."

But surely it were to consider too curiously (as Horatio says to Hamlet) to consider thus. For (as the elegant author of Fitzosborne's Letters observes) altho' fame with posterity should be, in the strict analysis of it, no other than what is here described, a mere uninteresting proposition, amounting to nothing more than that somebody acted meritoriously; yet it would not necessarily follow, that true philosophy would banish the desire of it from the human breast: for this passion may be (as most certain it is) wisely implanted in our species, notwithstanding the corresponding object should in reality be very different from what it appears in imagination. Do not many of our most refined and even contemplative pleasures owe their existence to our mistakes? It is but extending some of our senses to a higher degree of acuteness than we now possess them, to make the fairest views of nature, or the noblest productions of art, appear horrid and deformed. To see things as they truly and in themselves are, would not always, perhaps, be of advantage to us in the intellectual world, any more than in the natural. But, after all, who shall certainly assure us, that the pleasure of virtuous fame dies with its possessor, and reaches not to a farther scene of existence? There is nothing, it should seem, either absurd or unphilosophical in supposing it possible at least, that the praises of the good and the judicious, the sweetest music to an honest ear in this world, may be echoed back to the mansions of the next; that the poet's description of fame may be literally true, and though she walks upon earth, she may yet lift her head into heaven.

To be convinced of the great advantage of cherishing this high regard to posterity, this noble desire of an after-life in the breath of others, one need only look back upon the history of the ancient Greeks and Romans. For what other principle was it which produced that exalted strain of virtue in those days, that may well serve, in too many respects, as a model to these? Was it not the *consentiens laus bonorum*, the *incorrupta vox bene judicantium* (as Tully calls it), "the concurrent approbation of the good, the uncorrupted applause of the wise," that animated their most generous pursuits? Glos. I. Glossopetra.

In short, can it be reasonable to extinguish a passion which nature has universally lighted up in the human breast, and which we constantly find to burn with most strength and brightness in the noblest and best formed bosoms? Accordingly revelation is so far from endeavouring to eradicate the seed which nature has thus deeply planted, that she rather seems, on the contrary, to cherish and forward its growth. To be *exalted with honour*, and to be *had in everlasting remembrance*, are in the number of those encouragements which the Jewish dispensation offered to the virtuous; and the person from whom the sacred Author of the Christian system received his birth, is herself represented as rejoicing that *all generations should call her blessed*.

GLOSS, a comment on the text of any author, to explain his sense more fully and at large, whether in the same language or any other. See the article COMMENTARY.—The word, according to some, comes from the Greek γλωσσα, "tongue;" the office of a *gloss* being to explain the text, as that of the tongue is to discover the mind.

GLOSS is likewise used for a literal translation, or an interpretation of an author in another language word for word.

GLOSS is also used in matters of commerce, &c. for the lustre of a silk, stuff, or the like.

GLOSSARY, a sort of dictionary, explaining the obscure and antiquated terms in some old author; such are Du Cange's Latin and Greek Glossaries, Spelman's Glossary, and Kennet's Glossary at the end of his Parochial Antiquities.

GLOSSOPETRA, or GLOTTOPETRA, in natural history, a kind of extraneous fossil, somewhat in form of a serpent's tongue; frequently found in the island of Malta and divers other parts. See Plate CC.

The vulgar notion is, that they are the tongues of serpents petrified; and hence their name, which is a compound of γλωσσα, "tongue," and πετρα, "stone." Hence also their traditionary virtue in curing the bites of serpents. The general opinion of naturalists is, that they are the teeth of fishes, left at land by the waters of the deluge, and since petrified.

The several sizes of the teeth of the same species, and those of the several different species of sharks, afford a vast variety of these fossil substances. Their usual colours are black, bluish, whitish, yellowish, or brown; and in shape they usually approach to a triangular figure. Some of them are simple; others are tricuspidate, having a small point on each side of the large one: many of them are quite straight; but they are frequently found crooked, and bent in all directions; many of them are serrated on their edges, and others have them plain; some are undulated on their edges, and slightly serrated on these undulations. They differ also in size as much as in figure; the larger being four or five inches long, and the smaller less than a quarter of an inch.

They are most usually found with us in the strata of blue clay, though sometimes also in other substances,

Glottis || Glover.

and are frequent in the clay-pits of Richmond and other places. They are very frequent alſo in Germany, but no where ſo plentiful as in the iſland of Malta.

The Germans attribute many virtues to theſe foſſil teeth; they call them cordials, ſudorifics, and alexipharmics: and the people of Malta, where they are extremely plentiful, hang them about their childrens necks to promote dentition. They may poſſibly be of as much ſervice this way as an anodyne necklace; and if ſuſpended in ſuch a manner that the child can get them to its mouth, may, by their hardneſs and ſmoothneſs, be of the ſame uſe as a piece of coral.

GLOTTIS, in anatomy, the narrow ſlit at the upper part of the aſpera arteria, which is covered by the epiglottis when we hold our breath and when we ſwallow. The glottis, by its dilatation and contraction, modulates the voice. See ANATOMY, n° 116.

GLOVE, a covering for the hand and wriſt.

Gloves, with reſpect to commerce, are diſtinguiſhed into leathern-gloves, ſilk-gloves, thread-gloves, cotton-gloves, worſted-gloves, &c. Leathern gloves are made of chamois, kid, lamb, doe, elk, buff, &c. Gloves now pay a duty to the king, which increaſes according to their value.

To throw the glove, was a practice or ceremony very uſual among our forefathers; being the challenge whereby another was defied to ſingle combat.—It is ſtill retained at the coronation of our kings; when the king's champion caſts his glove in Weſtminſter-hall. See CHAMPION.

Favyn ſuppoſes the cuſtom to have ariſen from the eaſtern nations, who in all their ſales and deliveries of lands, goods, &c. uſed to give the purchaſer their glove by way of livery or inveſtiture. To this effect he quotes Ruth iv. 7. where the Chaldee paraphraſe calls *glove*, what the common verſion renders by *ſhoe*. He adds, that the Rabbins interpret by *glove*, that paſſage in the cviiith Pſalm, *In Idumeam extendam calceamentum meum*, "Over *Edom* will I caſt out my ſhoe."—Accordingly, among us, he who took up the *glove*, declared thereby his acceptance of the challenge; and as a part of the ceremony, continues Favyn, took the *glove* off his own right hand, and caſt it upon the ground, to be taken up by the challenger. This had the force of a mutual engagement on each ſide, to meet at the time and place which ſhould be appointed by the king, parliament, or judges.—The ſame author aſſerts, that the cuſtom which ſtill obtains of bleſſing *gloves* in the coronation of the kings of France, is a remain of the eaſtern practice of giving poſſeſſion with the *glove*, l. xvi. p. 1017, &c.

Anciently it was prohibited the judges to wear gloves on the bench. And at preſent in the ſtables of moſt princes, it is not ſafe going in without pulling off the gloves.

GLOVER (Richard), the author of Leonidas and ſeveral other eſteemed works, was the ſon of Richard Glover a Hamburgh merchant in London, and was born in St Martin's-lane in the year 1712. He very early ſhowed a ſtrong propenſity to and genius for poetry; and while at ſchool, he wrote, amongſt other pieces, a poem to the memory of Sir Iſaac Newton, prefixed to the view of that incomparable author's philoſophy, publiſhed in 4to, in 1728, by his intimate friend Dr Pemberton. But though poſſeſſed of talents which were calculated to excel in the literary world, he was content to devote his attention to commerce, and at a proper period commenced a Hamburgh merchant. He ſtill, however, cultivated literature, and aſſociated with thoſe who were eminent in ſcience. One of his earlieſt friends was Matthew Green, the ingenious but obſcure author of ſome admirable poems, which in 1737, after his death, were collected and publiſhed by Mr Glover. In 1737, Mr Glover married Miſs Nunn, with whom he received a handſome fortune; and in the ſame month publiſhed Leonidas, a poem in 4to, which in this and the next year paſſed through three editions. This poem was inſcribed to Lord Cobham; and on its firſt appearance was received by the world with great approbation, though it has ſince been unaccountably neglected. Lord Lyttelton, in a popular publication called Common Senſe, and in a poem addreſſed to the author, praiſed it in the warmeſt terms; and Dr Pemberton publiſhed, Obſervations on Poetry, eſpecially epic, occaſioned by the late poem upon Leonidas, 1738, 12mo, merely with a view to point out its beauties. In 1739, Mr Glover publiſhed "London, or the Progreſs of Commerce", 4to; and a ballad intitled, Hoſier's Ghoſt. Both theſe pieces ſeem to have been written with a view to incite the public to reſent the miſbehaviour of the Spaniards; and the latter had a very conſiderable effect.—The political diſſenſions at this period raged with great violence, and more eſpecially in the metropolis; and at different meetings of the livery on thoſe occaſions, Mr Glover was always called to the chair, and acquitted himſelf in a very able manner, his conduct being patriotic and his ſpeeches maſterly. His talents for public ſpeaking, his knowledge of political affairs, and his information concerning trade and commerce, ſoon afterwards pointed him out to the merchants of London as a proper perſon to conduct their application to parliament on the ſubject of the neglect of their trade. He accepted the office; and in ſumming up the evidence gave very ſtriking proofs of his oratorical powers. This ſpeech was pronounced Jan. 27. 1742. Glover.

In the year 1744 died the Ducheſs of Marlborough, and by her will left to Mr Glover and Mr Mallet 500l. each, to write the Hiſtory of the Duke of Marlborough's Life. This bequeſt, however, never took place. It is ſuppoſed that Mr Glover very early renounced his ſhare of it; and Mallet, though he continued to talk of performing the taſk almoſt as long as he lived, is now known never to have made the leaſt progreſs in it. About this period Mr Glover withdrew a good deal from public notice, and lived a life of retirement. He had been unſucceſsful in his buſineſs; and with a very laudable delicacy had preferred an obſcure retreat to popular obſervation, until his affairs ſhould put on a more proſperous appearance. He had been honoured with the attention of Frederic Prince of Wales, who once preſented him with a complete ſet of the Claſſics, elegantly bound; and, on his abſenting himſelf for ſome time on account of the embarraſſment in his circumſtances, ſent him, it is ſaid, 500l. The prince died in March 1751; and in May following Mr Glover was once more drawn from his retreat by the importunity of his friends, and ſtood candidate for the place of chamberlain of London. It unfortunately

Glover. happened that he did not declare himſelf until moſt of the livery had engaged their votes; by which means he loſt his election.

In 1753, Mr Glover produced at Drury-lane his tragedy of Boadicea; which was acted nine nights, in the month of December. It had the advantage of the performance of Mr Garrick, Mr Moſſop, Mrs Cibber, and Mrs Pritchard. From the prologue it ſeems to have been patronized by the author's friends in the city; and Dr Pemberton wrote a pamphlet to recommend it.—In 1761, Mr Glover publiſhed Medea, a tragedy written on the Greek model; but it was not acted until 1767, when it appeared for the firſt time on the ſtage at Drury-lane for Mrs Yates's benefit. At the acceſſion of his preſent majeſty, he appears to have ſurmounted the difficulties of his ſituation. In the parliament which was then called, he was choſen member for Weymouth, and continued to ſit as ſuch until the diſſolution of it. He, about this time, intereſted himſelf about India affairs, at one of Mr Sullivan's elections; and in a ſpeech introduced the fable of the man, horſe, and bear; and drew this concluſion, that, whenever merchants made uſe of armed forces to maintain their trade, it would end in their deſtruction.

In 1770, the poem of Leonidas requiring a new edition, it was republiſhed in two volumes 12mo, corrected throughout, and extended from nine books to twelve. It had alſo ſeveral new characters added, beſides placing the old ones in new ſituations. The improvements made in it were very conſiderable; but we believe the public curioſity, at this period, was not ſufficiently alive to recompenſe the pains beſtowed on this once popular performance. The calamities ariſing from the wounds given to public credit, in June 1772, by the failure of the bank of Douglas, Heron, and Co. in Scotland, occaſioned Mr Glover's taking a very active part in the ſettling thoſe complicated concerns, and in ſtopping the diſtreſs then ſo univerſally felt. In February 1774, he called the annuitants of that banking-houſe together, at the King's Arms tavern, and laid propoſals before them for the ſecurity of their demands, with which they were fully ſatisfied. He alſo undertook to manage the intereſts of the merchants and traders of London concerned in the trade to Germany and Holland, and of the dealers in foreign linens, in their application to parliament in May 1774. Both the ſpeeches made on theſe occaſions were publiſhed in a pamphlet in that year. In the ſucceeding year he engaged on behalf of the Weſt-India merchants in their application to parliament, and examined the witneſſes and ſummed up the evidence in the ſame maſterly manner he had done on former occaſions. For the aſſiſtance he afforded the merchants in this buſineſs, he was complimented by them with a ſervice of plate, of the value of 300l. The ſpeech which he delivered in the houſe was in the ſame year printed. This, we believe, was the laſt opportunity he had of diſplaying his oratorical talents in public. Having now arrived at a period of life which demanded a receſs from buſineſs, Mr Glover retired to eaſe and independence, and wore out the remainder of his days with dignity and with honour. It is probable that he ſtill continued his attention to his muſe, as we are informed that, beſides an epic poem of conſiderable length, he has left ſome tragedies and comedies behind him in manuſcript. After experiencing for ſome time the infirmities of age, he departed this life 25th November 1785; leaving behind him a moſt eſtimable character as a man, a citizen, and a writer.

Glow || Glue.

GLOW-WORM, in zoology. See LAMPYRIS.

GLUCKSTADT, a ſtrong and conſiderable town of Germany, in the circle of Upper Saxony, and duchy of Holſtein, with a ſtrong caſtle, and ſubject to Denmark. It is ſeated on the river Elbe, near its mouth; E. Long. 9. 15. N. Lat. 52. 53.

GLUE, among artificers, a tenacious viſcid matter, which ſerves as a cement to bind or connect things together.

Glues are of different kinds, according to the various uſes they are deſigned for, as the common glue, glove-glue, and parchment-glue; whereof the two laſt are more properly called *ſize*.

The common or ſtrong glue is chiefly uſed by carpenters, joiners, cabinet-makers, &c. It is made of ſkins of animals, as oxen, cows, calves, ſheep, &c.; and the older the creature is, the better is the glue made of its hide. Indeed whole ſkins are but rarely uſed for this purpoſe, but only the ſhavings, parings, or ſcraps of them; or the feet-ſinews, &c. That made of whole ſkins, however, is undoubtedly the beſt; as that made of ſinews is the very worſt.

The Method of Making GLUE. In making glue of parings, they firſt ſteep them two or three days in water: then, waſhing them well out, they boil them to the conſiſtence of a thick jelly; which they paſs, while hot, through ozier-baſkets, to ſeparate the impurities from it; and then let it ſtand ſome time, to purify it further: when all the filth and ordures are ſettled to the bottom of the veſſel, they melt and boil it a ſecond time. They next pour it into flat frames or moulds; whence it is taken out pretty hard and ſolid, and cut into ſquare pieces or cakes. They afterwards dry it in the wind, in a ſort of coarſe net; and at laſt ſtring it, to finiſh its drying.

The glue made of ſinews, feet, &c. is managed after the ſame manner; only with this difference, that they bone and ſcour the feet, and do not lay them to ſteep.

Of this commodity there is a very great exportation from England; the Engliſh glue being univerſally allowed to be the beſt in Europe, partly from the excellency of the materials, and partly from the ſkill of the manufacturers. Next to this is the Flanders glue. In both countries it is made by the tanners from fragments of good ſkins dried with much care. In France it is a ſeparate trade: and the glue-makers pick up their materials as they can, from the ſeveral dealers in ſkins, and boiling theſe with cow-heels make their glue; which as they purchaſe every thing, muſt render it dear, as well as of an inferior quality. The duty on exportation is tenpence, and on importation three ſhillings and tenpence, on every hundred weight.

The beſt glue is that which is made from the ſkin of the oldeſt beaſt, eſpecially if a bull's hide is uſed. Experience likewiſe ſhows that glue is conſiderably improved in quality by keeping after it is made; and the ſureſt way to try its goodneſs is to lay a piece to ſteep three or four days, and if it ſwell conſiderably without melting, and when taken out reſumes its former dryneſs, it is excellent.

A glue that will hold againſt fire or water, it is ſaid,

Glue ‖ Gluttony.

ſaid, may be made thus: Mix a handful of quicklime with four ounces of linſeed oil; boil them to a good thickneſs; then ſpread it on tin-plates in the ſhade, and it will become exceeding hard, but may be eaſily diſſolved over a fire, as glue, and will effect the buſineſs to admiration.

Neumann obſerves, that glue diſſolved in a ſolution of lapis calaminaris in ſpirit of nitre, and afterwards inſpiſſated, forms an extremely ſlippery tenacious maſs, which might be of uſe for entangling flies, caterpillars, and other inſects, if it was not too expenſive.

Method of Preparing and Uſing GLUE. Set a quart of water on the fire, then put in about half a pound of good glue, and boil them gently together till the glue be entirely diſſolved and of a due conſiſtence. When glue is to be uſed, it muſt be made thoroughly hot; after which, with a bruſh dipped in it, beſmear the faces of the joints as quick as poſſible: then clapping them together, ſlide or rub them lengthwiſe one upon another, two or three times, to ſettle them cloſe; and ſo let them ſtand till they are dry and firm.—Mr Boyle gives a receipt for preparing a fine ſtrong glue from iſinglaſs in the following manner: Steep the iſinglaſs for 24 hours in common brandy. When the menſtruum has opened and mollified the iſinglaſs, they muſt be gently boiled together, and kept ſtirring till they appear well mixed, and till a drop thereof, ſuffered to cool, turns into a ſtrong jelly. Then ſtrain it, whilſt hot, through a clean linen cloth into a veſſel to be kept cloſe ſtopped. A gentle heat ſuffices to diſſolve this glue into a tranſparent and almoſt colourleſs fluid, but very ſtrong; ſo that pieces of wood glued together with it will ſeparate elſewhere rather than in the place where they are joined. See ISINGLASS.

GLUME *(gluma)*, among botaniſts, a ſpecies of calyx, conſiſting of two or three membranous valves, which are often pellucid at the edges. This kind of calyx belongs to the graſſes.

GLUT, among falconers, the ſlimy ſubſtance that lies in a hawk's paunch.

GLUTA, in botany; a genus of the pentandria order, belonging to the gynandria claſs of plants. The calyx is campanulated and deciduous; there are five petals glued below to the column of the germ; and the filaments inſerted on the top of the column, on which alſo the germen ſits.

GLUTÆUS, a name common to three muſcles whoſe office it is to extend the thigh. See ANATOMY, *Table of the Muſcles*.

GLUTTON, in zoology. See MUSTELA.

GLUTTONY, a voracity of appetite, or a propenſity to gormandizing.

There is a morbid ſort of gluttony, called *fames canina*, "dog-like appetite," which ſometimes occurs, and renders the perſon ſeized with it an object of pity and of cure as in other diſeaſes: (ſee BULIMY.) — But profeſſed habitual gluttons may be reckoned amongſt the monſters of nature, and deemed in a manner puniſhable for endeavouring to bring a dearth or famine into the places where they live. For which reaſon, people think king James I. was in the right, when a man being preſented to him that could eat a whole ſheep at one meal, he aſked "What he could do more than another man?" and being anſwered "He could not do ſo much," ſaid, "Hang him then; for it is unfit a man ſhould live that eats ſo much as twenty men, and cannot do ſo much as one." Gluttony, Glycine

The emperor Clodius Albinus would devour more apples at once than a buſhel would hold. He would eat 500 figs to his breakfaſt, 100 peaches, 10 melons, 20 pound weight of grapes, 100 gnat-ſnappers, and 400 oyſters. "Fye upon him (ſaith Lipſius); God keep ſuch a curſe from the earth." *Lipſ. Ep. MS.* 51. p 457.

One of our Daniſh kings named *Hardiknute* was ſo great a glutton, that a hiſtorian calls him *Bacca de Porco*, "Swine's-mouth." His tables were covered four times a-day with the moſt coſtly viands that either the air, ſea, or land, could furniſh: and as he lived he died; for, revelling and carouſing at a wedding-banquet at Lambeth, he fell down dead. His death was ſo welcome to his ſubjects, that they celebrated the day with ſports and paſtimes, calling it *Hock tide*, which ſignifies ſcorn and contempt. With this king ended the reign of the Danes in England.

One Phagon, under the reign of the emperor Aurelianus, at one meal, eat a whole boar, 100 loaves of bread, a ſheep, a pig, and drank above three gallons of wine.

We are told by Fuller*, that one Nicholas Wood, of Harriſon in Kent, eat a whole ſheep of 16 s. price at one meal, raw; at another time, 30 dozen of pigeons. At Sir William Sidley's, in the ſame county, he eat as much victuals as would have ſufficed 30 men. At Lord Wotton's manſion-houſe in Kent, he devoured at one dinner 84 rabbits; which, by computation, at half a rabbit a man, would have ſerved 168 men. He eat to his breakfaſt 18 yards of black pudding. He devoured a whole hog at one ſitting down; and after it, being accommodated with fruit, he eat three pecks of damoſins. * *Worthies*, p. 86.

A counſellor at law, whoſe name was Mallet, well known in the reign of Charles I. eat at one time an ordinary provided in Weſtminſter for 30 men at twelve-pence a piece. His practice not being ſufficient to ſupply him with better ſort of meat, he fed generally on offals, ox-livers, hearts, &c. He lived to almoſt 60 years of age, and for the ſeven laſt years of his life eat as moderately as other men. A narrative of his Life was publiſhed.

GLYCINE, KNOBBED-ROOTED LIQUORICE-VETCH: A genus of the decandria order, belonging to the diadelphia claſs of plants; and in the natural method ranking under the 32d order, *Papilionaceæ*. The calyx is bilabiate; the carina of the corolla turning back the vexillum with its point. There is but one ſpecies commonly cultivated in our gardens, *viz.* the fruteſcens, or Carolina kidney-bean tree. This hath ſhrubby climbing ſtalks, twining round any ſupport, 15 or 20 feet high, adorned with pinnated leaves of three pair of follicles terminated by an odd one, and from the axillas cluſters of large bluiſh-purple flowers, ſucceeded by long pods like thoſe of the climbing kidney-bean. It flowers in June and July, but the ſeeds do not ripen in this country. It is eaſily propagated, either by ſeeds imported from America, where it is native, or by layers. —The ſtalks and roots of the abrus, another ſpecies of glycine, which grows in Egypt and the Indies, are very ſweet to the taſte. Herman affirms, that the juice ob-

Glycir hiza.

tained from them by decoction is little inferior to liquorice; whence its name of *wild-liquorice* in those parts of America where it is native.

GLYCIRRHIZA, Liquorice: A genus of the decandria order, belonging to the diadelphia class of plants; and in the natural method ranking under the 32d order, *Papilionaceæ*. The calyx is bilabiate; the upper lip tripartite, and the under one entire; the legumen ovate and compressed. There are two

Species. 1. The glabra, or common liquorice, hath a long, thick, creeping root, striking several feet deep into the ground; upright, firm, herbaceous stalks annually, three or four feet high, garnished with winged leaves of four or five pair of oval lobes, terminated by an odd one; and from the axillas erect spikes of pale blue flowers in July, succeeded by short smooth pods. The root of this is the useful part, which is replete with a sweet, balsamic, pectoral juice, much used in all compositions for coughs and disorders of the stomach. 2. The echinata, or prickly-poded liquorice, is nearly like the common sort, only the seed-pods are prickly. Both these species are very hardy perennials; but the first is the sort commonly cultivated for use, its roots being fuller of juice and sweeter than the other. The roots are perennial; but the stalks rise in spring and decay in autumn.

Propagation and culture. Their propagation is effected by cuttings of the small roots issuing from the sides of the main ones near the surface of the earth, dividing them into lengths of six or eight inches, each having one or more good buds or eyes; and the proper season for procuring the sets for planting is any time in open weather from October till March, though from the middle of February till the middle of March is rather the most successful season for planting. An open situation is the most suitable for a plantation of these plants. Particular regard should also be had to the soil: it ought to be of a light loose temperature, and three or four feet deep if possible; for the roots of the liquorice will arrive at that depth and more, and the longer the roots the more valuable they are for sale by weight.

Having fixed on the ground, let it be trenched three spades deep, if the depth of proper soil will admit; then having your sets ready, proceed to plant them by line and dibble, planting the sets a foot distance in each row; putting them perpendicular into the ground, with the tops about an inch under the surface; and let the rows be a foot and a half asunder; though the London gardeners seldom allow more than twelve inches between row and row. These gardeners also sow a crop of onions on the same ground the first year; which, as the onions root but slender, and spread but little at top, may be done without any detriment to the liquorice, or to the onions, as it does not rise above ten or twelve inches high the first summer; observing to keep the ground clean from weeds during that season by hoeing. If there is a crop of onions, use the small hoe, cutting out the onions to four or five inches distance, clearing away such as grow immediately close to the liquorice plants; and when the onions are gathered, give the ground a thorough hoeing with a large hoe, to loosen the surface and destroy all weeds effectually; and in autumn cut down the decayed stalks of the liquorice, and nothing more is necessary to be done till spring; when, in February or March, give a slight digging between the rows; during spring and summer, keep down all weeds by broad-hoeing; and in autumn, when the stalks are in a decaying state, cut them down to the surface of the earth. Glycirrhiza. ‖ Gmelin.

In three years after planting, the roots of the liquorice will be fit to take up: and the proper season for this is, any time from the beginning of November till February; for it should neither be taken up before the stalks are fully decayed, nor deferred till late in spring, otherwise the roots will be apt to shrivel and diminish in weight. In taking them up, the small side-roots are trimmed off, and the best divided into lengths for fresh sets, and the main roots are tied in bundles ready for sale. It is of advantage to sell them as soon as possible after they are taken up, before they lose much of their weight. They are sold to the druggists from about twenty to thirty or forty shillings *per* hundred weight; and an acre of ground has produced three thousand and upwards, which has been sold for more than sixty pounds: but the price is commonly in proportion to the goodness of the roots.

Uses. The common liquorice is cultivated in most countries of Europe for the sake of its root. That which is cultivated in Britain is preferable to such as comes from abroad; this last being generally mouldy, which this root is very apt to become, unless kept in a dry place. The powder of liquorice usually sold is often mingled with flour, and probably too often with substances not quite so wholesome: the best sort is of a browniſh yellow colour (the fine pale yellow being generally sophisticated), and of a very rich sweet taste, much more agreeable than that of the fresh root. Liquorice is almost the only sweet that quenches thirst; whence it was called by the Greeks *adipson*. Galen takes notice, that it was employed in this intention in hydropic cases, to prevent the necessity of drinking. Mr Fuller, in his *Medicina Gymnastica*, recommends this root as a very useful pectoral; and says it excellently softens acrimonious humours, at the same time that it proves gently detergent; and this account is warranted by experience. An extract is directed to be made from it in the shops; but this preparation is chiefly brought from abroad, though the foreign extract is not equal to such as is made with proper care among ourselves.

GLYPH, in sculpture and architecture, denotes any canal or cavity used as an ornament.

GMELIN (Dr Samuel), professor at Tubingen, and afterwards member of the Imperial Academy of Sciences at St Petersburgh, commenced his travels in June 1768; and having traversed the provinces of Moscow, Voronetz, New Russia, Azof, Casan, and Astracan, he visited, in 1770 and 1771, the different harbours of the Caspian, and examined with peculiar attention those parts of the Persian provinces which border upon that sea, of which he has given a circumstantial account in the three volumes of his travels already published. Actuated by a zeal for extending his observations, he attempted to pass through the western provinces of Persia, which are in a perpetual state of warfare, and infested by numerous banditti. Upon this expedition he quitted, in April 1772, Einzillee, a small trading place in Ghilan, upon the southern shore

Gmelina. Gnaphalium.

shore of the Caspian: and, on account of many difficulties and dangers, did not, until Dec. 2. 1773, reach Sallian, a town situated upon the mouth of the river Koor. Thence he proceeded to Baku and Kuba, in the province of Shirvan, where he met with a friendly reception from Ali Feth Khan, the sovereign of that district. After he had been joined by 20 Uralian Cossacks, and when he was only four days journey from the Russian fortress Kislar, he and his companions were, on the 5th of February 1774, arrested by order of Usméi Khan, a petty Tartar prince, through whose territories he was obliged to pass. Usméi urged as a pretence for this arrest, that 30 years ago several families had escaped from his dominions, and had found an asylum in the Russian territories; adding, that Gmelin should not be released until these families were restored. The professor was removed from prison to prison; and at length, wearied out with continued persecutions, he expired, July 27th, at Achmet-Kent, a village of Mount Caucasus. His death was occasioned partly by vexation for the loss of several papers and collections, and partly by disorders contracted from the fatigues of his long journey. Some of his papers had been sent to Kislar during his imprisonment, and the others were not without great difficulty rescued from the hands of the barbarian who had detained him in captivity. The arrangement of these papers, which will form a fourth volume of his travels, was at first consigned to the care of Guldenstaedt, but upon his death has been transferred to the learned Pallas.

GMELINA, in botany: A genus of the angiospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 40th order, *Personatæ*. The calyx is nearly quadridentated; the corolla campanulated or bell-shaped; there are two bipartite and two simple antheræ; the fruit is a plum with a bilocular kernel.

GNAPHALIUM, CUDWEED, GOLDY LOCKS, ETERNAL FLOWER, &c.: A genus of the polygamia superflua order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Compositæ*. The receptacle is naked; the pappus feathered; the calyx imbricated, with the marginal scales roundish, parched, and coloured. There are 41 species; the most remarkable of which are, 1. The margaritaceum, or pearly white eternal flower, hath creeping, very spreading roots, crowned with broad, spear-shaped, white, hoary leaves; herbaceous thick, woolly stalks, a foot and an half high, branching outward, garnished with long, acute-pointed, white, woolly leaves, and terminated by a corymbose cluster of yellowish flowers, which appear in June and July, and are very ornamental. 2. The plantaginifolium, hath large woolly radical leaves, decumbent running roots, and herbaceous simple stalks, rising six or eight inches high, terminated by a corymbus of white flowers in June, July, &c. 3. The stechas, hath a shrubby stalk, dividing into slender branches three feet long, terminated by corymbose clusters of yellow flowers, appearing in May and June. 4. The orientale, or oriental goldilocks, hath three varieties, with yellow, gold-coloured, and white silvery flowers. They have shrubby stalks, rising two or three feet high. 5. The odoratissimum, or sweet-scented eternal flower, hath shrubby winged stalks, branching irregularly a yard high, with corymbose clusters of bright yellow flowers, changing to a dark yellow. 6. The arboreum, or tree gnaphalium, hath a woody stem, branching four or five feet high, narrow sessile leaves, with revolute borders, smooth on their upper side, and roundish bunches of pale yellow flowers. The first three sorts are hardy, and will thrive in any soil or situation. The two first increase exceedingly by their roots; and the third is easily propagated by slips. The fourth, fifth, and sixth sorts are somewhat tender; and therefore should be kept in pots, to be sheltered in a green-house or garden frame in winter. Others may be planted in the full ground, in a dry and warm situation, especially the oriental kind and varieties, and likewise the sweet-scented kind; for these two species will struggle tolerably through an ordinary winter, and make a pretty appearance during the summer months. All these are propagated by slips or cuttings of their shoots.—The flowers of all these species are remarkable for retaining their beauty for years, if carefully gathered in a dry day, soon after they are blown.

Gnat || Gnomon.

GNAT, in zoology. See CULEX.

GNESNA, a large and strong town of Great Poland, of which it is capital, and in the palatinate of Calish, with an archbishop's see, whose prelate is primate of Poland, and viceroy during the vacancy of the throne. It was the first town built in the kingdom, and formerly more considerable than at present. E. Long. 18. 20. N. Lat. 52. 28.

GNETUM, in botany; a genus of the adelphia order, belonging to the monœcia class of plants. The amentum of the male is a single scale; there is no corolla, and but one filament with a pair of antheræ. The calyx of the female is of the same form; there is no corolla; the style with the stigma is trifid; the fruit a monospermous plum.

GNIDIA, in botany; a genus of the monogynia order, belonging to the octandria class of plants. The calyx is funnel-shaped and quadrifid, with four petals inserted into it: there is one seed somewhat resembling a berry.

GNOMES, GNOMI, certain imaginary beings, who, according to the cabbalists, inhabit the inner parts of the earth. They are supposed small in stature, and the guardians of quarries, mines, &c. See FAIRY.

GNOMON, in dialling, the style, pin, or cock of a dial, which by its shadow shows the hour of the day. The gnomon of every dial represents the axis of the world: (See DIAL and DIALLING.)—The word is Greek, γνώμων, which literally implies something that makes a thing known; by reason that the style or pin indicates or makes the hour known.

GNOMON, in astronomy, a style erected perpendicular to the horizon, in order to find the altitude of the sun. Thus, in the right-angled triangle ABC are given, AB the length of the style, BC the length of its shadow, and the right angle ABC. Hence, making CB the radius, we have this analogy for finding the angle ACB, the sun's altitude, viz. BC : AB : : radius : tangent of the angle C. Plate CCXXI.

By means of a gnomon, the sun's meridian altitude, and consequently the latitude of the place, may be found more exactly than with the smaller quadrants. See QUADRANT.

Gnomon
ll
Gnoſtics.

By the ſame inſtrument the height of any object GH may be found: for as DF, the diſtance of the obſerver's eye from the gnomon, is to DE, the height of the ſtyle; ſo is FH, the diſtance of the obſerver's eye from the object, to GH, its height.

See further on the uſes and application of Gnomons, the article GEOGRAPHY, n° 49—53.

GNOMON of a Globe; the index of the hour-circle.

GNOMONICS, the art of dialling. See DIALLING.

GNOSTICS, ancient herctics, famous from the firſt riſe of Chriſtianity, principally in the eaſt,

It appears from ſeveral paſſages of the ſacred writings, particularly 1 John ii. 18. 1 Tim. vi. 20. and Col. ii. 8. that many perſons were infected with the gnoſtic hereſy in the firſt century; though the ſect did not render itſelf conſpicuous, either for number or reputation, before the time of Adrian, when ſome writers erroneouſly date its riſe.

The name is formed of the Latin *gnoſticus*, and that of the Greek γνωστικος "knowing," of γινωσκω "I know;" and was adopted by thoſe of this ſect, as if they were the only perſons who had the true knowledge of Chriſtianity. Accordingly, they looked on all other Chriſtians as ſimple, ignorant, and barbarous perſons, who explained and interpreted the ſacred writings in a too low, literal, and unedifying ſignification.

At firſt the Gnoſtics were only the philoſophers and wits of thoſe times, who formed for themſelves a peculiar ſyſtem of theology, agreeable to the philoſophy of Pythagoras and Plato; to which they accommodated all their interpretations of ſcripture. But

GNOSTICS afterwards became a generical name, comprehending divers ſects and parties of heretics, who roſe in the firſt centuries, and who, though they differed among themſelves as to circumſtances, yet all agreed in ſome common principles. They were ſuch as corrupted the doctrine of the goſpel by a profane mixture of the tenets of the oriental philoſophy, concerning the origin of evil and the creation of the world, with its divine truths. Such were the Valentinians, Simonians, Carpocratians, Nicolaitans, &c,

GNOSTICS was ſometimes alſo more particularly attributed to the ſucceſſors of the firſt Nicolaitans and Carpocratians, in the ſecond century, upon their laying aſide the names of the firſt authors. Such as would be thoroughly acquainted with all their doctrines, reveries, and viſions, may conſult St Irenæus, Tertullian, Clemens Alexandrinus, Origen, and St Epiphanius; particularly the firſt of theſe writers, who relates their ſentiments at large, and confutes them at the ſame time: indeed, he dwells more expreſsly on the Valentinians than any other ſort of Gnoſtics; but he ſhows the general principles whereon all their miſtaken opinions were founded, and the method they followed in explaining ſcripture. He accuſes them with introducing into religion certain vain and ridiculous genealogies, i.e. a kind of divine proceſſions or emanations, which had no other foundation but in their own wild imagination.

In effect, the Gnoſtics confeſſed, that theſe æons or emanations were no where expreſsly delivered in the ſacred writings; but inſiſted at the ſame time, that Jeſus Chriſt had intimated them in parables to ſuch as could underſtand him. They built their theology not only on the goſpels and the epiſtles of St Paul, but alſo on the law of Moſes and the prophets. Theſe laſt laws were peculiarly ſerviceable to them, on account of the allegories and alluſions with which they abound, which are capable of different interpretations: Though their doctrine, concerning the creation of the world by one or more inferior beings of an evil or imperfect nature, led them to deny the divine authority of the books of the Old Teſtament, which contradicted this idle fiction, and filled them with an abhorrence of Moſes and the religion he taught; alleging, that he was actuated by the malignant author of this world, who conſulted his own glory and authority, and not the real advantage of men. Their perſuaſion that evil reſided in matter, as its centre and ſource, made them treat the body with contempt, diſcourage marriage, and reject the doctrine of the reſurrection of the body and its re-union with the immortal ſpirit. Their notion, that malevolent genii preſided in nature, and occaſioned diſeaſes and calamities, wars, and deſolations, induced them to apply themſelves to the ſtudy of magic, in order to weaken the powers or ſuſpend the influence of their malignant agents. Gnoſtics.

The Gnoſtics conſidered Jeſus Chriſt as the Son of God, and conſequently inferior to the Father, who came into the world for the reſcue and happineſs of miſerable mortals, oppreſſed by matter and evil beings: but they rejected our Lord's humanity, on the principle that every thing corporeal is eſſentially and intrinſically evil; and therefore the greateſt part of them denied the reality of his ſufferings. They ſet a great value on the beginning of the goſpel of St John, where they fancied they ſaw a great deal of their æons or emanations under the *Word*, the *Life*, the *Light*, &c. They divided all nature into three kinds of beings, viz. *hylic*, or material; *pſychic*, or animal; and *pneumatic*, or ſpiritual. On the like principle they alſo diſtinguiſhed three ſorts of men; *material*, *animal*, and *ſpiritual*. The firſt, who were material, and incapable of knowledge, inevitably periſhed, both ſoul and body; the third, ſuch as the Gnoſtics themſelves pretended to be, were all certainly ſaved; the pſychic, or animal, who were the middle between the other two, were capable either of being ſaved or damned, according to their good or evil actions.

With regard to their moral doctrines and conduct, they were much divided. The greateſt part of this ſect adopted very auſtere rules of life, recommended rigorous abſtinence, and preſcribed ſevere bodily mortifications, with a view of purifying and exalting the mind. However, ſome maintained, that there was no moral difference in human actions; and thus, confounding right with wrong, they gave a looſe rein to all the paſſions, and aſſerted the innocence of following blindly all their motions, and of living by their tumultuous dictates. They ſupported their opinions and practice by various authorities: ſome referred to fictitious and apocryphal writings of Adam, Abraham, Zoroaſter, Chriſt, and his apoſtles; others boaſted, that they had deduced their ſentiments from ſecret doctrines of Chriſt, concealed from the vulgar; others affirmed, that they arrived at ſuperior degrees of wiſdom by an innate vigour of mind; and others aſſerted, that they were inſtructed in theſe myſterious parts of theological ſcience by Theudas, a diſciple of St Paul, and by Matthias, one of the friends of our Lord. The tenets of the ancient

Gnoſtics ‖ Goa.

ancient Gnoſtics were revived in Spain, in the fourth century, by a ſect called the *Priſcillianiſts*.

The appellation *Gnoſtic* ſometimes alſo occurs in a good ſenſe, in the ancient eccleſiaſtical writers, and particularly Clemens Alexandrinus, who, in the perſon of his Gnoſtic, deſcribes the characters and qualities of a perfect Chriſtian. This point he labours in the ſeventh book of his Stromata, where he ſhows, that none but the Gnoſtic, or learned perſon, has any true religion. He affirms, that were it poſſible for the knowledge of God to be ſeparated from eternal ſalvation, the Gnoſtic would make no ſcruple to chooſe the knowledge; and that if God would promiſe him impunity in doing of any thing he has once ſpoken againſt, or offer him heaven on thoſe terms, he would never alter a whit of his meaſures. In this ſenſe the father uſes Gnoſtics, in oppoſition to the heretics of the ſame name; affirming, that the true Gnoſtic is grown old in the ſtudy of the holy ſcripture; and that he preſerves the orthodox doctrine of the apoſtles and of the church; whereas the falſe Gnoſtic abandons all the apoſtolical traditions, as imagining himſelf wiſer than the apoſtles. At length the name *Gnoſtic*, which originally was the moſt glorious, became infamous, by the idle opinions and diſſolute lives of the perſons who bore it.

GNU, or GNOU, in Zoology. See CAPRA, n° xiii.

GOA, a large and ſtrong town of Aſia, in the peninſula on this ſide the Ganges, and on the Malabar coaſt. It was taken by the Portugueſe in 1508, and is the chief town of all their ſettlements on this ſide the Cape of Good Hope. It ſtands in an iſland of the ſame name, about 12 miles in length, and ſix in breadth; and the city is built on the north ſide of it, having the conveniency of a fine ſalt-water river, capable of receiving ſhips of the greateſt burden, where they lie within a mile of the town. The banks of the river are beautified with a great number of handſome ſtructures; ſuch as churches, caſtles, and gentlemens houſes. The air within the town is unwholeſome, for which reaſon it is not ſo well inhabited now as it was formerly. The viceroy's palace is a noble building; and ſtands at a ſmall diſtance from the river, over one of the gates of the city, which leads to a ſpacious ſtreet, terminated by a beautiful church. This city contains a great number of handſome churches, convents, and cloiſters, with a ſtately large hoſpital; all well endowed, and kept in good repair. The market-place takes up an acre of ground; and in the ſhops about it may be had the produce of Europe, China, Bengal, and other countries of leſs note. Every church has a ſet of bells, ſome of which are continually ringing. There are a great many Indian converts; but they generally retain ſome of their old cuſtoms, particularly they cannot be brought to eat beef. The clergy are very numerous, and illiterate; but the churches are finely embelliſhed, and have great numbers of images. In one of theſe churches, dedicated to Bon Jeſus, is the chapel of St Franciſco de Xaviere, whoſe tomb it contains: this chapel is a moſt ſuperb and magnificent place; the tomb of the ſaint is entirely of fine black marble, brought from Liſbon; on the four ſides of it the principal actions of the life of the Saint are moſt elegantly carved in baſſo relievo; theſe repreſent his converting the different nations to the Catholic faith: the figures are done to the life, and moſt admirably executed: it extends to the top in a pyramidical form, which terminates with a coronet of mother-of-pearl. On the ſides of this chapel are excellent paintings, done by Italian maſters; the ſubjects chiefly from ſcripture. This tomb, and the chapel appertaining to it, muſt have coſt an immenſe ſum of money; the Portugueſe juſtly eſteem it the greateſt rarity in the place. The houſes are large, and make a fine ſhew; but within they are but poorly furniſhed. The inhabitants are contented with greens, fruits, and roots; which, with a little bread, rice, and fiſh, is their principal diet, though they have hogs and fowls in plenty. The river's mouth is defended by ſeveral forts and batteries, well planted with large cannon on both ſides; and there are ſeveral other forts in different places.

Goa ‖ Goat.

Goa is the reſidence of a captain-general, who lives in great ſplendor. He is alſo commander in chief of all the Portugueſe forces in the Eaſt Indies. They have here two regiments of European infantry, three legions of ſepoys, three troops of native light horſe, and a militia; in all about five thouſand men. Goa is at preſent on the decline, and in little or no eſtimation with the country powers; indeed their bigotry and ſuperſtitious attachment to their faith is ſo general, that the inhabitants, formerly populous, are now reduced to a few thinly inhabited villages; the chief part of whom have been baptized: for they will not ſuffer any Muſſulman or Gentoo to live within the precincts of the city; and theſe few are unable to carry on the huſbandry or manufactures of the country. The court of Portugal is obliged to ſend out annually a very large ſum of money, to defray the current expences of the government; which money is generally ſwallowed up by the convents and ſoldiery.

There was formerly an inquiſition at this place, but it is now aboliſhed; the building ſtill remains, and by its black outſide appears a fit emblem of the cruel and bloody tranſactions that paſſed within its walls! Proviſions are to be had at this place in great plenty and perfection. E. Long. 74. 0. N. Lat. 15. 31.
