Railway Mechanical Engineer

Established 1832

Section No. 2. January, 1922

INDEX TO VOLUME XCV

1921

INDEX, 1921

VOLUME XCV

A

Abrasive adhere to ground surface? Does.. 478§
Abrasive Machine Tool Co., Exhauster attachment for surface grinder............ 52*
Abrasive Machine Tool Co., Small sensitive vertical spindle surface grinder.......... 198*
Adams, A. D., Safety stake pocket for logging cars 719*
Air area through grates and ashpans...... 734§
Air Brake Association: A good piece of committee work .... 477§
Air Brake Association executive meeting... 362*
Air compressor, Five-step clearance control for, Ingersoll-Rand Co................. 717*
Air Compressor, Gasoline-driven portable Chicago Pneumatic Tool Co............ 527*
Air compressor pistons, Device for removing, by J. H. Hahn........................ 510*
Air compressor repair, Erie Railroad...... 191*
Air compressor units, Compact portable, Ingersoll-Rand Co. 135*
Air consumption of locomotive auxiliary devices 484*
Ajax Mfg. Co., Brake shoe key taper rolling machine 323*
Ajax Mfg. Co., New model scrap reclaiming-rolls 383*
Albert, J. J., Table for oxy-acetylene cutting 708*
Allman, Wm. N., Insulation of freight and passenger cars....................444*, 608‡
Allman, Wm. N., Reducing the fuel consumption of power plants............88*, 154
Aluminum parts for locomotives.......... 734§
American Engineering Societies' meeting.. 21
American Metal Products Co., A new electric headlight 264
American Railway Association, Division V—Mechanical, meeting postponed.......... 565
American Railway Association; The June convention program .... 669§
American Railway Bridge and Building Association (see Bridge and Building Association)
American Society of Mechanical Engineers, Problems in design and operation of large locomotives 277*
American Society of Safety Engineers, Safety code for compressed air machinery. 712
American Society for Steel Treating (see Steel Treaters' Society)
American Society for Testing Materials.... 493
American Steel Founders, Lamont six-wheel truck for freight cars.................. 254*
Amsler & Co., Alfred J., Measuring locomotive and car wheel loads................ 722*
Anderson, A. H., Straightening car ends with a pull jack.......................... 239*
Angle plate with second face and T-slot, Nelson Tool & Machine Co............ 129*
Angularity, Locomotive main rod, by William Ulrich 519*
Ann Arbor Railroad, Trailer box with lateral adjustment, J. E. Osmer............ 20*
Anthony, J. T., Important factors in design of locomotive boilers.................... 683
Apprenticeship in France................ 275§
Apprenticeship, Specialized training vs.... 734§
Apprentice work organized, Paris-Orleans.. 313*
Arbitration committee, Report of (Div. V.—Mech.) 569*
Armstrong, G. W., Notes on general shop practice at Du Bois (B. R. & P.)........ 179*
Armstrong, G. W., Revivifying the railroad shop. 341*
Ash pans, Air area through grates and.... 734§
Ashton Valve Co., Locomotive driving wheel quartering gage........................ 658*
Atchison, Topeka & Santa Fe, Air hose coupling of simple design, John Ph. Weber.. 404*
Atchison, Topeka & Santa Fe, Four efficient machine shop devices, by J. Robert Phelps. 317*
Atchison, Topeka & Santa Fe—Grinding chilled cast iron car wheels.............. 181
Atchison, Topeka & Santa Fe, Power punches and dies 50*
Austin, E. A., Emergency truck for car repairs 228*
Automatic connector (see Connector)
Automatic Machine Co., Combination clutch brake for shaping planer................ 262*
Auxiliaries, Maintenance of air operated.... 484*
Averill, E. A., The effect of the feed water heater on superheat and back pressure.... 619*

B

Babbitting furnace, An easily made, by E. A. Miller 248*
Baggage trucks, Locking device for station, C., M. & St. P........................ 30*
Bailey, Carl C., Locomotive weighing plant of large capacity...................... 749*
Bailey-Lewis, Regulating valve for liquid fuels 194*
Baily, T. F., Relative economy of electric, oil, gas and coal-fired furnaces.......... 507
Baker Bros., Boring and drilling machine.. 136*
Baker, C. B., Easily detachable hand rail column 592*
Baker, C. B., Easily detachable running board bracket 722*
Baker, R. & L. Co., Duplex compensating suspension for tractors................ 257*
Baker, R. & L. Co., Electric truck equipped with carrying ram.................... 391*
Baltimore & Ohio, Handling milk in specially constructed tank cars............ 763*
Baltimore & Ohio, The Futrell automatic train line connector.................... 102*
Bangor & Aroostook cinder pit(Bridge & Bldg. Assn.) 707*
Barholt, A. F., Pencil repairs and inexperienced foremen .... 71‡
Barnes Drill Co., Self-oiling all geared gang 406*
Basford, George M., Getting better results from railroad organizations............ 151
Basford, George M., Vitalizing locomotives to improve operation.................. 357*
Bast, P. E., Preparation and distribution of fuel 682
Bath & Co., John, Expanding internal thread micrometer 463*
Bath & Co., John, Internal micrometer of unusual design 326*
Bearing, Staggered roller, Hart Roller Bearing Co. 396*
Bearings for railway cars, Ball............ 23*
Bearings for railway cars, Ball, by E. F. Maas .... 146‡
Bearings, Some facts regarding, by Louis A. Shepard 312
Beatty Machine & Mfg. Co., Vertical bulldozer for steel car work................ 526*
Becker Milling Machine Co., Heavy planer type milling machine.................. 388*
Bellevue Industrial Furnace Co., Semi-automatic twist drill grinder.............. 400*
Belting, The effect of relative humidity on leather, by F. W. Roys................ 190*
Belt service and length of life, by F. D. Rich 37*
Belts, Chart gives power of, by W. F. Schaphorst 687*
Bertschy Engineering Co., Cone or single pulley driven shaper.................... 398*
Betts Machine Co., Heavy car wheel boring machine 653*
Billing repair card, Supplying additional information on 753
Black & Decker Mfg. Co., A new post drill. 256*
Black & Decker Mfg. Co., Eight-inch electric bench grinder 785*
Black & Decker Mfg. Co., Portable electric grinder with pistol grip.................. 469*
Blowpipes, Tests of oxy-acetylene, Bureau of Standards 449
Blue print bath, A, by A. G. Johnson...... 101
Boiler, Inspection act: A decision that may be misconstrued, by A. G. Pack........ 336§
Boiler, A scale-proof locomotive crane, Industrial Works 133*
Boiler design, Progress in................ 672§
Boiler Makers' Association (see Master Boiler Makers' Association)
Boiler ruptures with man in firebox........ 590
Boiler scale, The cost of, by W. F. Schaphorst 292*
Boiler shell cracking, Cause of, through girth and seam rivet holes (Master Boiler Makers' Assn.) 712
Boiler shop tools, Two, by E. A. Miller.... 765*
Boiler, Stool for supporting front end of, by E. A. Miller 48*
Boiler tubes (see Tubes)
Boiler welding practice, Examples of proved, by G. M. Calmbach.................... 772*
Boilers, Important factors in design of locomotive, by J. T. Anthony.............. 683
Boilers, Repairing tube-sheet cracks in locomotive 704
Boilers, The care of locomotive............ 87
Bolster attachments for metal draft arm, R. C. Taft.............................. 130*
Bolt puller, Frame........................ 340*
Booster applied to Mikado locomotives for the Nickel Plate........................ 737*
Booster, Self-adjusting wedge, feed water heater and (Traveling Engineers' meeting) 616
Booth for timekeepers and foremen, Metal, Lyon Metallic Mfg. Co.................. 406*
Borden Co., Ratchet die stock.............. 408*
Boring mill, Taper attachment applied to, Cincinnati Planer Co.................. 53*
Boring mill (see Machine Tools)
Boston & Albany, A welded locomotive tender tank, by J. W. Murphy............ 550*
Bouysov, M. A., Turntable indicating device 688*
Bowen Motor Railways Corp., Gasoline motor driven passenger car (Pittsburg & Shawmut) 697*
Brake, Demonstration of double-capacity, Virginian Railway 428*
Brake equipment, Safety hand, Minich Railway Appliance Corp...................... 472*
Brake, Final trials of Kunze-Knorr air..... 218†
Brake for shaping planer, Combination clutch, Automatic Machine Co.................. 262*
Brake heads for uniform shoe wear, Designing, by H. M. P. Murphy.............. 107*
Brake power on tank cars, Adjustment of.. 227
Brake shoe and brake beam equipment, Report on (Div. V—Mech.)................ 579*
Brake shoe key taper rolling machine, Ajax Mfg. Co. 323*
Brass, The heat treatment of copper and, by F. H. Helrigel (Steel Treaters' convention) 647
Brexton, George, Reaming tube sheet holes... 318*
Bridge & Bldg. Assn., Construction and maintenance of cinder pits.............. 707*
Bridgeport Safety Emery Wheel Co., Heavy duty motor driven face grinder.......... 126*
Brinckerhoff, Frank M., The safety of passengers in steel railway cars.............. 223*
British views on fuel-oil installations....... 764
Bronze, Welding cylinders with Tobin, by Joseph T. Paight........................ 374*
Brookes, John H., Assigning engines........ 71‡
Brown & Sharpe Mfg. Co., Easily applied high speed milling attachment............ 51*
Brown & Sharpe Mfg. Co., Improved tools for machinists and toolmakers............ 389*
Brown Instrument Co., Cold junction compensated pyrometer...................... 595*
Brown Instrument Co., Long distance recording thermometers 471*
Brush for cleaning metal surfaces, Wire, Ingersoll-Rand Co. 387*
Brush for cleaning operations, Rotary wire, Independent Pneumatic Tool Co.......... 257*
Buck, D. M., Rusting of steel containing copper .... 538‡
Buckeye Steel Castings Co., Six-wheel freight car truck 522*
Buell, D. C., Standards of fuel economy (Fuel convention) 425
Buffalo, Rochester & Pittsburgh, An improved locomotive throttle valve, by W. J. Knox 216*

* Illustrated article; § editorial; † short, non-illustrated article or note; ‡ communication.

- Buffalo, Rochester & Pittsburgh cinder pit (Bridge & Bldg. Assn.) 707*
- Buffalo, Rochester & Pittsburgh, Notes on general shop practice at Du Bois, by George W. Armstrong 179*
- Buffing machine, Electric grinder and, U. S. Electrical Mfg. Co 390*
- Bulldozer for steel car work, Vertical, Beatty Machine & Mfg. Co 526*
- Bureau of Explosives, Annual report of the. 298
- Bureau of Explosives, Tank car outlets and other projections 170
- Bureau of Locomotive Inspection, Report of the 18*
- Bureau of Safety, Annual report of the 29
- Bureau of Standards, Tests of oxy-acetylene blowpipes 449

Books

- Carlton Machine Tool Co., Ball bearing heavy duty radial drill 386*

Car

- Bad order, 14.2 per cent 335§
- Bad order: A difficult problem 69§
- Bad order: An eye to the future 209§
- Bad order: A unit that will measure 1§
- Bad order, reached maximum in August 635*
- Bad order situation, Causes of the present, J. E. Muhlfeld 738
- Bearings (see Bearings)
- Bolster attachments for metal draft arm, R. C. Taft 130*
- Box, Fix, or have them retired 3§
- Brakes (see Brakes)
- Equipment, Standardizing 506
- Cost of, in 1920 80*
- Coupler (see Coupler)
- Deterioration, Relative effect of time and service on 238
- Draft gear (see Draft gear)
- Ends, Straightening, with a pull jack, by A. H. Anderson 239*
- Frame, An efficient straightening, N. B. Messimer (N. Y. C.) 31*
- Freight, Cause of the present condition of, by J. C. Fritts 97
- Freight: What are the real remedies? 69§
- Grain, Coopering 694
- Handling of, A check on rough 696

Car—Continued

- Insulation of freight and passenger, by Wm. N. Allman 448*, 608‡
- Insulation of passenger and refrigerator, by Arthur J. Wood 547*
- Interchange, Car inspectors and foremen propose changes in rules of 233, 304, 375, 441
- Interchange rules: Make car owners' responsibility complete, by C. J. Wymer 695
- Loaded: The business situation 273§
- Loaded, Unnecessary transferring of 690
- Maintenance (see Maintenance)
- Ordered and built in 1920 77
- Repairs (see Repairs)
- Seat, New coach, Scarritt Car Seat & Mfg. Co. 467*
- Seat, Single Pedestal swivel type, Frank Smolar 125*
- Stake pocket for logging, Safety, A. D. Adams 719*
- Tank outlets and other projections, Bureau of Explosives 170
- Hopper, Thawing frozen, by E. A. Miller 638*
- Truck (see Truck)
- Weak, New lease of life for 536§
- Wheels (see Wheels)
- Wood, The use of, in freight construction, by H. S. Sackett 105

Cars

- Coaches, Illinois Central steel suburban 755*
- Coal, 100-ton, for the Chesapeake & Ohio 627*
- Coal, 120-ton, on the Virginian Railway, 163*, 228
- Coal, Norfolk & Western 100-ton, by John A. Pilcher 293*, 367*
- Container, in express service on the N. Y. C. 171*
- Container, in use in Poland, S. Rodowicz 689*
- Design, Henry Ford on 670§, 689
- Design, Notable innovation in, Freight. 274§
- Design, Suggestions for passenger, by George S. Clouser 754
- Diesel electric, on the Swedish Railways 156*
- Freight, Factors to be considered in designing, by Albert H. Lake 495
- Gasoline motor, for branch line service 670§
- Passenger, Gasoline motor driven, Bowen Motor Railways Corp. (Pittsburg & Shawmut) 697*
- Postal, New plans and specifications for, and fixtures 101*
- Refrigerator, Fruit express, Union Pacific 25*
- Sleeping, New, for the Canadian Pacific 691*
- Tank, Handling milk in specially constructed, Baltimore & Ohio 763*
- Tank, Report of committee on (Div. V—Mech.) 586
- Tank, Sulphuric acid, of 70 tons capacity, General Chemical Co 95*

- Case-hardening, The effect of temperature in, by Theodore G. Selleck 648*
- Castings, An alloy for high temperature, Electro Alloys Co 654*
- Castings, Bronze-faced semi-steel 670§

GENERAL NEWS:
- Notes 61

A Unit That Will Measure

There is hardly a phase of railroad operation which does not have some unit of measurement with which may be made comparisons that throw more or less illumination on situations and the trend of events. The real value of these units must be judged, first, by the accuracy with which the results of their use may be interpreted and, second, by the convenience of their application. It is unfortunate that some of those commonly used units have little to recommend them except the latter quality, and among these must be included the per cent of cars in bad order as a measure of freight equipment conditions. The percentage of freight cars in bad order conveys little real information as to the general condition of freight equipment. Neither is it an accurate measure of the amount of work awaiting the shop and repair track forces. This is evident from the fact that bad orders even now are classified as lights and heavies, but with the wide range in the amount of work which may fall in the latter group, the value of this classification for comparative purposes is open to serious question. The cars in bad order may require from four or five to several hundred man hours each, and before this rough classification can be made the estimated amount of work on each car must be known. The information, therefore, is available from which the bad order situation can be stated in terms of car repair hours almost as readily as the number of bad order cars are now roughly classified as lights and heavies. The number of car repair hours conveys an accurate picture of the size of the job facing the repair forces, and the trend of car repair hours will show much more accurately than the trend of the number of bad orders, to what extent the demands for repairs are being currently met. Furthermore, with this information it would be a simple matter to arrive at the number of repair hours per car. This would be a most useful unit, not only for following the trend of car conditions in general, but for comparing cars of one class with those of another in a study of the relative merits of different designs. It does not appear that there should be sufficient added inconvenience in the computation of car repair hours, with the basic data already at hand, to overbalance the value of the information as an aid to a more accurate understanding of freight car conditions.

Higher Steam Pressure in Locomotive Service

For approximately ten years past the steam pressure used on locomotives has remained practically unchanged. The increase from 140 lb. or 160 lb. to 200 lb. per square inch occurred in a period of a few years. Some roads went to extremes and designed locomotives for 240 lb. pressure, but the investigation of Dr. W. F. M. Goss showed that in a locomotive of a given weight, greater economy could be secured by using a pressure of about 200 lb. than by raising the pressure and decreasing the size of the boiler to keep within the prescribed weight limit. Later when tests with superheated steam proved that the steam consumption per horsepower hour was practically constant over a considerable range of pressure, some roads went back to lower pressures of about 180 lb. to 185 lb. As the diameter of locomotive cylinders has now been increased as much as the clearance on many roads will permit, the next logical step would seem to be an increase in the boiler pressure. In fact this is an inevitable development, for since the stroke of the cylinder and the diameter of the driving wheels are practically fixed, the power output is limited unless the pressure can be raised. The Pennsylvania System adopted a pressure of 250 lb. for its Decapod locomotive and while this is a special case higher pressures are likely to be more generally adopted in the near future. Previous experience shows that satisfactory boiler maintenance becomes much more difficult at pressures above 220 lb. per square inch, but when the necessity for higher pressures develops, some means of overcoming it will surely be found though it may lead to the adoption of a different type of boiler for locomotive service.

Responsibility for Heat Treatment

With carbon tool steel at 18 to 25 cents a pound and high speed alloy steel costing around $1.25 a pound, the question of responsibility for the heat treatment of tool steel in railway shops becomes all important. In by far the larger proportion of shops the furnaces, small automatic air hammer, brine baths and other equipment used for dressing and hardening tools is located in the tool-room, but in many cases the tool-maker is responsible to the blacksmith shop foreman for both the quality and quantity of his work. This practice is a mistake. The tool-room foreman should have control of the heat treating department and specify the steel that goes into all tools heat treated at the shop where he is located. Knowing the conditions under which each tool is used, he is the one best adapted to specify the kind of steel needed and the particular heat treatment which will give the best results. The condition of a tool depends upon two things other than the workmanship in its manufacture; namely, the kind of steel as to carbon or alloying elements, and their percentage proportion; the other, the heat treatment. The man doing the heat treating should not be placed under the master blacksmith who often has too many other duties to specialize in the finer art of heat treating tools. In practically every case the manufacturers' recommendations as to the best heat treatment for a particular high speed steel should be rigidly adhered to. The tool foreman, having ordered the steel, is in a position to know what treatment is recommended and should be made fully responsible for the apparatus, methods used and men employed in the heat treating department.

The Conservation of Lumber

Few mechanical engineers appreciate the fact that following labor and fuel, lumber is the largest single item of expense to the railroads. It is quite possible that the unit cost of this material may drop more rapidly in the immediate future than the cost of either labor or fuel; but, in the long run, lumber is certain to increase in price as the available supply approaches a state of exhaustion. This is best emphasized by the fact that approximately one-half of all the available timber in this country is now located in three states bordering on the Pacific ocean. A survey of the records showing the annual rate at which lumber is being consumed in this country is even more startling. As a result of this situation, the railroads are already using grades that not many years ago were thought impossible and it is a certainty that within an equally short period mechanical engineers will be faced with the necessity for specifying grades of lumber for cars and other structures that are now regarded as unfit for this use. But, this being a fact, why should not mechanical engineers anticipate this situation, particularly if the use of a slightly lower grade at this time will reduce the cost of the lumber? In this connection the following is quoted from a paper presented at a recent meeting of the Forest Products section of the American Society of Mechanical Engineers:

"In the early days when the supply of wood in this country was thought to be inexhaustible, clear grades of wood were generally demanded by the car builders, and in the construction of new cars this is generally the practice at the present time, especially for car roofing and siding—sound-knotted stock being used for decking and lining. Some of the more progressive railroads, however, have gone a step further in recent years and many are now using sound-knotted stock for siding and roofing for repair and maintenance work. There is no doubt but that such a practice is economical and based on sound judgment, for certainly there is no necessity for using clear material for the repair of many classes of freight equipment, the life of which may not be in excess of seven to ten years. One large railway system which not only constructs its own cars but does repairing on a large scale, has adopted practice as to grades which has resulted in a saving to this railroad of over half a million dollars per year."

Undoubtedly mechanical engineers would prefer to follow the safe course and specify only those grades of lumber which they know have proved satisfactory. It is advisable, however, that they should do more than this; they should make certain that a less expensive grade will not answer the purpose before committing the railroad to the more expensive grades. This calls for a departure from the beaten path and a degree of courage which, however, should not be lacking.

Advantages of Standard Motion Pins and Bushings

Elsewhere in this issue is an article on "Standard Valve Motion Pins and Bushings" which should be of especial interest and value to railway shop executives and those responsible for the accurate and prompt repair of motion work in machine shops. It is a notorious fact that in repairing locomotive valve gear parts, pins and bushings of almost every possible size are used and the time required for making so many different sizes together with the individual fits, represents a large amount of money at the present cost of labor. The subject of standardization has already received careful attention in certain railroad shops and the article referred to outlines a method of manufacturing and fitting standard grade sizes of motion work pins and bushings with a considerable decrease in cost and increase in shop production. Among the important advantages resulting from the method explained is the fact that it permits manufacturing pins and bushings in large quantities with modern machines at central production shops. By grinding all of the bearing surfaces in one shop, this work can be performed more economically and accurately than heretofore. Most railroad shops are limited in output due to inadequate machine departments and valve work especially is often not completed on schedule time. The advantages of carrying standard pins and bushings in stock finished to the point of turning the taper ends and the outsides of bushings is especially apparent in these cases. Another advantage from the back shop point of view results from the fact that any pin will fit any bushing of the same class. Levers can thus be changed from one locomotive to another without refitting, a condition which is impossible without standard parts.

The Problem of the Railroad Clubs

Addressing members and guests of the New York Railroad Club at the recent annual dinner, the retiring president referred to the excellent character of the papers that had been presented to the club during his term of office. But he also commented upon the lack of discussion following the presentation of these papers and stated that it had proved a most difficult matter to draw out the sort of discussion that is most needed. Those who are best informed upon a subject are often the most reluctant to participate in the discussion, which, as a result, frequently terminates before any additional facts are developed or it drifts into other channels that have no particular bearing on the subject. This is indeed the problem of every railroad club, the real value of whose activities may usually be judged by the breadth and scope of the discussion. In fact, many papers presented at these clubs are designed mainly to provoke a discussion that will bring out the most salient points in connection with the subject. Since a majority of the papers presented at all the railroad clubs relate to mechanical matters, this situation should be of particular concern to all mechanical men who are so fortunately situated that they can attend these meetings.

Any man who holds decided opinions upon the subject of a paper and has the courage to deliver these views before a body of men, should not fail to take advantage of the splendid opportunity presented at these meetings for accustoming himself to public speaking. If he can deliver his remarks without the aid of notes, so much the better, provided he bears in mind that it is the text rather than the manner of delivery that is most important. In this connection, the activities of the Railroad Section of the American Society of Mechanical Engineers should not only be commended but might well be observed as a model for the railroad clubs. Following the choice of a subject and the selection of a speaker, the committee proceeds to invite a number of the best posted men available to discuss the paper following its presentation. Having secured the acceptance of a sufficient number of men to assure a well rounded discussion, the matter is not allowed to rest but each of these men is advised the length of time available for his discussion of the subject, and subsequent notices are addressed to him in reminder of the meeting. As a result, a broad instructive discussion is developed. In answer to any objection on the ground that this mode of procedure would tend to stifle general discussion of the subject, it may be said that the plan, if it does not involve too lengthy a discussion, will in fact, tend to stimulate more animated general discussion than would occur had no part of the discussion been planned in advance.

Fix Box Cars or Have Them Retired

The outstanding features of recent developments in the car situation, so far as it affects the car department, are the marked increase in the number of cars being returned home and the increasing number of heavy bad order box cars. Between July 15 and November 15 the cars at home increased from 26 per cent to 32.5 per cent of the cars on lines. During the same period the per cent of bad order cars of home ownership increased from 57 per cent to 67.6 per cent of all bad order cars. For box cars alone this increase has been from 46.5 per cent to 63 per cent, and a somewhat similar, though smaller, increase also applies to gondolas. But there has been an appreciable reduction in the number of bad order gondolas, both light and heavy, while the increase of about 8,000 heavy bad order box cars has been only partially offset by a decrease of about 3,500 in the number requiring light repairs. These figures indicate that the large amount of heavy repairs that were made to gondolas during the summer and fall, both in railroad and contract shops, is proving effective, but that the opportunity has only recently presented itself for effectively attacking the box car situation. Such an opportunity presents itself only when traffic is comparatively light, because box cars scatter rapidly when there is a car shortage. It is evident, therefore, that any improvement in the situation must be made now and during the remainder of a period of light business of uncertain duration if it is to be made at all. The need for supreme effort to bring about this improvement before the cars get away from home again is greater than can be inferred directly from the accumulation of bad orders. The retirement of about 135,000 freight cars with replacements probably not exceeding 20,000 or 30,000 has caused a depletion in the supply of equipment, of which probably three-quarters is box cars. This depletion was caused not by deferred retirements alone but by deferred maintenance as well, and should the present opportunity to rehabilitate large numbers of the older cars which are now at home in bad order, be neglected, their retirement from service may become compulsory before another opportunity to salvage them is offered. The railroads can ill afford any further extensive depletion of the box car supply during a period of heavy traffic until deliveries of new cars have become extensive enough to greatly outnumber the retirements.

The Labor Policy of the Railway Mechanical Engineer

Among the Letters to the Editor in this issue there appears a communication from a subscriber who evidently feels that the policy of the *Railway Mechanical Engineer* in regard to labor matters is unfair to the workers. While some of the statements made are apparently based on a misconception of the intent of the articles to which they refer, they are printed in full, as a few comments on the letter should serve to bring out clearly the editorial policy on this important subject.

The entire tone of the letter indicates that the writer feels that labor conditions were uniformly bad prior to federal control and the only hope for the employees in the future lies in the adoption of the Plumb plan. The autocratic stand taken by some railroads in the past is criticized. It must be admitted that abuses existed, but they also existed in other industries at the same time. Labor conditions in general have improved in the last few years and the railroads have developed their policies in accord with the spirit of the time.

The right of the employees to have a voice in fixing wages and working conditions is now generally conceded. This right is assured to the railway workers under the Transportation Act. The form which employee representation should take is a matter that should be left open to be determined by the management and employees on each individual railroad. Certainly the close contact between the management and the workers necessary for harmonious and efficient relations will not be promoted by the centralization of authority in national boards of adjustment. Granting the right of the employees to organize, the employers on the other hand have a right to demand that each employee shall give a fair day's work, that working agreements shall be so framed that they do not hamper production without cause and that promotions to supervisory positions shall be based not on seniority but on ability.

The section of the letter dealing with the Plumb plan compares it with the present Transportation Act. The writer makes a statement that the railroads are guaranteed a definite rate of return, but this has been disproved so often that it hardly seems necessary to point out once more that the return is conditional on the efficient operation of the property. The statement that interest is paid on watered stock is equally misleading. The value upon which the earnings are based is determined by the Interstate Commerce Commission. With the data obtained in the federal valuation reports the commission is certainly in a position to decide on a fair value for the property of the carriers.

To deal with all the questions brought up in the letter would make this article too long, but some of the statements regarding the present attitude of the railroads toward their employees can hardly be passed by without comment. To complain because the railroad managers did not acquiesce in all the demands made by the employees of the labor board hearings seems unreasonable. The Transportation Act places responsibility for efficient operation on the management, but it would hardly be consistent for them to claim that they were managing their property efficiently if they advocated fixing rates for labor higher than the prevailing scale in other industries. As a matter of fact, the railroads recommended that some classes of employees be given the full amount of the increase which they requested.

The concluding paragraph of the letter discloses a lack of knowledge of the fundamentals of economics that is responsible for much of the labor trouble at the present time. Wages, prices and business conditions are not manipulated by any small group of individuals, but are determined by fundamental economic laws. The employees and the managers have far more interests in common than is generally realized. The hope of improved conditions in the future lies in the more general realization of these mutual interests and the development of a spirit of co-operation instead of antagonism. A masterly treatment of this question will be found in the address by Herbert Hoover published in this issue, which outlines a program for industrial and social progress that should appeal alike to employer and employee.

NEW BOOKS

The Engineering Index for 1919. Published by the American Society of Mechanical Engineers, 29 West 39th street, New York. 527 pages, 6 in. by 9 in. bound in cloth.

The purpose of the Engineering Index is to provide a convenient and satisfactory guide to engineering literature. The 1919 edition of this index is the most complete and comprehensive work of its kind ever published. It contains over 12,000 references to articles published during the year 1919 in nearly 700 engineering and allied technical publications. The compilation of this index is based upon a review of approximately 1,100 periodicals, reports, and other publications by the engineering staff of the American Society of Mechanical Engineers. These publications are printed in ten different languages and comprise what is probably the most complete collection of scientific and engineering publications in the world. All of the publications referred to in this index are now a part of the Engineering Societies Library in New York.

Fuel Oil In Industry. By Stephen O. Andros. 240 pages, 6 in. by 9 in. Illustrated. Bound in cloth. Published by the Shaw Publishing Company, 910 South Michigan Boulevard, Chicago.

The use of fuel oils by the railroads is by no means new and the problems involved in its application to the locomotive have been carefully studied by railway engineers for many years; in fact, the value of this book to the railway mechanical or civil engineers might be questioned if it were not for the tremendous expansion in the use of fuel oil in all industries within recent years. Thus the increased price of bituminous coal has assisted in promoting the use of fuel oil both in maritime service and in many hundreds of stationary plants along the eastern seaboard. This in turn has introduced new problems relating to its transportation in bulk and storage in large quantities. Moreover, it must be admitted that refinements bearing upon the handling and burning of fuel oil are generally given more consideration in stationary and maritime service than in railroad use. For this reason, there is a field for a book of this character in railroad as well as industrial service which outlines, as it does, not only the principles of fuel oil combustion and the properties of fuel oils; but the methods of testing, storing and burning it together with a full description of its application to industrial and domestic furnaces. For instance, the book not only describes many of the details involved in the construction of steel storage tanks but refers to an interesting development in concrete oil storage tanks and describes at length all of the pipe setting and auxiliary machinery involved. While the book describes many types of burners that would not be applicable to locomotive service, still there are many points in connection with this subject as outlined in this book that will prove of particular interest to railway fuel engineers. The use of fuel oil in the manufacture of iron and steel and the heat treating furnaces is also described and illustrated in an interesting way.

Export Register of the Federation of British Industries. 328 pages and catalogue section of 312 pages, illustrated, 7 in., by 9½ in. Bound in cloth. Published by the Federation of British Industries, 39 St. James street, London, S. W.-I, England.

The trade organization movement in Great Britain has made great progress in recent years. One of the most notable recent developments was the inauguration of the Federation of British Industries in the summer of 1916. This body has enrolled 1,300 members including 200 trade associations. The Export Register recently published by the federation is probably the most comprehensive directory of British industrial firms yet prepared. The industries are divided into 20 groups which are in turn subdivided according to the specialized branch of the industry which the producer serves. A list of companies, firms and their agents, with sufficient information to enable the buyer to get in touch with the nearest agent, is given. Another section of the book is devoted to a very complete list of products with the names of the manufacturers represented in the federation. An extensive section devoted to advertising enables the individual manufacturers to give further information concerning their wares. This book might well serve as a model for American export associations in furthering their interests in the foreign field.

The Locomotive Up to Date. By Charles McShane. Revised edition, 893 pages, illustrated, 6 in. by 9 in. bound in cloth. Published by Griffin & Winters, Chicago.

The remarkable development of the locomotive and locomotive appliances which has taken place since this well known book first appeared in 1899, made a revision imperative if it were to continue to be of current interest. This work has been performed by Charles L. McShane. The book is non-technical in character and in many respects perhaps too superficial in its treatment to be of value to any one but a novice in locomotive design, maintenance or operation. Its great appeal will probably be to the young machinist and the apprentice, and perhaps to some extent to the locomotive fireman. By far the greater part of the space devoted to descriptive material is taken up with locomotive specialties rather than with the construction of the locomotive itself and the revision has consisted largely in bringing these sections up to date. So many of the more recently developed locomotive appliances, some of them well established, are so lightly touched, if touched at all, that the volume can hardly be said to justify its title, even in the field to which most attention has been given. In the revisions of those sections dealing with breakdowns and shop work no account has been taken of the requirements or effects of the Interstate Commerce Commission locomotive inspection rules and the revision has failed to disguise the fact that these sections are most directly applicable to the motive power of 20 years ago. Over one-third of the volume is devoted to valves and valve motions, and the sections dealing with these subjects are the most thorough and complete of any in the book. The fundamentals of valve motion and the determination of valve proportions and events have been thoroughly handled in so simple a manner that they may readily be comprehended by the novice while still offering much of interest to those of greater experience. All of the valve motions now used in locomotive service are described and instructions for valve setting are given in each case. From the standpoint of the young machinist, only second in importance to the sections dealing with valves will be found those on shoes and wedges, the laying out and fitting of which have been fully explained, numerous sketches adding to the clearness of the explanation.

COMMUNICATIONS

The New Haven Mountain Type Locomotives

New Haven, Conn.

To the Editor:

I noticed with considerable interest the description of the Mountain type locomotives for the New Haven and at the same time I have observed a few things that are not absolutely correct. This article states that engines were equipped with a Unit drawbar. This is not true, as it was necessary, by reason of design, to forego the use of the Unit drawbar. It is also stated that the Lewis power reserve gear is used, whereas the locomotives are equipped with Ragonnet, Type *B*. Moreover, the cylinders were not cast with by-pass valve chambers as stated in the last paragraph of "changes in the standard design."

On the same page, second column, it is stated that the object of designing a single hopper ash pan was to facilitate future application of the booster. While in a measure this is true, it was also found possible to increase the capacity of the pan approximately 15 per cent over the government design and at the same time dispense with necessity for two hoppers.

The Union Viewpoint on Labor Questions

San Antonio, Texas.

To the Editor:

I find an article in your November issue in which the writer says much will have to be done before we get back to pre-war conditions. As a representative of labor, I beg to inform him that the workers have no intention of going back to pre-war conditions, now or at any other time, as we suffered too many hardships under those conditions. We have therefore formed ourselves into different organizations and made ready to protect ourselves and our families from the employer who would have us work for a bare living under whatever conditions he saw fit to impose.

We fully understand that pre-war conditions means that the employer wishes again to have undisputed control over his employees, to deal with them as he sees fit, regardless of what they may want or desire; in other words, he wants them to become automatons, without the right to think for themselves.

We can all remember the time when the workers first asked for the eight hour day, how these same men told the public that the eight hour day meant the destruction of the country, and again when the nine hour day was forced upon them, they tried to make the public believe that the workers were trying to destroy the commerce of this country by not producing enough to supply the demand. Now we have the eight hour day and wages which allow us some of the comforts of life and a chance to give our children an education which before we were compelled to deny them.

We find that according to the newspapers the workers are again about to destroy the universe in which they live, but we have lived through the signing of the Declaration of Independence, the abolition of slavery, the establishing of prohibition, woman suffrage, and we will allow the workers to get their rights without destroying the country or even being sorry for any of these changes for the betterment of mankind.

This writer complains that the shops are burdened with a class of men who claim to be mechanics, but who are not able to produce a day's work for a day's pay. The most of these men were employed in these same shops before the war and were classed as handy-men; their wages averaged very little more than that of the common laborer. They were trained by their employers in order to get cheap labor, instead of paying mechanics to do mechanical work. The employers insisted on using these men as long as they could get them for small wages and force them to work under conditions that no mechanic would tolerate. Now that these men are demanding that they be paid a living wage, he has no further use for them, but wants to throw them out until such time as they have been starved into submission and the acceptance of a lower wage, or he would be even willing to use them as he has in the past as a strike breaker, in case his mechanics get too bold and demand their just share of the profits of the business of which they are the most vital part.

When the railroads went under federal management there was established a sliding scale of wages for this class of employees; under its provisions a man became a full rated mechanic after he had worked four years at a trade. If the management had done their part and given these men a chance to learn all branches of the trade during this four years, they would have had nothing to complain about at the present time. They made no effort to train these men, and now they find themselves confronted with the problem of making these men earn their salary, when they are only able to do one class of work.

I find these men very anxious to learn and make something of themselves and using every means in their power to make themselves mechanics. Some even go so far as to quit the shop and go to a strange shop and hire out as a mechanic, working as long as they will allow him, and then going to some other place where he is not known and repeating the same thing, until at last, after many hardships, he is able to hold a job. These are the men the writer complains about and asks the mechanics to allow them to turn them out on the streets.

I believe these shops owe it to these men whom they have started to make mechanics of to allow them to finish their trade in the shop where they started and where the employer received the benefit of their cheap labor before the war. Make them proficient workmen; give them mechanics' pay, and then stop making jack-leg mechanics and handymen.

The railroads are asking that they be allowed to deal with their employees individually, but they are not willing to be dealt with individually; they still want to be guided by their organizations and be banded together as one body in dealing with the employees; we want a fifty-fifty deal, that's all.

In the other article to which I take exceptions we find this statement, "Under the Plumb Plan the public would buy the roads and guarantee their operating expenses and the interest on the money invested in them."

Under the present plan we are not buying the railroads, but we are guaranteeing the operating expenses, and the interest on not only the money invested, but also six per cent on the watered stock. In this way the public is assuming all the risk and getting absolutely nothing in return.

The statement is made that under the Plumb Plan the surplus money earned would be divided, one-half going to the workers. How about the present plan; what will become of the surplus earnings? Will the worker get their share, or will the public get any of it, or will it be as it has been in the past: the favored few stockholders adding a little more watered stock and getting away with the cash? This article claims that no business is well managed unless it is handled by the owners or in their behalf. How, then, are we to account for the many successful enterprises now being run under municipal management? We find cities running water works plants, street cars, light plants and many others too numerous to mention, and they are paying better than they did under private management. Besides, the employees are better paid than they were under private control.

As an instance of this I beg to call your attention to the city of Cleveland where a few years ago the city was taxed to pay for the collecting of the garbage, while at the present time, under municipal management, the city receives several thousand dollars by the sale of its garbage, besides having it collected free to the public.

The language of this article would lead one to believe that the last increase in pay granted the railroad men was given by the private owners, whereas they used every means which they had in their power to prevent the men getting this increase.

The claim is made that this shows that the men would be able to get just treatment under private management, but their actions in the past, to say nothing of the present, does not bear out this claim. In the past the men were forced to work piece work, premium work and bonus work and goodness knows what else, no matter how much they protested against it.

During federal control these things were done away with by the vote of those who were trying to exist under these systems, and this vote was so strong in favor of abolishing these methods that the government granted the request of the employees.

Since the roads have gone back to private control they are using every means in their power to reestablish these old practices, which the men who work in the shops have said they do not want.

You state that it would be possible for the men to own the roads by simply buying up the stock of the different roads. My experience has been that some of the large roads have tried this plan to get control of smaller side lines, which they needed as feeders for their main lines. If history is correct in its statement on these deals, and I believe it is, they found this not only an expensive proposition but often an impossibility, as the stock markets are not so easily handled as this statement would lead us to believe.

The money to make this purchase possible is to be taken from the last increase in wages which the workers received, but it is a well known fact that this increase was only granted after it was conclusively shown that the men were not able to live on the wages they were receiving, yet they must take this money and buy the roads and deny themselves the necessities of life. This is called thrift, but it is the kind of thrift we always want the other fellow to practice but do not care to indulge in ourselves. The writer sees in the failure of the employees to do this proof positive that they would not be able to run the roads if they were given the chance. He overlooks one essential point, and that is that the owners do not run the roads but hire men to do it for them. We find that few of the men who are held responsible for the running of the roads own any of the stocks of the road they are managing. We well know that when there is any question of any consequence to be settled it is the men who are paid a salary that are called upon to handle it and not the owners. It is the brains that a road is able to buy that makes it a success or failure, not the brains of the men who own the stocks. The owners are more concerned about the price of the stocks and the amount of their dividends than they are about the way their roads are run, except as an investment.

The managers are trying to make the public believe that the workers are being paid too high a wage. Did you ever stop to think why wages were so high? Most of the men who own the greater part of the railroad stocks are also owners in part of some other business which was responsible for these high prices of which we all complain. Then they must be responsible for the high cost of living and also the high cost of labor of which they are now complaining. They are even now trying to create a bread line to reduce the price of labor and make the worker submissive to their will.

L. S. Kronheimer,
Chairman, Local Federated Shop Crafts, G. H. & S. A.

Management in Railroad Shops

Salt Lake City, Utah.

To the Editor:

The editorial on Systematizing Management in Railroad Shops, published in the November issue of the *Railway Mechanical Engineer,* deals with a subject of the utmost importance. I believe that a close study of this question will lead to the conclusion that job analysis and job specification, carried on by a competent committee of both officers and employees, and under the supervision of a personnel department is the only logical solution. The committee on job analysis should be composed in part of mechanical officers who would work with a committee appointed from each shop on the line, and in this way the benefits derived in one shop would be passed on to all the shops coming within the sphere of the study. One of the chief values of this plan would be that a certain number of employees would gain first-hand knowledge of the work and would have a chance of expressing their views of any changes that might be recommended that would affect the employees. These objections would receive due consideration and for this reason all employees would more readily accept any changes in method that might be adopted.

I have also read with interest the editorial on page 683 entitled "Training the Foreman." To my mind the foreman is the key to the whole problem of efficiency and safety. Every large shop at least should provide a definite and systematic training course for all of its foremen. This work should have a competent instructor in charge of it, and the course of instructions should not only provide courses in the mechanical details of the foreman's work, but should be designed to develop executive ability and give the foreman a larger outlook on the transportation business as a whole.

This work should also be under the general supervision of a personnel department.

J. C. Clark,
Asst. to General Manager in Charge of Safety, Oregon Short Line.

Save Fuel by Keeping Valves Square

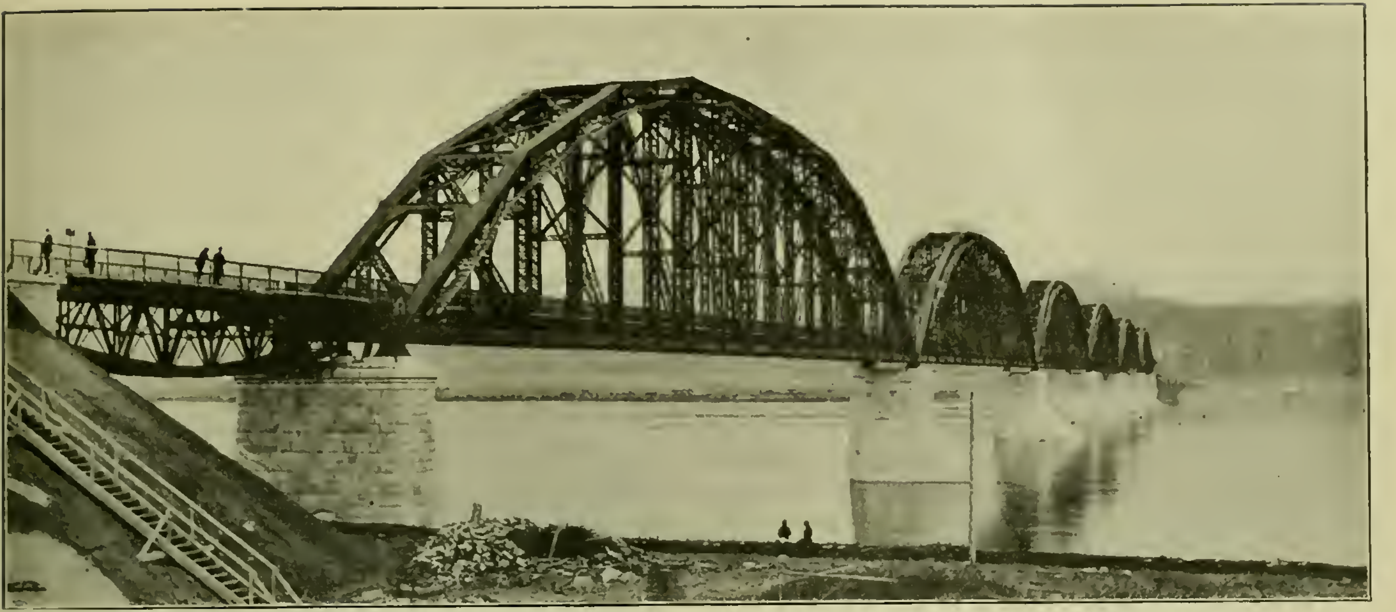
Heath, Mass.

To the Editor:

Why is not valve setting given more attention in large engine terminals? Much money is spent, and rightly too, on the upkeep of devices for economy in the production of steam but little attention is given to the device that determines the economy secured in the use of steam; namely, the valve gear. With pooled engines, very often a locomotive out of square will not be reported as requiring attention in that respect, or an engine may be out of square and yet handling its train all right and so nothing is done. Then there is the rarer case of an engine sounding square but in reality being out.

The effects of a lame engine on fuel consumption are so well known that it is unnecessary to repeat them. But a point often not realized is the tendency of a lame engine to slip. This results in difficulty in starting and liability of stalling on a hard pull. The valve setting should be checked on each engine regularly. In the larger terminals, a valve setter and helper could probably be kept busy squaring valves. An engine should be inspected after perhaps 20,000 miles. In a good many cases where there is much lost motion and the engine has considerable mileage to cover before the next visit to the back shop, it would pay to renew bushings in the valve gear and thus have the valve move as intended and not lag.

W. G. Landon.



Bridge on the Tomsk Railway Crossing the Yenisee River at Krasnoyarsk

Mechanical Equipment on the Tomsk Railway

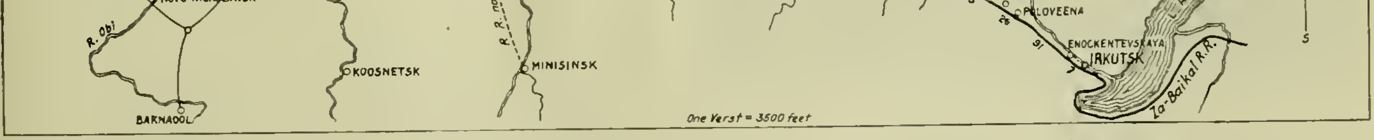
An American's Impressions of the Locomotives. Cars and Shops of the Trans-Siberian System

BY JAMES GRANT
Late Captain, Russian Railway Service Corps

THE Tomsk railway is that part of the Trans-Siberian system, between Irkutsk and Novo-Nickoliavsk. The main line is all double tracked, a distance of 1,734 versts. As one verst is 3,500 ft., this is, in English units, approximately 1,156 miles. There are very few branches, the most important being the branch from Tiaga to Tomsk, about 80 versts long. There is a line in course of construction from Achinsk to the city of Minisinsk. By glancing at the map of the railroad it will be observed that Achinsk, which is a small town, is about 170 versts west of Krasnoyarsk, while Minisinsk is an important city about 250 versts south of the railroad, on the Yenisee River. This latter city was always a Bolshevik stronghold, an army of 15,000 being stationed there all the time that the Kolchak forces controlled Siberia. The Kolchaks were never able to oust them from Minisinsk because the town was too far away from all transport facilities. The road connects with the Za-Baikal at Irkutsk and the Omsk Railway at Novo-Nickoliavsk.

The section through which the Tomsk railway runs is perhaps the most fertile and productive region in all Siberia. The scenery along the road is very pretty, consisting of fine agricultural districts, coal mining concessions and dense forests. The road crosses great rivers and runs directly through the wealthy Yenisee province. This province was always known as one of the most independent in all the old Romanoff's broad domains. Considering the past years of revolution, the roadbed is in excellent condition; it is all ballasted and has 72 lb. rails. The section work at the time the American forces were in Siberia was done mostly by women, nearly all men of fighting age being engaged either with the old Russian army or the Bolsheviki.

This sector of the country has been the scene of much



Map of the Tomsk Railway Showing Distances in Versts Between Principal Stations bloody strife since 1917, the Czecho-Slovak forces and Bolsheviki having many pitched battles all along the right of way. As a result many fine bridges have been blown up, tracks torn up and many station buildings wrecked. In May, 1919, the station at Tyshet, one of the main terminals, was practically blown away after a battle between Czecho-Slovaks and Bolsheviki, approximately 200 Reds being annihilated in this struggle. While the writer was stationed at Krasnoyarsk he saw seven train wrecks between that station and the next terminal in one week of September, 1919. These wrecks were all caused by Bolsheviki pulling out rails, usually wrecking Russian military trains, resulting in much damage to the motive power and invariably causing quite a loss of life. At this time there is a sad collection of equipment in the ditch, awaiting some semblance of order so that it can be brought to the shops and be rebuilt.

The Tomsk railway has always been recognized as the banner railroad in Siberia, especially in regard to mechanical equipment. The road has seven main terminals, with seven turn-around terminals located between. The terminals and verst posts are as follows:

Irkutsk (Terminus of Za-Baikal Railway)	0 v.
Enockentevskaya	7 v.
Poloveena	98 v.
Zeema	235 v.
Tooloon	366 v.
Nishni-Udinsk	475 v.
Tyshet	628 v.
Elanskaya	757 v.
Kluckvennaya	896 v.
Krasnoyarsk	1,020 v.
Chernorechenskaya	1,154 v.
Bogotol	1,256 v.
Marinsk	1,386 v.
Taiga	1,520 v.
Bolotnaya	1,616 v.
Novo-Nickoliavsk (Terminus of Omsk Railway)	1,734 v.

The stations shown in italics are main terminals.

Elanskaya is the station at which Colonel Blunt and six other American engineers were captured by the Bolsheviki while endeavoring to evacuate eastward towards Vladivostok in January, 1920. The writer left Colonel Blunt and his party at Krasnoyarsk on December 19, 1919, and it took seven weeks to make the trip to Vladivstok, a distance of 4,036 versts. The remainder of the engineers started evacuation eight days later, but only got as far as Elanskaya, where they were captured. They were, however, later turned over to the Czecho-Slovaks, who had their echelons strung out all along the line, trying to get to Vladivostok.

A Train at Vladivostok Station

Terminals

Each of the main terminals on the Tomsk railway is well equipped, usually having large and commodious yards. The engine houses generally consist of two rectangular sheds with capacities for about 50 locomotives, a rectangular shop for nine engines (in which all light repairing is done), machine shop and blacksmith shop. The engine sheds are equipped with drop pits and hydraulic traversing rams for dropping wheels. One fine feature is that the drop pit rails all swing on hinges, so that when dropping wheels there is no lifting of heavy rails. All shops are equipped with electric hoists of the same type as used in the main shops and described later in this article.

Main terminals have both a turntable and a "Y," while turn around stations have a "Y" only. Turntables are operated by an ingenious air device, connected to the train line on the engine or tender. This consists of a horizontal air cylinder with a clamp attached to the piston, so designed that it seizes and releases the rail, as controlled by the operator with a three-way valve. This device, while probably not as good as some of the air driven attachments in this country, works surprisingly well and extreme cold weather causes it very little trouble.

Station at Pograneechnaya, Showing Type of Freight and Passenger Equipment

Motive Power

The road has between 500 and 600 locomotives in operation, and these engines are composed of seven distinct types only, as follows: 1. 0-6-0 or Switcher type. This is the so-called government type of locomotive, so common in Russia. These engines were built in 1893 and 1896 by the Putilov works of Petrograd. There are only a few of this type on the road and they are used for switching service. The principal dimensions are:

Weight on drivers	34.50 tons
Total weight, engine and tender, loaded	60.10 tons
Diameter of drivers	1,292 m.m. (52 in.)
Length of engine and tender, overall	14,313 m.m. (47 ft. 0 in.)

2. 0-8-0 or Eight Wheel Switcher. The road owns about 200 of this type. Most of them, however, are stored away out of service, replaced by more modern power. They were built at different times, between the years 1895 and 1906, by seven different locomotive works in Russia. They are generally used for switching. The principal dimensions are:

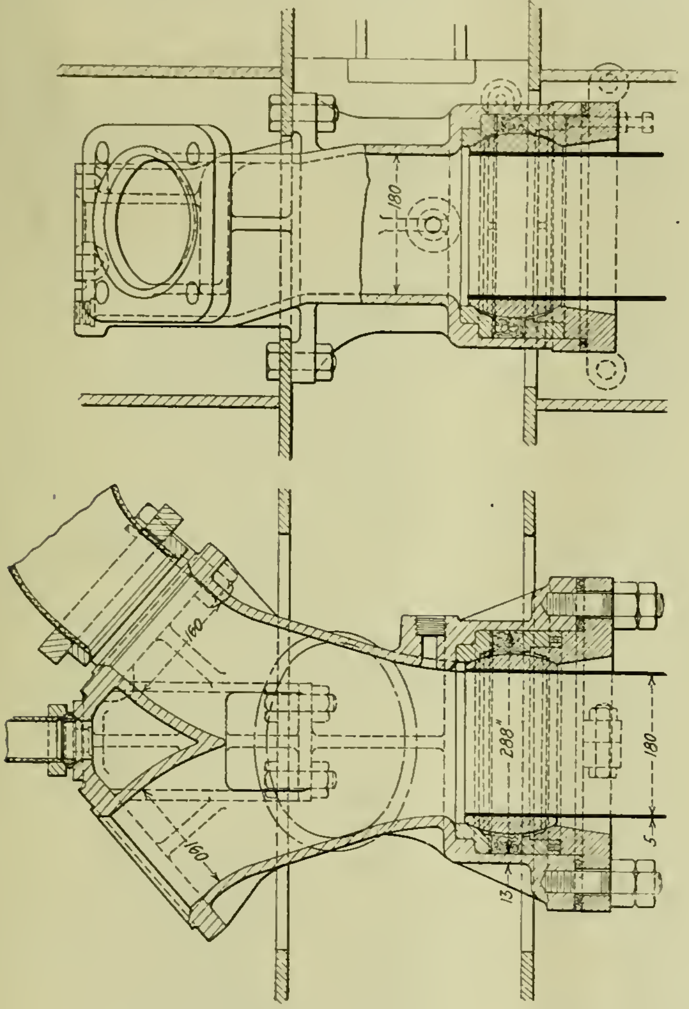
Weight on drivers	51.5 tons
Total weight, engine and tender, loaded	103.03 tons
Diameter of drivers	1,200 m.m. (47.3 in.)
Length of engine and tender, overall	18,691 m.m. (61 ft. 5 in. app.)

3. 0-6-6-0 Mallet Articulated. The road owns about 230 of this type of locomotive, which is one of the most successful for freight service on the whole Trans-Siberian system. Although not so large as our American Mallets, yet they have many noteworthy features. These engines were built between 1899 and 1906 by the Bransk, Putilov and Kolomensk locomotive works. They have slab frames (as have all Russian built locomotives) of 1¼-in. plate, and breakage is a thing unknown. The high and low pressure engines are connected by upper and lower steel castings; riveted to the frames, and hinged on two 4½-in. pins, brass bushed. The driving box jaws are bolted or riveted to the frames, so that they can be removed and machined, when the engines undergo repairs. The driving box shoes and wedges are made of steel, while

the box faces are brass lined. The receiver pipes have both ball and sleeve joints of special construction, as shown in the drawings, which are so designed that there is little trouble from steam leakage. The engines have Walschaert valve gear, piston valves, fire boxes and flue sheets all made of copper, with copper stay bolts, and a special type of Freidman injectors. The principal dimensions are:

Weight on drivers	84 tons
Weight of engine and tender, loaded	135 tons
Diameter of drivers	1,200 m.m. (47.3 in.)
Diameter of H.P. cylinder	475 m.m. (18.7 in.)
Diameter of L.P. cylinder	710 m.m. (28.0 in.)
Diameter of H.P. and L.P. piston valves, both	300 m.m. (11.8 in.)
Length of stroke	650 m.m. (25.6 in.)
Maximum steam pressure	12 atmospheres (176 lb. per sq. in.)
Length of engine and tender, overall	21,097 m.m. (69 ft. 3 in. app.)

4. 2-4-4-0 Mallet Articulated (used for passenger service). The road has 112 locomotives of this type built between 1903 and 1909 by the Kolomensk Locomotive Works. These engines are quite similar in design to the freight Mallets, and can get over the road with remarkable speed. The principal dimensions are:



Tee and Ball Joint on Receiver Pipe of Russian Mallet

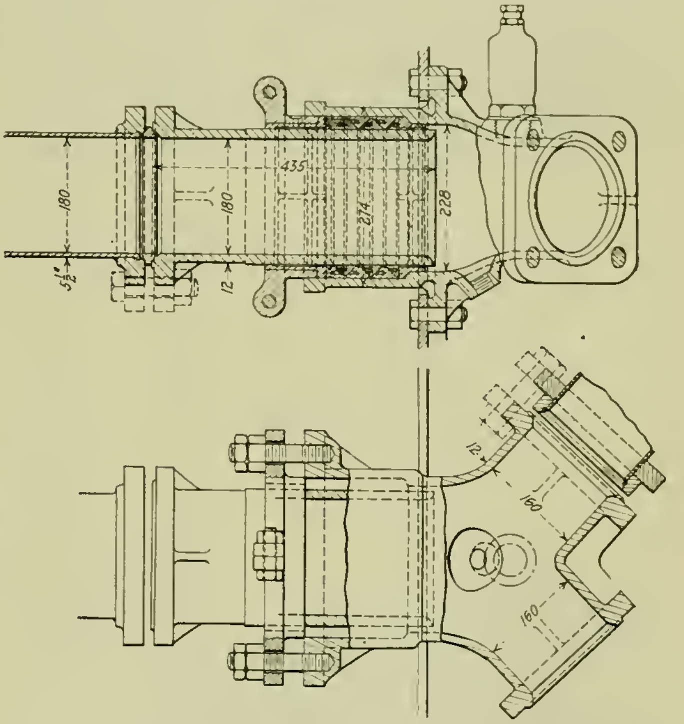
Weight on drivers	65 tons
Weight of engine and tender, loaded	116.07 tons
Diameter of drivers	1,350 m.m. (53.2 in.)
Length of engine and tender, overall	19,723 m.m. (64 ft. 9 in. app.)

5. 2-10-0 American Decapod (built by the Baldwin and American Locomotive Works between the years 1913 and 1916). The road possesses about 50 of these engines. Their tonnage on the Tomsk railway is rated just the same as the freight Mallets. They have a Schmidt superheater and carry a steam pressure of 12.7 atmospheres (187 lb. per sq. in.). A description of these locomotives has appeared in a former issue of the *Railway Mechanical Engineer**. Many of this type, built for the Russian government, are now operating in this country.

6. 2-6-2 or Prairie type (used in passenger service). The road has 13 of these locomotives, built in 1915 by the Sormov Locomotive Works. These are a fine passenger engine and compare favorably with any of our American power. Equipped with Walschaert valve gear, and Schmidt superheaters, carrying a steam pressure of 13 atmospheres (191 lb. per sq. in.) they are capable of great speed. They have a special design of piston rod packing, using a double packing ring. Officials claim that this packing runs from shopping to shopping, without renewing. It seldom blows even in the coldest of weather. The principal dimensions of this class are:

Weight on drivers	47.1 tons
Weight of engine and tender, loaded	126.3 tons
Diameter of drivers	1,830 m.m. (72.1 in.)
Length of engine and tender, overall	21,271 m.m. (69 ft. 11 in. app.)

7. 4-6-0 or 10 Wheel type (used in passenger service). The road has 44 of this type, built in 1910 and 1911 at the Kolomensk and Putilov works. They are quite similar in design to the Prairie type being equipped with Walschaert valve gear and Schmidt superheaters and carrying a steam pressure of 12 atmospheres (176 lb. per sq. in.). The principal dimensions are:



Slip Joint on Receiver Pipe of Russian Mallet Locomotives

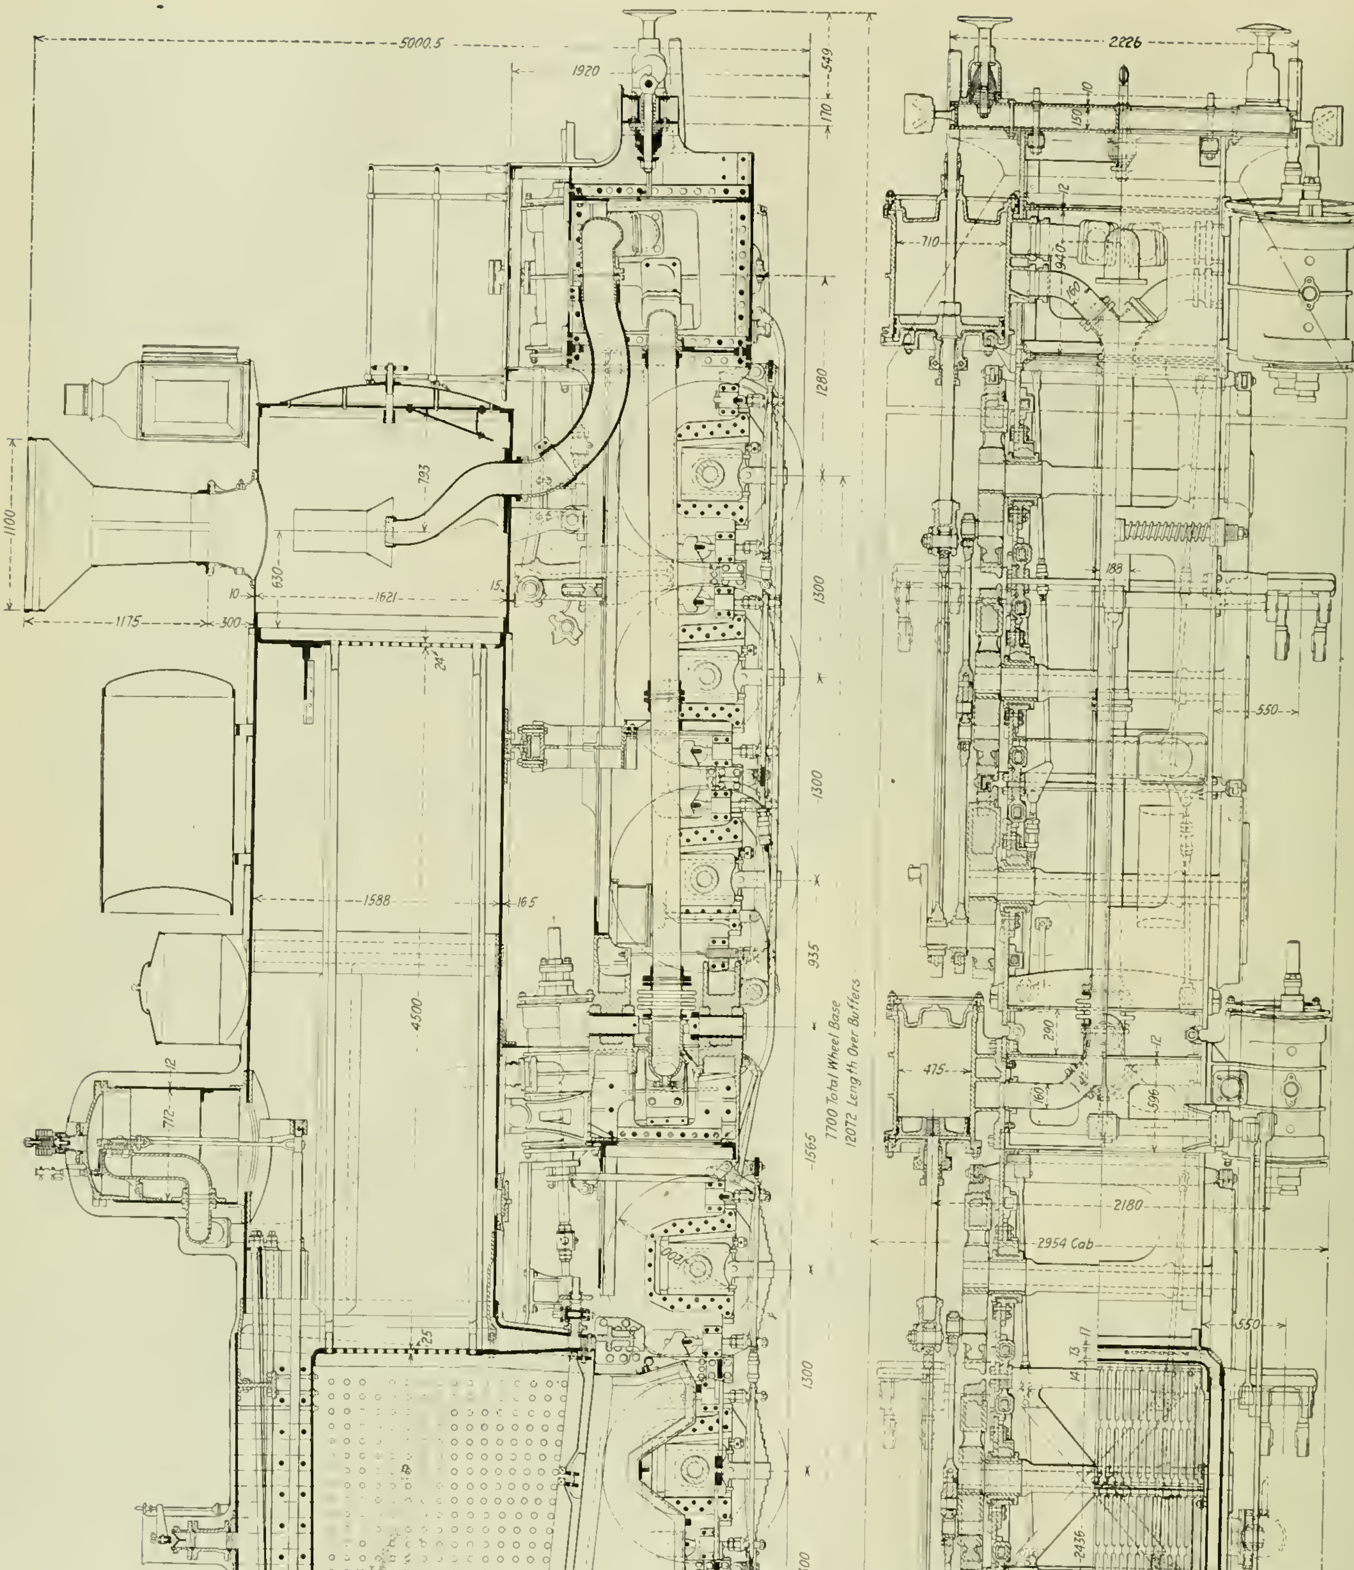
Weight on drivers	46.5 tons
Total weight, engine and tender, loaded	124 tons
Diameter of drivers	1,700 m.m. (67.0 in.)
Length, engine and tender, overall	19,689 m.m. (64 ft. 8 in. app.)

An engine crew consists of three, an engineer, assistant engineer and fireman. Many women now work as firemen, there is such a scarcity of able-bodied men. The engineers as a rule are bright, capable fellows, highly trained in their occupation. It is a rule that all engineers running a locomotive, must first serve an apprenticeship in the shops so they are thus taught the repairing and upkeep of locomotives. Afterwards they graduate as firemen, assistant engineers, then first engineers, an examination being necessary before being promoted to a higher grade. The statistics often given that 60 per cent of the Russian working people are illiterate certainly does not apply to the railroad workers.

A train crew usually consists of about five men, a chief

---

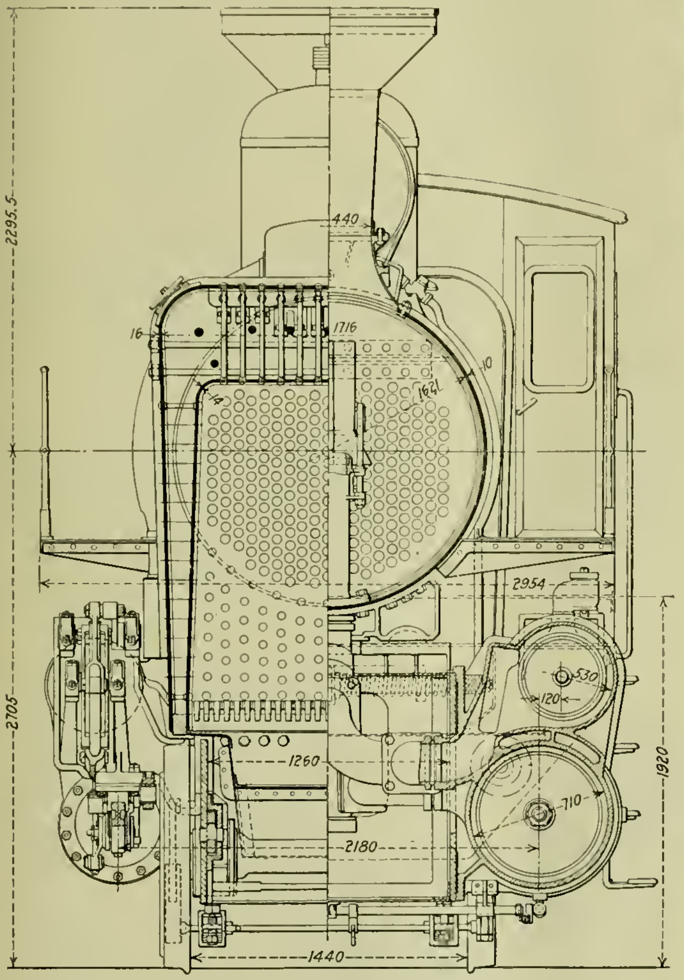
*Issue of October, 1917, page 545.



Elevation and Plan of Russian O-6-6-0 Mallet Freight Locomotive. (All Dimensions In Millimeteres.)

conductor and four assistants. This number, however, varies according to the tonnage of the train. There are no air brakes on the freight cars, hence about every tenth car is required to be a brake car, and is manned by one of the assistant conductors. The tonnage of the usual train is 60,000 poods, or about 1,000 tons. On certain sections of the road helper engines are necessary, but the grades as a rule are very slight. Riding these open brake cars in winter is a strenuous occupation. Quite frequently the thermometer goes down to 60 degrees below zero and stays there for months. The road furnishes brakemen with big fur lined coats and high felt boots, which are very necessary for the Siberian winters.

The rolling stock is the usual type of equipment seen in Russia. Passenger coaches are divided into first, second, third and fourth classes. Passenger coaches are much run down on account of lack of attention, the provodnecks or porters being lazy and discipline lacking. Coaches are all built with coupes to accommodate two or four people, and a corridor runs along one side.

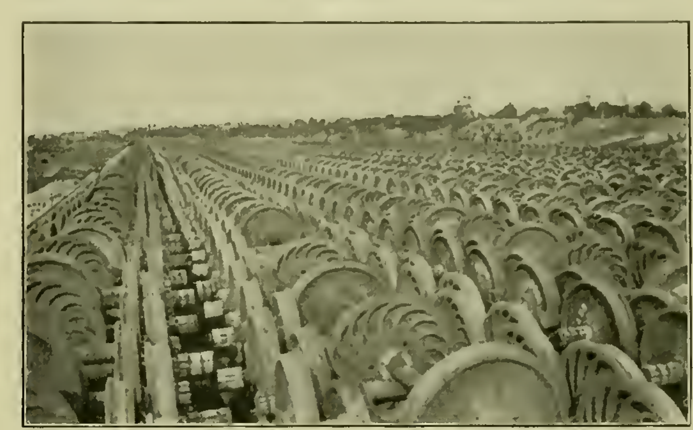


Cross Section of Mallet Freight Locomotive, Tomsk Railway

The freight equipment consists mostly of tepluskas or four wheeled box cars, with a capacity of 1,000 poods or 16 tons, all with turnbuckle couplers. However, many of the American 3,000 pood or 50 ton gondolas are now in operation on this road, and it is doubtless only a question of a few years when the small cars will be superseded by those of larger capacity.

Fuel is obtained from two different sources located near each end of the road. Large coal mines are operated at Cheromkovo, shown on the map about 100 versts west of Irkutsk and near Tiaga, about 200 versts east of Novo-Nickoliavsk. A good grade of lignite coal is obtained, and there is a plentiful supply at different points along the road, although only these two sources are worked by the railway. It was at Cheromkovo that the Social Revolutionary party sprung up in December, 1919, which overthrew the Kolchak regime in Siberia.

The main office of the road is located at Tomsk, on a branch of the railroad. It seems a peculiar place for the office and the advisability of moving it to Krasnoyarsk on the main line has often been mooted. During the Bolsheviks' short tenure in 1918, the moving of the main office was one of the things contemplated. The office is located in two or three different buildings, with a multiplicity of employees, something over 2,000. The Russians have a splendid system of records, and to keep up this system requires countless help. They are highly technical in everything, the officials of the roads being graduates of some of the best European technical colleges. There are very few important railway positions in Russia held by anyone except graduates of some technical college.



American Car Wheels Stored at Osgulnaya, 40 Miles from Vladivostok

Tomsk is the seat of learning of Siberia, and is the location of the famous Tomsk University. It is the ambition of all the better class Russians to graduate through this school. The university has a fine mechanical institute and many engineers graduate there. The city is one of the prettiest in Siberia, being built on the banks of one of the tributaries of the Obi river, which is navigable to the Arctic Ocean.

Snow Plough Commonly Used on Russian Railroads

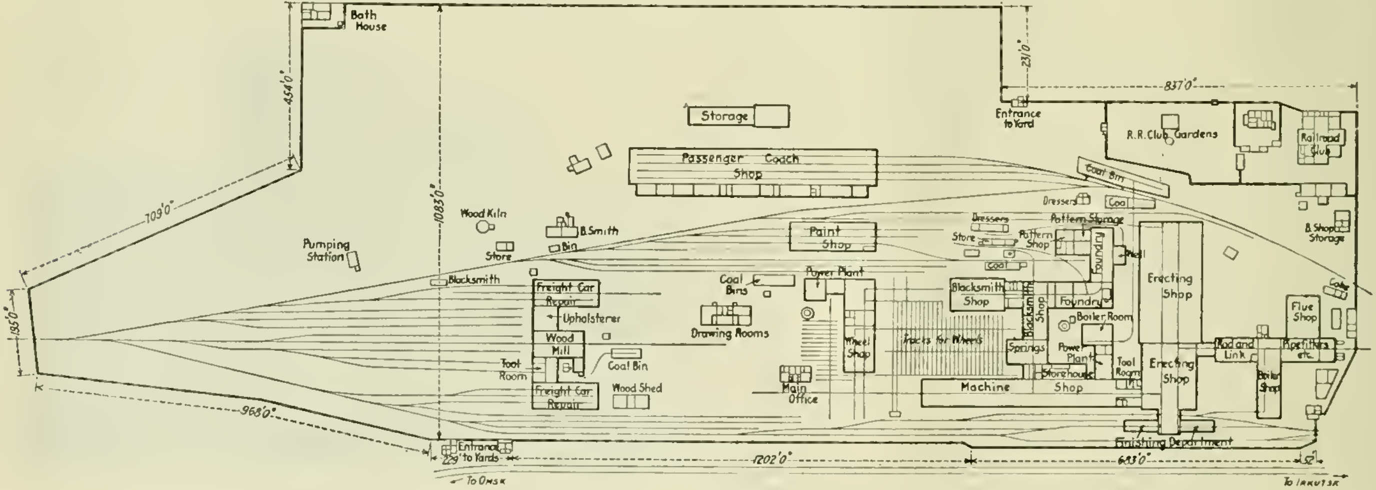
The Krasnoyarsk Shops

The main shops of the road are located at Krasnoyarsk and are undoubtedly the largest repair shops in Siberia. Krasnoyarsk is an important commercial city with a population of about 100,000 and is built directly on the banks of the great Yenisee river. This immense river, from its source in Mongolia, winds its way north to the Arctic Ocean. The railway bridge across the river at this point is a magnificent structure, 400 sagenes or 2,800 ft. long, built in six spans. The river is navigable by steamboat to the ocean, but only for a few months in the year.

The shops have always been recognized as among the most progressive and efficient in all Russia. During the past years of revolution this plant has been the scene of much turmoil, and one really wonders how it has performed its functions so well. In 1918 the whole roof of the erecting shop was burned, supposedly by the Bolsheviki. Practically deprived of all sources of supply for the past five years, the shops have managed to keep the condition of the power about normal, and when the writer was there in 1919 their statistics showed that engines on the Tomsk railway were really up to their normal standard of peace times. The only engines clogging up the shop were those from European Russia evacuated by the Kolchak government in their retreat before the Bolsheviki.

The superintendent of shops (if he has not been removed by the Bolsheviki) is a clever Russian engineer, Mr. Korkin. A superintendent's position is no sinecure in a large plant in Russia, grievances being in front of him practically all the time. The employees have always had so many special privileges granted them by the government railways that a superintendent must be endowed with exceptional administrative abilities.

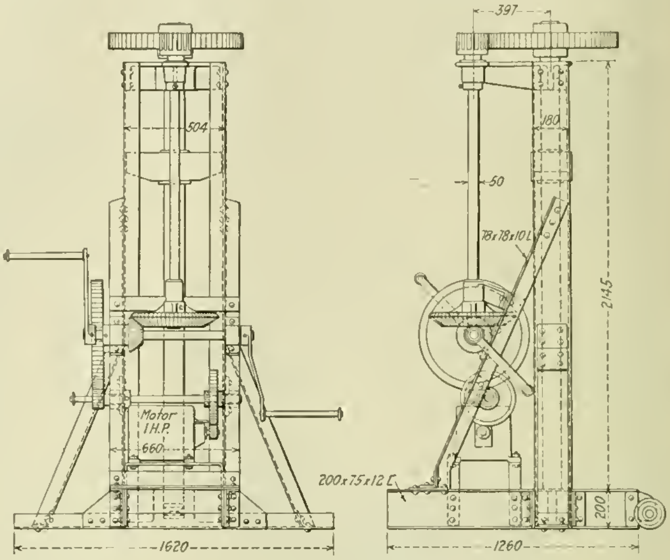
The drawing will give some idea of the extent of this plant. The erecting shop is a substantial brick building 464 ft. long and 154 ft. wide, with a high roof. An electrically driven transfer table runs up and down the center of the shop. There are 44 locomotive pits, 22 on each side of the transfer table. Tenders are also repaired in the erecting shop. Locomotives are raised by ingenious electric hoists, which are portable and can be moved to any pit. Four of these hoists are usually required to raise a locomotive, two at each end with structural iron beams across the pit. One of the drawings shows the general design of these hoists. They are operated by a one horse power direct current motor geared at a ratio of about 20 to 1. All main terminals on the road are also furnished with these hoists, which make heavy repairs considerably easier. A locomotive can be raised high enough to take out wheels in about ten minutes. The shop is served by four 5-ton overhead electric bridge cranes, which are quite suitable for all requirements. At one end of the shop is a building known as the finishing shop, to accommodate two engines. When an engine nears completion it is taken to this shop, fired up and tested before going on its trial trip.



Arrangement of Tracks and Buildings at Krasnoyarsk Shops

All necessary departments are accessible from the erecting shop without going out of doors, a great advantage in the extremely cold winter weather.

The machine shop, which is located directly off the erecting shop, consists of a long narrow building 528 ft. long and 63 ft. wide. There are a great number of machines in this building, and it is very crowded, but work is taken away as soon as finished, thus relieving matters. The machines are mostly of Russian or German make; there are very few American tools in this part of the world. Two new bolt cutters arrived at the plant in December, 1919, and these were the only American machines. The machines are arranged in groups and driven by electric motors. Since the war the shops have had to make all their small tools, such as taps, dies, reamers and drills, and this work keeps many machines busy. Tool steel was also at a premium, and in 1918 and 1919 this shop was forced to use tire steel as a substitute, in order to keep the wheels turning. Crossheads had to be forged here, as no steel castings were available. This was a costly operation, something over 80 hours' machine work being necessary on these forgings.



Locomotive Hoist Used on the Tomsk Railway, Operated by Hand or by Motor

The blacksmith shop is located in two buildings joined to the machine shop. Both are well equipped with steam hammers, but are in great need of forging machines. They have been forced to make nuts, bolts and rivets, which in pre-war days were bought from the factories, and there is no special machinery for this work.

The foundry, which extends out from the blacksmith shop, consists of two main buildings, one building for small work and one for large work served by a 5-ton overhead electric traveling crane. All the cylinders are cast here and all stock supplies for the road. There is also a brass foundry in connection. The pattern shop is an integral part of the foundry.

East of the erecting shop is located the rod and link department. There is a very fine type of link grinder in this department, a German invention. Rods are very thoroughly and systematically overhauled, although much unnecessary filing and polishing is performed.

The main boiler shop is a building 200 ft. long by 56 ft. wide. It is served by a 30-ton overhead electric bridge crane, which is sufficient for lifting any of the boilers. As the building has a high roof, one boiler can easily be lifted over another. They are equipped with the usual boiler shop machinery, including bending rolls, two radial drills, two lathes and double-ended punch and shears. The main deficiency is lack of air equipment, so that much of the work must be done by hand. The stay bolt drilling is efficiently taken care of by portable electric drills, and these machines can be used in almost any place around the boiler. During the stay of the American engineers, the plant was laid out for air equipment, but the compressor and tools did not arrive before the occupation by the Bolsheviki. There is a great future for air tools in Russia.

The first thing that strikes an American on entering a boiler shop in Russia is the great amount of copper used. All Russian built engines are equipped with copper fire boxes, flue sheets and stay bolts. This entails great expense, but there certainly is very little boiler trouble on the road, leaky flues being quite a rarity. However, very good water is available over nearly the whole Trans-Siberian system.

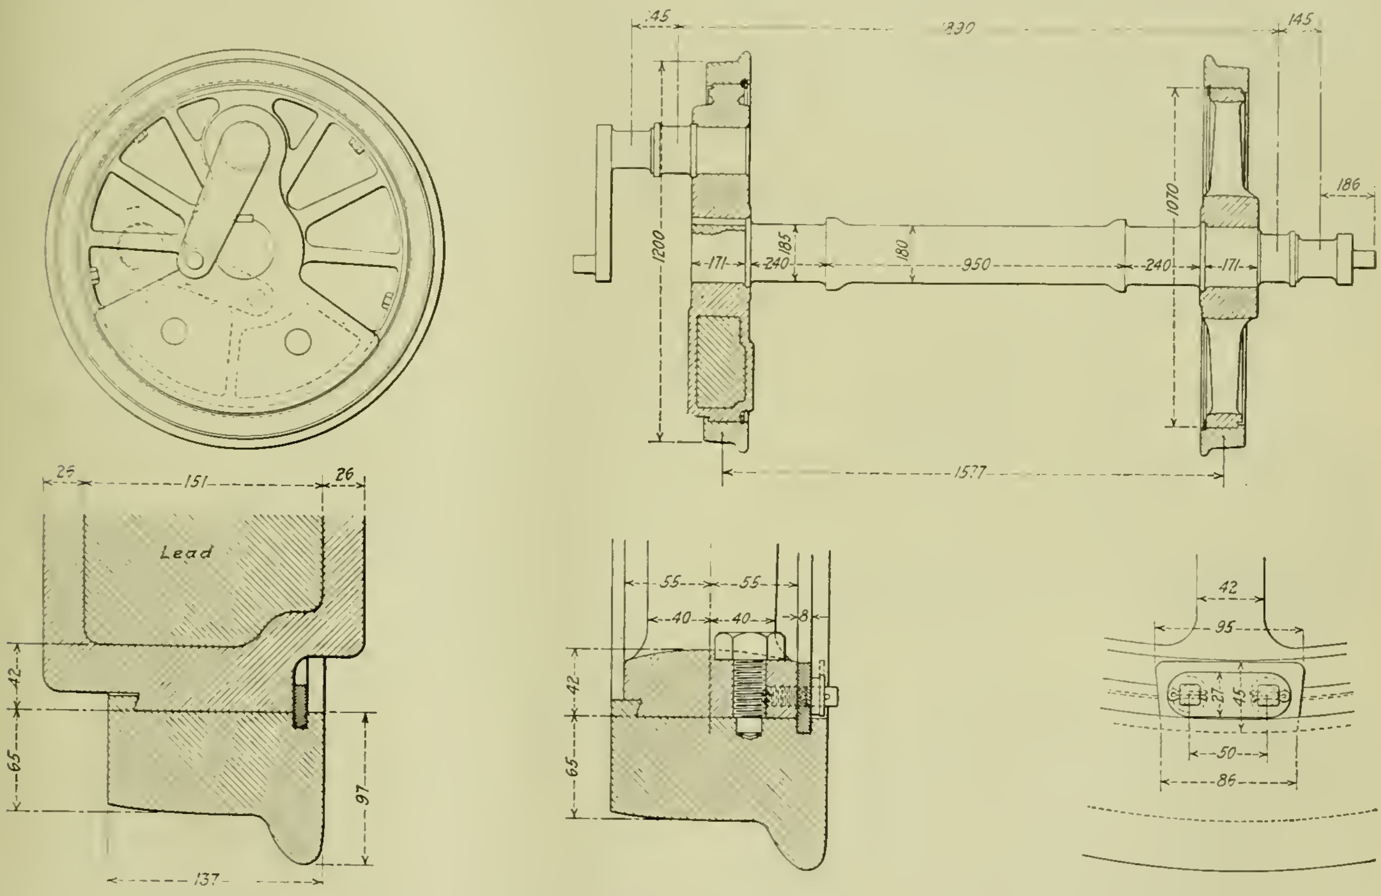
The flue shop adjoins the boiler shop. The tubes are well taken care of, the tips being welded by power driven rollers, and the flues cut off by a friction saw. The flue rattler is a motor driven cylindrical cast iron drum, similar to many of our older types.

The wheel shop is a neatly arranged building, served with overhead electric traveling cranes. The wheel lathes, which are all Russian built, are strong, powerful machines, equipped with two back and two front compound slide rests. They have been badly handicapped, however, for the past few years for lack of tool steel. The shop has a fine type of quartering machine, specially designed for main pins on Russian locomotives. On the Siberian roads crank arms are all forged solid with the pin, so it is a difficult matter to machine these pins without special tools.

Tires are changed by up-ending the wheel centers, using coal burners for heating. Oil is too precious a thing at this time in Siberia, hence the shops are forced to use coal. Oil was formerly obtained from the south of Russia, but since the revolution this source has been shut off and oil for the road is now obtained through Japanese firms.

The paint shop is a building capable of holding about 20 passenger coaches.

The main car shop is a large building, 606 ft. long by 85 ft. wide, with four tracks running the full length of the building. This gives ample space, so that it is seldom necessary for men to work outside in severe weather. An annex runs along the whole length of this building, in which are located the different departments necessary for coach work. There is a very modern nickel plating room in this building, which takes care of all utensils for dining cars, coach trimmings and other articles.



Russian Design of Driving Wheels, With One-Piece Pin and Return Crank and Tire Retaining Devices

Two other car shops, each 161 ft. by 63 ft., serve for repairing freight cars. The planing mill is located between these two shops and is equipped with an average amount of wood working machinery.

The shops have their own power plant, which contains two d. c. generators for power and one a. c. machine for lighting. The boiler room is a poor lay out, having a mixture of locomotive type boilers and return tubular boilers. All coal and ashes are handled by hand labor, no mechanical devices being installed. There is another auxiliary plant with six return tubular boilers, used only in winter for heating. All buildings are well heated by large steam radiators.

The general stores are located close to the shops and consist mostly of brick buildings. The stock at the time the American forces were there was much depleted. Before the war there was a standing order that a three years' supply of everything must always be kept on hand, and this foresight was about all that kept them able to run during the days of chaos. During the year 1919 the Allied Technical Board helped them greatly to obtain stock through Vladivostok. In normal times all steel, copper and metal goods came from the Ural mountains, while other supplies came from the interior of Russia. The stores department has a good system of keeping records of stock on hand at all times, but employs lots of help to do this.

Engines are repaired according to a well tabulated schedule, and when a locomotive makes the stipulated verstage, it is tied up and the work done as specified in the railroad's book of rules and repair laws.

In the following table is shown the assigned mileage for shopping engines:

FREIGHT LOCOMOTIVES

30,000 versts	Change of wheels
60,000 versts	Second change of wheels
90,000 versts	Medium repairs
120,000 versts	Third change of wheels
150,000 versts	Fourth change of wheels
180,000 versts	Capital repairs

PASSENGER LOCOMOTIVES

40,000 versts	Change of wheels
80,000 versts	Second change of wheels
120,000 versts	Medium repairs
160,000 versts	Third change of wheels
200,000 versts	Fourth change of wheels
240,000 versts	Capital repairs

The main shops do only the capital or general repairs, and what is known as accidental repairs. Changing of wheels and medium repairs are taken care of at the small shops located at each main terminal. Changing of wheels means the replacement of wheels with worn tires for another set and necessary repairs to driving boxes, machinery and so forth. Each terminal has always on hand a few spare sets of driving wheels and the worn ones are all shipped to Krasnoyarsk shops, where all wheel and axle work is taken care of. The law requires in Russia that all tires must have retaining rings, hence wheel and tire work is quite a large operation. The details of the tire fastenings are shown in the drawing of the wheels and axles.

Some details from the report of work at Krasnoyarsk shops for the years 1916-17-18 and '19 will prove interesting. In 1918 the plant was under Bolshevik control, and a glance at the figures shows that year as the lowest output of the four years, with the greatest number of employees. For example, during January, 1916, there were 1,389 mechanics and laborers employed and the output was equivalent to 7.92 general repairs of four-axle locomotives. In June, 1918, the force had been increased to 2,865, but the output on the same basis was only 1.13 general repairs. The cost of general repairs to locomotives increased 808 per cent from 1916 to 1918. Probably conditions may now be different, as it is a well known fact that the workers became intoxicated with their liberty during the early period of the Bolshevik regime in 1918.

One cannot but admire the quality of workmanship that is put on all repairs. Everything is put together to the closest possible working margin, the matter of expense not being considered. To the mind of the American engineer, too much time is wasted in ornamentation and elaboration; much unnecessary machine and finished work is put on equipment, when the rough article could just as well serve the purpose.

When an engine leaves the shops it must be able to go on the train, make the time, and pull full tonnage on the first trip, or is not accepted by the operating department. This usually necessitates quite a few trial trips before finally leaving the shops, and it is no unusual thing to see the engine raised off the wheels, boxes taken out and refitted between these trips. Diagrams and tests are also made by the mechanical engineers, to be sure that the engine can give the maximum efficiency. The locomotive must be passed as O. K. by trial and inspection before being finally turned over for service.

Taking past conditions into consideration, it is remarkable how well the motive power and rolling stock have been kept up. The next few years will undoubtedly show great changes. The 1,000 pood (16 ton) box cars will likely be replaced by the larger type of American box cars and gondolas. At Vladivostok, American cars were being assembled just as fast as the plant at First river could turn them out, and these cars were getting to be quite numerous on the Trans-Siberian.

Undoubtedly a heavier type of locomotive will also be built in the near future. The roadbed is excellent and bridges are all built with a high enough factor of safety to carry any weight of locomotive we have in America today. The wide gage of five feet is also a good argument in favor of heavier equipment.

There is great opportunity for American ideas and industry in Siberia; now that the embargo has been lifted, let us hope that soon satisfactory trade relations can be established between both countries. The Russian people have a warm feeling for the Americans and have a great craving for American goods.

The writer had 27 months' experience on the Siberian railways and during that period has met many of the leading mechanical engineers on the various systems there. They are all courteous, intelligent and highly trained men. Most of these officials talk either French or German, but it is a rarity to find one who speaks English. If we are to become connected with them commercially, we must study their language. At first it is quite difficult, there is so much difference in the alphabet, but it is absolutely phonetic and can be learned by diligent study. The Russian people have been the victims of circumstances for some years now, but we trust their dark days are nearly over, and that they may soon emerge from their chaotic condition. The rest of the world needs a real Russia; and it is to be hoped that they may not be disappointed.

ACCIDENT BULLETIN 74.—The Interstate Commerce Commission has issued Accident Bulletin No. 74 containing the record of collisions, derailments and other accidents on the railroads of the United States for the last quarter of 1919 and also the tabular statements for the twelve months ending with December. Remarkable decreases are shown in many items, as compared with 1918. In the twelve months of the year now reported, 110 passengers, 366 employees and 41 other persons were killed in train accidents, and 4,549 passengers, 3,202 employees and 124 other persons were injured; as compared with a record in the preceding year of 286 passengers, 554 employees and 156 other persons killed and 4,655 passengers, 4,250 employees and 500 other persons injured.

The Locomotive Terminal an Operating Factor*

Best Use of Terminal Facilities Dependent on Organization, Supervision and Good Management

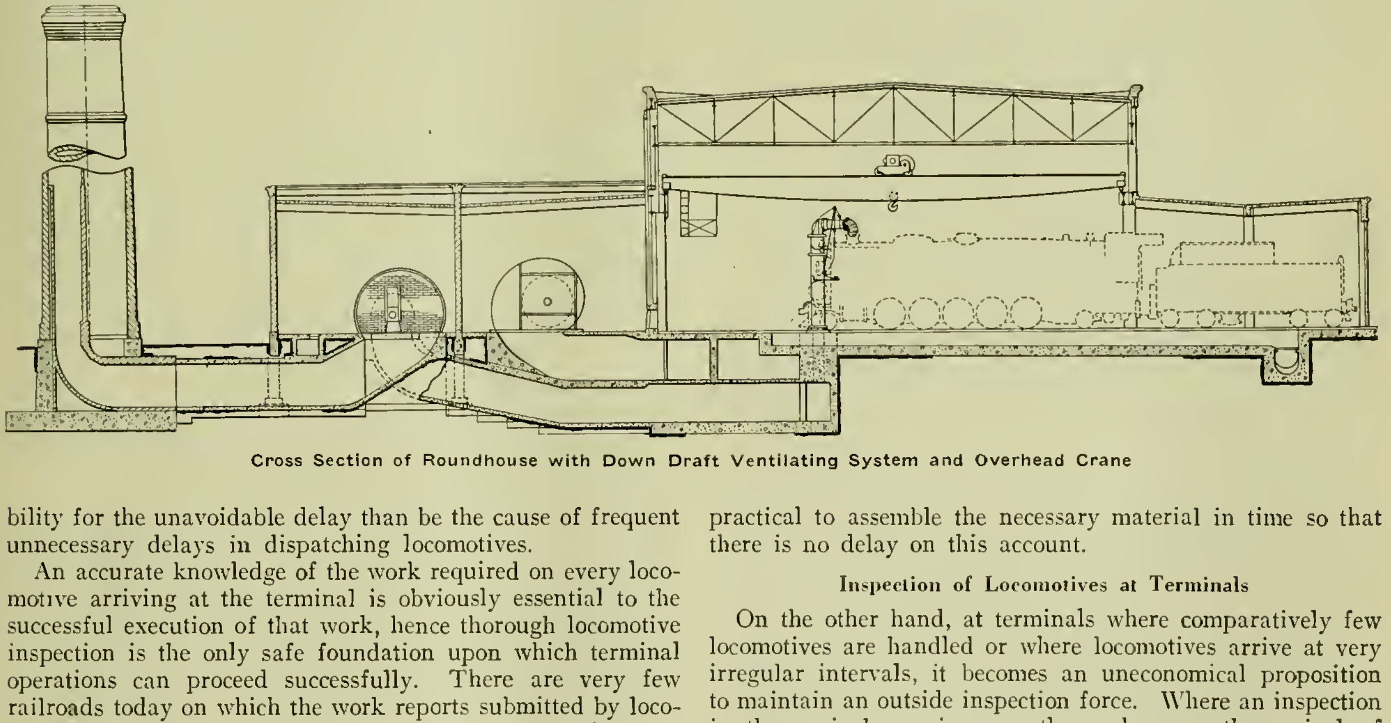
BY L. G. PLANT

Associate Editor of the Railway Mechanical Engineer

WHILE it would be as impossible to prescribe any fixed mode of terminal operation as to describe equipment that would be universally applicable, there are certain operations in the terminal that are fundamental. Moreover, all terminal operations should proceed with as great regularity and as much expedition as possible.

Operation of Locomotive Terminals

Terminal operations constitute an unwritten page on every time table and should be conducted accordingly. The habit of waiting until repairs are actually completed before advising the transportation department that the locomotive is available for service cannot be too strongly condemned. The time at which a locomotive will be available for service should be anticipated as far as possible and the transportation department notified accordingly. It is better to assume responsibility for the unavoidable delay than be the cause of frequent unnecessary delays in dispatching locomotives.



Cross Section of Roundhouse with Down Draft Ventilating System and Overhead Crane

An accurate knowledge of the work required on every locomotive arriving at the terminal is obviously essential to the successful execution of that work, hence thorough locomotive inspection is the only safe foundation upon which terminal operations can proceed successfully. There are very few railroads today on which the work reports submitted by locomotive engineers can be depended upon as a reliable index to the work to be done. Enginemen cannot be relieved of the responsibility for a locomotive condition report and something might be said in favor of educating the engineers to submit a more intelligent report but as matters stand the most careful inspection of arriving locomotives must be made.

More might be said in favor of educating air brake and other inspectors responsible for inspecting locomotives upon arrival at the terminal. Frequent changes in the personnel of the inspection force and appointment on the basis of seniority are bound to result in a certain amount of incompetence in the inspection of locomotives. The railroads will surely be held responsible in the event of accidents resulting from incompetent inspection and if they cannot always pick trained men for this work, should see that instruction of some sort is available to these men. The air brake instruction car should not only be available to every air brake inspector, but these men should be subject to certain examinations that will serve to establish their competence.

Inspection may either be conducted immediately upon arrival or as soon as the locomotive is placed in the house. Where locomotives are arriving at frequent evenly spaced intervals throughout the day, the system of outside inspection in covered pits has very great advantages. The delay over the inspection pit should not average in excess of 15 minutes and a statement of the work required of each gang foreman may be available before the locomotive has actually been placed in the house. Moreover, an advance report in regard to the condition of the locomotive frequently makes it more practical to assemble the necessary material in time so that there is no delay on this account.

Inspection of Locomotives at Terminals

On the other hand, at terminals where comparatively few locomotives are handled or where locomotives arrive at very irregular intervals, it becomes an uneconomical proposition to maintain an outside inspection force. Where an inspection in the enginehouse is promptly made upon the arrival of every locomotive there can be no serious objection to this method. In fact, there is frequently a great advantage to conducting inspection in the enginehouse since it is frequently practical and economical to have inspectors make repairs on certain classes of defects. Locomotive inspection should be subdivided as far as possible. Excellent results are often obtained from assigning one inspector to certain defects that have been causing serious trouble. For instance, it is the practice on one railroad that has made a conspicuous success of Mallet locomotive operation, to assign one mechanic and assistants at each terminal during the winter months to inspect and repair steam leaks exclusively.

One of the most remarkable examples of intensive terminal operation in this country is accomplished by departing boldly from the conventional routine. Approximately 170

---

*From a paper presented before the New England Railroad Club on November 9, 1920. An abstract of the first part of this paper was published in the December issue of the *Railway Mechanical Engineer.*

locomotives are handled through this terminal each day and as each of these locomotives arrives it is first subjected to the most thorough inspection. There are three parallel inspection pits under the direction of a foreman inspector. The number of men and the facilities at this inspection point are such that many light repairs can be executed during the time that the inspection is being completed. Upon the basis of the reports made by each of the principal inspectors, the foreman decides whether the character of repairs necessitates placing the locomotive in the enginehouse. Where the repairs are not of a heavy nature and do not require the services of a drop pit or crane the locomotive after passing over the ash pit is routed directly to a longitudinal repair shed. This shed covers two parallel track pits approximately 400 ft. in length. The building is of concrete and steel sash construction and the illumination, both overhead and in the pits, is very complete. The work at this repair shed is under the direction of an assistant roundhouse foreman and the number of mechanics employed is equal to any emergency. Moreover, the stores department have erected special facilities to provide for the material requirements at this point. While the work in this light running repair shed is conducted with the same degree of system and thoroughness as should characterize roundhouse work, it will readily be appreciated that these repairs can be executed far more expeditiously under the circumstances than were it necessary to place each locomotive in the enginehouse. In fact, it would be practically out of the question to handle 170 locomotives in and out of a 30 stall roundhouse each day and the general plan adopted at this point is one that might well be put into effect at other points where fewer locomotives are handled.

Locomotive Terminal Organization

Any consideration of the locomotive terminal as an operating factor must take into account the organization of the terminal. This is just as essential in the make-up of the terminal as the physical equipment. In fact the usefulness of this equipment depends wholly upon the extent to which its potential possibilities are developed. The most elaborate terminal equipment will be of little value to the railroad if we do not have men who know how these facilities can be used to the best advantage and who are on the ground to see that the equipment is so used. Nowhere on the railroad will the lack of organization show up more quickly than at the locomotive terminal.

Supervision is an essential element in organization; we must not only have men who can execute repairs promptly and handle locomotives expeditiously but we must have men whose duty it is to see that these things are done. In this connection we must clearly differentiate between mere system and organization. What I wish to infer is that organization in this case is more than a question of the number of supervisory officers, their titles or relative positions. It is entirely possible to have too many supervisors as well as too few, to reach a point where the organization becomes top heavy and each man becomes a cog in the wheel rather than an individual unit. It is particularly essential in terminal operation that individual initiative be fostered and that each foreman's authority and responsibility be as broad as possible.

The roundhouse foreman's position is not an office job and unless he is a live wire who is on the job every minute of the day and has the entire situation constantly at his finger tips, we cannot expect 100 per cent service no matter how elaborate the equipment. In this fact lies the only explanation I can offer for the phenomenon which we have all witnessed wherein the results obtained in a poorly equipped enginehouse with some boomer foreman are found to surpass the performance of a far better equipped terminal operating under the direction of a far more elaborate complement of supervisors.

The problem of getting and holding the type of men most needed for terminal operation is a serious one. When the railroad is fortunate in finding such men it must deal wisely and liberally with them. The proper course would be to develop material from within the ranks and it is not improbable that within a short time the railroads will see the wisdom of establishing central schools in which prospective foremen can be taught the rudiments of foremanship and be carefully examined in regard to all the details with which they should be familiar.

Locomotive Terminal Management

The problem of terminal management is very closely identified with that of organization because the strength of the organization depends greatly upon the character of the management. Constructive management can often develop excellent foremen out of the most unpromising material. On the other hand poor management which may be characterized by the lack of any broad fixed policy with respect to terminal operation or organization or failure to set any standard of achievement to which terminal forces may aspire, may deprive the railroad of some of its best talent.

It should be the policy of every railroad to establish a positive standard for every terminal and it is the duty of the mechanical officers who are responsible for terminal performance to see that these standards are lived up to. There are very few men who will not do better work and more work when it is known that this work will be subject to the most detailed scrutiny by superior officers. No matter how competent the foreman, the operation of any terminal can be improved by keeping a close check upon its performance. It is in this connection that the full value of statistical control must be appreciated. While there are no statistics which can be relied upon to take the place of a first hand knowledge relating to the condition of motive power from a maintenance standpoint, there is no question but that the operation of the average terminal can be accelerated by means of a daily operating report, without in any way impairing maintenance. In many instances a close check on the performance of the terminal has resulted in speeding up the movement of locomotives across the ash pit which is a clear gain so far as it concerns the time available for necessary maintenance.

The Value of Terminal Statistics

The efficacy of various reports dealing with the movements of locomotives at the terminals as a practical means for improving terminal operation has been questioned. Mechanical department officers who are critically inclined should bear in mind that the results of such reports not only indicate enginehouse detention but all terminal delays including those that are wholly chargeable to the transportation department It cannot be denied, moreover, that statistics of this character have served to focus attention on terminal movements and bring about improvements that might otherwise have been overlooked. Records relating to terminal movements have become very useful to progressive mechanical officers in demonstrating the relative efficiency of various features of terminal equipment. They have made it possible for a mechanical superintendent to estimate with reasonable accuracy the return that can be expected from an investment in a new ash pit or a boiler washing outfit. Statistics have served to demonstrate the extent to which use is made of the facilities available. With the assurance that existing facilities are being utilized to the utmost limit, executives have been encouraged to spend money towards improving these facilities.

There is undoubtedly a growing appreciation of the fact that the locomotive terminal is in reality an operating factor, that a block in the terminal may mean a block on the main line and that co-operation between the mechanical and operating departments must be the keynote to terminal management. Mechanical officials must realize that in their connection with the movement of locomotives through the terminal they are operating men in every sense of the word. Also operating officials should appreciate the fact that the locomotive terminal is not purely a mechanical facility identified with locomotive maintenance but a very important link in their main line.

Terminal Development Policies

In conclusion something should be said in regard to the policies that should be adopted toward locomotive terminal development. Being firmly convinced of the importance of the locomotive terminal as an operating as well as a maintenance factor on the railroads, it would appear to be the duty of every mechanical officer responsible for the performance of locomotive power to urge upon his superior officers the necessity for adequate terminal development.

It should be the policy of the railroads to maintain a proper relationship between locomotive and locomotive terminal development based on the safe assumption that the full value of a modern locomotive can never be realized in an antiquated terminal. One railroad might be cited as having made a conspicuous success of Mallet locomotive operation over long operating divisions because their terminal facilities were equal to the burden and because their terminal organization was trained to the task. On another railroad the absolute failure of well-designed Mallet locomotives can be ascribed largely to inadequate terminal facilities and lack of terminal organization.

If the problem were always as plainly understood it would not be so difficult to develop a proper policy. As it is, terminal development calls for foresight and the most discriminating judgment. Every expenditure for terminal improvement should conform to a broad comprehensive plan embracing ultimate terminal development so far as this can be forecast. The erection of an expensive concrete coaling station at some point where other facilities are inadequate and where terminal development along other lines must always be limited illustrates a pitiful lack of foresight. While the locomotive terminal cannot be regarded as a suitable dumping place for worn out machine tools from larger shops, there can be little excuse for going to the other extreme and buying a wheel lathe for terminal use that will turn a pair of tires in 45 minutes when the maximum requirement at that terminal will seldom exceed one set of tires per week. Undoubtedly many projects for locomotive terminal development are discredited by just such lack of foresight or failure on the part of mechanical officers to comprehend the purely business viewpoint that in the last analysis must dictate every good move in the conduct of our railroads.

Looking into the future, it is reasonable to predict that terminal development will undergo greater relative development than any other phase of transportation. It is of the utmost importance to mechanical officers that they not only have the foresight to realize the extent to which terminal equipment must be rehabilitated and the organization strengthened but the courage to command a program that will make the locomotive terminal a successful operating factor.

Boards of Adjustment to Be Abolished

John Barton Payne, director general of railroads, has issued a circular announcing the abolition of the boards of adjustment created by the Railroad Administration as follows:

"A committee representing the Association of Railroad Executives has brought to my attention the fact that General Orders 13, 29 and 53 provide in terms that,

> 'Personal grievances and controversies arising under interpretation of wage agreements and all other disputes arising between officials of a railroad and its employees covered by this understanding will be handled in their usual manner by joint committees of the employees up to and including the chief operating officer of the railroad (or some one officially designated by him). If an agreement is not reached, the chairman of the joint committee of employees refers the matter to the chief executive officer of the organization concerned. If the contention of the employees' committee is approved by such executive officer, then the chief operating officer of the railroad and the chief executive officer of the organization concerned shall refer the matter with all supporting papers to the director of the Division of Labor of the U. S. Railroad Administration, who will in turn present the case to the Railway Board of Adjustment, which board would promptly hear and decide the case, giving due notice to the chief operating officer of the railroad interested and to the chief executive officer of the organization concerned of the time set for the hearing.'

"That after the order of May 29, 1920, and amendment under which the time limit of July 15 was fixed within which claims growing out of the subject matter of said orders should be presented the claimants, without complying with the procedure specified in said general orders, presented their claims direct to the office of the director general and, in view of this fact, none of the said claims are now properly before said adjustment boards.

"I have given careful consideration to each contention and am advised that if said contention is sustained, practically all of the cases now pending before Boards of Adjustment 1, 2 and 3 will fall and must fail of consideration.

"The point made by the representatives of the executives appears to me to be sound and there is nothing contained in the limitation order of May 29, 1920, changing the mode of procedure. But as I look upon the matter the railroads as such are not concerned in the pending claims, if the claims are limited, as in my judgment they must be limited, to the period of federal control. That is, it is for the director general to determine and to pass upon claims against the government by persons who were the employees of the government during the period of federal control and to provide for the payment of all just claims arising during federal control, just as he must pass upon and provide for the payment of all other claims arising from federal control.

"If, however, the decision of these claims is to affect the railroads after the end of federal control, then the railroads have the right to insist upon a strict compliance with the terms of the said general orders.

"I am further advised that Board No. 1 will be able to dispose of all leases pending before it by February 15, that the number of cases pending before Boards 2 and 3 are so large that many months must elapse before said Boards could dispose of them.

"My conclusion, therefore, is that as to cases pending before Boards 2 and 3 some other means must be found to deal justly by the claimants as to any money due them arising out of federal control.

"The application of all decisions hereafter made to be limited in their effect to money due claimants between January 1, 1918, and March 1, 1920.

"It is, therefore, ordered that Board No. 1 be abolished as of February 15, 1921; that Board No. 2 and Board No. 3 be abolished as of January 10, 1921; i. e., by 30 days' notice, as provided in said General Orders.

"Meantime, means will be provided to adequately, justly and promptly dispose of all claims which said boards may leave undisposed of."

The views of railroad officials and representatives of organized railroad employees are widely at variance as to the desirability of establishing national boards.

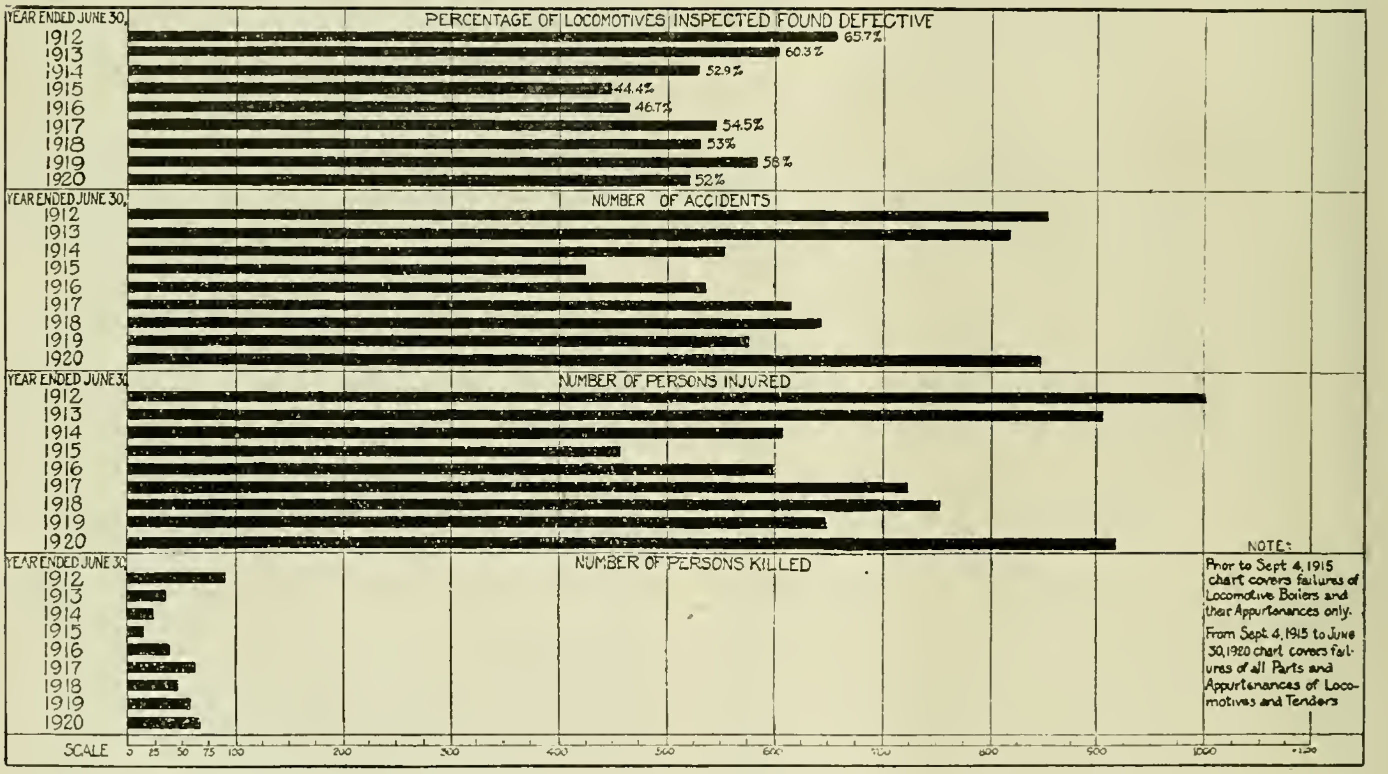
The directors of the Chamber of Commerce of the United States recently adopted a resolution opposing the creation of national boards of adjustment as not in the public interest. The preamble states that the public interest is involved in that no provision is made for public representation on the proposed boards. The resolution goes on to state that the establishment of the boards would tend to bring about a state of nationalization of the railroads, that they would lessen efficiency and impair the discipline necessary to successful operation of the railways. Furthermore, they would prevent open shop operation on the railroads and this would inevitably be extended to other industries.

Report of the Bureau of Locomotive Inspection

Application of Water Columns and Other Devices Advocated; Accidents Increase in Fiscal Year 1920

THE outstanding feature of the report of the chief inspector of locomotive boilers to the Interstate Commerce Commission for the fiscal year ending June 30, 1920, is the increase in the number of accidents and casualties resulting from failures of parts of locomotives and tenders. Although the percentage of locomotives inspected which were found defective decreased from 58 per cent in 1919 to 52 per cent in 1920, the number of accidents increased 49 per cent, the number killed 15 per cent and the number injured 41 per cent. A summary of the chief inspector's report is given below.

The succeeding tables and charts have been arranged so as to permit comparison with previous reports, as far as consistent, and show in concrete form the number of locomotives inspected, the number and percentage of those inspected found defective, and the number ordered out of service because of not meeting the requirements of the law, together with the total number of defects found. They also show the total number of accidents caused by failure from any cause of the locomotive or tender, including the boiler, and all parts and appurtenances thereof, reported by the carriers, or discovered by inspectors, together with the number of persons killed or injured due to such failure.



Graphic Summary of Results of Inspection and Accidents Due to Locomotive Failures, 1912-1920

LOCOMOTIVES INSPECTED, NUMBER FOUNO DEFECTIVE, PERCENTAGE INSPECTED FOUND DEFECTIVE, NUMBER ORDERED OUT OF SERVICE, AND TOTAL DEFECTS FOUND BY COMPARISON

	1920	1919	1918	1917
Number of locomotives inspected....	49,471	59,772	41,611	47,542
Number found defective............	25,529	34,557	22,196	25,909
Percentage found defective.........	52	58	53	54.5
Number ordered from service.......	3,774	4,433	2,125	3,294
Total defects found................	95,066	135,300	78,277	84,883

NUMBER OF ACCIDENTS, NUMBER KILLED, AND NUMBEB INJUBED, REPORTED, AND INVESTIGATED, COVERING FAILURES OF ALL PARTS AND APPURTENANCES OF THE ENTIRE LOCOMOTIVE AND TENDER BY COMPARISON

	1920	1919	1918	1917
Number of accidents................	843	565	641	616
Decrease from previous year.......	[1]49.2	[1]11.8	[1]4.1	....
Number killed	66	57	46	62
Decrease from previous year......	[1]15.8	[1]23.9	25.8	....
Number injured	916	647	756	721
Decrease from previous year.......	[1]41.6	14.4	[1]4.8	....

---

[1] Increase.

The following table shows the number of accidents, number of persons killed, and number injured, due to the failure of some part or appurtenance of the locomotive boiler only, which were reported by the carriers, with their percentage of decreases by comparison of the fiscal years ended June 30, 1912 and 1913, with the fiscal years ended June 30, 1919 and 1920:

	1920	1919	1913	1912
Number of accidents..............	439	341	820	856

NUMBER OF DERAILMENTS DUE TO DEFECTS IN OR FAILURE OF PARTS OF THE LOCOMOTIVE OR TENDER, REPORTED TO AND INVESTIGATED BY THIS BUREAU, AND NUMBER OF PERSONS KILLED AND INJURED AS A RESULT, BY COMPARISON

	1920	1919	1918	1917
Number of derailments[1]................	7	7	2	4
Number killed	7	6	..	1
Number injured........................	18	7	2	21

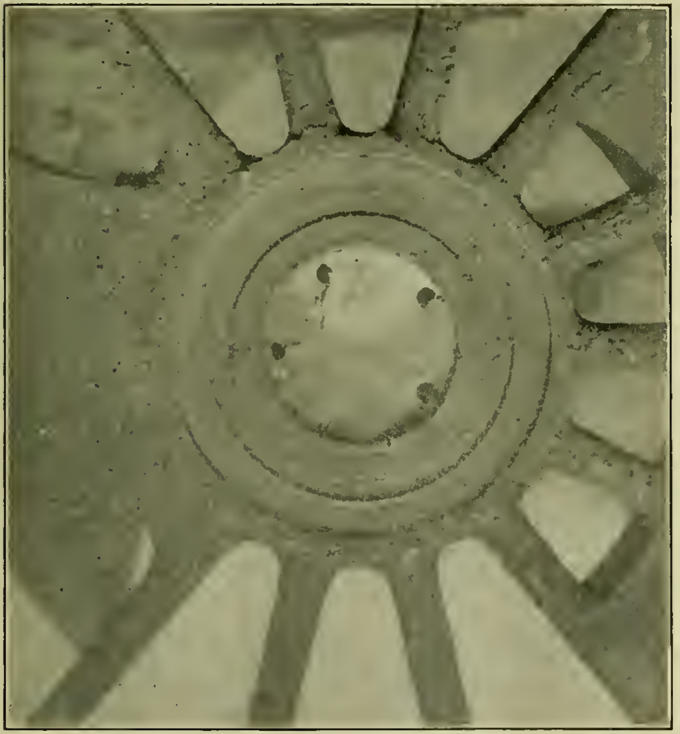
---

[1] Only derailments, reported as being caused by defects in or failure of parts of the locomotive or tender bave been investigated by tbis bureau.

The following table shows the total number of persons killed and injured by failure of locomotives or tenders, or some part or appurtenance thereof, during the four years ended June 30, 1917-1920, classified according to occupations.

	1920		1919		1918		1917	
	Killed	Injured	Killed	Injured	Killed	Injured	Killed	Injured
Members of the train crew:								
Engineers	16	272	14	194	11	245	16	230
Firemen	20	404	22	265	19	306	21	304
Brakemen	9	77	11	82	6	62	13	60
Conductors	2	19	2	16	..	21	3	14
Switchmen	4	19	1	7	2	..	..	8
Roundhouse and shop employees:								
Boiler makers	2	9	1	9	..	11	..	11
Machinists	1	20	..	5	..	11	..	8
Foremen	..	3	..	3	1	4	..	1
Inspectors	..	1	..	6	4	4	..	3
Watchmen	4	3	..	2	..	3	..	5
Boiler washers	..	13	..	7	1	4	..	7
Hostlers	..	13	..	6	..	8	..	6
Other roundhouse and shop employees	3	30	1	11	2	19	2	19
Other employees	4	26	3	23	..	26	5	22
Nonemployees	1	7	2	11	..	24	1	23
Total	66	916	57	647	45	756	62	721

A summary of all accidents and casualties occurring during the fiscal year ended June 30, 1920, as compared with the year ended June 30, 1919, covering the entire locomotive and tender and all of their parts and appurtenances, shows an increase of 49 per cent in the number of accidents, an increase of 16 per cent in the number killed, and an increase of 42 per cent in the number injured. This increase is due almost wholly to disregard for the requirements of the law and rules as well as to safety of construction and operation. This is especially true with what are sometimes considered unimportant parts; for instance, 26 per cent of the increase in accidents and injuries was due to failure of grate shakers; 10 per cent was due to failure of reversing gear; and 10 per cent to failure of squirt hose.



Failure of Driving Axle Caused by Fracture Starting at Bottom of Holes Drilled for Plugs Used in Attempt to Tighten Wheel Fit

A summary of all accidents and casualties caused by failure of the boiler and its appurtenances only, for the fiscal year ended June 30, 1912 (the first year of the existence of the law), as compared with the year ended June 30, 1920, shows a decrease of 47 per cent in the number of accidents, a decrease of 48 per cent in the number killed, and a decrease of 49 per cent in the number injured. These decreases are especially gratifying when considering the increased number of locomotives in service and the increased traffic being handled, together with the increased duties imposed on the inspectors by the amendment to the boiler-inspection law, which extended their duties to the entire locomotive and tender and the parts and appurtenances thereof, which has added greatly to their work. These decreases demonstrate the wisdom of complying with the requirements of the law and rules, and the wisdom and foresight of its advocates when requesting its enactment.

As shown by the table, derailments due to defects in or failure of parts of the locomotive or tender have been the direct cause of a number of most serious accidents and the loss of life and limb as well as damaged property and have forcibly demonstrated the necessity for proper inspection and repair of the running gear, driving gear, and brake rigging.

Corroded Main Air Reservoir Which Exploded, Causing the Death of One Person

During the year the inspectors of this bureau were called upon by the commission to perform various duties not in connection with their regular work, which materially reduced the number of locomotives shown inspected by them, as well as the number ordered out of service, and it appears that certain railroad officials and employees have taken advantage of their temporary absence and permitted locomotives to remain in service with serious defects, which would have been known to them had proper inspections been made and reports rendered as required.

It was found necessary to ask the courts to inflict the penalty provided in section 9 of the law, because of the defective condition in which locomotives were being operated by one carrier and its willful violation of the requirements of the law and rules. This case is now pending and is set for the October term of the court. It is evident that unless an immediate improvement is made by certain other carriers it will be necessary to file similar suits in the near future. That the law places the burden of proper inspection and repair and compliance with the rules of inspection on the carriers owning or operating the locomotives seems to have been lost sight of, and this is reflected in the increased number of accidents and casualties during the year.

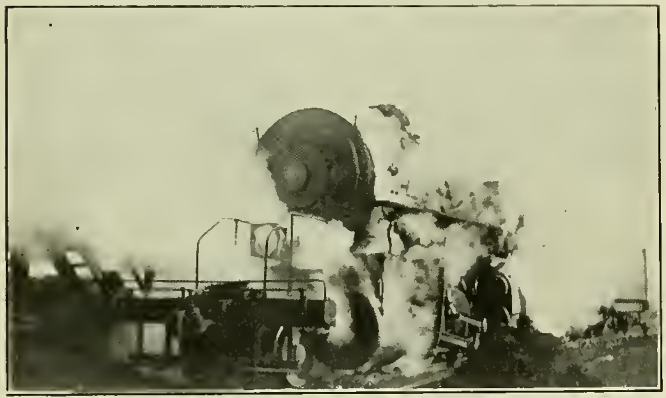
Referring to failures of seams in boilers welded by the autogenous process, the recommendation made in the last annual report that such methods should not be applied to any part of the boiler where the strain is not carried by other construction nor in the low water zone of the firebox, is repeated, with the further recommendation that this should apply to all parts of the locomotive and tender subject to severe stresses and shocks where failures might cause accidents. During the year, 258 applications were filed for extension of time for the removal of flues, as provided in rule 10. Investigation showed that in 31 of these cases, the condition of the locomotives was such that no extension could properly be granted. Twenty-five were in such condition that the full extension requested could not be granted, but an extension for a shorter period within the limits of safety was allowed. Ten extensions were granted after defects disclosed by our investigation had been repaired. Thirty-seven applications were withdrawn for various reasons and the remaining 155 were granted for the full period requested.

During the year, close attention was given to the equipping of locomotives with headlights that would meet the requirements of the commission's orders of December 26, 1916, and December 17, 1917, and reports indicate that on July 1 practically all locomotives in service were equipped in accordance therewith.

No formal appeal has been taken from the decision of any inspector, during the fiscal year.

A large part of the report is devoted to an account of the tests of water indicating devices conducted by the bureau which were described in the *Railway Mechanical Engineer* for September and October, 1920, pages 575 and 630.

The chief inspector calls attention to the fact that services of the inspectors were required in making various investigations during the year and, in view of this fact, recommends that the act of February 17, 1911, be amended so as to provide for additional inspectors, to be appointed by the commission, upon the recommendation of the chief inspector, as the needs of the service develop. Other recommendations that are repeated are as follows:



A Locomotive That Is Not Only Unsafe But Also Uneconomical

That all locomotives not using oil for fuel have a mechanically operated fire door, so constructed that it may be operated by pressure of the foot on a pedal or other suitable device.

That all locomotives be provided with a bell so arranged and maintained that it may be operated from the engineer's cab by hand and by power.

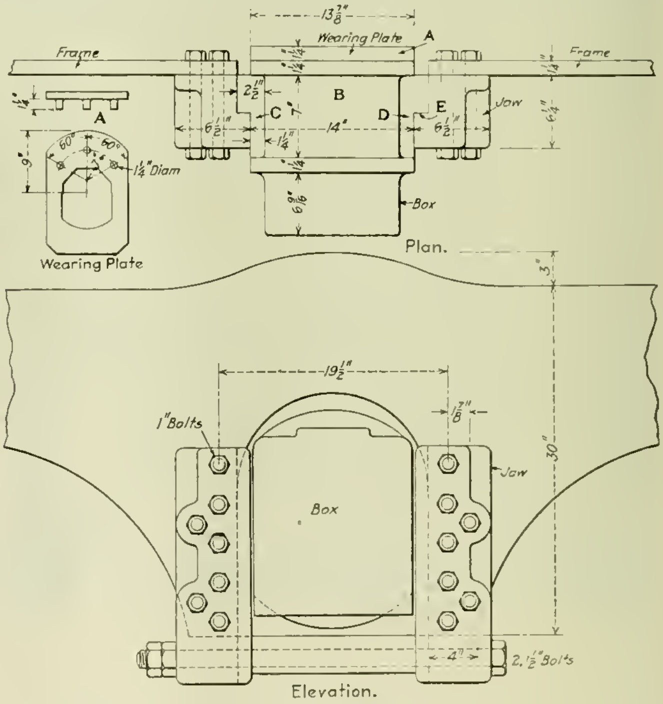
That cabs of all locomotives not equipped with front doors or windows of such size as to permit of easy exit, have a suitable stirrup or other step, and a horizontal handhold on each side, approximately the full length of the cab, which will enable the enginemen to go from the cab to the running board in front of it; handholds and steps or stirrups to be securely fastened with bolts or rivets; the distance between the step and handhold to be not less than 60 inches nor more than 72 inches.

That all locomotives where there is a different indication between the gage cock and water glass of two or more inches of the water level under any conditions of service be equipped with a suitable water column to which shall be attached three gage cocks and one water glass with not less than 6 in., preferably 8 in., clear reading, and one additional water glass with not less than 6 in., preferably 8 in., clear reading, located on the left side or back head of the boiler. The water glasses to be so located, constructed, and maintained that they will register the approximate general water level in the boiler under all conditions of service and show a corresponding level within 1 inch and be so located, constructed, and maintained that the engineer and fireman may under all conditions of service have an easy and clear view of the water in the glass from their respective and proper positions in the cab. The gage cocks to be so located that they will be in easy reach of the engineer from his proper position in the cab.

The usual chart showing the number of accidents occurring during the fiscal year from 1912 to 1920 due to failure of various parts of a locomotive, is shown, and this information is also given in tabular form. Another section of the report lists the accidents occurring on each railroad under the jurisdiction of the bureau, with a summary in tables which show also the number of locomotives inspected and the numbers found defective and ordered from service. A supplement at the conclusion of the report shows typical examples of defective conditions and accidents resulting from defects with a short account of the causes of the failure.

Trailer Box With Lateral Adjustment

The Ann Arbor railroad has equipped its Atlantic type locomotives with a trailer box and pedestal that permits the application of the lateral plate without dropping the wheels and also makes possible the taking up of lateral play until the plate is entirely worn out. The arrangement is illustrated in elevation and plan in the drawing shown herewith.



A Unique Type of Trailer Box Pedestal Designed to Facilitate Repairs

In this design, the jaws are set far enough apart to permit the withdrawal of the box *B* as keys *C* and *D* are raised vertically out of place. This permits the application of a wearing plate *A* after which the box is replaced in position and the keys *C* and *D* dropped into their places. In order to use up the wearing plate completely and at the same time keep the lateral motion within the prescribed limits, keys of bar iron may be inserted at the shoulder marked *E*. After the plate is completely worn out by the application of these filling blocks, a new wearing plate may be applied. This arrangement, which was originated by J. E. Osmer, superintendent of motive power of the Ann Arbor, has been very successful in service.

Federated American Engineering Societies' Meeting

Herbert Hoover Speaks on Some Phases of Relationship of Engineering Societies to Public Service

THE first meeting of the Federated American Engineering Societies as an independent organization was held at the New Willard Hotel, Washington, D. C., on November 18, 19 and 20. Herbert Hoover was unanimously elected president of the American Engineering Council, and thus becomes the active head of this organization. Twenty-one member societies and nine societies which have not yet taken final action, participated in the meeting.

The executive board of thirty members was elected in part. As there were a number of societies which were expected to join shortly, four vacancies were left on the board in order that these societies might later be given proper representation. According to the societies' constitution, the country was divided into six districts as follows:

District 1—New England and New York.
District 2—Michigan, Wisconsin and Minnesota.
District 3—Ohio, Indiana and Illinois.
District 4—New Jersey, Pennsylvania, Delaware, Maryland and the District of Columbia.
District 5—All the southern states, including Louisiana and Texas, and
District 6—All other states west of the Mississippi river.

Of the national societies, the American Society of Mechanical Engineers received 4 places; the American Institute of Mining and Metallurgical Engineers, 3; the American Institute of Electrical Engineers, 4; the American Institute of Chemical Engineers, 1; the American Society of Agricultural Engineers, 1; and the Society of Industrial Engineers, 1. The executive officers elected are Herbert Hoover, Palo Alto, Cal., president; Calvert Townley, New York, vice-president; W. E. Rolfe, St. Louis, Mo., vice-president; D. S. Kimball, Ithaca, N. Y., vice-president; J. Parke Channing, New York, vice-president; and L. W. Wallace, Baltimore, Md., treasurer. Members of the executive board were elected to represent the organizations mentioned above and also some of the local districts.

No permanent location for headquarters was chosen, although the majority felt that in order to carry on the work of public service for which the federation was organized, it would be necessary to maintain an office in Washington. It was decided that the headquarters be located in that city after January 1, 1921, and until that time the society would carry on its work in the Washington office of the Engineering Council through the courtesy of that organization.

The Committee on Plan and Scope presented a large number of topics of interest to the public at large which would give the society an opportunity for constructive work. The more important of these included the conservation of labor or the reduction of economic waste, transportation, the establishment of a department of public works, national fire protection, patents, licensing of engineers, education, compensation, service bureau and numerous others, some of which are now in the hands of the Engineering Council.

Of the public service work to be undertaken, the reduction of economic waste will probably receive first consideration. Mr. Hoover emphasized this strongly in an address on "Some Phases of Relationship of Engineering Societies to Public Service." An abstract of the address follows:

Address of Herbert Hoover

The greatest of the problems now before the country and, in fact, before the world, are those growing out of our industrial development. The enormous industrial expansion of the last 50 years has lifted the standard of living and comfort beyond any dream of our forefathers.

We have built up our civilization, both political, social and economic, on the foundation of individualism. We have found in the course of development of large industry upon this system that individual initiative can be destroyed by allowing the concentration of industry and service, and thus an economic domination of groups over the whole. While our present system of individualism under controlled capitalism may not be perfect, the alternative offers nothing that warrants its abandonment. Our thought, therefore, needs to be directed to the improvement of this structure and not to its destruction.

A profound development of our economic system apart from control of capital and service during the last score of years has been the great growth and consolidation of voluntary local and national associations. These associations represent great economic groups of common purpose, and are quite apart from the great voluntary groups created solely for public service. This engineers' association stands somewhat apart among these economic groups in that it has no special economic interest for its members. Its only interest in the creation of a great national association is public service, to give voice to the thought of the engineers in these questions. And if the engineers, with their training in quantitative thought, with their intimate experience in industrial life, can be of service in bringing about co-operation between these great economic groups of special interests, they will have performed an extraordinary service.

Relations Between Employer and Employee

We have just passed through a period of unparalleled speculation, extravagance and waste. We shall now not only reap its inevitable harvest of unemployment and readjustment, but we shall feel the real effect of four years of world destruction, and from it economic and social problems will stand out in vivid disputation. One of the greatest conflicts rumbling up in the distance is that between the employer on one side and organized labor on the other. There are certain areas of conflict of interest, but there is between these groups a far greater area of common interest, and if we can find measures by which, through co-operation, the field of common interest could be organized, then the area of conflict could be in the largest degree eliminated.

The American Federation of Labor has publicly stated that it desires the support of the engineering skill of the United States in the development of methods for increasing production, and I believe it is the duty of our body to undertake a constructive consideration of these problems and to give assistance not only to the Federation of Labor but also to the other great economic organizations interested in this problem, such as the Employers' Association and the chambers of commerce.

The Three Great Wastes in Production

It is primary to mention the three great wastes in production; first, from intermittent employment; second, from unemployment that arises in shifting of industrial currents, and third from strikes and lockouts. Beyond this elimination of waste there is another field of progress in the adoption of measures for positive increase in production.

In the elimination of the great waste and misery in intermittent employment and unemployment, we need at once co-ordination in economic groups. For example, in the bituminous coal industry where the bad economic functioning of that industry results in an average of but 180 days' employment per annum, a great measure of solution could be had if a basis of co-operation could be found between the coal operators, the coal miners, the railways and the great consumers. The combined result would be a higher standard of living to the employees, a reduced risk to the operator, a fundamental expansion of economic life by cheaper fuel. With our necessary legislation against combination and the lack of any organizing force to bring about this co-operation, the industry is helpless unless we can develop some method of governmental interest, not in governmental ownership, but in stimulation of co-operation in better organization. In the great field of seasonal and other unemployment, we indeed need an expansion and better organization of our local and federal labor exchanges. The individual worker is helpless to find the contacts necessary to make this seasonal shift unless the machinery for this purpose is provided for him.

In the questions of industrial conflict resulting in lockouts and strikes, one mitigating measure has been agreed upon in principle by all sections of the community. This is collective bargaining, by which, whenever possible, the parties should settle their difficulties before they start a fight. The point where the universal application of collective bargaining has broken down is in the method of its execution. The conflict arises almost wholly over the question of representation and questions of enforcement. The second Industrial Conference proposed a solution to this point by the provision that where there was a conflict over representation the determination should be left to a third and independent party. It also proposed that each party should have the right to summon skill and experience to its assistance. It further proposed that where one of the parties at dispute refuses to enter upon collective bargaining, the entire question should be referred to an independent tribunal for investigation as to the right and wrong of the whole dispute—but only for investigation and report.

Hours of Labor

There are questions in connection with this entire problem of employer and employee relationship, both in its aspects of increased production and in its aspects of wasteful unemployment, that deserve most careful study by our engineers. There lies at the heart of all these questions the great human conception that this is a community working for the benefit of its human members, not for the benefit of its machines or to aggrandize individuals; that if we would build up character and abilities and standard of living in our people, we must have regard to their leisure for citizenship, for recreation and for family life. These considerations, together with protection against strain, must be the fundamentals of determinations of hours of labor. These factors being first protected, the maximum production of the country should become the dominating purpose.

The precise hours of labor should and will vary with the varying conditions of trades and establishments, but the proper determination of hours, based upon these factors, is an immediate field demanding attention of engineers. There is no greater economic fallacy than the doctrine that the decrease of hours below these primary considerations makes for employment of great numbers, and it is an equal certainty that the 84-hour week of some employments transgresses these fundamentals to a point of inhumanity.

Incentive and Increased Production

There is a broad question bearing upon stimulation of self-interest and thus increase in production that revolves around the method of wage payment. I need not review to you the advantages, difficulties and weaknesses of bonus, piece work, profit or saving sharing plans that are in use as a remedy for the deadening results of the same wage payment to good and bad skill alike. A suggestion for your consideration is the possible use of another device in encouragement of individual interest and effort by creating two or three levels of wage in agreements for each trade, the position of each man in such scale to be based upon comparative skill and character. This plan should be developed upon the principle of graded extra compensation, for added skill and performance, above an agreed basic wage. In order to give confidence, the classification under such scales must be passed upon by representatives of the workers in such shop or department. This plan is now being successfully experimented with.

We must take account of the tendencies of our present repetitive industries to eliminate the creative instinct in its workers, to narrow their field of craftmanship, and to discard entirely the contribution to industry that could be had from their minds as well as from their hands. There has been a great increase in shop committees as a method to relieve this tendency. Where they have been elected by free and secret ballot among the workers, where they are dominated by a genuine desire on both sides for mutual co-operation in the shop, they have resulted in great good. Organized labor has opposed some forms of these committees because of the fear that they may break down trade organization covering the area of many different shops.

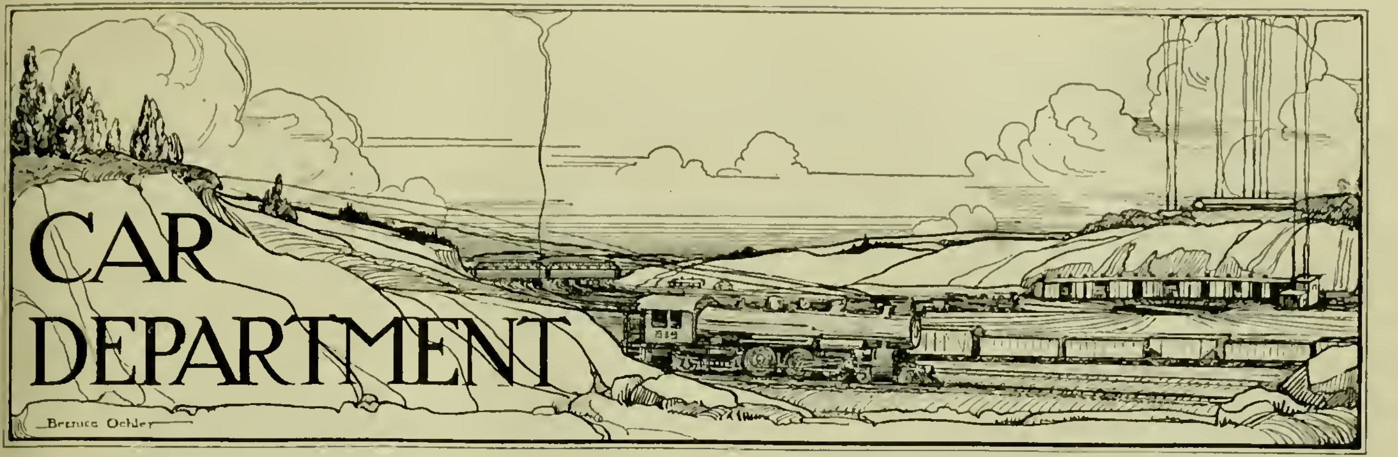
Co-operation with Labor Organizations

Again I believe the engineers could assist in the erection of a bridge of co-operation if organized labor, which has already made a beginning, would extend more widely its adoption of the principles of a shop committee settling its problems of wage and conditions of labor in general agreement and applying its energies through shop committee organization to development of production as well as to the correction of incidental grievance. There would be little outcry against the closed shop if it were closed in order to secure unity of purpose in constructive increase of production by offering to the employer the full value of the worker's mind and effort as well as his hands.

While it is easy to state that increased production will decrease cost and by providing a greater demand for goods secure increased consumption and ultimate greater employment, yet the early stages of this process do result in unemployment and great misery. It takes a variable period of time to create the increased area of consumption of cheapened commodities, and in the meantime, when this is translated to the individual worker he sees his particular mate thrown out of employment. We accomplish these results over long periods of time, but if we would secure co-operation to accomplish them rapidly we must take account of this unemployment and we must say to the community that if it is to benefit by the cheapening costs and thus the increased standard of living, or alternatively if the employer is to take the benefits, the entire burden should not be thrust upon the individual who now alone suffers from industrial changes. Nor can this be accomplished except by co-operation between groups.

I am not one of these who anticipates the solution of these things in a day. Durable human progress has not been founded on long strides. But in your position as a party of the third part to many of these conflicting economic groups, with your lifelong training in quantitative thought, with your sole mental aspect of construction, you, the engineers, should be able to make contribution of those safe steps that make for real progress.

Coal Output Per Miner.—The average production for each underground worker employed in the coal mines of the United States during 1918 was 1,134 short tons, according to statistics published by the United States Bureau of Mines. Our closest competitor is New South Wales, where each underground worker in 1918 produced 814 tons. The smallest individual output of recent years was that of Japan in 1917, with an average of 155 tons.



CAR DEPARTMENT

Ball Bearings for Railway Cars

During recent years ball bearings have been developed for use under very heavy loads and have been successfully applied under difficult conditions. The allowable pressure on ball bearings decreases as the speed increases and the adaptation of ball bearings to the high speeds and heavy loads met in passenger cars is therefore a difficult problem. One of the latest developments is the application of a modified type of ball bearings in the trucks of passenger cars. This form of bearing is in service in Sweden and its use in this country is now being considered.

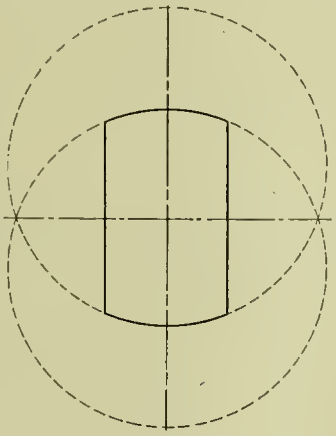


Fig. 1

The use of ball bearings in railroad equipment was discussed in a recent paper before the Swedish Technological Society of Stockholm. The author of the paper, A. Danielson, pointed out that the advantages of ball bearings are due to the smaller loss of energy through friction, the lessening of danger of overheating, greater ease of handling, smaller consumption of oil and less attendance required. Where heavy loads are carried, roller bearings have come into competition with ball bearings, but the author pointed out that the coefficient of friction was higher and the saving of energy with the common types of roller bearings, compared with plain bearings, is often very small. Moreover, the application of most roller bearings is limited, due to the fact that very few types can take any end thrust.

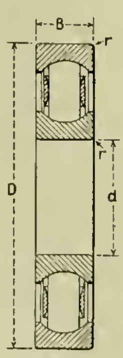

Fig. 2

Experiments conducted by Stribeck showed the coefficient of friction in roller bearings with spiral rolls was about 0.4 per cent and in a bearing with long cylindrical steel rollers between 0.7 and 1.4 per cent. The coefficient of friction in a ball bearing is 0.1 to 0.15 per cent. The increased friction of the roller bearing is due to the fact that the rollers tend to go crosswise, thus setting up a sliding motion. It is therefore desirable that the rollers in a roller bearing should be self-alined and, with this in mind, the so-called disk bearing manufactured by the Nordiska Kulluager Aktiebolaget (Northern Ball Bearing Company), Gothenburg, Sweden, was designed. It has been found that rollers of the form shown in Fig. 1 when moving between two planes have a peculiar rolling motion. Provided the upper plane can rise and fall, the horizontal axis will assume a normal position at right angles to the direction of motion. This also holds true when the disks move between round and not between plane surfaces, as in the disk bearing. By the form of roller shown, the strength of the roller bearing is combined with the easy running of the ball bearing, the effective capacity of the disc being the same as for a ball of the diameter shown by the dotted lines.

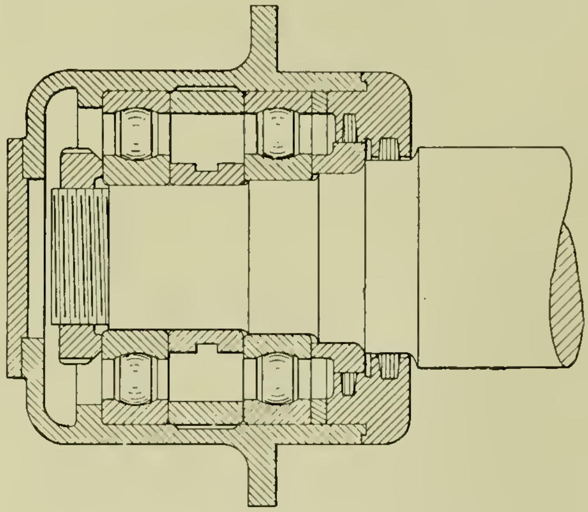

Fig. 3—Journal Box With Disc Bearings Used On the Swedish State Railways

The arrangement of the rollers or disks, as they are called, with the races and cage, is shown in Fig. 2. The race rings have concave grooves which conform fairly closely to the outline of the disks. As any axial displacement of the outer ring tends to compress the roller, such a bearing is able to carry a thrust load. Due to the self-alining feature, the disks adjust themselves at an angle so that the resultant pressure is normal to the axis of the disk. If the axial stress arises suddenly, the disk does not immediately adjust itself, but takes the stress nevertheless. The cage for disk bearings is so formed that the disks can adjust themselves under the influences of axial pressure.

The load capacity of the disk bearing is stated to be about 60 per cent greater than for ball bearings of corresponding dimensions. The coefficient of friction is about 0.13 per cent, or about the same as for ball bearings. The design of disk bearing box used on the Swedish railways is shown in Fig. 3. On each journal are placed two bearings of the same type and dimensions which are coupled together so that they take up axial pressure in common.

In the absence of test data to show the saving effected by the reduction of friction, Mr. Danielson submitted calculations on a theoretical basis. The average resistance of the car with journal bearings was assumed to be as shown in Fig. 4, these curves being the results of tests of cars with plain and ball bearings conducted on the Swedish state railways. From these experiments modified on a basis of Stribeck's investigations of journal friction, the resistance curves for trains with disk bearings and with journal bearings have been derived as shown in Fig. 5. On the basis of a train consisting of an engine weighing 70 long tons with the weight of the tender and cars equal to 400 tons, operating over a given section of road, 200 kilometers long, the coal consumption was assumed to be 0.323 kilograms per car axle kilometer (1.15 lb. per car axle mile) and the price of coal was taken at 155 kroner ($31.00) per ton.* Assuming an annual traffic of 140,000 car-axle kilometers, the saving amounted to 983 kroner (about $196.60) per car. On this basis, the saving would pay the cost of the new bearings in about a year and a half, including the expense of periodical overhauling.

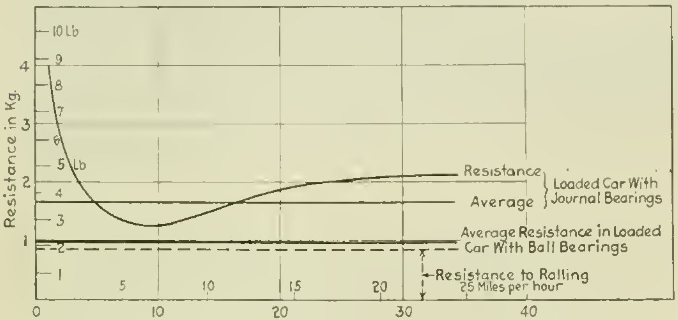

Fig. 4—Rolling and Total Resistance of Cars With Ball Bearings and Journal Bearings

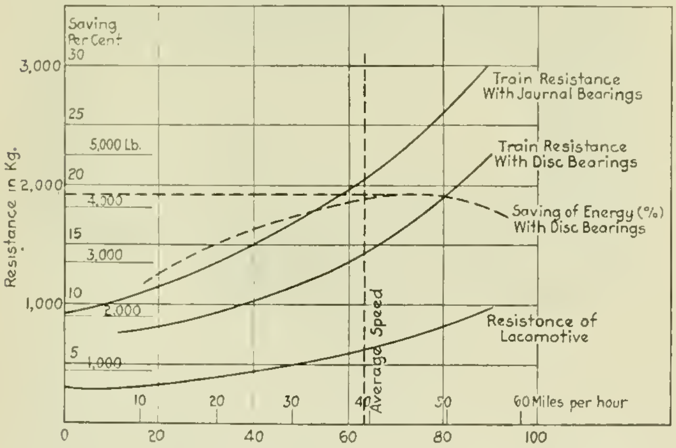

Fig. 5—Train Resistance With Journal Bearings and Disc Bearings and Saving of Energy

In freight service, the percentage of coal saved would not be so great as the distance traveled in a year by each car would be less, but since the life of the bearings is likely to be greater, it is believed that even on freight cars disk bearings would prove economical. With freight cars the advantage of easier starting would assume greater importance. In ore traffic on the Swedish State Railways it has been established that the same engine with equal coal consumption is able to haul 28 or 33 cars provided with sliding bearings and ball bearings, respectively, on the line between Kiruna and Gellivare, equal to a coal saving of 18 per cent. On the line from Ripats to Lulea the corresponding numbers are 29 and 38 ore cars, equal to a coal saving of 31 per cent. On an electric road a four-axle car equipped with ball bearings has shown a saving of energy, measured in electric units, of 23 per cent.

The first car to which the disk bearings were applied weighs 36 tons, including the weight of passengers, which makes the pressure on each journal 4.5 tons. The car had covered 190,000 kilometers (118,000 miles) in fast passenger service on Nov. 9, 1920, and the original set of bearings was still in use.

The Swedish State railways have also had ball bearings in service since 1913 on cars weighing 42 and 43 tons, an average journal pressure of 5.2 tons. The first defect developed after the car had traveled 240,000 kilometers (149,000 miles). One car has been in service for two years without any defects in the bearings. Other companies are developing entirely new types of ball bearings and further improvements are anticipated.

Periodical Repairs for Freight Cars*

BY F. S. GALLAGHER

Engineer of Rolling Stock, New York Central

A freight car is constructed and the manufacturers are instructed to deliver it to some point where it is put in service and there it stays until it is about ready to drop to pieces. In the case of locomotive or passenger car it is different. Locomotives are usually brought into the shop and given designated repairs after certain mileage, and the same is true with the coach, but it is usually based on a time period. But the freight car, the most important of all vehicles, is put into service and given no attention whatever except the attention necessary to keep it in running condition and maintain safety appliances. Why should we not treat a freight car in the same manner as we do a passenger car or locomotive, by bringing it into the shop after a certain designated mileage, or after a certain length of service, and make certain repairs, thus always keeping the car in first-class condition?

This is a scheme which would take some study to work out properly, but when once worked out I believe would work to the advantage of the railroad company, because at all times we would know the condition of the equipment. To successfully work out a scheme of this kind would require the co-operation of all of the railroads in the country. If cars were stenciled in a manner to indicate during what period they should receive their periodical repairs, the railroad in whose possession the cars might be would be responsible to the owning road to see that the repairs are made or the cars are returned home for repairs. This would necessitate making it a requirement in interchange that the cars be either repaired or sent to the home road for repairs.

This periodical repair might not amount to much, it might possibly be painting or proper attention to the draft gear, or repairs to some of the brake apparatus. but it seems to me that there should be some designated time when a freight car should be brought into the shops for necessary repairs other than depending upon the judgment of the yard inspector as to whether or not the car should continue. I think we would have a large decrease in so-called heavy repairs and rebuilding if we could periodically bring the cars in and do certain things to them.

---

*The normal value of the kroner is about 26 cents and the present value about 20 cents.

*From a paper presented before the New York Railroad Club.

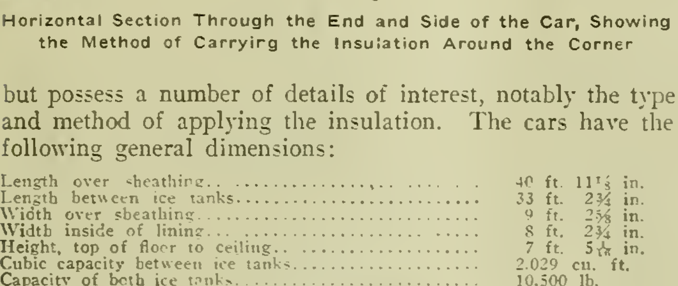
Pacific Fruit Express Refrigerator Cars

Insulation Around the Sides and Ends is Unbroken: A Continuous Layer of Cork in the Floor

THE Union Pacific has recently placed in service 4,000 refrigerator cars for the Pacific Fruit Express, 1,000 of which were built in the company's shops and orders for 3,000 of which were distributed among the following builders:

Pullman Company	900
American Car & Foundry Company	900
Haskell & Barker Car Company, Inc	700
Mt. Vernon Car Manufacturing Company	300
Pacific Car & Foundry Company	200

These cars in general follow conventional lines of design but possess a number of details of interest, notably the type and method of applying the insulation. The cars have the following general dimensions:



Horizontal Section Through the End and Side of the Car, Showing the Method of Carrying the Insulation Around the Corner

Length over sheathing	40 ft. 11⅛ in.
Length between ice tanks	33 ft. 2¾ in.
Width over sheathing	9 ft. 2⅝ in.
Width inside of lining	8 ft. 2¾ in.
Height, top of floor to ceiling	7 ft. 5 1/16 in.
Cubic capacity between ice tanks	2.029 cu. ft.
Capacity of both ice tanks	10,500 lb.
Distance from center to center of body bolsters	30 ft. 8 in.
Truck wheel base	5 ft. 6 in.
Capacity	60,000 lb.
Truck capacity	80,000 lb.
Light weight of car complete (built up centre sill)	53.500 lb.
Light weight of car complete (Bettendorf)	52,200 lb.

The cars were built to two designs, differing only in the trucks and underframe construction. In one of these the Bettendorf single I section center sill and Bettendorf trucks are used while the other involves a double fish belly center sill built up of plates and structural sections, and is carried on Vulcan trucks.

Underframes

The principal member of the Bettendorf underframe is an 18-in., 92-lb. Bethlehem girder, the depth of which is reduced to 14 in. at the bolster. The bolster is an 8-in., 34.5-lb. H-section, which is framed through the center sill and the rear ends of the draft sill castings.

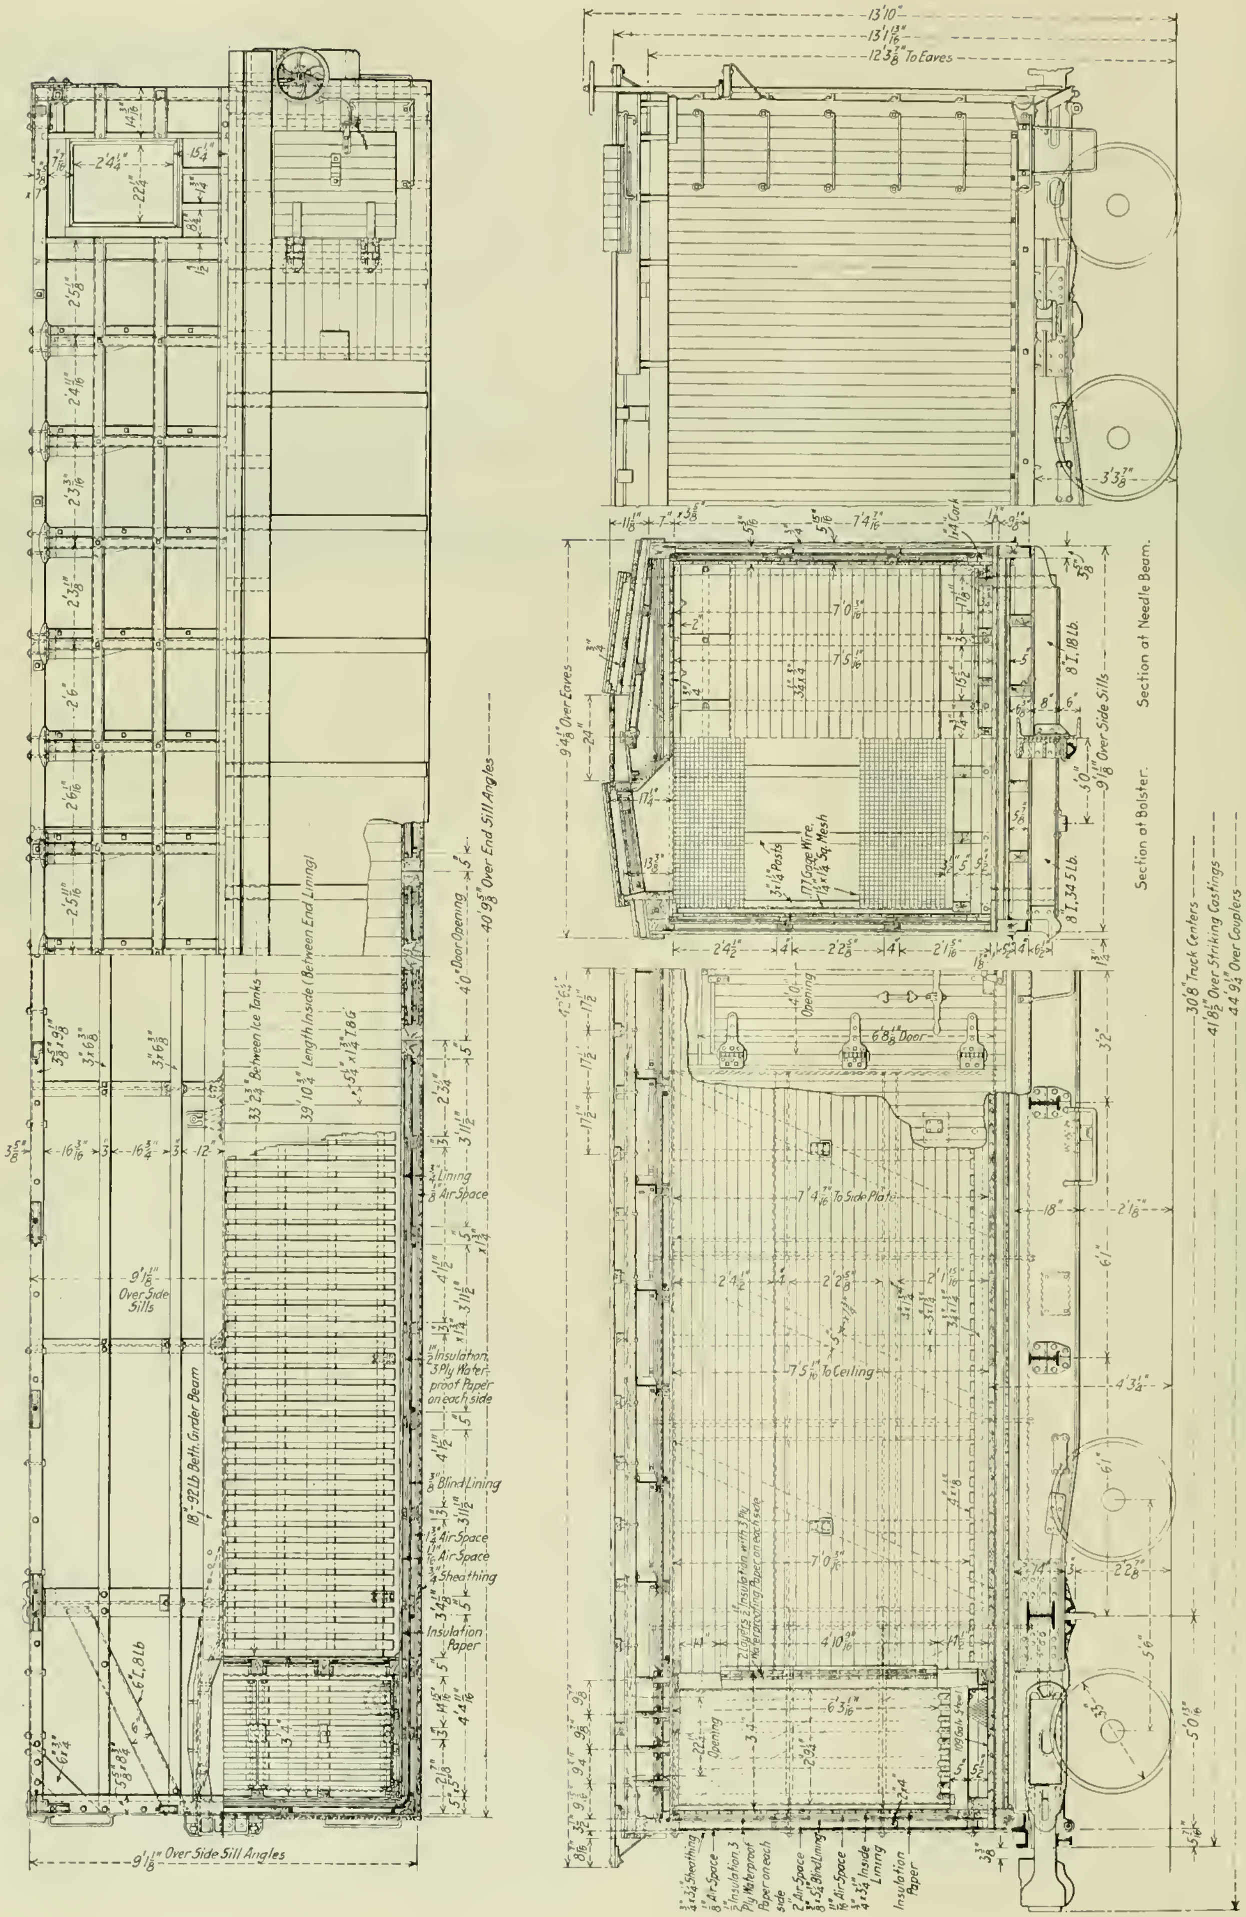
The center sills of the other underframe are built up of 5/16-in. web plates with 3-in. by 3-in. by 5/16-in. angle flanges at the top on the outside only and 3-in. by 3-in. by ¼-in. angle flanges on the inside and 3-in. by 3-in. by ½-in. angle flanges on the outside at the bottom of each plate. The sills are completed with two ¼-in. superimposed top cover plates, the lower one extending the entire length of the sills and the other extending 8 ft. toward each end from the transverse center line of the car. The bolsters on this underframe are also of built up box section; the 5/16-in. web plates are spaced 8 in. back to back and reinforced with 2½-in. by 2½-in. by 5/16-in. angles on the outside at both top and bottom. The bolsters are completed with top and bottom cover plates, the latter being continuous and are attached to the center sills on either side with one horizontal and two vertical corner angles.

In other respects the two underframes are similar. Both have four 8-in., 18-lb. I-section needle beams, and in each case the end and side members are 4-in. by 4-in. by ⅜-in. and 4-in. by 3-in. by ⅜-in. angles, respectively.

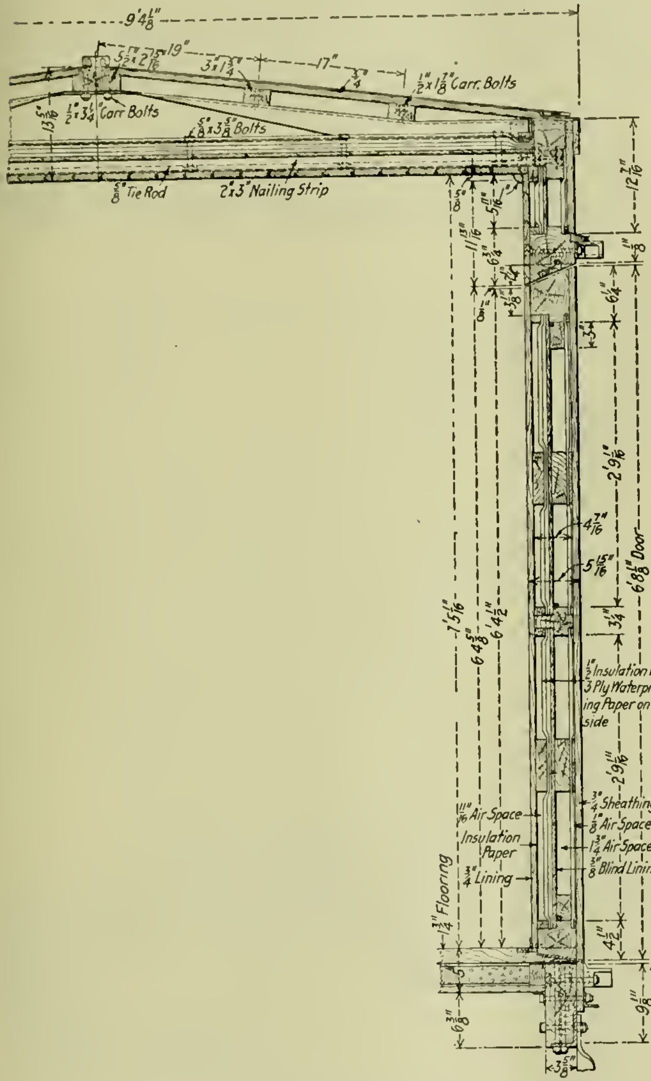
The Car Bodies

The construction of both car bodies is essentially the same. Both have wood frames with the exception of the carlines, which are of pressed steel. The bodies are built up on wood sub-sills; those for the sides and ends are framed into and bolted to the angle members of the steel underframe; while the intermediate sills are bolted on top of the needle beams.

The entire floor construction is placed above the inter-



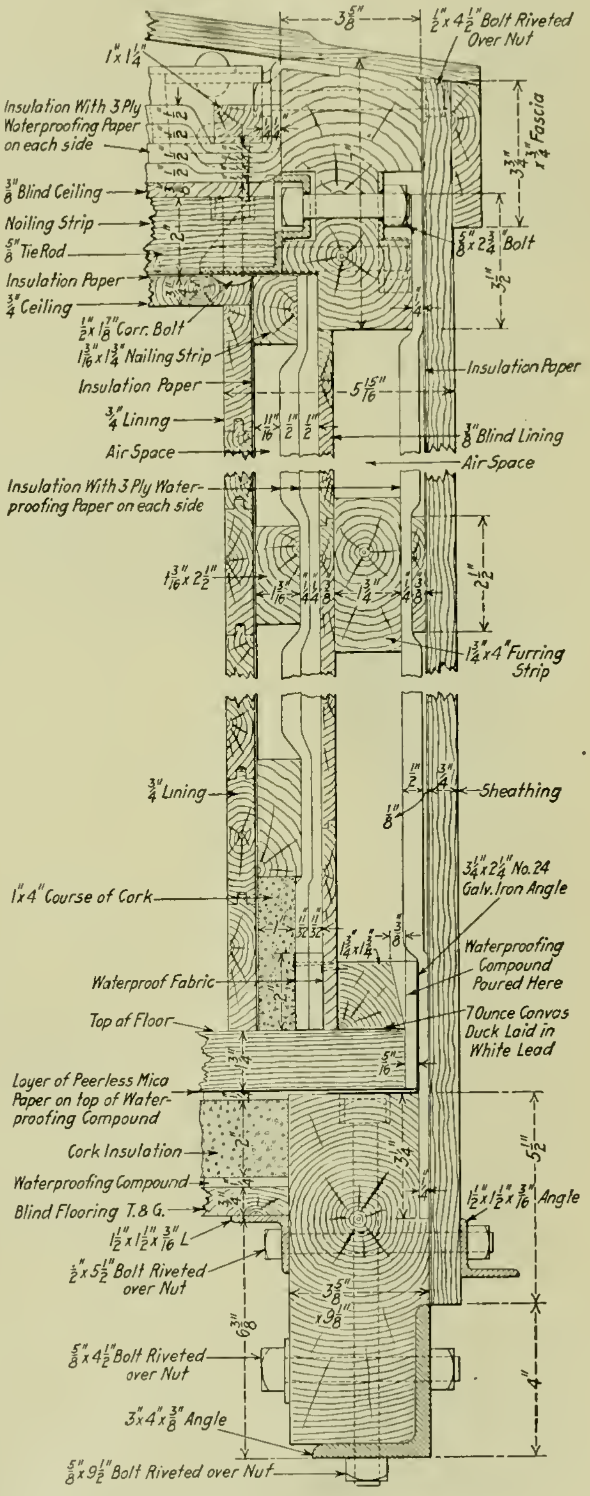
General Drawing of the Pacific Fruit Express Ventilator Refrigerator Cars, with Bettendorf Underframe mediate sub-sills with no enclosed air spaces, which makes it possible to provide continuous floor insulation. The lower floor is ¾-in. tongued and grooved material nailed directly to the top of the intermediate sub-sills, the ends of the boards resting on 1½-in. by 1½-in. angle supports bolted to the inside faces of the side sub-sills. This floor is covered with a ¼-in. coat of Sarco Bituminous Seal, applied hot. A 2-in. course of Nonpareil Cork Board is then laid while the bituminous compound is still hot and this is sealed with another ¼-in. coat of the hot waterproof compound. The insulation thus built up is covered with a layer of Peerless mica surfaced insulating paper with the seams carefully joined to prevent moisture passing through and the upper floor, of 1¾-in. tongued and grooved material is then laid. The ends of the flooring are nailed to the tops of the side sub-sills and the boards are further secured by nailing through the insulation into the two center sub-sills.



Cross Section of the Car Body at the Door

The side construction provides three air spaces between the inside lining and the sheathing. The first course of insulation, consisting of one layer of ½-in. Keystone hair felt between courses of three ply, waterproofing paper is placed outside the frame before the outside sheathing is applied. This insulation, as is shown in one of the drawings, extends continuously from door post to door post around each end of the car and is secured to the frame members by ⅜-in. nailing strips. After a layer of Per Bona insulating paper, also extending continuously from door post to door post, has been laid over the nailing strips, the sheathing is applied. There is a nominal air space of ⅛-in. between the unrestrained portions of the insulation and the sheathing.

An intermediate lining of ⅜-in. ship lap material is nailed to the inside of the frame members, and against this is laid the inside insulation, consisting of two thicknesses of the hair felt covered on each side with three-ply waterproofing paper. This extends continuously around the ends of the car from door post to door post, and is held in place by 1-3/16-in. nailing strips over which is placed a continuous covering of Per Bona insulating paper before the inside lining is applied.



Section Through the Side of the Car, Showing Details at the Junction of the Side With the Ceiling and Floor

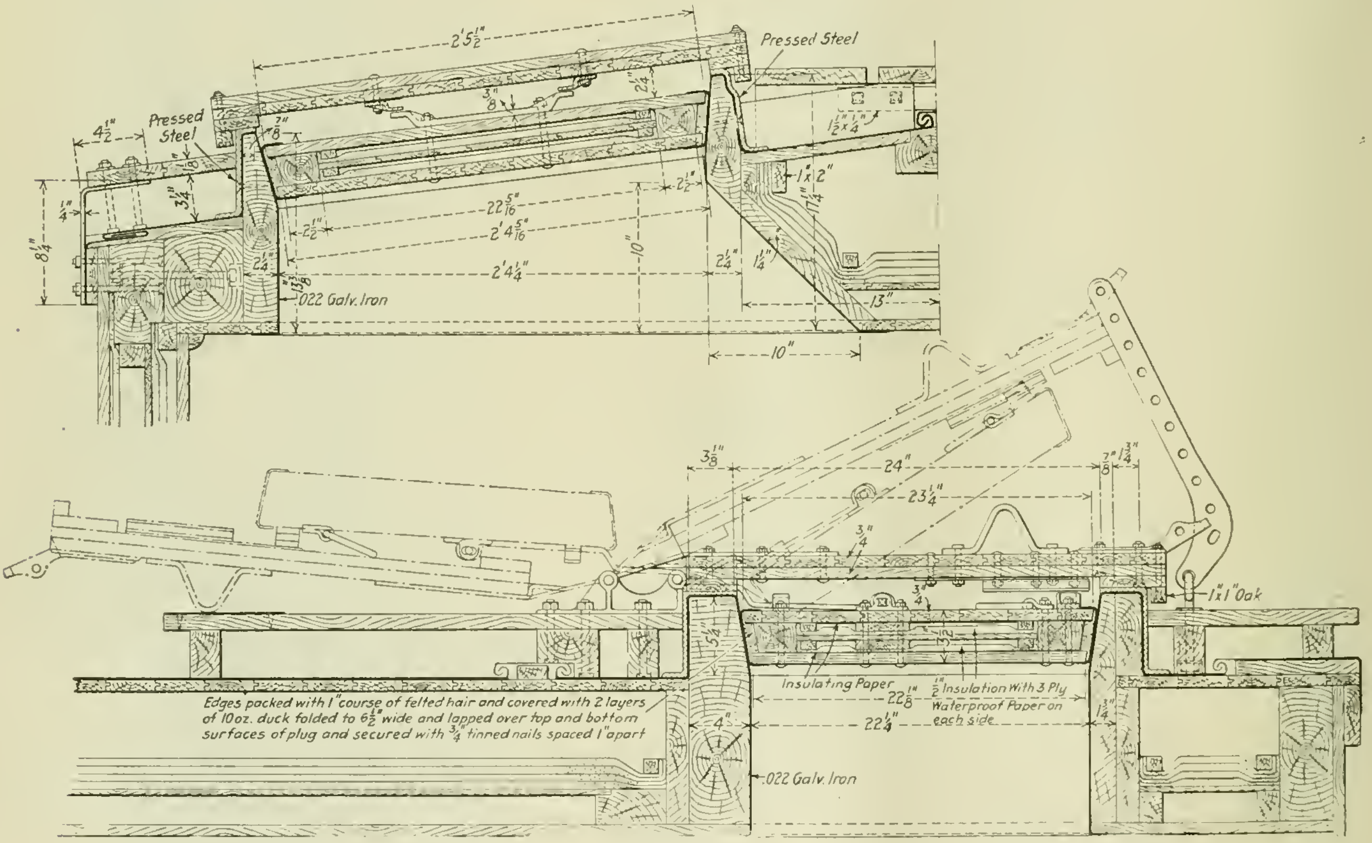
In the bottom of the side and end walls, a strip of 1-in.

by 4-in. cork board is laid on top of the floor between the inside lining and the inside layers of insulation. This is held in place against the floor by a 1-3/16-in. belt strip placed directly above it. To further protect the insulation and the concealed wood work at the floor line from the penetration of moisture, the lower edges of the two inside layers of hair felt are enclosed in a waterproof cotton fabric placed under the edges of the insulation and folded up the sides for a distance of two inches above the floor; the nailing strips for the blind lining at the floor are covered with canvas laid in white lead on the floor and lining sides, and the 5/16-in. spaces between the ends of the floor boards and the outside faces of the side sills are filled with hot waterproofing compound extending up $3\frac{1}{2}$-in. to the top of the blind lining nailing strips. The doors are built up with the same arrangement of insulation as that in the sides of the car. They are fitted with Miner fasteners and insulation for the joints between and around the doors.

The Roof

The cars are fitted with the Murphy X L A outside metal roof and, with the exception of those at the ends of the hatchways, the car-lines are of pressed steel of inverted U-section with one side extending down to form a support to which the ceiling structure is bolted.

The roof insulation consists of four layers of the $\frac{1}{2}$-in. hair felt insulation, covered on each side with three-ply waterproofing paper. This insulation is placed between the steel car-lines and the blind ceiling, which is built up of $\frac{3}{8}$-in. ship lap material on top of 2-in. by 3-in. transverse nailing strips. On the lower face of the nailing strips the $\frac{3}{4}$-in. tongued and grooved ceiling is applied and the whole structure is secured to the car-lines by $\frac{5}{8}$-in. bolts.



Edges packed with 1" course of felted hair and covered with 2 layers of 10oz. duck folded to 6½" wide and lapped over top and bottom surfaces of plug and secured with ¾ tinned nails spaced 1" apart

Transverse and Longitudinal Sections Through the Hatch, Showing Method of Ventilating the Car

The details of the construction of the hatchway openings and the methods of securing the insulation at these points are shown in the drawings. The hatch covers and plugs are both hinged from single sets of hinge fixtures with separate hinge connections and they are arranged so that the hatches may be opened for ventilator service. The cover is held open by a simple adjustable support and the plug is supported from the cover by a sliding attachment, normally not connected, but easily brought into play when both are fully opened.

The Bunkers

The bunkers are enclosed by a bulkhead, the outside face of which is 3 ft. 4 in. from the end lining. The bulkhead is built up on 3-in. by 4-in. oak posts and consists of two courses of $\frac{3}{4}$-in. tongued and grooved material separated by two $\frac{1}{2}$-in. thicknesses of hair felt insulation covered with three-ply waterproofing paper. The first course is laid against nailing strips between the posts and the outer course is nailed directly to the faces of the posts. The top bulkhead opening is 14 in. deep and the bottom 12 in.

The ice tank is fitted with a floor pan of galvanized steel and the lining of the end and sides of the car is covered with galvanized iron from the floor pan flashing to the ceiling.

The galvanized wire ice basket is spaced $1\frac{1}{2}$ in. from the end lining, $1\frac{5}{8}$ in. from the side linings and is attached directly to the inside faces of the bulkhead posts. The bottom of the basket is closed with an oak grate made up of $3\frac{1}{2}$-in. by $1\frac{1}{2}$-in. bars extending across the car and supported on six supports of 3-in. by 5-in. oak, the tops of which are $10\frac{1}{2}$ in. above the floor.

The floor racks are built in two longitudinal sections at each end of the car, hinged at the sides to swing up against the lining. Each section is supported on four $1\frac{3}{4}$-in. by $3\frac{3}{4}$-in. longitudinal members and is made up of $1\frac{1}{8}$-in. by 4-in. boards spaced 1-9/16-in. apart.

The trucks on the cars with the built up underframes have Vulcan side frames and Buckeye bolsters, the ends of which rest on Barber roller spring seats. The axles have 5-in. by 9-in. journals and the trucks are fitted with Creco No. 2 brake beams.

Annual Report of the Chief of the Bureau of Safety

Defective Air Brakes Still Constitute Majority of Safety Appliance Defects; Two Devices Tested

The percentage of cars found defective, as shown in the annual report of the chief of the Bureau of Safety for the year ending June 30, 1920, is higher than any of the past five years. However, there is some improvement in the statistics of casualties to employees for the year 1919 as compared with 1918. The recommendations made by the chief of the bureau in previous years regarding the maintenance of air brakes and the control of freight trains on heavy grades by air brakes exclusively are repeated. A brief summary of the report is given below.

Safety Appliances

The following statement affords opportunity for ready comparison of the results of inspections with previous years. It has been compiled from the figures for the fiscal years ended June 30, from 1915 to 1920, inclusive.

	1916	1917	1918	1919	1920
Freight cars inspected...	993,566	1,100,104	1,059,913	1,023,942	864,775
Per cent defective......	3.72	3.64	3.92	3.7	4.59
Passenger cars inspected.	27,220	29,456	25,732	23,712	19,849
Per cent defective.......	1.82	0.85	0.56	0.39	0.77
Locomotives inspected...	31,721	37,199	33,806	30,707	23,883
Per cent defective......	3.66	2.69	2.18	1.84	2.38
Number of defects per 1,000 inspected	45.56	41.16	44.01	40.92	52.08

As shown by this summary, the number of cars inspected was less than for the preceding years, but the percentage for each class of equipment, as well as the number of defects found per thousand inspected, have materially increased. The decrease in the number inspected was occasioned by the numerous special investigations which the inspectors were called upon to make during the year, thus rendering it impossible to devote as much time as heretofore to regular inspection work. The proportionate increase in defects reported is attributed largely to the abnormal operating conditions which existed during the year, resulting in the use of equipment regardless of its age or condition and its continuance in service without necessary repairs, these conditions being aggravated by inadequate shop facilities and repair forces.

Of the total of 47,319 defects of all classes, 3,791 were to couplers and parts, 5,035 to uncoupling mechanism, 22,375 to air brakes, 4,049 to handholds, 1,940 to height of drawbars, 557 to sill steps, 1,444 to ladders, 2,399 to running boards, 5,507 to hand brakes, 36 to safety railings, 130 to footboards, 12 to pilot beam sill steps, 36 to handrails, 3 to steps for headlights, and 5 to power brakes on locomotives.

It will be noted that air-brake defects continue to represent by far the most numerous class. Nearly 50 per cent of all defects reported were to visible parts of air brakes, more than 20,000 of these defects being found in but five parts. The number of cars with brakes cut out of service continues unduly large. Of the 22,375 air-brake defects reported, 7,344, or nearly 33 per cent of the whole number, were cut-out brakes. At numerous terminals it is a common occurrence for cars with cut-out brakes to be made up in trains and permitted to depart in that condition, although facilities exist at such terminals for making necessary repairs to place all power-brake equipment in operative condition. This practice should be discontinued.

The condition of the air brakes in trains prior to departure, as ascertained by the commission's inspectors by means of terminal or standing tests, is tabulated in the report. This table shows the results of tests of 938 trains, composed of 30,578 cars. The brakes on 94.7 per cent of these cars were in operative condition when the trains tested departed from the terminals. Of the total number of cars, there were 5 nonair cars, 178 cars with the brakes cut out, and 1,431 cars on which the brakes did not apply, making a total of 1,614 cars on which the brakes were not operative when leaving terminals.

Another table represents the condition of the air brakes, as ascertained by the commission's inspectors by means of terminal or standing tests, upon arrival of trains at terminals. This table shows that in 149 trains, consisting of 5,819 cars, the brakes were operative on 88 per cent of the cars. Of the total number of cars in these trains there were 194 with the brakes cut out and 477 on which the brakes did not apply, or 671 cars with inoperative brakes. This table shows that of 41 roads on which arriving tests were made there were 14 on which trains did not have an average of 85 per cent operative brakes. It is apparent that the law is not being complied with as to the minimum percentage prescribed by the order of the commission of June 6, 1910, nor as to the requirement that all air-brake cars associated with the minimum percentage must also be used and operated. The arriving tests show the condition of air-brake equipment from a practical operating standpoint. Carriers should take necessary measures to insure strict compliance with the law and see to it that trains at all times are operated not only with the minimum percentage of operative brakes specified by law, but also with all associated air brakes used and operated.

On March 2, 1920, application was filed by the American Railroad Association for a further extension of time within which to equip cars in service on July 1, 1911, to conform to the standards of equipment prescribed by the commission's order of March 13, 1911. This application for an extension of time was denied by the commission on August 7, 1920.

The report calls attention to violations of the Safety Appliance Act occurring at interchange points. One carrier delivers cars to another with defective safety appliances and the receiving carrier moves the cars to its yard, thus making two violations of the law. Adequate inspection and proper repairs prior to assembling cars for interchange movement are recommended to eliminate this difficulty. The practice of permitting defective cars to accumulate and making them up in a train for movement to a repair point is also condemned. Recently two suits were instituted against carriers for movement of trains of this nature.

The handling of logging trains is again referred to and the chief inspector states, in view of the conditions existing, the law should be amended by placing further restrictions upon the operation of such trains.

Mention is again made of the handling of trains down heavy grades by means of hand brakes supplemented by air brakes. Suits are being instituted for the purpose of compelling strict observance of the law. A statement is made that controlling trains by air brakes alone is the safer and better practice and is dependent merely on proper maintenance of air brake equipment. Defective hand brakes are also mentioned as the source of many suits.

Summary of Casualties

The casualties on steam railroads in connection with the operation of trains during the calendar year 1919 are summarized in the table shown on the following page.

In addition there were 483 persons killed and 96,452 injured in nontrain accidents during the year, in comparison with 589 killed and 110,431 injured during the previous year.

During the calendar year 1919 there were 108 employees killed and 1,975 injured in coupling or uncoupling locomotives or cars, as compared with 164 killed and 2,332 injured during 1918. Casualties to employees in 1919, due to coming in contact with fixed structures, resulted in 56 deaths and 1,009 injuries, the corresponding figures for 1918 being 83 and 1,367. In 1919 there were 97 employees killed and 6,219 injured in getting on or off cars or locomotives.

	Number of persons	
Class of persons	Killed	Injured
Trespassers	2,553	2,658
Employees	1,759	36,601
Passengers	273	7,456
Persons carried under contract, such as mail clerks, Pullman conductors, etc.	28	691
Other nontrespassers	1,882	5,195
Total of above classes	6,495	52,601

During the year ended June 30, 1920, 90 train accidents were investigated by this bureau, consisting of 58 collisions and 32 derailments. The collisions resulted in the death of 179 persons and the injury of 1,158 persons; the derailments resulted in the death of 60 persons and the injury of 481 persons, a total of 239 killed and 1,639 injured.

Investigation of Safety Devices

During the year tests were conducted of the device of the United States Train Signal Co., of Portland, Me. This device is an electropneumatic signal system providing means of transmitting signals between the cars and the locomotive in a train, and vice versa. It consists of electropneumatic valves controlled by a series circuit, one valve being installed in each car or locomotive cab, and provided with indicators, both audible and visual, which are operated when the circuit is interrupted; circuit controllers for operating the device are provided in each car and locomotive. The examination and tests of this device demonstrated that visual and audible signals, which are displayed and sounded simultaneously on each equipped vehicle, can be transmitted as rapidly as the circuit controller can be operated; and signals can be acknowledged by engine crew or transmitted from engine crew to train crew without the use of the locomotive whistle.

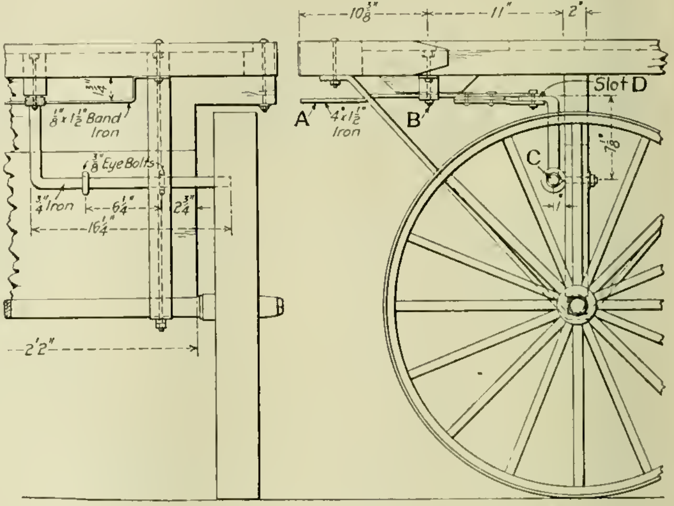
An inspection has been made and demonstrations witnessed of the automatic connector of the Robinson Connector Co., New York, N. Y., as installed on passenger equipment of the New York Central operating between Dunkirk, N. Y., and Titusville, Pa. This connector is of the butt face, straight port type, with wing type guiding members, which form the gathering and registering devices. As a result of the inspections and demonstrations of this device, the Robinson connector is considered well adapted to accomplish its intended functions when used on passenger-train equipment. The few irregularities of operation noted during these demonstrations were without exception due to details of construction and installation which can readily be improved. The use of gaskets of special design is undesirable from an operating standpoint. It is believed the gathering range and registering means employed by this device are adequate and reliable and that with this connector tight joints can be maintained.

Preliminary steps have been taken and plans are being formulated for the administration of section 26 of the interstate commerce act, conferring upon the commission authority to require the use of automatic train stop or train control devices and other safety devices in designated locations and to prescribe specifications and requirements therefor.

The report includes the usual tabulation showing the results of the inspection of safety appliances and tests of air brakes on trains arriving at and departing from terminals. Numerous judicial interpretations of the safety appliance law are summarized in the report.

Locking Device Applied to Station Baggage Trucks

It occasionally happens that baggage trucks when left on slight inclines start of their own accord and occasion more or less damage by running into and injuring passengers. Sometimes trucks are started unintentionally by persons bumping into them. To prevent the possibility of accidental starting, a locking device has been developed and put into use on baggage trucks on the Chicago, Milwaukee & St. Paul. A sketch of the detailed application of this device is shown in the illustration. The lock *C* consists of a piece of ¾-in. round iron, bent at right angles and guided by two ⅜-in. eye bolts. In order to lock the truck this iron is extended between the wheel spokes, and when moved back out of the way the truck is unlocked and free to move. Movement of the locking bar *C* is controlled by the handle *A*, pivoted at *B*. The slot *D* prevents any binding action and the handle *A* moves freely when it is desired to lock or unlock the truck. The handle *A* is supported by and slides on a band of ⅛-in. by 1½-in. iron. The entire locking device is under the truck, out of the way, and has proved most efficient for the purpose for which it was designed.



Locking Device Applied to Chicago, Milwaukee & St. Paul Baggage Trucks

An Efficient Car Straightening Frame

Counterweighted Jacking Beams, Power Jack and Winch Facilitate Work on Steel Cars

BENT end sills, bulged sides, damaged corners and buckled cars are bugbears for shops that repair steel freight equipment. Sledging or jacking the parts into position involves much hard work and oftentimes an indifferent job results. Jacking frames are now widely used for stresses when pulling or jacking with the car blocked against the frame. A general view of the stall is shown in Fig. 1 while Fig. 4 shows the details of the structural work. Figs. 5 and 6 show the appliance used for straightening by means of an air motor which forms the unusual feature of this installation. In straightening the bent parts of cars, the jacks or blocks are placed against movable horizontal jack beams.

Fig. 1—Jacking Stall at Avis Shops, Showing Jacking Bars and Power Operated Jack

this class of work and with good success. To facilitate the operations performed with this appliance, N. B. Messimer, superintendent of the Avis, Pa., shops of the New York Central, devised an ingenious arrangement for using a power jack.

Fig. 2—A Badly Buckled Car as Received for Repairs

Fig. 3—Car Shown in Fig. 2 After Being Straightened

The jacking stall itself consists essentially of a structural steel framework of sufficient strength to withstand the

The side jack beams are made of two 8 in., 16.75 lb. channels riveted to spacing blocks, each of which has a 1¾ in. rod extending between the vertical posts. By tightening the nuts extending between the vertical posts of the jacking frame.

on these rods, the jack beams can be securely held in position. The end jack beams are of similar design; but since the distance between the center of the posts is greater, they are made of 10 in., 30 lb. channels. Each jack beam is counterbalanced by two weights attached to wire ropes which pass over sheaves keyed to a 1¾ in. shaft mounted above the top tie beam as shown in Fig. 4. This facilitates raising or lowering the jack beam and keeps it horizontal.

On the jack beam is mounted a pneumatically operated jack as shown in Figs. 5 and 6. This consists of a train of gears driven by an air motor and operating a large gear having a recess in the hub for a 1½ in. hexagon nut and a two-inch hole through the center of the gear. A threaded keybolt is passed through the gear and between the two channels of the jack beam. Various hooks for reaching across the car, around end stakes, end sills, etc., are readily attached to the end of the keybolt by a loose key, after which the nut is inserted in the recess in the jack gear.

The frame holding the jack gears is fitted with rollers which run on the upper flange of the jack beam and clamps by which it can be locked to the lower flange. In straightening the cars, the jack beam is placed adjacent to the part where the stress is to be applied and it is blocked in such a manner that by pulling with the power jack, the part can be straightened. Journal jacks are often used for blocking the cars and these have lugs welded to the base by which they are held to the jack beams.

Bad kinks, as for example a crumpled corner, require heating, after a strain has been imposed, to insure a good smooth job. The majority of straightening, however, can be done cold by properly blocking the car or portion of the car being worked upon and then pulling with the motor gear box or jacking with ratchet jacks.

That this car straightening jack will take care of the big job as well as the small kinks is evidenced by the repairs to a steel gondola which was badly buckled in a wreck. This gondola (Fig. 2) was placed upside down on a pair of trucks for convenience in working and run into the straightening

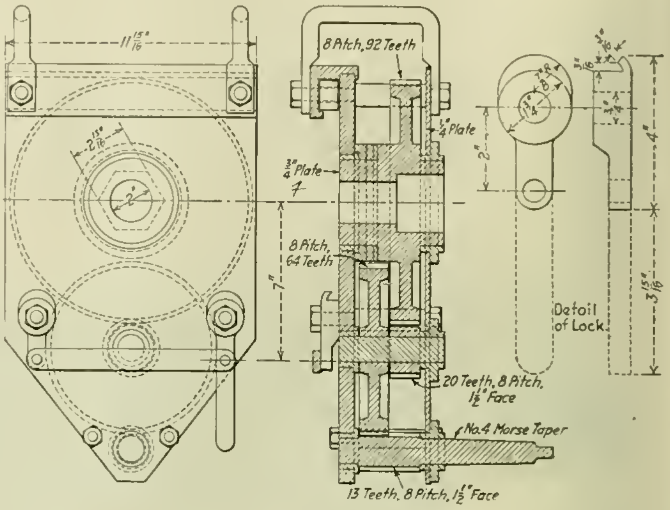

Fig. 5—Details of the Jack Gear

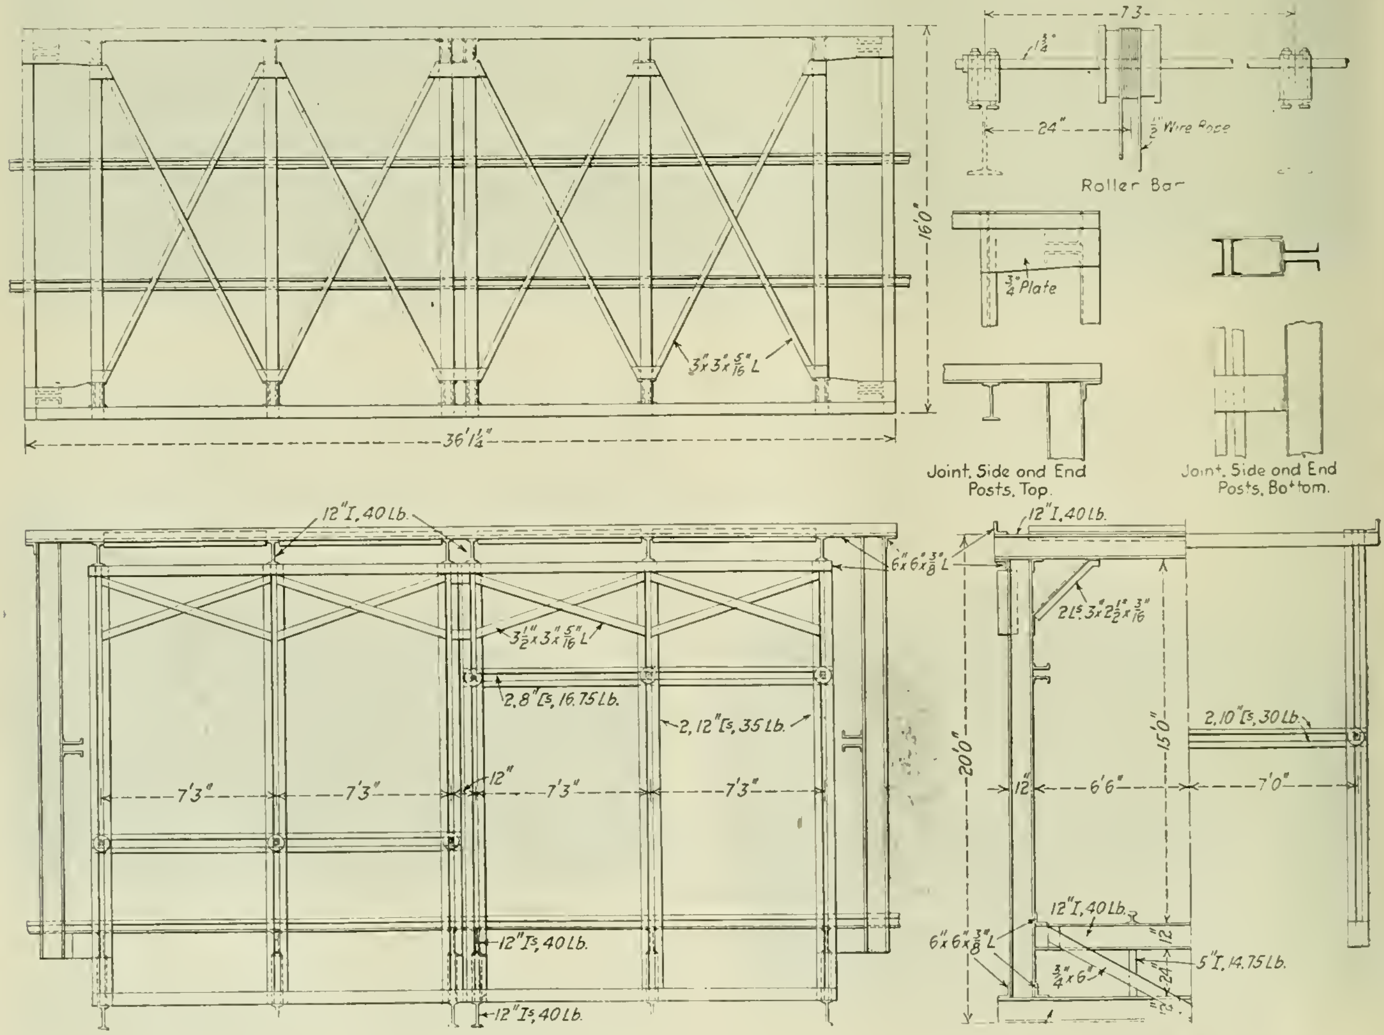

Fig. 4—Assembly Drawing of Jacking Stall Showing Arrangement of Structural Steel Parts

frame. The car straightened and ready for service is shown in Fig. 3. Close inspection will show the reinforcing angle along the top of the side, the use of which has been found to be advisable in stiffening a badly crumpled sheet. While this method of straightening avoids the bad effects of heating sheets, a sheet that has been bent is not as stiff or strong as the original plate; consequently, this stiffening angle is often added after straightening.

Fig. 6—Power Jack in Position to Straighten the Side of a Hopper Car

An interesting device used in connection with the jacking frame is the motor winch shown in Fig. 7. This is located beside the track at the end of the stall and is used to pull cars by means of a rope passing around a sheave which is driven through gearing by an air motor.

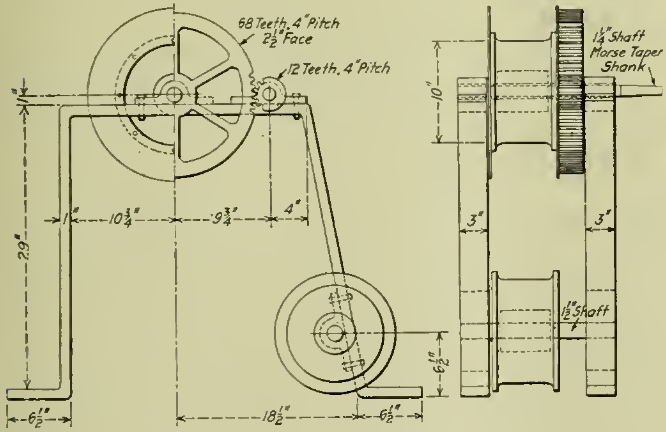

Fig. 7—Winch for Pulling Cars Operated by Air Motor

Preventing Theft from Freight Cars.—There is one thing that would help to reduce theft and that is to make it physically hard to break into cars. The seal we put on a car door offers no resistance. The morale of the people who pilfer cars is not such as to deter them with merely a seal and, therefore, it would seem that physical resistance to their entrance to the car would offer us the greatest amount of protection.—*D. R. MacBain, before the Western Railway Club.*

Lubrication of Freight and Passenger Equipment*

BY M. J. O'CONNOR
Mechanical Inspector, New York Central

The subject assigned the speaker is fully realized as one of the most important subjects that the railroads have to contend with at the present time, and one of the most expensive in the operation of their trains, both passenger and freight. My experience as a special lubrication inspector for the past twelve years with the New York Central Lines, leads me to believe that we should not take any radical action in the handling of lubrication without careful and due consideration, especially after we have proven that the methods shown to be satisfactory are in vogue.

The practices of the trunk lines that I have the honor to represent are more or less, briefly speaking, as follows:—The journal box packing used by our company is prepared on a standard 48 hr. basis for saturation. The equipment used in connection with this material consists of metal tanks equipped with screens located about two inches from the bottom and is fitted with 1¼-in. faucets which are used in draining off the surplus oil which is placed in the tank during the process of saturation. For example, we place 50 lb. of dry waste in the tank and submerge same in 60 gallons of oil. After same is thoroughly saturated in accordance with our standard practice, we drain off 35 gallons of oil, thus leaving 25 gallons of oil, or four pints of oil for each pound of dry waste so saturated. The draining off of this surplus oil automatically makes the preparation tank a storage tank and the faucet is then used for drawing off the oil that settles in the bottom of the tank. This oil is poured over the packing several times daily until all of the material is used. By this method, we are reasonably sure that such packing contains four pints of oil to each pound of waste when placed in journal boxes under cars.

It is not our custom to use any free oil in the handling of freight trains as prepared packing is used almost exclusively in shops, terminals and enroute in trains.

The packing that we use and from which excellent results have been obtained, also a much better service performance, consists of a cotton-wool mixture, which is our standard journal box packing at the present time. Briefly outlined the reason for favoring the combined cotton-wool preparation, is the fact that our men know at all times when adjusting the packing in the boxes on cars in trains whether or not it is carrying sufficient oil, which cannot be determined with the all-wool waste so readily, for the reason that the wool waste will not hold the oil in suspension, thus depriving the metal of the proper lubrication that the combined cotton-wool waste gives it on the start.

Many papers have been prepared on this most important subject, and the idea is that the discussion will bring out many points of interest that I shall be very glad to reply to when propounded.

The mileage on the system that I represent runs on an average as follows:

Freight—31,000 miles per car per hot box for the year 1919.

Passenger—170,000 miles per car per hot box for the year 1919.

The figures shown for the passenger performance represents mileage on the very highest class of trains. The service performance on our local passenger trains was still better and averaged more than 650,000 miles per car per hot box during the year 1919.

With reference to the freight car performance, we averaged approximately one hot box on less than one-quarter of one per cent of the cars handled during the year 1919.

---

*A paper presented at the convention of the Chief Interchange Car Inspectors' and Car Foremen's Association.

I sincerely hope that the points brought out fully meet the question and will cause an extensive discussion for the welfare of the service throughout the United States and Canada.

Discussion

B. F. Patram (Southern): We have what we term standard saturation tanks, with faucets. We have a tank that holds 50 lb. of dry waste which is saturated with 60 gallons of oil. We leave it for 48 hours or longer, sometimes a week, then draw off 35 gallons of the oil. As the material is used the effort is made to maintain the proportion of four pounds of oil to one pound of waste.

T. S. Cheadle: What is done in reference to conserving the portion that is taken out on the repair track? Do you make any preparation to save it and bring it into a reclaiming plant? All packing removed from the boxes is put into a bucket, whether out on the line or in the shop. We have a form submitted each month. If we send to the station 600 lb. of packing, the report the first of the month shows that on one side and we show the amount of material disbursed or delivered. We have a column on the opposite side that shows the amount received and if we do not get back at least 75 per cent of the amount that we send out, we immediately get on the job and find out why.

A Member: How do you arrive at the average mileage per hot box? I understood one man to say they got 31,000 miles per hot box. How do you get the data from the various divisions and how are the reports made? What are hot boxes, when they are smoking or when they are blazing?

M. J. O'Connor: This performance record was based on any car that was rebrassed or repacked, whether it caused a detention of the train on arrival at the terminal or not. If we have to base that on failures, our performance would be nearly 60,000 miles.

B. F. Patram: There was a lively discussion at the A. R. A. convention about using a plug of waste in front of the journal or having it just packed flush with the end of the journal.

M. J. O'Connor: The standard practice on the railroad I am connected with is to leave out the so called plug. There has been a lot of agitation about the front plug. One fellow says if you do not put the plug in the front, you cannot keep the packing in behind the journal. The proper method is to place the roll in the back of the box and work it up evenly so that you do not have it up on one side more than on the other. It is there better to exclude the dirt. It is a very important thing and it is a hard matter to maintain when you have trouble out on the road. The proper method is to pack boxes so that there is a continuous feeding of the packing, so that when it is in, it is practically all in one piece. If it is put in properly, the only lateral play you will have, is the distance between the end of the journal bearing and the inside face of the journal. If it does extend out a little, after the car has gone over the division and shows indication at the next terminal point of working out, the car oiler, or whoever is looking after the journal boxes, knows that. If you have a plug in front, he does not know it. The only indication you have is when the collar of the journal has worked out into the packing. I know it will not work out sufficiently to cause any trouble. When we began the method of packing boxes by eliminating the front plug, we started it out on the very best trains.

T. J. O'Donnell: Do you feel that a practical lubrication man riding the trains is an advantage?

M. J. O'Connor: Absolutely. We are going to get more cars over the road with less cut-offs. It was really a matter of education to the men. If something happened and the car man was not at fault they might try to blame him just the same. In traveling around the very fact that you recognize his little complaints increases the co-operation. A man out on the road is of great benefit to the department, if nothing more or less than in the matter of education.

T. S. Cheadle: As I understand you pack without a front plug. When a car comes to you with a front plug in there, do you take it out?

M. J. O'Connor: No, not unless we change the wheels or bearings.

T. S. Cheadle: Lack of uniformity is giving us considerable trouble. The inspector cannot tell whether it is there for the purpose of forming a front plug. I do not think we can get much improvement until we have a uniform practice. I believe a letter ballot should be taken.

A Member: What system have you for treating hot boxes when delivered in interchange? At the point of interchange do you take care of the boxes immediately, or do you allow them to cool off?

M. J. O'Connor: The cars received in interchange are marked to the repair track. It is our practice in the terminals not to allow the men to use their own judgment.

C. E. LaMontagne (Rutland): We ran into quite an epidemic of cut journals at one of our interchange points in connection with your road, and I think the matter can be overcome if these boxes are treated, and a little oil or new waste applied to keep the journals from cutting, which is very expensive.

M. J. O'Connor: It is my opinion that where a journal becomes hot to the extent of blazing, there is no question about its being cut. Some roads cool it and pack it and hand it on to the other fellow. Let the man get that car in its original condition.

A. Kipp (N. Y. O. & W.): I understand Mr. O'Connor to say that they have two systems on the N. Y. C. of treating boxes: If a car comes in that had a plug in it, they put in a plug; if they didn't have a plug, they packed it without a plug. Do I understand correctly?

M. J. O'Connor: No. The question was: "Do we remove the plugs?" and I said "No." But if we change the wheels on a car or rebrass a car, we will not put the plug back in there.

C. E. LaMontagne: If a car delivered into a train from one connection to another has a hot box, don't you think that the box ought to get immediate attention?

T. J. O'Donnell: If we deliver 50 cars across the dead line to the delivering line and there is a car blazing, the car will be on the repair track in an hour and a half. That is the attention we give it.

C. E. LaMontagne: The point I was getting at is not to have the cars switching around.

T. J. O'Donnell: In our district it is all receiving line inspection.

C. E. LaMontagne: Couldn't a lot of these cut journals be eliminated if the boxes were taken care of at the time of delivery?

M. J. O'Connor: No, for the reason that the movement does not amount to anything. That condition exists when the car moves in the terminal.

G. Lynch: I would like to ask Mr. O'Connor if there is any attempt at uniformity of practice in packing boxes, and what he would propose as the best method.

M. J. O'Connor: There are representatives here of a few railroads that are packing boxes along the line that is standard with the New York Central. I think I outlined the method they considered proper; that is, placing the roll in the back of the box and feeding the packing in, not rolling it on the side. Some do not put any roll in the back at all. Then the box packer reaches down in a bucket and takes a handful and shoves that back, and he keeps on until he has the box packed in sections. The result is, if you have any lateral, which you have in most all boxes, the piece becomes dislodged and twists the next piece, and so on. How many men here have seen where lids were forced open? If it is packed in in a continuous strand, knitted together, you will never have that condition. That is a hard thing to accomplish. I am after that day after day, particularly when we put on new men. That is the first thing I look for. It is my duty to instruct them. In that way we have uniformity, and everybody in the car department, from the superintendent down to the doper, takes an interest in it.

G. Lynch: The important question is to get uniformity of practice on all railroads. I find there is nothing but individual practice, and I wonder if it would not be practicable to incorporate a rule in the book of rules, making it compulsory to pack in a certain way, whichever way it is decided best. I think your paper is very fine and your explanations good, but we have no uniform practice on the railroads. All of the railroads in the A. R. A. should get together and adopt some method.

M. J. O'Connor: That is one of the things I hoped somebody would talk about; that is the principal thing to do, and the other is a method of reclaiming journal box packing. The railroad I am connected with has spent thousands of dollars installing reclamation plants at central points to cover certain territories. The reclamation of packing answers two purposes. In the first place if a man reports to his general foreman "We repacked 90 cars last month, periodical packing and stencil," you will use in packing 90 cars, about 9,000 lb. of material, it runs about 100 lb. per car. If that man hasn't used 9,000 lb. of that material, you then know that some of that material removed was not sent in to be reclaimed. It is a check on the work and it also insures better service.

Mr. O'Donnell said on arrival in the terminal that an inspection was made for safety appliances. The car would then go possibly 15 miles to a receiving line, and it would then be given an inspection. On a car coming in with a box smoking pretty badly, the journal bearing ought to be changed if it must be done, in four or five hours. It is cool and may run over fifteen miles, but when it gets on the main line, the journal will be cut.

T. J. O'Donnell: You might just as well stop every 15 miles on a 100 mile division and poke your hook in the box. If the box is blazing, we will get it on the delivering line. What is the use of holding the train up?

A Member: The car doesn't have to be blazing to have a cut journal in the terminal before it is delivered to the connecting line.

T. J. O'Donnell: You do not see a blazing car going across a dead line once in two weeks. If you have a meat car it will be shipped across to the other fellow.

A Member: Is the use of free oil entirely eliminated on the New York Central or have the men access to it at certain interchange lines where you receive high class freight? Do you allow the use of oil at points where they receive meat cars in interchange? What method is used in taking care of these boxes?

M. J. O'Connor: We do not use any free oil on freight cars. The last place that was used was at Sixty-third street in Chicago.

T. S. Cheadle: Is it the fault of lubrication or the fault of the mechanical conditions of the brake that causes hot boxes?

M. J. O'Connor: Quite a percentage of hot boxes are due to mechanical defects. Some roads apply journals with white lead on them. One of the worst conditions is the hollow journal bearing wedge. We destroy thousands of these hollow back wedges when we find them worn flat. Wedges are supposed to have 1/16 in. crown at the top. The function it performs is to distribute the load evenly to the bearing. If some of the other railroads will get after it as we have, we will have less hot boxes.

G. Lynch: When a wedge is worn, do you have it replaced with a new wedge?

M. J. O'Connor: Yes, or a good second hand one.

G. Lynch: We have found that where the wedge is worn, and a new wedge applied, before the car runs 20 miles, that new wedge is often broken because of the uneven bearing, due to the worn condition of the box. Under such conditions the box should be examined to see what condition the roof is in and if worn badly, the box should also be removed and a new one applied with the new wedge.

M. J. O'Connor: The boxes that you have reference to have had a wedge in with four pockets, some with two pockets, and instead of having 1/16 in. crown spread over the entire radius of the wedge, you have only that little bar. That is what wears the roof of the box. Where a solid wedge with a steel back is used I have never yet found them broken. Our standard is the solid back wedge and has been for three years.

A Member: Does the New York Central line confine the use of reclaimed packing entirely to its own cars? In repacking passenger cars do you use reclaimed packing?

M. J. O'Connor: Reclaimed packing is used on passenger cars the same as on freight. We found out when we had a high grade wool waste, it would not hold oil in suspension, particularly if the strands were more than 14 or 18 in. in length. With new waste, heat is required to saturate the oil.

A. J. Baumbush (N. Y. C.): At Grand Central Terminal we noticed that all of the boxes that were packed with new long wool waste were running hot. We tried using half cotton and half wool waste and found the journals ran cool. We are taking half wool and half cotton now, the majority new waste mixed in with the old. Our hot box trouble at Grand Central Terminal is almost gone. We do experience some hot box trouble when we do not catch them in time. The majority of the trouble is with cracked linings.

It is important for the car packer to use a knife on both sides of the box to crowd the loose ends down because when the brakes are applied, the journal picks up the loose ends. I guarantee if you leave the front plug out and the journal is all right, you will not have any hot boxes.

Mr. Clair: I have spent the last seven years to determine the best method of lubricating journals. I visited the railway waste plants throughout the country, with a view to getting journal box packing up to specifications. Unfortunately, it is a fact that the personal element enters into it and we have never been able to get a standard journal box packing. An honest endeavor was made to standardize the journal box packing. The problem was whether it would be cotton or wool or a mixture of both, which meant that some grades should be eliminated—these things which enter into journal box packing under the guise of waste materials.

Cotton and wool are considered to be the essential elements that might enter into the thread and yet there are many railroads calling for one hundred per cent wool and material is being accepted when there isn't one atom of wool in it. Often in treating waste to find out how much wool there is in it, everything in the shape of animal matter is credited as wool. There are some specifications which call for all wool waste long threaded stock. The threads might have been two miles in length if they were spun for journal box packing. It is bought for wool but it is cattle hair and steer hair, with nothing to bind the materials together except fuel oil. The hair that comes off of the back of sheep runs in lengths from two to ten inches and that is what you want in journal box packing. You do not want long threads, but you do need long staples. Sheep wool is covered with minute scales, similar to the back of a fish. When they are spun together they form a thread and if you take the thread and endeavor to separate it, you will find that it holds together. If you take the so-called red yarn and pull it apart, you will find the staples in the spinning similar to that spun with fuel oil which is worth two cents a pound for journal box packing.

The journal box packing should be cotton or wool, or something mixed together; it should be certain grades of cotton and certain grades of wool; not all good but there should be nothing put in there that was not calculated to lubricate the journal. We refused muck yarn, but after it was dyed red and filled with mineral matter it was accepted. The reason that the long threads of wool did not function in our boxes, is that they were not wool and were filled with a mineral dye to make them look better. Two years and a half ago, we got 200,000 lb. of cotton, and found that it had been loaded with water glass or sodium silicate. The staples are bound together with starch in order to weave sheets. When potatoes rose in price, water glass was substituted and that was the material that was entering into practically all journal box packing.

It is well to understand the journal box packing that you are getting. Some of the waste industries are nothing more than rag industries. There is one concern that takes old felt hats and that refuse goes into journal box packing. Until the United States Railroad Administration undertook to define these particular things which should not enter into journal box packing, they tried to eliminate them by stating that packing should be true fleece wool. Leave it up to your inspectors to go into the mill and analyze the material to see that it is true fleece wool. Material that comes in such long threads is not waste material. It is hair taken off the backs of cattle and spun for journal box packing. If you take the oil out of it, you will find it is a decidedly choppy mass of hair.

It is necessary to take such materials as can be produced in quantities. A proper source of material would be mills that weave overcoats, blankets, carpets and some tapestry. A source of materials for the cotton should be confined strictly to mills that produce shirting and some of the high grade linens. The cheap American cotton cannot be produced without putting potato starch in. Avoid the use of jute absolutely and specifically. The cheap grades of carpet are made out of jute and when treated it rots and becomes a powder. The shredded stock is used in order to cheapen it and it is well to get away from it.

I believe the day is not long distant when each and every railroad will honestly say to itself, "When we buy cheap materials for journal box packing, it would be better if we would adopt some standard, all good wool or all good cotton. Let it remain a waste problem but let everyone for once and all decide what it is which constitutes a standard journal box packing."

There are some roads that pay 30 cents a pound for journal box packing; it is not worth it. The cotton that enters into an honest journal box packing is worth 14 cents a pound, and when material sells for 10 cents, you will find that it is sweepings. That was my experience after having made a study of what honestly would constitute journal box packing of good quality that might be produced in a tremendous volume and uniform quality.

Mr. Geiser made some good tests. They were able to calculate how much oil was necessary to lubricate a journal, and it only took 5 per cent of the oil that was in the waste. We were looking for a journal box that would hold four pounds of oil per packing; it was too much. There are those who say the use of free oil is improper. They think they save money by not using oil and they do not think they pay 15 or 10 cents for the waste and burn it up without securing lubrication.

Reclaiming pays but not the reclamation that necessitates the erection of a $10,000 building with its equipment. But the conservation of waste material when you take out good journal box packing that is not all choppy, and shake the dirt out of it, if there is any in it, saturate in oil and put it back into the box is a good thing. But in the reclamation that necessitates some one saving it, it does not pay. If it is good waste it is fit to go back into the box. If it is bad waste, it ought to be destroyed right there. There is lots of money wasted by saving bad waste. Today waste is billed in accordance with the specifications that the threads should be clean, long, strong, true fleece wool. Other specifications say it must be long strands, none shorter than 18 in. in length. Good wool comes from mills and is honest waste material. The stuff that is long is not waste. It is spun for journal boxes; it looks good but you will find it is not at all satisfactory.

Another peculiar thing is that wool is necessary. Wool does not lubricate; it is cotton that lubricates, but it has to be good cotton. If it is foreign it is better. The test of the thread that enters into a journal box packing should be its fineness. When the staples are long you can spin the thread as fine as a needle and that is good. When the thread is thick the staples are short, and that is bad material. It is true of cotton, a thread spun 120 will not measure over 0.003 in. in diameter, but it is good cotton. The test of high quality is not length; if other things are equal, it is thinness of thread.

Another thing that serves no function is the flyings. There is no reason why anybody should take anything that looks like feathers and mix it in a journal box. If your specifications insist on cheap material, you have got to go to the cotton mills and buy the sweepings from the floor for 3½ cents a pound and introduce it into the journal box packing in order to sell it. It will require 2½ lb. for a journal box of 3½ cent cotton. It is cheaper to use the cotton than wool. Your journal box packing costs 15 cents and the lubricating oil is worth about 2 cents, and if you are not careful you will get 10 per cent lubricating packing; you do not get packing, you get oil. Look out for the waste that is saturated with oil. The functions of the journal box packing are first to hold the oil and then to feed it.

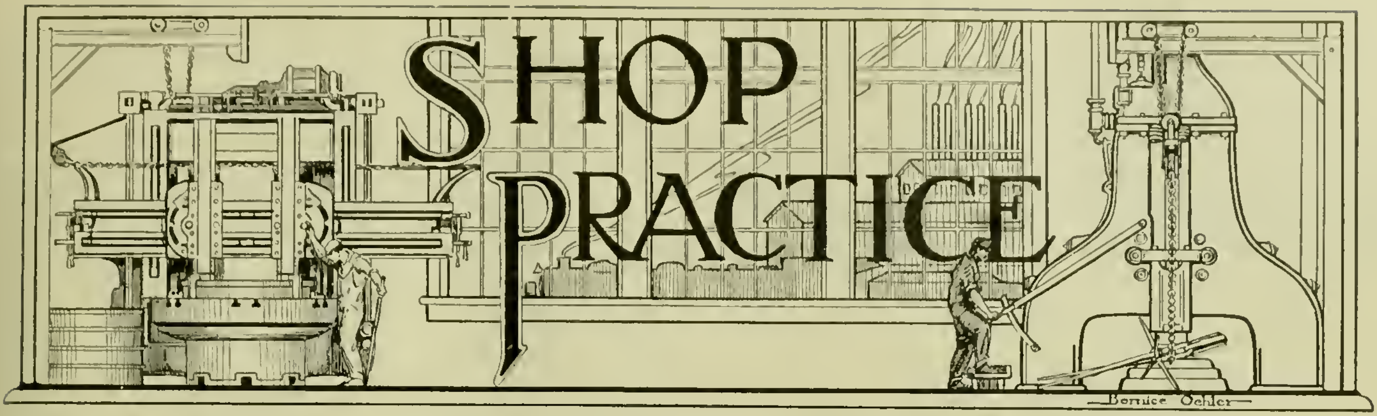
Cotton and wool combined do not afford elasticity to overcome the shocks and keep it up against the journal; you have got to impart some elasticity.

The best method of packing journal boxes in my mind is twist a rope and put it back against the mud guard, and put the biggest wad of packing that you can get in that box; take these threads and fold them over and under and put one piece of journal box packing in the box. The use of the plug is a disputable thing. If there is no plug in the front, the face of the journal will present one thing in vision; if the box is running hot the center of the journal will be dry. If there is a plug there you won't see whether the journal is running hot or not. Whether it is a good thing to offset your lateral motion, I do not know.

Avoid the use of what you call wipers. A piece of waste as big as an egg will wipe the oil off before the oil hits the brass. One little piece of waste improperly placed in that box will give trouble. Keep the little pieces of waste buried down; do not let them get on top of the journal box or there will be trouble.

F. W. Trapnell: This is a subject that has brought out a lot of discussion before in the A. R. A. convention, but I believe that those of us who are here have received more benefit from the discussion relative to the maintenance and packing of journal boxes that we ever got at Mechanical Section No. 3, because we have got right down to the ground floor of the work, as it ought to be done.

I am sure it is a pleasure to listen to Mr. Clair and to the reading of the paper by Mr. O'Connor. They have made it very plain and explicit to us. I move that a vote of thanks be extended to Mr. O'Connor and to Mr. Clair. (Seconded and carried.)



Belt Service and Length of Life

BY F. D. RICH

Sales Engineer, Crescent Belt Fastener Co., New York

Cutting the ends of a belt seems such a simple operation that often the belt man does not give it the consideration necessary to secure the best results, and much of the difficulty with otherwise good belts is due to their not being cut and joined accurately. With proper care, it is easy to make a belt joint which will run the same as an endless belt.

When a belt runs "wobbly" or races back and forth across the pulleys, it is not giving its best service nor can it have a long life. Power is lost and production limited.

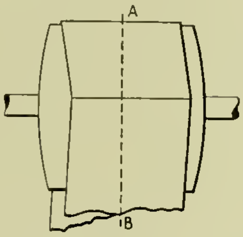


Fig. 1—A Belt Which Will Not Run True

Belt ends should always be cut to a line carefully laid out with a square. If a square is not used, one or both ends of the belt will be cut unevenly or irregularly, which prevents smooth running. Even the use of a straight edge does not assure the results obtained by using a square, for the slip of a fraction of an inch will bring the belt ends together at an angle, as shown in Fig. 1. As the belt moves from side to side, the line of direct pull, *A-B*, moves from one side of the belt to the other, imposing shifting and irregular strains, which no belt can stand indefinitely.

There is only one way to obtain correct results, which is to use a belt square and to keep it in place until the belt is cut all the way through. Cutting to the square assures an even cut all the way through the belt and all the way across. Then the belt ends can be brought together in a tight, but evenly running, flush joint. For belts up to 15 or 18 in. wide, the ordinary square can be used, pressed firmly against the edge of the belt with the knife held vertically. The knife should be sharp with the point wet occasionally in order to cut more easily. When a number of belts have to be cut, a good method is to drive two nails in a large block of wood, and against these set the edge of the belt and the edge of the square. This prevents either the belt or the square slipping.

Wide belts are more difficult to square correctly, and the difficulty is often increased by slight variations in width, which throws the square out. To avoid this and assure perfect results, the method illustrated in Fig. 2 has proved valuable. At any point near where the belt is to be cut, measure across and find the center, as at *A-A*. At any distance back of this, say, 2 or 3 ft., find the center again, as at *B-B*. Between the two center points draw a clean, sharp line, marking the center axis of the belt. Using the square against the center line, trim off the end of the belt, holding the square firmly in position. Two small nails driven in the center line will keep the square from slipping.

For cutting the other end of the belt, find the center line, as just described. At any point on this line other than where the belt clamps will come, take a point *C*, as in Fig. 2, and, using the square as illustrated, draw a line *D-C-B* at right angles to the axis, and all the way across from edge to edge. It is sometimes easier to draw this line by marking the points *D* and *B* and then placing a straight edge through the points *D-C-B* to draw the line. This line *D-C-B* will constitute a "base line" to measure from after the belt is in the clamps. Do not cut on this line.

The exact position where the belt is to be cut can be determined after the clamps have been put on and the belt brought into position. Measure forward from the line *D-B* an equal distance on each side of the belt to the cutting point, using calipers to measure over the belt clamp or running the ruler through the edges of the clamp. As a matter of convenience, always cut one end of the belt square and get it ready for making the joint before putting the belt into the clamp.

Remember that when doing a job, it is much easier to do it right than to do it over. This applies to making the completed joint as well as to cutting the belt. Therefore, it is best when joining a belt to do so in a way which is permanent and which assures the belt's most satisfactory service.

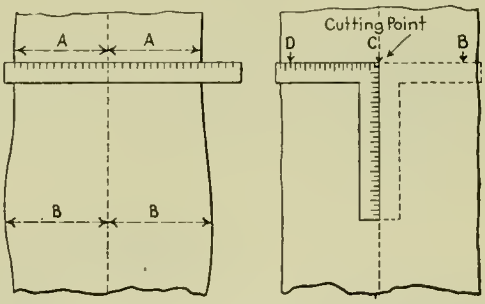

Fig. 2—Method of Squaring Uneven Belt

The writer has had considerable experience working with belting manufacturers in solving the problems of efficient belt joining, and is much opposed to methods which require punched holes in the belt or which in any way cut or weaken the lengthwise, power-carrying fibres of the belt. No belt can give better service than its method of joining will permit, and if wasteful or destructive means are employed, the strength of the belt is lessened, its service impaired and its life shortened. Laced belts are frequently found in which from 40 per cent to 70 per cent of the cross section of the belt is removed in punched holes. Such a belt joint cannot be expected to give the full service of the belt.

The ideal belt joint is one which would run the same as endless without the drawbacks of difficulty in making and later shortening to take up stretch. Belting manufacturers themselves estimate that only a small percentage of belts need to be made actually endless. Their estimates range from ½ of one per cent to two per cent. It is possible to make belt joints which run the same as an endless belt and which meet practically all requirements of the belting field, without having any of the objections noted above.

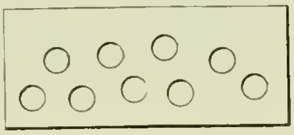

Fig. 3—Aggregate Amount Punched Out is 75 Per Cent of Total Cross Section

The accompanying list shows the qualifications of a belt joint, by which any engineer can check up the comparative efficiency of his own methods:

The Efficient Belt Joint

1—Will maintain the maximum strength of the belt.
2—Will avoid destruction or weakening of the lengthwise power-carrying belt fibres.
3—Should prevent breaking the belt back of the joint.
4—Must not hammer on the pulleys.
5—Must not be subject to wear or crystalization.
6—Will insure continuous, uninterrupted operation without supervision.
7—Hugs the pulleys tightly and assures full transmission of power.
8—Runs silently, the same as an endless belt.
9—Can be easily taken apart for removing or shortening the belt.
10—Is safe against accidents or breakdowns.
11—Must be easily and quickly made without special equipment.
12—Will last for the life of the belt.

The leading manufacturers of belt fasteners are always willing to give engineers full data regarding their products, and a check of the different methods against the qualifications above should enable any engineer to determine for himself which is going to assure getting the most satisfactory results and service from belting.

Limitations of Thermit Welding for Repairing Cast Iron

In a recent issue of Reactions the following explanation regarding the conditions governing the welding of cast iron by means of thermit is given:

In thermit welding, the superheated steel produced by the reaction, when tapped into the mold surrounding the weld, naturally fuses back into the fractured parts two or three inches on either side and the whole mass solidifying at one time effects the repair. The excess metal of the weld may then be removed or not as the necessity indicates.

In cast iron welding, steel is the welding medium and the weld material will, therefore, necessarily consist of a mixture of this steel and the cast iron of the parts being welded. The graphitic carbon in the cast iron, therefore, combines with the thermit steel, thus making a high carbon steel which usually can be machined only by grinding. This material, however, is not so brittle as cast iron and is physically stronger.

In the second place, in considering thermit repairs of cast iron, it should be borne in mind that the weld material is steel and, therefore, has double the shrinkage of the cast iron. This difference in shrinkage is of no importance where the section being welded is approximately square or equiaxed. However, where the length of the section at the fracture is four or five times its thickness, this difference in shrinkage is evidenced by one or more minute cracks perpendicular to the line of the weld and extending through the weld material only. These cracks are naturally caused by the difference in shrinkage, the cast iron parts tending to restrict the shrinkage of the thermit steel along the length of the piece. Such hairline cracks will be found in the welding of sections such as, for instance, 12 in. by 24 in., but would not be found in sections 12 in. by 12 in. The cracks are unimportant, as they are parallel to the line of strain.

Experience proves conclusively that where the length of a fracture is not more than four or five times its thickness and where the subsequent machining can be accomplished by grinding, a thermit weld can be made with entire success.

The Equalization of Spring Rigging

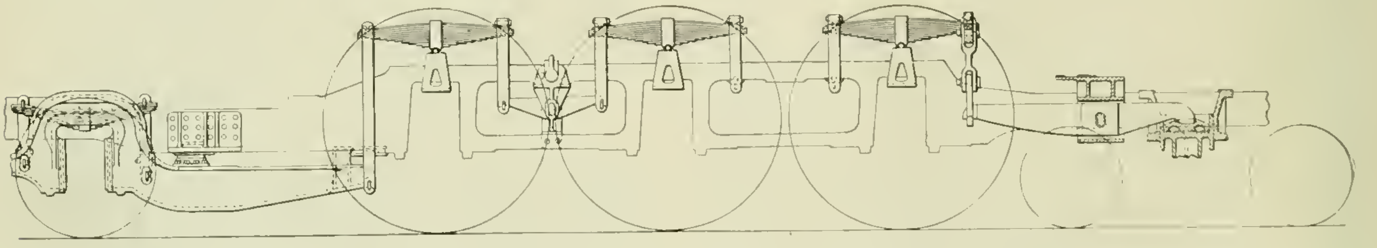
BY J. McALLISTER

General Foreman, West Albany Shops, New York Central

Because the springs and spring rigging used on a locomotive cannot be classed as motion work, there is a strong tendency to underestimate its importance and become careless in making necessary repairs and maintaining the dimensions called for by the blue prints. The improper equalization of springs and spring rigging has very serious effects, the most important of which, perhaps, is the resultant incorrect distribution of weight. This causes excessive pressure on certain bearings, which means that they will run hot and require new brasses frequently.

Hot bearings necessitate frequent repacking and oiling of boxes, wasting a large amount of oil. They also cause many engine failures and many stops to cool the boxes and repack the cellars. In more serious cases where the cutting action has gone on too long, new brasses must be applied to the driving boxes and the cut journals turned. In addition, hot bearings tend to make indifferent engine and train crews on account of the extra disagreeable work necessitated by cooling and repacking the boxes.

Improper spring equalization is caused by poor methods of repairing and assembling spring rigging. It is the usual practice to repair spring hangers to standard sizes. When a locomotive is being broken in, it is usually found too low and must be returned to the shop to be raised. This operation is performed by jacking up the locomotive, shortening a hanger here and there, putting a liner in the center casting, etc. This, of course, results in all idea of equalization being lost and puts excessive weight on one or more of the bear-



Elevation Showing Arrangement of Spring Rigging On Pacific Type Locomotive ings, causing them to run hot, which brings about the evils previously enumerated.

The very best engineering talent is employed in designing locomotives and it should be the aim when repairing them to perpetuate the designer's idea of the locomotive as a whole. To do this it is necessary to equalize springs by shortening the hangers to correspond with tire wear, for example:

The original thickness of the tire is 3½ in. and all parts of the spring rigging are made to blue print sizes. If the locomotive is shopped and the tires turned to 3 in. all spring hangers should be sent to the blacksmith shop and shortened ½ in. A ½-in. liner in the engine truck center casting and a ½-in. liner under the trailing springs will bring the locomotive to its original level.

It is well for the gang foreman to examine and measure the thickness of crown brasses before putting wheels under a locomotive. If one brass is found ⅛ in., for example, thinner than the other, a suitable liner should be placed under the spring saddle of that box. When spring rigging repairs are handled in this way, the designer's idea of equalization is maintained and hot bearings, with their attendant evils, are reduced to a minimum.

Standard Valve Motion Pins and Bushings

A Method of Standardizing, Manufacturing and Fitting Pins and Bushings in Locomotive Valve Gears

BY M. H. WILLIAMS

In certain central production shops of the larger railways, valve motion pins and bushings required for locomotive valve gear repairs are blanked out and finished to predetermined grade sizes. Surfaces, like the straight part of the pin and the bore of the bushing, are finished complete at the time of manufacture and do not require additional machining when being fitted to the levers. The taper ends of pins and the outer surfaces of bushings are made sufficiently large to admit of machining to such sizes as may be necessary to fit worn levers.

Important results have been made possible by a careful study of the requirements and standardization of the bearing surfaces in reference to each other so that they are interchangeable. For cases where the lever holes are greatly worn, the running fits also are standardized to grade sizes. That is, if the original size of the running fit of these pins and bushings is 1½ in., grade sizes are made 1 9/16 in., 1⅝ in., etc., or such sizes as may be necessary.

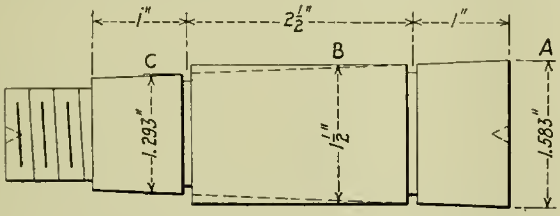


Fig. 1—Standard Pin With Taper of 1-In. per Foot

Standardization of Parts

On account of the many sizes of holes resulting from frequent reaming of the lever clevises, it is not generally considered desirable to make the taper ends of pins to finished sizes, but rather to blank them out, leaving sufficient metal for fitting at the time of application. In some cases the taper ends also are finished to grade sizes and both of these methods will be explained later.

With most designs of pins, especially where the taper is more than ¾ in. per foot, it is possible to increase the diameter of the taper ends somewhat more than called for on the locomotive drawings without encroaching on the straight surfaces. Where the rod clevises are greatly worn, however, it becomes necessary to enlarge the bearing surface and the bore size of the companion bushing which is done to grade sizes.

Grade sizes are determined in the following manner for the pin illustrated in Fig. 1. The ends have a taper of 1 in. per foot, the bearing surface *B*, being 1½ in. in diameter by 2½ in. long. The two ends are each 1 in. long. The size of the large end at *A* is shown as small as it may be made: 1.583 in. The diameter of the opposite end at *C* must correspondingly be 1.293 in. which agrees with the 1 in. per foot taper as shown by dotted lines. A pin made to these dimensions can be used in a bushing having a 1½ in. bore and admit of finishing the full length of the taper surfaces. If the tapers are smaller, the beginning of the large taper will be smaller than the bearing surface.

A pin of the greatest extreme of taper end sizes with the same bearing surface *B* is shown in Fig. 2. The small taper at *C* equals the 1½ in. bearing size. The head is shown enlarged to 1.790 in., which is the largest that may be used with a 1½ in. bushing. It is evident that to go to a larger taper end will result in not having a full taper end at *C*. Figs. 1 and 2 show the smallest and largest taper ends that can be used with a taper of 1 in. per foot in a 1½ in. bushing, 2½ in. long. The diameters of the taper ends and the grade sizes are calculated as follows: The taper per inch is obtained by dividing the taper per foot by 12 and is 0.083 in. This figure multiplied by the length gives the variation for any length or section of the pin. Likewise the taper per inch multiplied by the length of the bearing surface *B* will indicate the greatest difference in diameter possible between grade sizes. In Fig. 1, the diameter at *A* is the bearing size of 1½ in. plus the taper for 1 in. length, or 1½ in. + 0.083 in. = 1.583 in. In Fig. 2, the diameter at *A* is the taper calculated from the 1½ in. diameter at *C* which is 3½ × 0.083 in. + 1.500 in. = 1.790 in. These calculations are necessary in order to settle on the largest diameters to which the head end at *B* should be blanked out.

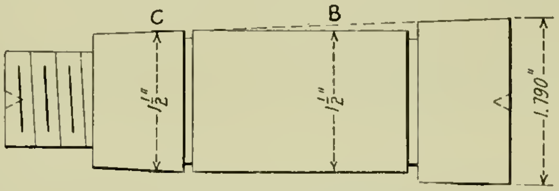

Fig. 2—Standard Pin With Greatest Extreme of Taper End Sizes

The maximum increase of grade sizes for pins having a bearing surface 2½ in. long will be 2½ × 0.083 in. = 0.207

in. It is evident that the second grade size of *B* can be 1.707 in.; the third 1.914 in., etc. From simple calculations of this nature grade sizes for any size and taper may be quickly calculated.

As a general proposition, the grade sizes of bearing surfaces *B* are calculated and tabulated or card indexed for all pins frequently used. One large shop advances the grade sizes by 1/16 in., that is, the pin bearing surfaces are made standard, 1/16 in. and ⅛ in. larger than standard which works out in a very satisfactory manner. The objection to too large an advance in grade sizes is the enlargement of the bushing bore which results in a thinner wall of that member.

Having determined the grade sizes, it is next necessary to set tolerances for bearing surfaces and the bore of bushings. There should be between 0.004 in. and 0.006 in. play between the pin and bushing when the two are in place, in order to allow for a running fit and flow of the oil. When pressing the bushing into the lever, the bore will be reduced about 0.002 in. to 0.004 in. depending on the thickness of the wall and the care with which the fit is made. Therefore, the bushing bore should be made about 0.008 in. larger than the pin.

When manufacturing, the taper ends are preferably blanked out as shown in Fig. 2 with the larger end of the smaller taper shown at *C*, equal in diameter to bearing surface *B*, the large end being the taper extended from *C* as determined by calculation and shown by dotted lines. From a manufacturing standpoint, it is an advantage where the sizes are standardized as the number of sizes will be reduced, consequently, the number of one size called for at one time will be increased to the point where they can profitably be made on automatic screw machines or turret lathes.

Blanking Out and Finishing Pins

No attempt will be made to explain, except in a general way, the machine operations employed when blanking out pins and bushings. They are generally made from hot rolled low carbon or screw machine stock, or some soft steel that is free turning and free threading. When manufacturing, the taper ends are rough machined to the approximate size, the threaded portion made to correct size and the holes for lathe centers drilled in the ends. In some cases a groove is made at each end of the bearing surface next to the tapers for clearance when grinding as shown in Figs. 1 and 2. The bearing surface that should be close to gage is machined about 0.020 in. large to admit of final finishing, as will be explained later. The threads are cut on a bolt threader, or in some cases this threading is done when blanking out. Holes for cotter keys or taper pins and spline keys are drilled with a drilling jig. The pins are in some cases used in a soft state with brass bushings. Where this is the practice, they are ground on the bearing surface *B* to the exact micrometer or gage sizes for which a limit is set that should not be more than 0.001 in. above or below the nominal size.

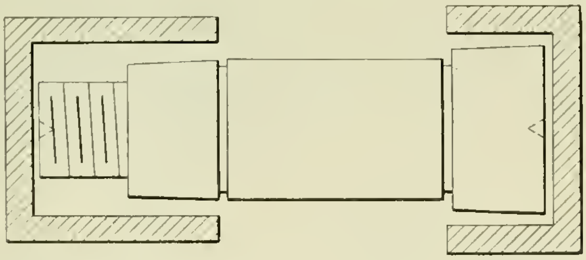

Fig. 3—Method of Protecting Ends When Case Hardening

Where pins are to be casehardened, it has been found good practice after blanking out to grind the bearing surface *B* previous to hardening about 0.010 in. larger than the final size required. This is done in order to true up this surface and correct errors resulting from the lathe centers not being true and to remove roughness left when blanking out.

The pins are now ready for casehardening, an operation governed by the machines available in shops where the pins are to be finally fitted to the levers. If grinding machines have been installed, the pins are casehardened all over except the threaded portion which is protected by covering with fire clay. If grinding machines have not been installed, one of two plans mentioned below is followed. First, the pins are carburized only. That is, the threaded end is protected as explained above, placed in the casehardening box and heated in the usual manner. When removed from the furnace the box and contents are allowed to cool and anneal. This results in a soft high carbon surface that may be machined when fitting to levers similar to annealed tool steel and may be turned as desired. Second, the threaded ends and also both taper ends may be covered with fire clay held in place by cast iron cups or gas pipe as shown in Fig. 3. Pins, cups and fire clay are then placed in the casehardening box, heated and quenched in the usual manner. This results in hard bearing surfaces and soft taper ends, and as a result the ends may be turned when fitting to the levers.

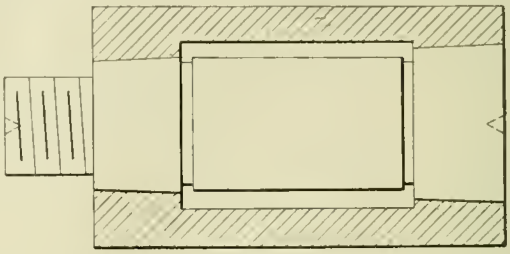

Fig. 4—Female Gage for Taper Ends

The bearing surfaces of pins that have been casehardened or carburized only are then returned to the central shop and ground on the bearing surface to exact gage sizes as explained in connection with soft pins. In some cases, this practice is modified by grinding the taper ends to grade sizes that may vary by 1/64 in., 1/32 in., etc., the ends being carefully fitted to taper female gages as shown in Fig. 4. After completion by either of these methods, the pins are placed in stock.

Blanking Out Bushings and Fitting to Rods

Bushings are made from the same material as the pins, in automatic screw machines, the holes being drilled and reamed about 0.010 in. small to allow for final grinding. The outside is rough machined to such sizes as may have been set when standardizing these parts. The oil holes are drilled and the oil ways milled, after which they are casehardened or carburized by one of the methods that have been explained for hardening pins. The bore is ground to plug gage sizes that should not vary more than 0.001 in. from set sizes. The diameter of bore at this grinding is made 0.008 in. larger than the pin bearing size. If grinding machines are not available for machining the outside of the bushings, they are carburized as explained in connection with pins, the bore being ground to gage size and placed in stock.

A flat gage, as shown in Fig. 5, has proved very useful for checking the accuracy of the taper reaming of clevises and also for measuring the diameter of holes at any point. The gage is made of hardened steel about ¼ in. thick, the edges fitting the taper holes being ground on centers similar to the practice when grinding cylindrical gages. One side of the gage is graduated, each line marked with figures indicating the exact diameter at that point.

Pins and bushings made as above explained in the central production shop are finished on the bearing surfaces and the final work is confined to machining the taper ends of pins and the outsides of bushings. When measuring the diameter of clevis taper holes, the graduation nearest the inside of the smaller jaw is usually read. This point is chosen because it is desirable that the shoulder on a taper pin shall stand away a small amount from the clevis to allow for drawing up when wear takes place. Also in the event of the width of clevises not being correct, the error will not affect the fitting of the pin at this point. Should the hole be irregular, the gage will show the error, in which event, the lever is reamed just enough to true up or to reduce to gage sizes according to the method used when fitting the pins.

Grinding Taper Ends

By the use of suitable cylindrical grinding machines, the taper ends of pins are ground to fit the different sized holes found in repaired levers in from 10 to 15 minutes. The pins while being ground are driven from the threaded end, a method which admits of finishing both ends without reversing the pin in the machine. The machine table is set to the correct taper after one or more trials, and when once set, any number of pins of the same taper may be ground without resetting.

The exact diameter in thousandths required is read from the taper gage as shown in Fig. 5. In order that the pin shall fit properly, the diameter of the taper at that point must be the same as indicated on the gage. When grinding, the pin is measured over the taper as shown at *C*, Fig. 6, with micrometer calipers and finished to a size agreeing with that read on the gage. This measurement is readily made where a groove has been made in the pin as shown.

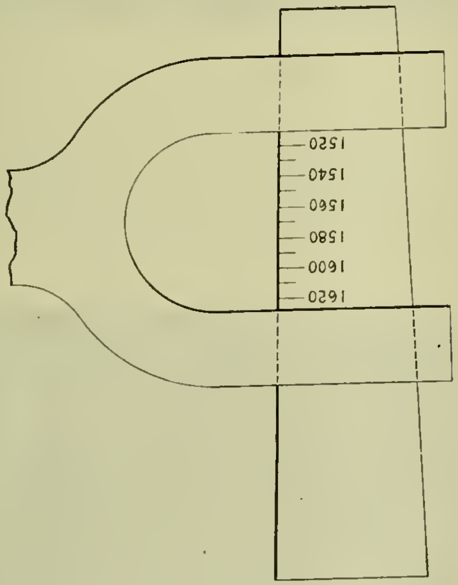

Fig. 5—Flat Gage for Checking Accuracy of Taper Reaming

When the smaller taper has been ground to the proper size, the micrometer-dial or throw-out on the grinding machine governing the in-feed of the grinding wheel is set. The wheel is then transferred to the large taper end and the wheel fed in to the same marking or setting of the throw-out stop used for the small end. This results in the two ends having the same taper and the pin will generally fit the lever at the first trial. Errors may result from the spring of the machine, or the personal equation, but with an operator who has had practice, about 75 per cent of the pins will fit at the first trial. The grinding machine should be one of the larger sizes and have the necessary weight and stiffness in order that the grinding wheel shall not spring away from the work when grinding the two ends.

A grinding wheel as thick as the length of the taper ends is fed directly onto the work and not traversed. Where the wheel is kept true by occasionally passing a diamond over the surface, this method has been found quicker than traversing the wheel.

Where soft pins are machined on lathes, the same general plan is followed. If the pins have had selective case-hardening, they will be completed in this operation and can be placed in service.

Where pins are carburized only, they are fitted in a similar manner and hardened, after which with a slight rubbing up of the bearing surface, they are ready for service.

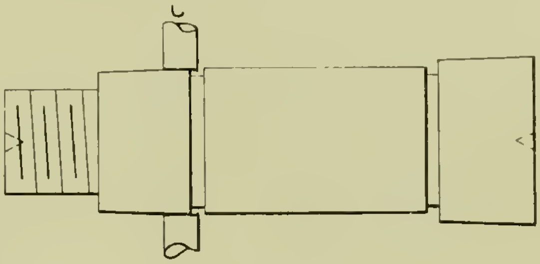

Fig. 6—Position of Micrometer Calipers in Measuring Largest Taper Diameter

In order that the bushings previously ground in the bore shall not be distorted when forced into levers, it is necessary that the lever holes be trued up by grinding on a planetary grinding machine such as that made by the Heald Machine Company or by reaming. The bushings are ground on the outside from 0.004 in. to 0.005 in. larger than lever holes and forced into place. Should it happen that the taper holes in clevises have been enlarged so that the smaller or new size pins and bushings will not answer, the next larger size is used.

Advantages of Grade Sizes

Making pins and bushings as above explained has certain advantages. It permits of manufacturing in larger quantities with the use of the most modern machines and methods at central production shops. On account of concentrating the grinding of bearing surfaces in one shop, this work can be done more economically and accurately. In repair shops, the fact that these parts are finished up to the point of grinding or turning the taper ends of pins and the outside of bushings is a great advantage. Also the fact that any pin will fit any bushing of the same class often makes it possible to change levers from one locomotive to another without fitting, a condition which is hard to attain unless these parts have been standardized.

Cost of Tool Breakage.—Convincing evidence of the high cost of tool breakage is afforded by the records of a Portland, Ore., factory. According to the Iron Age: "The records are a convincing testimony to the expense of putting good tools in the hands of careless or incompetent workmen. A charting of tool breakage shows that it is particularly heavy when numbers of new men are put to work. Damage to tools is a big problem, and careless men can destroy in a short time tools far in excess of their labors for weeks and months. But greater than the loss in money is the fact that it is in some cases almost impossible to replace at once many special high speed tools that are destroyed. Breakage of several important implements at about the same time compelled the plant to lay off a machine and hold up the entire progress of production."

The Management of a Locomotive Repair Shop*

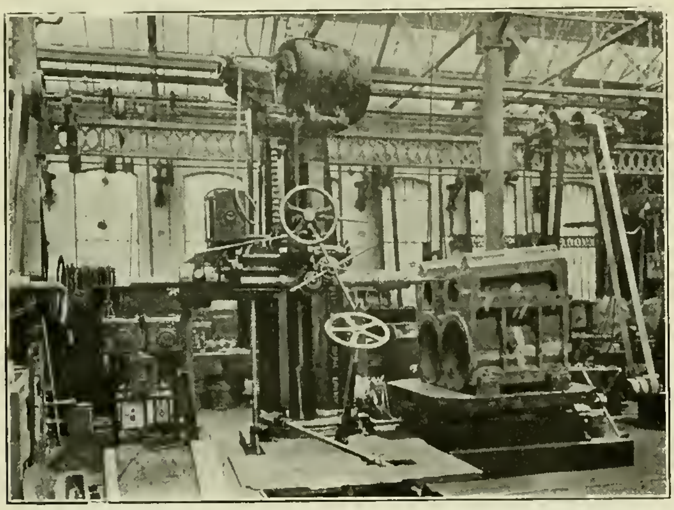
English Railway Practices; Modern Tools and Cost Records Necessary; The Repair Shop's Customer

BY COLONEL H. E. O'BRIEN, D. S. O.
Deputy Chief Mechanical Engineer, Lancashire & Yorkshire, Horwich, England

THE main objective of the management of a railway locomotive workship is essentially different from that of a commercial manufacturing works; the engineering management of a commercial engineering works desire to see a constant expansion of their shops, while in the case of a railway management their desire should be to see a constant shrinkage of the shops brought about by:

(1) Improved methods of manufacture.
(2) Improved organization.
(3) Rectification of errors in design and material with the object of reducing renewals and repairs to a minimum.

It is possible to effect this because the capital expansion of the locomotive stock is very slow on English railways, and therefore the capacity of the works should more than keep pace with the demands if the management is progressive, in spite of the increased weight and power of the more modern stock. The number of locomotives on the Lancashire & Yorkshire has only increased from 1,326 to 1,645 in the last 20 years.



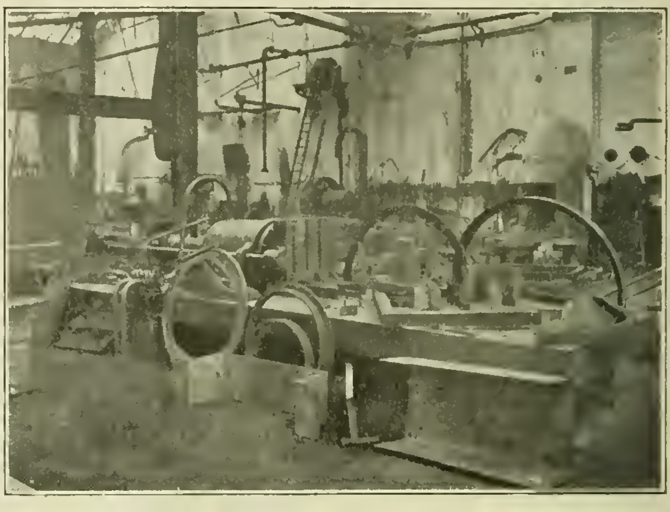
Asquith Horizontal Drilling, Milling and Tapping Machine Used With Eminent Success on Cylinders in the Horwich Shops

Modern Tools Should Be Installed on a Commercial Basis

While patient attention to methods of manufacture on existing machines will result in increased output, the best results will not be attained unless the most modern and most highly productive and specialized machinery is, on a commercial basis, applied to the work as rapidly as the machine tool manufacturers make it available.

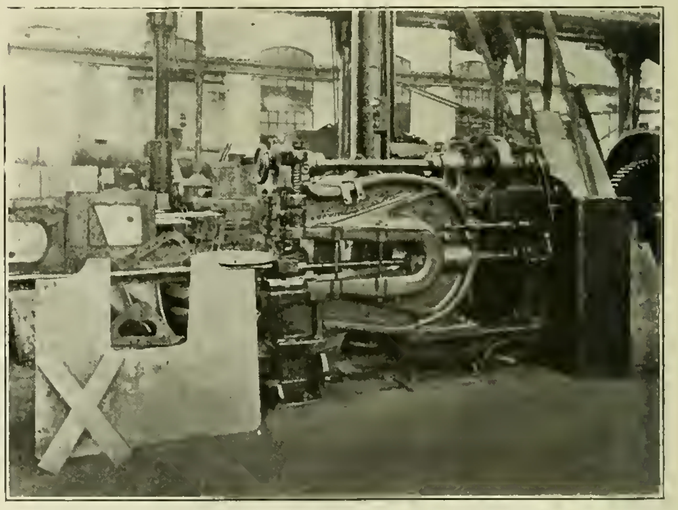
A machinery renewal fund should exist in every works based on a ten years' life of the machinery in order to allow for both wear and tear and obsolescence. The introduction of high speed steel between 1903 and 1910 put many machines simultaneously on the scrap heap; higher speed steels and compound cutting metals such as "Stellite" are in sight, and funds should be available in every shop to enable the fullest advantage to be taken of such improvements.

The author does not advocate the wholesale purchase of new and more powerful machines purely on an arbitrary basis. The method of procedure must be based on a knowledge of the existing annual output of each article dealt with. These records are easily obtainable from the time sheets.



A Bending Press for All Kinds of Work That Has Given Splendid Results

To illustrate this procedure more fully an example is given in connection with drilling operations. These jobs carried out on three old machines have been tabulated with existing prices or costs; new piecework prices have been worked out for these articles by the rate fixer on the basis attainable with the new machine (in most cases it is good policy to send samples to the machine tool maker and obtain guaranteed times), a balance sheet is then prepared as illustrated in Fig. 1, showing the return obtainable on the capital expenditure. After all necessary allowances have been made the return should be such as to enable the machine to make its own contribution to the renewal and obsolescence fund, or in other words, it is



Gray's Sheet Metal Cutting Machine

---

* An abstract of a paper presented to the Institution of Locomotive Engineers, England.

hardly justifiable to purchase a new machine unless a return of approximately 8 per cent on the capital expenditure is obtainable.

There is another broader and more approximate way of looking at the problem on the basis that where two new machines can be installed to do the work of three existing ones, the gain in floor space and the reduction in labor cost will justify a capital expenditure of £2,000 ($10,000), 10 per cent on this sum representing the cost of one machinist's wages per annum. When the purchase of a machine has been decided upon, a profit and loss ledger account is opened in the works manager's department, which shows the work done by the machine and the economy effected over the piecework prices, which would have had to be paid had the old machine been retained. The exact return attained by the purchase of new machines over a period of years is therefore known. The above are both rough and ready methods, open to considerable criticism from an accountant's point of view, but in practice they produce good results.

Factors in Economical Shop Production

Modern high speed machines must be filled with work to their full capacity if an adequate return is to be obtained from them; this requirement involves either a large stock of locomotives very fully standardized or the manufacture of parts for stock, or a combination of both these requirements. Intelligent manufacture for stock involves a knowledge of the maximum and minimum weekly or monthly demands for each article, which in turn demands the issue of all machined or manufactured parts, whether new or repaired through the books of a finished work store.

Other salient points requiring the closest possible attention are:—

(1) The reduction of unnecessary work to a minimum; this can be effected by—

(*a*) Inspection of all parts of the locomotive after stripping and cleaning for both flaws and wear; this procedure confines the functions of the machine shop to their legitimate sphere of effecting repairs on definite lines laid down by the management.

(*b*) Elimination of all unnecessary machining operations; this can only be satisfactorily effected by the use of operation sheets, samples of which are shown in Figs. 2 and 3 Close scrutinizing of machining operations by a competent staff of young foremen with modern ideas will often result in a surprisingly large elimination of unnecessary operations.

(*c*) Elimination of fitting operations by the use of limit gages, jigs, machining particularly by grinding instead of scraping, filing, and chipping, *e. g.*, no scraping should be done on any surface which can be reached by a grinding machine; every use of the chisel or file should be regarded as an adverse criticism of the quality of the machine work or the system of standardization, or the design.

(2) The reduction of unnecessary transportation of material by—

(*a*) Such methods as the arrangement of all white metalling and coppersmiths' work in the closest vicinity to the erecting shop; suitable location of the cleaning beshes and labor-saving appliances in connection therewith.

(*b*) Locating benches in the vicinity of the machines principally dealing with the work of those benches.

(*c*) By the retention in the erecting shop of all material proved by inspection not to require repairs.

(3) The closest economy in the use of material to be effected—

(*a*) By specialized inspection for wear, relieving the fitter of the responsibility for deciding when a part is to be renewed.

(*b*) By a continuous watch for fresh points where wear can be reduced by the use of hardened and ground surfaces.

Fig. 4—Table Showing Particulars of Boiler Repairs on L. & Y. Boilers, 20 Years Ending December, 1919

(*f*) By the elimination of the more expensive metals wherever possible.

(*g*) By the judicious use of welding and patching, it being remembered that all patching likely to prove a source of maintenance at sheds should be rigorously avoided.

(*h*) As 80 per cent of the engines stopped for back shop repairs are taken out of service on account of the condition of the boiler, a close watch of the trend of boiler repairs is necessary and a statistical record is kept, as shown in Fig. 4.

Boiler Repairs

The efficiency of the methods of boiler repairs in the shop is checked by the reports of three boiler inspectors on the works manager's staff, specially selected for independence and matureness of judgment in connection with boiler work. These inspectors report quarterly on the condition of the boilers examined. Fig. 4 shows particulars of boiler repairs for 20 years by half yearly periods. A summary of the reports for the last nine years is also given in Fig. 5, from which it will be seen that, in spite of the fact that the ratio of the total number of boilers repaired to the total engines in stock is becoming smaller, the condition of the boilers generally shows a steady improvement.

Particulars	1911	1912	1913	1914	1915	1916	1917	1918	1919

Fig. 5—Summary of Boiler Inspectors' Report, 1911 to 1919 Inclusive

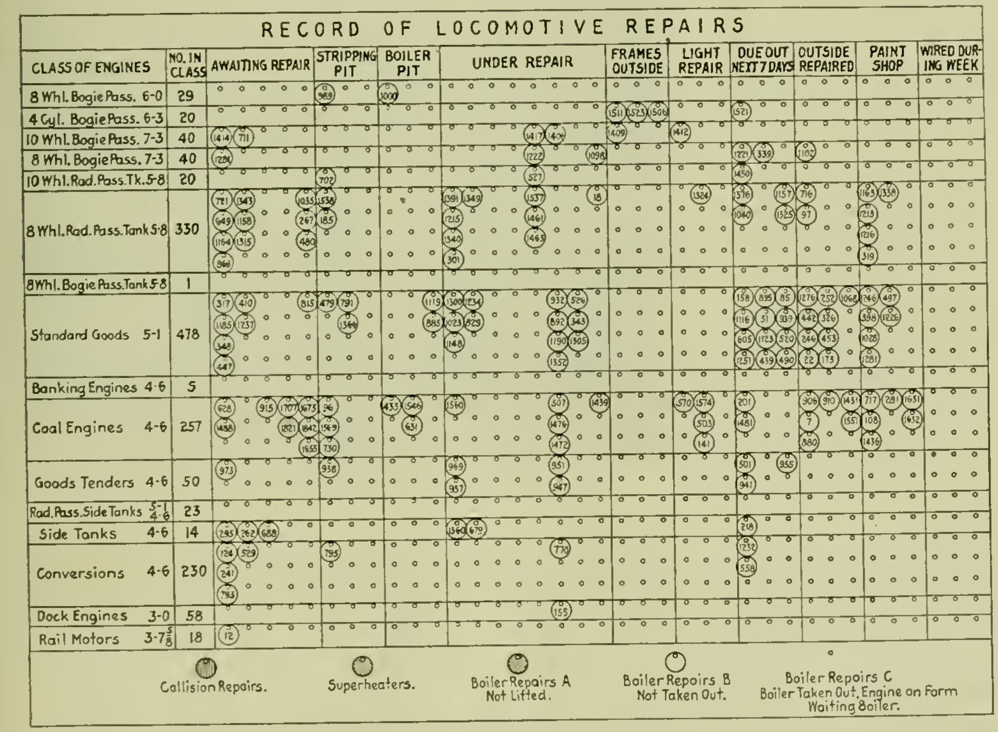

Fig. 6—Repaired Engine Output Board

The erecting shop usually represents about 25 per cent of the total area of a locomotive repair shop; every effort therefore should be directed to reducing the time spent on the erecting shop pits to a minimum.

It is good policy to have a small stock of boilers of each class tubed, mounted, and tested ready to drop into the frames as soon as the frame repairs permit after the old boiler has been lifted out.

To avoid transport of boilers, as much of the boiler repairs as possible should be carried out in the erecting shop. By this is meant such repairs as do not involve machining other than that which can be done by pneumatic or electric portable tools, of which there should be a generous supply; all such tools should be under the special supervision of one man and such an occurrence as an inefficient tool, an air leakage or waiting for a tool should be made an impossibility. The author in his own practice has to a large extent standardized patches which are sent across from the boiler shop shaped and drilled.

Scheduling Repairs

While systematic scheduling of dates on which repair material is to be ready and engines are to be ready for trial is essential, such scheduling is ineffective unless regulated and modified by a daily foremen's conference consisting of the machine, erecting and boiler shops, foundry and smithy foremen as official members, with other foremen called in as required. At Horwich this conference is presided over by the chief works inspector. Supplementing this daily foremen's conference is the work of the progress man attached to each of the principal shops. The progress man's sole duty is to follow up the material required by the charge-hands according to the output boards for repaired engines, and the schedule for new engines. An illustration of the repaired engine output board is shown in Fig. 6.

In dealing with engine repairs the work continually fluctuates, due to defects developing on examination after stripping and to changes in the requirements of the outdoor department; daily changes are therefore necessary in the repair program and the method of conference by the foreman enables immediate decision to be taken to meet the change of circumstance.

Points to Be Remembered

Before describing repair methods the author would like to emphasize a few cardinal points which have, as far as possible, been always kept prominently before the management at Horwich:—

(1) The necessity for keeping the boiler stock young; the L. & Y. have a definite renewal fund which permits of the building of boilers at a rate equivalent to a life of 16 to 17 years.

(2) The desirability of reducing firebox patching to an absolute minimum *vide* the table in Fig. 4.

(3) The importance of the greatest possible use of machinery in order to economize labor.

(4) The adoption of piecework or payment by results throughout the shops coupled with an endeavor to secure the reasonable and intelligent co-operation of labor in obtaining a maximum output.

(5) The infusion of a spirit of broad-minded economy and esprit-de-corps into the supervisory staff.

(6) The most vigorous adhesion to standards; in this connection the author regards the drawing office staff acting in collusion with the outdoor locomotive department,* as tending unconsciously to be the worst offenders against standardization; it is generally far too easy to set a radical change in motion in some small detail which may have far-reaching consequences. No alteration should be permissible in any drawing which has not been considered by a committee representing the shop, drawing and outdoor locomotive departments. Adherence to old standards which are unsuitable in strength or design for the mere sake of standardization is, of course, undesirable.

The only road to progress is that of continual criticism and continual dissatisfaction with the results obtained; the point may be illustrated by the story of the man who said "he had

---

*Outdoor locomotive department, as the words indicate, refers to the organization for handling locomotives out on the road and at engine houses.

done his best"; his superior's answer was "that will not do for me; you must try to do better than your best."

Costs

There is no essential need for the management to know the actual cost of every article manufactured or repaired; but it is essential to have accurate costings of groups, *i.e.*, the cost of repairs each year of each class of engine must be known, as must also the cost of each batch of new engines; these costs again should be subdivided into the costs of boilers, smokeboxes, tanks, frames and stays, cylinders, valves, motion, wheels and axles, brake gear, injectors, piping, etc. However, the works manager should be able to call for and obtain within a reasonable time the cost of any article; this is the case on the L. & Y., though the method of sudividing the cost of class repairs into cross headings of groups has not as yet been adopted.

It may not be obvious why extensive costing is not of great value in locomotive repair work, but a little consideration will show that the price of materials is dictated by the outside market, and the piecework prices of labor are fixed, and all reductions of cost must be made by new methods or new machinery or economy in material. Whether these reductions are being made is revealed by the balance sheets and ledger accounts for new machines, by the wages sheets of individual shops, and by the returns of scrap sold or utilized.

The broad costing divisions show tendencies; they indicate, for instance, in the case of tank engines, whether the time is coming when a large number of new tank engines would not be a more profitable investment than repairing the old ones.

In addition to the above costing and statistical checks on the efficiency of the organization, the management must have other figures constantly before them; on the L. & Y. this consists of:

(1) Monthly statements of the weight and cost of materials issued.

(2) Weekly statements of the wages paid, and number of men employed in each shop.

(3) A cross division of the wages paid under the following heads:

- Engine repairs.
- Boiler renewals.
- New engines.
- Renewal of machinery and plant, subdivided under—
  - (*a*) Machinery and plant generally.
  - (*b*) Engines and boilers.
  - (*c*) Hearths and furnaces.
  - (*d*) Cranes.
  - (*e*) Sundries.
- Other workshop expenses, subdivided under—
  - (*a*) Foremen.
  - (*b*) Checking and inspectors.
  - (*c*) Cranemen, tramwaymen, stationary enginemen, etc.
  - (*d*) Laborers.
  - (*e*) Light and power.
  - (*f*) Tools and fittings.
  - (*g*) Pattern-making.
  - (*h*) Sundries.
- Repairs to premises, and various other miscellaneous items.

The cost of castings, forgings, and smithy work is watched by means of balance sheets which are prepared on the same lines as if the smithy, foundry or forge were working as an outside shop supplying the machine, erecting and other shops; therefore so far as the supply of semi-manufactured material is concerned, the works manager is in the position of knowing exactly how he stands in regard to the comparative costs as compared with supplies from outside manufacturers. Owing to the standardization of the product, the actual works cost is necessarily little if any higher than that of a manufacturer, while the manufacturer's general charges, which are bound to be high on account of his necessity for advertising, preparing quotations and estimates, etc., are saved.

Operating Department the Shop's Customer

There is a further test of efficiency and financial solvency. The outdoor locomotive department must be considered as the customers of the shop. No commercial shop can be solvent that has dissatisfied customers. Unfortunately there is and can be no financial test of the commercial solvency of a locomotive repair works, but the satisfaction or otherwise of their customers, the outdoor locomotive department, is probably the best possible test under the circumstances. The policy of the works should therefore be to invite complaints from the outdoor locomotive department, and this is done as far as possible on the L. & Y. by the system of returned waybills and by the trial run of each repaired engine on an easy traffic job, the report of the trial being made by a driver who is independent of the shop staff, and is not hampered or prejudiced by the presence on the engine of any of the men who repaired it.

This does not mean that the outdoor locomotive department should be under any control other than that of the chief mechanical engineer. Any such system means the setting up of co-equal rival authorities in a technical subject within one organization which cannot make for harmony or efficiency.

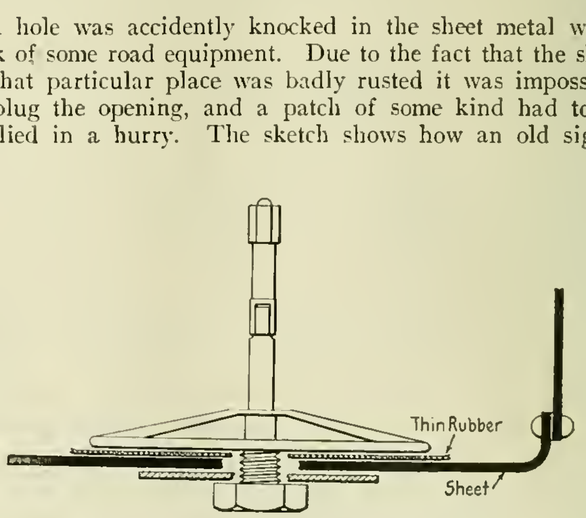
Co-operation the Keynote

The nearest possible approach to the best results in dealing with locomotive repairs is only attainable if the whole of the grades and groups engaged in the work deal with it in a spirit of self-sacrifice, completely sinking their own personal interests for the good of the whole; the general outline of locomotive repair work is so standardized that except in so far as progress on the broad lines indicated earlier in this paper is concerned, there is more engineering of human nature than of material in the work.

Note: *The author included two appendices to the paper describing the routine of engine repairs and the application of limit gages and progressive sizes in the machine shop which will be published in future issues*—Editor.

Emergency Patch Plate Made of Old Air Signal Valve Part

A hole was accidently knocked in the sheet metal water tank of some road equipment. Due to the fact that the sheet in that particular place was badly rusted it was impossible to plug the opening, and a patch of some kind had to be applied in a hurry. The sketch shows how an old signal valve stem and plate was utilized in making a very satisfactory small patch. The sheet did not allow a full nut to be drawn, but to hold the water and stop the opening it served the purpose very well. The idea might be useful under similar circumstances where an emergency application of a patch on thin metal sheet is necessary.



Air Signal Valve Part Used in Patching Sheet Metal Tank

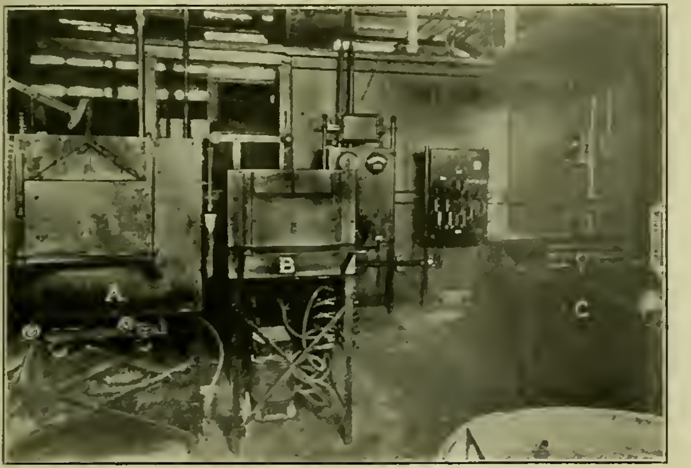
Heat Treating Steel in Railway Shops

Essential Methods and Equipment Needed in the Heat Treatment of Tool Steel for Railway Shops

BY HENRY OTTO
Tool Foreman, Topeka Shops, Atchison, Topeka & Santa Fe

THE controlling factor in all heat treatment is temperature, whether the operation is annealing, hardening or tempering and for any certain steel and particular use thereof, there is a definite temperature point which alone gives the best results. Insufficient temperatures do not produce the results sought. Excessive temperatures, due either to ignorance of what the correct point is or the inability to tell when it exists, will cause "burned" steel. This is a common failing resulting in great loss. Very slight variations from the proper temperature may do irreparable damage.

Due to temperature variation alone, carbon steel may be had in any of three conditions: First, In an annealed state, when not heated to a temperature above 1,350 deg. F.; Second, In a hardened state, by heating to a temperature between 1,350 and 1,500 deg. F.; Third, In a state softer than the second, though harder than the first, when heated to a temperature which exceeds 1,500 deg. F.



Furnaces and Equipment Used in Heat Treating

The hardening of carbon steel is the result of a change of internal structure which takes place in the steel when heated properly to a correct temperature. This change for practical purposes is effective only in those carbon steels in which the proportion of carbon varies from two points to twenty points.

Hardening Steel

The process of hardening steel consists essentially of heating it to the required temperature and quenching it suddenly in some cooling medium. The methods of heating and the different kinds of quenching baths used are numerous. Generally speaking, the furnaces are heated either by gas, oil, electricity, or solid fuel. Each of these methods has its advantages according to the local conditions. Electrical furnaces for hardening and tempering are used in the tool room of the Santa Fe shops at Topeka, Kans.

In the actual heating of a piece of steel several requirements are essential to good hardening: First, Small projections or cutting edges must not be heated more rapidly than is the body of the piece; Second, All parts must be heated to a uniform temperature, as low as will give the required hardness. A higher temperature is uneconomical and dangerous.

Any temperature above the "critical point" of steel tends to open its grain, to make it coarse and to diminish its strength. The temperatures at which internal changes in the structure of a steel take place, are frequently spoken of as the "critical" points. These are different in steels of different carbon contents. The carbon steel used for making reamers, taps, shear blades, etc., at Topeka shops has its decalesence point at 1,385 deg. F. and its recalescence point at 1,280 deg. F. The decalescence point is the proper temperature for hardening and the recalescence point is the proper temperature for annealing.

Furnace Equipment

In the tempering room, there are two electrically heated furnaces made by the Hoskins Manufacturing Company. One of these, known as the Type F. C. furnace, is shown at *A* in the illustration. It has a carbon resister and top carbon plates. The service life of these plates is about 125 hours. The graphite bottom plates and electrodes have a life of about 300 working hours and it is necessary to renew them at regular intervals. The time required for renewing depends entirely upon the condition of the walls or lining. This furnace is used only to bring the tools made of high speed steel to the final heat or from 1,700 deg. F. to 2,300 deg. F. Good results have been obtained with the above furnace on high speed steel tools.

The Type F. B. furnace, shown at *B*, is of the hair pin heat unit type, and is designed for lower temperatures, the maximum being 1,800 deg. F. This furnace is used for carbon steel tools and for preheating all the high speed steel tools in connection with the Type F. C. furnace. The heat units are easily renewed and the cost of maintenance is very low. All carbon steel tools are heated in this furnace for hardening. Both of the above furnaces were installed March, 1917, and have given very good results. They are supplied with alternating current through special transformers.

Oil Tempering Bath

The electrically heated oil tempering bath shown at *C* is made by the General Electric Company, and is used in accurately drawing the temper on carbon steel tools. The oil is heated up to the required temperature and the tool left in the bath until it is heated thoroughly to the temperature of the oil. The tool is removed and after cooling is ready for grinding and use.

Not long ago, it was the practice to send a finished tool to the blacksmith shop for tempering. The blacksmith would guess when the temperature was high enough and quench the tool, afterwards drawing the temper to whatever color he thought was right. The results were always non-uniform and unsatisfactory. With up-to-date electrical equipment, it is a matter of reading the pyrometer and bringing the temperature up to that recommended by the steel company.

High Speed Steel

High speed steel must be heated to a much higher temperature for hardening than carbon steel, a temperature from 1,800 to 2,300 deg. F. being used. The usual method of hardening high speed steel tools, such as lathe, planer, slotter tools, etc., is to heat the cutting end slowly to a temperature of about 1,800 deg. F. and then rapidly to about 2,250 deg. F., or until the end of the tool is at a dazzling white heat and shows signs of melting down. The tool point is then cooled either by plunging it in a bath of oil or by placing the end in a blast of dry air.

The exact treatment varies for different steels and it is advisable to follow the directions given by the steel makers. The following is a table of heat colors when tools are heated without using a pyrometer.

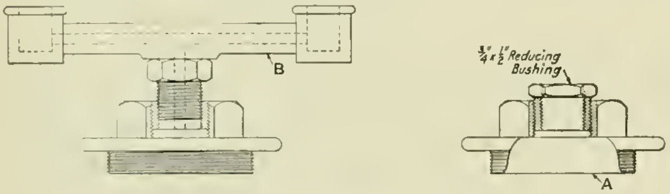
Heat Colors	Degrees Fahrenheit	Heat Colors	Degrees Fahrenheit
White	2,200	Cherry or full red	1,375
Light yellow	1,975	Medium cherry	1,250
Lemon	1,825	Dark cherry	1,175
Orange	1,725	Blood red	1,050
Salmon	1,650	Faint red	900
Bright red	1,550		

In annealing high speed steel an iron box or pipe is used, of sufficient size to allow at least one-half inch of packing between the pieces of steel to be annealed and the sides of the box or pipe. It is not necessary that each piece of steel be kept separate from every other piece, but the steel must be prevented from touching the sides of the annealing pipe or box. It should be packed carefully with powdered charcoal, fine dry lime, or mica and covered with a cap which should be air-tight. The pipe is then heated slowly to a full red heat, about 1,475 or 1,500 deg. F., and held at this heat from two to eight hours, depending on the size of the pieces to be annealed. The parts should be cooled as slowly as possible and not exposed to the air until cold. A good way is to allow the box or pipe to remain in the furnace until cold. Local conditions in heat treatment of steel must be taken into consideration for what is advisable in one place may not be practical in another place.

Repairing Cylinder Cap of Air Compressor Governor

BY F. W. B.

The ½-in. pipe thread in the cylinder cap body of an air compressor governor is often found badly worn, allowing a loose fit for the thread end of the diaphragm body or Siamese fitting. As long as the cap has good close threads, the diaphragm portion or the Siamese fitting can be safely turned to suit the angle or direction of the controlling pipes, but loose threads many times allow the hexagonal wrench portions above to strike the top of the cap with the connections in decidedly contrary directions.



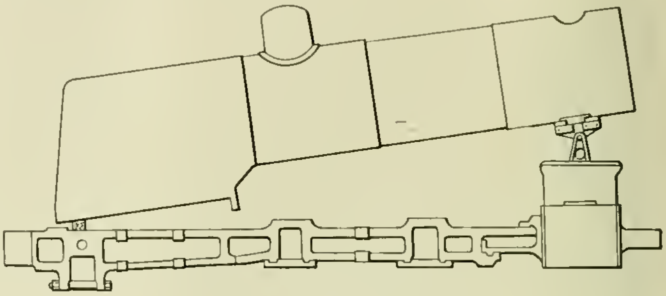
Cylinder Cap After Being Repaired

The illustration shows a quick and inexpensive method of repairing the caps where a number of them can be done at a time. The cap *A* is drilled out for a ¾-in. pipe thread, tapped and a ¾-in. to ½-in. reducing bushing screwed firmly into it. The square of the bushing is then cut off flush with the top of the cap. This affords a good ½-in. thread, perhaps a little small, but just right to take the thread of a body or Siamese fitting *B*, itself somewhat worn. The idea is simple, but provides a most effective way to remedy this defect.

Stool for Supporting Front End of Boiler

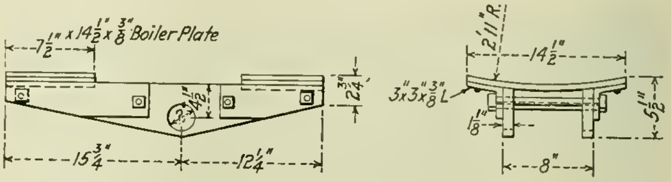
BY E. A. MILLER

When a new saddle is to be applied to a locomotive, it is bolted between the front ends of the frames, and the boiler is put in place. The top flange of the saddle is chalked or painted all around and a line scribed along the sides, front and back of the saddle ¼ in. or any convenient depth below the boiler, to follow as a guide in chipping the saddle to the proper contour. After being so marked the front end of the boiler is lifted up and the stool set in place as illustrated.



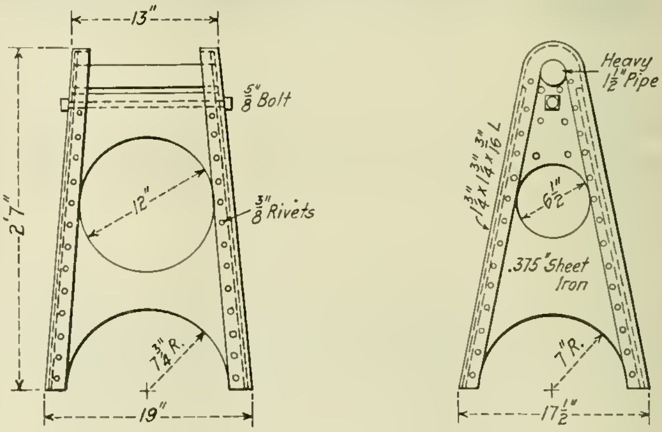
Sketch Showing Application of Stool

The frame of the stool is made of 1¾ in. by 1¾ in. by 3/16 in. angle iron bent at the top around heavy 1½ in. wrought iron pipe, which extends from one side to the other. The frame is stiffened by ⅜-in. sheet iron riveted to the angle irons as shown. A 6½-in. hole is cut in the sides and 12-in. holes in the front and back. The bottoms are cut out as shown.



Fulcrum Plate

The fulcrum plate consists of two 1⅛-in. by 28-in. wrought iron plates, cut to the shape shown and provided with 2-in. holes. The fulcrum plate rocks on a heavy 2-in. wrought iron pipe. Four pieces of 3 in. by ⅜ in. angle are bolted to the plates, and curved plates extend from side to side. These curved plates are made of ⅜ in. boiler plate and are riveted to the angle irons, the rivets being countersunk on top.

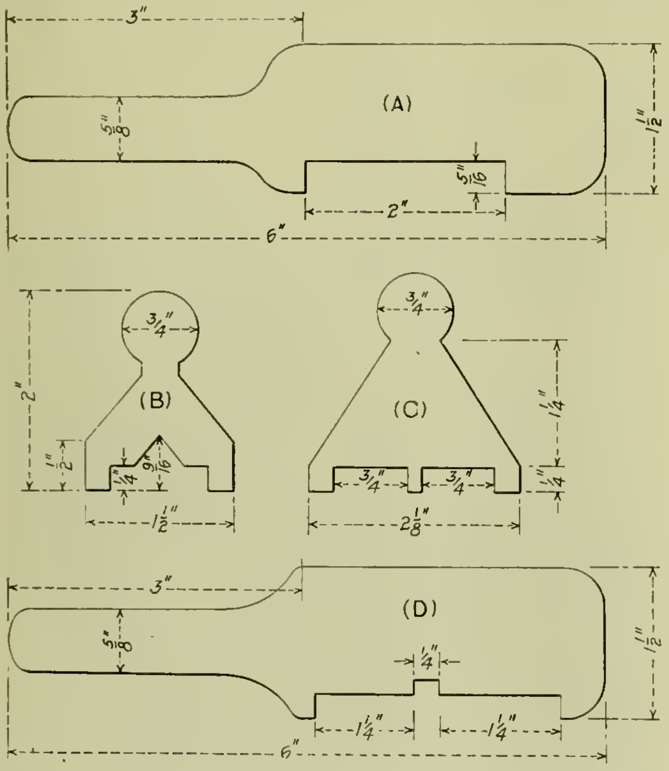


Details of Stool Construction

Standard Gages Facilitate Repairing Valves in Air Brake Department

BY F. A. SKINNER
Air Brake Foreman, Santa Fe Reclamation Yard, Corwith, Ill.

By the use of comparatively simple gages, it has been possible to save a large amount of material and greatly facilitate the work of repairing the various valves used in the air brake equipment. The gages and tools used for this repair work, the majority of which are home-made, have proved their value. The gages are made of 1/16-in. boiler steel carefully shaped to the forms shown. Referring to the illustration, *A* is a gage for testing the springs in pressure retaining valves. There is a tendency among many repair men to stretch this spring with the idea of increasing its tension and thereby preventing the retainer from leaking down. The use of gage *A* will detect springs that have been stretched and they may be replaced by standard springs. This will assure the correct action of the pressure retainer, thereby preventing slid flat wheels.



Gages Used in Air Brake Repair Work

Gage *B*, shown in the illustration, was devised for the purpose of testing the diaphragm in the maximum pressure head of the pump governor. To use the gage, the parts of the head are assembled and the gage is placed directly over the diaphragm or valve. If it fills the opening, the valve is of the proper length and, if not, it is too short. A new valve can then be installed and no trouble will result from leaky diaphragm valves.

Gage *C* is used to measure the length of the regulating valve in a slide valve feed valve after it has been assembled and the spring box removed. The gage is used in the manner of a straight edge and shows at a glance whether the regulating valve is of the proper length. The slide valve feed valve is one of the most difficult parts of the air brake equipment to repair and its action is absolutely dependent upon the correct length of the regulating valve, so the importance of this gage can be readily appreciated.

Gage *D* is provided for testing the vent valve in an auxiliary release valve, and by its use much time can be saved by assuring that the vent valve is not too short before making the test. To test the vent valve, the part containing the rubber seat is placed in the 1/4-in. slot and if the top of the vent valve touches the top of the gage, the valve is of the proper length and can be reseated. Upon testing the release valve, the length of the vent valve will be found to be correct.

Power Punches and Dies*

The punch and die is one of the most abused tools in the shop. It has to work under all kinds of conditions. Sometimes it has lubrication and more times not, and seldom does the operator take pains to see that the punch is central with the die.

C. M. & St. P. Practice

Fig. 1 shows Chicago, Milwaukee & St. Paul standard punches and dies. The punches are made on automatic machines, the large ones at a labor cost on the machine of 4½ cents each, and the small ones at 3½ cents each, and one cent each for tempering them.

Tool Steel

Fig. 1—Large and Small Shank Punches and Dies, C. M. & St. P.

Fig. 2 shows a punch and die for punching convex steel staybolt nuts. These nuts are used in the firebox on radial staybolts, and on crown sheets. The nuts are punched from boiler steel and tapped in a nut tapping machine. Some trouble has been experienced on these punches, the face of the punch pulling off in the stripping. This has been overcome by putting a double taper on the body of the punch; that is, giving it the regular clearance for half of the body and reversing the taper on the other half, so that the punch will act as a drift to open the top of the sheet where it has drawn in. This makes the sheet strip from the punch very easily. More damage is done to a punch in stripping than in punching.

The punches are made of 90 to 100-point carbon tool steel. The larger sizes, when in bad condition on the cutting end, are annealed and reclaimed to a smaller size.

---

*From a paper read before the American Railway Tool Foremen's Association.

A. T. & S. F. Practice

The sketches show sizes of the standard punches and dies used. These may be ordered on requisition, by a symbol number from one central point—Topeka, Kan.—where a sufficient stock is kept on hand to meet the requirements of the different shops along the line. These tools are mostly bought from the manufacturers.

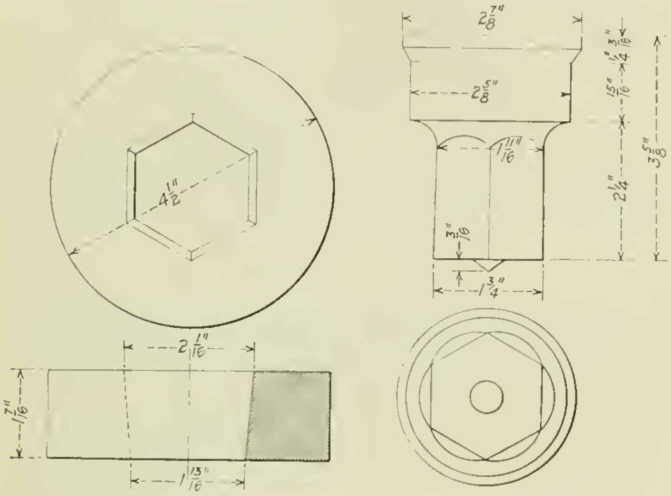

Fig. 2—Punch and Die for Convex Steel Staybolt Nut

In establishing a standard, the size and shape of the body of the punches and the diameter of the die are the essential points to consider, as the length in a good many cases will depend on the nature of the work and the construction and style of the machine.

Fig. 3—Standard Punches and Dies—A. T. & S. F.

Four different sizes of punches and two of dies are shown, although in practice the larger sizes are not much used, as the average punching machine will not handle work large enough to require them.

For the ordinary boiler shop punch the coupling nut for the holder is made to fit the larger punch and a bushing or reducer is used to adapt the smaller, or symbol *L* punch, to the same coupling nut. As the punches and dies are of the same length, blocking is not required, unless the punches have been reworked and made shorter.

N. & W. Practice

There were no less than 15 machines distributed in different departments of the Norfolk & Western shops at Roanoke, Va., each having a different type of punch and punch post, with coupling nuts ranging from 1½ in. in diameter to 2¼ in. in diameter, with threads 10 to 14 per inch. Some held the punch in place with set screws, which often could neither be tightened nor loosened. An outfit for one machine was designed that could be standardized and all the machines have been fitted with the standard equipment.

Standard Punch Post, Nuts, Dies and Punches, Norfolk & Western

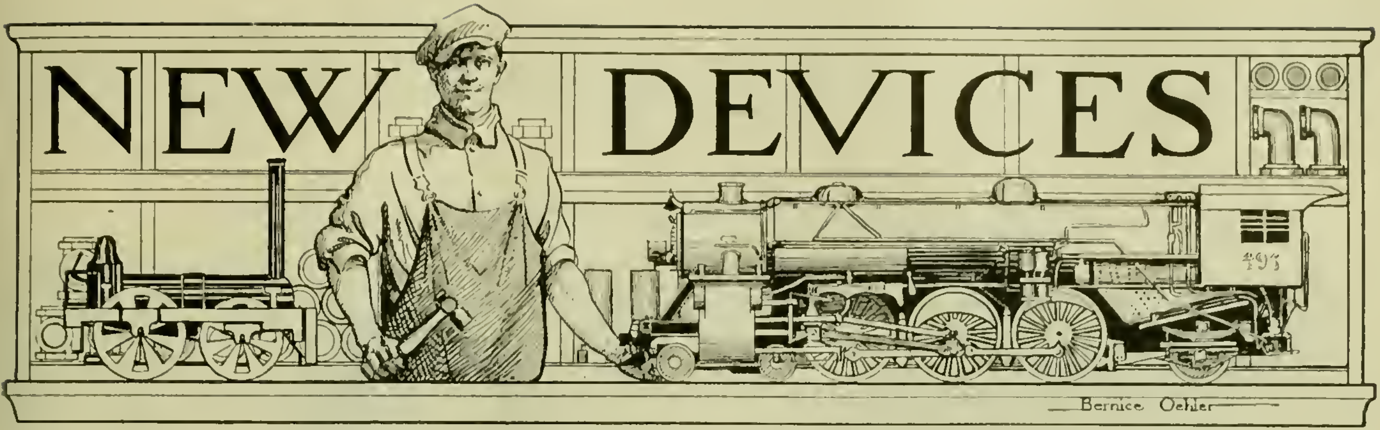
All punch posts have threaded ends 1⅞ in. in diameter, 10 threads per inch. The standard punch is 2¼ in. long. Four sizes of coupling nuts are used:

No. 1 nut taking size 3/16 in. to 5/8 in.—⅞ in. stock.
No. 2 nut taking size 11/16 in. to 13/16 in.—1 1/16 in. stock.
No. 3 nut taking size ⅞ in. to 15/16 in.—1⅛ in. stock.
No. 4 nut taking size 1 in. to 1¼ in.—1⅜ in. stock

The details of this equipment are shown in Fig. 4.

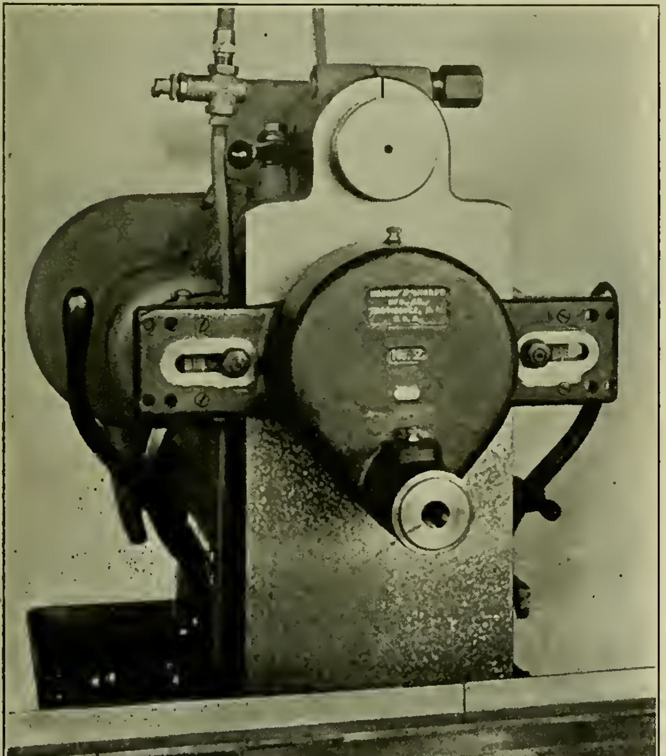
Discussion

The discussion was confined largely to the operation of punches rather than to the development of a standard type of punches, couplings and dies. Owing to the difficulty of getting satisfactory production in drilling flue holes in front tube sheets the St. Louis-San Francisco is experimenting with a spiral punch, sized to leave 1/16-in. stock in the hole to be finished by reaming. So far, it has been found that this punch does not disturb the metal as much as had been expected. No other railroad represented at the convention has taken up this proposition. The Santa Fe practice is to punch a 1-5/16-in. hole and then run through a reamer or two-lip drill. At one time sixty of these holes were drilled an hour, but when the war broke out the schedule was cut to forty an hour and actual production now does not exceed twenty-five an hour.



Easily Applied High Speed Milling Attachment

THE accompanying illustrations show a new design of high speed milling attachment made by the Brown & Sharpe Manufacturing Company, Providence, R. I., for use on milling machines of their manufacture. As will be noted, the mechanism is simple in construction and easily attached to the milling machine, no auxiliary fixtures being required. The bracket and spindle support is a one piece casting of substantial construction, so designed as to protect the mechanism from dirt and injury.

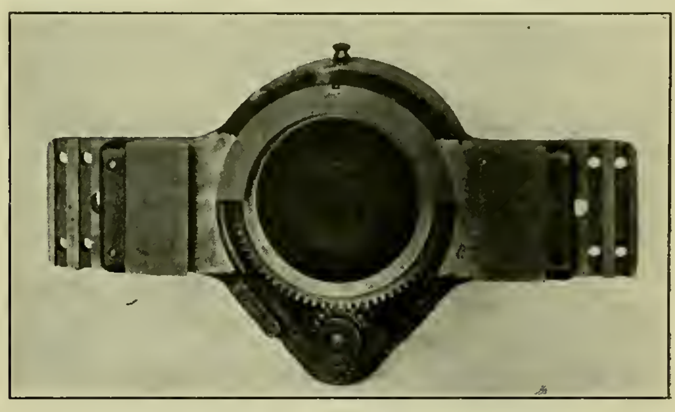


Brown & Sharpe High Speed Milling Attachment

The attachment is built in two sizes: the No. 1 for the smaller machines and the No. 2 for the larger machines. The No. 2 size is adaptable by means of adjustable gib stops to the larger machines having columns with different widths of face, thus eliminating the necessity of a separate attachment for each different size of machine column.

The positive means of locating the attachment is particularly noteworthy. To assure a positive vertical position, the attachment is provided with a locating segment which rests upon the spindle box of the machine. This spindle box projects beyond the face of the column and acts as a centering guide. The horizontal position is determined by first tightening the gib on the right hand side of the attachment, thereby locating the attachment. The gib on the left hand side securely clamps the attachment to the face of the column. This affords a large bearing surface, assuring rigidity and making the attachment practically an integral part of the machine.

Particular attention has been given to the drive that it may be positive and simple, the only gearing being the large ring gear that fits on the taper nose spindle of the machine and the pinion on the attachment spindle. The large gear is made with an internal taper, ground to fit on the taper nose of the machine spindle and is held in position by the regular cutter driver. This gear is made of machinery steel and left soft to provide a smooth drive and eliminate chatter and the objectionable "ring" often produced by hardened gears at high speed. On the No. 2 attachment the pinion is heat treated and keyed to the attachment spindle, while on the No. 1 attachment the teeth of the pinion are cut directly on the spindle.



Rear View of High Speed Milling Attachment

The spindle is hardened and ground and runs in a long phosphor bronze bearing, the bearing being tapered so that wear is taken up by tightening an adjusting nut, thereby forcing the spindle into the taper. Once having adjusted the spindle, a small set screw securely clamps the adjusting nut in position. End thrust is taken by hardened steel and babbitt washers located directly behind the shoulder on the front end of the spindle. The front end of the spindle has a taper hole to receive cutters, the smaller attachment having a No. 7 taper hole and the larger one a No. 9 taper hole. Oiling the spindle bearing is effectively taken care of by means of an oil pocket on the front of the attachment containing wool, which insures a constant and even distribution of the oil at all times.

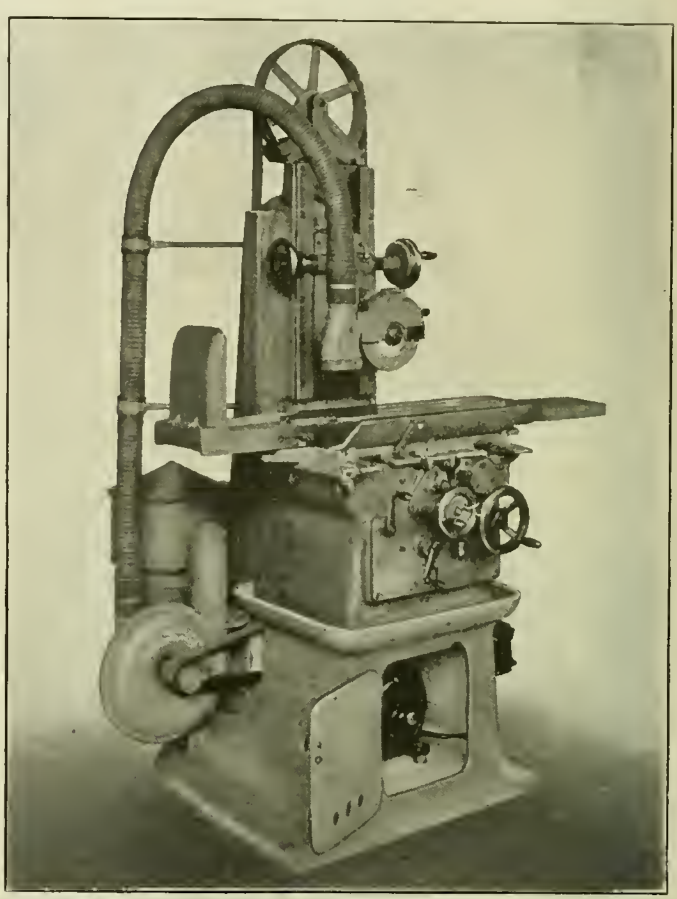
The cutter is held in position by the taper in the spindle and is driven by the tenon. Cutters are readily removed by a releasing bolt which provides a positive means of ejection. This bolt is a part of the attachment and remains in the spindle.

Exhauster Attachment for Surface Grinder

MODERN requirements for the safety and health of the employee demand an efficient device for disposing of the dust generated by grinding machines, especially surface grinders, when operating without the use of water, which is frequently necessary. Where these machines are not placed in groups to be served from one central exhaust system, it is desirable to have the individual machine equipped with its own unit, and in many cases it is really more economical to have each machine of a group individually equipped, as the exhauster is then running only while the machine is in operation. This is especially true where individual motor drive prevails.

Realizing the importance of collecting as much of this dust as practicable, the Abrasive Machine Tool Company, East Providence, R. I., has designed a complete new system for its machines, as shown in the illustration. The exhauster is a machine-tool-built product, equipped with S-K-F ball bearings, and aluminum fan, running at 4,000 r. p. m. The exhauster is connected with the aluminum dust collector on the wheel hood by means of flexible wire-insert rubber suction tubing. The wheel dust is drawn in through the flexible tubing, and forced into the centrifugal drum attached to the rear of the machine, where the dust is separated and deposited at the bottom of the cone. The free air passes out through a circuitous route, and, it is stated, is practically dustless. The accumulation of dust can be removed by unscrewing a cap at the bottom of the separator drum.

The illustration shows the dust exhauster attachment applied to one of the Abrasive Machine Tool Company's No. 3 surface grinders but the application could easily be made to many other types of machines. The question simply resolves itself into a matter of piping to the machine and designing the proper collector for sucking in the dust at the point where it is generated. Application of the parts is then easily made.



Motor Driven Dust Exhauster System

Self-Loading Type Electric Truck

AN industrial self-loading truck of improved design has recently been placed on the market by the Industrial Truck Company division of the Cowan Truck Company, Holyoke, Mass. The truck is of all-steel construction and is guaranteed for 5,000 lb. capacity. It has a quick acting elevating mechanism and elevates in five seconds when equipped with 28 cells and six seconds with 21 cells.

The lifting mechanism is operated by an independent, heavy duty, series wound motor and worm gear reduction. The platform lifts vertically, the rise being 4½ in. The platform may be stopped at any point going up or down, and requires only three seconds for full lowering. The rear end is equipped with a heavy bumper which effectually takes all shocks, and protects the lift platform. A drawbar attachment also is provided which enables the truck to be used as a light duty tractor.

An automatic brake and circuit breaker application, four-wheel steer, single reduction worm drive of the power axle and easy accessibility of batteries, lifting, driving and control mechanism are features of the truck. It will operate in intersecting aisles 60 in. wide.

The extreme turning radius, outside point, is 7 ft. 10 in. By folding the foot pedal and steering handle into a vertical position, the overall length is shortened for use on elevators. The length is 102 in. overall or 91½ in. with the

I. T. C. Self-Loading Electric Truck

step raised. The width is 36 in. overall and the height over steering shaft head 51 in. Either alkaline or lead batteries are used. The controller is of the drum type with three speeds forward and three reverse.

The new truck has been subjected to rigid tests under actual operating conditions, and promises enduring service due to its all-steel construction, low center of gravity, and general compactness and ruggedness.

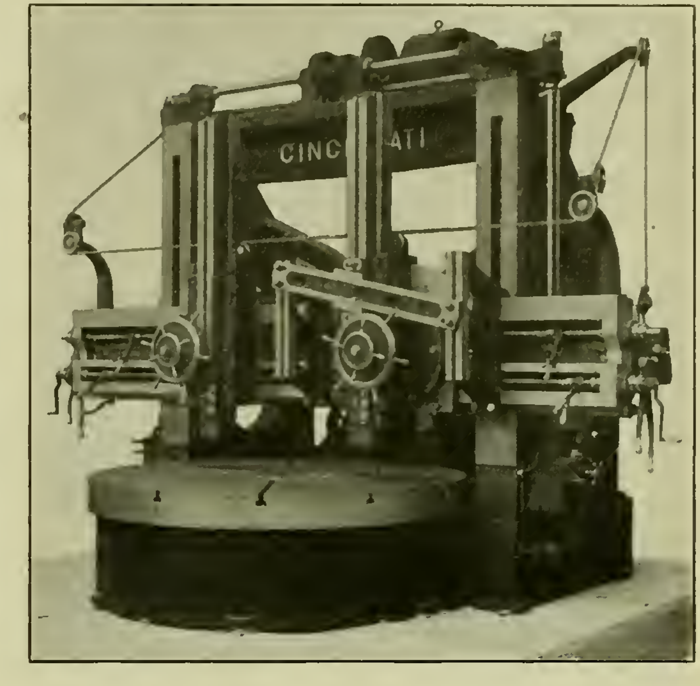
Taper Attachment Applied to Boring Mill

FOR turning and boring tapers approaching nearly a horizontal line to which swiveling the head is not adaptable, a taper turning and boring attachment has been designed for use on boring mills manufactured by the Cincinnati Planer Company, Cincinnati, Ohio. The illustration shows the attachment applied to an 8 ft. mill but it can be adapted to use on all sizes from 42 in. up to 12 ft.

The component parts such as sine bar supports, sine bar, and sine bar guide are all clearly shown in the illustration. To provide up and down adjustment to the ram without loosening the sine bar and thereby changing its position, the faces of the rams are specially machined and fitted with a tee slot in length equal to the up and down travel.

When mounting, the sine bar supports, sine bar guide and sine bar are placed in position loosely and clamped securely in place after the proper angle has been determined. The power feed to the ram is then disengaged by means of the small handwheel making it ready for operation. The use of the taper attachment is recommended for angles up to and including 18 deg.

When the taper to be turned on a boring mill is so nearly horizontal that it is beyond the range to which the head can be swiveled, the transverse and vertical feeds are sometimes used together but this method is inconvenient. The correct setting of the swivel head must be obtained by trial but with the taper attachment the setting can be made directly.

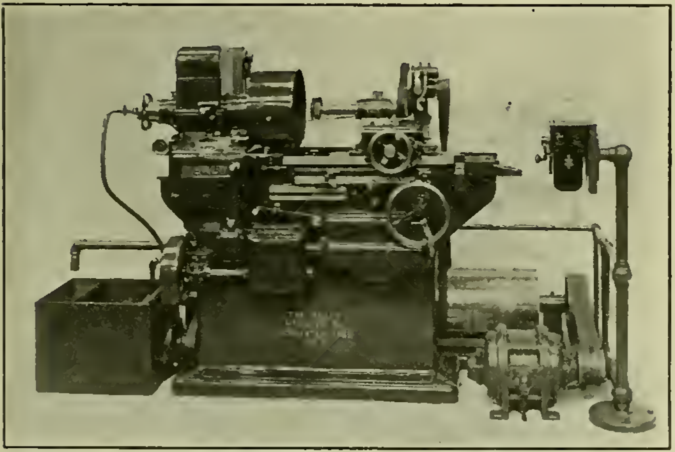


Cincinnati Taper Turning and Boring Attachment

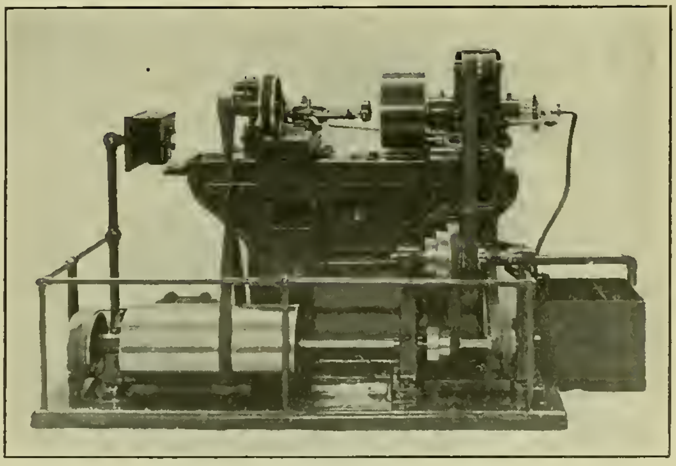
New Motor Drive for Internal Grinder

WITH the idea of securing a more compact design, together with other advantages, a new motor drive unit for the Nos. 70 and 75 internal grinders has been designed by the Heald Machine Company, Worcester, Mass. The old solid idler is eliminated and a new flexible idler gives proper tension to the wheel-head belt, as well as the vertical belt between the drum and the idler.

There is a slight change at the head end where power is taken for the work head. A swinging arm is furnished which swivels on a bracket that holds the driving cones for giving the various speeds to the work head. The swinging arm is connected to the work head with a rod which is so fastened that it will allow swiveling the head either way and still keeping the proper belt tension. In other words, the rod acts as a distance feed. Providing the head has been swivelled around to a certain angle and the proper tension is not fur-



New Motor Drive for Heald No. 71 Grinder



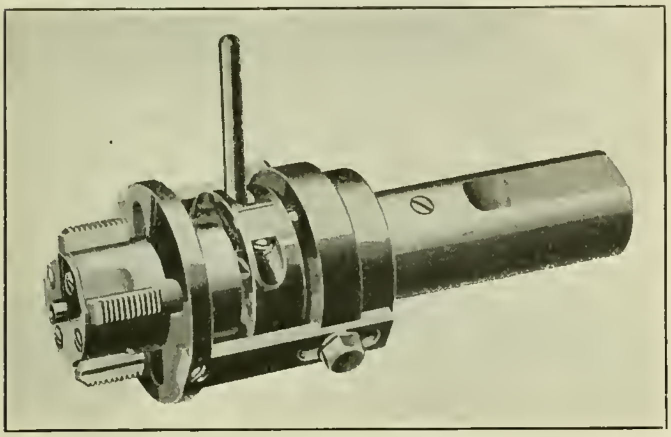
Rear View Showing Drive Arrangement

nished, the nut on this rod may be adjusted to give the proper tension.

Attachment of the new motor drive arrangement is very simple since it only requires moving the standard guard over the work-head pulley, replacing it by a box containing the idler pulleys.

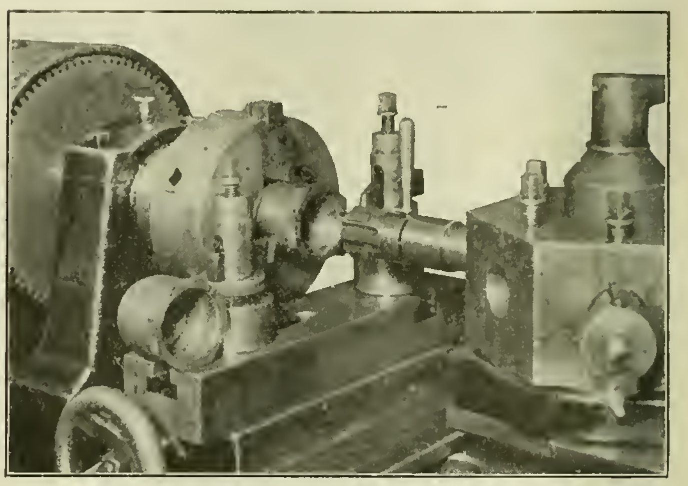
Improved Automatic Collapsing Tap

AUTOMATIC collapsing taps are becoming more and more a necessity for threading operations and when introduced into railway shops, for example, will effect economies many times greater than their cost. Automatic taps are necessary because of the requirement for accurate work and as a safety feature to prevent spoiling work, but their greatest value lies in the greater production made possible.



Namco Automatic Collapsing Tap

The National Acme Company, Cleveland, Ohio, has recently developed and placed on the market an improved automatic collapsing tap known as the Namco, which is designed to fulfill the requirements stated above. The taps are provided with an inside trip, or outside trip, as illustrated, and can be furnished in all sizes for ordinary tapping operations. They are economical for use on general shop work because of their ease of adjustment and quick adaptability.



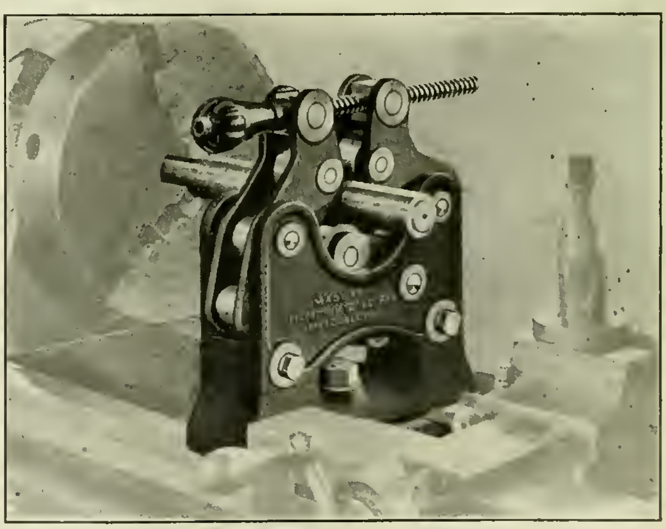
Collapsing Tap Used for Threading Operation on Turret Lathe

The illustrations show a general view of the tap and its use in a practical threading operation on a turret lathe. As an example of its adaptability, an inside trip Namco tap can be equipped with a cammed tripping sleeve and reamer blades for reaming instead of standard chasers for thread cutting. While this is strictly special equipment, it shows the adaptability of the collapsing principle to smooth and positive collapsing action, as simple as throwing a gear out of mesh, and as positive.

Easily Applied Self-Centering Steady Rest

A STEADY REST has been developed recently by the McCrosky Tool Corporation, Meadville, Pa., with several special features and important advantages in operation. It is especially recommended for all operations to be performed on the end of a piece such as facing, boring, turning and practically all work that could be done on the old style steady rest. The self-centering feature is secured by means of three rollers which engage the work and are brought quickly and simultaneously toward the center by closing the jaws. The jaws are interacting, universal and therefore not independent. The three rollers are hardened and run on Hyatt roller bearings which reduces friction to a minimum. The power consumption is small and there are no contact points to wear off.

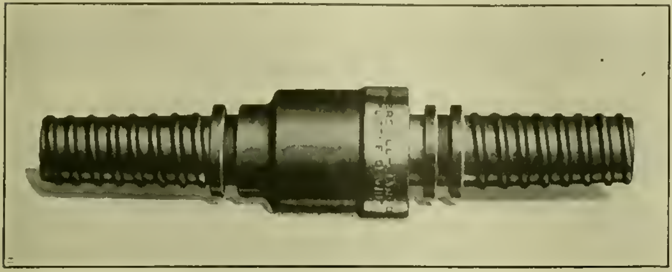
In operation the work is inserted in the lathe chuck and the steady rest placed in the desired position. The jaws are closed until the rollers engage the work and with a turn of the tightening screw, the machining operation may begin. Once adjusted to the lathe centers, the steady rest remains always adjusted and can be taken off and put on the lathe frequently in a few moments and without readjustment. A large range of diameters may be handled and the desired change made at any time without any adjustment except a few turns of the tightening screw. The No. 1 steady rest, illustrated, is designed for 12 to 18 in. lathes and has a range of ⅜ in. to 3¾ in. For soft, highly finished work, stationary cast iron jaws are recommended.



McCrosky Self-Centering Steady Rest

Hose Couplings for Pneumatic Tools

A HOSE COUPLING with several new and important features has recently been placed on the market by the Ingersoll-Rand Company, New York. It is called the "Little David" hose coupling and will be distributed as an accessory to the line of pneumatic tools manufactured by the Ingersoll-Rand Company. Hose couplings which become leaky after short use are the cause of serious air losses, whether in the small shop or the large plant using hundreds of hose connections. Another trouble commonly experienced with many couplings is jamming or sticking through some slight injury, making them difficult or almost impossible to connect or disconnect.

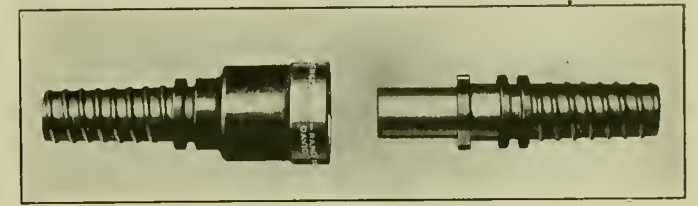


Little David Pneumatic Hose Coupling

The design of the new coupling has been made with the view to overcoming the above troubles. The main features claimed for it are sturdiness and simplicity, and an all around ability to stand lots of abuse without affecting its service. Actual tests over long periods of service have demonstrated its reliability. The coupling consists of two parts, male and female. The female end is fitted with a V-shape rubber gasket providing an air tight joint. The gasket is prevented from blowing out, should the coupling accidentally be disconnected under pressure, by a protective shoulder inside the coupling. The female end is exceptionally sturdy, there being no exposed parts which might be liable to injury and cause jamming or sticking.

The locking shoulders are heavy with large bearing surfaces, the locking spring being strong and durable. It can be replaced if necessary. The parts are made of a metal not subject to ordinary rusting or corrosion. The male end has a very liberal bearing in the female end, which assures alinement and long wear. Another feature is the absence of any outer sleeve exposed to injury. The air ports are straight and of uniform diameter, offering the least restriction to the flow of air.

The coupling may be connected or disconnected by a quarter turn. A groove in the hose end of each part allows using a hose clamp to attach securely to the hose.

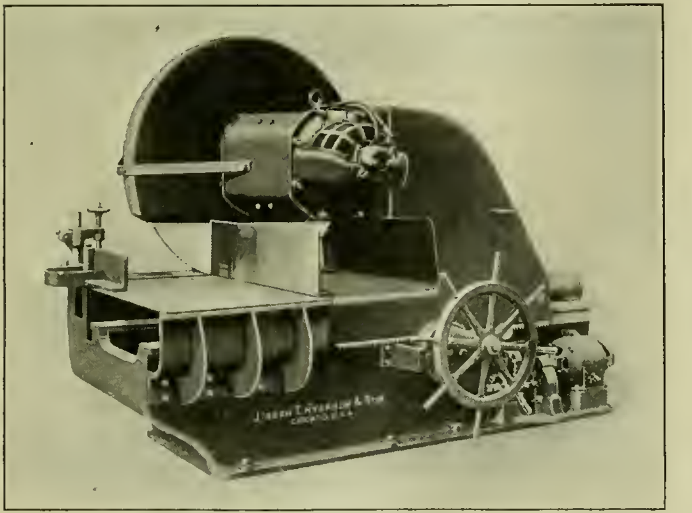


View of Coupling Parts Separated

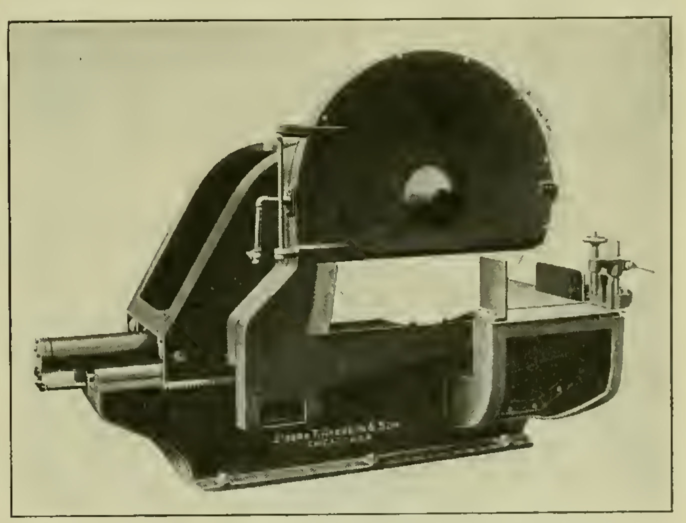
These hose couplings are manufactured in ½ in. and ¾ in. sizes, which are interchangeable; that is, a ½ in. male piece may be used with a ¾ in. female end or vice versa. Gaskets are also interchangeable between the different sizes.

High Speed Friction Metal Cutting Saw

FOR the rapid cutting of structural steel shapes, the high speed friction saw, illustrated, has been developed recently by Joseph T. Ryerson & Son, Chicago. The machine consists of a heavy cast iron box base, on top of which is mounted a horizontal rolling carriage. The carriage operates on roller bearings, mounted on eccentric pins to provide for adjustment. The hood is of heavy sheet metal construction, one side being hinged for greater ease in examining or removing the blade.



Ryerson High Speed Friction Saw



View Showing Table Arrangement and Water Connections

The blades are made of a special grade of soft steel, balanced, hollow-ground and nicked on the edge to increase the friction. Each blade is held in a carefully balanced collar and is cooled by jets of water directed against the cutting edge. Ample power is provided by means of an enclosed motor, especially designed for heavy duty. In operation the saw blade is fed forward through the work by means of the hand wheel or by the electro-hydraulic feed. Power feed, when applied to the machine, is a complete unit consisting of an hydraulic cylinder and piston and a motor-driven pump. This feed is operated by a four-way valve conveniently located. Miter cutting is easily handled.

The new Ryerson friction saw is made in four sizes, similar in design and differing only in capacity. For shops handling lighter structural work, sizes No. 1 and 2 are recommended, with hand feed. For handling heavy structural work and work in railroad shops, sizes No. 3 or 4 are recommended, with power feed. Among the important advantages of this machine may be mentioned the fact that varying sizes and shapes of material can be cut in immediate succession without any adjustment of the machine. The work does not need to be clamped and the cutting operation is performed in a fraction of the time required by other means. The expense of operation is slight due to the entire absence of belts, fly wheels, etc., and the machine is easily operated by one man. From the standpoint of maintenance cost, the blades cost much less than slow speed saws and last longer.

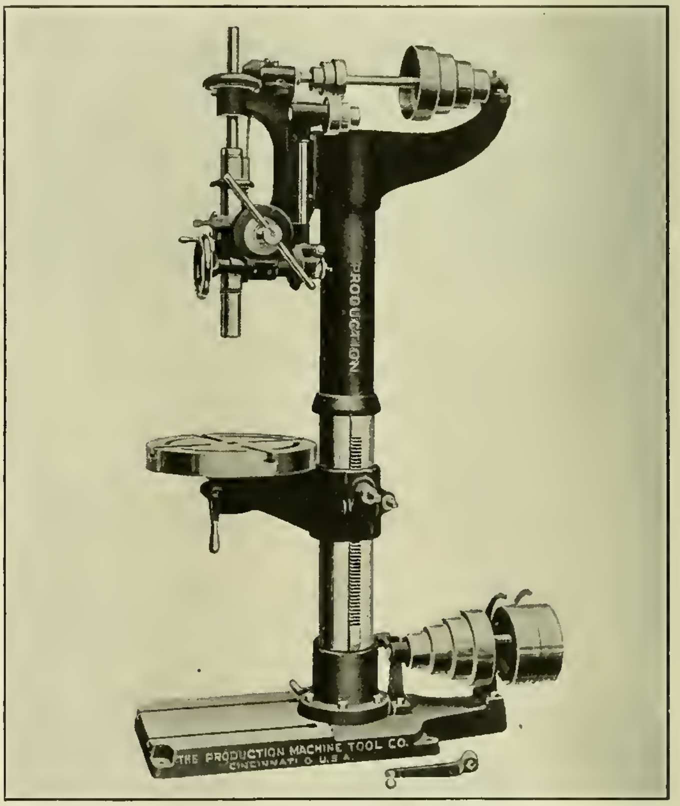
Twenty-Two Inch Drill With Stationary Head

THE Production Machine Tool Company, Cincinnati, Ohio, has recently developed and placed on the market a twenty-two inch upright drill with a stationary head and a capacity to drill, bore, tap, and ream holes up to and including 1¼ in. in diameter. This drill is bronze bushed throughout and the entire design is such as to make each part strong enough to withstand any ordinary strain to which it may be subjected. Centralized controls have been provided for convenience of operation and increased production.

The machine is regularly built with power feeds, but this feature may be omitted if desired. Back gears and tapping attachments can be added, together with the type of drive best suited to the conditions under which the machine is to be used; either regular tight and loose pulley, right angle or belted or geared motor drive. The unit system of construction has been followed throughout which eliminates individual fitting and assures interchangeability of parts. Bronze bushings are provided for all bearings and this prolongs the life of bearings in addition to facilitating the replacement when necessary. All details and units undergo a careful inspection and rigid test as to power before being assembled in the finished product.

The base of the machine is well ribbed and provided with T-slots, as is also the table. Clamping bolts are interchangeable and the radius slots in the table are especially convenient for some jobs. The table arm is of box construction in one casting, and has a wide bearing on the substantial tubular column. The drill head is of the box type with spindle driving gear bearing and head cast integral. This allows the spindle bearings to be bored and reamed at one setting with a resultant accurate alignment of the spindle.

The new drill is adapted for production work in assembly departments, as well as in jobbing and repair shops. Holes may be drilled to the center of a 22 in. circle. The spindle speeds when back gears are provided are 20, 33, 53 and 88 r. p. m. The spindle speeds without the back gears are 117, 196, 318 and 530 r. p. m. The power feeds per revolution of the spindle are .006, .010 and .105 in.



22-In. Stationary Head Production Drill

Lubricant for Locomotive Hub Liners

RAILROADS are constantly confronted with a great number of items of expenses which, seemingly small in themselves, total a large amount. One of these items is the expense resulting from the wear of locomotive hub liners. Failure properly to lubricate the various parts of locomotives, such as shoes, wedges, hub liners, etc., necessitates withdrawing locomotives from service and sending them to the shops on account of wear in excess of safe limits.

It is important to maintain driving box lateral play within specified limits and numerous devices have been invented and placed on the market to make it possible to remove driving boxes and reapply lateral liners without dropping the wheels. Much of this work can be eliminated, however, if the proper lubrication is applied in a systematic manner. Ordinarily a service of 30,000 miles may be expected before it is necessary to take up lateral play on driving boxes but in some cases where lubrication has been neglected the adjustment has to be made at the end of approximately 5,000 miles. Not only is the service of the locomotive lost for at least a day, but the operation itself is expensive and requires the time of several men.

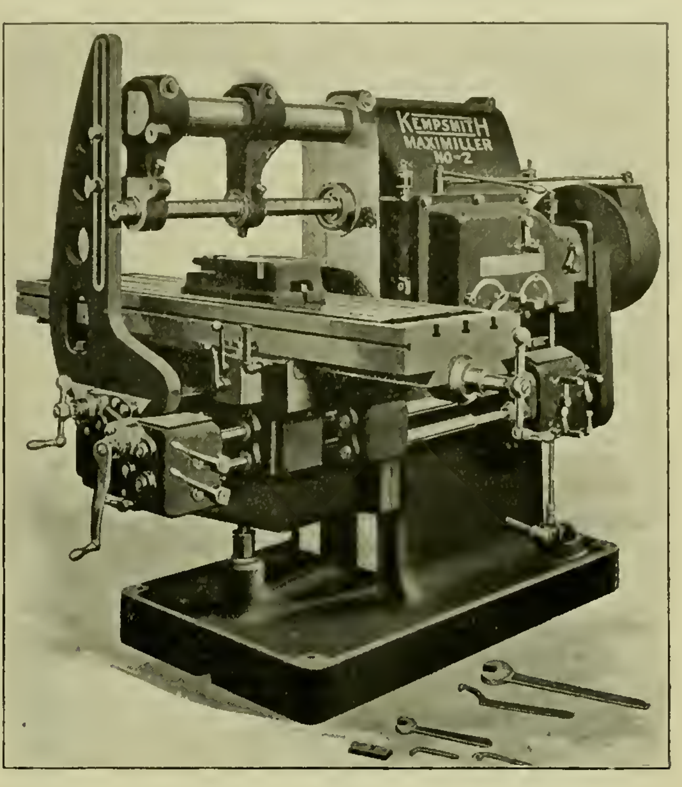
A lubricant known as Dixon's graphite hub liner grease has been developed by the Joseph Dixon Crucible Company, Jersey City, N. J., to be applied with a grease gun. It is claimed that this grease, properly applied, will greatly reduce the heating, wearing and cutting of working parts and lengthen the life between shoppings.

Plain Milling Machine for Medium Heavy Work

The No. 2 plain Maximiller, illustrated, is a recent addition to the line of milling machines made by the Kempsmith Manufacturing Company, Milwaukee, Wis. The machine is practically the same in all points of design as the Kempsmith No. 4 plain Maximiller and is adaptable for medium heavy classes of work. The new machine is designed for maximum rigidity, convenience of operation and efficiency in production. All important parts have been carefully designed in regard to relative weight and strength. The sloping column lines not only add to the appearance, but are true lines of strength. The large area of the base provides stability for the entire machine. The knee is of the solid top design with no opening, a construction which serves to resist clamping strains and the torsional effect of the table overhang. The column is well ribbed internally and has only a few small openings. The saddle, as shown in the illustration, is long, heavy and rigid. Drive to the table is located near the end of the saddle, which leaves the center solid, where most of the strain comes. The table is 12 in. wide with 56 in. working surface length.

The drive pulley is 15 in. in diameter, takes a 3½ in. double belt and runs at 400 r. p. m. It is mounted on ball bearings and with the clutch is enclosed in a protected housing. The control levers are conveniently located and proper safety devices are incorporated throughout. The speed change mechanism provides 18 changes of speeds ranging from ⅝ in. to 25 in. per minute in geometrical progression. Power quick traverse is available for all table movements without disturbing the set-up for whatever rate of speed may be in use. The longitudinal power quick traverse is at the rate of 100 in. per minute, while the cross and vertical travel is at the rate of 36 in. per minute.

By means of a train of gears, 18 changes of spindle speed may be obtained ranging from 16 to 400 r. p. m. When desired and especially ordered, the machine can be arranged for motor drive through a belt, in which case the motor recommended is 7½-hp. running at 1200 r. p. m.

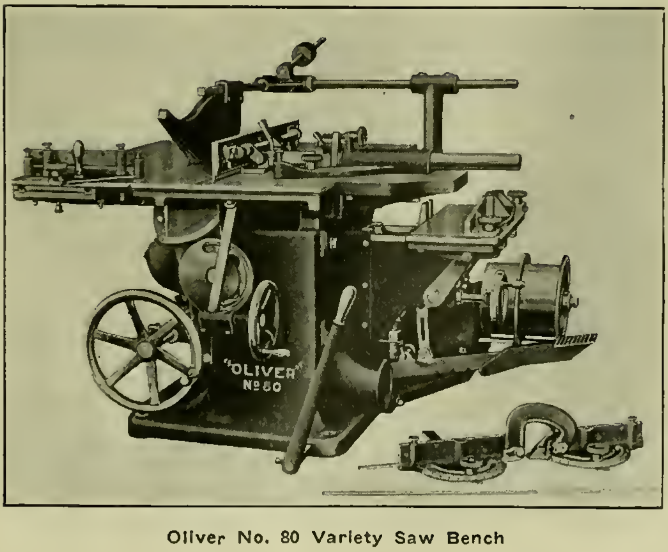


Kempsmith Plain Maximiller No. 2

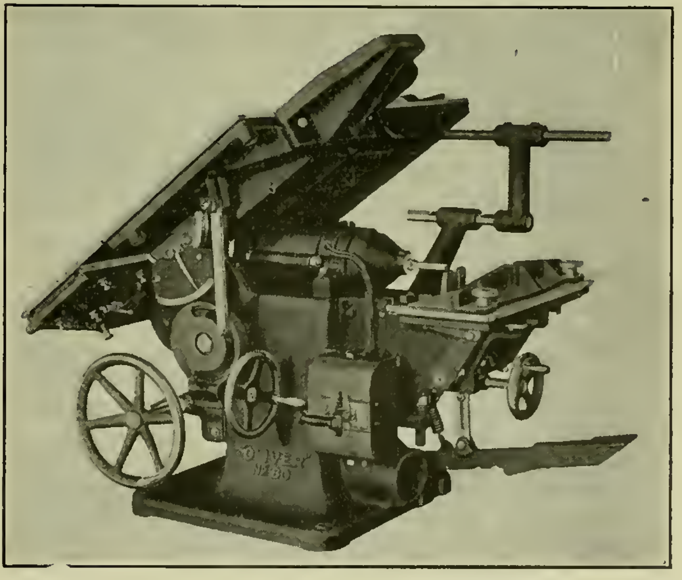
Belt or Motor Driven Variety Saw Bench

The machine illustrated, which can be arranged for either belt or motor drive, has been designed by the Oliver Machinery Company, Grand Rapids, Mich., to do ripping, cross cutting and dadoing in an efficient and thorough manner. It will cut a practically perfect miter and measure any angle quickly and accurately. It will cut off to lengths or rip to width, all without the operator doing any calculating or referring to a rule. The machine is rigid and accurate and parts are interchangeable. A 14-in. saw is regularly supplied, although a 16-in. saw may be used. The machine is arranged with or without a mortising and boring attachment.

One of the valuable features of this saw bench is the table, which is 36 in. by 44 in., tilting to 45 deg. to the left. The table has vertical adjustment and may be furnished either



Oliver No. 80 Variety Saw Bench



Variety Saw Bench With Table Tilted

plain or universal. The universal table shown in the illustration has a rolling section which is located at the left of the saw and rolls on ball bearing ways having vertical adjustment for alinement and for wear. The table may be moved several inches from the saw, permitting the use of dado or special heads. This table is said to operate so easily that it is well suited for production work and multiple cuts.

The universal ripping fence is furnished regularly with a quick adjustment of 12 in. without changing the locating pins to the next set of holes. The ripping fence may be tilted to an angle of 45 deg. and is adjusted to and from the saw by an extremely accurate micrometer adjustment. Miter cut off gages are supplied as regular equipment as well as auxiliary rods and stops which are intended to be used with gages.

For motor drive, a motor operating at about 1800 r. p. m. is mounted on a subbase bolted securely to the machine and belted directly to the main driving belt, eliminating the necessity of a countershaft.

The machine will rip up to 23 in. wide and cut off 32 in. wide by the use of the universal ripping table; will rip 27 in. wide and cut off 15 in. wide by the use of the plain table; will cut up to 3 in. thick with a 14-in. saw, or 4 in. thick with a 16-in. diameter saw, and will work dados up to 4 in. wide. With mortising and boring attachment it will bore holes 6 in. deep up to 2 in. in diameter, and will mortise holes up to ¾-in. square and 4 in. deep.

Measuring Temperatures in Stored Coal

A NEW DEVICE for indicating the thermal conditions of stored soft coal has been placed on the market recently by F. C. Thornley & Co., Inc., New York, and is called the Thornley coalometer. Bituminous coal has the well known property of spontaneously heating in certain spots and at varying depths. This heating does not always cause actual combustion, in the sense that the coal burns with the presence of flame, although this condition is often encountered. There does exist almost universally, however, in stored coal of this character, a slow combustion which is even more destructive than combustion by flame, owing to the fact that it cannot be so readily detected. This slow combustion goes on unnoticed throughout an ever-increasing zone beneath the surface of stored coal.

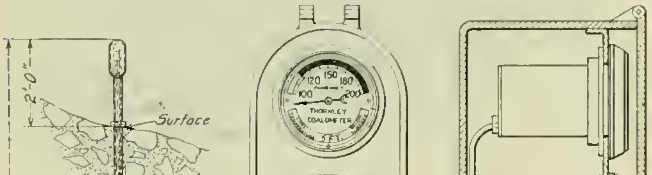


Fig. 1—Triple Unit Thornley Coalometer

The Thornley coalometer consists of a set of temperature indicators encased in a long pointed steel tube, carrying at varying depths metal bulbs (corresponding to the bulbs of thermometers), and at its upper end a set of dials and pointers, which indicate, under all atmospheric conditions, the exact temperature of the bulbs which actuate them. These units are forced down into the coal pile to definite depths and at various points, and collectively furnish definite data to the consumer as to the exact temperatures existing beneath the surface. If an accurate record of daily readings of these instruments is kept, the slightest rise in temperature is at once detected, and should it become excessive, the consumer can remove this particular portion of fuel, thus saving the greater part of the heating value of the coal which has started to dissipate.

Tests have shown that an installation of one coalometer each 50 ft. in both directions from its neighbor will efficiently indicate conditions of temperature below the surface. Thus the installation of one triple unit will protect approximately 900 tons of coal if the volume is about 50 ft. by 50 ft. by 16 ft.

A triple unit coalometer for use in coal piles from 15 ft. to 20 ft. deep is shown in Fig. 1. A galvanized steel tube, having a hardened steel diamond point drill at its lower end, carries three pressure bulbs at depths of 5, 10 and 15 ft., respectively. Tubes from these three bulbs register temperatures in deg. F. on three dials, by means of pointers provided for that purpose. The scale on each dial starts at 32 deg. F., and is colored black. At and above 120 deg. the scale is red, indicating excessive heat at a point in this zone, and warning the coal man to remove this portion of the coal. The depth of the hot spot is determined at a glance, for the dials are plainly marked 5 ft., 10 ft. and 15 ft., respectively. The dial showing the hottest temperature thus indicates the depth at which the heat is generating.

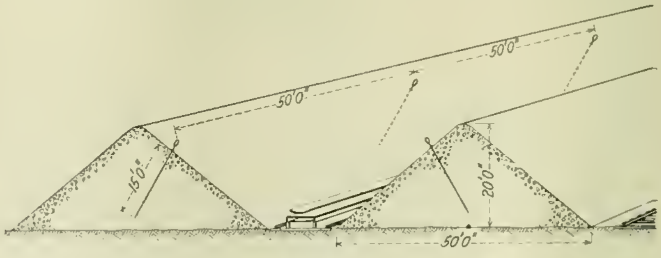

Fig. 2—Typical Installation of Coalometer

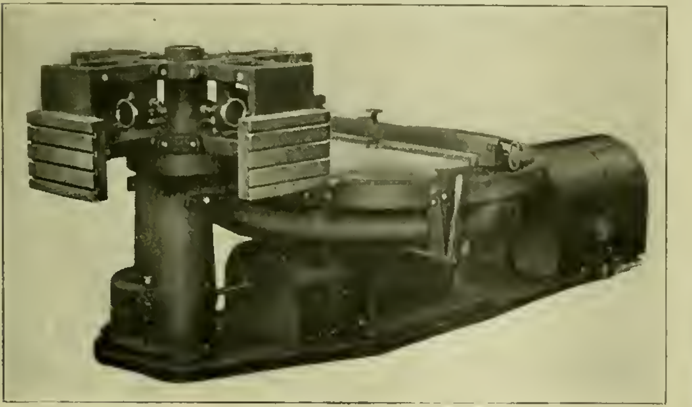
The dials are enclosed in weathertight metal cases with thick crystal faces, and the set is again enclosed in a galvanized cast iron case. This furnishes ample protection when not in use, and added protection when in service. A slidable pipe wrench is provided on each unit to aid the rapid and easy boring of the tube to the desired depth. A large, plainly-marked lug, 12 in. below the instrument head, determines the exact depth at which the coalometer is to be placed, and thus allows of no guess-work on the part of the man who does the installing. The construction throughout is very rugged and will allow of the rapid removal and stacking of one or more units repeatedly, without fear of damage to the temperature indicators themselves. These indicators are especially constructed to indicate accurate temperatures under the varying conditions encountered throughout the year. They will indicate exact bulb temperatures regardless of the temperature of the head of the instrument, and will retain their calibration under conditions of extreme vibration or violent shocks. They are easily readable and amply protected from breakage in handling.

Thornley coalometer units are supplied in two lengths, 12 ft. and 17 ft., which carry, respectively, two and three temperature indicators, a typical installation being shown in Fig. 2. The indicated temperatures when taken daily and recorded furnish complete knowledge of conditions beneath the surface of the coal.

Continuous Feed Disc Grinding Machine

The No. 24 grinder illustrated is made by the Gardner Machine Company, Beloit, Wis., and represents one of the latest developments in disc grinding machinery. It is a continuous feed disc grinder, being semi-automatic in operation and eliminating the labor expended in using the ordinary hand-operated machine. With any hand-operated machine, where the human element is the main factor in production, it is impossible to secure a uniform output all through the day. The operator grows tired and is certain to "let up a little" near the end of the day, thus affecting the total production possibly more than is realized.



Gardner No. 24 Continuous Feed Disc Grinder

The machine illustrated carries one horizontal disc wheel 54 in. in diameter and is provided with a revolving reel which carries four work tables. The work to be ground is attached to these tables by means of suitable fixtures mounted on them, and the revolving wheel brings it over the surface of the grinding wheel. The tables are automatically lowered onto the wheel. Pressure, to assure quick removal of stock, is secured through gravity, but by means of a compression spring this pressure may be adjusted. The weight of the table provides application of a uniform pressure, which can be increased by adding extra weight if the character of the work necessitates it. A micrometer stop screw makes it possible to remove stock to definite dimensions which may be required.

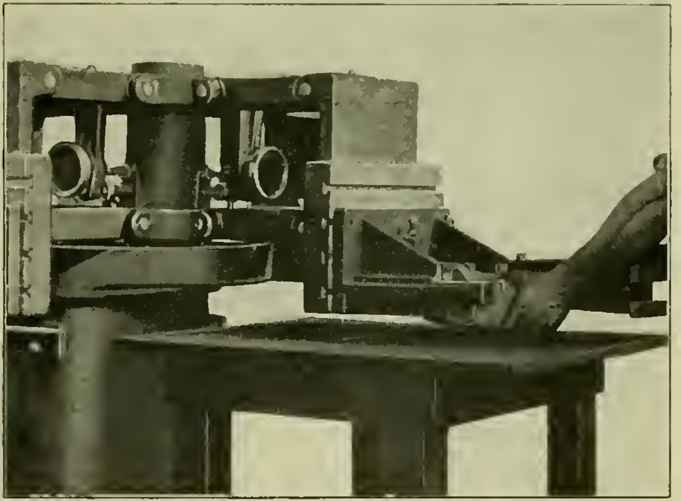
The revolving wheel is mounted on a vertical shaft of special piston rod stock 3½ in. in diameter, and is driven through worm, spur and bevel gears from the gear driving the main spindle of the machine. By means of change gears the reel may be made to revolve ¼, ½ or 1 r.p.m., thereby producing one, two or four finished pieces per minute. Other speeds, if desirable, may be obtained by substituting special gears.

The driving shaft is provided with a friction clutch, operated by a lever placed in a convenient position, which makes it possible to start or stop the feeding mechanism independently from the grinding wheel. The reel and the shaft which drives it are mounted in bronze bearings, all other shafts being carried in ball bearings. The gears are totally enclosed, which protects them from dust and dirt and allows them to be amply lubricated.

The feeding stand is bolted directly to the base plate upon which the machine is mounted and, to accommodate various sizes of work, has an adjustment of 6 in. along this base plate. Because the work tables are at right angles to the grinding wheel, accuracy of the work being ground is assured. A micrometer stop screw permits grinding to definite dimensions and also allows the grinding of a surface to a required relation with some other area on the piece. This is an important advantage.

Rigidity and strength are important features of this machine, which weighs about 7,600 lb. when crated for domestic shipment. The disc wheel is mounted on an extra large and heavy cast iron flange. The driving spindle is of large diameter and runs in two self-alining radial ball bearings. All down or end thrust is taken on a self-alining ball thrust bearing which contains ten 1¼ in. diameter balls. Power is transmitted to the disc wheel by hardened special steel bevel gears.

An extra pulley is mounted on the driving shaft for belting to an exhaust fan, which is set on the floor in back of machine. There is a dust channel cast into the base of the machine and an efficient dust exhaust system is provided. A cast iron guard ring is fastened to the top of the base with collar head screws and any portion of the guard ring is removable, permitting the grinding of work carrying a lug projecting above the plane of the ground surface. The machine is adapted to a large variety of flat surface operations. It is provided with Gardner improved abrasive discs, a new type of abrasive structure reported to cut twice as fast as the old time glue bond circles, and to last from six to twenty times as long. They are recommended for use on the No. 24 continuous feed machine and increase its efficiency to a marked extent.

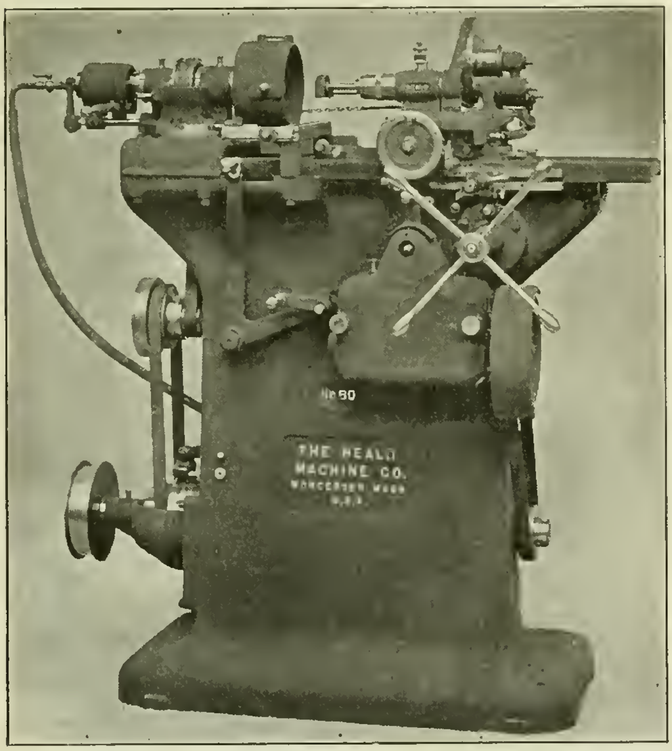


Method of Mounting Work Preliminary to Grinding

Power Feed Internal Grinding Machine

Careful design and building of the style No. 80 internal grinder by the Heald Machine Company, Worcester, Mass., have produced a relatively massive, rugged machine for precision grinding of small work. It is modeled on the lines of the successful style No. 85 internal grinder, having all its mechanical features and, in addition, an automatic feed for the table, which is desirable for work of small diameter and longer than 1½ in. A unique feature of this machine is the vertical pinion for driving the table, which is equipped with a double friction. If only the hand feed for the table is required, throwing in the upper friction engages the pilot wheel, disconnecting the power feed, which is controlled by the lower friction, and the machine becomes suitable for production work on small, short holes.

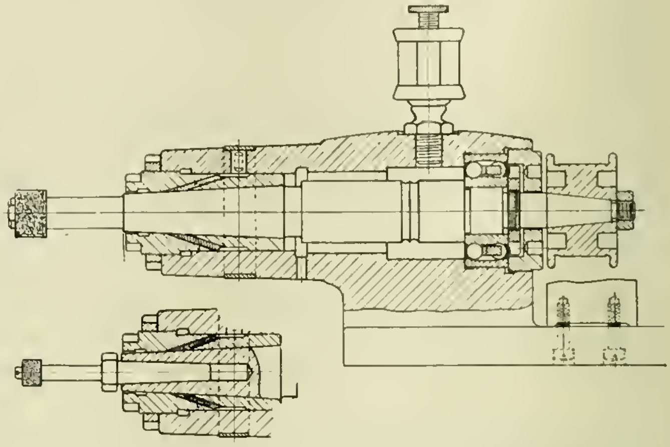
Ordinarily, while the wheel is actually grinding, the power feed is used, but as the wheel leaves the work the operator, by pulling the vertical lever at the head end, disconnects the clutch operating the power feed to the table and engages one connecting the hand feed, allowing rapid hand movement of the wheel-head table out of the way. At the same time, automatically, a guard swings over the wheel, the water and work stop, making plugging or removal of the work instantly possible. The machine can be used to grind holes ranging from ¼ in. to 2 in. in diameter up to a maximum length of 3¾ in. The actual swing inside the water guard is 6 in., while without the guard, it is 10 in. The work-head is driven by a cross belt through the base from a cone giving three speeds of 160, 290 and 530 r.p.m. It is arranged to swivel and is graduated to 45 deg. or 4 in. taper per foot. The rotation of the work head and the pump is automatically and quickly stopped as the grinding wheel is drawn from the work.



Heald No. 80 Power Feed Internal Grinder

The feed to the cross slide is calibrated to read to one-half thousandth of an inch on the diameter of the work. This can be operated by power or hand as desired. The main table has flat and V ways and is very rugged for this size machine. The travel of the table can be either by power, reversing accurately at any point desired or by hand feed with the power thrown out entirely. A two-step cone drive gives two speeds of travel with the power feed. The wheel head has a solid adjustable taper bearing at the wheel end with ball bearings at the pulley end.

Various holding fixtures have been designed and can be furnished on order. The one usually supplied and giving the largest range consists of a quick acting collet chuck with jaws, having a capacity of ⅜ in. diameter up to 3 in. This is operated by a lever with an adjustable compensating device which prevents the work from being distorted from pressure. In railway machine shops, the Heald No. 80 internal grinder would be of particular value for such work as grinding hardened motion work bushings made in quantity to be carried in stock and later fitted to valve motion levers.



Cross Section Through Wheel Spindle

Fundamental Principles of Handling Men

In a talk to foremen published in Industrial Management, George D. Halsey lays down the following principles as requisite for securing best results in handling men:

1. Delegate and supervise the work.
2. Keep compensation fair and strictly proportional to output or general value to the company.
3. Study each individual carefully and fit the method of handling to the individual.
4. Make a careful sub-division of all duties based on a study of individual abilities.
5. Prepare careful and, wherever possible, written instructions showing just how each job should be done, and fair time in which to do it.
6. Plan and schedule your work carefully and always let the workmen see plenty of work ahead.
7. Co-operate with and use staff aids as much as possible.
8. Maintain proper dignity.
9. Endeavor, whenever possible without intruding, to lead your employees into habits of right and sound thinking and clean living.
10. Cultivate in yourself a real and unselfish desire to be of help to your employees.

Entered at the Post office at New York, N. Y., as mail matter of the second class.

Subscriptions, including the eight daily editions of the Railway Age, published in June, in connection with the annual convention of the American Railroad Association. Section III—Mechanical, payable in advance and postage free: United States, Canada and Mexico, $4.00 a year; elsewhere $5.00, or £1 5s. 0d a year. Foreign subscriptions may be paid through our London office, 34 Victoria Street, S. W. 1., in £ s. d. Single copy, 35 cents.

WE GUARANTEE that of this issue 10,200 copies were printed; that of the 10,200 copies, 9,240 were mailed to regular paid subscribers, 8 were provided for counter and news company sales, 260 were mailed to advertisers, 32 were mailed to employees and correspondents, and 660 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 10,200, an average of 10,200 copies a month.

The *Railway Mechanical Engineer* is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.).

The shops of the Southern Pacific at Houston, Tex.—the paint shop, air brake shop, storehouse and office—together with a number of cars, were badly damaged by fire on December 7. Estimated loss $350,000.

In the annual inspection of the Pere Marquette, Charles Montgomery, master mechanic at St. Thomas, Ontario, was awarded the prize of $100 offered by the railroad to the officer showing the highest grade on condition of shop, shop grounds, repair tracks and engine houses.

In order that the names of the American Railway Master Mechanics' Association and the Master Car Builders' Association, the two organizations now comprising the mechanical division of the American Railway Association, may be perpetuated, both are now being included on the circulars and other publications of the mechanical division. The names "Master Car Builders" and "Master Mechanics" appear directly under the formal name of the organization.

Since the introduction of welded steel pipe, the term "wrought pipe" has been used indiscriminately to denote both welded wrought iron and welded steel pipe. This has led to confusion as the average consumer of pipe is not familiar with the manufacturing processes. In order to avoid this confusion, the National Pipe & Supplies Association has recommended that the terms employed by the American Society for Testing Materials in differentiating between iron and steel pipe, viz., welded wrought iron pipe and welded steel pipe, should be accepted and adhered to.

Two of Chicago's leading technical institutes, with the cooperation of the American Society for Steel Treating, will offer evening courses in the subjects of forging and heat treatment of steel. These courses are specially planned for the benefit of the practical men in the forge shop or heat treating departments or those who wish to qualify for such work. The course will embrace the following phases of the work: pyrometer, microscope, forging, annealing, alloy steels (dealing with the effects of different alloys and treatments upon the physical characteristics of steel), hardening and drawing of tool steel and case hardening. The plan and formation of this course was carried out by the Chicago chapter of the society through their educational committee and its seven sub-committees. The texts, lectures and demonstrations were prepared voluntarily.

The Southern Pacific has just completed a motion picture depicting graphically the story of oil, tracing its history from production to consumption. The film will be shown at all terminals and at principal points of the system as an aid in teaching the conservation of this product, of which the Southern Pacific uses 60,000,000 gallons a month, or about 16 per cent of all oil produced in California. The company, in notifying its employees of the picture, states that there is a message to be learned by all who see this film. Further, that the fuel industry faces a crisis; that those who depend upon the industry must take heroic measures if they would stave off disaster and that the picture shows what these measures are. It is further stated that the consumption of fuel oil now exceeds production by 30,000 barrels a day and reserve stocks in California are being depleted by 1,000,000 barrels a month.

Freight Car Orders

The Louisville & Nashville has ordered 1,500 steel hopper cars of 55 tons capacity from the American Car & Foundry Company and 500 from the Mt. Vernon Car Manufacturing Company.

Locomotive Orders

The Missouri Pacific has ordered 50 locomotives from the American Locomotive Company, divided as follows: 25 Mikados, 5 Pacifics, 5 mountain type and 15 switchers.

The Rio Grande do Sul State Railway (Brazil) has ordered 20 Mikado type locomotives from the American Locomotive Company. These locomotives will have 16 by 22 in. cylinders and a total weight in working order of 110,000 lb. and will be equipped with superheaters.

The Missouri Pacific has ordered 15 switching, 5 Mountain type and 5 Pacific type locomotives from the American Locomotive Company. The switching locomotives will have 6 wheels, and cylinders 21 by 28 in., and a total weight in working order of 165,000 lb.; the Mountain type locomotives will have 27 in. by 30 in. cylinders, and a total weight in working order of 345,000 lb.; the Pacific type locomotives will have 26 by 26 in. cylinders, and a total weight in working order of 265,000 lb. All these locomotives will be equipped with superheaters.

Union Pacific Develops New Safety Organization

As a means of spreading the gospel of safe practice to all of its employees most effectively, the Union Pacific has reorganized its safety department. Heretofore this has consisted of a general safety agent, with three assistants, all of whom had concurrent jurisdiction, and also three mechanical safety inspectors located in the large shops. In place of this organization there is now a general safety agent with five division safety agents and two shop safety inspectors. One division safety agent is assigned to each of the larger divisions, with one agent covering two divisions of lighter traffic. The two safety inspectors are assigned to the two larger shops, respectively, where they will supervise all operations, with a view to promoting safety, and also give safety lectures to each employee taken into the force before he is permitted to go on duty.

Another innovation covering the entire Union Pacific System, including the Union Pacific Railroad, the Oregon Short Line and the Oregon-Washington Railroad & Navigation Company, is a safety banner contest to be carried on for a period of one year, at the end of which time banners will be awarded on the basis of safety records made under the following conditions: (1) A banner to the system unit making the lowest record in casualties per one million locomotive miles. (2) A banner to one division on each system unit making the lowest casualty record per one million locomotive miles. (3) A banner to the one of the six large shops on the system, *i.e.*, Omaha, Kansas City, Denver, Cheyenne, Pocatello and Portland, making the lowest casualty record per 100 employees. Employees of the St. Joseph & Grand Island Railroad, which is a part of the Central Division of the Union Pacific, will be included in this contest. These banners will be awarded for a period of one year and at the end of the year following if another system unit or division on a system unit or one of the large shops on the system has made a better record in safety than that holding the banner for the preceding year, it will then be entitled to the banner for the ensuing year. It is expected that keen competition will be developed to win these banners and the result of this campaign is looked forward to with interest by the officers and employees of the Union Pacific System.

Mechanical Associations' Plan for Joint Exhibit

At a meeting of the official representatives of a number of minor railway mechanical associations and the associations of supply men exhibiting at the conventions of the railroad organizations, schedules were arranged for holding the conventions of a number of the associations at the Hotel Sherman, Chicago, during a continuous period of two weeks beginning September 6, 1921. The railroad organizations definitely committed to the plan are the Traveling Engineers' Association, the International Railway General Foremen's Association, the American Railroad Master Tinners', Coppersmiths' and Pipe Fitters' Association and the Chief Interchange Car Inspectors' and Car Foremen's Association. Others may possibly be included at a later date.

In order to carry out the details of the plan for conducting a continuous joint exhibit and to arrange for simultaneous meetings of some of the associations, a resolution was passed that a committee be organized consisting of a representative from each of the railway and supply associations interested, to take care of features of the arrangements which would not regularly be handled by the individual associations, and that this committee be prepared to present a report at a joint meeting to be held in September, 1921, recommending the form of a permanent joint organization, if such an organization seems to be desirable.

Shop Construction

Atchison, Topeka & Santa Fe.—This company is constructing 10 additional stalls at its enginehouse at Amarillo, Tex., each stall to be 120 ft. long. The company is also lengthening 12 of the present engine stalls from 92 to 102 ft. The construction is of concrete and will cost approximately $125,000.

Chesapeake & Ohio.—This company will add 10 stalls to its engine house, install a new turntable, and erect an ice plant, storeroom and office building at Clifton Forge, Va., at an approximate cost of $600,000.

Chicago, Indianapolis & Louisville.—This company has awarded a contract for the construction of car repair shops at Lafayette, Ind., to A. E. Kemmer, Lafayette. The structure, which will have dimensions of 85 ft. by 440 ft., will be of brick and steel construction and will cost approximately $140,000.

Denver & Salt Lake.—This company is rebuilding its shops at Utah Junction, Colo., which were destroyed by fire, at a loss of $250,000.

Missouri, Kansas & Texas.—This company has awarded a contract to H. D. McCoy, Cleburne, Tex., for the construction of a roundhouse, shop, storehouse, and roundhouse foreman's office at Oklahoma City, Okla. The company contemplates enlarging its roundhouse and car facilities at Osage, Okla.

Norfolk & Western.—This company is adding 16 stalls to its 24-stall engine house at West Roanoke, Va. The company is also adding 8 stalls to its engine house at Bristol, Va.

Land Slide Covers Pennsylvania Tracks at Pittsburgh

The operation of the Pennsylvania Railroad was seriously hampered during the month of November by a slide which for a time threatened to cover all the main line tracks. The failure of the retaining wall east of the Union Station allowed material which had been filled into a gulley to slide onto the tracks. The movement of the earth was gradual and measures were taken to excavate the material as fast as it slid onto the tracks. Eventually 9 large steam shovels, 2 small ditching machines, 120 40-yd. steel dump cars, 300 12- and 16-yd. wooden dump cars and about 500 gondola cars were used to keep back the slide. The maximum encroachment of the slide onto the railroad property occurred on November 22, when the toe of the slide extended 200 ft. from the mouth of the ravine. The main tracks were again placed in service on December 6.

Subjects for 1921 Convention—Traveling Engineers' Association

The list of subjects of committee reports to be presented at the 1921 annual meeting of the Traveling Engineers' Association, which has recently been issued, includes the following topics:

The Best Method of Operating Stoker Fired Locomotives to Obtain the Greatest Efficiency at the Least Expense; Joseph Kelley (L. V.), Chairman.
A Comprehensive Standard Method of Employing, Educating and Examining Engineers and Firemen; J. B. Hurley (Wabash), Chairman.
What Are the Advantages of the Self-Adjusting Wedges, the Feed Water Heater and Devices for Increasing the Tractive Power of the Locomotive in Starting and at Slow Speed; T. F. Howley (Erie), Chairman.
Subjects for Discussion: J. H. DeSalis (N. Y. C.), Chairman.
Distribution of Power and Its Effect on Operating Costs; Robert Collett (N. Y. C.), Chairman.
Recommended Practice for Conservation of Locomotive Appurtenances and Supplies; J. P. Russell (Southern), Chairman.

Railroad Wages in Need of Reform

Hon. George W. Anderson, of Massachusetts, judge in the United States District Court and former Interstate Commerce Commissioner, in a speech at Boston on Monday, November 29, denounced the present system of railroad wage rates as absurd and unjust, and called upon all interested to work for its correction. Speaking before a conference of commercial and railroad interests, called to take action to induce the Interstate Commerce Commission to "save the railroads and industries from ruination," threatened by the present financial condition of the roads, he condemned in strong terms "the absurd scheme of paying the same scale of wages all over the country, regardless of living conditions and of the amount of work required, to all men holding a job carrying the same name." He urged that inflexible standards of wages be abandoned, in the interests of the working men themselves, and characterized as absurd the labor unions' proposal to secure a standardization of working conditions. Labor must alter its policy in this matter, or the public must compel the Railroad Labor Board to alter it. It is a menace to the public interest.

The artificial standardization of wages, on a mere money basis, that is, regardless of money purchasing power in various sections and of the quantity and quality of service required of such employees as station agents and freight handlers in large overworked sections, as compared with the necessary labor at small stations in which the business is limited to two or three hours a day, cannot be justified.

Transportation of Explosives During 1918

During the year 1907, which immedately preceded the enactment of the act to promote the safe transportation in interstate commerce of explosives and other dangerous articles, etc., 79 accidents in the transportation of explosives resulted in 52 deaths, 80 personal injuries and a total known property loss of nearly $500,000. During the year 1918 our military program required the production and transportation of more than 2,000,000,000 pounds of military explosives. In addition to this, the normal movement of explosives for commercial use amounted to about 600,000,000 pounds. It is deduced from careful estimates that at all times during the year 1918 there were on the tracks of the railroads in the United States not less than 55,000 carloads of explosives of an average weight of 40,000 pounds each. Notwithstanding the tremendous increase in the volume of these explosives transported during that year, the casualties resulting therefrom were only two persons injured and the damage to property was about $33,000.

In the transportation of dangerous articles other than explosives, however, 1,204 accidents occurred during 1918, resulting in 17 persons killed, 86 persons injured, and a known property loss of approximately $1,300,000. The remarkable success in transporting explosives is attributed to the penal provisions of the act of March 4, 1909, and the enforcement thereunder of our regulations governing such transportation. —From the Annual Report of the Interstate Commerce Commission.

MEETINGS AND CONVENTIONS

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations and railroad clubs:

Air-Brake Association.—F. M. Nellis, Room 3014, 165 Broadway, New York City.

American Railway Association, Division V—Mechanical.—V. R. Hawthorne, 431 South Dearborn St., Chicago.

Division V.—Equipment Painting Division.—V. R. Hawthorne, Chicago.

American Railway Association, Division VI.—Purchases and Stores.—J. P. Murphy, N. Y. C., Collinwood, Ohio.

American Railroad Master Tinners', Coppersmiths' and Pipefitters' Association.—C. Borcherdt, 202 North Hamlin Ave., Chicago.

American Railway Tool Foremen's Association.—R. D. Fletcher, 1145 E. Marquette Road, Chicago.

American Society for Testing Materials.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.

American Society for Steel Treating.—W. H. Eisenman, 154 E. Erie St., Chicago.

Association of Railway Electrical Engineers.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.

Canadian Railway Club.—W. A. Booth, 131 Charron St., Montreal, Que. Meeting second Tuesday in each month except June, July and August, at Windsor Hotel, Montreal, Que.

Car Foremen's Association of Chicago.—Aaron Kline, 626 N. Pine Ave., Chicago. Meeting second Monday in month, except June, July and August, New Morrison Hotel, Chicago.

Car Foremen's Association of St. Louis.—Thomas B. Koeneke, 604 Federal Reserve Bank Building, St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis.

Central Railway Club.—H. D. Vought, 95 Liberty St., New York. Next meeting January 14. Film pictures of Baldwin Eddystone plant will be shown and an explanatory address given by A. H. Ehle, general sales manager.

Chief Interchange Car Inspectors' and Car Foremen's Association.—W. P. Elliott, T. R. R. A. of St. Louis, East St. Louis, Ill.

Cincinnati Railway Club.—W. C. Cooder, Union Central Building, Cincinnati, Ohio. Meetings second Tuesday in February, May, September and November, Hotel Sinton, Cincinnati, Ohio.

Dixie Air Brake Club.—E. F. O'Connor, 10 West Grace St., Richmond, Va.

International Railroad Master Blacksmiths' Association.—W. J. Mayer, Michigan Central, 715 Clarke Ave., Detroit, Mich.

International Railway Fuel Association.—J. G. Crawford, 702 East 51st St., Chicago.

International Railway General Foremen's Association.—William Hall, 1061 W Wabasha Ave., Winona, Minn.

Master Boilermakers' Association.—Harry D. Vought, 95 Liberty St., New York. Convention May 23 to 26, 1921, inclusive, Planters' Hotel, St. Louis, Mo.

New England Railroad Club.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Next meeting, January 11. Paper on the Service of Supply will be presented by H. C. Pearce, general purchasing agent, Seaboard Air Line.

New York Railroad Club.—H. D. Vought, 95 Liberty St., New York.

Niagara Frontier Car Men's Association.—George A. J. Hochgrebe, 623 Brisbane Building, Buffalo, N. Y. Regular meetings January, March, May, September and October.

Pacific Railway Club.—W. S. Wollner, 64 Pine St., San Francisco, Cal. Meetings second Thursday in month, alternately in San Francisco and Oakland, Cal.

Railway Club of Pittsburgh.—J. D. Conway, 515 Grandview Ave., Pittsburgh, Pa. Meetings fourth Thursday in month except June, July and August, American Club House, Pittsburgh.

St. Louis Railway Club.—B. W. Frauenthal, Union Station, St. Louis, Mo. Meetings second Friday in month except June, July and August.

Traveling Engineers' Association.—W. O. Thompson, N. Y. C. R. R., Buffalo, N. Y.

Western Railway Club.—Bruce V. Crandall, 14 E. Jackson Boulevard. Next meeting January 17, 1921. Paper on Cause of the Present Condition of Freight Cars and Suggestions for Their Improvement will be presented by J. C. Fritts, master car builder, D. L. & W.

PERSONAL MENTION

GENERAL

H. B. Smith has been appointed fuel agent of the Kansas City Southern, with headquarters at Kansas City, Mo., succeeding B. B. Brain, who has been promoted to purchasing agent.

H. L. Worman

H. L. Worman, assistant superintendent of motive power of the St. Louis-San Francisco, has been appointed superintendent of motive power, with headquarters at Springfield, Mo., succeeding C. C. Higgins, deceased. Mr. Worman was born at Salem, Ohio, July 19, 1877. He entered the service of the St. Louis-San Francisco in 1905 as a machinist in the shops at Kansas City, Mo. In 1906 Mr. Worman was appointed roundhouse foreman at Kansas City. In 1907 he became erecting foreman and in 1908 machine foreman in the same shop. In 1911 he was appointed general foreman at Fort Scott, Kan., and in 1916 he became traveling roundhouse foreman for the entire system. In 1917 he was appointed master mechanic at Memphis, Tenn. In 1919 he was appointed assistant superintendent of motive power, with headquarters at Springfield, Mo., which position he held at the time of his recent promotion.

Eugene R. Gorman

Eugene R. Gorman, superintendent of motive power and machinery of the Chicago, St. Paul, Minneapolis & Omaha, with headquarters at St. Paul, Minn., was born on December 3, 1879, at Gorman Town, Minn. He entered railway service in April, 1900, as a locomotive fireman on the Chippewa Valley & Northern, a road owned and operated by the Arpin Hardwood Lumber Company, Bruce, Wis. In September, 1901, he became a locomotive fireman on the Western division of the Chicago, St. Paul, Minneapolis & Omaha. He was promoted to engineman and transferred to the Northern division in February, 1907, but left the company's service in May, 1908, to go with the Northern Pacific, working out of Missoula, Mont. In May, 1912, Mr. Gorman was appointed traveling engineer on the Northern division of the Chicago, St. Paul, Minneapolis & Omaha, with headquarters at Spooner, Wis., and served in this position until December, 1915, when he was promoted to trainmaster on the same division. In May, 1917, he was made acting assistant superintendent of the Western division, with headquarters at St. James, Minn., this temporary promotion being made permanent in November, 1917. At the time of his recent promotion, Mr. Gorman was assistant superintendent of the Eastern division, with headquarters at Eau Claire, Wis., where he had been transferred in April, 1919.

Alfred A. Klein has been appointed lubrication supervisor of the Santa Fe at Richmond, Cal., and will be directly under C. T. Ripley, general mechanical supervisor. Mr. Klein is one of the Santa Fe machinist apprentices graduated several years ago at the Topeka shops and has served in various capacities. During the last two years he was apprentice school instructor at Richmond.

Captain H. P. M. Beames has been appointed chief mechanical engineer of the Crewe Works and the hydraulic department of the London & North Western Railway, with offices at Crewe, England, succeeding C. J. Bowen Cooke, deceased. Captain Beames entered the Crewe Works as an apprentice in January, 1895, and, after his elementary training, held numerous positions of responsibility in the chief mechanical engineer's department, becoming locomotive works manager in April, 1916. At the outbreak of the South African war, he volunteered and served as a private, later becoming a sergeant. When the European war broke out, he again volunteered for military service and was given a command in the Royal Engineers, returning later to his position at the Crewe Works.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

W. A. George was appointed master mechanic of the Jacksonville Terminal, effective December 10.

H. G. Bonney has been appointed assistant master mechanic of the Lehigh & New England, with headquarters at Pen Argyl, Pa., succeeding N. R. Wright, resigned.

L. C. Tyler has been appointed road foreman of engines of the Cleveland, Cincinnati, Chicago & St. Louis, with headquarters at Urbana, Ill., succeeding Charles McCarty, transferred.

H. C. Gillispie, master mechanic of the Chesapeake & Ohio, with headquarters at Peru, Ind., has been transferred to a similar position at Huntington, W. Va., succeeding W. S. Butler, promoted. E. R. Woody, assistant master mechanic at Fulton, Va., succeeds Mr. Gillispie as master mechanic at Peru.

J. W. Lemon, master mechanic on the Central Kansas division of the Missouri Pacific, with headquarters at Osawatomie, Kan., has been transferred to the Colorado division, with headquarters at Hoisington, Kan., effective December 15. S. L. Landis has been appointed acting master mechanic succeeding Mr. Lemon.

W. M. Green has been appointed road foreman of engines of the Big Sandy division of the Chesapeake & Ohio, with headquarters at Paintsville, Ky., succeeding D. S. Baals, resigned. W. A. Mordica has been appointed road foreman of engines and assistant trainmaster, Shelby coal district, with headquarters at Shelby, Ky.

CAR DEPARTMENT

F. O. Erickson has been appointed car foreman of the Chicago, Rock Island & Pacific at Manly, Ia., succeeding M. B. Flaherty, who has been transferred.

J. W. Johnston, chief inspector of car lighting of the Canadian National, with headquarters at Toronto, has had his jurisdiction extended to include the Grand Trunk Pacific.

J. Gutteridge, foreman of the car department of the Kansas City Southern at Pittsburg, Kan., has been appointed general foreman, car department, with headquarters at Pittsburg, with jurisdiction over the entire line. C. E. Oakes has been appointed shop superintendent at Pittsburg, succeeding William Turley, resigned.

SHOP AND ENGINEHOUSE

L. E. Fletcher, master mechanic on the Atchison, Topeka & Santa Fe, with headquarters at La Junta, Colo., has been promoted to superintendent of shops, with the same headquarters. G. M. Lawler succeeds Mr. Fletcher.

Francis P. Howell, whose appointment as shop superintendent of the Atlantic Coast Line at Waycross, Ga., was announced in the December issue, was born on October 11, 1876, at Tarboro, N. C. He received a high school education and entered the employ of the Atlantic Coast Line on April 11, 1896, at Rocky Mount, N. C., as a machinist apprentice. In April, 1902, he was promoted to night roundhouse foreman; in May, 1903, appointed gang foreman; and in March, 1908, promoted to erecting shop foreman. In January, 1909, he was transferred as erecting shop foreman to Waycross, and in July, 1917, was promoted to general foreman. In July, 1918, he became master mechanic, with headquarters at Savannah, Ga., which position he held at the time of his recent appointment.

Clarence W. Adams, whose appointment as shop superintendent on the Michigan Central at Jackson, Mich., was announced in the December *Railway Mechanical Engineer,* was born on March 17, 1885, at St. Thomas, Ont. He attended the Collegiate Institute and entered the service of the Michigan Central on September 1, 1902, as a machinist apprentice. After finishing his apprenticeship in 1906, he was employed by the Pere Marquette, and also by the Burroughs Adding Machine Company, Detroit. In October, 1907, he returned to the Michigan Central at St. Thomas as a machinist. In 1912, he was promoted to gang foreman and erecting foreman; in 1916, enginehouse foreman; and finally, general foreman of shops and enginehouse, which position he held at the time of his recent appointment.

PURCHASING AND STOREKEEPING

J. B. Fowler has been appointed division storekeeper on the Pennsylvania, with headquarters at Fort Wayne, Ind.

H. W. Concannon has been appointed division storekeeper of the Salt Lake division of the Southern Pacific, with headquarters at Ogden, Utah, succeeding S. J. DeGraff, assigned to other duties.

F. Osterman, chief clerk of the purchasing department of the Chicago Great Western, has been appointed assistant purchasing agent of the Pere Marquette, with headquarters at Detroit, Mich.

L. Lavoie, assistant general purchasing agent of the Canadian National, with headquarters at Toronto, has been appointed general purchasing agent, with the same headquarters, succeeding E. Laugham, who is retiring from active service.

H. P. Buchenery, assistant division storekeeper of the Southern Pacific, with headquarters at Sparks, Nev., has been promoted to division storekeeper, with headquarters at Tracy, Cal., succeeding V. R. Taylor, transferred to Tucson, Ariz. J. F. McAuley succeeds Mr. Buchenery.

B. B. Brain, whose appointment as purchasing agent of the Kansas City Southern was noted in the December issue, entered railway service in 1885 with the Kansas City, Fort Scott & Memphis (now a part of the St. Louis-San Francisco). In 1902 he went to the Kansas City Southern as general storekeeper, with headquarters at Kansas City. Later he served as chief clerk in the purchasing department and, since 1912, has been fuel agent for the company, which position he held at the time of his recent appointment.

G. W. Bichlmeir, purchasing agent of the Kansas City Southern, has been appointed purchasing assistant of the Union Pacific, with headquarters at Omaha, Nebr. Mr. Bichlmeir was born at Cincinnati, Ohio, September 10, 1886, and entered the employ of the Cincinnati, Hamilton & Dayton in 1906 as a clerk in the office of the purchasing agent. In 1909 he became a clerk in the department of supply of the Missouri Pacific at St. Louis, Mo., and the following year was appointed chief clerk to the division storekeeper at Osawatomie, Kan., where he remained until January, 1911, when he became chief clerk to the general storekeeper of the Kansas City Southern. He remained in this position until 1917, when he resigned to engage in business. In April, 1918, he again entered the employ of the Kansas City Southern as chief clerk to the purchasing agent, and in August of the same year was appointed assistant to the purchasing agent. Mr. Bichlmeir was appointed purchasing agent of the Kansas City Southern in March, 1920, and was holding that position at the time of his recent appointment.

OBITUARY

C. J. Bowen Cooke, chief mechanical engineer of the London & North Western, died October 19. Mr. Bowen Cooke entered the Crewe works of the London & North Western as a premium apprentice in February, 1875, and in 1880 was appointed assistant to the superintendent of the running department for the southern division. In 1899, when the running departments of the London & North Western were put under one jurisdiction, he became assistant superintendent for the southern division, which position he held until June, 1909, when he was appointed chief mechanical engineer.

ROBERT SPEER MILLER, master car builder of the New York, Chicago & St. Louis, died suddenly of heart failure at his home at Cleveland, Ohio, December 1. Mr. Miller was born in Washington county, Pennsylvania, September 13, 1856. He entered railway service in 1879 with the Pittsburgh, Cincinnati, Chicago & St. Louis as a rodman in the engineering department. In 1882 he entered the service of the New York, Chicago & St. Louis, and subsequently served as foreman, general car inspector and master car builder of the same road, which latter position he held at the time of his death.

H. J. SMALL, for many years general superintendent of motive power and machinery of the Southern Pacific, died October 28, at Berkeley, Cal. Mr. Small was born at Cobourg, Ont., November 15, 1849, and was educated at Toronto Normal School. He entered railway service in 1868 as a machinist on the Chicago North Western. A year later he became a draughtsman for the Kansas Pacific (now a part of the Union Pacific), which position he resigned in 1871 to become chief draughtsman for the Northern Pacific. In 1873 he went to Texas to become a general foreman on the International & Great Northern, which position he held until 1877, when he became master mechanic for the Galveston, Houston & Henderson. He left this position in 1879 to become master mechanic on the Texas & Pacific. In 1881 he was appointed superintendent of machinery of the Northern Pacific, and in 1887, assistant superintendent of motive power of the Philadelphia & Reading. Mr. Small became superintendent of motive power and machinery of the Southern Pacific in 1888, and, in 1902, was appointed general superintendent of motive power and machinery. He remained in this position until 1915, when he retired on account of ill-health.

H. J. Small

Railway Accidents in the United Kingdom During 1919

The Ministry of Transport recently issued a report on the accidents which occurred on the railways of the United Kingdom in 1919. There was a total of 932 people killed, as against 870 in 1918, while the number of persons injured last year totaled 23,983. Of accidents in which the movement of trains and railway vehicles was not concerned, only the fatal cases were required to be reported in 1918, so that a comparison under that head is not possible. The number of killed in 1919 included 361 trespassers—comprising suicides—and 318 servants of companies or contractors met their deaths by accidents in which the movement of trains was concerned. There were 827 persons killed and 5,897 injured during the year in accidents caused by the movement of trains and railway vehicles (exclusive of train accidents). Twenty-seven passengers were killed and 810 injured by falling between trains and platforms or on to platforms, ballast, etc., when attempting to enter or alight from trains, nine were killed and 13 injured when crossing lines at stations, 28 were killed and 76 injured by falling out of carriages during the running of trains, and 10 were killed and 927 injured from other causes.

There were 28 collisions during 1919, and of a total of 30 cases of train accident 10 were ascribed to the failure of enginemen to obey danger signals.

SUPPLY TRADE NOTES

George Baker, formerly general sales manager for the Illinois Steel Company, Chicago, who retired from active service about two years ago, died on November 18.

The General Railway Devices Company has been organized at Racine, Wis., with W. H. Osborne, president, John G. Osborne, vice-president, and W. V. Osborne, secretary and treasurer.

James C. Carlton, formerly connected with the Thompson Machinery Company, Pittsburgh, Pa., has entered the employ of the sales department of the Sherritt & Stoer Company, Philadelphia.

P. V. Burwell, who has been acting as an assistant for the advertising manager of the Black & Decker Manufacturing Company, Baltimore, Md., has been appointed assistant advertising manager.

The Air Reduction Sales Company, New York, has just completed building a four-story addition to its apparatus plant, Jersey City, N. J. It is of brick construction with reinforced concrete floors.

Edward Buker has been appointed representative of the car seat department of the Heywood Brothers & Wakefield Company, Wakefield, Mass., with office and exhibits at 1415 Michigan avenue, Chicago.

The Bastian-Blessing Company, Chicago, Ill., manufacturer of Rego oxy-acetylene and oxy-hydrogen products, has appointed the Beck-Hill Corporation, 22 Thames street, New York, as its sole eastern railway representative.

C. A. Eggert, who was for a number of years connected with the sales department of the Consolidated Car Heating Company, Albany, N. Y., has entered the employ of the O. M. Edwards Company, Inc., as sales manager, at 1425 Edison building, Chicago, Ill.

C. B. Merrell, who has been for a number of years in the general offices of the Economy Fuse & Manufacturing Company, Chicago, has been appointed district sales manager of its Philadelphia office, 523 Widener building, vice E. J. Watson, resigned.

J. C. Kopf, formerly manager of the engineering department of the Duff Manufacturing Company, has been appointed research engineer and placed in charge of a newly established research department. F. W. Schwerin has been promoted to manager of engineering.

A report has been published in some trade papers that the operation of the foundry of the Modern Steel Casting Company, Milwaukee, Wis., had been suspended because of a fire. The company states that this report is not true, as the damage was slight and the foundry is running at normal capacity.

A. E. Smith has been elected a vice-president of the Union Tank Car Company in charge of the construction and maintenance of plant and equipment. Mr. Smith will handle all correspondence regarding repairs to cars and M. C. B. matters. The office of master car builder has been discontinued.

The consolidation of the Whiting Foundry Equipment Company, of Harvey, Ill., and the American Foundry Equipment Company, of New York, as announced in the October issue, has not been consummated, and the two companies will continue to operate as separate concerns the same as heretofore.

H. G. Keller, manager of the Philadelphia, Pa., office of the Independent Pneumatic Tool Company, Chicago, has been promoted to manager of the New York office and F. H. Charbono, manager at St. Louis, Mo., has been promoted to manager of the Philadelphia office to succeed Mr. Keller.

P. C. Cady, who was for several years with the mechanical engineering department of the New York Central, has opened an office at 133 Greenwich street, New York, and will represent the following concerns: Guilford S. Wood Company, Chicago; J. Faessler Manufacturing Company, Moberly, Mo.; Coale Muffler

& Safety Valve Company, Baltimore, Md.; W. C. Dunn Company, Cincinnati, Ohio, and the Virginia Equipment Company, Oak Harbor, Ohio.

Ethan Viall, who for ten years served as an editor on the staff of the American Machinist, has resigned to take over the management of a middle-western manufacturing plant in which he has been interested. Mr. Viall's place has been taken by H. K. Condit, the former managing editor, and L. C. Morrow succeeds Mr. Condit.

The Falls Rivet Company, Kent, Ohio, has bought from the Ohio Wire Goods Manufacturing Company, Akron, Ohio, all its machinery, patents and patterns relating to the manufacturing of cotter pins and flat spring keys. The machinery has been moved from Akron to Kent and is now in operation. Lawrence Kneifel, of the organization at Kent, has become associated with the Falls Rivet Company.

Bruce Hartman, of Bloomsburg, Pa., a director of the Bell Locomotive Works, has been appointed receiver of the company by Federal Judge Witmer at Sunbury, Pa. The company's office is at 23 Water street, New York, and its works are at Bloomsburg. J. S. McCormack, sales manager, and William Stevenson, chief engineer, in the New York office, will probably remain with the company under the receiver.

Richard Sanderson, manager of the New York office of the Baldwin Locomotive Works and the Standard Steel Works Company, Philadelphia, Pa., has been transferred to Philadelphia as vice-president in charge of sales of the Standard Steel Works Company, succeeding Robert Radford, resigned. Mr. Sanderson was born on July 30, 1888, at Lynchburg, Va., and was educated at Worcester Polytechnic Institute, leaving there in 1910. He started as an apprentice on the Seaboard Air Line, later finishing his apprenticeship at the Baldwin Locomotive works. In 1912 he entered the New York office as assistant representative of the sales department for both the Baldwin Locomotive Works and the Standard Steel Works Company, remaining in that capacity until April 1, 1919, when he was made manager of the New York office for both companies. On December 1 he was elected vice- president of the Standard Steel Works Company, as above noted.

R. Sanderson

The Chicago Pneumatic Tool Company announces the appointment of J. F. Huvane as eastern manager of compressor and engine sales, with headquarters at 6 East Forty-fourth street, New York, and G. C. VandenBoom as western manager of compressor and engine sales, with headquarters at 300 North Michigan boulevard, Chicago. H. L. Dean, formerly manager of the compressor and engine sales division, has resigned.

The following companies have been appointed representatives of the Pneumatic Safety Valve Company, Woonsocket, R. I.; Frank E. Harrison, 56 Pine street, New York; the R. C. Neal Corporation, 76 Pearl street, Buffalo, N. Y.; the Sixt & Day Company, Guardian building, Cleveland, Ohio; Midgley & Borrowdale, 1550 McCormick building, Chicago, Ill., and the Charles A. Dowd Sales Company, 320 Market street, San Francisco, Cal.

Mr. Pasley, metallurgist, and Mr. Clowes, a mill production man, of Samuel Osborn & Co., Ltd., Sheffield, England, who have been visiting various plants in the United States and Canada making a study of American conditions and requirements, have returned to England. Their visit followed that of Arnold Pye-Smith, the London director, who was here during the summer for about five weeks. B. M Jones & Co., Inc., is the American representative of Samuel Osborn & Co.

S. C. Wilson has been appointed sales engineer in the Pittsburgh, Pa., office, 1224 Fulton boulevard, of the Whiting Foundry Equipment Company, Harvey, Ill., succeeding C. H. Martin. Mr. Wilson for the past year and one-half has served at the main office and works of the company. J. D. James, who has been with the Whiting company for the past eleven years, serving in various capacities, has been appointed assistant to George F. Crivel, the company's representative at 430 Ellicott Square, Buffalo, N. Y.

The Dunbar Manufacturing Company announces that the corporate name of the firm has been changed to the Morton Manufacturing Company. H. U. Morton is president; H. H. Schroyer, vice-president, and Charles D. Morton, secretary and treasurer. The factory and general offices are situated at 5133-39 W. Lake street, Chicago, as formerly. Among the railway appliances handled by this company are vestibule diaphragms (canvas and steel), steel doors for passenger and baggage cars, Chanarch steel flooring, car window curtains and fixtures, curtain rollers, sash locks and racks.

Harry U. Morton

Harry U. Morton, president of the Morton Manufacturing Company, entered railway service with the Pullman Company in 1891. He served this company for 4 years in the manufacturing department, and 13 years in the operating department. In 1907, he was appointed vice-president and general manager of the General Railway Supply Company, and seven years later became vice-president and secretary of the Acme Supply Company, Chicago. The corporate name of this company was changed to the Dunbar Manufacturing Company in 1917, and on April 1 of that year Mr. Morton was elected president and treasurer of the company. Charles D. Morton is the son of H. U. Morton. He is a graduate of the University of Wisconsin, class of 1917. He entered service with the company immediately upon receiving his discharge from the army in January, 1919.

C. D. Morton

The Toledo Crane Company, with main office and works at Bucyrus, Ohio, chartered in Ohio, with a capital of $500,000, succeeds the Toledo Bridge & Crane Company, of Toledo, Ohio, as builders of Toledo cranes. The new company has bought all drawings, patterns, records, and every item pertaining to the crane business. W. F. Billingsley, who for the past 11 years has been active in the management of the crane department for the Toledo Bridge & Crane Company, holds an executive position and is active in the management of the new company and has with him intact the present crane department organization of the Toledo Bridge & Crane Company.

H. W. Jacques, for the past six years manager of the railway supply department of the Simmons Hardware Company, St. Louis, Mo., has left the service of that company and has established an office at 404 Parkway building, Philadelphia, Pa. He will represent in the railroad field the following firms: Baldwin Tool Works, Parkersburg, W. Va.; Fayette R. Plumb, Inc., Philadelphia, Pa.; Columbus Handle & Tool Company, Columbus, Ind.; American Handle Company, Jonesboro, Ark.; Keller & Tamm Manufacturing Company, St. Louis, Mo.; Western Tinware Company, St. Louis, Mo.

James C. Currie, eastern representative of the Nathan Manufacturing Company, New York, was killed in an elevator accident in New York City on December 11. Mr. Currie was born in Scotland 69 years ago and came to the United States when he was 12 years of age. Shortly afterwards he entered the service of the Pennsylvania Railroad as a fireman and later served as engineman on the Congressional Limited. About 26 years ago he went to the Nathan Manufacturing Company as its eastern representative and was with that firm until his death. Mr. Currie was well known in the railway supply field and was assistant grand chief of the Brotherhood of Locomotive Engineers.

Don L. Clement will again represent Pratt & Lambert, Inc., Buffalo, N. Y., in the railroad field, with headquarters in New York. Mr. Clement represented Pratt & Lambert, Inc., in a like capacity until November, 1917, when he was commissioned in the Engineer Corps of the United States Army, and was immediately assigned to the 35th Engineers, a unit organized for the purpose of erecting railroad cars in France. He was overseas 16 months, and during the greater part of this time was assistant adjutant and adjutant of the 35th Engineers, which eventually became one of the grand divisions of the Transportation Corps. He was discharged in May, 1919, with the rank of captain. Since Mr. Clement's return to civilian life, he has been connected with Pratt & Lambert, Inc., on inside work of a special character.

The American Malleable Castings Association inaugurated a research program in 1915 to improve the works' practice of the member companies and insure a uniform high-grade product. The improvement in the properties of malleable iron, which has been brought about as a direct result of this policy, is set forth in a statement recently authorized by the association. Records of tests made in 1911 showed the average ultimate strength of malleable iron as manufactured to be about 39,000 lb. and the elongation under 5 per cent. A report made in September, 1920, showed an average ultimate strength of over 53,000 lb., and an average elongation of over 14 per cent. The report also showed that the result of this co-operative research work was not only to increase ultimate strength and elongation, but to increase the uniformity of the product.

Metal & Thermit Corporation

The Metal & Thermit Corporation has opened a branch office at 141 Milk street, Boston, Mass. Robert L. Browne is the New England district manager. O. E. Falls, who has had many years of experience in charge of foundry and thermit welding work at the Norfolk Navy Yard, Portsmouth, Va., has accepted a position with the Metal & Thermit Corporation, New York. Mr. Falls obtained his earlier foundry experience from positions held at the Norfolk & Western shops, Roanoke, Va.; the Richmond Locomotive Works, Richmond, Va.; the Pennsylvania Engineering Works, New Castle, Pa.; the Franklin Air Compressor Works, Franklin, Pa.; and the Seaboard Air Line shops, Portsmouth, Va. At the last mentioned company, Mr. Falls began his first thermit welding work. In 1905, he joined the Goldschmidt Thermit Company, New York, and in 1907, returned to the Norfolk Navy Yard and for ten years did all or supervised the thermit welding work of that company. In 1917, he became superintendent in the steel foundry of the Bay View Foundry Company, Sandusky, Ohio. Later he was appointed superintendent of the steel foundry of the Weatherley Steel Castings Company, Weatherley, Pa., and still later superintendent of the iron and brass foundry of the Gaskins Foundry Company, New Bern, N. C. When he accepted his present position with the Metal & Thermit Corporation, he was superintendent of the iron and brass foundry of the Manning Manufacturing Company, Rutland, Vt.

TRADE PUBLICATIONS

Handbook for Drillers.—A 37-page booklet has been designed for students of drilling by the Cleveland Twist Drill Company, Cleveland, Ohio. It is in reality a thoroughly revised, rewritten and reillustrated edition of "Uses and Abuses of Twist Drills."

Lifting Jacks.—The Duff Manufacturing Company, Pittsburgh, Pa., is distributing catalogue No. 104, a new 148-page book illustrating and describing the complete line of Duff lifting jacks. It includes jacks of all types for steam railway work—track jacks, car jacks, locomotive jacks, bridge jacks and journal box jacks.

Leather Belting.—The manufacture and renovation of leather belting are treated in Catalogue No. 12 of the Consolidated Belting Company, Philadelphia, Pa. A valuable feature of the catalogue is a concise discussion of belting problems and their solution and formulae for calculating the proper sizes and speeds for belts.

Lubrication.—Technical discussion of lubrication and the use of lubricating oils in various industries form the subjects of the articles in the monthly publication of the Texas Company, New York City. This magazine is distributed without cost to those who are especially interested in the use and selection of lubricants.

Thermit Welding.—An instruction book, especially prepared for use by men actually performing thermit welding repairs in railroad shops, has recently been issued by the Metal & Thermit Corporation, New York. This booklet, which is known as Pamphlet No. 41, is of convenient pocket size for ready reference.

Lathe and Planer Tools.—A 32-page catalogue has been issued recently by the Ready Tool Company, Bridgeport, Conn., showing the various kinds and sizes of tools manufactured by this company. These tools include high-speed lathe centers; lathe, grinder and milling-machine dogs; lathe and planer tools, hold-downs, and belt sticks.

Radial Drills.—The Western Machine Tool Works, Holland, Mich., has recently issued catalogue No. 21, in which its line of plain and universal radial drills is fully described and illustrated. The special feature of these drills is the low hung drive in which the spindle driving gear is located at the lower end of the spindle just above the socket.

Hoists.—The Wright Manufacturing Company of Lisbon, Ohio, manufacturers of high speed hoists, screws and differential blocks and steel trolleys, have issued an attractive new catalogue descriptive of their line. It contains much data of use to those interested in hoists and a portion of the catalogue is devoted to a discussion of the various types of hoists and the field of usefulness of each.

Instruction Book for Railroad Shops.—The Metal & Thermit Corporation, New York, has just issued a small Thermit railroad instruction book, No. 41, expressly prepared for use by men actually performing Thermit welding railroad repairs. The pamphlet is of a convenient pocket size and the instructions have been condensed into the smallest possible space consistent with clearness aand thoroughness.

Spanish Leaflet.—That the English-speaking race is not the only large user of thread-cutting machinery is indicated by the fact that the Landis Machine Company, Waynesboro, Pa., has issued recently a 16-page leaflet, in Spanish, describing Landis thread-cutting machinery. This leaflet is intended for distribution in Spain and South America and includes many illustrations of different types of machines, together with their descriptions, from the earliest days to the present time.

Reilly Feed Water Heater.—Bulletin No. 260 has been issued by the Griscom-Russell Company, New York, describing two types of Reilly feed water heaters. It is pointed out in the first part of the bulletin that the prime function of a boiler is to generate steam, not to heat water. Special emphasis is laid on the value of feed water heaters in saving fuel, increasing boiler capacity, reducing the cost of maintaining a boiler and increasing its life. A method of computing the actual saving resulting from the use of a feed water heater is given. Complete tables of dimensions for the different sizes of heaters are included in the bulletin. The proper methods of installing Reilly heaters are shown in detail, together with the information required when ordering.

Radius Tools.—The advantages of standard radius lathe and planer tools are plainly indicated in a little booklet issued recently by the R. G. Smith Tool & Manufacturing Company, Newark, N. J. Illustrations are included showing how convex or concave surfaces of any standard radius can be machined by the use of special cutters. A holder is provided for the cutter, which may be used almost indefinitely, as it can be reground many times without altering the cutting radius.

Rail Welding.—The Metal & Thermit Corporation, New York, has issued a new and revised Thermit rail welding pamphlet, No. 39, which describes the various ways in which Thermit welding can be advantageously used for rail welding, such as for eliminating rail joints and track maintenance expense in ordinary paved track, for making low cost and low maintenance frogs and crossings, for repairing motor cases and truck frames and for welding steam railroad rails in paved streets or where main highways cross the tracks.

Tubular Steel Poles.—Bulletin No. 14-C of the National Tube Company, Pittsburgh, Pa., is an attractive 48-page booklet which sets forth the advantages of tubular steel poles. The application of this type of support to high automatic or manual signals, trolley wires, telegraph and telephone lines, transmission lines and lighting fixtures, is illustrated and described. A tabulation of sizes, weights. etc., facilitates the selection of the pole best suited for the particular service. The closing pages of the bulletin are devoted to tables, giving the properties of steel pipe.

Carbonfree Metals.—The Metal & Thermit Corporation, New York, has issued the fourth edition of its Thermit Carbonfree Metals and Alloys Pamphlet No. 20. The pamphlet, in addition to containing a detailed description of the properties and characteristics of the various carbonefree metals and alloys manufactured by this company, includes also for the first time an explanation of the advantages of using tungtabs or tablets of pure tungsten metal in the production of high speed steel and other alloys containing tungsten instead of using tungsten powder and ferro-tungsten.

Wrought-iron Pipe.—Bulletin No. 1, issued recently by the Reading Iron Company, Reading, Pa., is a finely illustrated 31-page bulletin describing wrought-iron pipe, both in manufacture and service. An interesting account is given of the origin and development of the wrought-iron industry. Illustrations and descriptions are given of the various processes entering into the manufacture of wrought-iron pipe, including the puddling process, manufacture of the skelp, and the different operations in making the final product. The advantages of wrought-iron pipe over steel pipe are commented upon, and the last few pages of the bulletin show some interesting examples of the use of wrought-iron pipe.

Die Blocks.—Catalogue No. 3 entitled "Die Blocks" has been issued by the Pennsylvania Forge Company, Philadelphia, Pa. The catalogue explains that quality and uniformity should be the first consideration in ordering die blocks. The first cost of the steel is negligible compared with the expense of sinking and the risk of cracking in hardening. It is stated that die blocks made by this company are made of acid open hearth steel in 10-ton furnaces, insuring uniformity of product. A description of the various grades of die blocks is given in the catalogue, together with recommended heat treatment. A complete table of the weights of die blocks is shown; also a table of draft angles for die sinkers.

Skin Sores and Boils.—"Causes of Skin Sores and Boils Among Metal Workers" is the title of a 51-page booklet issued recently by E. F. Houghton & Co., Philadelphia, Pa. One of the serious problems confronting the metal-cutting industries is that of boils and skin sores among operators, and this booklet presents the results of a complete investigation of the subject made by the Houghton research staff. The work is thoroughly practical and shows that wherever the suggestions for prevention of infection have been applied in a common sense manner, the infection has been cut down and in some cases eliminated. The investigation also showed no grounds for the widespread belief that cutting compounds are primarily responsible for the various forms of infection among metal-cutting operators.

Industrial Relations Work of Westinghouse Air Brake Company.—An attractive illustrated book describing the agencies that have been established to promote the general well-being of the employees and to facilitate pleasant, harmonious industrial relations, has recently been issued by the Westinghouse Air Brake Company as publication 9044. The efforts of this company to cooperate with its employees have extended over more than a half century. At present the company has an Industrial Relationship Committee, a pension system, a relief department, a workmen's compensation fund, Y. M. C. A. and Y. W. C. A. buildings and other social activities. All these are outlined in a manner that makes the book valuable to anyone interested in the subject of relation between employer and employee.

Magnesia Pipe and Boiler Covers.—The field for heat insulating coverings for pipes and boilers is covered in a thorough manner in an attractive booklet entitled "Defend Your Steam" published by the Magnesia Association of America, Philadelphia. Numerous accounts of tests and extracts from technical papers are given to show the efficiency of magnesia as insulating material. The process of manufacture from Dolomite rock is described and descriptions and illustrations of typical installations are given. The book contains tables showing the losses from bare steam pipes and the saving in fuel and in money effected by the use of magnesia insulation. The specifications of the Magnesia Association are included and charts are shown from which the thickness of covering for the maximum net saving can be obtained.

Leather Belting.—Bulletin No. 101, entitled "Standardized Leather Belting," and containing 96 pages, has been issued by the Graton & Knight Manufacturing Company, Worcester, Mass. The advantages of standardization, not only in the manufacture of leather, but power transmission belting, are explained and illustrations given of the kinds of belting used for different purposes. Among other sections of interest in the bulletin are two devoted to the machine and woodworking shops. In each case, full directions are given for ordering the best belts for the individual machines. The belt widths are shown, together with the horsepower transmitted under various conditions. The last few pages of the bulletin are devoted to different methods of lapping belts, rules for obtaining tension belts, and tables containing information of value to belt users.

Packless Valves.—Every engineer, architect, fitter and user of valves realizes the importance of eliminating leaks at valve handles. The actual expense of repacking a dozen or more valves on a system may not be in itself a big item, but when the repacking of important valves necessitates tying up part of the power house equipment the incidental cost is very high. Packless valves are coming into more common use and an effective form of this valve is described in an eight-page folder published by the Defiance Packless Valve Company, Chicago, Ill. This valve has a metal to metal seat with a non-rising double taper stem upheld by a spring. It is claimed to be non-leakable. Valves of this type are fully tested before shipment and may be used for low and high pressure steam, hot and cold water, oil and air, up to and over 2,000 lb. Among the advantages claimed for the Defiance Packless Valve are simplicity of design and construction, elimination of all packing and easy turning under high pressure.

Thermit Mill and Foundry Practice.—The Metal & Thermit Corporation, New York, has just issued the third edition of the Thermit welding pamphlet No. 17, for mill and foundry repairs. The new edition has been revised and brought up to date both as regards new practices recommended and illustrations showing recent interesting repairs on certain types of equipment which were executed since the publication of the former edition.

The pamphlet begins with a general discussion of the proper applications and fields for oxy-acetylene, electric and Thermit welding, respectively. It then describes in detail the methods to be followed and apparatus used in welding iron and steel sections in general. Later it outlines thoroughly special applications of Thermit welding, such as for crankshaft, pinion and roll repairs, and also for cast-iron welding. Not previously included in former editions of this pamphlet is a description of a new method of welding teeth in pinions. The pamphlet concludes by explaining the various applications of Thermit in foundry practice, such as for increasing the temperature of iron and steel, facilitating the introduction of other metals which it is desired to alloy for special purposes, keeping metal and risers liquid for a considerable period and making small steel castings.

A Difficult Problem

The statement made by J. C. Fritts, master car builder of the Delaware, Lackawanna & Western in a paper before the January meeting of the Western Railway Club, that a very large part of the present bad order equipment can be confined to approximately 400,000 cars is a fact which should be kept clearly in mind in considering the present unsatisfactory car conditions. The real problem may be even more sharply defined. Probably not less than three-quarters of these 400,000 cars are 30-ton and 40-ton box cars, with weak draft sills and ends, which are in circulation all over the country when the demand for cars is great. How can the extravagant maintenance expenditures, the constant delays to traffic and the constant risk and frequent damage to which the lading in these cars is subjected be eliminated? When cars are in demand there is little opportunity to improve the condition of this equipment. At such times much of it is on foreign lines and the frequent sojourns on the repair track at best result only in repairs in kind, which are not of constructive value. When away from home the only constructive measure possible is the retirement and dismantling of these cars under Rule 120. But it is evident that owners are refusing to authorize extensive retirements under this rule, and it is probable that until confidence is restored in the stability of equipment prices most of these old cars may be expected to remain in service. How, then, are they to be made fit for service? Evidently this can only be done by the owning road and the opportunity for rehabilitation is offered the owning roads only when there is a surplus of cars such as has been created by the present business recession. It is unfortunate that the opportunity is only offered at a time when the railroads are financially unable to take full advantage of it, and for that reason the results of every hour's labor that is expended should be made to produce the utmost return by thoroughly overhauling a few cars and not attempting to turn out as many cars as possible with the least amount of work per car. Only in this way may any improvement in the condition of freight cars be expected.

What Are the Real Remedies?

A careful consideration of the present unsatisfactory condition of freight cars does not suggest the possibility of finding a remedy the application of which may be expected to effect an immediate cure. The malady long ago became chronic and the symptoms are now only a little more acute than usual. No permanent improvement can be expected until the deep-seated causes are located and removed. The present conditions are due in a very large measure to the failure of each railroad to give to all cars "equal care as to inspection and repairs, regardless of responsibility for expenses of repairs." There are two principal reasons for this failure. The first is the inability of the roads to make thorough repairs in kind to cars differing from their own standards without excessive delays, and the inability under the rules to apply betterments to other than their own cars. The second reason for this failure is the lack of any incentive for the individual road to do more than the minimum amount of work necessary to get the foreign car off its line as more than this amount of work is of no direct benefit to itself. Two possibilities suggest themselves for removing the first difficulty; either a change in the rules removing some of the limitations on foreign car repairs, or the development of a more complete program of standard and interchangeable details. The first is obviously unfair to the car owners until the latter has been developed and it is improbable that any accomplishment will be obtained in either direction, except as the result of a long period of slow and painful effort. There is only one way to overcome the second great cause for the chronic state of dilapidation of freight cars and that is to provide the now lacking incentive. In the commercial and industrial world the one incentive which produces activity is the hope or prospect of profit. Railroad corporations are no different in their nature than those in other fields, and the prospect of profit on any transaction is the only incentive likely to cause whole-hearted performance. The suggestion that prices for labor and material be set high enough to show a profit above the cost of labor and material plus the overhead, offers a means of supplying this incentive. The effect of such an incentive would probably be less manifest in the amount of repairs to foreign cars than in the greater efforts by owning roads to keep their own cars in the best possible condition, in order to avoid as much as possible the payment of the high repair bills. The most beneficial effect immediately following the adoption of such a plan would probably be the retirement or complete rehabilitation of the large number of cars now in service which long since ceased to be economical carrying units. What disadvantage to such a plan can offset its value as a potent force to raise the standard of freight car maintenance?

Sharp Tire Flanges

"An ounce of prevention is worth a pound of cure" and the old saying was never more true than when applied to the malady commonly known as sharp flanges. Locomotives credited with only 20,000 or 30,000 miles keep coming again and again to repair shops with flanges worn thin on the front driving wheels. The prevention of this excessive cutting action would save the railroads thousands of dollars annually. With the long wheel base of a modern locomotive, it is practically impossible to eliminate excessive side pressure on the front driving wheel flanges, especially when rounding sharp curves. Provision for additional side play on the front wheels and in some cases setting the tires slightly nearer together helps, but by no means solves the problem. Cutting action continues, front flanges are worn to the limit of thickness, and there is a resultant serious loss of revenue while locomotives are held out of service waiting for and receiving necessary repairs.

When flanges become sharp after only a few months service, the machinery is usually in good condition and repair work on the locomotive consists of dropping the front wheels, removing the tires, applying and turning another pair and replacing them under the locomotive. In case second-hand tires, which will turn down to the required diameter, are not available, it is necessary to apply a pair of new tires and turn them, in an extreme case, from three and one-half down to two inches thick, with a resultant waste of material. In addition, the entire shop schedule is disarranged by injecting this light repair work, especially if the wheel department is already working to capacity.

It is not overstating the case to say that the problem of sharp flanges can be greatly simplified if not solved by the application and proper maintenance of some form of automatic flange lubricator, of which several are on the market. These lubricators have demonstrated their ability to reduce flange wear and cutting action to a minimum and indirectly increase the life of rails on curves and locomotive mileage. Flange lubricators are for the most part simple and automatic in action, requiring little attention, but without this little attention they become absolutely valueless for the purpose intended. If examined at least once each trip to make sure that they are not clogged with dirt or caught in such a way as to be rendered inoperative, automatic flange lubricators will go far toward solving the problem of sharp flanges.

Next Step in Welding Development

It is natural that the early stages of the development of an art such as fusion welding should be devoted exclusively to the technique of the process itself. The process has continually been put to new uses with little thought beyond questions of manipulation, the controlling factor being the convenience with which the work may be done and the large saving to be effected in material. It is not surprising that in some cases the results of the application of the process have raised serious questions in the minds of railroad officers as to the safety of the use of the process on some classes of work already well within the field of application. Cases have occurred where the employment of fusion welding to fill out tires with flat spots, heat treated parts or pieces forged too small to finish, has apparently led to failures. The only satisfactory answer to the questions raised by such instances is one founded on knowledge and not on unsupported theory. Investigations such as that made by the Chicago, Rock Island & Pacific, described elsewhere in this issue, are of the utmost value, and strongly indicate that at present there is more need for attention to the effect of the welding operations on the metals worked on than to refinements in the technique of the operations themselves. General investigation in this phase of the subject will do much to direct intelligently the future extensions in the application of the art, and by avoiding some of the pitfalls such as have already been encountered, prevent the placing of reactionary limitations on the great possibilities for economy yet unattained.

Maintain Locomotive Valve Gears

No doubt exists as to the important part played by valve gears in locomotive operation. Ease of handling, quick response of a locomotive to its throttle and economical fuel consumption all depend upon an efficient valve gear, properly maintained. Valves must be square, with leads and cut-offs adjusted to predetermined standards, or the fuel wasted in the course of a few months or a year will amount to many tons for each locomotive. Designers of the several valve gears now on the market have bent every effort to perfect them, but this is of no avail unless they are maintained so as to make efficient locomotives. In far too many cases, the irregular exhausts of passing locomotives show at once that their valves are not square, caused by careless work in the back shops or lack of attention at roundhouses. In either case, the fault should be remedied to allow railroads to profit by the resultant increased train acceleration and decreased fuel consumption. Ordinarily it takes about eight hours to set the valves on a heavy locomotive, but it is not safe to insist on an arbitrary length of time for this operation. An unexpected difficulty may often develop and delay the work two or three hours. The only safe way is to develop dependable valve setters and allow them time enough to overcome difficulties and do the job right. Valve setting is one of the last operations in repairing a locomotive and unfortunately there is a tendency to slight the work rather than delay a locomotive in the shop. This is false economy. With the high price of coal, it is especially important that locomotive valve gears be properly set and maintained in the best possible operating condition.

Turret Lathe Practice

Somewhere between the automatic and single purpose turning machine lies the field of use for turret lathes, bounded by fairly distinct lines of demarcation and within which the turret lathe has no close competitor. For quantity production, the automatic affords great possibilities of increased output at less cost per piece, while for work involving a single turning operation the common lathe usually is best adapted. Between these two extremes, however, there is a range of work best performed on the turret lathe which thus becomes an important factor in machine shop operation. Turret lathes of American make are adapted for both bar and chucking work, the change from one to the other being made easily and quickly. By working the tools in the turret and carriage simultaneously, a large amount of time is saved and the arrangement of cutting tools and stops for work involving several operations eliminates resetting many tools, reduces measurements required and speeds up the work. Many railroad shops today should be equipped with additional turret lathes and provision made for the more effective use of those already installed. Methods of tooling are very important in any attempt to secure maximum production, and attention is called to an article in this issue, showing the tooling of turret lathes for machining several locomotive parts. The sequence of operations, methods of tooling and respective times are given and the article should be of particular value to those interested in machine shop production. Probably the greatest value of the *Railway Mechanical Engineer* to shop men lies in the opportunity it offers for comparing experiences and finding out what the other fellow is doing. It is suggested that the article referred to be carefully studied and information submitted regarding any methods of machining which, in the opinion of the reader, will turn out as good work in less time than those shown.

For a Sound Knowledge of Heat Treating

The need for the greatest care, based on accurate knowledge, in the heating of steel either for forging or hardening has been quite generally too little appreciated. The wide range of possibilities for the control of the physical properties of steel by skillful heat treatment which have only recently been opened up to industry, has brought into strong relief this general lack of accurate information on the subject. To the Chicago chapter of the American Society for Steel Treating belongs the credit for one of the first practical steps to overcome this handicap. A committee of the chapter composed of men engaged in the metal working industries of Chicago has prepared the texts for a course on forging and heat treatment of steel, with the co-operation of the Armour Institute of Technology and the Lewis Institute, and evening classes are now being organized at both of these institutions. These courses are the beginning of a movement which may rapidly accelerate the practical application of possibilities in all industries which so far have nowhere been fully realized unless perhaps in the automobile industry. Manifestly, such a course cannot take the place of practical experience. Experience in the shop alone, however, unsupplemented by laboratory research or the study of the results of such research, will never make a really skilled heat treater. In no other lines of work is so much of vital importance hidden from the operator as in those involving the heating of metal, and real advancement can only come when to practical skill is added a thorough knowledge of these hidden facts.

COMMUNICATIONS

Pencil Repairs and Inexperienced Foremen

Mechanicsville, N. Y.

To the Editor:

I have read numerous letters in the *Railway Mechanical Engineer* about the mechanics in the motive power department not being efficient in their work. I disagree with some of these letters, for there is too much work done right at the foreman's desk on the reports of the inspectors and engineers with a well-sharpened lead pencil and not by the mechanic. No power can stand up under the workmanship of a little lead pencil.

It looks at times as though the superior officers would rather have the payroll look good at the end of the month than to keep the power out of the back shop, though engines cannot make any money in the shop. What is saved in one month on the payroll is taken out of one engine in one trip.

When an engine comes out of the shop, it is all painted up and the roundhouse foreman may think it does not need the wedges or the back ends keyed up for some three or four months. He may finally get around to have the wedges set up after the boxes are pounded to pieces and the old rod bushings that were taken out in the shop would sound better in the rod than the new ones. Hundreds of dollars are spent on the engine because of the roundhouse foreman who is trying to keep the engines from coming across the turntable to be inspected and the necessary work done to keep the power in shape.

This appeals to me as very poor management, not on the part of the master mechanic, but the supervisory forces under him. Just for the want of about three hours' work to reduce a back end or a front end the engine is allowed to go out and the next day it is towed in on account of a piston rod, crosshead or back end strap broken and then it is laid to poor workmanship on the part of the mechanical forces.

No foreman can bring power back to first-class shape that is ready for the shop but the new power out of the shops and from the locomotive works can be kept up and inside of eight or nine months you can see the vast difference in the number of engines that have been going to the back shop but are now in service on the road. The railroads of today need system and efficient work foremen, not a bunch of school kids to be foremen over a body of mechanics. The foremen of today ought to be in a position to direct the men, not have them directing him how a job had ought to be done along with the handling of his forces.

A. F. Barbolt.

Assigning Engines

Chapleau, Ont., Canada.

To the Editor:

In your issue of November I read over very carefully a communication by Geo. N. Clouser on assigning engines. I do not know whether Mr. Clouser has reference to some particular railroad or railroads in general; if not the latter, then it would appear that the road he has reference to has some local conditions, coupled with a shortage of power, that would make it difficult to always have a suitable engine to handle the different sizes of trains, or it shows a deplorable lack of supervision and organization to run engines of different capacity indiscriminately on all trains regardless of size.

The third paragraph, complaining of big engines on small trains and small engines on big trains, would indicate that there was absolutely no co-operation between the yard office and the engine house. If the traffic superintendent had to explain to some superior officer who knew the game *why* the locomotives were not pulling 100 per cent trains, at least in one direction and give the reason in each individual case, there should be an improvement before long or a new man on the job.

Surely the assignment of engines should be placed where it belongs, viz., with the general superintendent and master mechanic of each district. They are in a position to know where to place the right proportion of light and heavy power. It is then up to the division officers to see that each engine has 100 per cent of its haulage capacity hooked on behind the tender and it is up to the road foreman or division master mechanic and locomotive foremen to see that they are kept in a condition to do it. If there is sufficient motive power on the division or territory in question to handle the traffic, or even if they are short of power occasionally, it is the duty of the chief despatcher to know just what is doing, and get suitable engines back to the terminals where they are required in time to be put in shape to do it.

On the road where I have the pleasure of working, the operating officials are very much concerned not that they have an engine big enough to haul the train, but that they have a big enough train for the engine to handle, and this is true in the month of July as well as the month of January with its 50 below zero.

In the last paragraph of his letter Mr. Clouser advises increasing the efficiency by giving some officer the job of knowing the whole road, weight of train, profile, condition of track, characteristics and condition of each engine on the road, train schedules and all the other things that affect the problem, and from these things, plan the distribution of the motive power, while he is keeping his eye on the order in which the engines come in and out of the shop, and in a general way see that the right engine is always available. This is quite a large sized order for this particular official, especially if he has a large territory to look after.

I don't think Mr. Clouser has solved the power problem of this particular road yet if he expects to get efficiency out of a "particular officer" who has assigned to him the multitude of duties that Mr. Clouser would hang on to him. Railroads are not run in a general way any more; in this country they are run by an organization, each one of which knows his particular part of the business and he has to put up the goods; then there is a blue print sent to him to let him know how he is getting along, and if the figures on this print do not compare favorably with performances in the past, then there is a note asking him "why" and his job depends on his explanation.

JOHN H. BROOKES,
Division Master Mechanic, Canadian Pacific.

NEW BOOKS

The Engineering Index for 1919. *Published by the American Society of Mechanical Engineers,* 29 *West 39th Street, New York.* 527 *pages,* 9 *in. by* 6 *in. bound in cloth.*

The purpose of the Engineering Index is to provide a convenient and satisfactory guide to engineering literature. The 1919 edition of this index is the most complete and comprehensive work of its kind ever published. It contains over 12,000 references to articles published during the year 1919 in nearly 700 engineering and allied technical publications. The compilation of this index is based upon a review of approximately 1,100 periodicals, reports, and other publications by the engineering staff of the American Society of Mechanical Engineers. These publications are printed in ten different languages and comprise what is probably the most complete collection of scientific and engineering publications in the world. All of the publications referred to in this index are now a part of the Engineering Societies' Library of New York.

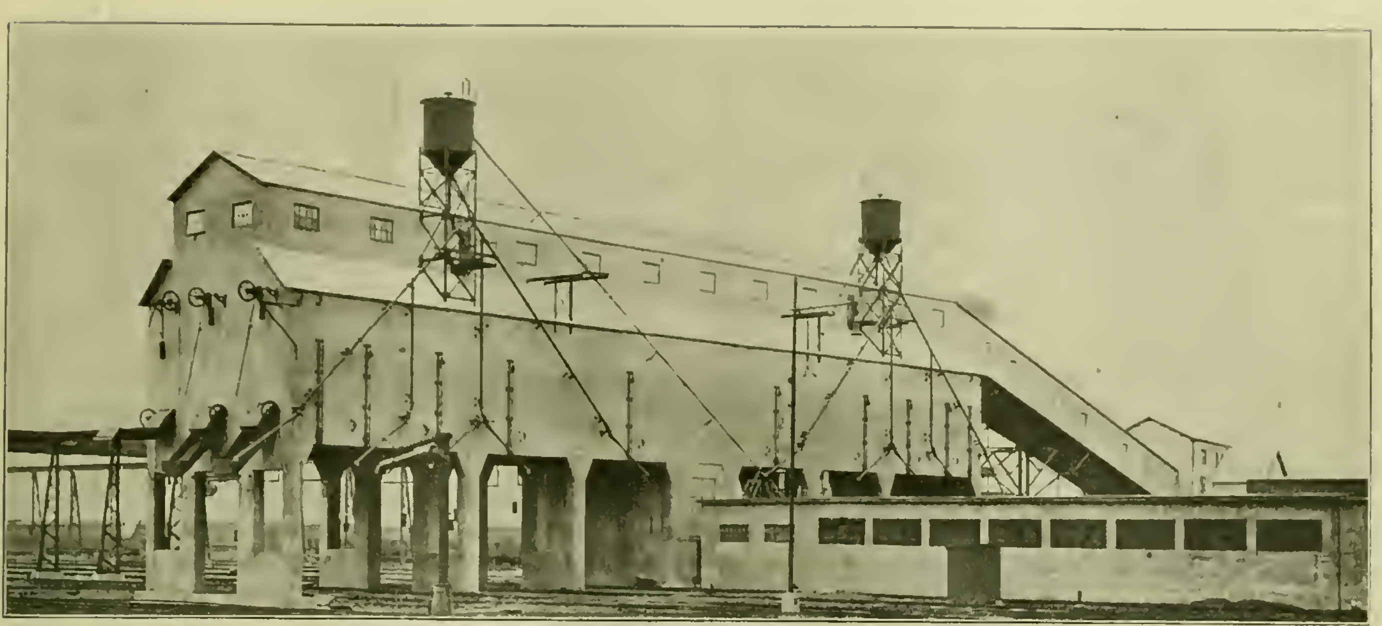
Practical Locomotive Running and Management. By W. G. Knight, 519 *pages,* 5 *in. by* 7 *in., illustrated, bound in cloth. Published by the author, W. George Knight,* 35 *Cushing street, Medford, Mass.*

This is the second edition of a very popular book on locomotive operation that is distinguished by its plain common sense treatment of the many difficult problems encountered by those responsible for the operation of locomotives. The first chapters of this book are devoted to the fundamental facts relating to combustion and the generation of steam. In this connection the function of the brick arch of the superheater and other smaller appliances essential to the efficiency and capacity of the locomotive are described. The maintenance as well as the operation of these devices is dealt with in a commendable manner. There is also a chapter on locomotive front end appliances with particular references to the effect of these appliances upon the operation of the locomotive. Locomotive valve gears and the air brakes are discussed in separate chapters. The chapter on locomotive running is one that could be read to advantage by any locomotive engineer or supervisor of locomotive operation. The final chapter, which deals with a general study of the modern locomotive, does not, of course, deal with this subject in its entirety but contains a good deal of information in a convenient form relating to the principles involved in the design and operation of these modern locomotives. It should be understood, however, that this book does not add any amount of original matter to the subject and would not appeal to anyone who has already made a thorough study of the entire field. The great value of the book will be found in its use as a reference and guide by enginemen, fuel and locomotive supervisors.

Fuel Oil in Industry. By Stephen O. Andros. 240 *pages,* 9 *x* 6 *in. Illustrated. Bound in cloth. Published by the Shaw Publishing Company,* 910 *South Michigan Boulevard, Chicago.*

The use of fuel oils by the railroads is by no means new and the problems involved in its application to the locomotive have been carefully studied by railway engineers for many years; in fact, the value of this book to the railway mechanical or civil engineers might be questioned if it were not for the tremendous expansion in the use of fuel oil in all industries within recent years. Thus the increased price of bituminous coal has assisted in promoting the use of fuel oil both in maritime service and in many hundreds of stationary plants along the eastern seaboard. This has introduced new problems relating to its transportation in bulk and storage in large quantities. Moreover, it must be admitted that refinements bearing upon the handling and burning of fuel oil are generally given more consideration in stationary and maritime service than in railroad use. For this reason, there is a field for a book of this character in railroad as well as industrial service which outlines as it does not only the principles of fuel oil combustion and the properties of fuel oil but the method of testing, storing and burning it, together with a full description of its application to industrial and domestic furnaces.

For instance, the book not only describes many of the details involved in the construction of steel storage tanks but refers to an interesting development in concrete oil storage tanks and describes at length all of the pipe setting and auxiliary machinery involved. While the book describes many types of burners that would not be applicable to locomotive service, still there are many points in connection with this subject as outlined in this book that will prove of particular interest to railway fuel engineers. The use of fuel oil in the manufacture of iron and steel and the heat treating furnaces is also described and illustrated in an interesting way.



1,600 Ton Reinforced Concrete Coaling Station, C. of N. J., Communipaw, N. J., Serving Ten Tracks with Three Kinds of Coal

Modernizing Existing Locomotive Terminals*

Important Details of Locomotive Terminal Design Outlined at Railway Section Meeting of A.S.M.E.

BY G. W. RINK

Asst. Supt. Motive Power, Central Railroad of New Jersey

LOCOMOTIVE terminals play an important part in the operation of the railroad, as the transportation department is at all times entirely dependent upon them for its supply of serviceable power for the movement of both passenger and freight cars. Should the capacity of the terminal or the facilities for making repairs be inadequate, the result will soon reflect itself in more time being required to prepare engines for service and more frequent detention on the road due to failures.

The general layout of engine terminals, also the extent of shop facilities provided, depends entirely on their location with reference to the general locomotive repair shop. When located in close proximity it is necessary to provide only such facilities as may be necessary to make the general run of roundhouse repairs, depending upon the main shop for the manufacture and supply of a large percentage of materials required for use at the terminal. But when engine terminals are located some distance from the general locomotive repair shops, they should be provided with enlarged facilities so as to perform all the necessary machine, blacksmith, and boiler-shop operations required when making more extensive repairs, and be entirely independent of the main shop. It is important, however, to eliminate at the terminals the manufacture of such standard parts as may be produced elsewhere at less cost. At outlying points where only light repairs are made to maintain locomotives in serviceable condition, such facilities as described above are not necessary.

At all important terminals the measure of efficient operation is the time required to prepare locomotives for service and the mileage which can be obtained between shoppings for class repairs. Any saving in time of course permits more intensive use of locomotives when transportation requirements make it necessary, but this saving can only be accomplished by providing a first-class terminal layout with proper equipment so as to enable the terminal organization to handle all engines with promptness and despatch. This requires a properly balanced organization to perform the various classes of work required and, coupled with modern labor- and time-saving facilities, should tend to reduce congestion materially and maintain the equipment properly.

Repairs at Locomotive Terminals

The location of the engine terminal with reference to the general locomotive repair shop will have some bearing on the necessity of performing relatively heavy repairs at the terminal. Where they are within reasonable distance of each other, it may be desirable to have a considerable part of the heavy repair work transferred to the main shop, where the repairs can be performed more expeditiously and the engine returned to service. On the other hand, this class of work has a tendency to interfere with the output of the locomotive repair shop, and especially so if it is found difficult to maintain the necessary quota of class repairs, considering the equipment as a whole. In such cases it would appear more desirable to increase the engine-terminal forces and provide sufficient facilities to at least make Class 5 repairs and the general run of heavy running repairs, including the removal and reapplication of a part or complete set of flues.

Where it is found desirable to perform such heavy repair work, it should preferably be done in a small building located adjacent to the machine shop, and provided with several tracks for holding engines and an overhead crane or power-driven locomotive screw hoist for the removal of all wheels. This feature is very desirable, especially if heavy locomotives are to be handled. It also increases the track capacity within the roundhouse to that extent and repairs can be made more promptly and economically.

With reference to existing terminals, a careful study of the

---

*From a paper presented at the annual meeting of the American Society of Mechanical Engineers, December 8, 1920.

property will no doubt disclose the fact that improvements can be made whereby greater efficiency may be obtained. Modern facilities should be installed wherever it is possible to produce a saving in time and labor.

Coal, Sand and Ash Handling Facilities

The type of coaling stations selected must depend on the number of engines handled, the number of tracks which may be available for coaling engines and the kind of coal to be handled. Some roads in the East use bituminous, broken anthracite, and buckwheat. Where the quantity of coal handled is small, the locomotives can be coaled from an elevated platform using one-ton buckets or by means of a locomotive crane direct from car. When it is necessary to deliver coal to two or more tracks, a mechanical type of coal-handling apparatus is generally installed. Marked improvements have been made in receiving, hoisting and distributing equipment, which has resulted in smaller operating forces being required. Measuring devices are also installed for recording the amount of coal delivered to tenders. An electric winch should be provided at large terminals at the loaded coal-car track so that cars can be hauled to position over track hopper.

The sandhouse should be located at the coaling station. Sufficient wet-sand storage space should be provided as well as means for drying the sand by coal stove or steam. Compressed air should also be available so that the sand can be delivered to overhead storage bins, having suitable outlets to deliver the sand direct to engine by gravity. All important engine terminals should have a complete installation of this character.

During recent years the tendency when constructing large terminals has been to install pits filled with water. The cinders drop directly into the water and move toward the center of the pit, due to the outer wall sloping inwardly, and are removed either by a locomotive crane or by an overhead crane traversing the entire length of the cinder pit, the cinders being deposited by means of grab buckets directly into cars located on the loading track. The pit is filled with water to a depth of about five feet, water being admitted at one end of the pit and overflow provided at the opposite end. Provision is made to protect the floor of the pit against injury by the grab bucket, by imbedding old rails in the concrete. Due to the quantity of water required for large installations of this character, provision should be made if possible for a supply from a nearby stream or other natural source.

Steam-jet ash conveyors can be installed to advantage where ample supply of steam is available. The system consists of an 8-in. cast-iron pipe made exceedingly hard to withstand wear, with intakes provided at suitable intervals. The cinders are drawn by suction through the main pipe line and then propelled by means of the steam jet direct to car or storage bin, suitably located. Cinders handled in this manner are not wetted down until they enter storage bin, where a water spray is provided. This type of cinder conveyor has proved very satisfactory for handling cinders in power houses and should give good service when installed in connection with small engine terminals.

Inspection Pits

Inspection pits are now being installed at a number of large engine terminals. These are located on the inbound tracks with the view of making inspection of locomotives before they are placed over the cinder pit. Fires can then be withdrawn when the engines pass over the cinder pit, if inspection develops defects which warrant this procedure, thus saving time and expense involved if engine was inspected within the roundhouse after passing over cinder pit. There are many advantages in having inspection made at this time as the foreman by means of pneumatic tubes can be furnished with both the engineer's and inspector's reports showing work to be done before engines are placed in the shop.

These inspection pits are generally made about 100 ft. long, two in number, and covered with a protection shed. Special arrangements are provided to permit inspectors to enter the pits. Proper drainage and lighting facilities are also provided. In lieu of reporting on inspectors' reports such work as loose nuts, missing cotters, etc., it would be desirable to station at these inspection sheds mechanics who can perform this work at once, thus saving time in locating these defects in the shop after being reported.

Heating and Ventilation

Heating and ventilation is of first importance in a modern and efficient roundhouse. With the possible exception of small isolated houses in mild climates a properly designed system combining heating and ventilation should be adopted. An installation of this kind consists of a blower drawing air through hot-blast heaters located in a fan room which forms a projection on the outer wall of the roundhouse. The heated air is discharged through an underground concrete duct system.

A combined heating and ventilating system should supply sufficient air for the quick removal of smoke, gas and vapors. Ventilating sash, louvers and other openings should be provided at the high points of the room to supplement the forced system by directing the flow of air currents and facilitating the removal of hot gases. This feature should be carefully considered, for in roundhouse ventilation it is not so much a question of diluting the air as it is of establishing a positive flow of air which will carry the gases along with it.

It is sometimes necessary, due to the requirements of local ordinances or because the type of house prevents the use of smoke jacks above the locomotive stacks, to install an exhaust system so as to remove gases directly from the locomotive smokestacks. In the latter case connections are made to the smokestacks by means of swinging hoods. This system is not necessary from a ventilating standpoint, and should only be installed where conditions compel its use.

With the usual type of indirect system the fan rooms, one or two in number depending on the size of the house, should be located midway of the length of the house to be served, thereby reducing the temperature drop of the air in the duct as well as the friction head against which the fan must work. The quantity of air supplied together with the number, size and location of air outlets depends largely on the type, size, and location of the roundhouse. The amount of heat to be supplied with the air is also a variable factor and should have careful study so as to provide a comfortable working temperature under the conditions obtaining in roundhouse operation.

The question as to whether the fan should be motor- or engine-driven depends on the quantity of exhaust steam available for heating and whether or not it is desired to operate the fan for ventilation in the summer time. The hot-blast heaters should be operated through a two-pipe vacuum system, particularly where exhaust steam is available, so as to reduce the back pressure and provide a positive circulation of steam through all parts of the heaters. The temperature of the air can be regulated to suit the variable outside temperature by subdividing the heater into units with a control valve on each. The fan should be operated at a constant speed so as to make the ventilation independent of the heating and to provide a uniform condition at all times.

Lighting

Adequate daylight facilities through large window areas together with light, cheerful surroundings are highly desirable. The windows should be spaced and located so that daylight conditions are fairly uniform. They should also provide sufficient daylight so that artificial light will be required only during those portions of the day when it would naturally be considered necessary. Good natural and artificial light will reduce accidents, provide greater accuracy in workmanship and simplify the supervision of the men.

Much needed improvement is desired in connection with artificial lighting of engine terminals. In the roundhouse proper, lights mounted on the outer wall and reflected between engine pits have given satisfactory results when augmented by sufficient lights suspended from the ceiling to afford general illumination. Machine shops, etc., should be provided with a general or overhead lighting and also supplemented by individual lamps conveniently placed, preferably on brackets so that they may be adjusted.

For lighting the roundhouse circle, flood lights should be used whenever possible as general illumination will add considerably to the safe movement of locomotives to and from turntable and engine house. Ash pits can be illuminated by rows of reflector lights placed on poles, and similar provisions should be made at other points beyond turntable or by the use of flood lights on the tops of coaling stations. The introduction of many new types of lamps has made it possible to provide better illumination when changing from an old to a new lighting system. A study should be made of the conditions and proper lamps selected for the purpose.

Modern Ash Pit of the Central of New Jersey

Hot-Water Washout and Refilling System

Facilities should be provided for washing out boilers, using hot water under pressure and refilling with hot water after washing. There is an actual saving in time as compared to the old system of washing out and refilling with cold water; with this system boilers are washed out more thoroughly and strains within the boiler due to expansion and contraction are considerably reduced, with the result that the cost of boiler maintenance is reduced.

There are two types of installations for this purpose in general use, one of which utilizes the blow-off water for washout purposes only, while the other utilizes as much of the blow-off water as necessary for this purpose and the remainder, after being clarified, for refilling purposes. As blow-off water is always soft and becomes clarified soon after storage, it is of course the best water for the generation of steam and its reuse in this manner is responsible for the greater efficiency of the latter type of installations.

Hot-water washout and refilling systems can be economically installed in any size to meet the equirements in any engine terminal of moderate size. The usual practice is to deliver washout water at temperatures varying from 100 deg. to 140 deg. The refilling water generally has an average temperature of approximately 210 deg. Where such systems have been introduced, there is a material reduction in time required to do this work. Boilers have been blown off, refilled, fired, and steam pressure brought up to 100 lb. within from two to three hours. This does not include such time as may be required to make necessary repairs to boilers.

Wheel-Dropping Facilities

The usual wheel-dropping facilities consist of a drop-pit system which provides for depressed pits at right angles to shop track, using telescoping pneumatic or hydraulic jacks for lowering and raising wheels, separate pits and jacks being installed for handling driver and engine-truck wheels.

Screw-jack locomotive hoists especially designed for unwheeling locomotives are being more extensively used at engine terminals, and their use has made possible a larger saving in both time and labor. These hoists operate with a high degree of safety as compared with the drop-pit system; furthermore they can be located within the roundhouse or installed in a separate building, in which case it would be desirable to also install the wheel lathe and other tools and appliances for taking care of heavy running repairs.

When screw-jack locomotive hoists are installed, it does not eliminate the necessity for providing drop pits in the roundhouse, which may be needed in order to prevent loss of time in making repairs to locomotives which may only require the dropping of a single pair of drivers or engine-truck wheels.

Machine, Boiler and Smith Shops

Old and obsolete tools should be replaced by modern machine tools, which insure increased production at lower costs and the work being done more accurately and promptly and power maintained in better condition. Individual motor drive for the larger machines and group drive for the smaller machines are preferable. Facilities should include steam hammer, forges with down-draft hoods (number and size to suit work to be performed), punch and shear, plate-bending rolls, straightening plate, flange fire, etc.

Autogenous cutting and welding outfits are also considered indispensable and are used principally in making repairs to locomotive fireboxes, engine frames and in reclaiming miscellaneous parts which can readily be repaired by means of this process.

The Power House

Important engine terminals should be provided with a power plant of sufficient size to take care of the future as well as immediate needs of the terminal. In a number of cases this plant is required to provide steam for thawing snow at switches on main-line track leading to the terminal passenger station and supply heat and light to station buildings, and function in general as a service station. Labor-saving devices should be installed in the way of coal- and ash-handling machinery, automatic stokers and large-capacity overhead coal-storage bunkers. Consideration should be given to operating with condensers, requiring a cooling tower if fresh water is used, the surplus water being delivered to flood ash pit for locomotive cinders if this type is used. Tanks of ample capacity should be located at power house with water mains of proper size supplying water for shop use and filling of tenders at terminal tracks, locating water columns away from switches in cold climates to prevent freezing. At smaller terminals, discarded locomotive boilers are used to furnish steam for power and heat. A close study made of these installations will reveal the fact that in many cases money can be saved by the use of modern water-tube boilers.

Discussion

The discussion of this paper was featured by the remarks of a representative of the operating department of the Pennsylvania Railroad, Mr. Wm. Elmer, division superintendent at Altoona. Mr. Elmer discussed the most important phases of the locomotive terminal situation with particular reference to its effect upon locomotive performance on one of the busiest railroad divisions of the United States. Confronted with the problem of getting the utmost service out of every available locomotive, Mr. Elmer has developed a unique system of records indicating the service performed by each locomotive on his division which he described at some length in the course of his discussion.

The paper on Modernizing Locomotive Terminals was also discussed by representatives of the Robinson and Austin Construction Companies who have recently been engaged in very extensive terminal development. Appropriate emphasis was laid on some of the most vital features in terminal construction and an attempt was made to demonstrate that the value of terminal improvements can be arrived at by capitalizing the enhanced earning power derived from locomotives handled in modern vs. obsolete terminals.

The discussion was closed by L. G. Plant, associate editor of the *Railway Mechanical Engineer,* who stated that consideration of the locomotive terminal from any angle would be incomplete if it did not place sufficient weight on the outstanding function of the terminal, which is to expedite the movement of locomotives, and emphasized those features of terminal development which have the most direct bearing upon the time element involved in handling locomotives.

Grease Lubrication

BY T. J. HOLMES
Swain Company, Chicago

Friction prevents machinery from being efficient. One writer gives it as his opinion that 50 per cent of the power used in the United States is wasted on unnecessary friction.

The economical running of all kinds of machinery depends largely upon the character and application of the lubricant. From the smallest to the largest and most complicated machine, the question of lubrication is of foremost importance. The cost of a lubricant is often very small in comparison with the amount of loss that may be sustained through friction, if an inefficient lubricant is used.

The parts of a bearing cannot be turned absolutely true and smooth. Rough places not visible to the naked eye are likely to exist. If these are ground together without lubrication, friction and heat result. The lubricant is employed to fill in the bearing, and to prevent friction. As a means of filling up any rough places in a bearing, a lubricant which carries a small amount of flake graphite or mica may be used to good advantage.

The following discussion applies only to those bearings where a stiff grease lubricant should be used. The term "grease" strictly applies only to animal fats, especially when in a soft state. In recent years, however, the term has been enlarged to include other products, but it properly includes only those possessing unctuousness or a soapy, slippery feeling in a marked degree.

What particular thing is there in grease that gives it lubricating qualities? This question has long puzzled persons interested in lubrication. Experience and investigation have led to the conclusion that the lubricating quality of grease is largely produced by fatty particles or colloids, constantly in motion, which are characteristic of the structure of grease. Greases which have not been subjected to high temperature possess great lubricating qualities, while those greases which have been subjected to a high temperature, either in refining or in use on hot journals, do not have the best lubricating qualities. Heat is destructive of the moving colloids, and therefore destructive of the lubricating qualities of a grease.

Any material used as a lubricant should have the following qualities:

(1) Adhesion, the property which causes it to cling to the surface to be lubricated. It is well known that certain fats cannot be entirely rubbed off a smooth surface and that water will not remove them. Soap and water must be used in order to remove them effectually.

(2) Cohesion, the property causing the particles of a lubricant to hold together.

(3) Unctuousness, that property which gives a greasy, slippery feeling to the touch.

The lubricating colloids seem to have much to do with all three of these necessary qualities and without their presence any material is of little or no value as a lubricant.

Tests for melting point and flash, as applied to lubricants, would therefore seem to be of little use in determining lubricating qualities. To judge lubricating qualities, tests should more properly be aimed at the determination of the relative amount of lubricating colloids in the make up of the material.

It is generally conceded that a good lubricant should be neither strongly acid nor strongly alkali, but should be neutralized so that no injury may result to the bearings or to the essential qualities of the lubricant.

Action of the Lubricant

When the bearing is perfectly adjusted and the journal started in motion, the lubricant is gradually drawn down around the journal, filling the entire space between the journal and box, and adhering to both wearing surfaces. The colloidal globules permit the journal to roll and slide over them, and at the same time they slip or roll past each other. This motion of the particles of the lubricant takes place without friction and consequently without the generation of heat.

If a journal is removed after running in a grease lubricant, a magnifying glass will disclose a thin film or coating. This film may be destroyed by heat, by foreign substances, or mechanical defects in the machinery. Furthermore, if the lubricant contains few colloids, the running of the journal may be accompanied by high friction and the generation of a large amount of heat.

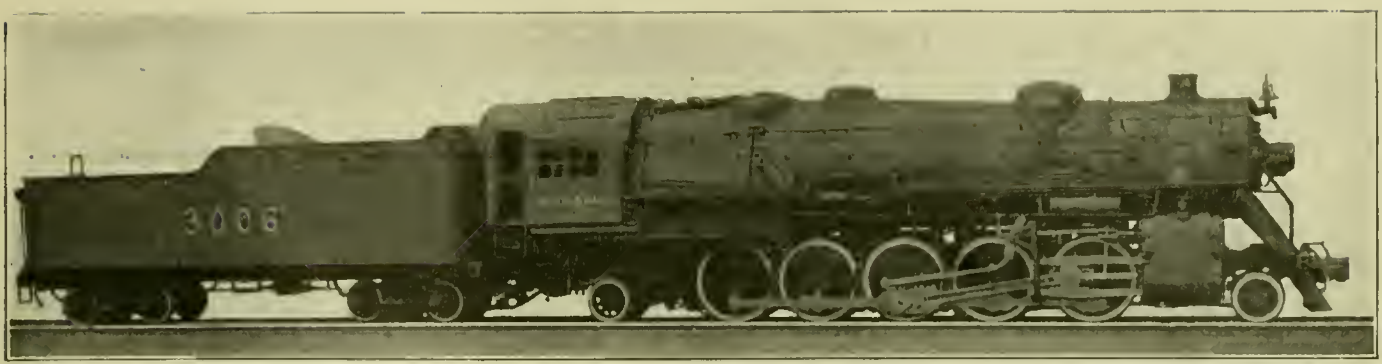
Every lubricant has its own lubricating temperature; that is, a point at which it yields the greatest degree of efficiency. The lubricating point should be low as no bearing should be permitted to "get hot." The efficiency point in a lubricant should not be confounded with the melting point. These two temperatures are often far separated and have little relation to each other. This relation varies with the materials used as lubricants.

As a rule, the degree of running temperature indicates the quality of the lubricant, but it may also be affected by the character of the work, or by mechanical defects in the bearing. Graphite or mica, although not lubricants themselves, may be used in moderate quantities to advantage in grease lubricants as they tend to fill up and smooth over rough or pitted bearing surfaces.

When machinery stands idle for a time, the weight of the journal is apt to force the lubricant out of the bearing, and it takes a little time for the re-establishment of a complete lubricating film. When a proper lubricant is used, the rotation of the journal will permit enough of the lubricant to work out at the ends of the box, to form rings which exclude moisture and dirt from the journal when it is not in motion.

It is necessary, not only to have good bearings and lubricants, but to have the lubricant applied by the proper method. The lubricator cup should fit tight and exclude all dust and grit. Indicators should be used on all bearings. Concealed lubricators often give rise to costly trouble because inspection cannot be readily made.

A poor system of lubrication, once installed, is difficult to change. It is advisable, therefore, when planning a new shop, that lubrication receive careful attention.



One of Twenty Santa Fe Type Locomotives Built by the American Locomotive Company for the Boston & Maine

Locomotives and Cars Ordered and Built in 1920

Considerable Increases Over 1919 Figures But Little Progress in Making Up Accumulated Shortage

THE locomotives ordered by the Class 1 railroads in 1920, according to the statistics of the Railway Age, reached a total of 1,668—almost eight times the number ordered for all domestic service in 1919. The orders placed by other railroads in the United States amounted to 103 and by industrial concerns to 227, making a total of 1,998 for all domestic purchases—more than nine times the similar total for 1919.

The orders by Canadian roads and industries from builders either in Canada or the United States were 189 and the orders received by American builders from foreign countries amounted to 718, making a grand total for all orders of 2,905. In 1919 the total Canadian orders were 58 and the foreign orders 898. Thus it will be seen that there was a considerable increase in orders from every source except in the export trade. Here the 1920 total is 180 less than the 1919 figure.

Table I—Locomotive Orders of 1920

For Class I Railroads	1,668
For Other American Railroads	103
For Domestic Industrials	227
Total Domestic	1,998
For Service in Canada	189
For Export to other Countries	718
Grand Total	2,905

The year 1919 set the low mark for locomotive orders as far back as records have been kept. In view of this fact, the 1920 orders cannot be considered excessive, as may easily be seen by reference to Table II. The totals for 1916, 1917 and 1918 all exceed the figures for 1920. The totals for 1917 are as large again as the figures shown in the present compilation. During these years greatly increasing demands on the railways together with a steady upward movement of prices which looked as if it would continue indefinitely brought about an economic condition which generally increases buying in almost every field. Then, too, during the war period it was felt that something approaching an adequate number of locomotives had to be provided regardless of cost, and under the regime of the Railroad Administration government credit was available for such purposes.

The orders this year were financed by the railroads themselves, with some help from the government to be sure, during the period of readjustment attendant upon the return of the carriers to their owners, when railway costs were nearing their peak and before adequate returns had been provided by a new rate structure. In view of these facts the showing for 1920 is not entirely unsatisfactory, although it is quite evident that nothing has been done during the past year to make up for deficiencies in the annual purchases of locomotives which have been accumulating since 1912.

The foreign orders for 1919 made up more than 75 per cent of all orders placed. In 1920 conditions were quite different, because foreign orders have been small. This decrease in orders from abroad is disappointing; it can be traced to the premium on the dollar which has increased generally throughout the year in most countries and which makes it possible in some cases for foreign manufacturers to underbid our own; to the fact that foreign competitors have been able to increase their production and to direct their efforts once more to their old markets; and to the generally impoverished condition of the countries which most need to replenish the inadequate stock of locomotives on their railways. One of the most noteworthy orders from foreign countries which was placed in the United States during the year was from Roumania for 50 locomotives. This order was divided equally between the Baldwin Locomotive Works and the American Locomotive Company and payment for it was made in petroleum.

Table II—Orders for Locomotives Since 1901

Domestic Orders Only

Year	Locomotives	Year	Locomotives
1901	4,340	1908	1,182
1902	4,665	1909	3,350
1903	3,283	1910	3,787
1904	2.538	1911	2,850
1905	6,265	1912	4.515
1906	5,642	1913	3,467
1907	3,482	1914	1,265

Domestic and Foreign

Year	Domestic	Foreign	Total
1915	1,612	850	2,462
1916	2,910	2,983	5,893
1917	2,704	3,438	6,142
1918	2,802	2,086	4,888
1919	272	898	1,170

The number of locomotives built in the United States for domestic service during 1920 was 1,857 and for export 1,582, making a total of 3,439. In Canada the production was 165 for domestic use and 68 for export, making a total of 233 and a grand total of all production in the United States and Canada of 3,672. This figure represents an increase of 400 over the similar total, 3,272, for 1919. The total built in the United States for domestic service in 1920 is some 200 less than the domestic production in 1919, but the figures for the Canadian and export production combine to show a definite increase in the grand total.

Due to the failure of two large locomotive builders to furnish figures showing the number built for export, it has been necessary to estimate the production of these builders from other sources, which, however, are believed to be sufficiently accurate for purposes of comparison.

Table III. The Locomotives Built

	United States	Canada	Total
Domestic	1,857	165	2,022
Foreign	1,582	68	1,650
Total	3,439	233	3,672

Comparison with Previous Years

*Includes Canadian output.
†Includes Canadian output and equipment built in railroad shops.

If the locomotive orders for the preceding year give any data by which production for the following year may be estimated, we can safely assume that the output of locomotives in 1921 should exceed measurably the production for 1920. The fact confronts us always that American roads have for several years fallen far behind in acquiring new motive power and that sooner or later the lack must be made good.

Table IV. The Passenger Car Orders of 1920

For Class I Railroads	1,115
Other Domestic (including Pullman Co.)	666
Total Domestic	1,781
For Service in Canada	275
For Export to other Countries	38
Grand Total	2,094

More Passenger Cars Ordered and Built

The totals for orders of passenger cars during the past year show an upward trend. A total of 1,115 cars was ordered by Class I roads during the year and 666 by other railroads and private car companies in the United States, including the Pullman Company. These figures added together give 1,781 as a total for the year's domestic orders, a figure which compares quite favorably with the orders in 1917 and 1918—as well as 1919.

Table V. Orders for Passenger Cars Since 1901

Domestic Orders Only

Year	Passenger cars	Year	Passenger cars
1901	2,879	1909	4,514
1902	3,459	1910	3,881
1903	2,310	1911	2,623
1904	2,213	1912	3.642
1905	3,289	1913	3,179
1906	3,402	1914	2,002
1907	1,791	1915	3,101
1908	1,319		

Domestic and Foreign

Year	Domestic	Foreign	Total
1916	2,544	109	2.653
1917	1,124	43	1,167
1918	131	26	157
1919	639	143	782

Canadian orders for the year were 275—72 less than the 1919 figure. Export orders have dropped even more sharply. Export orders for 1920 were only 38, which is a rather poor showing in comparison with the total of 143 in 1919. Passenger car building has, however, been at a minimum the world over for some years, although eventually it must increase greatly. The grand total of passenger car orders for domestic service and export in this country and in Canada was 2,094—1,312 more than the 1919 figure, an increase brought about entirely by greater orders from the roads and other buyers in the United States.

The production of passenger cars during 1920 in the United States for domestic use was 1,272 (including cars for Pullman Company service) and for export 168. These figures show decided improvement over the similar figures, 306 and 85 respectively, for 1919. The cars built are described as: all steel, 1,240; steel underframe only, 171; wood, 21, and not specified, 8.

1918	1,480	92	1,572	1	....	1	1,503
1919	306	85	391	160	....	160	551

Most of the larger orders for passenger equipment were placed relatively early in 1920. The car building companies started the year with orders for domestic service on hand and undelivered amounting to 407. The traffic congestion, the difficulty of securing raw material and related conditions prevented them from getting production under way with any great degree of speed. The orders on hand at the end of November had reached a total of 925.

Freight Car Orders Increase; Production Still Low

In the number of freight cars ordered during 1920 there has been, as was the case with the locomotives, a remarkable improvement over the 1919 showing. The orders by Class I roads were 51,250 cars, by other domestic roads 1,044 and by private car lines and industrials 31,913—making a total of 84,207 cars ordered in the United States for domestic service. To this figure are added the total orders of 12,406 placed by Canadian roads and industries and 9,056 ordered by foreign buyers, which brings the total orders received in this country and Canada during the year up to 105,669.

Table VII. The Freight Car Orders of 1920

For Class I railroads	51,250
For other American railroads	1,044
For private car lines and industrials	31,913
Total domestic	84,207
For service in Canada	12,406
For export to other countries	9,056
Grand total	105.669

In 1919 the total domestic orders were 22,062—scarcely one-fourth the 1920 total. Canadian orders of 3,837 for 1919 are scarcely a third of the purchases for 1920 and the export orders of 3,994 are less than one-half the total purchases for export during 1920.

As was pointed out in the review of the locomotive orders for this year, the showing for freight car orders is not entirely unsatisfactory in view of the uncertain conditions which prevailed throughout the greater part of the period, even the close of which brought no conclusive proof that the rate structure provided by the Interstate Commerce Commission was going to provide adequate returns to the carriers. The fact remains, however, that the acquisitions of freight cars in 1920 were far from sufficient to make up the deficiencies in orders which have accumulated during the past eight years. The showing of freight car orders for 1920 does not even compare favorably with the totals for any recent year with the exception of 1914 and 1917. The domestic orders in 1918 alone were for some 40,000 more than in 1920.

Table VIII. Orders for Freight Cars Since 1901

Year	United States			Canadian			Grand Total
	Domestic	Foreign	Total	Domestic	Foreign	Total	
1913	176,049	9,618	185,667	22,017	....	22,017	207,684
1914	97,626	462	98,088	6,453	....	6,453	104,451
1915	58,226	11,916	70,142	1,758	2,212	3,970	74,112
1916	111,516	17,905	129,421	....	....	5,580	135,001
1917	115,705	23,938	139,643	3,658	8,100	11,758	151,401
1918	67,063	40,981	108,044	14,704	1,960	16,664	124,708
1919	94,981	61,783	156,764	6,391	30	6,421	163,185

By far the greater part of the orders for 1919 were from private car lines. It is pleasing to note in connection with the 1920 totals, that, although the orders from private car lines are practically twice the 1919 figures, the railway orders are nevertheless much larger than those from the private buyers.

The export orders for 1920 are more than twice the total for 1919, but far below the average for the preceding four years. This falling off may be explained in the same manner as was the decline in locomotive orders from abroad, i. e., the premium on the dollar in foreign countries, the return of foreign manufacturers into active competition and the generally impoverished condition of buyers throughout the world.

Freight car production in the United States during 1920 for domestic service was 60,955 and for export 14,480, making a total of 75,435 cars built in the United States during the year. The totals for 1915 only in recent years are lower than those for the past year. This decline in production is but the natural outcome of the few orders placed during 1919. The heavier orders during 1918 gave 1919 an excellent showing from the standpoint of production in spite of the fact that the orders during 1919 were much lower than usual.

The production for export in 1920—14,480—represents a decline of more than 75 per cent over the 1919 figures. The production for export in 1919 bore a large ratio to the total production and the domestic orders a small ratio to the total. This condition has not obtained during the year just past and indeed the small total for export may well occasion some concern. It is true that foreign buyers are not acquiring new equipment in anything like the quantities which they actually require, but it is also evident that manufacturers abroad are once more directing their efforts toward regaining the markets lost to American concerns during the war and that the premium on the dollar gives them an opportunity in many cases to underbid American manufacturers.

In addition to the number of cars built and ordered during the year the Railway Age also asked the manufacturers for details regarding the type of cars built. The following details concerning the construction of cars built in the United States may be of interest. All-steel, 34,140; steel frames only, 6,537: steel underframes only, 22,862; steel center sills only, 635; all-wood, 2,451; not specified, 8,810.

If the orders for the preceding year are any measure of production for the following year, and it would seem that they are, the production in 1921 should greatly exceed the 1920 total. Orders in 1918 were comparatively high and production in 1919 was high. Few orders in 1919 resulted in low production totals for the past year. In like manner, then, orders having increased greatly in 1920, production in 1921 should show considerable advances. It is well to point out in this connection that the greater part of the orders for cars in 1920 were placed in the earlier part of the year but that conditions of transportation were such and raw material so difficult to secure that the manufacturing plants are only now getting up to anything like capacity production. The output of the car building companies has averaged only 3,000 cars a month for the greater part of the year. In October and November it reached 6,000.

Railroad Through a Coffee Plantation

Car and Locomotive Prices Reached Peak in 1920

Equipment Ordered During Year Cost Two and One-Half to Three Times 1910-1914 Average

THOSE railroads that purchased locomotives in 1920 paid prices for them averaging about two and one-half times the pre-war prices. The prices of freight cars were even higher in proportion than this, all-steel cars being priced at three times the pre-war figures and cars of composite construction at more than three times the pre-war prices.. The increase in passenger car prices was not as pronounced, the 1920 values having been slightly over twice the 1910 to 1914 average. These are the principal facts brought out by a study of equipment prices recently conducted by the Railway Age.

TABLE I—COMPARISON OF PRICES OF EQUIPMENT, BASED ON DATA RECEIVED FROM SIX PRINCIPAL EQUIPMENT COMPANIES IN THE UNITED STATES, USING THE WEIGHTED AVERAGE PRICE OF 1910 TO 1914 AS 100 PER CENT OR "BASE"

*Car companies report no steel passenger coaches contracted for in 1918 and 1919. Per cents for 1918 and 1919 estimated by car companies.

Detailed figures are given in this article showing this price relationship as between 1920 and the pre-war period.

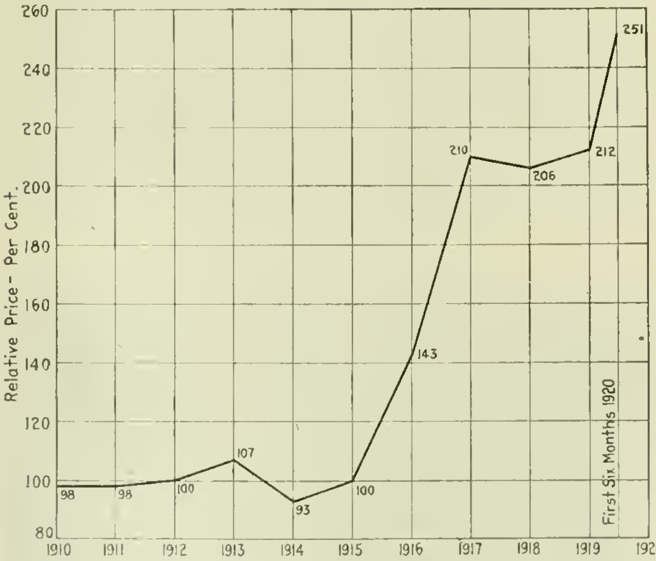

Fig. 1—Relative Prices of Locomotives 1910 to First Six Months of 1920 Shown in Terms of Average Prices 1910-1914 as 100

There is also given a table showing the prices paid for the U. S. R. A. standard equipment allocated to the railroads and, what is more important, data showing the prices which have been paid by a number of railroads for equipment which they have ordered in 1920. For purposes of showing more particularly the price trend during the year, there are also shown details of the prices of the basic iron and steel commodities which enter into the manufacture of all types of railway motive power and rolling stock.

Table I is a chart compiled for valuation purposes by the President's Conference Committee on Federal Valuation. The chart represents careful studies made by the engineers of that organization in co-operation with the equipment builders. The studies cover 10½ years, and to derive the figures shown, data were assembled covering the prices of 10,500 locomotives, nearly 275,000 freight cars and some 1,600 passenger coaches. The prices in all instances were "as sold" and cover the date of sale, not the date of delivery. The base price of 100 in the chart is taken for the period 1910 to 1914, both inclusive. The comparative percentages are worked out for the years 1910 to 1919 and for the first

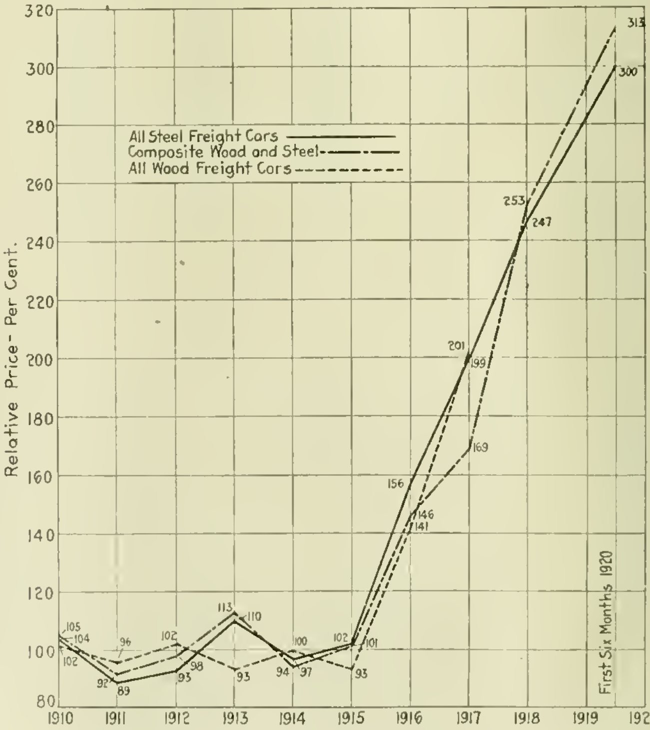

Fig. 2—Relative Prices of Freight Train Cars, 1910 to First Six Months of 1920 Shown in Terms of Average Prices 1910-1914 as 100

six months of 1920; the last figures are the ones of chief interest in this connection. The prices for the first six months of 1920 are given in the following percentages of the 1910-1914 base price:

Locomotives	251
Freight cars:	
All-steel	300
Composite	313
Passenger coaches	218

In using the figures for the first six months it must be borne in mind that approximately two-thirds of all the orders placed during the year were placed before July 1. The price trend for the year was slightly upward from January to May or June. It then ran on a level to about the latter part of October, and since that time it has fallen to slightly below the January figure. In view of these facts, and that but few orders have been placed in the last three months, it is apparent that the percentages given for the first six months are quite representative of the greater part of the orders placed for the entire year.

Table II giving the prices paid, or to be paid when finally ascertained, for the allocated U. S. R. A. standard equipment, needs but little comment. These prices are those set in connection with the equipment trust agreement made last spring to finance these cars and locomotives. They are, of course, for the year 1918, that being the year in which the orders were placed. It is interesting to note in this connection that Table I shows no freight car percentage for 1919, no orders having been reported for that year in the valuation studies.

Table III gives in detail the prices paid per unit for a large proportion of the cars and locomotives, orders for which were placed during 1920. The information is made available this year for the first time through the publicity given applications of the carriers for loans from the revolving fund or in the case of the approval by the Interstate Commerce Commission of issues of equipment trust certificates. The carriers show in their applications the details of the expenditures which the loan or equipment trust issue covers. The commission has adopted a policy of making this information public when its action, favorable or otherwise,

is announced; the information, however, is not available before that action is announced.

The details given vary in nearly every case, depending upon conditions. In compiling the data given herewith, the information made available by the commission has been supplemented by details obtained from other sources. Thus in the usual instance the road shows the number of locomotives (or cars) involved, the type and the total cost of the equipment of that particular type. For instance, a road may indicate that it desires to finance the purchase of 10 Mikado locomotives at a total cost of $800,000, and 10 Pacific locomotives at a total cost of $680,000. From this it is evident that the Mikado locomotives will cost $80,000 each and the Pacifics $68,000 each.· If the order has already been placed, this information has been supplemented from our own records with the name of the builder and the total weight in working order.

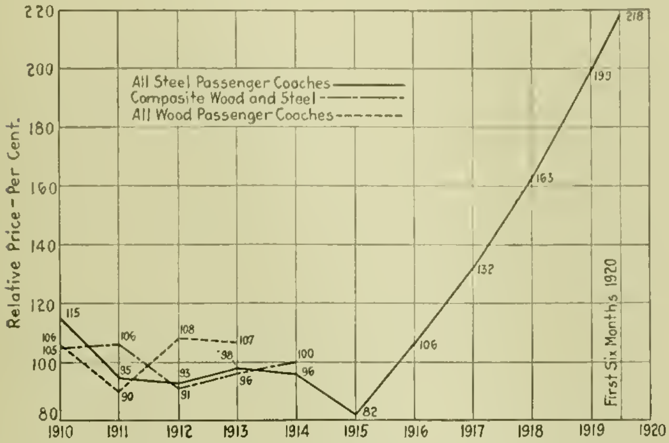

Fig. 3—Relative Prices of Passenger Coaches, 1910 to First Six Months of 1920 Shown in Terms of Average Prices 1910-1914 as 100

December	34.50	43.50	2.35	2.65

The data in the case of freight cars are similarly compiled, except that instead of total weight the details given relate to the capacity and class of construction. In the case of passenger cars the class of construction is given.

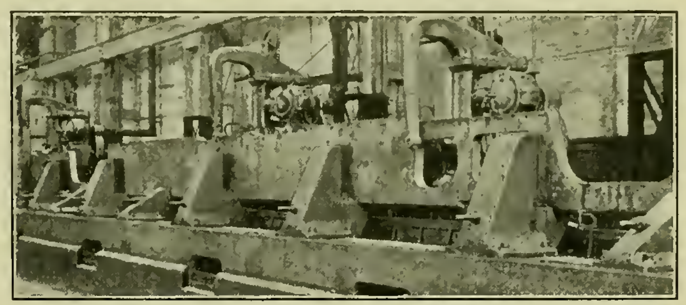
The feature concerning prices that is probably most important at the present moment is the trend of prices. It has been difficult to secure definite details as to the prices which have been paid for equipment ordered in the last month or two, one of the reasons being that details are not yet available for the public, the other and equally important reason being that so few orders have been placed. It is for this reason primarily that there are introduced in Table IV the relative prices of several basic iron and steel commodities which enter into car and locomotive manufacture. These prices have also been platted on a diagram, but, however they are shown, the rise to the peak in the early months of the year and the rapid decline in the latter months are plainly indicated. The prices of cars and locomotives presumably do not vary exactly with these commodity prices, but the lag behind them is not great. Investigation shows that car and locomotive prices have shown a decline in the last month or two. They are now approximately 10 per cent below the peak prices of the year.

Three Column Frame Milling Machine*

In Germany many locomotive frames are now made from plates, the full width of the frame section, rolled in armor plate mills. The recesses are cut out either by the oxy-acetylene torch or by machining. After cutting out with the torch, the frames are finished on the familiar type of slotting or milling machine.

The autogenous cutting process, however, is expensive and changes the quality of the material in proximity to the cut. For these reasons a firm of German machine tool builders has designed the interesting three column milling machine illustrated. The locomotive frames are clamped to heavy angle blocks rigidly fastened to the foundation shown. Suitable webs are cast to the angle blocks so that they are not in the way of the mechanic during the work and do not need to be shifted in the course of the operation.

Three milling columns are provided, entirely independent of each other and moving on common ways. Each has a horizontal milling spindle. Levers and hand wheels for the operation and control of the machine are arranged so that the entire machine may be conveniently operated from one central platform.



Three-Column Frame Milling Machine

Below the frame to be finished there is a templet which in the natural size shows the shape of the section to be milled. A copying roller fastened to the slide rest of the milling machine runs in the slot of the templet. The vertical and transverse feeds of the column and the slide rest with the milling cutters are thus mechanically controlled by the copying roller. For introducing the milling cutter into the frame recesses, the machine itself is arranged to drill the necessary holes.

The milling cutters are permanently cooled by water which returns to a water tank provided in the concrete foundation of the machine, a perforated sheet iron plate retaining all chips. The machine is stated to be capable of accurate work and high production.

*Abstract from an article in the December issue of Engineering Progress, entitled Milling Machine for Locomotive Frames.

Increasing the Capacity of Old Locomotives*

Suggestions for Modernizing Old Locomotives and the Possibilities of This Development

BY C. B. SMITH
Mechanical Engineer, Boston and Maine

IN these days of the high cost of railroading, responsible officers of the mechanical departments realize that the necessity for reducing the cost of all locomotive operation and maintenance is more urgent than ever. Such saving can be accomplished in two ways, one by using new and modern locomotives, the other by rebuilding old types.

On the majority of our roads there are still locomotives of the earlier modern types whose general features of construction are satisfactory, and which only require modernizing to make them economical transportation units. Improvements for such classes of locomotives may include, in addition to superheaters, piston valves in place of slide valves, outside valve gears in place of Stephenson motion, and such other improvements as are usually made upon engines at general shoppings.

When setting out to rebuild a locomotive the experienced supervisor appreciates the opportunity to apply many devices and facilities which will standardize the engine in accordance with the railroad company's practice, and in so doing, reduce repairs and stores department expense in maintenance.

The aggregate of such improvements results in a locomotive which in proportion to its capacity will produce service results comparable with those of entirely modern construction, and at a cost approximately one-half that for a new locomotive of similar capacity. The difficulty in carrying forward an extensive reconstruction program, however, is in finding the shop facilities either on the railroad or among the locomotive builders in order to advance the work at a satisfactory rate of progress. Despite this difficulty the results which could be obtained from the operation of reconstructed locomotives, if they could all be rebuilt within the next few years, would justify a special effort on the part of railroad managements to bring it about.

On roads where the number of old locomotives which warrant rebuilding is sufficient to require a period of more than three years to complete the work, it would seem necessary to arrange for enlargement of shop facilities in order to hasten the reconstruction. If, however, adequate shopping facilities are not forthcoming, the improvement program for locomotives must be confined chiefly to the application of superheaters and the substitution of piston for slide valves; together with the minor but relatively important betterments that may usually be applied at the shopping period. On some roads this work alone will require six years at the present rate to equip what can rightly be called the "early-modern" locomotives.

Some of the engines built within the past ten years have developed weaknesses in frames and in parts of running gear. It has proved justifiable to reconstruct them by substituting new parts of stronger design and thus avoid recurring breakages which interrupt both the road service of these engines and the repairs to others. On roads whose traffic and service conditions now demand and will continue to demand the use of light locomotives for passenger trains and freight trains on branch lines, the better classes of the light locomotives should also receive their share of improvements along with the heavier power.

Old locomotives requiring new boilers have very generally been scrapped, but where light train service demands no heavier engines than formerly, the writer believes it advisable to rebuild such engines with radial-stay boilers, superheaters, new piston-valve cylinders, main frames when necessary, and outside valve gears. If there is to be no increase in the boiler pressure over that formerly carried by the locomotive and the valve motion has given little trouble by breakages, the Stephenson motion may be connected to the piston valves through the usual rocker-shaft connections.

When rebuilding locomotives there is a favorable opportunity for replacing old tenders as well, transferring the latter to older locomotives for spare use or as substitutes for damaged equipment. When the condition of old steel tender frames requires that they be replaced, the one-piece steel casting and a larger-capacity tank should be used, as both will reduce future expense in repairs. The success of autogenous welding eliminates any objections to the use of large steel castings for fear of breakages.

Tanks should be reconstructed in coal space to permit gravity delivery of the greatest amount of fuel that is possible at the coal gates within reach of the fireman's shovel. Application of power-operated coal pushers should be made to tanks where alterations for the gravity delivery of coal cannot be satisfactorily made and where the service conditions will show a saving in expense by its use over hand methods of shoveling forward coal while on the road or at short lay-over stations.

Discussion

The discussion following the presentation of this paper at the recent meeting of the Railroad Section of the American Society of Mechanical Engineers was unusually broad and comprehensive. Through the efforts of the committee on meetings and papers, some of the best authorities on this subject had been engaged to participate in this discussion. The first to speak in regard to increasing the capacity of old locomotives was Frank McManamy, now assistant director-general of railroads. Without going into all of the details relating to those features essential to increasing the capacity of old locomotives, Mr. McManamy outlined some of the conditions essential to the successful modernization of power. It was pointed out that the value of any specialty applied for the purpose of increasing the capacity of old locomotives would be nullified unless the railroads possess a trained organization and adequate facilities for the proper maintenance of these appliances. The application of such appliances was strongly endorsed by Mr. McManamy, who claimed the credit for the liberal modernization program undertaken during the period of federal control.

The application of the superheater, the stoker and the feedwater heater were commented upon as among the best measures toward modernization, but with the application of these, as with other devices, intelligent handling and adequate maintenance are essential before they can be of any real value. The simple application of these devices is not sufficient; they must be properly used and adequately maintained. In view of this fact Mr. McManamy believes that the improved locomotive terminal is, in fact, the key to the

---

*Abstract of a paper presented at the Railroad Section of The American Society of Mechanical Engineers on December 8, 1920.

situation. So many complicated specialties are now being applied to locomotives that it is now common to refer to these locomotives as being "full-jewelled," and in many instances the application of these specialties has proved a detriment because the railroads did not have adequate terminal facilities to insure their maintenance.

In a written discussion of the subject submitted by W. O. Moody, mechanical engineer of the Illinois Central, the necessity for adequate shop, as well as locomotive terminal facilities, was emphasized. Mr. Moody pointed to the fact that in the absence of shop facilities adequate for current maintenance of locomotives, little could be hoped for toward the modernization of locomotives upon any considerable scale. In this connection it should be remarked that the locomotive companies which, until recently, have been busily engaged on new locomotive construction, are now in a position to undertake considerable modernization work for the railroads, and in view of the possibilities in this direction it would appear to be an opportune time for the railroads to assign some of this work to the locomotive builders, where they are unable to undertake it in their own shops and are not justified in the purchase of new locomotives.

Mr. Moody spoke of the locomotive booster as one of the most promising appliances designed to increase the capacity of old locomotives. It is believed that any comprehensive plan of modernization should include consideration of the booster. It was also pointed out that the modernization of locomotives offered an excellent opportunity for the further standardization of parts to such an extent as would permit a considerable reduction in the number of parts that must be carried in stock to protect the locomotives in service. Any reduction of this character should be welcomed as a means for reducing overhead charges.

J. C. Hassett, mechanical engineer of the New York, New Haven & Hartford, also advocated the modernization of old locomotives as a means to increase their capacity and laid particular stress upon the necessity for strengthening locomotive frames in connection with this development. Some interesting facts in connection with this work as undertaken on the New Haven were described by Mr. Hassett, who said that it had been found necessary to materially strengthen the frames of certain locomotives before they could be modernized and that this had also resulted in improving their riding qualities as well as increasing their capacity.

Forceful Arguments for Feed Water Heating

Some strong arguments in favor of locomotive feed water heating were presented by E. A. Averill, vice-president of the Locomotive Feed Water Heater Company, who contributed to the discussion as follows:

"Increasing the capacity of all old or semi-modern locomotives, whenever increased capacity can be used and increasing the efficiency of those which are in a service where increased capacity will not show a return, should be the first feature to be investigated and carefully analyzed.

"You will be astonished at the returns that can be obtained in investments made to this end. As an example of what can be accomplished on even some of the more modern locomotives, built within the last six or eight years, let me quote the results recently obtained from road tests with a locomotive feed water heater which is one of the appliances mentioned in this paper. These tests were made on three different railroads and each was as carefully conducted as is possible with tests made in regular operation. On the first road, the test showed a saving, due entirely to the appliance being investigated, of $252 a month, based on coal costing $5 a ton. On the second road, the direct saving was $233 a month, and on the third it was $226 a month. This is an average for the three roads of $237 saved per month per locomotive.

"Do you not think that a net saving of over $200 a month from each locomotive will make a welcome addition to the net operating income of any railroad? The feed water heater is applicable to all kinds and classes of locomotives at a moderate expense and offers one of the quickest and most positive methods by which the capacity of a locomotive can be largely increased. It has the further advantage of not requiring any additional shop facilities for its extensive application. From the standpoint of the motive power department doing its full share towards making visible the net profits of a railroad, I would recommend a thorough study of feed water heating to be placed near the top of the list of things to be considered.

"It may interest you to know that feed water heaters, which will raise the temperature of the water from 40 deg. or 50 deg. to from 230 deg. to 250 deg., have been in successful railroad service for over three years. Furthermore, these heaters filter all the water formed from the condensed exhaust steam and return it, free from oil, to the tender. This adds about 14 per cent to the capacity of the tender and greatly extends the distance that can be made between stops for water.

"On most locomotives an increased boiler capacity can be fully used in regular service and furthermore since any boiler is most economical and most efficient at its lower rates of working, an appliance which makes the boiler larger always shows returns. It gives the increased capacity when it is needed and it gives greater efficiency when the larger capacity cannot be used. A feed water heater lies entirely in this class of equipment. It permits the boiler to deliver 9 lb. of steam for each pound of coal burned where, without the heater, it would deliver about 7.8 lb. of steam for each pound of coal. If, however, service conditions were such that only the smaller quantity of steam could be employed, a boiler equipped with a feed water heater would be operating at 65 per cent efficiency, as compared with 61 per cent for the same quantity of steam, without the heater, and thus this appliance is giving a return of one sort or another at all times.

"I have mentioned the fact that there is a return to the tender of 14 per cent of distilled and filtered water, and inasmuch as any study of increased locomotive capacity must be based on a consideration of the locomotive as a producer of economical transportation, this feature, many times, is found to be one of great importance. The ability to continue the train in operation past a water station, where it would have been compelled to stop if not equipped with a feed water heater, frequently means a difference of hours in the arrival of the train at the terminal and a very large saving of overtime wages and loss of service of the locomotive. Again this feature at periods of congested traffic frequently permits the despatcher to keep everything moving on the division and opens up the possibility of very large returns from this cause alone. Where feed water heaters have been applied to locomotives, it is almost universal that the train despatcher is one of the strongest advocates of a heater on an engine."

Superheat as a Means to Increased Capacity

In commenting on the subject of increasing the capacity of old locomotives, H. B. Oatley, chief engineer of the Locomotive Superheater Company, took this opportunity of bringing out, somewhat in detail, the features which have prompted the very extensive superheating programs which have been in vogue on many of the railroads for a considerable period. A table presented by Mr. Oatley gave some comparisons between saturated and superheated locomotives. The locomotives considered were typical of each class. The cylinders, boiler pressure and maximum tractive power were shown as being the same for both the saturated and superheated steam conditions, although many engines have had the tractive power increased when superheaters were applied, under the conditions referred to later. .

"By the addition of a high degree superheater," Mr. Oatley said, "it has been demonstrated that the steam consumption per horsepower hour is reduced about 28 per cent. The figures commonly accepted as representing good practice are 27 lb. for saturated steam and 19.5 lb. for superheated steam. In the case of the 0-6-0 type boiler, the horsepower has been increased 15 per cent; for the 4-4-0 type 14 per cent; for the 2-6-0 type 13 per cent; for the 2-8-0 type 10 per cent, and for the 4-4-2 type 10.2 per cent. The maximum cylinder horsepower, using the American Locomotive Company's figures, has, by the addition of a superheater, been increased about 8 per cent.

"The ratio between boiler horsepower and cylinder horsepower, therefore, has been improved. When consideration is also given to the fact that a boiler with a superheater is at a greater advantage when worked under high rates of evaporation, for the reason that the degree of superheat increases under such conditions, the marked improvement is evident. It is very clear that the additional boiler capacity afforded by the addition of the superheater should, if possible, be utilized by providing greater maximum tractive power. When considering existing locomotives the increase in the maximum tractive power requires consideration of, 1st. The factor of adhesion. 2nd. The strength of the running gear which has to withstand the thrust of the piston.

"As in all other problems, the cost of making improvements must be balanced against the advantages which can be realized. For example: if the engine at the present time has adequate power for the work which is to be done, the expense in providing additional power would not be justified. Such cases are, however, believed to be rare, as the very large majority of existing locomotives are for all or a part of their working time required to handle every ton behind the tender that they will move. If the factor of adhesion and the strength of the parts taking piston thrust are such that an increase in cylinder tractive power can be utilized, such additional power may be attained by, 1st. Increasing boiler pressure. 2nd. Increasing cylinder diameter.

"If the amount that the maximum tractive power can be increased effectively is greater than can be obtained by boring existing cylinders, or by increasing boiler pressure, or a combination of the two, the use of new cylinders should be carefully considered. If new cylinders are applied a cylinder diameter should be selected which would permit the utilization of pistons, cylinder heads, steam chest covers, etc., and, if possible, cylinder patterns which are in use on other classes of engines on the road. It is many times found that a cylinder diameter can thus be selected which will give the desired increase in tractive power, even with a decreased boiler pressure. A decrease in boiler pressure in very many instances, particularly on the older boilers, is especially attractive, as such boilers are frequently of an age and condition which would in any event require either scrapping or operating at a lower pressure.

"Many instances will be found where for one or another of the conditions already mentioned, an increase of cylinder diameter above that which is obtainable by boring will not be advisable, and if, in such cases, slide valves are existent on the engine in question, the application of superheaters need not be foregone, as the use of piston valve steam chests fitted to existing slide valve seats has demonstrated its practicability and economy."

A Critical View of the Situation

In his remarks on the subject of increasing the capacity of old locomotives, J. T. Anthony, vice-president of the American Arch Company, stated that with 65,000 locomotives in service on American railroads, only 35,000 are equipped with superheaters; 43,000 with arches; 37,000 with automatic fire doors; 15,000 with power reverse gears; 2,000 with automatic driving box wedges, and only 30 with feed water heaters. The reasons commonly given for this condition, he said, "are lack of shop facilities and inability to get appropriations with which to carry on the work. But it is difficult to understand why the responsible officials who willingly make appropriations of millions of dollars for grade reductions, curve eliminations, etc., with the sole idea of increasing train loading and reducing operating expenses, should turn a deaf ear to the requests of the mechanical departments when they have the same object in view.

"The railway shop equipment is woefully inadequate at the present time; but this will not serve as an excuse for the fact that 22,000 locomotives are being operated today without brick arches. This simple device can be installed in the round-house in less than 24 hours, and its maintenance not only does not require any increase of the round-house force; but effects a reduction in boiler repairs and engine failures. Many years of use and a large number of carefully conducted tests have shown conclusively that the arch is good for a fuel saving of 7 to 14 per cent, or for an increase in boiler capacity of 8 to 16 per cent. To use a conservative figure the arch is good for an average reduction in fuel consumption of 10 per cent, or an increase in boiler capacity of 11

(2) American Locomotive Co.'s figures used.

per cent. Under the present condition of high price of fuel each dollar invested in the brick arch for old locomotives is equivalent to at least a five dollar reduction in operating expenses.

"There are only three methods of increasing the heating surface of an existing firebox, i. e., by the installation of a combustion chamber, or arch tube, or thermic syphons. At the present time there are only 6,000 locomotives equipped with combustion chambers, and something over 100 equipped with thermic syphons, this device being of rather recent origin. Many of the existing boilers can be improved by adding combustion chambers when new fireboxes are put in, thereby increasing the firebox volume and reducing the oft-time excessive flue lengths, and in other cases new back-ends should be put on when it is necessary to renew fireboxes of narrow and antiquated designs, thereby increasing the grate area and firebox volume. Too little attention has been paid to the possibility of improvements in old boilers by these means. While it is true that the addition of superheaters and brick arches often reduces the demands made upon it, there is still a lot of room for improvement, particularly in regard to the firebox as a furnace wherein fuel may be burned efficiently. In this connection, we might call attention to the poor designs of ash-pan on thousands of our present locomotives, on many of which it is impossible to secure an adequate air supply. Such conditions can be remedied at comparatively little expense and effect a large saving in fuel.

"As a tip to the skeptics who are prone to wait for someone else to demonstrate that improvements are possible, I quote the following figures obtained from tests of Consolidation locomotives on a large western road where the operating conditions were such that the locomotives made 40,000 engine miles per year; the cost of coal being $4.50 per ton on tender, which is much below the average price at the present time.

	Annual fuel consumption per locomotive		Annual saving	
	Tons			
Saturated Consolidation without arch	7,500	$33,750	......	
Saturated Consolidation with arch	6,752	30,384	$3,366	(Saving credited to brick arch)
Superheated Consolidation with arch	4,989	22,450	7,934	(Saving credited to superheater)
Superheated Consolidation with arch and syphons	4,257	19,156	3,294	(Saving credited to thermic syphon)

"The addition of the three devices mentioned resulted in an annual saving of $14,594 per locomotive; this 44 per cent reduction in the fuel cost being accompanied by an increase of approximately 20 per cent in tonnage hauled. And this does not represent the limit to improvements, for there are other devices that might be added, and changes made that would result in still further improvements.

"In the last paragraph of his paper Mr. Smith voices the hope that the discussion at this meeting will result in outlining some practical action to be taken by the various roads to hasten the work of reconstructing old locomotives, and states that the application of all desirable auxiliaries is prohibitive without radical provision for the carrying out of such a program. We join him in that fond hope, but, in our opinion, it will be necessary to first bring about a radical change in the attitude of many railway officials before any adequate provisions for such a program can or will be made.

"The many improvements that have been made in locomotive design in the past 10 or 15 years have not come about in answer to any loud and sustained cry from the railroads for more efficient locomotives. The railroads asked for larger and more powerful locomotives; but the devices that have made the locomotives of increased capacity and efficiency possible, have been largely left to the ingenuity of the railway supply companies and, in a smaller degree, to the locomotive builders. The development of the several well-known fuel economy and capacity increasing devices has been due to the labor and efforts of men who have left the railway service, in many cases on account of the lack of interest of the railroad in the device which the individual was trying to get perfected and used.

"If we can judge the future by the past, there will be no radical provisions made for the carrying out of a locomotive reconstruction program until the officials of the mechanical and operating departments awake to a full realization of the possibilities of reducing present operating expenses by the maintenance of a high standard of efficiency of *all* their locomotives, and by their urgent demands and intelligent presentation of facts, convince the higher authorities—those who have to dig up the money—of the feasibility and desirability of such a program."

The Care of Locomotive Boilers

Some interesting observations on the care of locomotive boilers are found in a paper on Locomotive Running Shed Practice by W. G. Bishop of the South African Railways, published in the Journal of the Institute of Transport. In discussing methods of washing out engines, Mr. Bishop says "The old method of washing out boilers with cold water is so well known that its disadvantages make one surprised at the tenacity displayed in the retention of such an obsolete method. As a time and money wasting process, it would be hard to beat. To wash out a boiler with cold water will take 12 hours at least to do properly and there is always the added danger that transportation calls are so pressing, that boilers are not allowed to cool properly before cold water is admitted. This is extremely detrimental to the life of the firebox."

Mr. Bishop estimates that in a terminal handling 100 locomotives in a fair water district, the hot water washout plant would effect a saving of 3,600 engine hours each month. There is a material saving in the cost of labor for washing in using hot water and the hot water system also effects additional savings in labor and material for repairs to boilers, in fuel used for firing up and in water. In conclusion, Mr. Bishop says, "Washing out with cold water is as obsolete as the tallow candle and no railroad concerned in the movement of traffic can afford to hang up its power by continuing to use cold washouts. It is a clear loss of 20 per cent of its power at least."

Much of the water used for boiler purposes in South Africa is of very bad quality and apparently the South African Railways have experienced the same difficulties as American roads in applying water treatment, for Mr. Bishop remarks, "Very few railways ever give any system of water treatment a chance. It is the job of a highly skilled specialist, the railway chemist. Too often plants installed are looked after in some sort of manner by a mechanical officer who may make chemistry a hobby and fairly successful results are obtained. A change comes and a new man arrives who does not specialize in chemistry and the water softener falls in disuse and finally goes out of action. A large corporation should have a chemist on its staff and water treatment should be considered of the highest importance. No softening plant or boiler compound will ever be a success until it is handled on the proper lines. The effect of good water on the life of the boilers and freedom from leaks and repairs is so great that one often wonders how any road can afford to be without its water treatment section, officered by a fully qualified, analytical chemist."

IN QUENCHING TOOLS be careful to have no sharp line of demarcation between the hardened and softer unquenched sections.—*The Melting Pot.*

Reducing the Fuel Consumption of Power Plants

Methods of Increasing Boiler Efficiency; Reducing Heat Losses by Insulating Steam Pipes

BY WILLIAM N. ALLMAN

THE matter of fuel conservation is now one of the big problems of the day. Coal prices have soared and costs are considerably more than just a few years ago. It is therefore evident that the power plant engineer has to confront problems that are reaching immense proportions. In summing up the whole matter the remedy for fuel waste resolves itself into a thorough knowledge of combustion and the initiative to apply such knowledge in such a way that results will be obtained. From this it is quite evident that trained men are desired to meet the requirements of economical operation.

To waste coal is to waste money and unless all possible heat units are being obtained from the coal a part is being wasted. What goes up the chimney as smoke and what coal is thrown away in ashes is absolutely lost. If this were unavoidable it could properly be called waste, but this is not altogether unavoidable and through proper methods may be saved to a large degree.

There are now available a great many fuel saving devices which should be considered by power plant operators, as the saving in fuel in a great majority of cases more than pays for their installation in a short time. Such devices as superheaters, feedwater heaters, stokers, feedwater regulators, fuel economizers, air and steam flow meters, water treating devices, etc., should receive careful attention, and a thorough study in order to determine their value.

Dr. Charles P. Steinmetz has also made the statement that he considers it hopeless to anticipate much improvement in the burning of coal and coke, and on an average we get barely more than 10 per cent of the value of the coal for power, the remainder going off as heat. The only solution is to use the carbonized fuel from the oven in such a way as to get out of it both the power and the heat. It is then a very important matter to give undivided attention to the conservation of the heat, and the biggest factor in this regard is proper insulation of exposed parts.

Another important phase is to make use of all exhaust steam (this represents heat) for heating buildings, drying materials, operating low pressure turbines, etc.

The power plant engineer who is wide awake is having his attention drawn very forcibly to the importance of strict conservation, as there have been endless circulars issued by the government, state and municipal authorities as well as numerous articles in the leading technical journals and with all this vast amount of literature emphasizing economy there is no excuse for undue waste. It is necessary, of course, to consider thoroughly conditions in the individual plant, for instance possible economies with superheat depend upon how far the plant has already been developed along lines of thrift. The only way to adequately judge the worth of superheating in any plant is to consider the economies made possible by its use, the first cost, maintenance cost and the simplicity of its installation. It has been claimed that it is possible to save as high as 15 per cent of fuel; in such cases the superheater would soon pay for its installation. This same application can be made to other appliances, and the merit of each should be studied and considered from all angles.

Efficiency versus Losses

The term "efficiency" when applied to a furnace means the combined efficiency of the boiler and furnace, this for the reason that losses are attributed to the complete apparatus.

The highest efficiencies that have been obtained with coal vary from about 82 per cent to 85 per cent. Loss of efficiency is therefore a direct waste of fuel, and failure to obtain full efficiency and capacity from a plant may result from:

Inleakage of air through boiler settings.
Improper methods of firing or draft control.
Insufficient draft.
Unsuitable fuel.
Unequal division of load between the several boilers.
Formation of scale and corrosion on heating surfaces.
Low temperatures of feed water.
Waste of exhaust steam.
Heat absorbed by boiler.
Improper or insufficient insulation.
Incomplete combustion of carbon.
Heat carried away in dry chimney gases.

The results of numerous tests indicate that a content of 10 per cent to 13 per cent CO_2 (carbon dioxide) should be obtained, and this would be considered good performance. Large excess of air is indicated by low CO_2 content and high-oxygen content, incomplete combustion being indicated by CO (carbon monoxide), which should be low in percentage. As a general rule the CO content in the flue gases should not be allowed to reach one-half of one per cent. Causes that may be assigned to excess of air, are: Holes in the fire, too large openings in the dampers of the firing door, badly warped fire doors preventing them from closing tightly, too frequent raking or slicing of the fire, leaky settings, fire doors being kept open too long.

It is quite possible to have the gases running as high as 14 per cent in CO_2 without a trace of CO, while in other cases a considerable amount of CO may obtain even with CO_2 running at 10 per cent. It should also be borne in mind that CO is only one of the combustible gases, and the actual loss from incomplete combustion may be twice as large as that indicated by the percentage of CO as there may be present H_2 (hydrogen) and in some instances a trace of CH_4 (methane).

Causes for Excess Air and Fuel Waste

One of the most common causes for excess air in flue gases is holes in the fire bed. This can be avoided through frequent firing and placing coal on the thin spots. It is highly important that the fireman understand combustion in order to get the maximum efficiency out of coal. He should keep in mind that it is his duty to make steam economically and not merely burn coal. He should not become discouraged if he finds it difficult to understand the principles of furnace efficiency, as there is no such thing as a royal road to knowledge, and it is quite necessary that the whole matter of combustion be carefully analyzed. Co-operation is also a big factor in the success of the plant and successful firemen and engineers do not overlook this very important matter.

To prevent waste of fuel it is necessary to see that all settings are tight in order to eliminate the infiltration of air. This is one of the largest single items of loss in the whole cycle of power production, and also one of the most common in its occurrence.

There are three important places to investigate for this air leakage:

1. Cracks in boiler walls and settings.
2. Leaks or air spaces between iron door frames and boiler walls.
3. Leaks around blow-off piping.

Cold air that leaks in absorbs heat until it reaches the temperature of the furnace gases, and hence wastes heat that would otherwise perform useful work. It is conservative to estimate on the following basis: if air leakage through boiler walls amounts to only 5 per cent of the actual quantity of air required for proper combustion and high efficiency, 1 per cent of the fuel burned is wasted. Leakage often amounts to more than 100 per cent and 100 per cent leakage causes fuel wastage of at least 20 per cent.

Cracks in the boiler walls may not be very apparent, yet may allow leakage enough to materially lower the efficiency of the boiler. Air leakage is easy to detect. A simple method is to take a sheet of paper about two feet square and cut out in the center a round hole about one inch in diameter. This sheet should be pasted on a square wooden frame made of four pieces of inch by inch stock. The frame should be held against the boiler wall with the paper side out, making the joints between frame and wall tight by using putty or fire clay. Then by holding a match or a candle in front of the hole, leakage through the four square feet of boiler-wall surface creates a draft through the one-inch hole in the paper. The amount of this draft is indicated by the sucking-in of the flame, and is usually quite surprising. To conduct this test successfully, it is essential that all joints between the frame and boiler wall be made air-tight.

Although air leakage is one of the most important causes of fuel waste, it is nevertheless one of the simplest to remedy. The application of a suitable insulation in sheet or block form and of proper thickness, finished with a smooth, tight surface not only prevents the infiltration of air but also reduces radiation or loss of heat from boiler walls. This remedy should always be used if boiler walls are hot and loss due to radiation correspondingly great.

Boiler walls may be made air-tight by applying to the outside of the wall a coating of material which will seal up cracks and which is itself sufficiently elastic to permit expansion and contraction without cracking. Wide or large cracks can easily be taken care of by caulking with material such as asbestos wick before the application of a coating as referred to above.

Open spaces around access and other door frames should be thoroughly sealed by means of a cement that will adhere to both iron and the brickwork and that will remain intact when subjected to heat and resulting expansion and contraction. Defective brickwork settings should be constantly repaired and the bricks should also be bonded together with a material which will not readily crumble or fuse away and which is capable of resisting heat and expansion strains. Additional protection to fire-brick settings may also be obtained by coating the interior surface with a refractory material.

Proper Amount of CO_2 (Carbon Dioxide)

A careful check should be made constantly in order to ascertain the percentage of CO_2 and particular care should be taken to see that this does not get too low. When it is found that the percentage of CO_2 runs below about 10 per cent it is time to study the conditions carefully and learn the cause, as it is certain that there is loss and waste of heat, which means loss in dollars and cents. It should also be understood that a definite percentage of CO_2 does not always indicate a certain efficiency, because it is quite possible to obtain a 10 per cent content of CO_2 with a certain efficiency while it is also possible with the same efficiency to show a 13 per cent content of CO_2.

The percentage of CO_2 indicates the volume of excess air flowing through the furnace and the boiler passes, or the ratio of the air that is taken in for the purpose of consuming the coal and that which is taken in and results in a wasteful cooling of the furnace gases. To burn one pound of coal requires about 14 lb. of air. This air enters the furnace at atmospheric temperature and leaves at a temperature of 500 deg. F. or more. During this transition it carries with it all the heat it has absorbed in being heated through this range of temperature. For each degree of temperature rise one pound of air absorbs approximately one-fourth of a heat

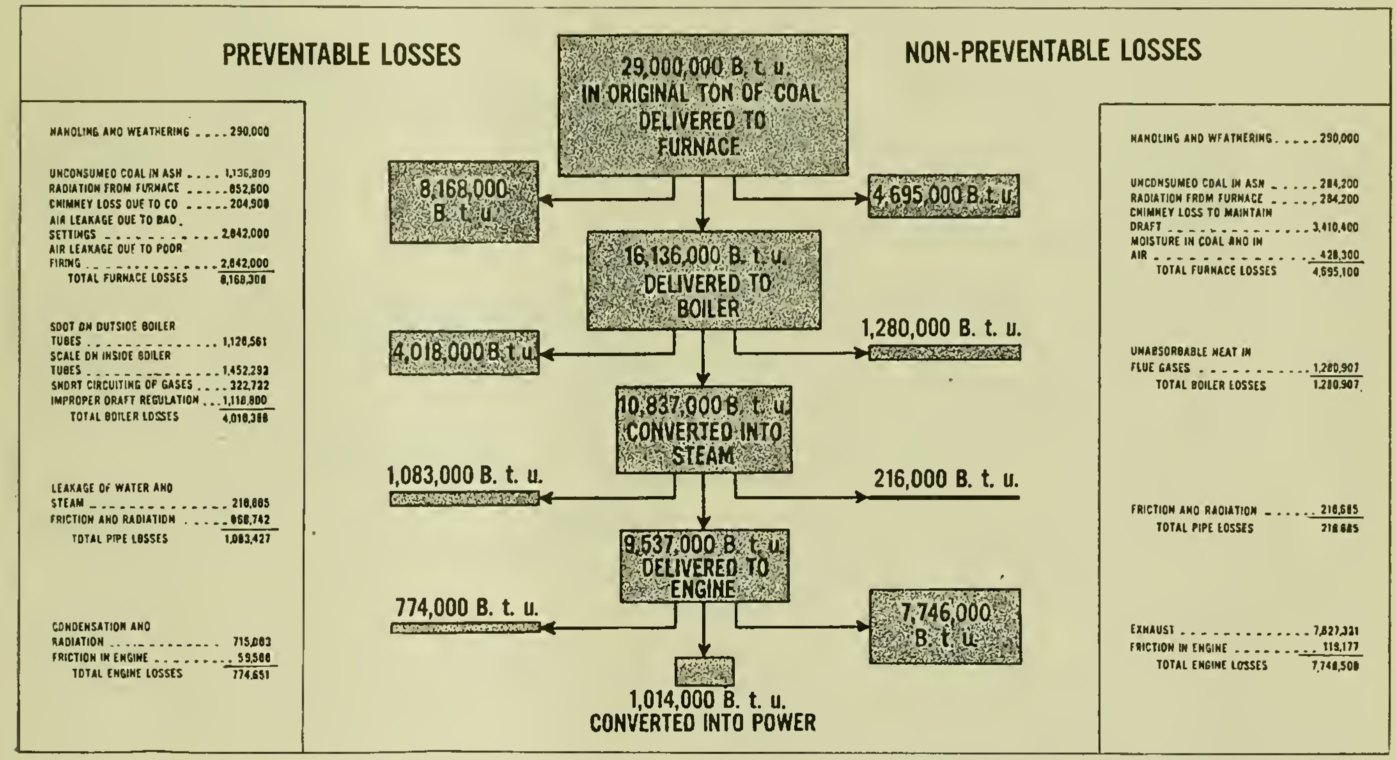

Fig. 1—Fuel and Heat Losses Between Mine and Crank Shaft

unit (B.t.u.), from which it is evident that each pound of air during the transition period on being heated to 500 deg. F., absorbs 125 heat units and therefore the 14 lb. of air required to burn each pound of coal absorbs 14 × 125, or 1,750 heat units. From this it is evident that all air in excess of this amount admitted to the furnace will carry away a large number of heat units, which is waste pure and simple. The waste then resolves itself into two factors, which include the amount of air entering the furnace and the temperature rise.

For determining the amount of CO_2 and CO the apparatus most frequently used is some form of the Orsat apparatus and no investment in power plant equipment will yield a larger rate of interest than a well used gas-analysis apparatus. Other equipment which is also indispensable includes the pyrometer and draft gage. By the use of the pyrometer the temperature of the excess volume can be determined, for in order to determine the preventable heat loss from excess air it is necessary to know the temperature as well as the volume. Draft regulation is one of the most important factors in combustion efficiency and the amount of draft should be such as to produce the best percentage of CO_2 without CO and still meet the load conditions.

These various appliances all have merit and conditions should be studied very carefully in the power plant with the view to their adoption as the initial cost is practically nil, considering the ultimate saving that can be realized by their installation. One of the greatest obstacles in the past has been the unwillingness of a large number of plant managers to spend a few dollars on the nonproducing part of their plants, but this is to a large degree being overcome, particularly during the past three or four years.

Fuel Waste and Where It Goes

The question is often asked, "How can coal be saved?" This is a question upon which much has been written during the past few years, and rightfully so, as the coal bill in all power plants has now become a vital factor and must necessarily receive the most searching kind of investigation.

When it is taken into consideration that a ton of good-grade coal delivered to the power plant contains approximately 29,000,000 B. t. u. and that the average plant delivers to the point of power only approximately 554,000 to 555,000 B. t. u. it is well nigh time to "sit up and take notice." As an illustration of where the losses occur in the average power plant the diagram in Fig. 1, taken from Joseph W. Hays' treatise on "How to Build Up Furnace Efficiency," will prove of interest.

It will be noted that by far the greatest waste is caused by the large amount of excess air that is permitted to enter the furnace and boiler setting and to escape up the chimney, which is carrying away heat that should otherwise be utilized to perform useful work. This unnecessary air is admitted in two ways, through uneven fires which leave part of the grates bare and through leaky boiler settings.

The loss due to uneven fires can properly be charged to improper operation and this is one of the important factors regarding which the fireman should be properly informed in order to correct it.

The loss due to leaky settings is even more important for the reason that it is not so easily detected. This forms an enormous preventable loss and the question of tight boiler settings is not debatable, therefore one of the first and important steps is to insure that the boiler settings are made tight with a suitable air-tight coating. This coating should be of a nature that it will expand and contract with the brickwork as well as being capable of withstanding the high temperatures, and retain its elasticity. Such a compound is on the market; it is cheap, easily applied and presents one of the best investments that can be made. Too much stress cannot therefore be brought to bear on this important matter of maintaining the settings in such a manner as to have them free from leaks. Fuel losses measured by CO_2 and flue temperatures are shown in Fig. 2.

Leaky Baffle Walls and Settings

Unless baffle walls are tight, part of the hot gases from the furnace will short-circuit or take a direct route from the fires to the stack, whereas with perfectly tight baffles the gases must follow the path prescribed for them and pass over the entire heating surface. Excessive leakage through the first baffle, or the one nearest the fire, can often be detected by looking through the dusting-doors or peepholes just beyond the baffle.

In constructing or repairing baffle walls, joints should be eliminated wherever possible, whether between sections of the baffle or around tubes. The more nearly air-tight the wall can be made, the higher will be the efficiency of the boiler; this is no doubt generally conceded to be a fact by all power plant men.

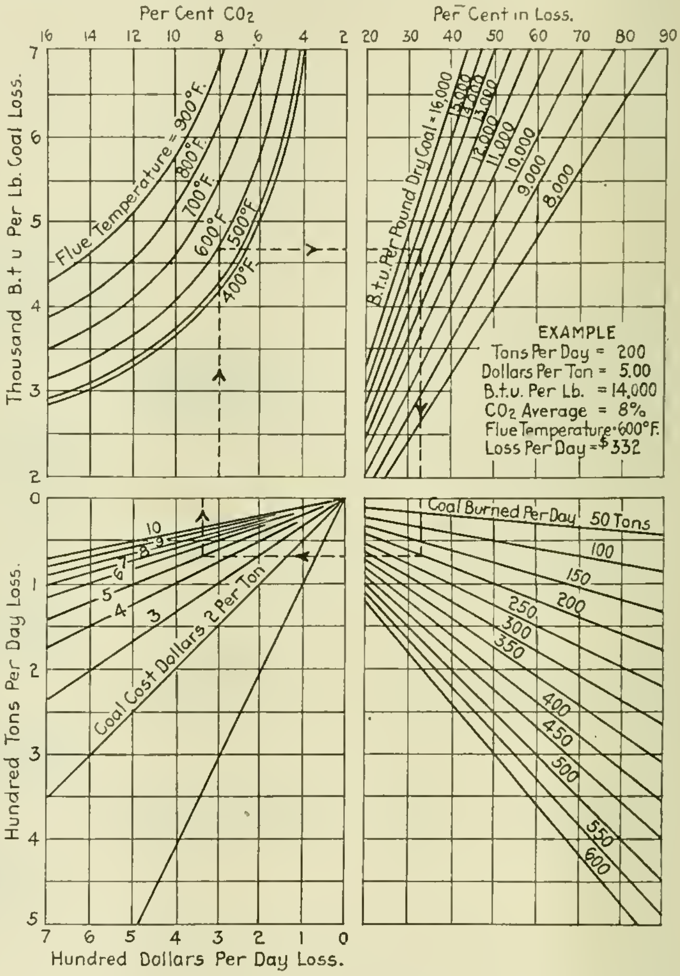

Fig. 2—Fuel Losses Measured by CO_2 and Flue Temperatures

Every substance expands and contracts under temperature changes. In each 180 deg. iron changes one part in 800 approximately, while firebrick changes one part in 2,000, which of course is a great variation. The result is that the iron-work expands more than the brickwork, and there is necessarily a slight relative movement between them as the expansion takes place. As the boiler cools the reverse condition occurs and this contraction and expansion soon develops cracks and openings so that the settings require close attention at all times. These leaks can be located by the method referred to heretofore or by throwing a scoop or two of green coal on the fire and closing the damper tightly. In this case the result is the reverse; the pressure inside the furnace is increased and smoke will soon be emitted through any opening or crack by which air would enter.

Another source of leakage commonly overlooked is in the division walls between boilers set in batteries. Leaks in these walls are just as bad as in outside walls, as the live boiler will draw cold air from the dead one and the ultimate results are the same

Efficiency of Combustion

It has been found that a proportion of about 11.5 lb. of air to every pound of carbon in the coal is necessary in order to insure complete combustion and furthermore this quantity of air must actually come in contact with the fuel. Incomplete combustion is due mainly to two causes, namely—insufficient air supply and failure of air to mix with the combustible rising from the fuel bed. Air is just as necessary for combustion as is the coal itself and for every pound of coal burned on the grate, 7 lb. of air must be admitted to flow through the bed of coal.

It is also very necessary that the bed be kept uniform and free from holes as the majority of air flowing through the holes does not aid in the combustion. On the other hand it absorbs a large amount of heat that is carried out and lost through the stack.

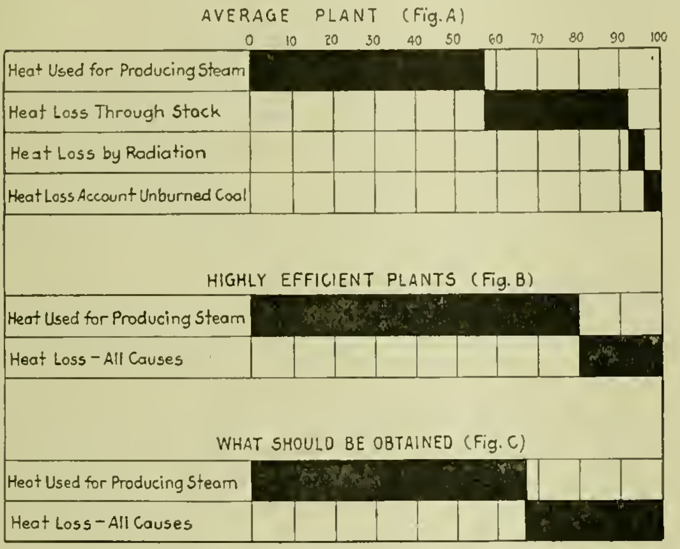

Fig. 3—Chart Showing Field for Saving in Heat Losses in Power Plants

The additional air needed to aid combustion should be admitted as close to the fuel bed as possible at a high velocity through small openings to bring the combustion up to the highest efficiency. Under no circumstances should this excess air be admitted through holes in the fire. As stated heretofore it requires approximately 14 lb. of air for burning one pound of coal, and in view of the fact that the swift passage of air causes some of it never to reach the fuel, air excess as high as approximately 40 per cent of the air conveying the oxygen required should be used, this depending upon the furnace construction. This matter of combustion could very easily be dwelt upon at length without covering the whole field and only the more important factors can be referred to in this article.

The construction of the furnace also regulates the quantity of excess air required for complete combustion and in some cases it may be as low as 12 per cent or 15 per cent, but it is not considered advisable to go below 20 per cent and may go as high as 40 per cent.

If the composition of the fuel is known, the percentage of excess air may be found approximately by the following formula No. 1:

$$\text{Percentage of excess air} = \frac{2100}{CO_2\ (1 + 3H)} - \frac{100 + 238H}{1 + 3H}$$

in which

CO_2 = Percentage of Carbon Dixoide in flue gases.

H = Weight of available hydrogen per pound of carbon in coal burned.

By the application of this formula when the percentage of CO_2 is known the important factor, excess air, can be ascertained. Efficient combustion results when the fuel is burned completely with the minimum amount of excess air and no further air is permitted to admix after combustion is completed. Complete combustion liberates all the heat contained in the fuel but efficient combustion requires that the heat be liberated in such a way as to give the maximum effect for producing steam; combustion efficiency can then be stated as shown by formula No. 2:

$$\text{Combustion efficiency} = \frac{\text{Heat available for making steam}}{\text{Heat contained in fuel burned}}$$

The heat carried away and lost up the chimney may be determined by formula No. 3. Although the results do not indicate all the heat wasted, yet it will be close enough for all practical purposes and shows the heat loss in B. t. u.'s per pound of carbon burned.

Formula No. 3

$$\text{Heat losses in flue gases} = \left(0.24 + \frac{58.46}{CO_2}\right) \times T$$

CO_2 = Percentage of Carbon Dioxide in flue gases

T = Difference between the temperature of the escaping gases and the temperature of air in boiler room in degrees "F."

It has been found in the average steam plant that the distribution of the heat in the coal is about as represented in Fig. 3. From figure A in this diagram it will be noted that for the average plant about 57 per cent of the heat is utilized for the actual production of steam, while about 43 per cent is lost. Figure B is representative of what is obtained by the best performances or about 80 per cent of heat utilized for producing steam and 20 per cent lost. Figure C shows what should be obtained and by increasing the percentage from 57 per cent to 67 per cent, which would mean a saving of about 15 tons of coal out of every 100 tons.

(*To be concluded in the March issue*)

If a belt slips after being cleaned and properly adjusted, it is probably overloaded, and the size of the pulleys should be increased.—*The Melting Pot.*

Labor Board Opens Hearings on Working Conditions

Carriers Oppose Perpetuation of National Agreements; Employees File Charges Against Roads

THAT the national agreements between the railroads and various classes of their employees, instituted within six months before the end of federal control, should not, in the interests of "honest, efficient and economical management" be continued longer under private operation, was contended by representatives of the railroads before the Railroad Labor Board on January 10 during the opening hearings on the demand of railway employees for the perpetuation of these agreements.

"The only parties who are fully qualified to consider such regulations are the individual managements and their employees," testified E. T. Whiter, chairman of the Conference Committee of Managers of the Association of Railway Executives, which is presenting the carriers' side of the controversy.

The reasons for the carriers' opposition to national agreements were outlined in the opening statement on behalf of the railroads. This opposition, according to Mr. Whiter's testimony, is based on the facts that:

(1) They are ultra-restrictive and therefore prevent the honest, efficient and economical management demanded by the transportation act;

(2) The variable conditions in different sections of the country make the universal application of their provisions impracticable;

(3) The existing rules, the continuation of which is proposed by the men, are capable of various constructions;

(4) The existing agreements provide that the rules contained therein shall apply to all employees of any particular craft regardless of the department of the railroad in which the man is employed; thus leading to a division of jurisdiction and a conflict in the working rules applicable to employees engaged in the same work;

(5) The existing agreements have destroyed acknowledged efficient and economical practices such as the piecework system for regulating rates of pay;

(6) The railroads must have relief from the rules controlling the employment of men, which are so restrictive as to prevent them from obtaining a sufficient number of employees in certain departments, thus interfering with output and causing delay to the movement of traffic;

(7) The agreements contain many rules which provide for payment of work not performed, and thereby cause many millions of dollars of unnecessary expense annually.

"The railroads do not object to schedules (the technical term for railway agreements) properly negotiated and entered into with their own employees," Mr. Whiter said, "as is evidenced by the fact that nearly all, if not all, of the roads represented by this committee, have had schedules with the various train service organizations for many years.

"Prior to federal control, some roads had schedules with other classes of their employees; many had no schedules with any crafts other than the train service organizations, but there were no so-called 'national agreements' which made all rules uniformly the same throughout the country. All roads that did have schedules directly negotiated them to fit their own conditions with their own men, and in every case the railroads had the undisputed right to negotiate their own schedules, which was denied during federal control.

"Under governmental control the railroads were unified, and the director general entered into so-called 'national agreements.' These agreements, which were of universal application for the period of federal control, were specifically recognized by the parties signatory thereto as effective during this period only."

During subsequent hearings Mr. Whiter presented testimony regarding the shop crafts agreement, showing how the rules operated to increase labor costs exorbitantly and decrease efficiency. As readers of the *Railway Mechanical Engineer* are familiar with this matter no attempt will be made to report the details of the testimony.

Mr. Whiter's testimony regarding this agreement was completed on January 18, following which representatives of several of the larger carriers presented detailed statistics to show that the abolition of the piece work system of pay in railroad shops has resulted in serious decreases in the efficiency of the individual worker and consequently in the output of the shops.

Unions Criticize Contracts for Repairs

At the opening of the hearings on January 10, B. M Jewell, representing the American Federation of Labor, presented a statement in which he attacked the contracts for repairs which the railroads have made with outside shops. W. Jett Lauck, representing the International Association of Machinists, filed a petition for an investigation of these contracts with the Interstate Commerce Commission, although the commission had already announced that such an investigation was already under way.

The petition charged that the big railroads, "especially those affiliated in a financial way with J. P. Morgan & Co., are closing their repair shops, throwing thousands of union men out of work and giving repair work at extortionate rates to large private equipment companies in which railroad capitalists or banking groups are heavily interested." It was also stated that more than 30,000 union men already have lost their jobs under this plan and a combination of figures was built up as the basis for a statement that the railroads are "milking the national treasury of three-quarters of a billion dollars and manipulating the funds in a campaign to drive the railroad unions out of business," and that in this fashion the railroad managements hoped "to send the unions on the rocks and charge the bill to the public through taxation to pay the subsidies guaranteed by the federal government or by maintaining present high rates."

Neither the press statement nor the petition explained that the car and locomotive repair work was sent to outside shops during the guaranty period during which, under the law, the railroads will be allowed to charge to maintenance expenses for the purpose of figuring the guaranty only an amount to be determined by the Interstate Commerce Commission, nor that most of the lay-offs of shop employees referred to occurred at a later period, after the volume of railroad traffic had been greatly reduced. The petition stated that locomotive repair work when done in the outside shops costs the railroads on an average four times as much as it costs in their own shops. The petition suggested the following policy for correcting the alleged evils:

"1. That no railroad company be permitted to enter into contracts for repair work on locomotives or cars by outside companies unless given a permit to do so by the commission, and

"2. That as a condition to securing such a permit, the railroad companies must show: (a) They cannot do the work which they wish to contract for, or (b) They cannot do it at as low a cost as they can have it done by outside companies, and (c) If a permit is granted, that the same rates of compensation and the same conditions of employment will be observed by the contractors as are recognized and guaranteed to railway workers by the Transportation Act of 1920, and the Awards of the Railway Wage Board established by this Act."

Later another statement was given to the press quoting Mr. Lauck as to the alleged actual records of contracts for repairing 617 locomotives and about 32,000 cars during the past several months. The following table was given as showing a comparison between railroad and private shop costs on the basis of the data secured by the unions and those ascertained by the Railroad Administration:

Cost of Locomotive Repair Work by Private Companies and Cost of Similar Work in Railroad Company Shops in August and September, 1920

Number of locomotives	Name of company doing work	Total cost	Average cost per locomotive
234	Baldwin Locomotive Works..........	$4,691,176	$20,048
27	Rome Locomotive Company............	459,000	17,000
41	American Locomotive Company.........	670,760	16,360
9	Lima Locomotive Works.............	149,535	16,615
11	Charleston Dry Dock Company.......	66,000	6,000
9	Southland Steamship Company.......	54,000	6,000
10	Merrill & Stevens	120,000	12,000
6	Broad Foot Iron Works.............	72,000	12,000
1	Pittsburgh Boiler & Mch. Co.........	1,670	1,670
2	Manufacturers Railway Shop.........	25,080	12,540
350	Total and weighted average......	$6,309,221	$18,026
1,080	Railroad Company Shops............	$5,504,144	$5,096

In this statement it was stated that the locomotive repair bill under the private contract system would be raised from $500,000,000 a year to $1,500,000,000 annually and the car repair bill from $400,000,000 to $800,000,000, a total increase of $1,400,000,000.

Practically all the data regarding the cost of repairs, as included in the statements of the machinists' union, were brought out in a speech by Congressman Huddleston of Alabama in a recent speech in the House of Representatives. In the report of the speech contained in the Congressional Record, a tabulation of contracts for repairs to locomotives and cars is shown with a further statement of the cost of classified repairs in certain railroad shops. The data regarding repair contracts show that the cost per locomotive ranges from $1,670 to $30,275.70. Practically no information is given as to the extent of the repairs. The work done in railroad shops is subdivided under the various classes of repairs, the cost being as follows:

Class 1..............................	$26.069.23	(one road only)	
Class 2..............................	8,195.64	to	$14.498.14
Class 3..............................	4.471.66	to	10,658.39
Class 4..............................	2,093 71	to	4,576.11
Class 5..............................	1,002.09	to	4,025.45

Railroads Reply to Charges of Labor Leaders

Following the publication of these charges many of the railroads gave out detailed statements defending the contracts for repair work. It was pointed out that in many cases the terms were the same as in contracts made by the Railroad Administration.

Thomas DeWitt Cuyler, chairman of the Association of Railway Executives, issued an official statement in which he denied the charges of labor leaders that railroads were paying excessive costs for equipment repairs as an attempt to deceive the public. At the conclusion of his statement Mr. Cuyler said:

"When the railroads were returned to private operation there was an abnormal percentage of cars and locomotives in bad order requiring repairs. The excess of bad order equipment was beyond the capacity of the railway shops, and the railway labor engaged in the repair of cars had declined in efficiency and output. These abnormal conditions required abnormal remedies to meet them. It was a matter of time and economy to utilize all the facilities of the equipment concerns of the country for these repairs.

"There is absolutely no truth in the charge that banks and railroad companies are in a 'conspiracy' against labor, the 'open shop,' or upon any other controverted point."

QUESTIONS AND ANSWERS

Location of Cylinder Center Above Center Line of Axles

Why is the center line of cylinders in most locomotives placed about 1½ or 2 in. above the center line of the axles?—H. C. Wilson.

The principal reason for placing the cylinder center line above the center line of the axles is to provide for wear in the driving box crown brasses and settling of the springs. If the cylinders and wheels are placed at the same level, the cylinder would be lower than the center line of the wheel after the engine had been in service or after the crown brasses had been bored. This would result in an undesirable condition as it would cause the thrust of the cross head to act downward at certain points in the stroke when running ahead. Normally, this pressure is against the upper guide.

Another advantage in locating the cylinder center above the center of the wheels is the fact that it raises the guides and reduces somewhat the amount of dirt that lodges on them. In some cases, it may also give increased clearance for the leading truck. Raising the center line of the cylinders above the center line of the axles increases the angularity of the main rods and shifts the dead centers so that they are not diametrically opposite. This introduces some errors in the valve gear but with the long main rods ordinarily employed, this is so small as to be negligible.

Finding the Speed of Trains

How can the speed of a train be found without timing it between mile posts?—J. B. Johnson.

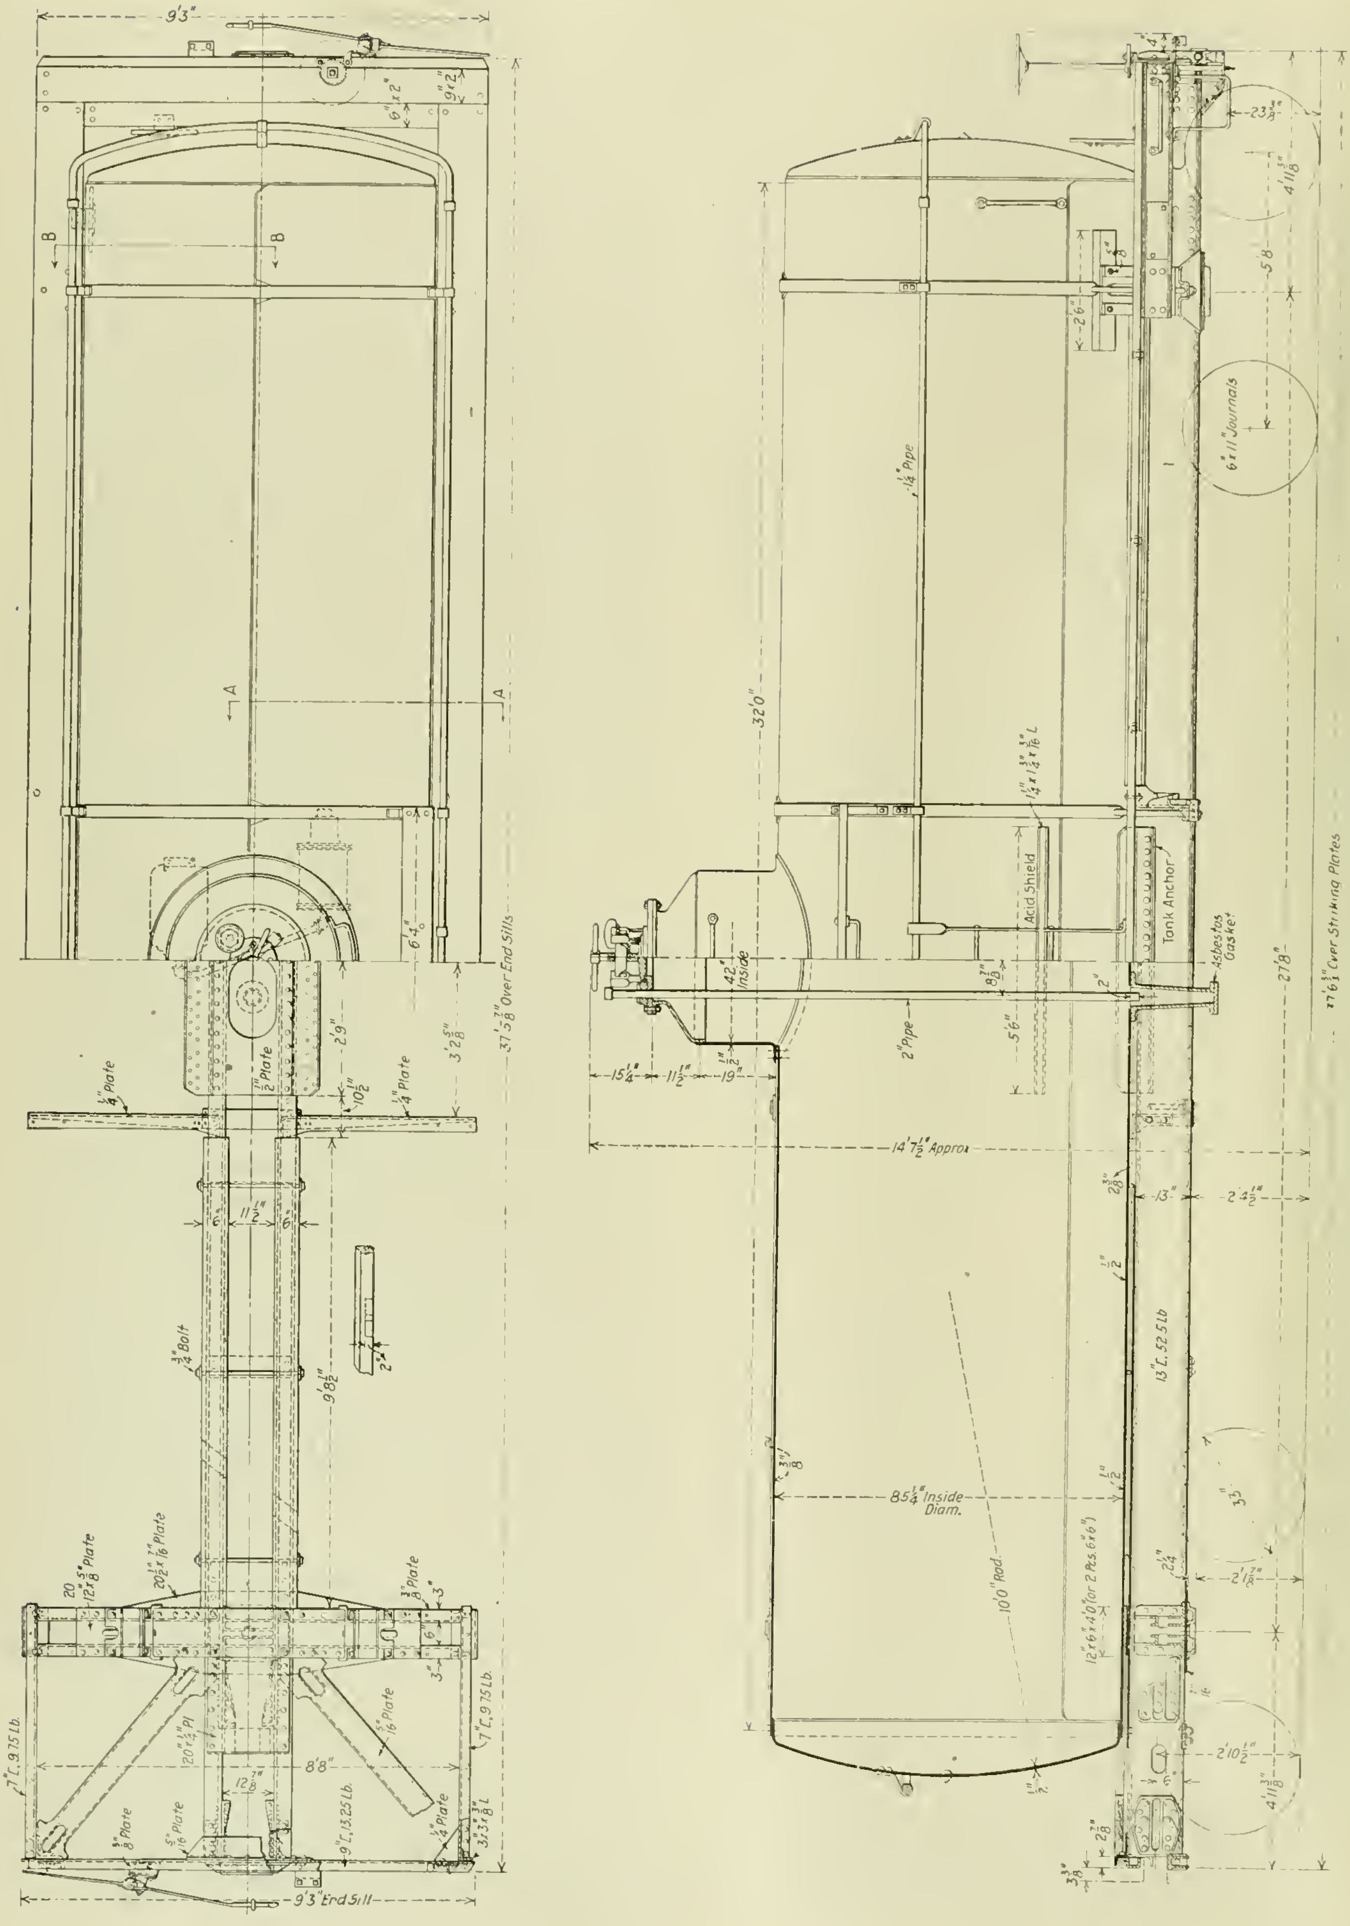
When running on double track, one of the easiest methods of finding the speed of a train is by counting the rail joints on the opposite track. Practically all rails are now made 33 ft. long, in which case the speed can be determined by counting the rail joints passed in 22½ sec. When riding in passenger cars, it is often possible to determine the speed by counting the clicks as the trucks pass over the joints.

In case the noise of the joints cannot be heard or if they cannot be seen, as for instance on single track, the speed can be found from the revolutions of the driving wheels. The time during which revolutions should be counted depends, of course, on the diameter of the drivers and can be determined as follows:

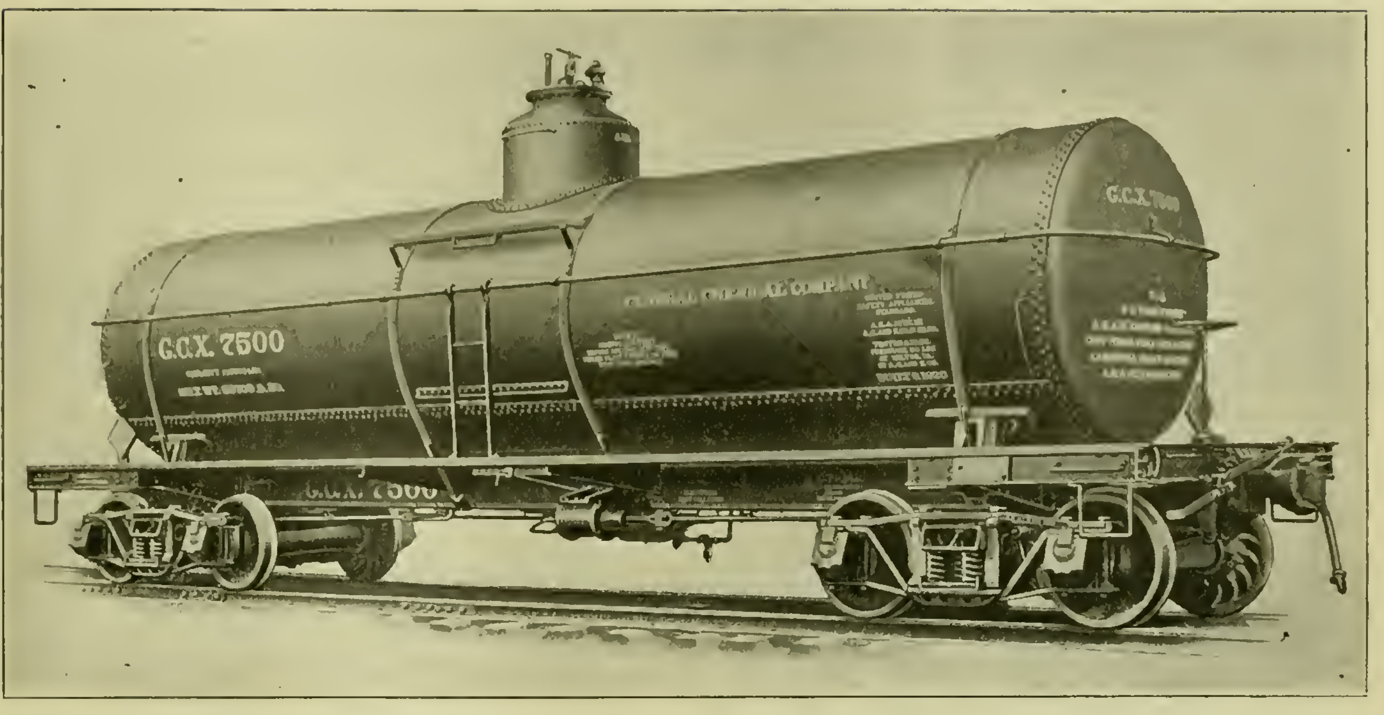
Find the number of revolutions per mile and divide this into 3,600 (the number of seconds in one hour). This will give the time in which the revolutions will equal the speed in miles per hour. For instance, if the drivers are 63 in. in diameter, their circumference is 16.46 ft. and they will make 312 revolutions per mile. The speed will be equal to the number of revolutions (3,600 divided by 312), or approximately 11½ sec.

Where trains made up of cars of uniform length are operated, the speed can be determined by counting the number of cars passing a given point, the time being found as above, substituting the length between couplers for the circumference of the drivers. Counting telegraph poles likewise affords approximate means of finding the speed.

Organized Railroad Labor, after a year of success in obtaining higher wages and promoting unity, faces the inevitable economic readjustments connected with post-war business reconstruction in 1921. The railroads face easier labor conditions, increased individual efficiency and a return to "an honest day's work for an honest day's pay" basis. Attitude and action of Railroad Labor Board will have a large influence upon a mutually satisfactory adjustment of the differences.—*Railway Age.*



Plan and Side Elevation of General Chemical Company 70-Ton Acid Tank Car

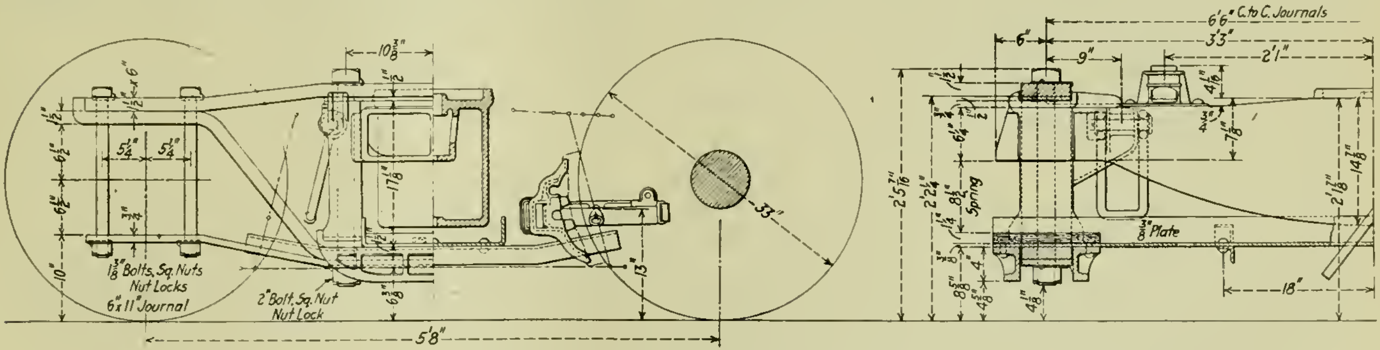


Sulphuric Acid Tank Cars of 70 Tons Capacity

Tank Made with Three Longitudinal Sheets Is Feature of Equipment Built for General Chemical Company

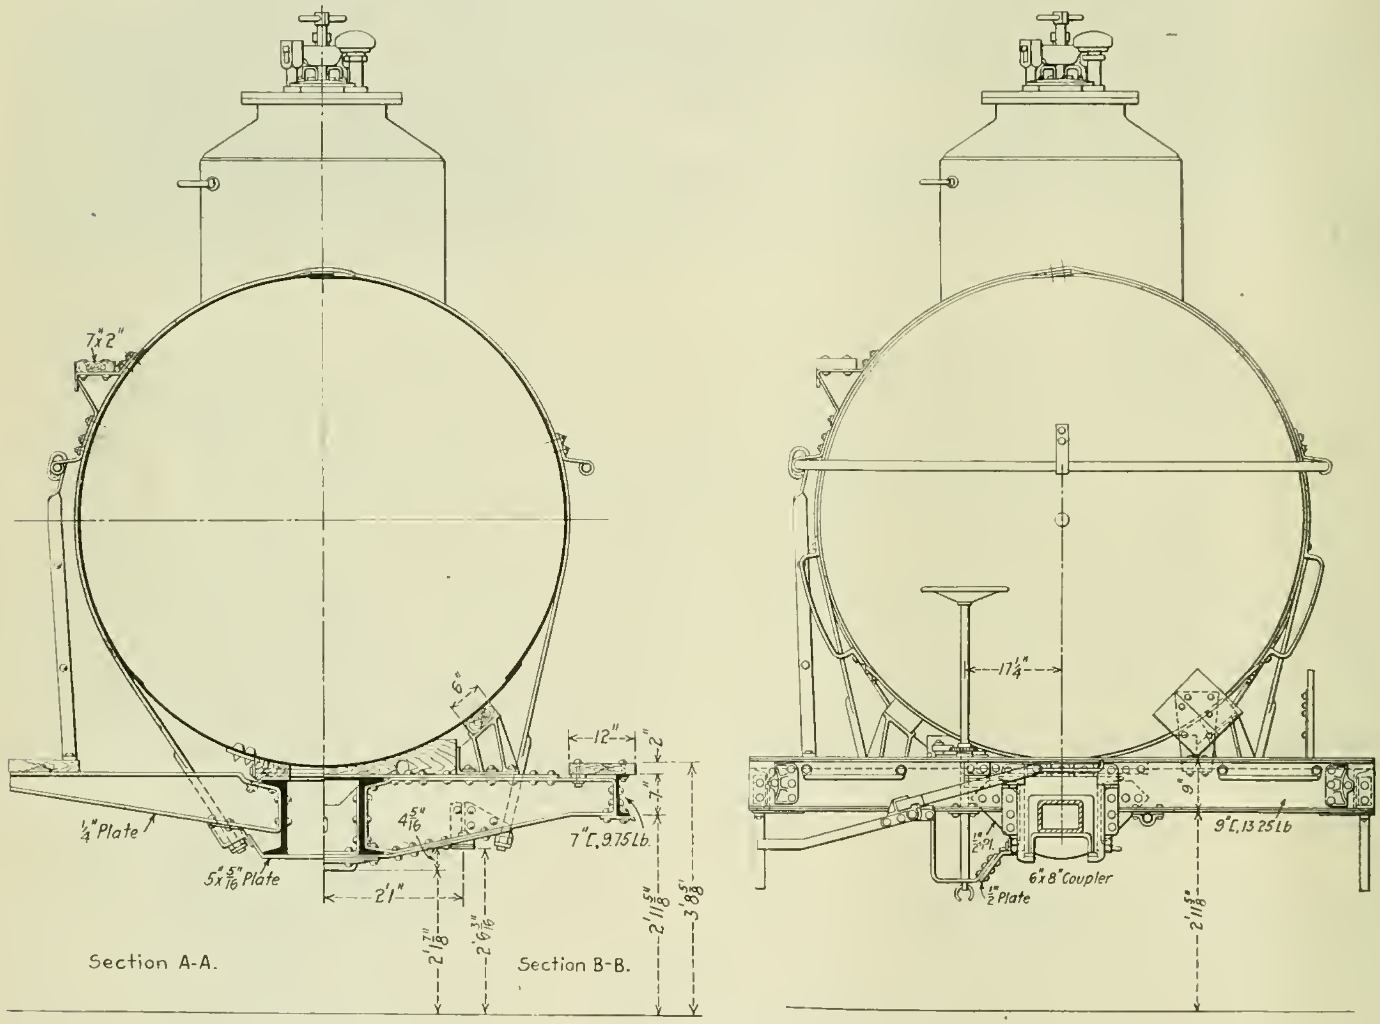
THE transportation of dangerous chemical products in large quantities has become so common that it receives but little attention from the railroads that move this traffic. To build equipment which permits handling such commodities in regular service without extraordinary precautions requires a high degree of skill in design and high-class workmanship. This is well exemplified in the recent order of 70-ton tank cars built by the American Car & Foundry Company for the General Chemical Company. These cars have a capacity of 9,800 gal. of sulphuric acid. The concentrated acid is nearly twice as heavy as water and if any considerable quantity of water comes in contact with the liquid, a violent explosion will occur. For this reason, the tanks must be strong, absolutely free from leaks and the dome must be tightly sealed.

With the exception of two cars built for the General Chemical Company in 1916, the 50 cars on this order are, so far as known, the first 70-ton acid tank cars constructed. The design was worked up jointly by the American Car & Foundry Company and the General Chemical Company, the owner's arrangement of dome fittings and outlets being applied. The tank conforms to the A. R. A. Class III tank specifications and is built to withstand a pressure of 300 lb. per square inch. The diameter inside the sheets is 85¼ in. and the length between the outer rows of rivets is 32 ft. The cylindrical section of the tank is made up of three longitudinal courses, each in one piece. The length of riveted seams is reduced considerably by this design. The bottom sheet is ½ in. thick, the upper sheets ⅜ in. thick and the heads ½ in. All rivets and seams are caulked on the inside and all seams are caulked on the outside as well. The dome has an inside diameter of 42 in. and is 30½ in. high with a cast steel dome head. The dome cover, which is also a steel casting, carries the usual safety vent with lead disc and a flange for the syphon discharge pipe. This pipe extends through the tank and into the outlet chamber,



Arch Bar Truck Used With 70-Ton Tank Car which is fitted with a blind flange at the lower end. The small filling cover is secured by a screw passing through the center of a removable yoke which fits into two toggle bars on the main dome cover.

The center member of the underframe is made of two 13 in., 52.5 lb. channels spaced 12⅞ in. apart. These extend continuously from end sill to end sill and are reinforced by a ¼-in. cover plate 20 in. wide. The bolsters are built up of pressed sections of ⅜-in. plate with top and bottom cover plates. The end construction comprises a 9 in., 13.25 lb. channel; short side sills of 7 in. 9.75 lb. channels; and diagonal braces of 5/16-in. plate. The running boards are supported by pressed steel cross bearers. A ½-in. anchor plate extends across the center of the underframe and the outer edges are bent down to conform with the outline of angle-shaped anchor plates riveted to the tank. The arrangement of the two parts of the anchor is such that the underframe is given a slight downward camber at the center and the tank is relieved of any stresses due to buffing shocks which otherwise would be transmitted to the sheets. The rivets which join the tank and the underframe are made readily accessible by this arrangement so that they can be riveted by machine and the tank can be removed for repairs without cutting any of the rivets in the tank itself. Practically all center anchorages on tank cars have been bolted to the underframes as outlined in the tank car specifications and a riveted anchor is a comparatively recent innovation. An acid shield on each side of the tank protects the anchorage and the air brake equipment in case acid is spilt from the dome while the tank is being filled or emptied. The ends of the tank rest on wood saddles held by bracket castings on each side of the bolster. An additional support is provided along the center sill by wedge-shaped wooden stringers which can be drawn together by transverse bolts.



End Elevation and Cross Section of General Chemical Tank Car

The trucks, which are of the arch bar type, have a base casting spanning the bottom of the bolster opening. This furnishes a means of attachment for the spring plank and also provides support for the lower end of the pedestal column. Many of the specialties applied to these cars were furnished by the General Chemical Company, including the safety vent, outlet castings, dome heads and fittings and all tank gaskets. Other equipment includes Cardwell G-11-A draft gear, Westinghouse type KD-1012 brake equipment, National journal boxes with coil spring lids, Huntoon brake beams and Stucki side bearings. The average light weight of the cars is 50,400 lb.

To Clean a Lead Spot, it is advisable to add dry, common salt, and stir thoroughly with the molten lead. All dirt and foreign matter will rise to the surface, and can be skimmed off with ease. —From Houghton's "Steel and Its Treatment."

Steam-proof Belt Cement.—Many engineers are of the opinion that lacing must be used on belts exposed to steam, as belt cement will not hold under such conditions. While this is true of some kinds of cement, steam will not dissolve a belt cement made on a pyroxylin base because it is waterproof and not affected by moisture.

Cause of the Present Condition of Freight Cars*

Pooling, Deferred Retirements, Labor Conditions and Abuse in Service; the Remedies Suggested

BY J. C. FRITTS

Master Car Builder, Delaware, Lackawanna & Western, Scranton, Pa.

WHEN a bad condition is found an effort should first be made to find the cause and then work out some method by which the evil can be combated. So much has been said in regard to tightening nuts, opening cotter keys, measuring piston travel, etc., that I thought we might pass that part of car maintenance tonight, assuming that it was being well taken care of, and go a little deeper, with a view of suggesting something constructive.

In order to properly analyze the present unsatisfactory condition of freight cars, it will be necessary to go back two or three years and ascertain what has occurred during that period that would contribute to the present situation. If this can be determined with any degree of accuracy, then we should be able to suggest something that will give us relief.

Effect of Pooled Equipment

Formerly it was common practice to maintain the majority of cars on home lines, but during the war the pooling of freight cars was deemed necessary, and cars on home rails in many instances were reduced to ten per cent of the equipment owned. It does not seem at present that we are going to get back to previous conditions in this respect for some time to come, if ever. The result has been, and still is, that a very large percentage of cars in bad order are of foreign ownership, for which the handling line does not carry in stock standard material, except a few M. C. B. parts. Therefore, in lieu of repairing in kind, improper and temporary repairs have been made in order to return the cars to service.

All railroads throughout the country have been repairing cars in this manner. It was the best they could do under existing conditions. Such methods are responsible in a very great measure for the condition of freight car equipment at this time.

A check and inspection of system cars received home at interchange points developed that a very large percentage were in need of extensive repairs and a large number had defects that could have been repaired by using standard material. This would seem to indicate that returning equipment to owners only when it has become unserviceable is being practiced to a very great extent.

Imagine what is going to happen with 75 per cent or more of all cars in the country on other than owning lines with conditions of this kind existing. I do not mean to say that there has been willful neglect on the part of railroads in general, but an analysis of the situation shows that these things have been forced upon them by the scarcity and mixing or pooling of equipment.

Repairs to cars have been retarded:

First, because the car department forces have not been familiar with the class of cars they have been required to repair and necessarily have consumed more time than was customary on home line equipment.

Second, it was formerly customary to manufacture parts for system cars in large numbers which were placed in stock and could be used as needed. They were made with standard patterns, formers, dies and other labor saving devices, at the minimum of time and expense, but with foreign cars in the majority on shop tracks this practice could not be continued, as there was not a sufficient number of system cars received to warrant the manufacture of various parts in any great amount. Practically all such parts for cars of foreign ownership require special operations through the manufacturing section of our shops, thereby losing the benefits of the labor saving devices that were previously in use. This has resulted not only in reducing the shop output, but has greatly increased the cost of production.

Old Cars the "Weakest Link"

Train tonnage is being increased from day to day; heavier locomotives are built with greater drawbar pull, and two or more are coupled together on heavy grades, or where it may be necessary to maintain fixed tonnage; heavy rails with rock ballast have been laid; new and stronger bridges have been constructed and all modern appliances for transportation have been adopted. The freight car from 15 to 20 years old is expected to take its place in this line of modern improvements and successfully perform service that is two or three times greater than was originally intended when the car was built. It is unreasonable to expect the old freight car to function efficiently against such odds.

If we were handling the same train tonnage with the same locomotives that were used when the cars that are failing were built less trouble would be experienced. The sooner railroads strengthen the weakest link in transportation, which is the car, the quicker results will be obtained. Many of these cars are of old and weak construction and their failure not only results in damage to themselves, but frequently causes serious damage to other good cars that are being handled with them. The majority of these cars are repaired in kind instead of being dismantled, as was formerly the practice.

Cars with short draft timbers, extending from end sills to body transom, of which there are many thousands in service, cannot be handled with any degree of success with present transportation methods. Cars of this construction that have had new sills and ends applied and generally repaired, in many instances have them torn out and destroyed within a few miles of the shop where repairs were made. A number of railroads, however, have started to apply reinforcements, some of which are of substantial construction, while others are little improvement, if any, over repairing in kind, and seem to have been contrived to reduce the expense of application rather than to give service. The results of such a practice is, that the expense of upkeep, not considering service, will soon equal the cost of proper reinforcements and the weak cars will still be on your hands. This is false economy, and it would seem that the design of reinforcements for freight equipment is not being given the thought its importance deserves.

If this is true, and we all know it is, then surely something should be done to eliminate or prevent repairs of this character.

Effect of Labor Conditions

The labor situation has also contributed very largely to present conditions. Many of the old employees have worked faithfully and endeavored to produce an honest day's work, but as a whole they have not manifested the same interest or given the same loyal support as was formerly their practice.

---

*Presented before the Western Railway Club, Chicago, January 17, 1921.

There seems to have been a spirit of getting by with the least possible amount of work and indifference as to the quality as well.

The leveling of rates for all mechanics in the carmen's craft has reduced shop output instead of increasing the production, as was expected by some of the advocates of this system. All men are not of the same ability, and the highly skilled mechanic feels that he should not produce more than one of lesser skill because he is receiving the same rate of pay. This is human nature, and we cannot expect a change in these principles until a different method of compensation has been inaugurated.

Railroad shops are among the very few manufacturing plants throughout the country where all mechanics are placed in one class regardless of skill, and where the thrifty and industrious employee is supposed to produce a sufficient amount of work without extra compensation as compared with the man with a shiftless and lazy nature. Such a system is wrong, as it not only works an injustice and hardship upon the employee, but the employer as well. The right of every man to earn in accordance with his skill and ambition to produce, should not be denied him. It is one of the fundamentals upon which the Constitution of our country is based.

Rules and regulations that required years to work out and establish for the other crafts, were put into operation at once in car department forces, with the result that there was a lot of confusion which finally was adjusted with not enough men in the country with the experience required by the rules, to cover the work then on hand. There was no method of creating more until three years had elapsed, and then only through the helper apprentice system. The duties of carmen are so varied and cover so many distinct lines of work that rules which govern blacksmiths, machinists and some of the other crafts cannot be applied to carmen in so short a period and meet all of the various conditions of car work.

The rules insofar as they refer to supplying carmen are not workable because they have closed the door on increasing the number of men that can be employed at this work. On account of the centralizing of authority, the former close personal contact between the employee and those in charge has ceased to exist; supervisors are not free to settle questions that may come up from time to time, but must be governed by decisions handed down by men who are many hundred miles away and who perhaps never have been on the grounds and certainly are not familiar with local conditions. Ability cannot be considered and is not a factor in promotion at this time. Seniority governs in all cases, at least to the extent of a trial, with the result that there are entirely too many trials and very little production in the meantime. All of these things and perhaps many others that could be mentioned have all had a tendency toward a general lowering of the employees' morale.

The effect of such a condition is reflected in the present condition of freight car equipment. These restrictions have affected shop operations to such an extent that it has been found impossible to maintain bad order cars within a reasonable percentage.

The Misuse of Equipment

We hear much in regard to speeding up and increasing efficiency in operation; that more cars must be loaded and carry a greater tonnage; that the miles per car per day should be increased. But those in charge seem to have lost sight of the fact that a great factor in bringing about these results is keeping the greatest possible number of cars in service, and that this in a great measure depends upon the manner in which they are handled. Very little, if any, attention or consideration is given to the misuse of equipment. The only thought seems to be of delivery and loading or unloading, and if damaging or mutilating the car would in any way assist in this operation, there is no hesitancy in doing so. It is not uncommon, however, to receive complaints about the large number of cars it becomes necessary to bad order after receiving usage of this nature.

These destructive methods have been gradually on the increase for the last two or three years, and have not been confined to hump and classification yards. At piers and wharves, and in fact, at all loading and unloading points, the abuse of cars is always in evidence. It has become almost impossible to maintain cross ties, brake staffs and wheels, where clamshell unloaders are in use, notwithstanding the fact that these must all be replaced before the car can be returned to service.

Roofs, doors, door tracks and fixtures, flooring, lining, and in fact any part of the car that might affect the unloading operation, are torn off and destroyed, apparently without the least thought of the important position the freight car holds in relation to moving the country's traffic.

Many thousands of cars are thus damaged and sent to shop tracks daily, which otherwise could be loaded again without repairs, not only reducing the cars out of service on account of bad order but greatly assisting in increasing car mileage and the number of cars loaded.

While the material situation has improved during the last two or three months, it has contributed its share in full measure to the difficulties that have been experienced in properly maintaining cars in serviceable condition. Manufacturers have received orders in excess of their capacity to produce, and when finished, the scarcity of cars very often prevented prompt shipment of the material. This and embargoes placed on company material from time to time made proper and prompt repairs impossible even though other facilities were adequate.

With all of these conditions existing, is it any wonder that we find freight cars run down and worn out, and need those in charge of car maintenance feel that they have fallen short in the performance of their duties? I believe you will all agree with me in stating that they have done well, all things considered.

The following suggestions will assist in relieving the present unsatisfactory condition of freight cars throughout the country.

When possible from a traffic standpoint, cars should be returned to owning lines where repairs can be made. The old and light constructed cars could then be dismantled or assigned to special home line service and those that warrant being continued in service should receive substantial reinforcements that would be in keeping with the service they are required to perform.

All railroads are under moral obligations to do this, because they expect such cars to be accepted and handled in through line traffic by other railroads. Under the present system of pooling equipment through Commission orders, etc., a railroad that builds and reinforces in line with good practice will receive very little benefit from so doing, unless all other roads do likewise, because the exchange of cars between railroads has increased to an extent that 75 per cent of equipment on line is of foreign ownership and cars that receive extensive repairs today will probably leave the home line tomorrow and not return for several years. Therefore, there should be some agency established between railroads that will prevent the application of reinforcements or the perpetuating and offering of cars in interchange traffic that are unfit from a strength standpoint for general service.

All railroads have had sufficient experience to indicate to them that cars with short draft arms extending from end sill to body bolster cannot be handled with any degree of success, especially on trunk lines in heavy tonnage trains, and after a reasonable length of time has been given, they should be refused in interchange regardless of type or capacity. A very large percentage of the present bad order equipment can be confined to approximately 400,000 cars in the United States.

All that the majority of these cars need to make them serviceable for many years to come is the application of proper reinforcements.

If the pooling of cars is to continue and it becomes impossible to return them to home rails, then so far as it may be practical, certain common standards applicable to the most of this equipment should be adopted. These should be applied regardless of where the cars may be. This would not only hasten placing them in proper, serviceable condition, but would very materially assist in their future maintenance.

The General Committee of the Mechanical Division of the A. R. A. should appoint a committee for this purpose, and work out a system that would enable all railroads to reinforce such cars when placed on shop tracks for extensive repairs, regardless of ownership.

The condition of many cars received home shows that repairs for which standard material could have been used have not been made, indicating that cars of foreign ownership are not receiving the attention that present conditions would warrant or permit.

Under the present arrangement a railroad should, so far as possible, give the same consideration to foreign cars that it does to its own cars, and the failure to do so will react against the proper maintenance of freight equipment as a whole.

It has been stated that the writer is in favor of no labor unions and low wages, and that in saying so, he has voiced the sentiments of the "higher-ups." Nothing could be further from the facts. I believe in labor organizations that are conducted on just and moral principles, and that every man is entitled to fair and just treatment and his day in court. No superior of mine has ever suggested or even intimated to me what my views should be on this subject. Employees are entitled to safe and sanitary working conditions and regardless of the class of work a man performs, if he is willing to produce an honest day's work, he is entitled to a good living wage—by that I mean, enough for himself and family to live comfortably, to educate his children, and without extravagance, to lay away something besides. And treating this as a basis, every man should be paid according to his ability and willingness to produce. It is the only fair and just method of compensation, and a system that would make this possible should be inaugurated.

Rules that have been found to be unworkable and those that have inflicted unjust and unreasonable penalties on employers should be replaced with others that will equitably and fairly meet the conditions they are intended to cover. Men who are thoroughly familiar with their class of work should be placed in charge. They should understand human nature and the difficulties under which employees must at many times perform their work; men that will keep in close personal contact with those under their charge and who are quick to see and correct a wrong, regardless of where it may exist. No man feels satisfied to perform his duties from day to day without some recognition from his superior outside of the salary he may receive. Every faithful employee is entitled to this consideration. It not only creates a relationship of good will and loyalty, but inspires the employee to do better and more efficient work.

Supervisory officers of this type with proper authority ought to be able to meet and settle questions that may arise from time to time without the necessity of referring them to higher authority. If this is done, we should get back the morale and co-operation of our employees, which is very necessary in order to build up our production to a normal output.

So many cars are being damaged through carelessness, in many instances bordering on malice, that something should be done to prevent the destruction of company property by the misuse of equipment. I am somewhat at a loss for a proper and effective solution of this problem, but some sort of a campaign is necessary, because in many instances, those in charge appear to give this very important question no more thought than the employees they supervise. Much money could be saved if it could be instilled in the minds of those handling them, including some transportation officers as well as dock foremen and yardmasters, that cars are constructed, not to be damaged and mutilated, but to perform a very important service in connection with the life of our nation.

In view of the fact that a very large percentage of the damage to freight cars is caused by shock, draft gear maintenance is worthy of serious consideration at this time. The question of type or style of gear must be left open for further tests and investigation, but I believe that we should get the best out of whatever type we have in service. They perform more work and receive harder usage than any other device on a car, and it is the only one for the inspection and maintenance of which there are no specific rules laid down.

The function of a draft gear is primarily to keep down the pressure in the car underframe when under impact, which is done by increasing the length of time the forces are distributed through the car during such impact, in other words, by draft gear travel. It should always be remembered that none of the forces resulting from impact or collision are destroyed, but all remain in the car underframe to be disposed of or dissipated in one way or the other. Any wear or broken part that causes slack, reducing the effective travel of the gear, hastens the closing point, after which the pressure in car sills or underframe increases very rapidly.

If the function of the draft gear is as important as I believe we will all admit, then surely some systematic method of inspection and repairs should be installed on all railroads. We find that this is necessary in the maintenance of air brakes, wheels, and couplers. The cost to make such inspection or adjustments would not necessarily be greater than the expense of cleaning and repairing the air brakes, which the law compels railroads to do at least once a year, and I feel sure that the saving would be many times greater than the cost.

A periodical inspection should be arranged for and the dates should be stenciled on the car in a manner similar to the present practice with respect to air brakes.

Discussion

The paper drew forth a discussion on a wide range of subjects pertaining to the maintenance of freight cars. Several speakers referred to the frequency with which draft gears and attachments and box car ends were damaged and the suggestion of the writer of the paper that standard repairs generally applicable to all old equipment be developed by the Mechanical Division of the American Railway Association was favorably received, particularly as to standard car ends and draft reenforcements.

Several speakers called attention to the extent to which old cars with wood draft arms extending only as far back as the body bolster are receiving extensive repairs, as much as $1,200 being expended on heavy repairs to such cars, which are liable to fail immediately on being placed in service. Although the retirement of such cars was advocated several times during the discussion, it is evident that Rule 120 of the interchange rules has not accomplished its purpose.

C. N. Swanson (Atchison, Topeka & Santa Fe) strongly advocated fixing the A. R. A. prices for labor and material so high that owners would be forced to take proper care of their own equipment and that when cars are repaired on foreign lines the repairing road would be able to do the work at a profit.

C. J. Wymer (C. & E. I.) also advocated the policy of setting A. R. A. prices high enough to include a profit. In

Plans for Interchangeable 60-Ft. Full Railway Post Office Car and 30-Ft. and 15-Ft. Apartment Cars, (R. M. S. Drawing, Sheet O.)

(1) 60-FT. FULL R. P. O. CAR

This floor plan shows size and location of doors and windows so as to permit car body being used as a 60-ft. full car, a 30-ft. or 15-ft. mail apartment. When used as a 60-ft. full car, the windows shown in full lines and the three skylights shown by dotted lines are required. The windows shown in dotted lines can be installed complete in original construction, or provision made in framing for completion as required.

To facilitate widening of side doors, so that the entire car, or part of car, may be used in other than distributing mail car service, extra posts may be provided in side walls, of such nature as will permit widening the doors at minimum cost.

(2) 30-FT. APARTMENT

This plan locates doors and windows so as to permit the apartment being reduced to 15 ft. without change in this respect. If car is fitted up as a 30-ft. apartment when originally constructed the windows shown in full lines and the skylight in dotted lines are required. The windows shown in dotted lines can be installed complete or provision made in framing, for completion when change to 15-ft. apartment is made.

If it is contemplated that car may be changed at any time into a 60-ft. full car, the additional doors, windows and skylights shown on the 60-ft. plan can be installed complete, or provision made for these in framing, to be completed as required.

(3) 15-FT. (15 FT. 8 IN.) APARTMENT

The use of this plan, in lieu of the standard plan shown on R. M. S. Sheet F revised February 2, 1920, is optional. This plan is designed to permit the apartment being extended to 30 or 60 ft. without change in size or location of doors or windows. This involves the use of side doors of same width as those in 30 and 60-ft. mail cars, and the same space for toilet as in the larger units. These differences make the apartment 8 in. longer than the 15 ft. 0 in. shown on Sheet F, although there is no increase in the facilities in the apartment. Apartments built on this plan will be rated the same as the 15-ft. apartment shown on Sheet F.

(4) If length of car, inside measurement, exceeds 60 ft., the excess over 60 ft. should be added between side door opening and end of car. If this excess is greater than 3 ft., stove should be located at same end of car, on opposite side, and adjacent to door opening, with bulk-head of insulated metal plates to height of stove and wire netting panel above. Face of bulkhead to be flush with edge of door opening.

(5) *Skylights*:—Total exposed glass area of each, 5 sq. ft.; 60 ft. full car, three should be provided; 30-ft. apartment, one should be provided as shown. Where it is contemplated changing apartment to 60-ft. full car, the other two skylights may be installed complete or provision made in framing only; to be used as required; 15-ft. apartment, none required. Where it is contemplated changing apartment to 60-ft. full car the three skylights may be installed complete or provision made in framing to be used as required. Where it is contemplated changing a 15-ft. apartment to 30-ft. skylight called for in 30-ft. plan, may be installed complete or provision made in framing only to be used as required.

(6) *Bulkhead Radiators, Wall Coils*:—If used in 60-ft. car, locate bulkhead radiator on stove side, and wall coil on opposite side, at this end of car. At hopper end locate bulkhead radiator in stall adjoining clothes-closet. In 30-ft. apartment, locate bulkhead radiator in stall adjoining hopper, when stove is used. When stove is omitted locate radiator on wardrobe side. In 15-ft. apartment, locate bulkhead radiator in stall adjoining stove.

Bulkhead radiators should be located so that wire guard will be flush with door opening. Bulkhead radiator may be considered as equivalent to one set of movable stanchions. Wire mesh only, of ½ in. mesh heavy gage, to be used as heat pipe guard.

(7) Electric lighting shall be designed to furnish specified illumination on distributing facilities as shown on plans and on additional facilities required, when a 60-ft. full R. P. O. car is changed into an apartment car, the generator box should be moved into the baggage or passenger apartment of the car. Provision for making such change at minimum cost may be made in original construction.

(8) *Drinking Water Container, Drains*:—Drain pipes should be curved immediately under the container to side of bulkhead, or preferably, should empty into lavatory drain pipe, to insure minimum interference with piling of mail.

(9) Stove, if required, to have coal box under bulkhead insulated to top of stove, with wire netting panel above.

(10) Side door pockets to be solid, with opening along face 1½ in. to 2 in. high for removal of dirt from track.

(11) Brake wheel chain not to be applied inside of car.

(12) *Catcher Arm Brackets*:—Brackets for catcher arms and cinder guards to be applied at all side doors. Center of core of catcher arm brackets to be not less than 3 ft. 9 in. from floor of car.

(13) *Ventilators*:—Arrange layout as far as practicable so that correct number and kind (exhaust and intake, or combination) of ventilators will be in the various sizes of mail rooms.

(14) Hoppers, both flushing and dry, shall have double lids.

(15) *Overhead water tanks*:—Capacity must meet specifications for any size of mail room that may be provided in car body.

(16) Wall, deck and floor attachments securing distributing facilities (letter cases, letter case tables, racks and boxes for papers) shall be of such design as will permit of ready removal of facilities without defacement of car body, and permit substitution of sections of letter case and table for sections of racks and boxes for papers and vice versa. Attachments for securing letter case and table to be used as far as practicable for securing racks and boxes for papers, and same design of attachments to be used on all cars of any one railroad system.

Frame to be furred to support lighting and heating fixtures, letter cases, racks, rack latch dog (to engage rod No. 2 of the rack), boxes for papers, stanchion sockets, etc., as applied in car originally or when size of mail room may be changed.

(17) Hooks to be applied on side walls, over racks or in storage stalls, for hanging bridges.

(18) Paper boxes to have their own back which shall not answer for headlining.

(19) Indicates candle lamp brackets.

(20) For complete details of construction, refer to specifications revised February 2, 1920.

Note:—If railroad companies do not desire to use convertible features in 30-ft. and 60-ft. plans, windows shown in dotted lines may be disregarded. This refers to construction of car body only. See Note 3 regarding use of Sheet F for 15-ft. apartment.

Railroad companies contemplating the ordering of new mail car equipment will notify the department of their decision on these points.

this connection Mr. Wymer also advocated making all defects owners' defects and balancing this with a rental charge high enough to reimburse the owner for the upkeep of the equipment.

The effect of the present condition of freight cars on operating costs was touched on by D. I. Bergin (Wabash), who stated that hot boxes and bad orders created enroute were prolific causes of excessive fuel consumption and crew overtime. He called attention to the fact that all a railroad has to offer in competition is the service it can render; weak equipment which causes delays in the movement of traffic seriously affects the quality of this service.

In closing, Mr. Fritts called attention to the 40-ton cars with short draft timbers, many of which are in service, as needing equally as much attention as the 30-ton cars frequently referred to in the discussion. These cars, from the very fact that they are permitted to carry heavier loads may be even a greater menace than the similar cars of lighter capacity.

New Plans and Specifications for Postal Cars and Fixtures

The United States Post Office Department, Division of Railway Mail Service, has recently issued new plans and specifications for the construction of steel full and apartment cars and drawings and specifications for fixtures for mail cars.

The outstanding differences in the floor plans are the convertible feature of changing a 15-ft. distributing unit into a 30-ft. unit, or a 30-ft. unit into a 60-ft. unit, or vice versa. In order to permit of these changes, a common arrangement of door and window openings has been adopted. The new plans, which are similar to the optional layout issued in 1917, are shown on the opposite page. The distributing facilities have been rearranged, especially in the full railway post office car, so that the paper racks are kept together in line. A different letter case has been adopted and the distributing facilities built in units and made detachable so as to secure easy rearrangement.

In all three sizes, the letter case boxes are now 10 in. deep. On account of the large proportion of correspondence passing through the mails being enclosed in long envelopes, it was necessary to discard the short letter boxes which were shown in former plans and which were 7½ in deep. This facilitates the distribution by the clerks and tends to eliminate errors which might occur due to the long letters, when placed in the short letter boxes, obscuring the labels designating the boxes.

Comparatively few changes have been made in the specifications for the construction of postal cars. A new paragraph has been added to cover the design of self-propelled cars where the weight of the operating unit does not exceed 200,000 lb. The specification for skylights, which formerly called for ¼ in. rough wired glass or ⅜ in. rough plain glass, now specifies ½ in. rough wired glass or rough plain glass of equal strength. A few minor changes have been made in the requirements for lighting. If Mazda Type C lamps are used, they must have frosted or enameled bowls. Lights at letter cases are required to be located high enough so that the shadow of the reflector is not cast on any of the label holders. For emergency lighting, candles melting at relatively high temperatures, 120 deg. or more, must be used such as the Argand-Stearine or equivalent. The earlier specifications provided that if globes or reflectors of certain types were used, the service illumination values might be reduced 20 per cent from the minimum values otherwise required. Aluminum reflectors have now been added to this list. In the construction of protection guards for heating pipes, the use of wire netting or perforated metal was formerly optional with the railroad but the present specifications call for wire netting only. A note has been added stating that steel vestibule diaphragms are preferred. The rule for the location of brake and signal equipment provides that where apartment cars have but one signal valve, this shall not be located in the mail apartment. A few minor changes have been made in the list of interior equipment.

In the section pertaining to trucks, the detailed requirements in regard to brake shoe pressure and maximum weight per journal have been eliminated. A new sheet has been issued showing the approved standard lettering for the outside of mail cars.

Specifications for Fixtures

The principal change in the specifications for fixtures is the requirement that letter cases, tables, racks and boxes for papers shall be made up in standard sections and shall be secured to the car body by attachments of such design as will permit of ready removal of these fixtures without defacement to the car body and will permit substitution of sections of letter case and table for sections of racks and boxes or vice versa.

As noted above the letter cases have been changed and all boxes are now required to be 9¼ in. deep. The use of wood is not permitted in backs or perforated bottoms. Where partitions are made of wood, the material must be three-ply, thoroughly seasoned. Slight changes have been made in the requirements for label holders. The use of wire screen for the back of letter cases is no longer permitted. The details of letter cases are shown on railway mail service drawings, Sheet 50, which supersedes Sheets 1, 2, 3 and 4 and Sheet 5, Fig. 3.

Minor changes are made in the requirements for racks. The specification for package boxes and boxes for papers states that when the deck of a mail car is of such width that the top of boxes for papers projects more than 5 in. into the deck opening, the top of that portion of the boxes projecting into the opening shall be covered with wire screen of not less than ½-in. mesh. When the boxes project less than 5 in., the fronts of the boxes at the top are to be beveled sufficiently to prevent the obstruction of light and to avoid a shelf on which dust can accumulate. The beveled front may be of wood or metal. Cages for registered mail were formerly required to be made of wire netting, but they may now be constructed of wire netting or perforated metal. The installation of a gas plate or a steam cooker and a portable cot is no longer required.

The specifications for catcher arms have been changed by adding the requirement that the round rod used in the arm must be made of open hearth steel of not less than 0.40 or more than 0.60 per cent carbon content. The bracket for the catcher arm applied to the side doors shall be located not less than 3 ft. 9 in. from the floor.

A Blue Print Bath

BY A. G. JOHNSON

Mechanical Engineer, Duluth & Iron Range, Two Harbors, Minn.

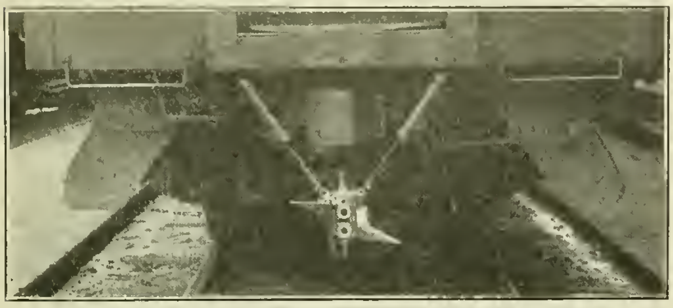
A solution of one ounce of bichromate of potash to three gallons of water makes an ideal bath in which to wash blue prints, as it will darken the color and fix the chemicals so the prints will not fade. The print must be exposed slightly longer than when clear water is used and it is well to rinse after removing from the bath. The solution can be used indefinitely by replacing the water that evaporates and, when running water is not available, it is almost a necessity.

It is always well to have a bichromate solution handy in any blue print room for use in bringing back over-exposed prints, in which case the best practice is to first wash the print in clear water for a few minutes and then immerse it in the bichromate bath and rinse. Nice clear whites will result.

The Futrell Automatic Train Line Connector

New Type Suspension, Positive Lock for Connector Heads and Removable Gasket Plate Are Features

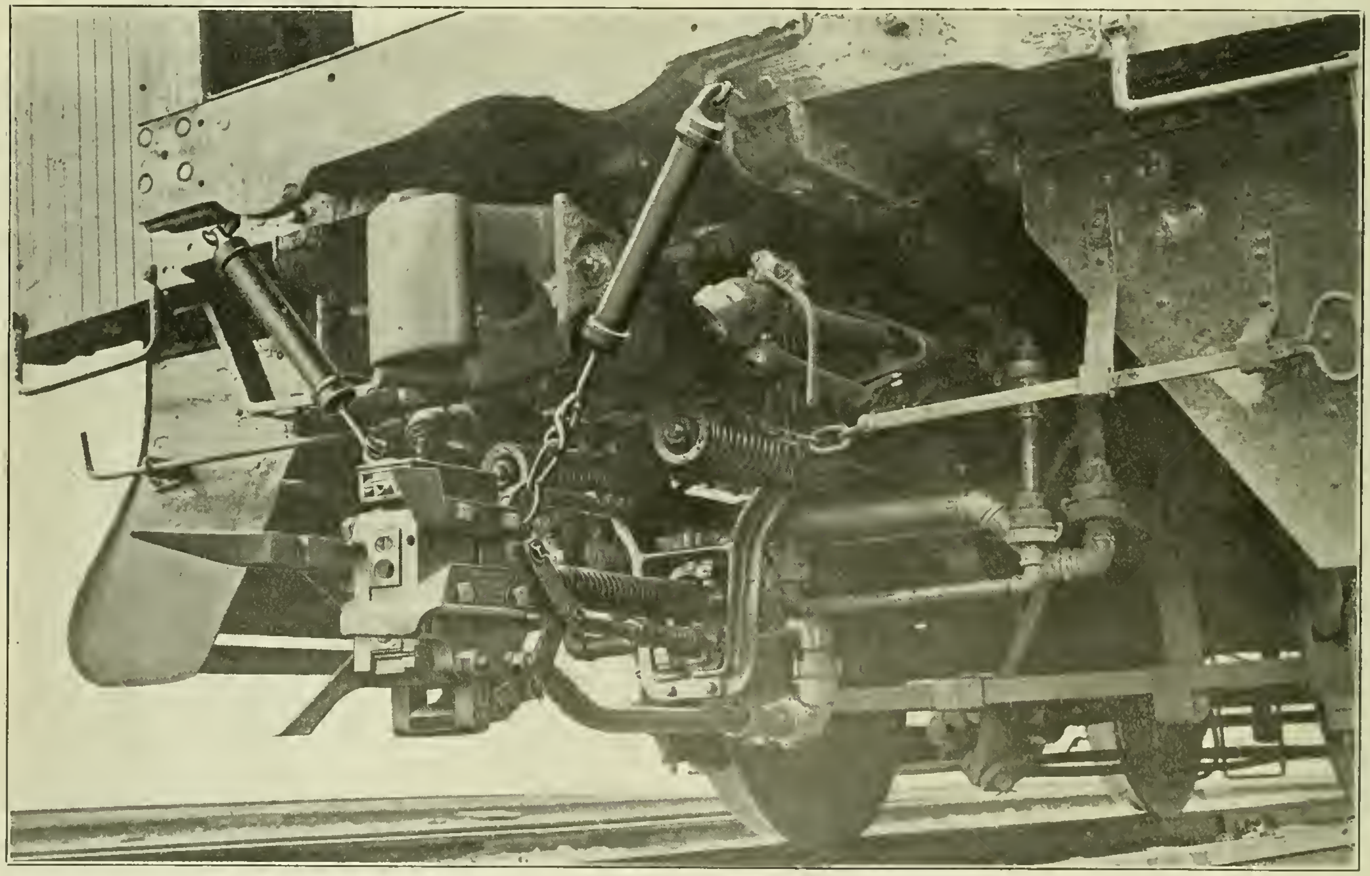
DURING the past 18 months the Baltimore & Ohio has had in service on a local passenger train a new design of automatic connector. This device, which is the invention of Thomas J. Futrell, is made by the Futrell Coupler Company, Streator, Ill. While the construction follows the general principles of some of the existing types, there are several unique features, the most notable being the arrangements for locking the heads and taking care of movement between coupled cars.



End View of a Car Equipped With the Connector

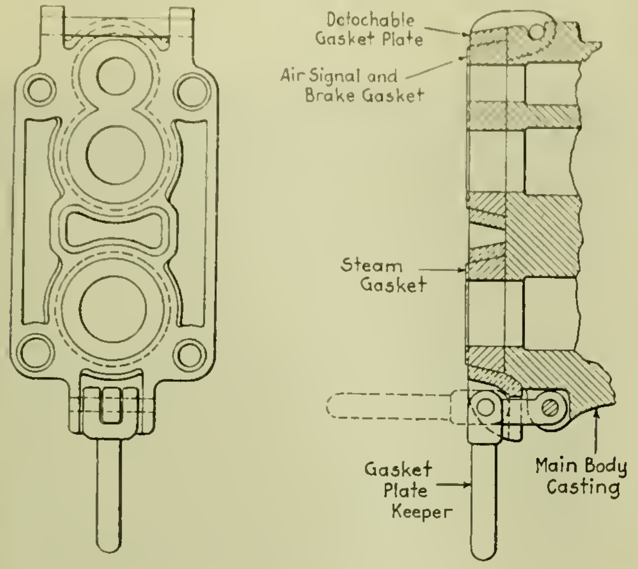
The coupler, as shown in the illustration, is of the butt-face, wing type. The head casting is suspended beneath the coupler by diagonal wire cables which are supported by an enclosed spring mechanism from the car body. A bracket is attached to the center sill behind the coupler carrier iron and a yoke shaped lever, pivoted to the bracket, supports a stem which extends from the rear of the coupler head. Two springs attached to the bracket force the yoke forward and another spring is applied to the stem of the coupler head. These parts are adjusted so that the connector when not coupled extends 5¾ in. ahead of the pulling face of the coupler knuckle.

Beneath the main stem of the connector is an auxiliary stem with a spring adjustment. This stem operates a lock through a toggle arrangement and after the connector faces are in contact the lock is caused to engage a slot in one of the wings as it mates with the coupler head. The details of operation of the locking arrangement are clearly shown by drawings of the side and front views of the head. In a recess in the head beneath the left side wing is a segment, *a*, pivoted near the upper edge. The portion of this segment lying within the head serves as a stop for the locking bar, *b*. The lower outer edge of the segment extends into the guide in which the wing of the opposing connector engages the head. Thus as the wing moves in it will force the segment upward and release the locking bar, which is then free to enter the slot in the wing. When the connectors are separated the locking bar is returned to the lower position and the segment, being released as soon as the wing is removed, returns to its original position by gravity.



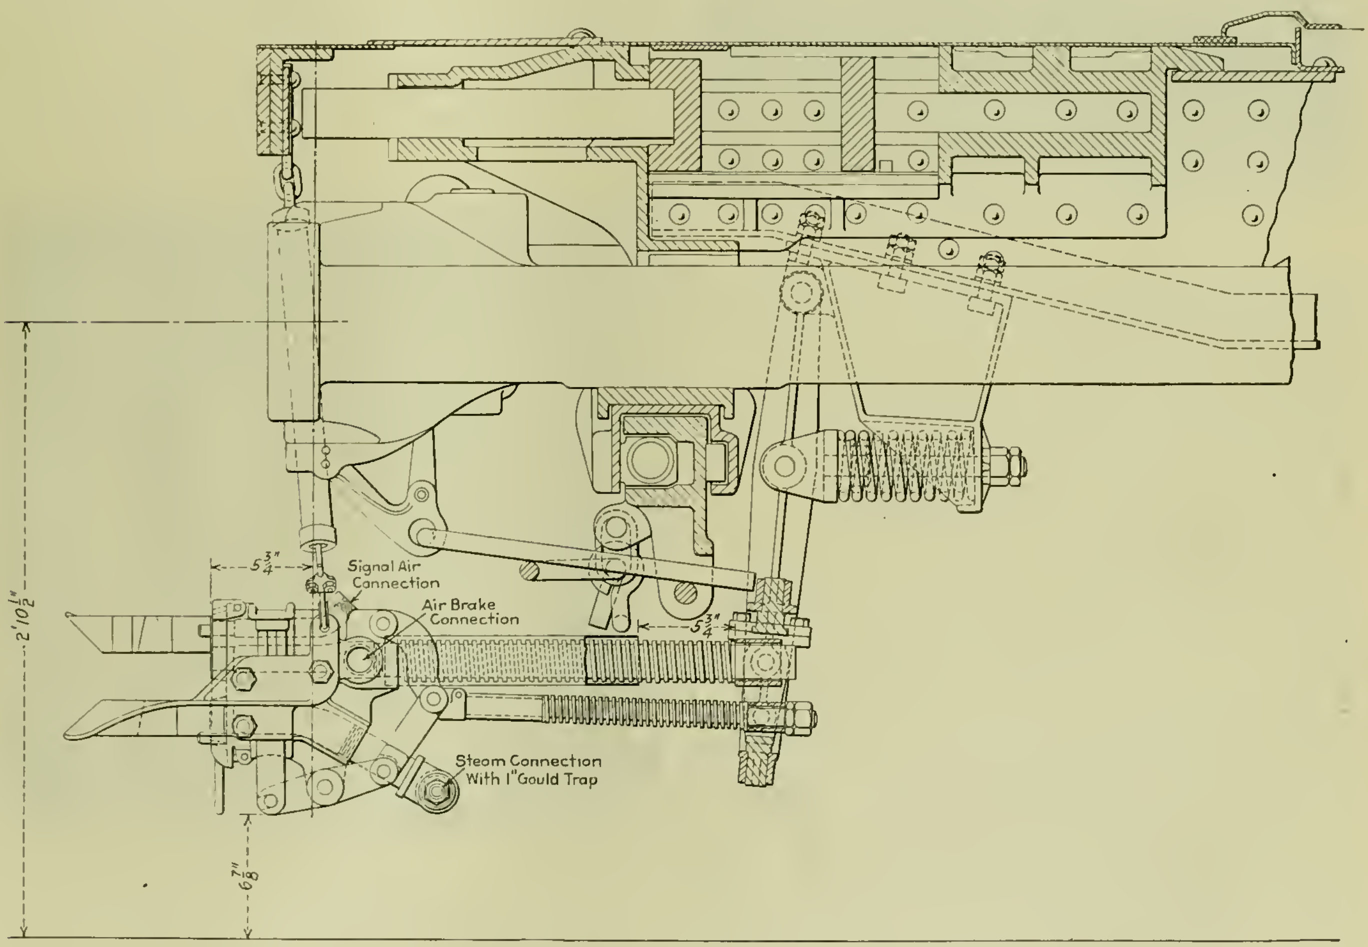
The Futrell Connector, Showing Suspension, Piping and Electric Contacts

The heads, when locked, form practically one solid part and since the connectors are supported from the car body, it is necessary to provide sufficient freedom of movement to insure that no additional stresses are placed on the heads by the relative movement between the ends of adjacent cars.



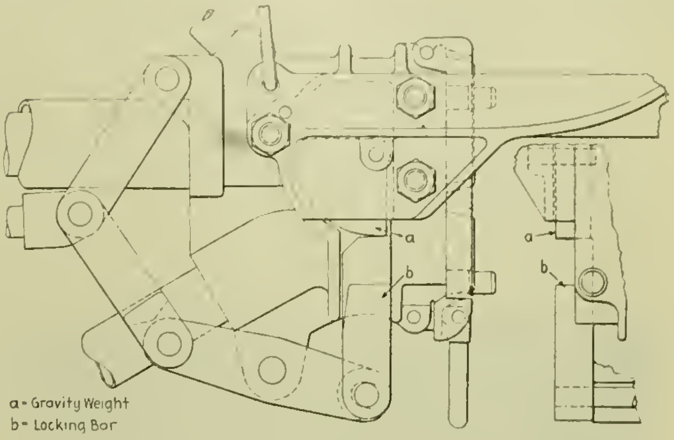
Details of Removable Gasket Plate

The yoke shaped lever, being pivoted at the upper end, is free to move forward or backward to take up motion resulting from the compression of the drawbar springs and a trunnion casting between this lever and the stem of the coupler head provides for lateral and vertical movement.



Side Elevation of the Connector Head and Suspension

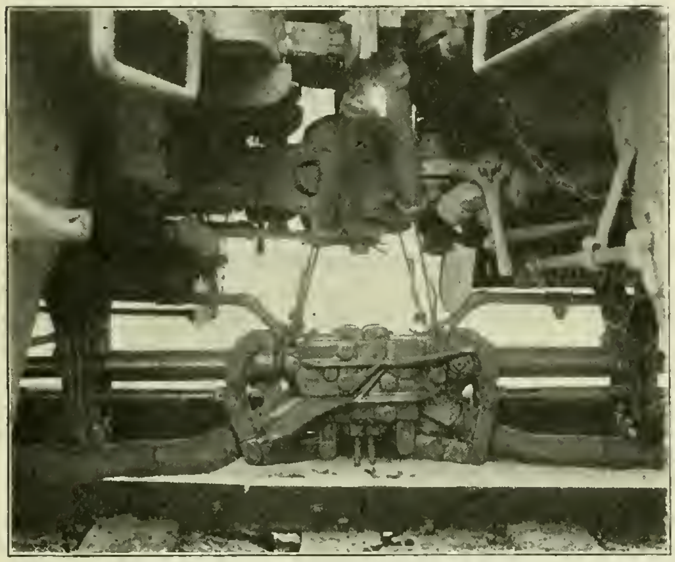
The wing type gathering mechanism has a vertical range of 7 in. and a horizontal range of 7 in. On the earlier designs, four wings were used, but the latest type has but two. An additional means of insuring perfect alinement in the head is provided by two pins in the face which register with recesses in the opposing connector head. As is the usual practice in this type, the ports are located on the vertical center line, the air signal connection being at the top; the air brake in the center and the steam heat at the bottom. The sizes of the openings are as follows: air signal ⅞ in.; air brake 1⅜ in.; steam heat 1½ in.



Side View of Head Showing Locking Mechanism

The gaskets are held in place by a detachable gasket plate fastened to the front of the head. The plate is hinged at the top and is locked at the lower end by a cam which forms part of the gasket plate keeper. In order to remove the gasket plate, the handle must be raised to the position shown by the dotted lines. When the two connectors are coupled, the handle is held in the vertical position and there is no possibility of the plate becoming unfastened. It will be noted from the illustration that the gaskets are tapered to fit the plate and the air brake and signal ports have a single gasket in common. With slight changes in the gasket holder, A.R.A. standard air hose gaskets could probably be used. In the design of the head, provision has been made for the attachment of electrical connections at the top of the head casting.

All connections between the connector head and the train line are made by pipe and flexible joints, both the Barco and McLaughlin type being used. In order to make the connections to the head, tees are inserted in the train lines behind the angle cocks. Ordinary air cocks are used in the air connections and a quick opening throttle valve in the steam passage. The levers for the operation of these cocks are placed toward the center of the car just behind the steps, where they can be reached from the side without going between the cars. The piping and cocks to which the rubber hose are connected are not disturbed in the installation of the coupler and for that reason no other provision is made for interchanging with equipment fitted with the standard connections.



A Side View of the Connectors in the Coupled Position

Journal Packing Reclamation

Journal packing represents a considerable item of cost in car maintenance. Various roads have developed different methods of reclaiming packing removed because of cut-journals, hot boxes or in the course of ordinary repairs. The method illustrated and described in this article has been devised and tried out with exceptionally good results.

The journal packing as received at the oil house is placed in the large vat shown in Fig. 1, in the bottom of which are steam coils. As it is "cooked" in the oil boiled out and left from previous boilings, the packing is stirred around from time to time. During this stage of the operation, much of the dirt, grit, babbitt, etc., is worked out, after which the warm, spongy packing is transferred to the table of an air press, shown at the end of the boiling vat. This press has a cylinder about 30 in. in diameter and exerts a pressure of approximately 35 tons, effectively squeezing out any oil remaining in the packing, the oil draining off through the base of the press and the molasses gate seen near the front of the press.

This oil, together with that secured in the boiling vat, is filtered thoroughly through a three-stage water filter illustrated in Fig. 2, the operation of which is as follows: With all tanks full of water to their respective overflow points, oil is poured into the right hand tank and overflows down the first pipe. The difference in head is sufficient to force the oil and water ahead of it down the first overflow pipe and into the bottom of the second tank, a movement which continues as long as oil is poured into the first tank. Being lighter than water, the oil rises slowly in finely divided parts through the water in the second tank to its overflow pipe. As the oil rises, solid particles of dirt and grit, heavier than water, separate from the oil and sink to the bottom of the tank. This operation of filtering the oil continues through the three stages when it is finally drawn off from the bottom of the last tank. As occasion demands, each tank is cleaned by opening the gate at the bottom and drawing off enough water to remove all sediment and collected dirt.

Fig. 1—Sheet Iron Boiling Vat Used in Initial Removal of Dirt and Babbitt from Journal Packing

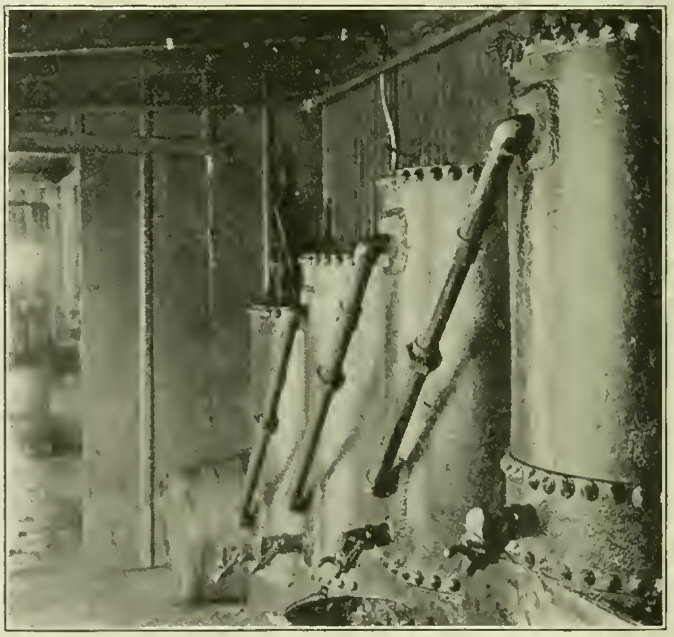


Fig. 2—Three-Stage Water Filter for Cleaning Oil

The dry wool waste is taken to a screening table with a diamond shaped screen opening, the length of each side being $1\frac{1}{2}$ in. Being thoroughly forked over this screen, all short lengths are worked through as well as any dirty residue. The resulting waste and filtered oil are used without addition of new material in making up packing for freight car equipment.

The Use of Wood in Freight-Car Construction[*]

Relative Merits of Steel and Wood for Open and Closed Top Cars—Use of Graded Lumber

By H. S. SACKETT
Assistant Purchasing Agent, Chicago, Milwaukee & St. Paul

THE fact that over two billion feet of lumber and timber are used annually in the United States for the maintenance of freight equipment and for the construction of new cars, representing an annual outlay for material alone of over $50,000,000, is ample evidence of the importance of wood in this big industry.

The first freight cars used for railroad transportation in this country were built of wood and this great natural resource has been an important factor in their construction ever since. In recent years steel has competed with wood, especially in the construction of gondola and other types of open-top cars, but whether this change has been an economical one or not remains a question.

From recent studies made of the subject by disinterested commissions, the indications are that even for open-top cars, wood is still the most economical material. With the growing scarcity of timber, however, and the apparently unlimited supply of steel available, it is probable that this latter material will always be a prominent factor in the construction of cars, and especially so, if some agent is found to reduce materially the present high rate of loss from rust and corrosion.

In the construction of the first cars wood was almost universally used for all parts, except of course the running gear. Within the past decade, however, with the introduction of heavy motive power, which spells long and heavy trains, it has been found that wood is no longer capable of withstanding the heavy shocks incident to such operation, and it is generally conceded by all car builders that the freight car of the future must be of steel underframe and steel draft rigging.

This limits the use of wood to unimportant parts of the underframe, such as intermediate sills and cross-beams, and to the superstructure of the car. In the case of open-top cars this means only posts and side and end plank and decking, but in box, stock, and furniture cars, etc., it means also siding, lining and roofing.

Steel vs. Wood for Open-Top Cars

To take up the question of open-top cars first, statistics gathered by operating officials of some of the larger railway systems seem to indicate that the cost of maintaining steel gondola cars over a period of years is greater than for composite (wooden and steel) cars of the same type. The data[1] collected show that all-steel gondola cars in their twelfth year of service cost over 36 per cent more to maintain than did the composite gondola. Of course, it is probable that during the first five years of its life the steel gondola cost less to maintain, but it is felt that taking the entire twelve years as an average, the cost would be more for the maintenance of the steel than the composite gondola.

It is furthermore interesting to note that but 60 per cent of the composite gondolas in service required repairs, while 72 per cent of the steel gondolas were obliged to be brought to the shops. The actual time that a car is in service and earning money for the road is an important consideration in determining its general utility. It is also interesting to note the conclusions in favor of the composite gondola, which are as follows:

> The initial cost of the composite gondola with the present price of steel is less than the all-steel gondola.
>
> The composite type of car costs less to maintain than the steel gondola.
>
> The sides of the composite car do not bulge as do those of the steel car.
>
> The records show that while the composite car costs more to repaint than the steel car, it does not require painting as frequently.
>
> A large portion of the repairs to composite cars can be taken care of at other than steel-car shops.
>
> Certain properties in coal cause corrosion to steel, and wood is not affected by them.

Table 1 shows the annual cost of repairing freight cars since 1908. It will be noted from this table that the cost of repairs per car has increased from $59.30 in 1908 to $80.30 in 1914, an advance of over 35 per cent. This higher cost is due, of course, to a number of factors, but it is felt that no small part of it is due to the use of steel, which requires a greater outlay for material and a higher cost to repair, owing to the fact that it takes longer to make like repairs on a steel car than on a wooden one. It must also be borne in mind that this higher cost is very largely due to the much rougher usage to which freight equipment is now subjected. In recent years the freight business of the railroads has grown enormously, and has necessitated the construction of gravity yards for switching, and the use of fewer switchmen per cars handled than in former years. This has resulted in severe handling of freight equipment, and is probably responsible to a greater degree than any other factor for the increased cost of repairs in recent years.

TABLE 1—ANNUAL COST OF REPAIRING FREIGHT CARS

Year	Number of freight cars	Cost of repairs per car	Ton-miles per $1 repair cost	1,000 ton-miles per freight car
1908	2,089,302	$59.30	1,762	104.5
1909	2,073,606	59.70	1,768	105.5
1910	2,135,121	65.60	1,821	119.5
1911	2,117,644	65.10	1,815	117.9
1912	2,140,687	65.50	1,858	121.5
1913	2,209,533	74.70	1,802	134.6
1914	2,263,015	80.30	1,565	125.8

Steel vs. Wood for Closed-Top Cars

In the case of closed-top cars, such as, for example, stock, box, and furniture cars, there is but little doubt that under present railroading conditions the understructure should be of steel with a wooden superstructure. The steel understructure is required to withstand the shocks of service and to give rigidity and stability to the car, while the wood is desired to give lightness and general utility to the body. Some all-steel box cars are in use today, but their heaviness and the fact that nails and cleats cannot be used in them to brace and hold the lading, are strong factors against the use of this material. It has not met with favor with shippers generally and probably will not as long as wood continues to remain available. No material has yet been discovered which combines the properties of strength, lightness, availability, and ease of working such as possessed by wood, and until

---

[*] Abstract of a paper presented at the annual meeting, New York, December, 1920, of the American Society of Mechanical Engineers.

[1] Paper by Wm. Queenan, assistant superintendent of shops, C. B. & Q.

such a material is developed and made available, wood will undoubtedly continue to be universally used for the superstructure of freight cars.

The dead weight of cars is also an important factor in considering the cost of and earnings from freight haul. There is no doubt but what the excessive weight of the all-steel car has been one of the most deterrent factors to its general adoption in freight-car construction, and this fact, together with its lack of readily available repair parts and the large expenditure required to equip shops to efficiently handle all-steel equipment, has combined to retard and limit its use.

Graded Lumber in Car Construction

It seems pertinent to say a word at this time as to the grades of material required for the different parts of the body of the car. In the early days when the supply of wood in this country was thought to be inexhaustible, clear grades of wood were generally demanded by the car builders, and in the construction of new cars this is generally the practice at the present time, especially for car roofing and siding, sound-knotted stock being used for decking and lining. Some of the more progressive railroads, however, have gone a step further in recent years and many are now using sound-knotted stock for siding and roofing for repair and maintenance work. There is no doubt but what such a practice is economical and based on sound judgment, for certainly there is no necessity for using clear material for the repair of many classes of freight equipment, the life of which may not be in excess of seven to ten years. One large railway system which not only constructs its own cars but does repairing on a large scale, has adopted the following practice as to grades:

FOR NEW CARS

Siding	No. 2 Clear and Better Fir
Roofing (double board roof)	No. 2 Clear and Better and Select Common Fir
Roofing (metal-covered)	Select Common Fir
Lining	Select Common Fir
Decking	Select Common Fir

FOR REPAIR WORK

Siding	No. 3 Clear and Select Common Fir
Roofing	Select Common Fir
Lining	No. 1 Common Fir
Decking	No. 1 Common Fir

On this particular railroad the saving on this amended practice amounts to over $500,000 per year, and its economy is apparent.

As far as specifications for end sills, door and side posts, belt rails, etc., are concerned, practice varies widely among the various railroads. Some still insist on oak for such purposes, and others have gone to fir and pine. With the rigid steel underframe it is believed the use of soft woods is more justified than ever for posts and belt rail, but unless well protected with steel plates it is believed the use of oak end sills is still to be recommended. Oak and other hard woods are becoming more scarce and higher in price each year and it is felt that the general practice very shortly will be pine or fir end sills properly reinforced with steel.

Some Advantages of Wooden Cars

An important feature of car construction which is decidedly in favor of wood, is its general ease of working and adaptability to repair, and this is brought about not only from its qualities, which make it easy to cut, saw and shape, but also by its almost universal availability. We have been a wood-using nation for over a century, and artisans familiar with its properties and able to work it are always at hand.

It is also rather curious that the salvage value of wooden cars is greater than that of steel cars, and no one doubts this who has seen the two types of cars in a seriously wrecked condition. The wooden car may be quickly and easily repaired, while the steel car is only rehabilitated at a high cost, or for the most part is fit for the junk pile.

The Importance of Well-Seasoned Wood

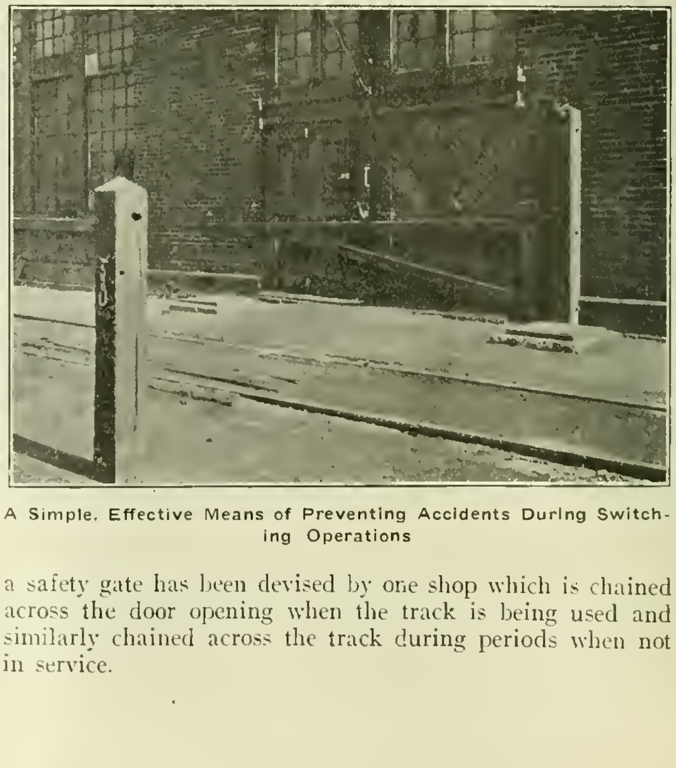
Before using wood in the building of freight cars it is vitally important that it be well seasoned. When our grandfathers built a house they expected it to last a century, and it usually did, for they took great care to properly season the wood before putting it to use. In the houses nowadays, however, we use wood almost before it is dry from the saw, and the result is that our American frame houses today are old at 15 or 20 years and we do not get anywhere near the service out of the wood that we should. Too often today we also see freight cars built of green lumber and timber, with the result that within a few months the bolts are loose, the wood having shrunk away from the original fastenings. This causes rapid deterioration and large timbers often quickly rot, particularly those containing sapwood.

It is safe to say that every railroad in the country should at all times carry on hand an 18 months' supply of oak and other hard woods and a 12 months' supply of fir, pine, and other soft woods. All this material when received should be properly piled for air seasoning, and in the case of clear material used for important parts, such as car siding, should be run through the dry kiln just prior to use.

Increasing attention has been given in recent years to the preservative treatment of certain parts of freight cars, and experiments have been made by some of the more important railway systems in the treatment of such items as stock-car decking, side and intermediate sills, roofing, etc. While these experiments have not been conducted for a sufficient length of time to determine actual results, the indications are that the preservative treatment of such car parts as are particularly liable to decay is profitable and will shortly be adopted as standard practice by the more progressive railroads. The conclusion is inevitable that the superstructure of freight cars will continue to be of wood as long as it is available at a reasonable price.

Shop Safety Gate

Many railroad shops are built upon such restricted properties that switching tracks are located close to shop buildings. This makes a dangerous condition when shop doors open out upon these tracks. To eliminate possible accidents, a safety gate has been devised by one shop which is chained across the door opening when the track is being used and similarly chained across the track during periods when not in service.



A Simple, Effective Means of Preventing Accidents During Switching Operations

Designing Brake Heads for Uniform Shoe Wear

Principles Applicable to Heads Used On Wheels Revolving in One or Both Directions

BY H. M. P. MURPHY

ALTHOUGH the unequal wear of brake shoes is frequently caused by imperfections in the metals employed in their manufacture and also by the use of improper forms of suspension hangers for brake beams, one of the chief causes of this undesirable result is the incorrect location of the hanger eye and the brake beam socket in the brake head. In order to overcome the last mentioned evil and thus to obtain uniform shoe wear as nearly as practical conditions will permit, the following methods should be employed whenever possible in the design of brake heads.

Methods for Determining the Leading Dimensions of Brake Heads

For reasons which will appear later, two cases must be considered in the design of brake heads, one applying to heads used on ordinary railway cars which run equal distances in both directions and the other applying to "single end" locomotives and motor cars which run practically in one direction only. Before discussing these two cases, the general conditions and dimensions which will be employed must first be outlined. In Fig. 1, the standard A. R. A. brake head and shoe are illustrated. The line, *EF*, represents the middle radius, or center line, of the shoe, the arc, *MN*, represents the shoe surface when the shoe is half worn (the wear being assumed as uniform), and the point, *f*, represents the middle point of the average wearing surface of the shoe; these same designations will be used in connection with the subsequent sketches and descriptions. Moreover, in Fig. 2, *W* represents the wheel center, *R* represents the radius of the wheel and *C* represents the vertical distance between the center, *W*, and the point, *g*, of the wheel tread with which the point, *f*, of the shoe is to coincide; or, in other words, *C* represents the vertical height between the horizontal center line of the wheel and the average central point, *f*, of the shoe.

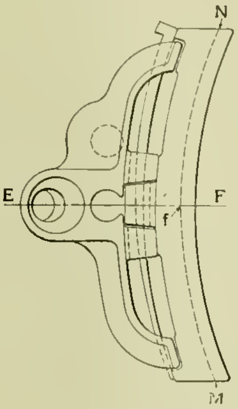


Fig. 1

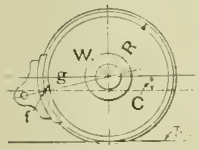

Fig. 2

The value of *C* as recommended by the Mechanical Division of the American Railway Association is approximately 3½ in. for cars. The symbols *C* and *R* will be employed hereafter to designate the dimensions indicated in Fig. 2.

CASE 1: *This case applies to brake heads to be used for wheels rotating equally in both directions.*

In order to obtain uniform shoe wear the following instructions should be observed: *The hanger eye* may be located at any point in the head providing that the hanger is of sufficient length to maintain an approximately constant angle with the center line, *EF*, Fig. 1, of the shoe, but as hangers are usually too short to produce this effect, the recommended location of the eye is directly on the center line *EF*, see Fig. 3.

The brake beam eye, or socket, should be located at some point on the line, *hk*, Fig. 3, the point, *h*, denoting the point of intersection of the center line, *EF*, and the center line of the hanger, whether the hanger eye be located as previously recommended or not. As indicated in the figure referred to the line, *hk*, is required to make the angle, *A*, with the center line *EF*, and it should be noted that this angle must be laid off towards the *top* of the shoe in every case, that is, the brake beam eye must be located on the line, *hk*, *above* the center line, *EF*, of the brake head. The value of the angle, *A*, depends on the radius, *R*, of the wheel and the vertical depression, *C* (see Fig. 2), of the central point, *f*, of the shoe. To determine the angle, *A*, when the values of *C* and *R* are specified, find the quotient of *C* divided by *R* and then refer to Table I, where the corresponding value of the angle, *A*, will be readily found.

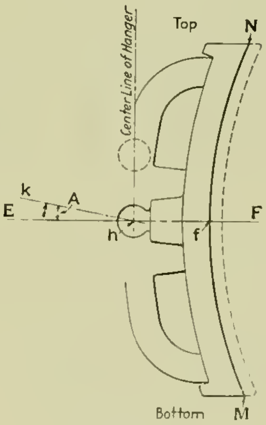

Fig. 3

Application of the Method

Example 1: To illustrate the method just described, let it be required to find the angle, *A*, which the line, *hk*, should make with the center line, *EF*, of the brake head (see Fig. 3) when the radius, *R*, of the wheel is 16½ in. and the vertical distance *C* (Fig. 2) is 3½ in.

Solution: To solve this problem divide *C* by *R* thus,

$$\frac{C}{R} = \frac{3.5}{16.5} = .212$$

By referring to Table I, it is seen that value of *A*, corresponding to this value (.212) of C divided by R, is 12¼ degrees, that is, $A = 12\frac{1}{4}$ degrees.

As the conditions of the preceding problem are those pertaining to the standard 33-in. car wheel and recommended location of the brake head, it is apparent that when the brake beam socket is located close to the hanger eye, the difference between the standard A. R. A. brake head, shown in Fig. 1, and that designed by making the angle A equal to 14¼ degrees is not of very great importance, but on the other hand if the brake beam socket is not located close to the hanger eye the difference may become quite worthy of consideration. The chief use of the foregoing method is, however, found in the case of "double end" locomotives where the distance C is often very great compared to R and, therefore, where the angle A has a correspondingly large value.

TABLE I

Table Giving the Proper Location of the Brake Beam Eye in Brake Heads on Cars and Locomotives in Order to Produce Uniform Shoe Wear

Value of Angle A, in Degrees, Corresponding to Various Values of C Divided by R

C/R	A	C/R	A	C/R	A	C/R	A

.0523	3	.1392	8	.2250	13	.3907	23
.0567	3¼	.1435	8¼	.2335	13½	.4067	24
.0611	3½	.1478	8½	.2419	14	.4226	25
.0654	3¾	.1521	8¾	.2504	14½	.4384	26
.0698	4	.1564	9	.2588	15	.4540	27
.0741	4¼	.1607	9¼	.2672	15½	.4695	28
.0785	4½	.1651	9½	.2756	16	.4848	29
.0828	4¾	.1694	9¾	.2840	16½	.5000	30

Case 2: *This case applies to brake heads to be used for wheels intended to rotate in one direction only.*

In order to obtain uniform shoe wear the following instructions should be observed: *The hanger eye* should be located on the line, fH, Figs. 4 and 5, which makes the angle, B, with the center line, EF, of the brake head. This angle, B, depends on the *average* running speed of the car or locomotive and may be determined directly by aid of Table II. In all cases B must be laid off in the direction in which the contact surface of the wheel moves, that is, in the direction of rotation, as indicated in Figs. 4 and 5. The point, H, located on the line fH, having been fixed at any specified distance from f, should, of course, represent the center of the hanger eye, but if a long hanger is employed the eye may be located at some other point on the center line of the hanger providing that its distance from H is not excessive.

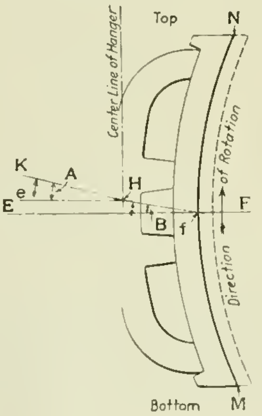

Fig. 4

Example 2: To illustrate the method of determining the angle B by aid of Table II, let it be required to find the value of B for a brake head to be used on the wheel of a "single end" car which has an average maximum speed of 30 m. p. h.

Solution: As the average running speed should be considered as one half the value of the average maximum speed, the former, in this case, will be ½ x 30 or 15 m. p. h., whence by referring to Table II it is seen that the angle B should be equal to 12¼ degrees.

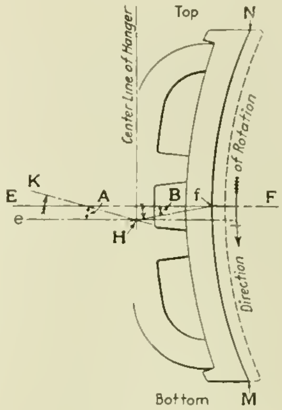

Fig. 5

The brake beam socket or eye should be located on the line, HK, Figs. 4 and 5. To determine this line, HK, draw the line eH parallel to the center line, EF, of the brake head and lay off the angle, A, towards the *top* of the shoe in every instance, as indicated in Figs. 4 and 5. The angle, A, depends on the radius R of the wheel and the vertical depression C (see Fig. 2) of the central point, r or g, of the shoe, and may be determined by aid of Table I in the same manner as that employed in Case 1.

TABLE II

Table Giving the Proper Location of the Brake Shoe Hanger Eye for Brake Heads, on Cars and Locomotives Adapted to Run in One Direction Only, in Order to Produce Approximately Uniform Shoe Wear

Average running speed in miles per hour	Values of Angle B in degrees	Average running speed in miles per hour	Values of Angle B in degrees
5	14¼	35	9¼
10	13¼	40	8½
15	12¼	45	7¾
20	11¼	50	7
25	10½	55	6½
30	9¾	60	6

Finally, it should be observed that, when the proper location of the brake beam socket (or eye) is specified as being "on a certain line," as HK, Figs. 4 and 5, or hk, Fig. 3, it must be understood that the line in question is to be the center line of the socket, that is, the socket must be constructed with respect to this line in the same manner as the socket shown in Fig. 1 is constructed with respect to the line EF.

To Show Up minute cracks in hardened pieces, apply oil, wipe off, and chalk the surface. The oil appears at the cracks, soaking through the chalk.—*The Melting Pot.*

The Shops, like other branches of the transportation system, were turned back to their owners in a bad state of demoralization, so that a great amount of work has been contracted for outside. It has actually been found both cheaper and quicker to reconstruct equipment in other than the railroads' own shops. Under political administration of the railroads a repair shop appears to have been a good deal of a loafing place.—*Providence Journal.*

Cylindrical Grinding in 1920*

BY W. H. CHAPMAN

Norton Company, Worcester, Mass.

This paper comprises a study of the laws involved in cylindrical grinding and an analysis of grinding action (1) for draw-in cuts and (2) for traversed cuts.

Grinding efficiency is usually considered as (production) ÷ (wheel wear). Accordingly formulas are derived for wheel wear in terms of grain size of wheel, work speed, wheel speed, feed, etc. By calculating values for wheel wear for different conditions and comparing them with production figures calculated under the same conditions, a proper selection of wheels may be made.

The fact that wheel wear is a comparatively unimportant item in the total cost of grinding, however, frequently leads to wrong conclusions if this is made the controlling factor. The all-important factor is the rate at which the wheel may be made to cut and still not get out of truth. Assuming wheel cost to be, for example, 7 cents per cu. in. and other production costs 5 cents per minute, production efficiency is materially increased by increasing production at the expense of wheel wear within defined limits. The paper concludes with a series of practical conclusions, the most important of which is that increase of traverse speed increases production without increase of wheel-wearing action.

The Job of Being a Foreman

As a foreman what is your goal—the pay envelope or the satisfaction of getting team work and quality and quantity production from your department? Do you regard your work as a job or as a profession?

How much time do you give to thought and study with a view to improving the relations between the workers and the management? What do you know about production management?

These are plain questions and your answer to them will measure your worth to the railroad and in a larger sense to the community.

Is there a real reason why foremen generally in railroad service have been paid comparatively low rates?

The author makes a mathematical analysis of grinding action for draw-in (non-traversed) cuts from which he derives the following laws of cylindrical grinding, operative *within the usual limits of speeds and dimensions.* For straight-in (draw-in) cuts a free-cutting wheel will wear according to the effect of wheel-wearing action as outlined below:

(a) Wheel-wearing action increases directly as: 1. Grain interval (grain size—inversely as grade). 2. Work speed (surface). 3. Square root of diametral cut (feed).

(b) Wheel-wearing action increases directly as the following are decreased: 1. Square of wheel speed (surface). 2. Square root of work radius.

A soft wheel is more susceptible to wheel-wearing action than a hard wheel and will more nearly follow the theoretical conditions. It is therefore more free-cutting and will cut more nearly the full chip than a hard wheel. There is consequently a gain in production as wheels of softer grades are used, all other conditions remaining constant, up to the point where the chips are geometrically perfect for a given condition of speeds and dimensions. It is clear from this standpoint that the softest possible wheel should be used. High wheel speeds up to the safe limit are of course necessary if the soft wheels are to perform in a satisfactory manner.

Traversed Cuts

The most important development in recent grinding machines is the recognition and utilization of the fact that overall operating efficiency for traversed cylindrical work *increases as traverse speeds are increased.* (This assumes that for a given traverse speed, width of wheel and revolution of work are so related as to cause the cutting face to just cover the lead of the work.)

From another theoretical analysis the following laws of grinding for traversed cuts are deduced:

(a) Wheel wear increases directly with every increase in the work speed.

(b) Wheel wear decreases directly as the decrease in the quantity which we term "traverse factor," which is work speed divided by the square root of the sum of the squares of traverse and work speeds.

(c) Wheel wear decreases directly as square of wheel speed increases.

(d) Wheel wear decreases directly as the square root of the work radius increases.

(e) Wheel wear increases directly as the square root of the feed increases.

Production Costs

Grinding efficiency is usually considered as (production) ÷ (wheel wear). It is expressed as cubic inches of material removed per cubic inch of wheel wear. If wheel wear were

---

*Abstracted from a paper read at the December, 1920, annual meeting of the American Society of Mechanical Engineers.

the most important element of production cost, grinding efficiency might be considered on this basis without leading to the fallacy which exists today. As a matter of fact, the wheel cost is almost negligible compared to the other costs, and wheel selection should be based upon the production capacity of the wheel under the given set of grinding conditions, allowing the wheel wear to be as high as is necessary to get a free action without excessive wear (which would cause difficulty in sizing work and the need for frequent dressing). The all-important factor is the rate at which the wheel may be made to cut and still not get out of truth. This affects the grinding time, any reduction of which is of vastly more importance than an increase of wheel wear which may result from such a reduction.

The overall production efficiency of the machine based upon all costs involved is indicated by production-cost factors proportional to the earning rate of the machine.

In Table I the production-cost factors are given for 1-in. and 4-in. diameters of work only. The factors may also be expressed as earnings per unit of time, or the relative amounts the machine would earn in equal lengths of time under the various conditions as given.

Note that, due to high traverse, a 2.3-in. wheel which earns $3.68 in a certain length of time when grinding 1-in. work at low traverse and work speeds, will earn $10.62 in the same length of time when using the high speeds. If the widest wheel (7.35-in. face) be used the machine will earn $11.70 in the same length of time. The grade of wheel is suitable in each case according to the speed changes. This clearly shows that high traverse speeds cause a corresponding increase in earnings in spite of the necessary increase in work speed.

Table I—Production-Cost Factors

Table speed, ft. per min.	Work, r.p.m.	Lead, in.	Diameter of work	
			1 in.	4 in.
10.02	53	2.3	3.68	13.45
14 00	53	3.1	5.16	18.80
14.00	72.5	2.3	4.95	17.85
17.00	53	3.8	6.00	21.00
17.00	72.5	2.8	6.00	21.80
17.00	87	2.3	5.85	22.00
19.70	53	4.4	6.40	23.70
19.70	72.5	3.2	6.80	23.50
19.70	87	2.7	6.84	23.45
19.70	101	2.3	6.75	23.30
26.90	53	5.9	9.05	29.80
26.90	72.5	4.4	9.34	29.85
26.90	87	3.6	9.00	29.00
26.90	101	3.1	9.03	29.10
26.90	138	2.3	9.00	29.15
32.60	53	7.35	11.70	35.70
32.60	72.5	5.3	11.30	34.60
32 60	87	4.4	11.00	33.60
32.60	101	3.8	10.90	33.40
32.60	138	2.8	10.80	33.30
32.60	167	2.3	10.62	32.90

Considering the cost of wheels 7.35 in. wide as compared to wheels 2.3 in. wide, and the relative power required to drive the two wheels, it is very evident that the use of a harder wheel 2.3 in. wide would offset the difference in wearing action without greatly reducing production and that the production of the 7.35-in. wheel is matched by the production of the 2.3-in. wheel using highest traverse and highest work speed.

The most striking conclusion from the above is the fact that in order to use a narrow wheel and get great production the high work speed does not cause excessive wheel wear *due to the relief* on the wheel brought about by the *high traverse speed.* This traverse speed is also necessary to allow the rapid exposure of fresh work surface to the cutting face, making for a highly economical combination.

The author sums up the paper as follows:

In cylindrical grinding the following theoretical conclusions are found to hold true: Greatest grinding efficiency is obtained by the use of the softest wheels suited to the nature of the material ground. This efficiency is dependent upon the control of the dimension and speed relations between the wheel and the work so that the individual chip may have the minimum depth for a given volume determined by the maximum allowable radial depth of cut. This means long arc of contact, low work speeds and maximum feeds. With the above conditions established, *an increase of traverse speed increases the production without an increase of wheel-wearing action.*

Machine conditions must be such as to maintain as accurately as it is reasonably possible the speed and dimensional relations of the wheel and the work. This includes a great number of individual factors, any one of which may serve to entirely or partially impair the successful operation of the machine in following the theoretical fundamental laws as previously stated. It is worth while to emphasize some of the most important of these practical conclusions.

(a) The power drive must not allow speed variations unless under the wilful control of the operator.

(b) The wheel must be in good running balance and in absolute truth, and must be held in its position relative to the work within the closest possible limits.

(c) The work must be accurately held with respect to the wheel and must be uniformly rotated. Relative traverse between work and wheel must be uniform.

(d) The work must be rigidly supported over its entire length and no vibration allowed to occur between centers.

(e) The feed control must be sensitive and accurate and feeding must be at a rate such that the feed increment *never exceeds the maximum grain penetration,* which varies directly with grain interval, work speed, and square root of radial feed and inversely with wheel speed, and square root of work radius. (This is the most frequently violated of the factors involved.)

(f) The work must be kept at a uniform temperature and local heating prevented at all times. A copious supply of grinding compound should be directed to the arc of contact at all times. In truing the wheel with a diamond, the use of the cooling medium is vital to accuracy. Save the diamond by using a dresser to roughly true a wheel, and never feed a diamond over 0.001 in. per traverse.

(g) Select wheels intelligently, and do not try to use a single wheel for a variety of work sizes or materials unless the job is too short to warrant efficient grinding as compared with the time of changing wheels.

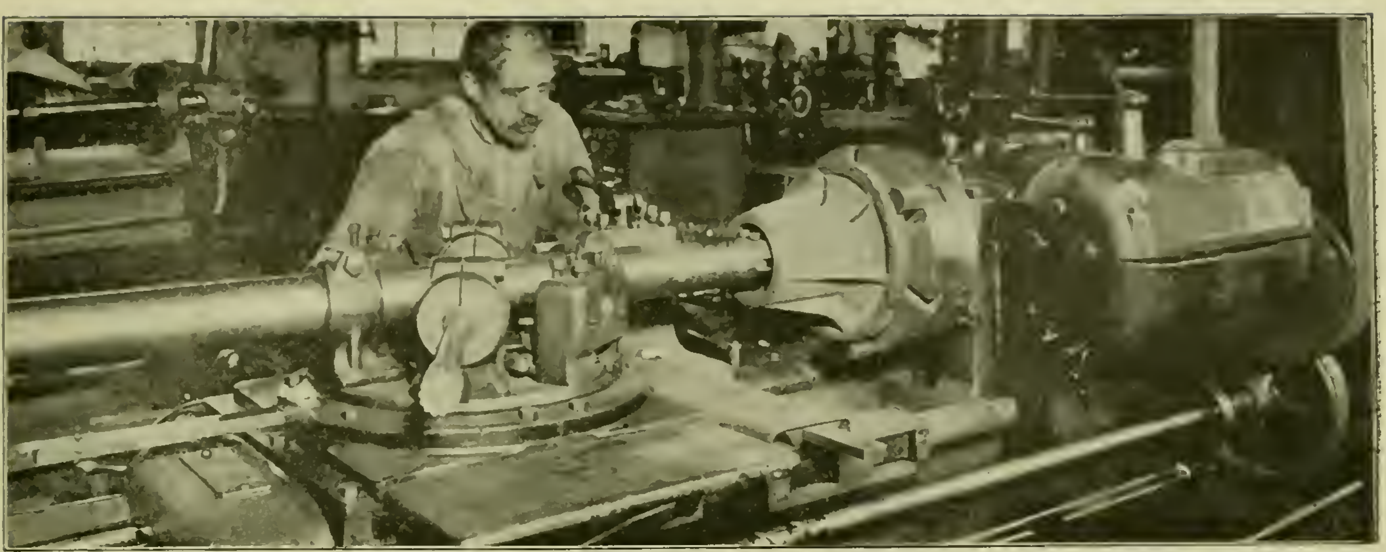
(h) An accurate finish requires the use of a soft, free-cutting wheel so controlled that the chips are very small. (Light feed and slow work speed with traverse to make the wheel face just cover the lead, should be used.)

(j) A burnished finish may be obtained by the peening action of a coarse, hard wheel trued dead smooth. Heating and inaccuracies of surface are likely to occur.

(k) Cases are rare where a wheel harder than grade M (Norton system of grades) may properly be used in cylindrical grinding. Low speed wheels, too small a wheel, too high a work speed and abusive feeding are usually the causes for the use of hard wheels.

(l) The contact of the wheel face with dry work at any time immediately ruins its value for finishing. The common practice of just touching the dry work when bringing up the wheel to contact is wrong, due to the charging of the wheel face with the uncooled chips (loading).

The Essential Requirements of tempering oils are: Flash and fire tests high enough to avoid serious evaporation loss or to incur high fire risk; comparative freedom from decomposition; absence of acid or acid forming substances, which would have a materially corrosive action on metals at high temperature; a fairly high heat capacity, and enough fluidity to permit rapid carrying away of the heat.—*The Atlantic Lubricator.*



Railroad Shop Turret Lathe Practice

The Turret Lathe; a Convenient and Efficient Tool for Accurately Machining Certain Locomotive Parts

BY HOWARD VOLZ
Engineering Staff Member, Acme Machine Tool Company, Cincinnati, Ohio

THE machines referred to in this article are combination flat turret lathes and universal flat turret lathes with cross sliding turrets adaptable to bar or chuck work. The chief advantage of the machine equipped with a flat turret is its adaptability to any class of turning or boring operation and the simplicity of its arrangement. All the tools are used to the full capacity of the machine. The side carriage with the four-way tool post or square turret is one of the main features of the universal flat turret lathe and this combination makes the machine practically universal for all turning and boring work within its range.

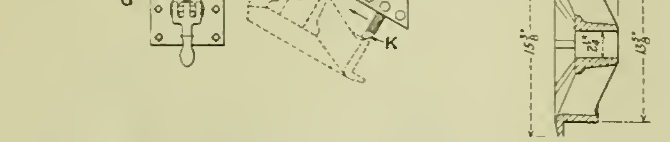


Fig. 1—Tooling Arrangement for Machining Valve Spider

Another advantage is the ease with which a turret lathe equipped for bar work can be changed over to one arranged for chucking work or on the other hand a chucking machine changed over to a bar machine. The following examples are special railroad jobs but typifying the work that can be performed on these turret lathes. Illustrations of tooling equipment used in each operation are given, as well as a detailed description of the entire sequence of operations.

Main Valve Spider

The valve spider illustrated in Fig. 1 can be machined complete on a No. 3 universal turret lathe in one chucking. The operations consist of finishing surfaces *A, B, C, D, E* and *F*. The work is held in a three-jaw chuck with high jaws cut out to hold the spider on the inside of the rim. Surfaces *A* and *C* are rough turned and surface *B* is faced by cutter *G* held in the square turret. At the same time, hole *F* is rough bored by cutter *H* held in a cutter bar in one end of a 3 7/16-in. boring bar at the first turret position. Surfaces *D* and *E* are faced by cutters *J* and *K* held in a tool plate or multiple tool holder at the second turret position. Surface *A* is finish turned by cutter *L* held in the square turret, and at the same time hole *F* is finish bored by cutter *M* in the cutter bar at the fourth turret position. Hole *F* is reamed by a reamer held in a tool holder at the fifth turret position, which completes all operations. Stellite cutters are used in the square turret. The time required is 12 minutes.

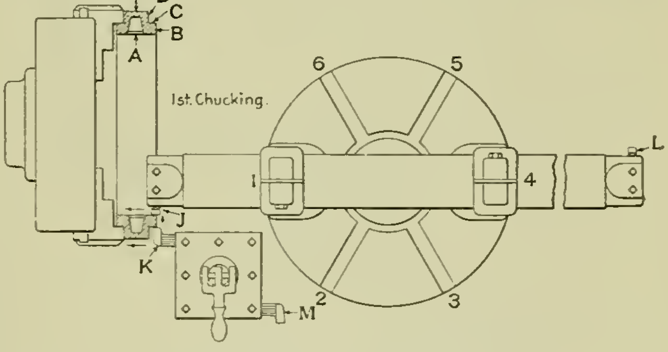

Fig. 2—Tooling of Universal Turret Lathe for First Operation in Machining Piston Valve Bull Ring

Piston Valve Bull Ring

Machining a piston valve bull ring in two chuckings on a

No. 3 universal turret lathe is illustrated in Figs. 2 and 3. In the first chucking surfaces *A*, *B*, *C*, *D* and *E* are finished. The work is held securely in a three-jaw chuck as shown in Fig. 2. Hole *A* is rough bored by a cutter *J* held in one end of a 3 7/16-in. boring bar at the first turret position. At the same time surfaces *C* and *E* are rough turned and surfaces *B* and *D* are rough faced by cutter *K* held in the square turret. Surface *A* is then finish bored by cutter *L* held in the opposite end of the 3 7/16-in. boring bar at the fourth turret position. At the same time surfaces *C* and *E* are finish turned and surfaces *B* and *D* are finish faced by cutter *M* in the square turret. This completes the operations to be performed in the first turret chucking. All cutters used are of stellite and the time required is 13 minutes.

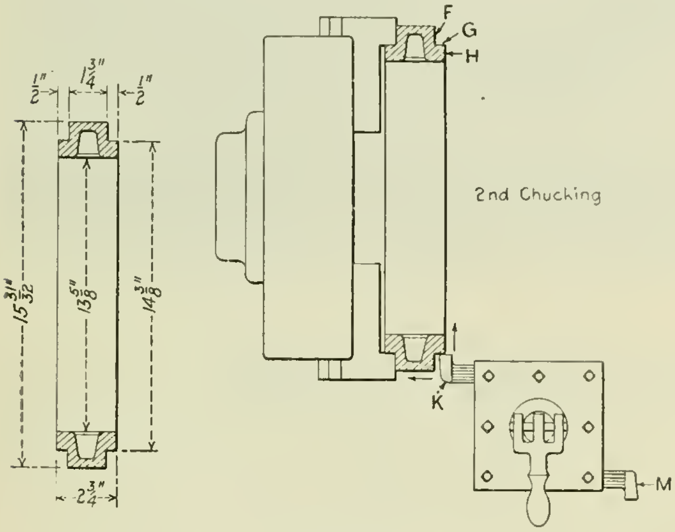

Fig. 3—Details of Bull Ring and Tooling Set Up for Second Operation

In the second chucking the work is held securely in soft jaws cut out to conform with the work as shown in Fig. 3 and the operations consist of finishing surfaces *F*, *G* and *H*. Surfaces *F* and *G* are rough faced and surface *H* is rough turned by cutter *K* held in the square turret. Surface *H* is finish turned and surfaces *F* and *G* are finish faced by cutter *M* held in the square turret. The work is removed from the chuck, all operations being completed. The time taken in the second chucking is 6 minutes, making a total time of 19 minutes required for machining the piston valve bull ring.

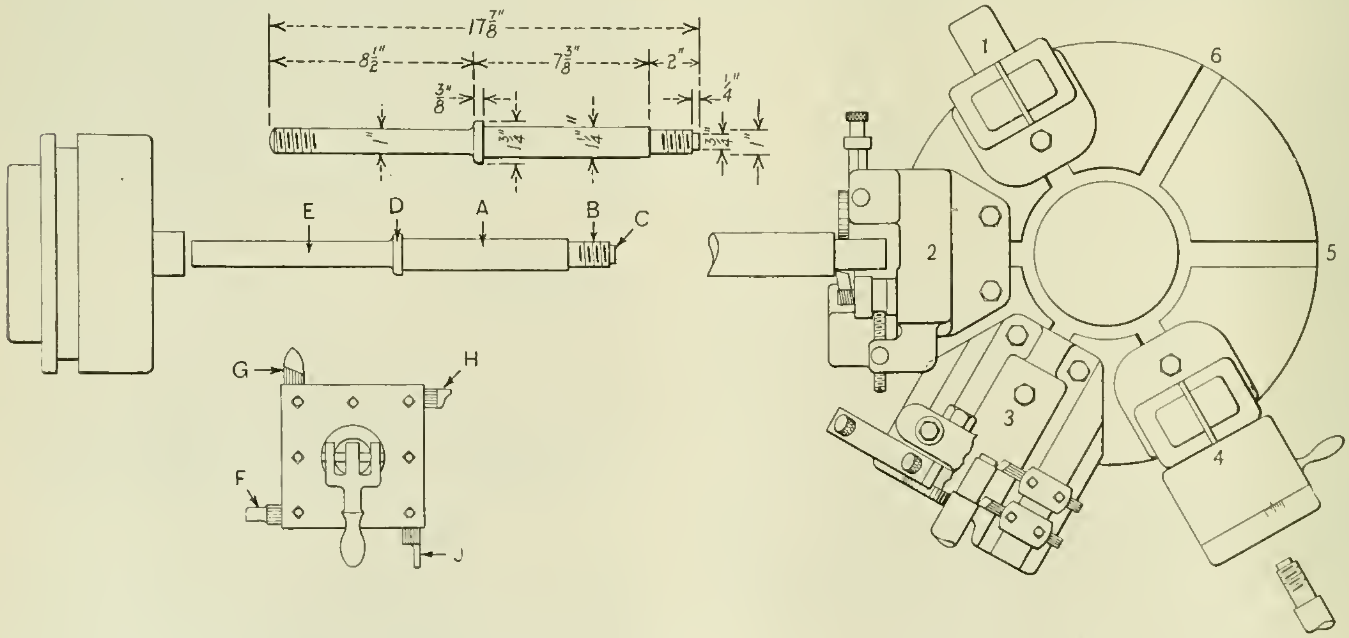

Fig. 5—Tooling of Universal Turret Lathe for First Operation on Emergency Valve Stem

Exhaust Pipe Packing Ring

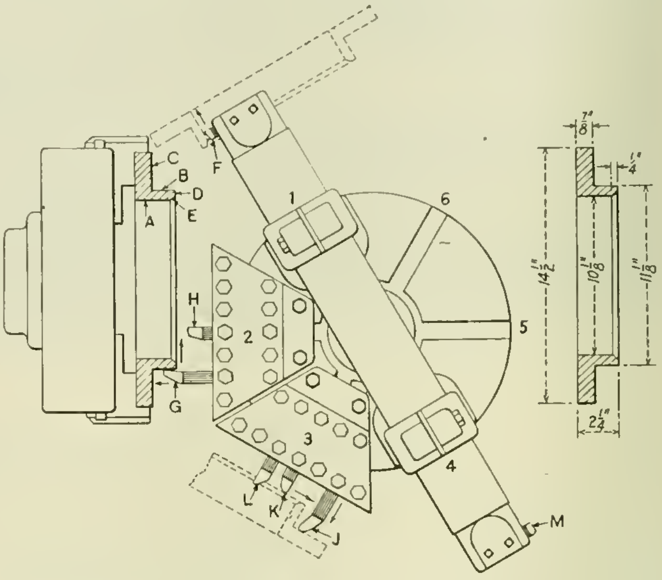

Fig. 4—Tooling of Combination Flat Turret Lathe for Machining Packing Ring

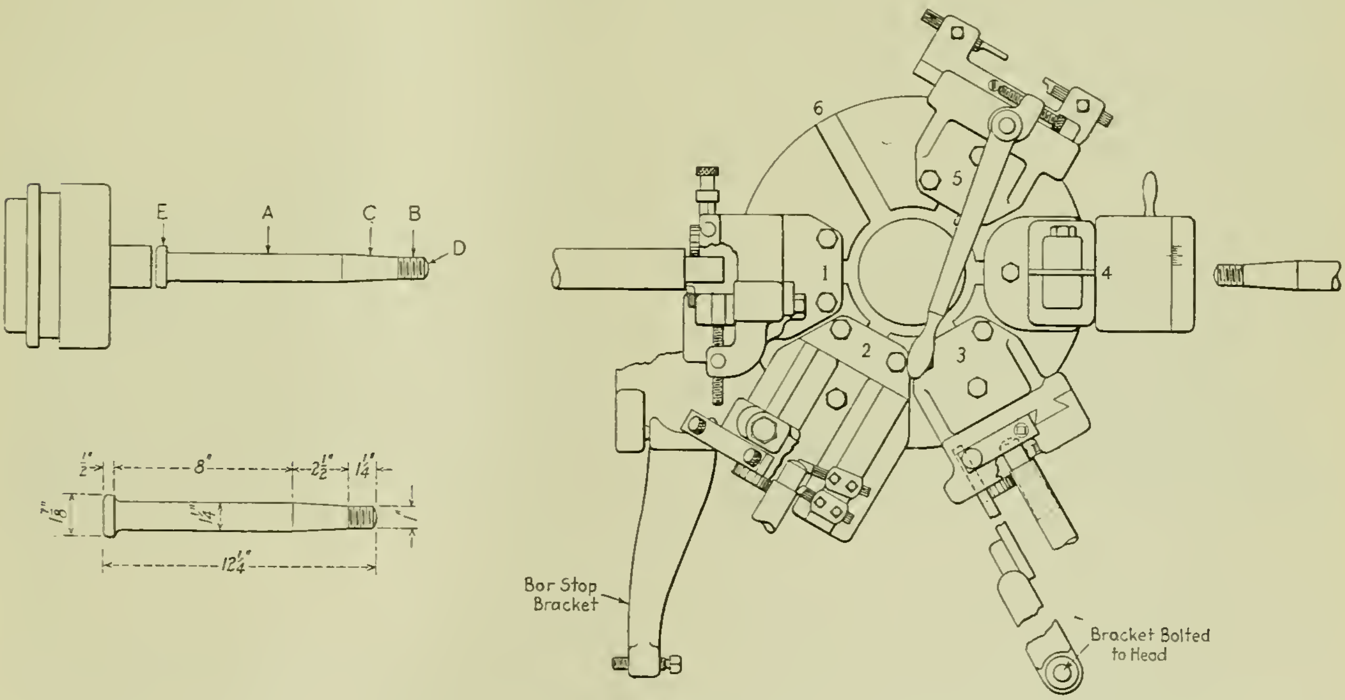
A packing ring for a low pressure exhaust pipe and slip joint machined on a 2¼ in. by 26 in. combination flat turret lathe with a cross sliding turret is shown in Fig. 4. The work is finished in one chucking and the operations consist of finishing surfaces *A*, *B*, *C*, *D* and *E*. A three-jaw chuck is used for holding the work on the flange diameter and the operations are performed in the following manner: (1) Hole *A* is rough bored by cutter *F* held in one end of a 3 7/16-in. boring bar at the first turret position. (2) Surfaces *C* and *D* are rough faced by cutters *G* and *H* and surface *B* is rough turned by cutter *G*, both cutters being held in a tool plate or multiple tool holder at the second turret position. (3) Surface *B* is finish turned by cutter *J*; surfaces *C* and *D* are finish faced by cutters *J* and *K*; and surface *E* is formed by cutter *L*, all cutters being held in a tool plate at the third turret position. (4) Hole *A* is finish bored by cutter *M* held in the opposite end of the 3 7/16-in. boring bar at the fourth turret position. The time required to finish the work in the foregoing sequence is 12 minutes.

Emergency Valve Stem

Machining an emergency valve stem from a steel bar on a universal flat turret lathe is illustrated in Fig. 5. The following is the sequence of operations: (1) The stock is fed up to the bar stop held in the first turret position. (2) Surface *A* is turned by a cutter held in a universal turner at the second turret position. At the same time, cutter *F* held in the square turret is fed into the work preparatory to turning surface *E*, after which this surface is turned by cutter *G*, also held in the square turret. (3) Surfaces *B* and *C* are turned by cutters held in a multiple cutter roller rest turner at the third turret position. At the same time the corner of surface *D* is rounded by cutter *H* held in the square turret. (4) Surface *B* is threaded by a screw cutting die head at the fourth turret position. (5) The work is cut off by cutter *J* held in the square turret. The time required to finish the work in the foregoing sequence is 8 minutes. It requires two chuckings to finish work all over, the second chucking consisting of rounding the end and threading surface *E*.

Reducing Valve Stem

A reducing valve stem, as shown in Fig. 6, can be finished complete in one chucking from a steel bar on a 2¼ in. by 26 in. combination flat turret lathe equipped for bar work. (1) The stock is fed against the bar stop bracket. (2) Surface *A* is turned by cutter held in a universal turner at the first turret position. (3) Surface *B* is turned and end *D* is rounded by cutters held in a multiple cutter roller rest turner at the second turret position. (4) Surface *C* is taper turned by a cutter held in a taper turner at the third turret position. The taper turner is aided by a taper bar made to conform with the taper desired. The bar is held on a bracket which in turn is bolted to the head stock. (5) Surface *B* is threaded by a screw cutting die head held at the fourth turret position. (6) The corner of surface *E* is rounded and the work is cut off by cutters held in a slide tool at the fifth turret position. The time required to finish complete is 11 minutes.



6—Stem for Reducing Valve Machined from Steel Bar on Combination Flat Turret Lathe

Prosser Flue Expander

Machining a prosser flue expander from a steel bar can be accomplished in one chucking on a 2¼ in. by 11 in. hand screw machine in the following sequence of operations: (1) The stock is fed up to the bar stop held in the first turret position. (2) Surface *A* is turned by a cutter held in a universal turner bolted to the turret face at the second turret position as shown in Fig 7. (3) Hole *C* is drilled by a drill held at the third turret position. (4) Hole *B* is drilled by drill held in fourth turret position. (5) Contour *D* and groove *E* are formed by cutters held in a form block bolted on the front of the cut off slide. (6) Hole *B* is taper reamed by a reamer held at the fifth turret position. (7) Hole *C* is taper reamed by a reamer held at the sixth turret position. (8) The work is cut off by a cut-off tool held in an open side tool post bolted on the rear of the cut-off slide. All operations are completed in 7 minutes.

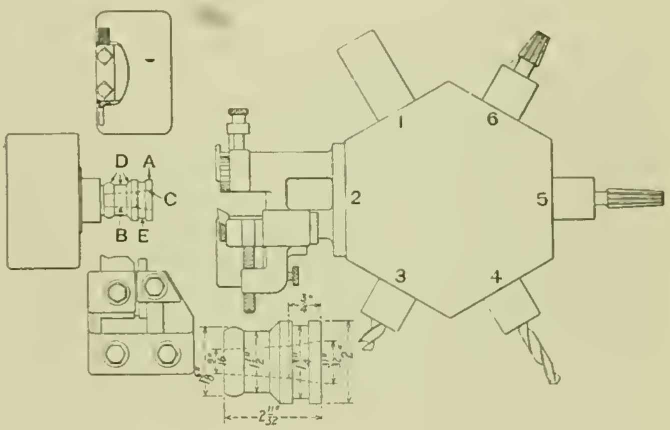


Fig. 7—Tooling of Hand Screw Machine for Making Prosser Flue Expander

The Reason Why Some Fusion Welds Fail*

Hardening Effect of Welding Heat Graphically Demonstrated and the Effect of Annealing Shown

BY T. D. SEDWICK

Engineer of Tests, Chicago, Rock Island & Pacific, Chicago

IN case of poor results from fusion welding shown either by laboratory tests or actual service, the inclination is to attribute such results to the material used, the method of making the weld, a poor operator, or the contributing effect of all three of these factors.

But there are other points that enter into the final results, and two of the important ones are as follows:

First—Was the metal in the casting or forging in such a physical condition that it was fit to be welded and afterwards give good service; did the metal originally fail on account of the presence of segregation of the various chemical elements; did it contain blowholes, porosity, or were there thermal stresses left from the original forging or casting operations; had the previous service fatigued the metal to the extent that it was inherently weak?

Second—Was the original metal adjacent to the weld deleteriously affected by the welding operation?

Some take the first mentioned factors into consideration, but I do not believe that very many, particularly the shopmen, give much thought to any action which may take place on the original metal. Tests and observations made on failed material and special test specimens have shown that welds fail although good conditions prevail in all other respects.

Investigation on various welds has shown that in the majority of the cases, especially in certain classes of material, the welding heat or the process of preheating has affected the metal in the sections being welded, causing a transformation of the physical structure of the steel, and in case of localized high temperatures the main body of the material absorbs the heat so fast that there results a quenching action on the heated metal. In the majority of instances the extreme hardening action will be localized near the surface immediately adjacent to the added metal. In some cases of preheating it has been shown that the high temperature causes a change in the physical structure of the metal, and while it is not usually so localized as in the case of the action of the welding heat alone, thermal stresses are set up in addition to those created by the heat of the welding process. These conditions have been found in material of thick sections where the heat would not be readily absorbed throughout the section and where the chemical content, especially the carbon, was such that it rendered the metal readily susceptible to structural changes, resulting in a hardened condition.

To illustrate some cases of this kind photographs have been secured showing several special tests and also some examples of failed material. A great many of these tests were made to demonstrate to the shopmen, that in the majority of the cases proper annealing should be done after the weld has been completed and that a thorough annealing would improve the physical condition of the metal, thereby causing it to render better service; this thorough annealing to be made by placing the metal in a furnace and giving it a soaking heat and then cooling it so that the whole mass could adjust itself to a uniform condition throughout.

The idea of causing a self or automatic annealing to take place by preheating is going at the proposition backwards and trusting to luck that we have not done more damage than good. It is necessary at times to preheat to take care of the shrinkage strains which might be set up in certain sections during the cooling after welding. What I am advocating is that after this has been done, we follow out a thorough annealing program. In this way any strain or hardened condition that has been set up by preheating, or by the welding heat, will be eliminated and we will then have a product the service of which will depend mainly on the quality of the material in the weld, and the perfection of the weld.

There are certain zones in any torch flame that are of a higher temperature than others, and as it too often happens that a sufficient length of time is not taken in preheating to permit a soaking heat, more or less locally heated areas are produced that multiply the thermal stresses not eliminated during the subsequent period of cooling.

In the majority of the shops, especially the larger shops, where special annealing furnaces have not been installed there are always some furnaces of sufficient size in which at least the smaller castings and forgings could be annealed and this annealing could be done at a comparatively low cost. At the close of the day, as space is being left unoccupied by the regular work of the shops, the welded material could be placed in the furnace and be annealed over night without any material increase in the cost of fuel. This plan would not check production of the regular work.

Too little attention is given to annealing in general even in cases where no welding is done. In reclamation plants where old material is re-worked, a worn out or failed forging will be reforged. When originally forged thermal stresses may have been set up in this material and not removed, or the material may have been overheated or even burnt. Later, during its actual service, fatigue stresses and unsatisfactory physical structure may have been produced. On reforging, further stresses may be set up and then without annealing to refine the grain and remove these stresses the forging will be returned to service. While it may give some service, if we had gone a little further and treated it properly, the extended service in my opinion would have been sufficiently great to more than justify any extra trouble or expense involved in a final annealing after forging. The same thought applies to welding of failed material.

There are a great many misconceptions of the process of annealing and a great many shopmen fail to observe the rule that it requires time for a piece of steel to adjust itself to the annealing temperature and be uniformly heated throughout. For instance, on one particular forging which the workman was instructed to anneal thoroughly he advised that he was doing so. But later it was found that he was simply sticking the forging into a blacksmith fire so that the welded area was buried in the fire. Under such conditions, while the extremely localized, highly affected areas will be removed, minor stresses will be set up back along the forging. To do the job right the forging as a whole should have been subjected to the annealing heat.

With such methods it is hardly fair to expect 100 per cent service out of material to which we have added or in which we have produced unsatisfactory conditions rather than reduced them. I am not looking at this matter from a strictly theoretical standpoint; the tests and the various failed material which have come to our attention justify these remarks. In a great many cases the only reason that a new forging may give good service is because the designer has allowed

---

*From a paper read before the American Welding Society, Chicago Section, December 22, 1920.

for such a great factor of safety that the shopmen can do almost anything with the material and there will still be some service left. Assuming that a designer had originally made provisions for a factor of 10 and later the section was broken and welded, this weld in reality may have a factor of five. The designer attempts to take into consideration not only the ordinary service requirements but abnormal requirements that the material might need in case of emergency. If we have reduced this factor 50 per cent, the material might be able to go along in ordinary service with safety but for the emergency cases we may have eliminated the safety margin entirely. Sometime during the life of the material, it is going to run into extreme conditions. Then, if we have not taken the proper precautions, it will fail. Even where the welder has increased the cross-sectional area the failure can be traced to some of the conditions mentioned above.

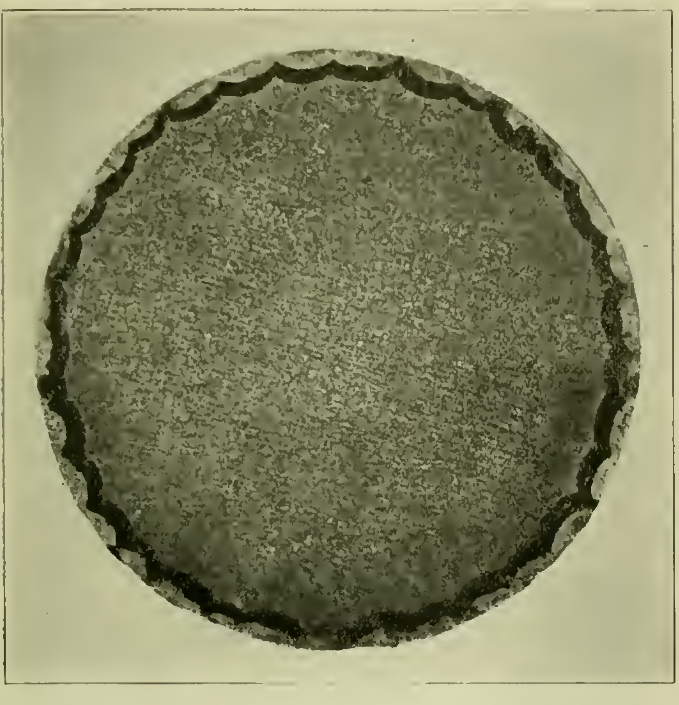

Fig. 1—Etched Cross Section of a Failed Piston Rod; the Crosshead Fit Had Been Built Up by Electric Welding

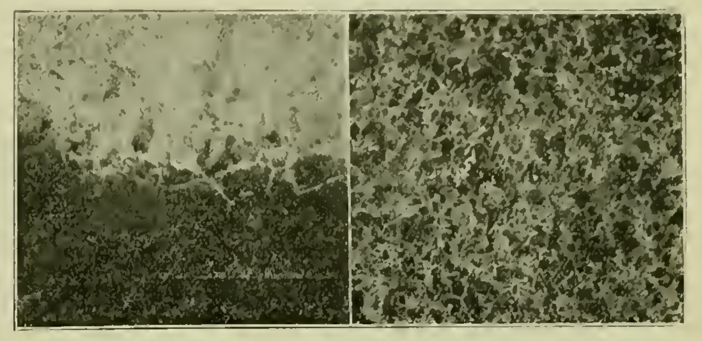
The photographs were taken in connection with some of the tests already mentioned, to illustrate the zones affected by the heat and the hardening effect of the welding operations. The method of bringing out visibly these hardened areas or structural differences without magnification involves the same procedure that can be used in checking the extent of the hardened or tempered areas in tools, such as chisels, hatchets, etc., and is comparatively simple. The surfaces are given a rough polish and dipped in nitric acid of specific gravity 1.13, or where this is not practicable the acid may be poured over the steel.

The hardened areas referred to, in a great majority of steels will correspond to the hardness that would have been produced had the steel been heated and quenched. In some of the tests illustrated strips were taken from the specimens so as to embody metal from the extremely hardened zones only, and then from adjoining positions progressing successively into the unaffected metal. It was found that in the zones where the hardened condition was highly localized these strips would not bend over 15 deg. before breaking or snapping off, but after annealing they could be bent flat on themselves, the same as the original metal.

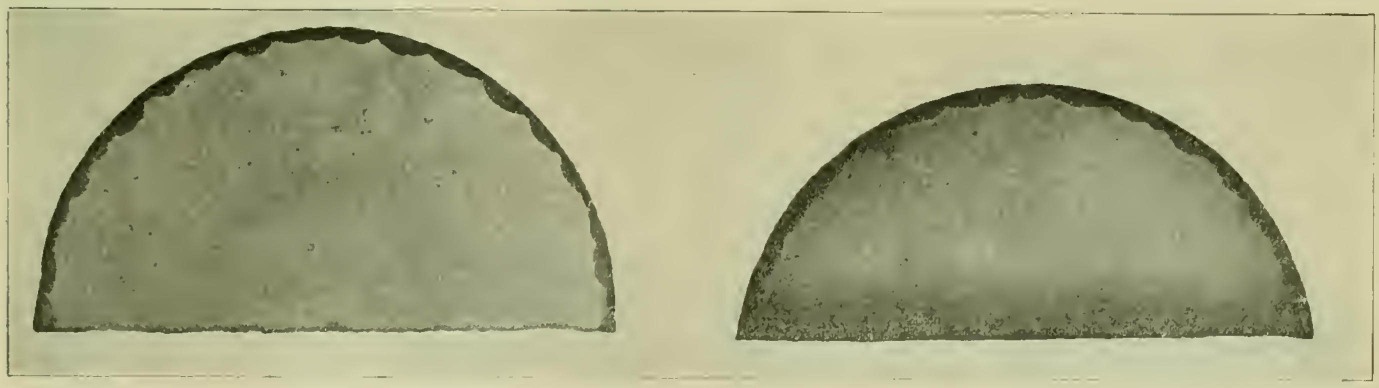


(a) (b)

Fig. 3—Microphotographs of the Metal in the Piston Rod Before Annealing; (a) the Added Metal and the Heat Affected Area; (b) Normal Structure at Center of the Rod

A failed piston rod on which the cross head fit had been built up by the electric welding process is shown in Fig. 1. The photograph shows the added metal on the outer area around the circumference and between this and the interior metal in the rod is a scallop-shaped area affected by the welding heat. This represents the condition of the metal in the rod at the time of the failure. The average scleroscope hardness of the added metal was 49, of the heat affected area 80, and of the metal in the rod proper 50.

The face of the same cut opposite to Fig 1 was cut in two and both pieces annealed, one-half being allowed to cool in the furnace and the other half in the air. It will be noted in Fig. 2 that the hardened area between the added metal and the parent metal has been eliminated in both cases.



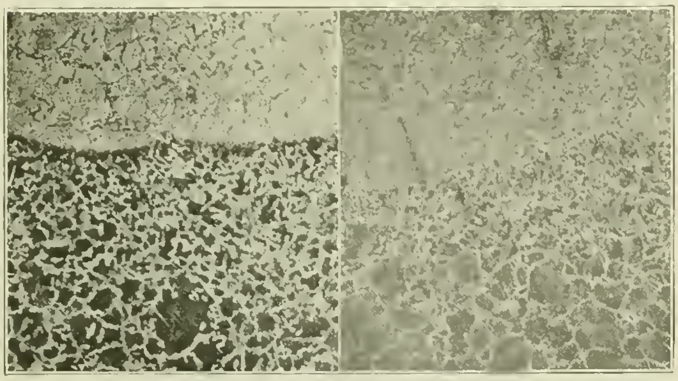
(a) (b)

Fig. 2—Two Halves of the Face Opposite to That Shown in Fig. 1 After Annealing; (a) Cooled in the Furnace; (b) Cooled in the Air

The scleroscope hardness of the added metal in the piece cooled in the furnace was 38 and of the metal in the rod, 55. The scleroscope hardness of the added metal in the piece cooled in the air was 38 and of the metal in the rod, 57.

The fact that the added metal in these two photographs is shown in black should not cause it to be confused with the darkened area on Fig. 1 as in the latter two cases this was a matter of etching to differentiate between the added metal and the metal in the rod proper.

Fig. 3 shows microphotographs of the metal in the rod before annealing; *a* shows the added metal and the heat affected area in the rod, *b* the normal structure in the center of the rod, all at a magnification of 100 diameters. Fig. 4*a* and *b* are the microphotographs (100 diameters) of the two annealed pieces shown in Fig. 2. Both were annealed for three hours at 1,500 deg., F., after which *a* was cooled in the furnace and *b* in the air.



(a) (b)

Fig. 4—Microphotographs of the Two Pieces Shown in Fig. 2, After Annealing; (a) Cooled in the Furnace; (b) Cooled in the Air

Both show the added metal and the structure in the rod proper, the heat affected area having been eliminated by the annealing process. There is less segregation of the ferrite around the grain boundaries in the piece cooled in the air than in the one cooled in the furnace.

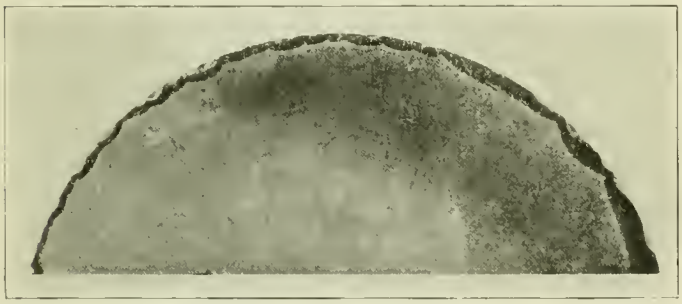


Fig. 5—Example of the Effect of Erratic Action by the Operator on the Uniformity of Heat Penetration

As a further illustration of the variation of the hardened zone, Fig. 5 is an etched cross-section of another piston rod on which the cross head fit had been built up, the rod originally being heat treated Nichrome steel. Attention is called to the variations in the area of this hardened zone in the parent metal. On comparison with the first rod shown, an unusually uniform movement and metal application by the welder is evident. It has occurred to me that an etching method similar to this might be adaptable for grading or examining welders as to their proficiency as well as for giving some indication as to the condition under which they were working.

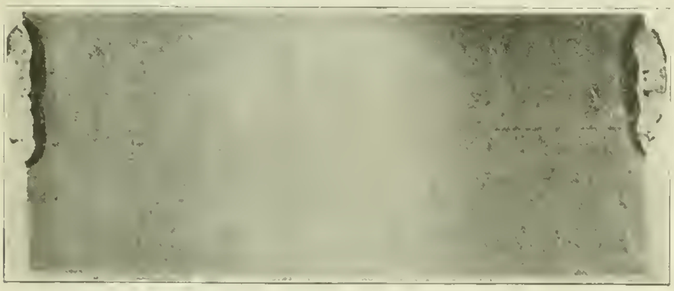

Fig. 6—Hardening Effected by Adding Metal Without Preheating—Electric Arc

The next few etched sections were made in an investigation to determine if a system of preheating could be developed to eliminate the hardened zones or heat affected areas created either through the preheating or the welding heat.

Fig. 6 is a crank pin, on which no preheating of any kind was done. The scleroscope hardness on the added metal was 33, on the hardened zone 58, and on the rod proper 46. The metal was added with an electric arc. Fig. 7 shows the previous piece after annealing, the added metal showing a hardness number of 34, and the pin metal proper 45. Fig. 8 is a piece of crank pin steel to which the patch was made after preheating the parent metal with the arc, resulting in the hardness numbers of 35 in the added metal, 50 in the hardened zone, and 47 in the rod. The metal was added with the electric arc. After annealing, the hardened zones were removed; the hardness number in the added metal was 35 and in the rod 45.

Fig. 7—The Hardness Removed by Annealing

Fig. 8—Metal Added After Preheating with the Arc

Another piece of the pin was preheated in the blacksmith furnace and metal added by the electric process; in this case the hardness number in the added metal was 34, in the

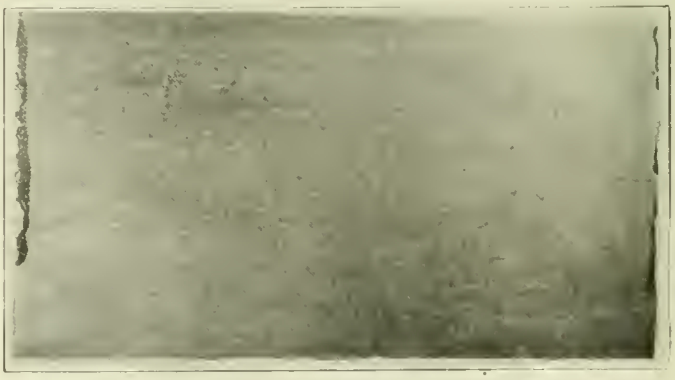

Fig. 9—Hardness Produced by Preheating with the Arc—No Metal Added

hardened zone of the pin 59, and in the body of the pin 46. After annealing, as in the previous instances, the hardened area was eliminated, resulting in a hardness number in the added metal of 34 and in the rod of 45.

Fig. 9 shows a pin which was preheated with the arc, but no metal added, resulting in a clearly defined hardened zone with a hardness number of 64, the body of the rod showing 44. After annealing of this piece the hardness was uniformly 45 out to the edge of the piece.

Metal was added around the section of a locomotive frame with the electric arc, without preheating. The metal was added in three layers with the idea that the succeeding layers might exert an annealing action on the affected area. The hardness number in the added metal was 34, in the affected area 57, and with the parent metal 47. After annealing this piece the affected zone was removed. The same frame member was preheated with the electric arc and metal again added in three layers, as in the former case, without showing any improvement in the hardening effect of the welding heat.

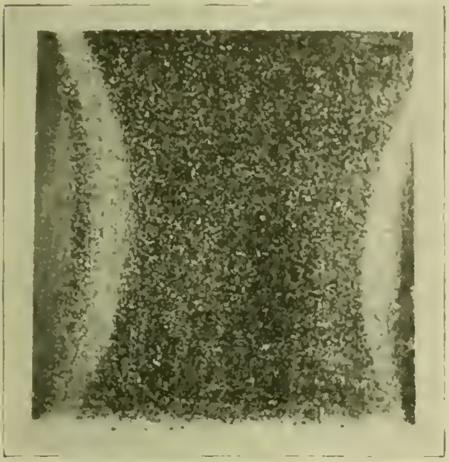

Fig. 10—Hardening Effect Produced by Preheating with Oxy-Acetylene Torch—No Metal Added

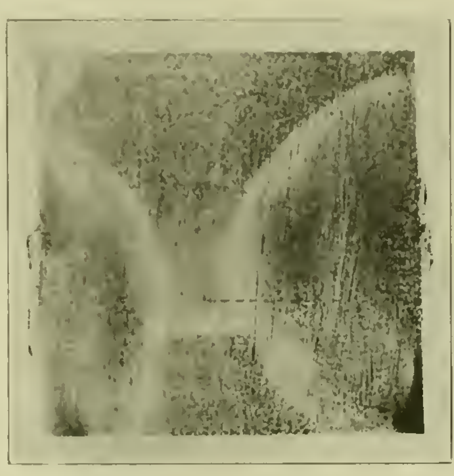

Fig. 11—Hardness Produced by Adding Metal with Oxy-Acetylene Torch After Preheating According to Regular Practice

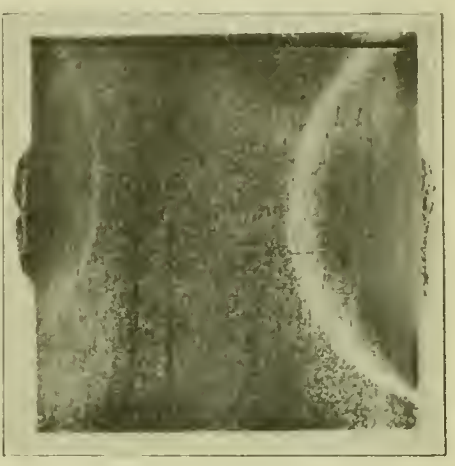

Fig. 12—Affected Zones Caused by Adding Metal with the Oxy-Acetylene Torch Without Preheating

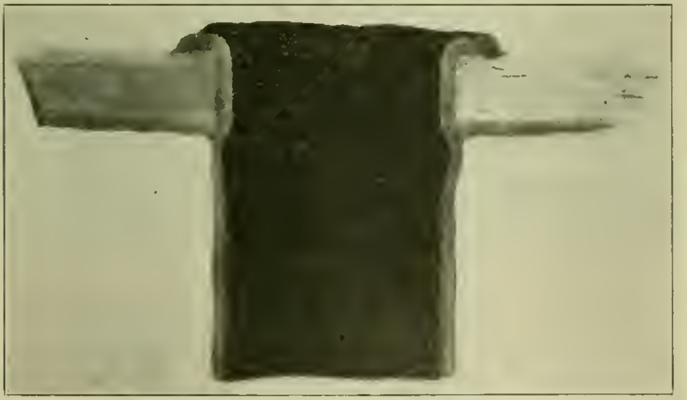

Fig. 13—Etched Section Through a Boiler Tube Welded to the Sheet; Metal of the Sheet Unaffected

Attention is called to the extension of the action of the arc ahead of the added metal, which may be observed in these photographs. It will be noted that the hardened zone extends about the same distance in front and back of the points where the welding operation starts and stops as it does beneath the weld. In a great many cases, in fact in the majority, it appears that a fracture will start by an initial check through the affected zone immediately back of or in front of the added metal, although there have been cases that unquestionably were a detail fracture starting from the area underneath the added metal. Fig. 10 is a piston rod which was preheated with the oxy-acetylene torch, no metal being added. The heat affected area is shown by the shaded zones, with a maximum hardness in the affected zones of 53, whereas the normal hardness in the rod was 44. After annealing, this piston rod showed a normal hardness of 45 throughout the rod section.

In the case shown in Fig. 11 the piston rod was preheated according to the regular practice and metal added by the oxy-acetylene process, producing the affected zones shown. The hardness of the added metal in this case was 32, in the affected zones 53, and in the rod proper 44. On annealing this piece the affected zones were removed; the added metal then showed a hardness of 34 and the rod 44. Fig. 12 shows the same affected zones when the metal was added by the oxy-acetylene process without preheating. The added metal shows a hardness of 32, the affected zones 53, and the body of the rod 42. On annealing, the affected areas were eliminated, resulting in a hardness number in the added metal of 35 and in the rod of 45.

A worn tire flange, with an original scleroscope hardness over the section averaging 49.2, was built up by electric welding. Before annealing the added metal had a hardness of 18, the hardened area of the original metal 67 and the body of the flange 48. After annealing, the hardness of the added metal was 20, that of the affected area 46 and the body of the tire 48.

Fig. 14—Example of Metal Too Poor to Weld

The average of several transverse tests on pieces of rail in which bolt holes were drilled, showed an average depreciation of the transverse strength of about 25 per cent as compared with the solid section. Where these holes were cut with the acetylene flame, this depreciation was 38 per cent.

The photograph, Fig. 13, of the boiler tube welded in the plate and then etched, does not develop the highly affected zones shown in the previous views. In this particular case the hardness number of the plate was 45, in the tube 50, and in the added metal 45. Even if the welding heat did cause unsatisfactory conditions along the lines in question, the service conditions would in themselves constitute more or less of an annealing process.

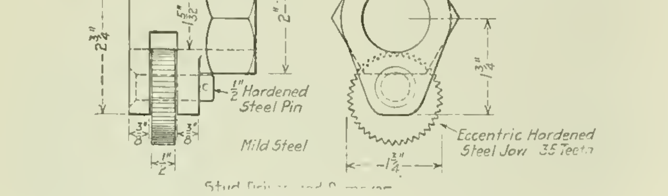
Fig. 14 is a piece of a member of a truck side frame which had been welded with the acetylene flame. It shows an unusually large area affected by the preheating and welding heat, particularly the white zone about the center of the section, which showed a penetration through the entire section. The metal is excessively porous and this casting should, in my opinion, never have been welded unless it was possible to cut away this area entirely.

I do not want to leave the impression that all welds fail on account of the structural changes due to the heating, or that I am advocating not doing any welding at all, or that I am in favor of any one particular process of welding. All the various methods of welding have their proper fields, and a great deal of profitable work can be done with them. However, if the points mentioned are taken into consideration by the party laying out the welding work, our welds will show fewer failures.

Stay-bolt and Stud Driver and Remover

BY F. OSBOURNE

It is the practice in some railroad shops to square the ends of stay-bolts for the purpose of driving with a box wrench or chuck driven by an air motor. This means that stay-bolts have to be squared in a forging machine or by some other method. The use of the devices, illustrated, eliminates the need for squared ends, thus saving a considerable amount of time and labor. The stay-bolt driver will drive 1-in., 1 1/16-in. and 1⅛-in. stay-bolts. If a bolt does not fit properly, it can be taken out with this driver by moving the eccentric steel jaw to grip the bolt, then reversing the motor.



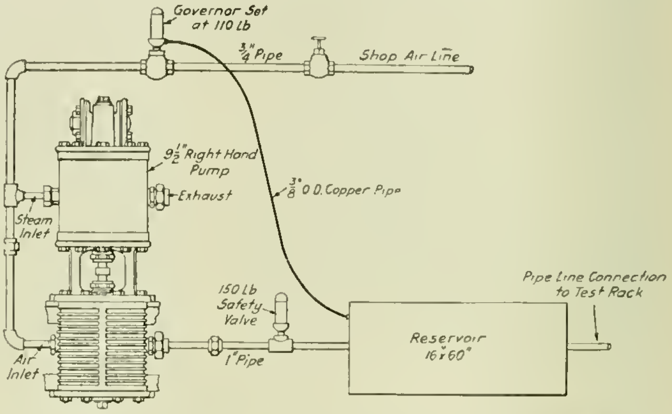
Tools for Driving Studs and Staybolts Without Squared Ends

Part of the stay-bolt driver is made hexagonal to fit a wrench and the other part is made a standard Morse taper to suit an air motor spindle. To use as a stud driver or remover, the device is made up without a Morse taper shank and has a hole bored through the driver. This will allow the eccentric jaw to grip any part of the stud and a wrench may be used. The stud driver shown will drive in or will remove old studs ¾ in., ⅞ in., 1 in. and 1⅛ in. in diameter.

High Pressure Pump for Air Test Rack

BY C. E. YOCUM

The piping arrangement shown in the sketch furnishes a simple means of increasing air line pressure to practically twice its normal value for testing feed valves, brake valves, etc. Air from the shop air line enters the pump at the steam inlet and also at the air inlet. If the pump is on either the upward or the downward stroke the shop line pressure is working on both the steam and air pistons. If the shop air line carries 90-lb. pressure this will give a maximum of 180 lb. per square inch. The governor may be used as shown and any desired pressure carried in the reservoir.



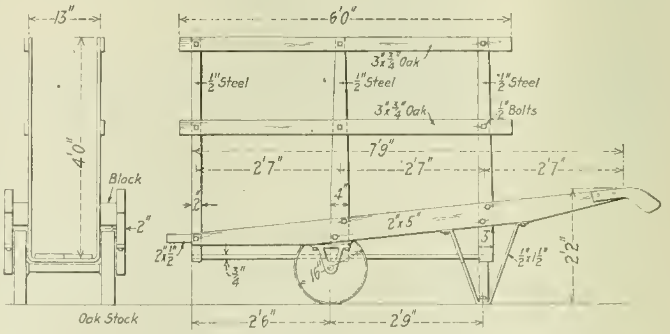
Pneumatically Operated Pump for Supplying High Pressure Air

Truck for Handling Jacket Iron

BY A. G. JOHNSON

Mechanical Engineer, Duluth & Iron Range, Two Harbors, Minn.

When the jacket is removed from a locomotive in the back shops, and is sent to the jacket shop for repairs or to be stored out of the way of other workmen, its removal and handling has always been a disagreeable, inconvenient job. This difficulty in handling can be overcome to a large extent by means of a special truck construction, as illustrated, at a small expense in each local shop. A shop truck is used as the foundation and high sides are provided, open at both ends. The sides consist of a frame-work of iron strips which may be riveted or welded at the joints. This truck will hold the entire jacket from one locomotive and enable it to be moved easily from place to place as desired.



Truck for Handling Jacket Iron

An English Locomotive Repair System*

An Outline of the Methods Followed by the Lancashire & Yorkshire in Putting Engines Through the Shop

BY COL. H. E. O'BRIEN

Assistant Mechanical Engineer, Lancashire & Yorkshire, Horwich, England

ENGINES are stopped at engine houses on the recommendation of either the boiler inspector or locomotive district superintendent, and the receipt of a waybill at the shops is a notification that repairs are required to such engine.

The waybill is filled in in duplicate, by the locomotive district superintendent and forwarded by him to the shops with a tubeplate diagram and a boiler stay chart.

The inspection department, when calling such engines into the shops, pay due regard, after conference with other departments concerned, to:

(a) Particular type of engine most urgently required by running department, varying with the season.

(b) Ability or convenience of the repair shops to deal with such repairs as may be required.

Light repairs are generally dealt with at once.

Waybills

Upon receipt of the waybill at the shops the duplicate is sent to the inspection department.

The waybill is a four-page sheet; on the front outside is stated the number and class of engine, the engine house to which it belongs, date stopped for repairs, experimental fittings (if any), flaws, date of last general repair, mileage since last repairs, mileage of tubes and crank axle, also additional remarks.

A Group of Automatics at the Horwich Shops of the Lancashire & Yorkshire

The first inside page provides a list of main items such as frames, pedestal jaws, wheels, axles, tires, axleboxes, cylinders, valves and valve gear, etc., for the engine and for the tender, with space for remarks.

The second inside page includes boiler fittings, boiler and tender tanks and coal bunkers.

The back, or fourth page, provides space for shop remarks upon details of repairs effected while the engine was in the shop, such as:

(*a*) Date left shop.
(*b*) Whether boiler had been out of frame.
(*c*) Cylinders out of frames.
(*d*) Experimental fittings, also boiler pressure, registered number of boiler, thickness of firebox side, type of valve and thickness of valves.

The bottom portion of this page also provides a space in which the engine house foreman can record the behavior of the engine in traffic during the first six days after receipt from the shops.

When the latter space is filled in, the waybill is returned for the shop superintendent's information and provides ground for exercising disciplinary methods in regard to the shops concerned.

Calling in to the Shops

The number of engines called in weekly depends upon the weekly output of repaired engines.

The number of engines of any one type standing at engine houses awaiting repairs is not allowed to exceed 10 per cent of that particular class.

A forecast of the engines likely to be sent into traffic during the following week is made, based on the above premises, and an equal number of engines are called in from the engine houses.

As far as possible, such engines are called in from particular engine houses as will permit the drivers and firemen of the outward-going engine bringing back with them one of the engines called in for that week, a considerable item in wages thus being saved.

Inspection Prior to Repair

Upon receipt of an engine at the shops for repairs an inspection is made while the engine is still in steam if possible.

This examination includes trial of injectors, whistle, steam sand and cylinder cock gear, cylinders and valves, ejector and boiler mountings in general, also tenders and tanks for leakage, etc.; any items missing are noted, and the brake cylinders and pipes are tested.

Where any of the items are found to be in good order the inspector marks the waybill to that effect.

At the end of the inspection the fire is dropped, tenders and bunkers are emptied of coal (this being transferred to engines coming out of the shops), and the engine is placed in a loop to await a vacancy on the stripping pit.

Stripping Pits

The method of dealing with engines on the stripping pits is as follows:

While fitters are uncoupling the motion and wheels, laborers are emptying the smokebox, taking grate bars out, brick arch down, and sweeping the firebox sides so that as soon as the ashpan is dropped the boiler examiner may examine the firebox.

During the stripping the chargehand stripper thoroughly inspects all parts and decides what bolt renewals are needed in cylinders, pedestals, etc., spring brackets to be cut off for bushing, and his report is added to the waybill sent to the erecting pits.

Heavy repairs (which alone are dealt with on the stripping pits) are, in accordance with the boiler inspector's report, subdivided into the following classes:

Class A.—Engines which have no large structural defects with the boiler and firebox in such condition that they can be repaired in the frames. All repair work for this class of repair should be dealt with as expeditiously as possible as it will be required back again to the engine in 18 days.

Class B.—Cases where the boiler has to be lifted and can be repaired in

---

*Taken from a paper read before the Institution of Locomotive Engineers, England.

erecting shop upon the boiler pit or can be supplied with a spare boiler. This also applies to cylinders.

The work for this class of repair has to be returned to the engine within 21 days.

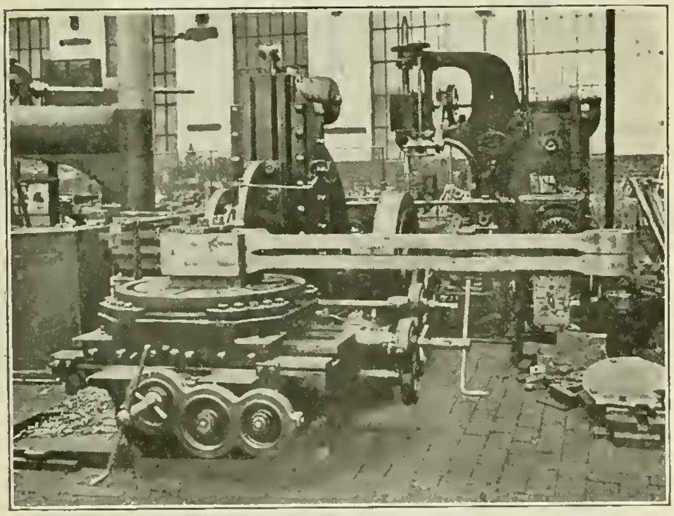
Class C.—All cases of heavy structural repairs such as cylinders, etc., or boilers needing boiler shop repairs. These engines are put outside of the shop when stripped until the main details are sufficiently advanced towards completion as to justify the engine being placed upon the erecting shop pit but no spare boiler is immediately available

Repairs of general details to such engines are not proceeded with in other shops until notice is given, which must be at least three weeks before engine is scheduled out.

The foreman stripper's report having been received in the office on the sixth day, with the order cards which have been made out showing all requirements in the way of new or repaired articles, and also the report from special examiners as to condition of motion, valves and faces, cylinders for renewal or boring, axleboxes, frames, etc., the actual ordering of the material upon the shop concerned is proceeded with.

These printed order cards are made out to the following benches, viz., piston bench, engine repair detail bench, motion bench, brasswork bench, cylinder bench, pick-up and spring bench. Copies are then made on tear-off pads, in triplicate, one set of which, with a copy of the engine house waybill, is sent to the gang foreman upon whose pit the engine is to be repaired; the second set is sent to the material progressman (a description of whose duties is given later), while the third set is sent to the department concerned with the repair or supply of the detail required.

The original order cards are forwarded to the finished work stores in the erecting shop. There each detail which can be supplied from the stock in hand is marked off.



Muir Puncher Slotter Slotting Main Rods

The cards are then forwarded to the holders of the third copy, and the finished work storekeepers' mark indicates to all concerned that such details will not be paid for.

Upon receipt of these cards shop orders are issued to the various gang foremen in the repair department, and as the work is completed the gang foreman enters opposite the article the date of supply; no work can be paid for other than this.

The cards are made to serve as a very useful check upon arrears in the details of any particular engine. Each gang foreman is provided with a box in which he keeps all his cards in three batches, each batch in numerical order; the front group represents material due out from his department in the next fortnight, the second group due out in three weeks, and the third due out in four weeks.

All detail work is expected out of the repair shops at least seven days before the engine is due out of the erecting shops; should, from any cause, an item be still unsupplied on the seventh day prior to the output date of engine, the card is taken out of the box and hung upon a special board provided, which is headed, "Work not supplied for engines due out in 7 days or less." The arrears are thus kept prominently before both the progressman and the foreman, and this has a tendency to keep arrears to a minimum.

In every department in the shops an output board, forecasting the output for the next four weeks, is posted, and this board has the engine numbers rearranged weekly as a result of conferences held in the chief inspector's department with the foremen concerned.

It is easy for the gang foreman, after each weekly alteration, to rearrange his cards accordingly.

In the event of any unforeseen development during the erection of an engine, such as the breaking of castings, or items having been overlooked on the stripping pit, application must be made to the material progressman, who issues a supplementary order card.

Out of shop..................				
Wired away				

Fig. 1—Inspection and Progress Card

This card is of a different color than the ordinary card and has a column in which must be stated the reason for such late order, thus checking any laxity of supervision, reckless handling of material, or carelessness in delivery of repaired details.

Boiler Pit

In the case of an *A* class repair which has been placed on a special pit set aside for boiler repairs, all loose rivets in frames, platforms and splashers are renewed, and bunker sides and bottoms repaired; this work is expected to be completed in 12 days, when the engine is transferred to the erecting shop.

A *B* repair class is dealt with in the same way except that the boiler is in some cases lifted and repaired at the end of the boiler pit while the frames, bunkers, etc., are receiving attention.

If the boiler needs such heavy repairs as tubeplate renewals or ½-side patches, then it is sent to the boiler shop and one of a similar type is pressed forward on the boiler mounting pit so that it may be tubed and tested in time for its delivery to coincide with arrival of frames in the erecting shop.

Where possible, with engines needing *C* class repairs, the frames, etc., are repaired on the boiler pit before being sent outside in order to prevent delay in dealing with the engine when the frames are brought back into the shop.

The following table shows the time allowed to perform the different classes of repairs:

Pit	"A" Repair. Number of days allowed	"B" Repair. Number of days allowed	"C" Repair. Number of days allowed	
Stripping	6	6	6	
Boiler	12	14	14	Note.—"C" type only brought into shops again when work is ready.
Erecting	12	14	18	
	—	—	—	
Total days in shops..	30	34	38	

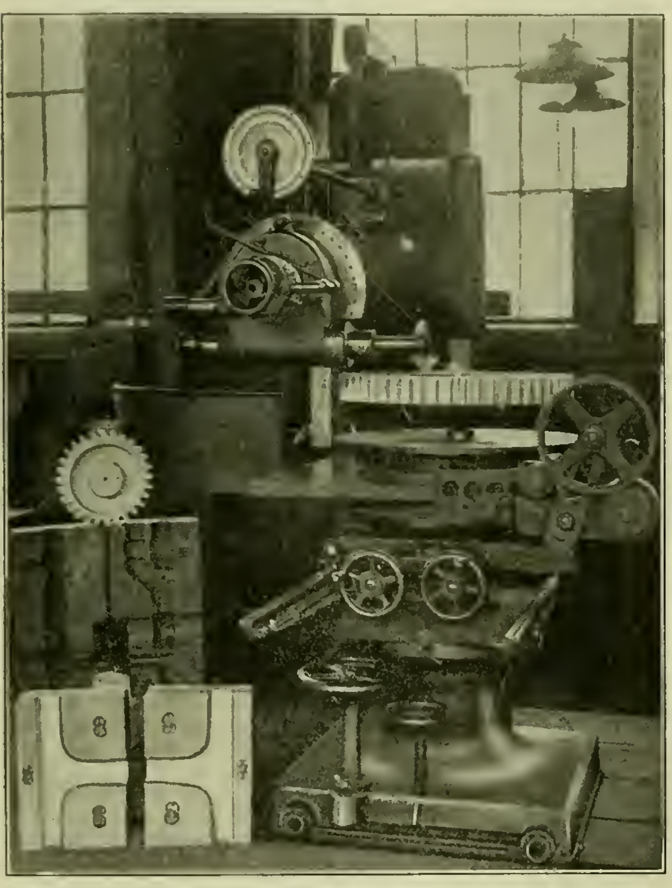
Progress Card

As a final summary of the system of engine stripping, examination and order progression a card system is used, the card being shown in Fig. 1.

These summary cards, described below, when completed, are returned to the chief inspector's office, and a monthly return of the average times taken for the various processes is shown.

Any card not completed within 10 working days of the date the engine goes on the stripping pit is sent to works manager's office for inspection.

The cards will be issued by the shop inspector, and when filled up, returned to his office so that the information may be summarized.



Universal Pattern Making Machine Working On a Spur Gear Pattern

In actual practice the summary for two separate months' working came out as follows:

	April	May
Engines sent away which have cards	59	66
Average days on stripping pit	6.19	6.46
Average days on boiler pit	7.85	6.65
Average days on erector's pit	27.96	26.06
Total time in shop	38.98	37.57
Finished off outside	7.33	6.95
Average days, tubes examined	3.33	3.92
Average days, tubes finished off	7.71	8.9
Average days, boiler examined	2.87	3.01
Average days, wheels examined	4.89	5.00
Average days, motion examined	3.97	4.52
Average days, axleboxes examined	6.09	8.12
Average days, cylinders examined	5.3	6.26
Material delivered to fitting shop	7.5	7.83
Material ordered from erecting shop	7.43	7.49

Duties of Erecting Shop Progressman and Progressing of Material

The delivery of material requiring repairs to the other shops is under the supervision of an erecting shop progressman, who is responsible for seeing that all engine details are stewed or cleaned and delivered to the other shops within 10 days from the receipt of the engine upon the stripping pit.

He is also responsible for the delivery of all repaired details to the erecting pit to schedule, having regard to the position of the engine on the output board.

By a daily perusal of the output board and the duplicated set of ordered material lists he is able to keep his finger on the pulse of the erecting shop, and to anticipate them as much as possible so as to keep items from figuring upon the arrears list (issued daily).

The arrears list, which is compiled by the progressman, contains all items not supplied to engines due out in the next seven days, and a copy is placed before each foreman at the daily conference, and later in the day is put before the manager together with the remarks made at the conference by the foremen concerned.

Twice daily, at specified hours, the progressman is interviewed by gang foremen who want such items as frame stays, pedestal blocks, etc., at an earlier date than the ordinary details; also by others who have material verging upon the arrears date and not yet to hand.

Finished Work Stores

In connection with the locomotive repair organization is a finished work store combined with a central order department.

The function of this store is to provide a daily and yearly record of new and repaired articles supplied to the erecting shop and the outdoor locomotive department. At the same time it insures that a maximum stock is not exceeded or a minimum stock depleted. At any time the stock of any item may be ascertained by the card index system in the store. By this means a system of central ordering is possible—which in its turn permits of articles being ordered in considerable quantities with consequent economy in production. It also provides a perfect and complete check on payment for machining and insures a ready supply for the erectors of the outdoor locomotive department of each article required.

Erecting Pits

The erecting shop crews consist of a gang foreman, five journeymen fitters, three apprentices, one hand driller, who acts also as laborer when not occupied with drilling. An additional laborer divides his time between two pits, sharing in any two-handed job as required, such as pinching or racking engine when valve-setting, replacing grate bars, etc.

Upon receipt of an engine, or frames from the boiler pit, the laborers at once scrape and clean the frames and pedestal blocks; the work of renewing loose pedestal and cylinder bolts is then commenced; where necessary the holes are opened out by drillers with portable electrically driven drills; fractured frames are chipped out to a feather edge and are afterwards oxy-acetylene or electrically welded, all studs upon cylinders and boiler (in the case of an *A* repair) are sounded and doubtful ones renewed, broken ones being drilled out.

Inequalities are removed from pedestal jaw cheeks, and the axleboxes (which, along with the brakework, etc., have been to the stewpot and are now delivered to the pit by the stripping pit gang) are tried up in the pedestal, adjusted and marked off for boring.

If a *B* class repair the boiler will now be to hand, and is at once placed in the frames and fastened down.

While the lagging nailing strips are being fitted on by a floating gang the erecting gang are; in the case of a changed boiler, setting the handrail brackets, jointing the steam teepipe and steam pipes, fitting the ashpan and grate bar brackets.

When this work is completed another floating gang of laborers place the asbestos mattressing in position. The sheathing is then applied, the cab is temporarily bolted, as is the smokebox, and the riveters take these in hand.

Meanwhile the guide bars are set and the motion work with the reversing gear are fitted by one fitter and apprentice, while another pair will have taken the wheels in hand and be mounting the axleboxes, hanging springs, etc., in readiness for wheeling; a fitter will also be engaged during the operations in placing all pipes, in the cab and below, in position.

After wheeling, the engine is placed upon a cradle and the valves are set by micrometer in accordance to figures supplied from the inspection department.

These figures are issued on duplicate slips, and based on vernier measurements taken of ports and valves.

Running Trial

This takes the form of about four hours' working of branch passenger traffic. Before trial the brake is tested by the brake inspector, who is responsible for the vacuum brakes and examination of all accessories.

The inspector keeps and maintains records of the life of all diaphragms and brake parts, and reports monthly upon their life.

It is possible to run four engines per day in this manner, but an average of about three per day is maintained, not including Saturdays. Saddle tank and dock engines, along with steam rail motors, however, are run in the shop yard and do not require to go on the branch line.

In all cases, at the conclusion of the run, the driver makes a report on the behavior of the engines, triplicate copies are then issued, one to the trial inspector, one to the foreman of the erecting department, and the third is sent to the gang foreman, under whose supervision the engine was repaired.

As soon as the engine is ready to go out, it is carefully examined by the trial inspector for possible defects or omitted repairs; the trial inspector takes the engine for a short run in the shop yard, after which, should everything be found correct, the engine is wired into traffic, unless it requires painting. The engine then goes to the weighbridge to have the weights adjusted and during this adjustment the trial driver's report enables the gang foreman to rectify any minor defects that may have revealed themselves on trial. The outdoor locomotive department are informed that the engine is ready for traffic unless it requires repainting.

Paint Shop

Engines are usually a month in the paint shop as all the old paint upon splashers, cab and sides, tanks and bunkers, needs removing with some detergent before repainting.

The covering will, in the majority of cases, have been sent to the stewpans while the engine was on the boiler or erecting pits and therefore is not in need of any further preparation.

Return Into Traffic

As soon as a repaired engine is wired into traffic the waybill is forwarded through the outdoor locomotive department to the district locomotive superintendent of the district to which it is allocated.

The waybill at this stage has upon it the whole of the repairs stated in detail, the condition of firebox sides, thickness of valves, etc., etc., and is accompanied by up-to-date stay and tube charts.

After the engine has been in traffic for six days the district locomotive superintendent fills in on the waybill repairs or adjustments which have been necessary during that period. The waybill is then returned to the shops and the defects are brought to the notice of the foremen for explanation.

Closing Triple Valve Piston Ring Grooves

An efficient device for slightly closing the packing ring grooves in triple valve main pistons is illustrated in Fig. 1 and shown in detail in Fig. 2. The principle of the device is simple, since it consists of delivering a heavy blow on the curved portion of the piston head by means of an air hammer, thus closing the ring groove not only at the outer portion, but the whole depth. This method is used to reclaim pistons with badly worn grooves and thus reduce the number of new ones to be bought.

The device consists of a steel shell turned and bored out to form an air cylinder as indicated. A removable anvil, *A* (Fig. 2) is supported on block *B*, which is drilled and slotted to receive the triple valve piston. Plunger *P* is normally held in its upper position by means of a coil spring and is operated by the piston shown. A packing leather with the customary expanding ring is used to make this piston tight in the cylinder. On opening the operating valve it is evident that a rush of air on top of the piston will cause its downward movement against the compression of the spring and will deliver a heavy blow at the desired point of the triple valve piston.

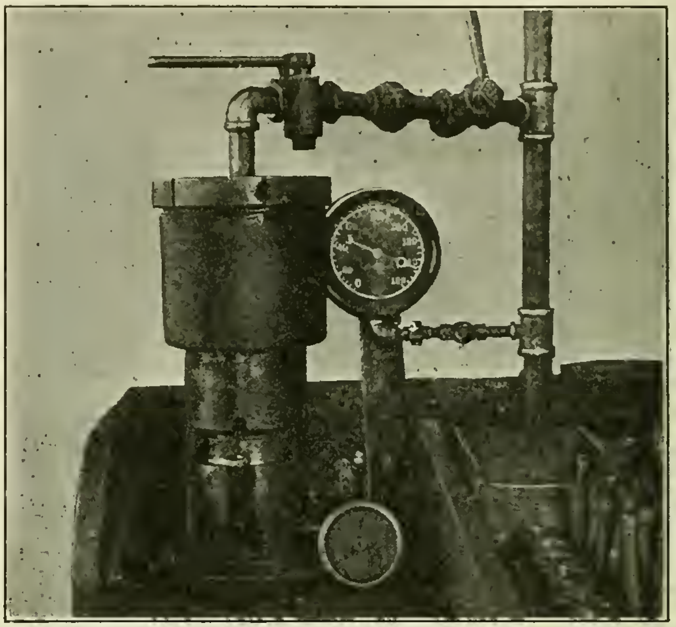


Fig. 1—Device for Slightly Closing Triple Valve Piston Packing Ring Grooves

The triple valve piston is absolutely centered on the anvil block by the holder and is sufficiently closed by one blow with 75 to 90 lb. air pressure per sq. in. After closing the grooves, the pistons are chucked in a small lathe and the grooves machined to the standard width, using a special tool holder. Standard cutting off tool blanks are used in this holder so that the only grinding required is on the end. Piston rings are fitted to the grooves after machining by lapping on fine emery cloth until they will just enter the groove under hand pressure.

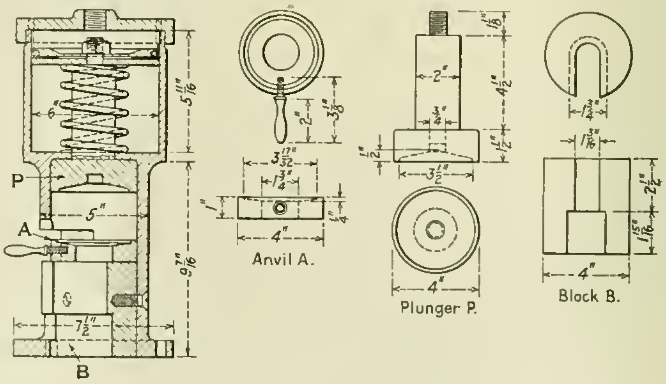

Fig. 2—Details of Groove Closing Device

A Short Cut in Squaring Locomotive Valves

Valves Are Squared by This Method Without Applying the Main Rods and Afterwards Removing Them

BY WILLIAM ULRICK
Foreman Valve Setter, Scranton Shops, Delaware, Lackawanna & Western

AT the present time when it is necessary to obtain maximum production in all locomotive repair shops, the following method of squaring either Baker or Walschaert valve gears without applying the main rods will be found a great time and labor saver. The process has been used for several months with good success, only an occasional readjustment of the valves being necessary, which is likely to happen with any method of valve setting.

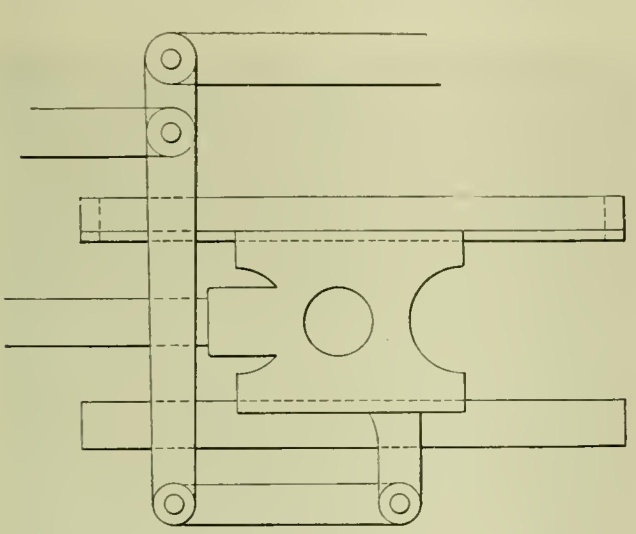

Fig. 1—Positions of Parts With Crosshead and Radius Bar on Center

In practically all railroad shops the practice is to apply main rods before setting the valves and afterwards it is necessary to remove them before applying the side rods. This is an unnecessary repetition of work and can be avoided by the following method. The first operation before setting either of the valve gears referred to is to apply the various parts of the motion work and see that all are in good working order without lost motion or undue friction.

Method of Procedure

After all parts of the motion work are in place, the port marks are taken as usual, using a tram to transcribe the marks to the valve stem. Dead center positions of the crank pin are scribed on the wheel center (right or left as the case may be), using the customary tram. Since the main rods are not up, a special light fish-tail tram has been devised to take their place simply while getting the dead centers. This tram consists of a brass plate cut in the form of a fish tail and bearing on the crank pin at two points. Attached to the brass plate is a light 1 in. by 4 in. wooden strip approximately equal to the main rod in length and having an adjustable scriber at the end. With the crank pin a little above the dead center a vertical line is scribed on the cross-head at a level with the wrist pin hole. The wheels are then rolled past the center until the scribing point on the tram comes back to the original mark. The two positions are marked on the wheel center in the usual manner and dividing the distance between them gives one dead center. The other dead center is obtained in a similar manner.

The main crosshead is now placed in the center of the stroke, determined from the travel marks, with the reverse lever also on center as shown in Fig. 1. If all motion work parts are the right length, properly adjusted, and the link block is at the link center, the center line of the combination lever will be vertical. If the combination lever does not stand vertical, it is due to a defect or combination of defects which will be explained later together with the remedies.

To check the position of the eccentric arm, the wheels are turned, catching either the front or back dead center and with one end of a tram at the center of the link foot, a line is scribed on the guide yoke or any other convenient stationary place. Then the other dead center is caught and the same tram used to scribe a similar line. If the two lines come in the same place, it is evident that the eccentric crank arm is properly located. If, however, the two lines come, for example, ½ in. apart, the eccentric crank arm is shifted on the main crank pin so that the tram mark will come halfway between the two lines. This setting will give the correct location of the eccentric crank arm but if trial shows that a slight error still exists, it will necessitate going through the operation twice.

The reverse lever is now thrown in full gear forward and the nearest center caught, rolling the wheels forward. The position of the valve is scribed on the valve stem, using the tram previously employed to scribe the port marks. The wheels are then rolled and the travel of the valve marked on the valve stem. With the reverse lever thrown to the full gear backward motion, the centers and travel marks are again obtained in the same way.

If the valves are properly set, all marks on the valve stem that were scribed by catching the dead centers, will come in the center of the port marks, because the lap and lead lever is stationary and the valve is not receiving any motion from the cross head. In other words, the effect of the lap and lead lever is eliminated.

The valve travel, as obtained by this method, is for all practical purposes correct since the extreme travel takes place when the engine is very nearly on the top or bottom quarter. This would bring the cross head practically to the center of the stroke, even if the main rod was applied. Port and travel marks when the valves are properly squared are shown in Fig. 2, although it is not necessary to have an equal amount of port opening, front and back, as long as there is the same amount of travel on both sides of the engine. For example, if the right side has 6 in. travel, the left side should also have 6 in. travel, which is obtained by shortening or lengthening the radius bar lifter or short reach rods, as in the ordinary method of valve setting. Fig. 2 is of rare occurrence in the Walschaert gear, as it is impossible in

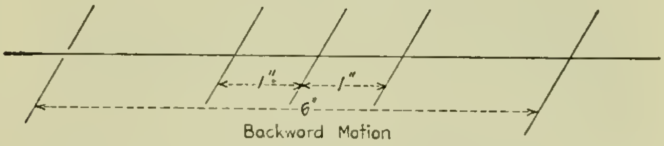

Fig. 2—Port and Travel Marks When Valves Are Square

some gears to get a square valve and the same amount of port opening on each end in full gear. In the Baker gear, it is a bad error as the maximum port opening nearly always will vary from ½ in. to ⅝ in., which cannot be overcome as the gear is at present designed.

Defects and Their Remedies

The positions of tram marks secured when the eccentric rod is ⅛ in. too short are shown in Fig. 3. It is evident that the valve must be moved ahead or to the left ⅛ in. in the forward and back ⅛ in. in the backward motion in order to make the valve square. As indicated in Fig. 3, due to the position of the radius rod, a change of ½ in. in the length of the eccentric rod would produce a movement of the valve of only ⅛ in., due to the ratio of 4 to 1. On account of the forward motion being direct and the backward motion indirect, the eccentric rod must be lengthened ½ in., which will bring both tram marks to the center.

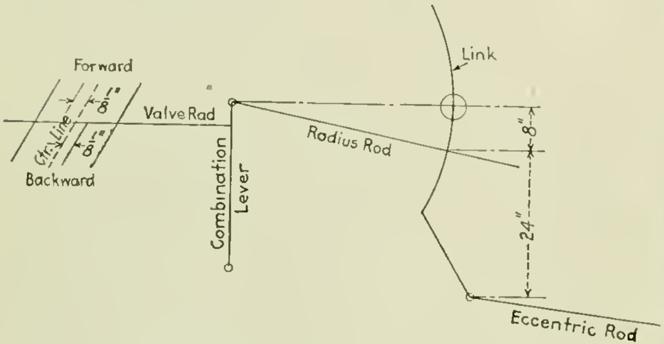

Fig. 3—Effect of Short Eccentric Rod

The positions of tram marks with a radius bar or valve rod ⅛ in. too long are shown at *A*, Fig. 4. It is evident that shortening the radius bar or valve rod ⅛ in. will correct this condition, but the question is, which shall be shortened? The radius bar should be maintained as nearly as possible the same length as the radius of the link, a condition which is easily checked as follows. With the link on center and a radius bar of the correct length, the reverse lever can be changed from full forward to full reverse gear without moving the valve. Alterations in the radius bar are made until this condition holds true. In the above problem, if the radius bar is checked and found to be the correct length, it is obvious that the valve rod must be shortened ⅛ in. or the valve adjusted on the rod, which amounts to the same thing.

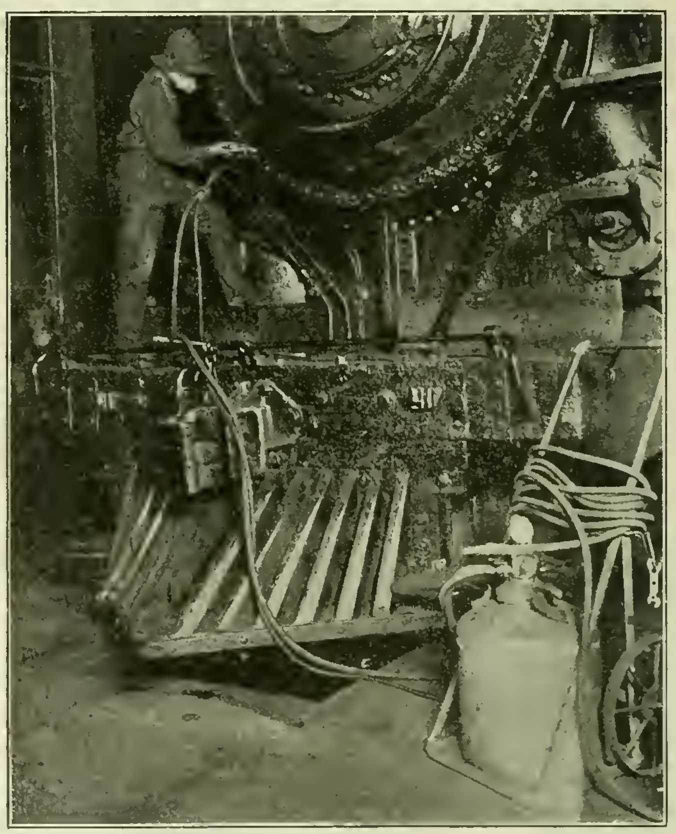
Fig. 4—Effects of Long Radius or Valve Rod and Short Eccentric Rod

The effect of a long valve rod and short eccentric rod are shown at *B*, Fig. 4. Shortening the radius bar or valve rod ⅛ in., will give the condition shown in Fig. 3, which can be corrected by lengthening the eccentric rod ½ in. When the front and back motion marks are all taken, it is advisable to throw the reverse lever nearly to the central position and turn the wheels one complete revolution, taking the complete travel marks. These will come equal distances either side of the port marks, according to the position of the reverse lever. If the lever is hooked up shorter, the distance will be larger; if thrown toward the corner, it will be less. If this is done in the forward motion or with the lever hooked up in the running position, any slight error due to lost motion or irregularity in the valve gear (especially in the Baker gear) will be overcome. If these measurements are not equal a slight adjustment on the valve, by shortening or lengthening, will overcome this error. The method of squaring valves described is not capable of the refinement of some other methods and does not give all of the events of the stroke. On the other hand, it reduces the time required for squaring valves by about three hours and saves the cost of labor for applying and removing the main rods. Several months' actual use of this method has failed to show that greater refinement was necessary.

Paint Spraying Locomotive Front Ends

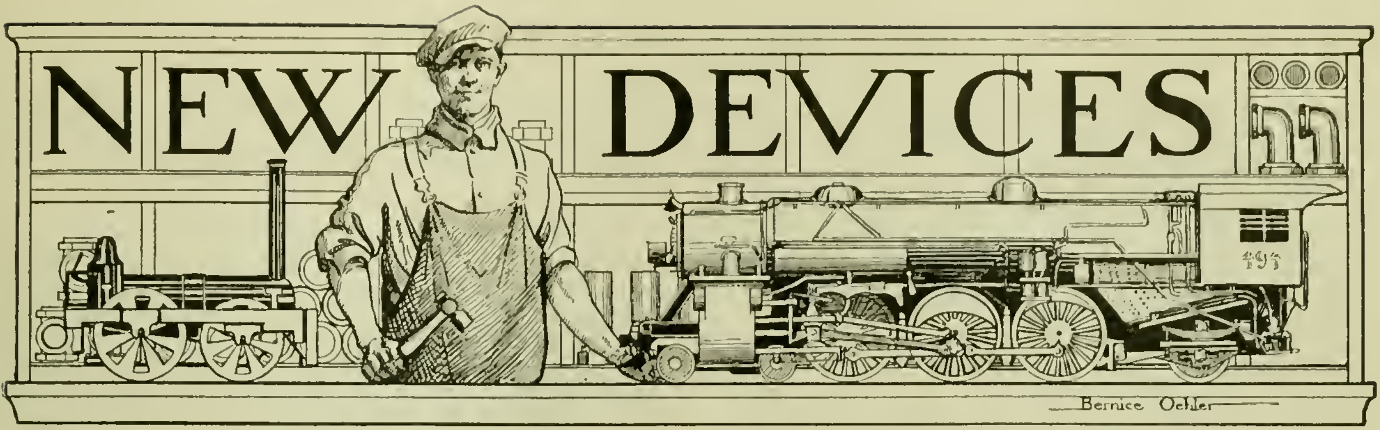
The proper maintenance of equipment requires frequent painting of locomotive front ends and this work consumes a large amount of time where it is done with a brush. To decrease the time required for the operation and permit keeping front ends in good condition, various forms of paint spraying equipment can be used to good avantage.

For greater convenience in moving about, the paint spraying equipment illustrated has been mounted on a two-wheel truck and can be moved readily from place to place by one man. Arriving at the engine to be painted, it is only a question of coupling the air hose, adjusting the respirator and starting to work. The job is finished in a short time and the outfit moved on to the next engine.



Easily Handled Paint Spraying Equipment

Trouble is Sometimes experienced by the lead sticking to the work. This can be avoided by dipping the article in a solution of cyanide of potassium and water—about one pound of powdered cyanide to one gallon of boiling water. This should be used cold and the article permitted to dry before placing in the lead bath. The pieces should be left in the lead only long enough to heat them through. The pieces can be quenched in oil, water or brine, as preferred.—From Houghton's "Steel and its Treatment."



Single Pedestal Swivel Type Car Seat

A CAR seat involving several important changes from the usual type of construction has been invented and patented recently by Frank Smolar, Dayton, Ohio, and will be placed on the market by the Dayton Car Seat & Manufacturing Company of the same city. One of the principal objects of the new invention is to provide a car seat with a back not normally inclined. The occupant inclines the back at will against springs in the arm rests to whatever position may be most comfortable and the springs return the back to its normal upright position when the seat is vacated. The inclined position of the back is indicated plainly by dotted lines in Fig. 1.

Fig. 1—Normal and Inclined Positions of Smolar Car Seat

The new car seat is light in weight, easy to install, and is not connected to the wainscoting. The latter feature eliminates drilling and tapping the wainscoting, and using the window sill as an arm rest. The seat may be easily and quickly assembled and dismembered for cleaning purposes without the use of tools. A greater height than usual is available for steam pipes and there is ample room for suit cases and traveling bags under the seat bottom. An especial effort has been made to secure simplicity of construction without complicated parts to break or get out of order; also a minimum weight consistent with strength and rigidity. The seat may be automatically locked when in either extreme position and is stated to reverse easily, no lubrication being required. The swiveling feature makes it necessary to provide only one foot rest.

A view of the Smolar car seat, disassembled, is shown in Fig. 2. *A* and *B* are the seat and back cushions respectively. The main seat support consists of a steel casting or pressed steel frame work supported upon and guided by the frusto-conical pedestal *D*. Each arm rest *E* is divided horizontally, the lower section having a deep longitudinal recess, containing the anchor piece, spring, slide piece *G* and guide. Tension of both arm rest springs through the connections shown holds the back cushion in its normal upright position. The top section *F* is provided to cover the recess and parts enclosed in the arm rest.

The foot rest *H* is secured by means of two hinges to the main seat frame. A dog is provided which engages the slot in the pedestal and holds the seat firmly in either of its extreme positions. A small spring holds the dog in engagement with the slot and foot pressure on a small pedal casting fastened to the foot rest releases the dog and allows the seat to be swiveled.

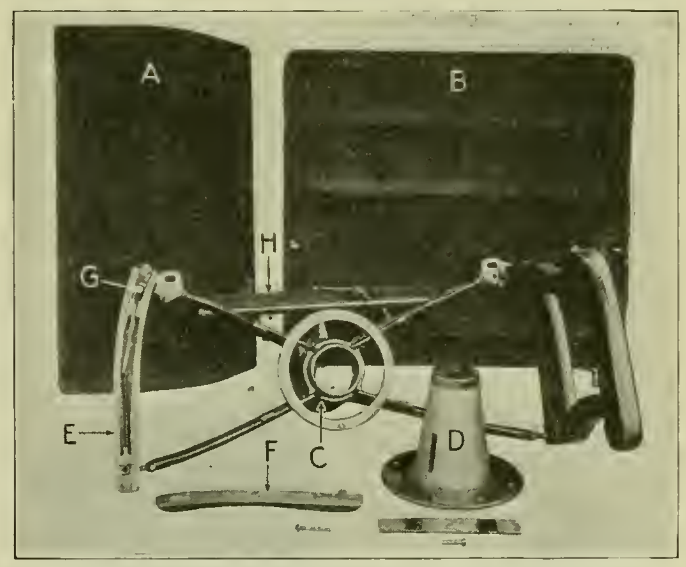


Fig. 2—View of Car Seat Parts Disassembled

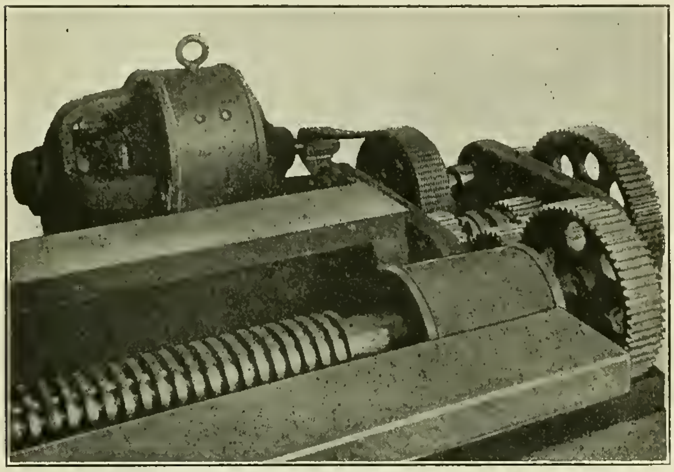
Owing to the fact that the back does not need to be pulled over, cushions for the new car seat can be made to practically any desired height, width or shape to provide the greatest comfort for the passengers.

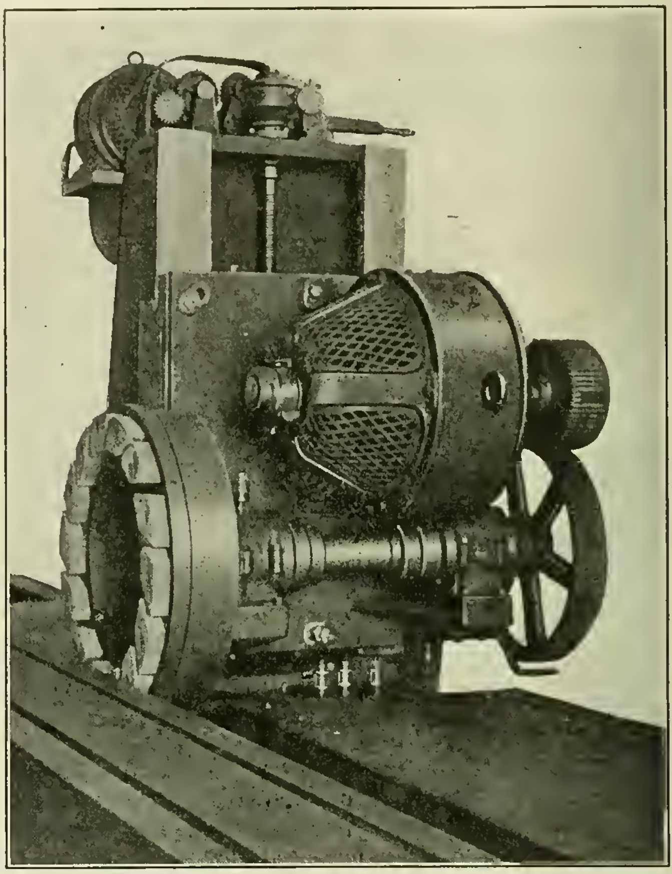
Heavy Duty Motor Driven Face Grinder

A MOTOR DRIVEN face grinding machine intended for heavy duty has been developed recently by the Bridgeport Safety Emery Wheel Company, Bridgeport, Conn. The new machine is arranged to be driven by an alternating current or direct current, 40-hp. motor, operating at a speed of 1150 r. p. m. For driving the lead screw and traveling head, a 7½-hp. motor running at the same speed is used. The grinding wheel is raised or lowered by a smaller 3½-hp. motor running at 850 r. p. m.



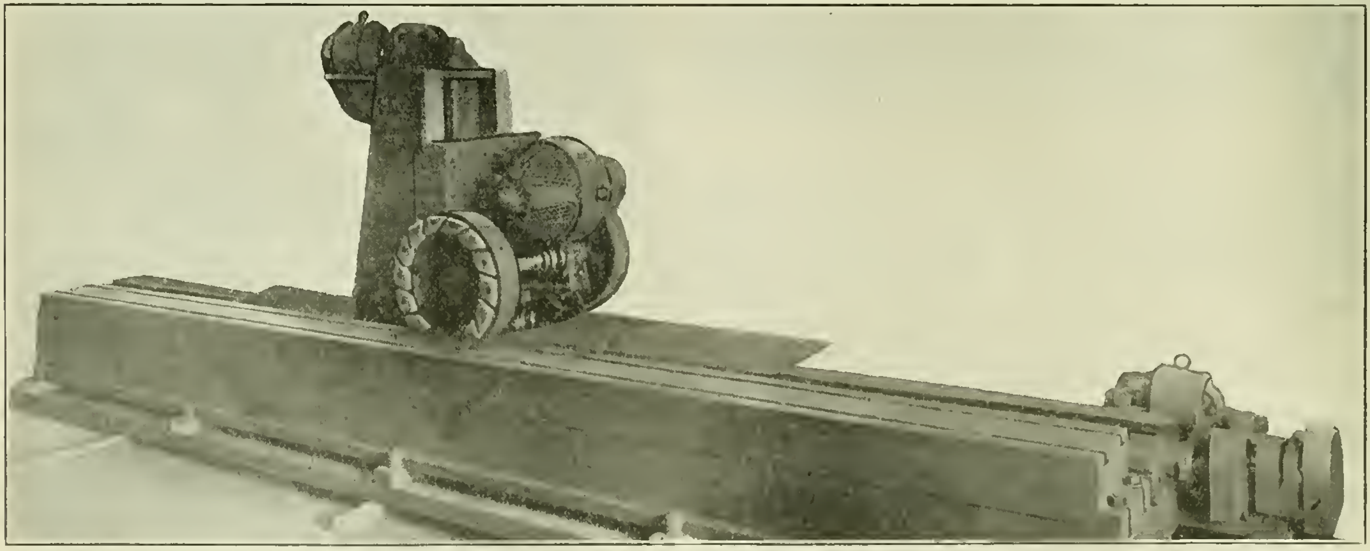
Mechanism Operating Lead Screw

The machine, designed to be set on mason work which forms a solid foundation, has a bed 30 ft. long for grinding work 24 ft. long. The bed has flat top rails, 6 in. wide, over which a short carriage is traversed, gibbed to take up for wear, with a heavy column securely mounted. The column has one upright face finished with wide, flat tracks and a gibbed carriage with a 2-in. elevating screw for vertical movement of the grinding wheel. On this carriage there are horizontal tracks with a carriage for feeding the wheel up to the work. Movement of the carriage is by means of a 1½-in. screw and a 14 in. hand wheel. On top of the horizontal carriage there is a turret pivoted at the center so as to grind the work square across or at an angle, with a clamping screw at each corner to hold the turret firmly where placed. The motor and grinding wheel spindle are bolted to the turret so that both move together when swiveled. The machine has a wide-faced fibre pinion meshing into a gear about twice its diameter on the back end of the grinding wheel spindle. This provides a back gear arrangement of about 2 to 1.



Wheel Drive and Elevating Mechanism

The wheel spindle runs in ball bearings with end thrust ball bearings each way, adjustable endwise for any wear. It is stated that machines have been run constantly for eight years on hard work, with bearings thus constructed, and have given the best of satisfaction. The grinding wheel is made up of 14 sectional blocks forming a wheel 32 in. in diameter, 8 in.



Heavy Duty Face Grinder With Traversing Column and Grinding Wheel deep, with a cutting rim 4 in. thick. An open space is provided between each section for material ground off to work into, as is common with metal-working tools. The motor on top of the upright column, designed to operate the grinding wheel head up or down through spur and worm gears, is back-geared down to a practical speed for the elevating screw. A shifting lever operates the gears to move the wheel head up or down as desired.

A suitable cast iron guard covers the gears on the motor and grinding wheel spindle. There is a 5 in. lead screw through the center of the entire length of the bed, connected at the left hand end to the 7½-hp., motor through a chain drive and a train of spur gears to get the right reduction of speed between the screw and the motor. There is in this train a toothed clutch operated by the shifting lever to revolve the lead screw in either direction to make an automatic traverse of the wheel. The lead screw runs in radial ball bearings at both ends and also has end thrust ball bearings on each side of the box at the right hand end of the lead screw, with adjustments for any slight wear. There are several supports under the lead screw, between the end bearings, to prevent the screw from sagging.

On the front of the column at the bottom is a stop that comes in contact with the shipping dogs for automatically reversing the traverse of the column. These dogs are on a shipping bar extending the full length of the bed, supported at about five points, and two shipping dogs between each bar support, pivoted so they can be thrown back quickly out of the way and only two of them used as required to cover the range of travel desired.

There is a work supporting bed the length of the machine, with a working face 18 in. wide, having two T slots the full length. The work is firmly bolted to this bed so the face to be ground comes in contact with the grinding wheel; if the work extends back from the table to any great extent, it should be supported by suitable horses. A full length supplementary table, 10 in. deep, is provided to go on the work table when small pieces or sheet stock is to be ground.

Tube Safe End With Square Shoulder

A NEW design of tube safe end, manufactured by the Coleman Boiler Appliance Company, Los Angeles, Cal., is provided with a square shoulder and a taper fit in the back tube sheet, the ends being beaded over as usual but not electric welded. The principal object of this new safe end is to hold the tube firmly against movement in either direction and eliminate leaks in the firebox, thus increasing the tube mileage and reducing engine failures due to leaky tubes. It is stated that the Coleman safe end is particularly effective in bad water districts and can be used successfully on oil burning locomotives. It has been tested over a period of 30 months on the Atchison, Topeka & Santa Fe with satisfactory results and is now being introduced on other prominent roads throughout the country.

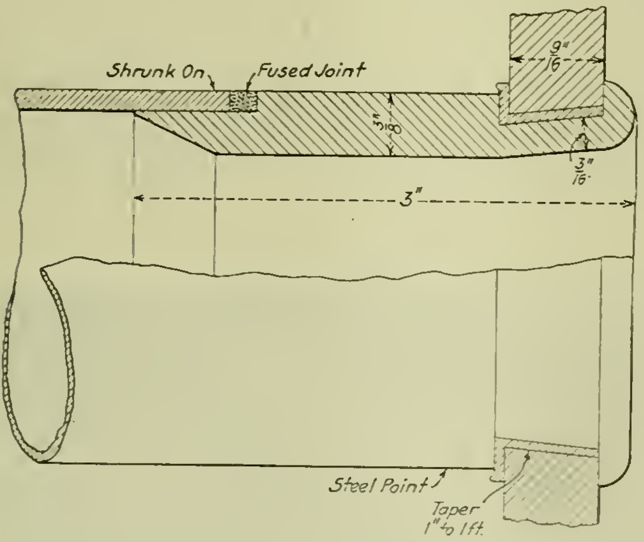


Fig. 1—Cross Section Showing Application of Coleman Safe End to Boiler Tube

The inherent objection to the common type of safe end, set by means of roller and Prosser expanders, is that the semi-circular corrugation on the water side of the tube sheet touches the copper ferrule at the edge only and cannot prevent more or less working of the tubes due to expansion and contraction. This working is bound to cause leaky tubes even when they are electrically welded and the results are serious and costly engine delays on the road and at terminals.

To overcome the above structural weakness, the Coleman tube safe end has a square shoulder, as shown in Fig. 1, which is pressed solidly against the copper ferrule and tube sheet. The tube sheet hole is slightly tapered (2¼ in. to the ft.) and the tube end is beaded over as usual. It will be obvious that the square shoulder prevents movement of the tube toward the firebox. The beaded end, in conjunction with the taper bearing, holds the tube against forward movement and this construction, by preventing any movement of the safe end in the tube sheet, eliminates leaks from this cause.

A comparison of the Coleman and the Prosser expander methods is shown in Fig. 2 and attention is called to the smaller tube sheet holes required. This results in wider bridges and therefore increases the strength of the tube sheet which will offer a greater resistance to stretching when the tubes are worked. Tools used for applying the Coleman safe end are the same as for the standard safe end, except that the Prosser expander is eliminated and a sectional expander with the correct taper substituted. A roller expander arranged to give the proper taper of 2¼ in. to the foot is used only on the initial installation of the tubes.

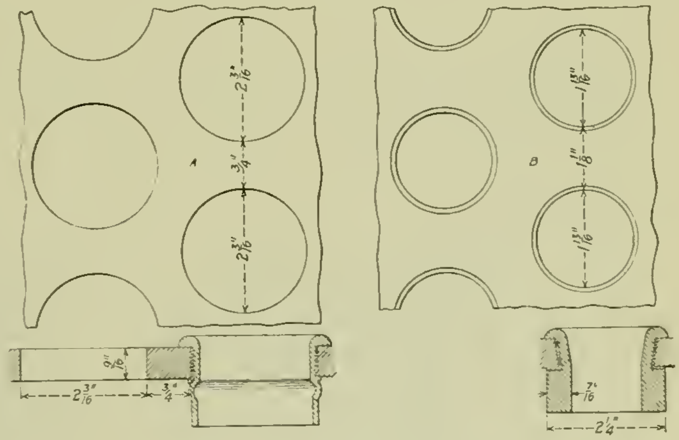

Fig. 2—Comparison of Prosser Expander and Coleman Methods

Elimination of the Prosser expander is an important advantage. After the old style tubes have been prossered two or three times, the tubes will be damaged by any further use of this tool unless exceptional care is taken. The use of a sectional expander without the Prosser, however, does not distort and weaken the tube nor cause it to crack on the water side of the sheet, as is often the case with the old style tube which requires frequent working to keep it tight. It is stated that owing to its structural design, the Coleman tube safe end requires about 10 per cent less working than the straight safe end which has been prossered.

In applying the new safe end to an old tube, the tube is shrunk on, as shown in Fig. 3, leaving a small space to be filled in and form the fused or welded joint. Either the electric or oxy-acetylene process may be used in making the weld, which is said to cost less than the ordinary lap weld and to be less likely to fail in service. The value of the Coleman safe end as a safety device is based on this claim.

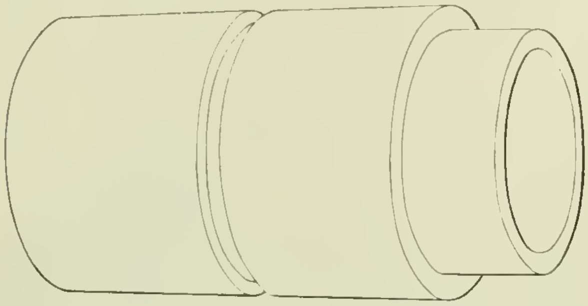

Fig. 3—New Safe End With Tube Shrunk on, Ready for Welding

Many tubes start to work in the tube sheet and leak soon after being applied because of sagging, especially when very long. Moreover, some tubes sag more than others, thus causing an uneven contraction and expansion. In order to prevent the above conditions, which are bound to result in leaks, a simple, inexpensive tube support has been designed as shown in Fig. 4. The first row of tubes is supported at the center on one continuous strip of iron properly bent and set on the bottom of the boiler. Above this row, individual supports of the form illustrated are used. Fig. 4 also shows a perspective view of the copper ferrule used with the new safe end.

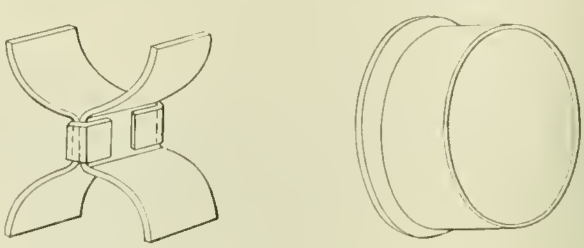

Fig. 4—Tube Support and Copper Ferrule

Careful tests indicate that the use of Coleman safe ends greatly increases the life of tubes over that obtainable with former methods of safe ending. In addition, leaky tubes are practically eliminated, thus reducing engine failures and delays on the road and at terminals. As a further important advantage, it is maintained that the decreased size of tube ends at the firebox tends to cause more complete combustion and make a better steaming locomotive; also one which burns less coal to develop the same tractive effort.

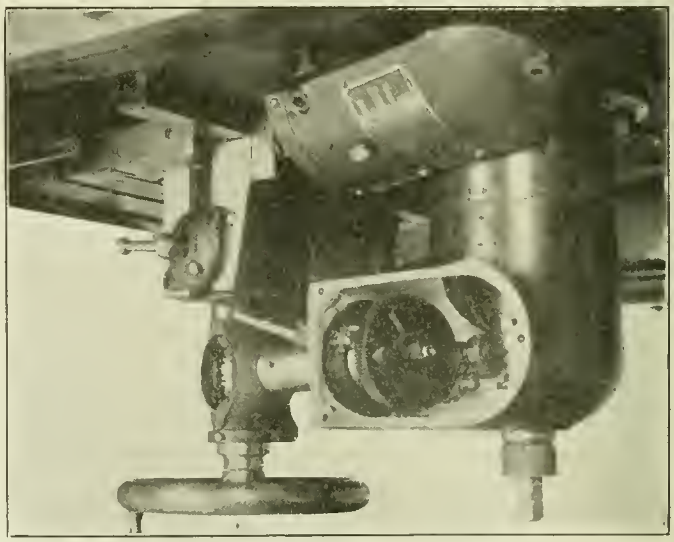
Two-Unit Feeding Device for Shapers

SIMPLICITY and sturdiness are features of the new feed for shapers introduced by the Queen City Machine Tool Company, Cincinnati, Ohio. The device consists of two units, the one at the bull wheel bearing regulating the amount, and that at the rail screw, the direction in which the table will be moved. At the end of the long bull wheel hub, a large face cam is mounted, revolving with an easy undulating motion and immersed in oil. The action of this cam through the large roller to the ratchet pawl is in a straight line, without links or intermediate parts, causing very little strain to the swinging arm that carries the roller.

The ratchet wheel is unusually large and drives the splined sleeve of the feed shaft through the medium of a safety friction. This is a great advantage, when it is considered how easily the table can be run to the limit of its traverse, or a wrench accidentally dropped where it will interfere with its working. If adjustments are necessary they can be made as easily as clamping the tool and with the same wrench, but powerful spider springs provide a driving pressure ample for all needs and an automatic "take up" for wear.

The swinging arm, mentioned as carrying the roller and pawl, has a large bearing on the outside of a sleeve which is pressed into the housing, upon the inside of which the double splined feed shaft sleeve is fitted. The swinging arm is held toward the cam by a long torsion spring. The amount of feed is controlled by a stop on the adjusting handle extension inside, which acts to limit the swing of the roller arm, the spring being automatically varied to the tension required by the movement of the handle. The feed controlling lever can be placed in zero position, at which point no part undergoes wear, or is in motion, and the movement of the parts is always proportionate to and no greater than the amount of feed which is being used throughout the sixteen changes provided.

The reverse box lever indicates, by its position, the direction in which the table will move and starts and stops the feed. The box contains the familiar bevel gear and clutch construction, the clutch teeth being integral with the gears and strongly proportioned, and the mesh of the gears being adjustable for wear. The use of a partition back of the cam, and the liberal use of felt oil retaining rings and wipers, makes practical the use of splash lubrication. The journals are all ground and of large proportions. The roller, pawl, ratchets, etc., are hardened and ground and the cam is accurately ground on a special machine.



Queen City Shaper Two-Unit Feed

The sliding connection to the rail is rigidly supported by a long sleeve. The driving keys are long and the shaft, by its position, prevents any binding tendency. All moving parts are enclosed and dust proof. The convenience of control is obvious, the feed always taking place upon the back stroke of the ram without attention or adjustment.

A strict schedule of interchangeability is maintained with a complete equipment of jigs and gages. It is stated that in a severe 55-hour test at excessive speed against a brake no weakness developed in this new feed.

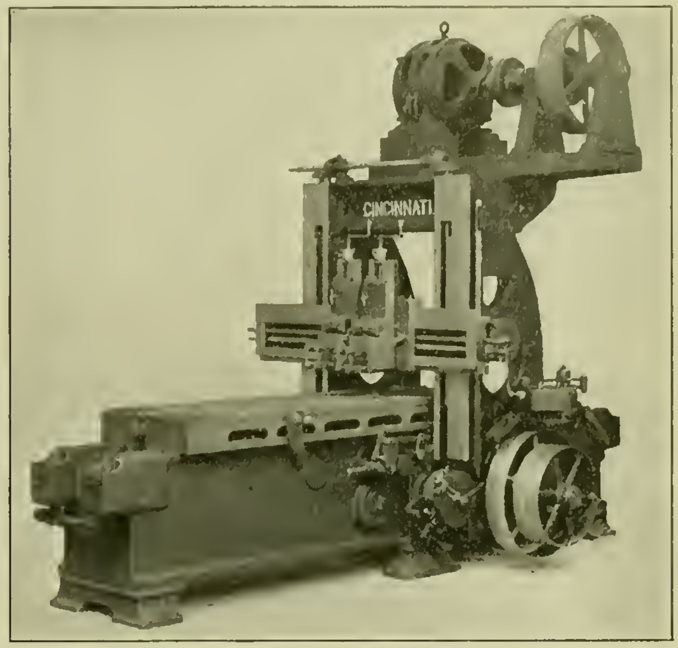
Thirty-Inch Shoe and Wedge Planer

Recent improvements in planer construction have been incorporated in the 30-in. shoe and wedge planer illustrated. The new machine, which is made by the Cincinnati Planer Company, Cincinnati, Ohio, is designed for heavy service and the extra heavy box bed has a cast closed top over its entire length except where the bull wheel meshes into the rack.

Herringbone gears and all steel gearing in the bed provide for uniform power transmission to the table and little possibility of interrupted service due to gearing troubles. All gears are well oiled by means of a force feed lubrication system. A deep and strong box table reduces the possibilities of springing and getting out of shape to a minimum. For convenience when setting up work, the stop holes are drilled all the way through the upper half. This saves time usually required for cleaning out stop holes before inserting a stop. The lower half, which is cast solid, prevents the dust and chips from falling through and into the vees.

Each housing extends to the bottom of the bed and is fastened in correct alinement to the side of the bed by means of a tongue and groove, bolts and dowel pins. The faces of the housings are exceptionally wide to provide a proper bearing surface for the back of the rail. A heavy box arch, provided for tying the housings together at the top, affords increased strength and rigidity. As noted, the saddle has a wide bearing surface on the rail.

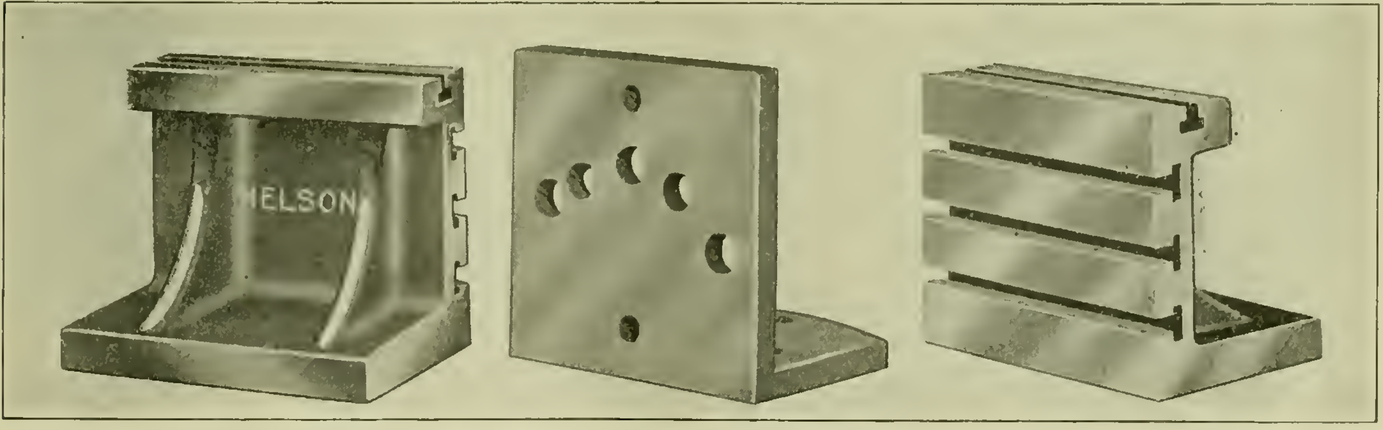
Both tool heads are mounted on one saddle, causing them to move crosswise in unison, but provision is made for moving them up and down independently by hand or by power. The widened bearing surfaces, in addition to the exceptional weight, strength and rigidity of all parts, assures a rigid cutting tool and a firm, smooth planing action. The new planer is regularly equipped with a two-speed counter shaft but can be conveniently arranged for plain or variable speed motor drive as shown in the illustration.



Cincinnati 30-In. Shoe and Wedge Planer

Angle Plate With Second Face and T-Slot

An additional face and T-slot have been provided on a 90 deg. angle plate manufactured by the Nelson Tool & Machine Company, Newark, N. J., and placed on the market recently by the Fairbanks Company, New York. This angle plate is made of high grade iron machined accurately and true to master plates, all T-slots being formed by milling. By means of an additional T-slot in the second face, work can be strapped in either of two planes, whichever is more convenient for the rapid, accurate machining of the piece. Nelson angle plates are made in four standard siges: 3 in. by 3½ in., 6 in. by 9 in., 10 in. by 12-in. and 14 in. by 18 in.; larger sizes are made to order. They are adapted for use on shapers, planers, millers, drill presses and other machine tools in railroad shops.



Comparative Views of Nelson and Home Made Angle Plates

Advantages of the Nelson 90 deg. angle plate as compared to a home-made angle plate are indicated in the illustration and include greater rigidity, greater ease of set up and adaptability to a greater variety of work due to the second holding face. It may be that the first cost of the home-made angle plate is low, but the final cost is high if account is taken of the time lost in setting up jobs with this type of angle plate which necessitates looking for special clamps and drilling holes for nearly every job.

With railroad shop machinists receiving 85 cents an hour for their time, it is evidently good economy and wise shop management to furnish an ample supply of jigs and fixtures which will facilitate machine operations and eliminate as far as possible time spent in setting up work. In many cases special jigs and fixtures can be manufactured locally in the shop where they are to be used, but when such home-made jigs are not as effective time-savers as similar products on the market at a reasonable price, the latter should be purchased and allowed to earn dividends on their own cost and on the cost of expensive machines with which they are used.

Bolster Attachments for Metal Draft Arm

The reinforcement of wood cars having weak draft sill and center construction has received much attention during the past few years. One of the most common methods of reinforcement is by the application of some form of metal draft arm. The application of such arms, of either structural or cast steel construction, in many cases makes practicable the retention in service of classes of equipment which otherwise would be too weak to withstand successfully the severe shocks of modern operating conditions.

In developing a program of reinforcement to these old wooden cars it may frequently occur that several classes of equipment with varying dimensions may be involved. In order that a minimum number of separate draft arm designs may be developed to meet the requirements of all classes of equipment involved in a given program and to provide a thoroughly satisfactory means of attachment of the draft arms to the bolsters, a scheme for the use of filler blocks and shims to compensate for the variations in the dimensions and location of the bolsters, without requiring a change in the draft arm itself, has been developed and patented by R. C. Taft, Moline, Ill. In all ordinary cases the scheme presupposes two designs of draft arms, one for all classes of high cars where the bolster passes under the center sill and another for all classes of low cars where the line of draft is between the center sills with a few possible exceptions. The proportions of these draft arms may be worked out on the basis of a composite diagram showing the location of the body bolster with respect to the end sill and its width and depth, for each class. The openings of the recesses in the draft arms are then designed to suit the maximum dimensions of the composite diagram.

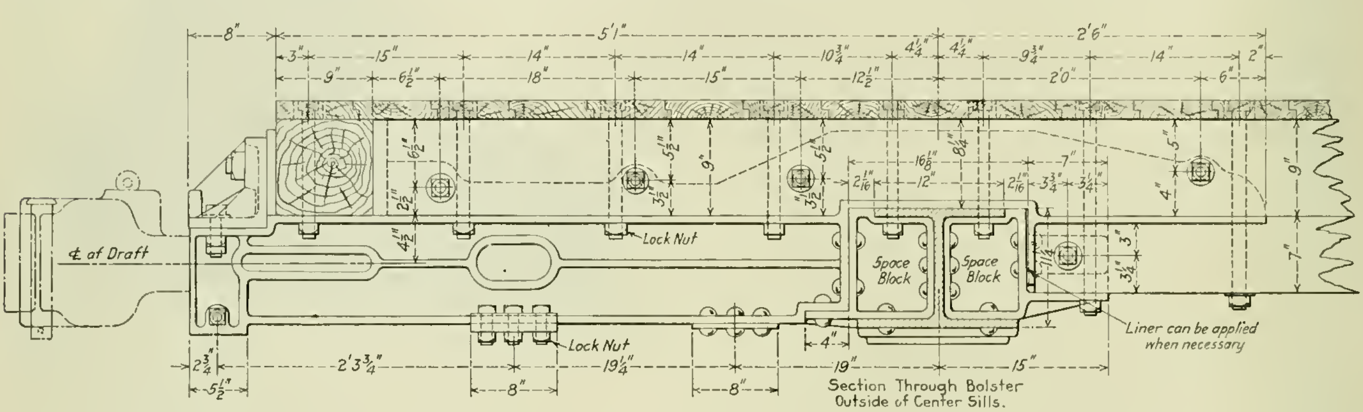


Fig. 1—Application of Spacing Blocks to a Cast Steel Draft Arm

In order that the draft arms thus standardized may be attached rigidly to the bolster in each case, filler blocks or shims, or a combination of the two, are designed for insertion between the bolster and the faces of the recess in the draft arm so that an unbroken metal path is provided between the draft arm and bolster for the transmission of buffing and pulling stress.

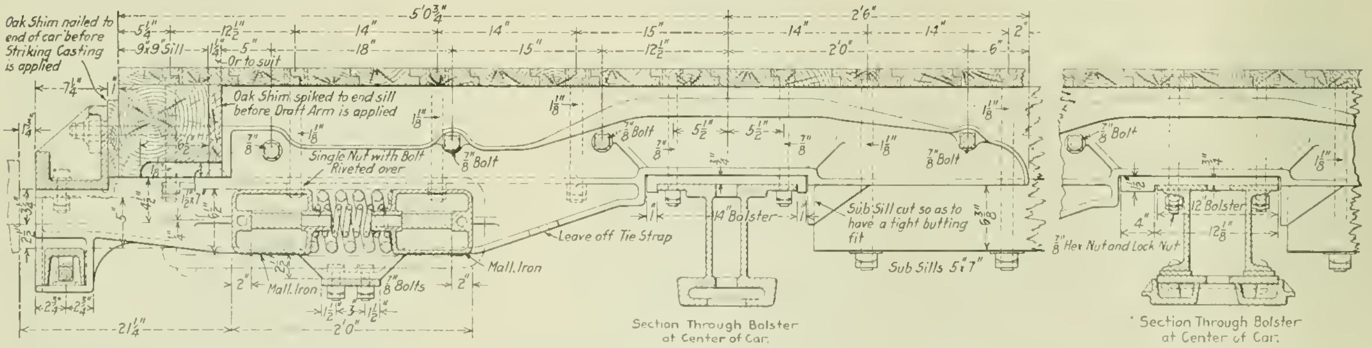

Fig. 2—Application of Shims With Cast Steel Draft Arms to Body Bolsters on High Cars

A typical application of cast spacing blocks in connection with a cast steel draft arm is shown in Fig. 1. Here it will be seen that the blocks are cast to fit the contour of the channels between the flanges and web of the H-section cast steel bolster, and that the forward spacing block is provided with a horizontal flange which is riveted to the bottom flange of the draft arm. Similarly, the rear spacing blocks have horizontal flanges extending under the ends of the sub-sills, which are butted against the rear vertical flanges of the bolster pocket in the draft arm. It will readily be seen that by variations in the dimensions of these filler blocks the same draft arm may be applied to cars with considerable variations in the location and dimensions of the body bolster.

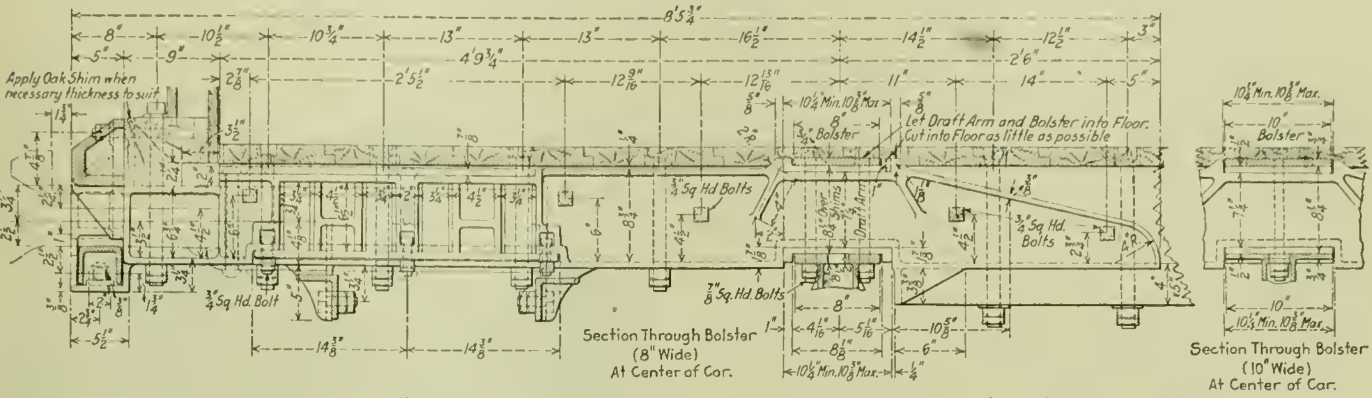

Fig. 3—Application of Shims With Draft Arms to Body Bolsters on Low Cars

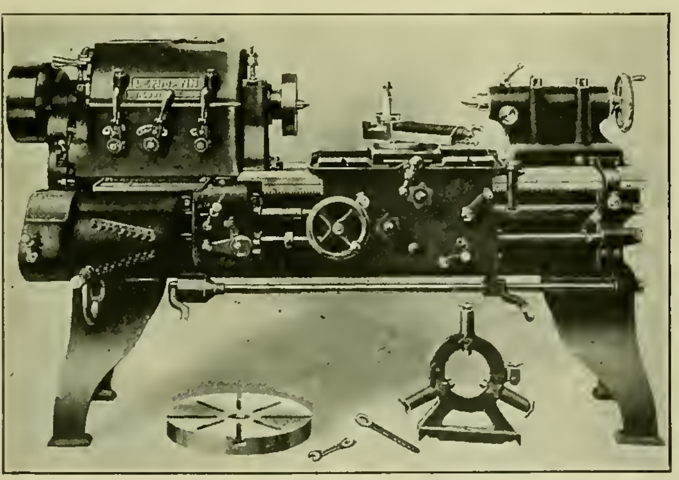
The use of shims instead of filler blocks on a similar application is illustrated in Fig. 2. This drawing clearly shows the method of adapting the draft arm to two sets of conditions. The flanges on the shims provide a complete metal-to-metal structure through the top or tension member of the bolster, for resisting stresses on the direct line of draft.

The method of using shims in the case of low cars, where the line of draft and the draft arm pass through instead of over the bolster, is shown in Fig. 3. These shims may be varied in dimensions as required to suit the relation of the bolster to the recesses in the draft arm.

Either the cast blocks or the shims may be utilized in the application of steel underframes to wood equipment. Their use has the same advantage of a standardized underframe design, a minimum of alteration in the car itself, and the solid anchoring of the bolsters in the underframe that obtains in the case of draft arm reinforcement.

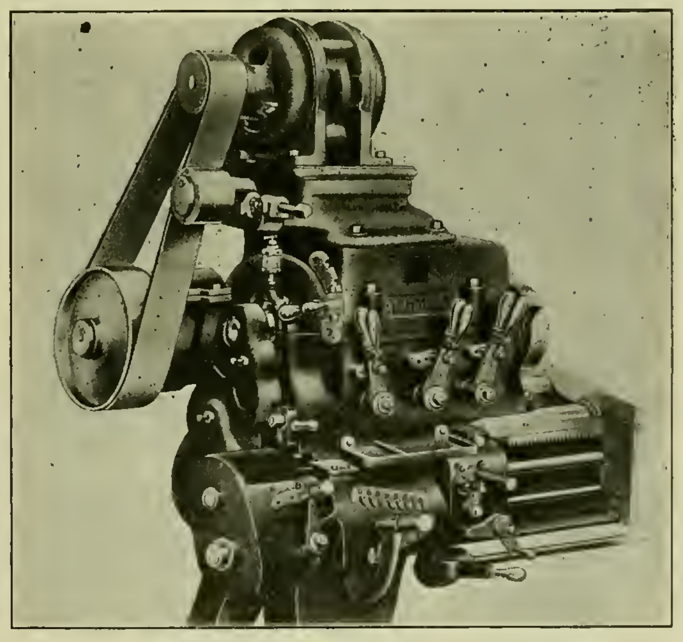
Compact Selective Head Engine Lathe

For toolroom work, especially where it is desirable to have a large number of speeds available, the improved, geared-head engine lathe manufactured by the Lehmann Machine Company, St. Louis, Mo., will be found well adapted. The lathe is built in a number of sizes and 16 spindle speeds are provided, ranging from 10.5 to 422 r.p.m. on the 16-in. lathe, and 8.5 to 330 r.p.m. on the 22-in. machine. These speeds are in almost exact geometrical proportion and are obtained without the use of a countershaft. Tooth travel of the 10 gears used in the head stock is moderate at all spindle speeds, which tends to make a quiet running machine. No safety or interlocking device is required to avoid engagement of different gear ratios at the same time, as the particular design makes it impossible for this accident to occur.



Lehmann Selective Geared Head Engine Lathe

Made of high carbon steel and running on ball bearings, all shafts with sliding members are provided with four keys milled integral with the shaft. Each shifting member is operated by a ring which runs in a groove completely encircling it, the compensating mechanism which connects the ring with the operating shaft being of substantial construction. Gear ratios of 57.1 to 1 and 70.6 to 1 are provided on the 16-in. and the 22-in. lathe respectively. This gear ratio permits the use of a high speed driving shaft and the large diameter driving pulley which gives a desirable belt speed and reduces the strain on belt and bearings. All part of



View Showing Application of Motor Drive

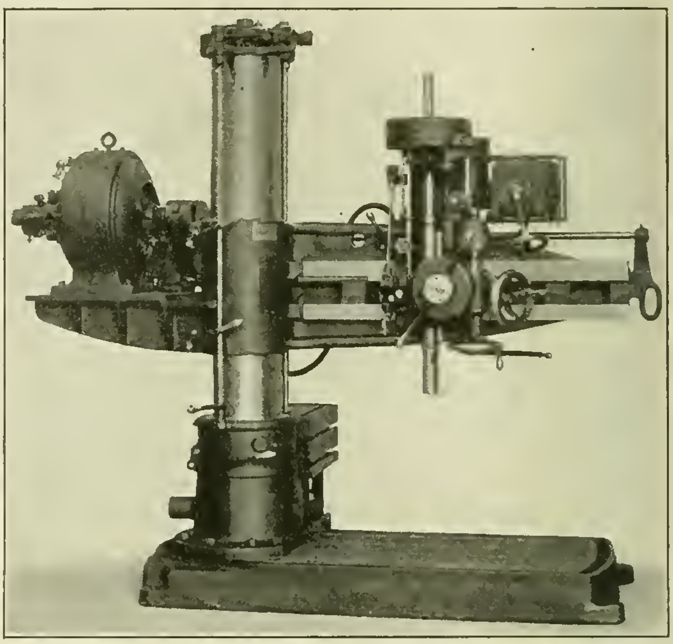
the head stock are designed to transmit power for the heavy cuts which can be taken on this machine.

The most popular drive for Lehmann lathes is a direct drive from a motor mounted on the head stock. Power is transmitted through a short belt and idler running on ball bearings and having ample arrangements for adjustment. With the fast belt travel this is found to be a satisfactory drive and no trouble is experienced on account of the short belt. In fact, the belt pull is much less than usual on account of the large diameter and high speed of the driving pulley. A high speed motor operating at 1800 r.p.m. is used, with a suitable guard provided for the belt and pulleys. If desired, motor drive can be furnished with the motor mounted on a base hinged to the leg of the lathe.

New Drive for Heavy Duty Radial Drill

A RECENT development of the Fosdick Machine Tool Company, Cincinnati, Ohio, is the new type of motor drive furnished on the company's 4, 5 and 6-ft. heavy duty radial drills. The illustration shows the Fosdick 4-ft. heavy duty radial drill with a 5-hp., three to one variable speed motor, on the arm, and a Cutler-Hammer controller directly on the spindle head. The saving of power through the elimination of two sets of bevel gears is a big advantage; also the location of the motor away from dirt which accumulates about the floor. The swinging arm is partially balanced, and additional floor space about the base is available.

The outstanding feature of this particular application is the standardized drive; that is, three to one variable speed motors of any standard make or speed may be used, thus avoiding the customary delay caused by making special patterns and castings for each particular type of motor. A Bakelite pinion on the motor shaft varies in size according to the speeds of the motor as selected. All other gears (aside from the elimination of the bevel gears) are kept standard. Special stress is laid on the fact that but one motor is used. The elevating mechanism is driven from this same motor through the regular standard gear arrangement, whereby all the safety devices are retained.

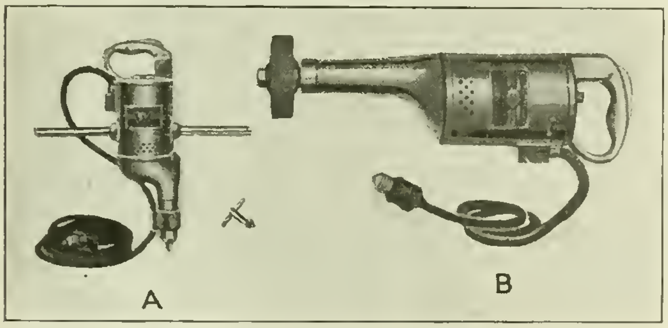


Fosdick 4-Ft. Heavy Duty Radial With New Motor Drive Arrangement

The controller, as shown mounted on the spindle head, is made more convenient of operation by the bevel gear connection to the handwheel below it. This type of control is preferred in shops where the work is usually on large castings with the spindle head frequently at the upper and outer extreme travel. A more popular location for the controller is on the arm girdle, convenient to the operator's left hand. This eliminates the large flexible conduit as seen in the rear of the arm, and is the most satisfactory position for the average run of work.

Portable Electric Drill With Automatic Switch

A LINE of portable electric drills and grinders, in which automatic power control similar to that in general use on all portable pneumatic tools, has recently been developed by the Wodack Electric Tool Corporation, Chicago. The special feature of these tools is the switch, the operating member of which forms part of the hand grip, so arranged that the pressure of the operator's hand closes the switch and is required to maintain it in the closed position. With the release of the operator's hand from the grip, the switch automatically opens. The switch itself is designed as a complete unit separate from the drill case and is enclosed in the vertical support at the front end of the hand grip.



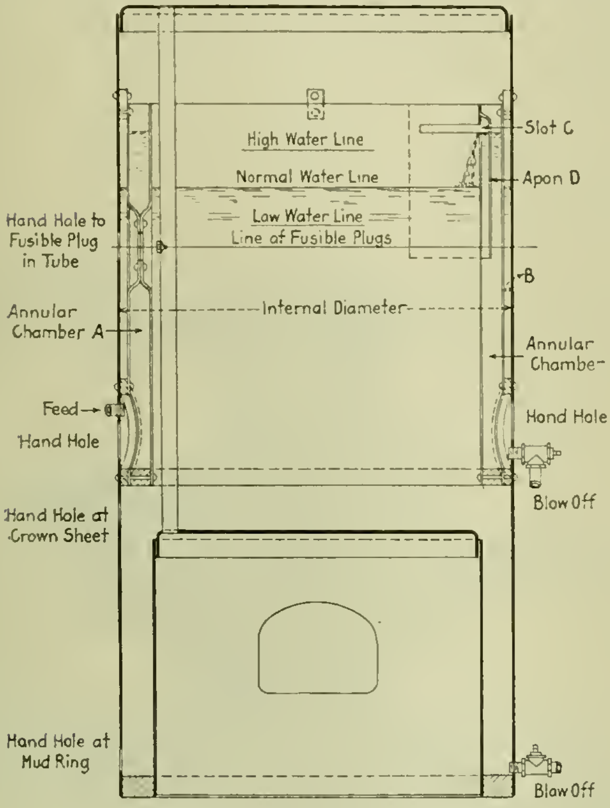
Wodack Portable Tools Equipped with Automatic Stop Feature

The motor and gear casing is of aluminum and a ventilating system is provided by which a positive flow of air is drawn into the casing, over the motor windings and forced out of the casing. In the design of these tools attention has been given to the elimination of screws, bolts and nuts to the fullest possible extent. In the design of the brush holder care has been taken to avoid the possibility for the accumulation of oil and grit and oiling is required only when the carbon brushes are changed. The gears and shaft are of chrome nickel steel and full ball bearings have been provided throughout.

The drills, one of which is shown at *A* in the illustration, are rated in six sizes ranging from 3/16-in. to ¾-in., and are said to deliver about 25 per cent more power than indicated by their ratings. The grinder, shown at *B*, is made in two sizes, one of which takes a wheel 3 in. by ½ in. by ½ in. and the other a wheel 4 in. by 1 in. by ⅞ in. The weight of the drills ranges from 5 lb. for the 3/16-in. size to 20 lb. for the ¾-in. size while the grinders weigh 5 lb. and 15 lb. respectively.

A Scale-Proof Locomotive Crane Boiler

For many users of locomotive cranes the largest single item of upkeep expense is the washing and maintenance work on the boiler. At best there is no ideal boiler feed water and locomotive cranes, working in sections remote from the central supply of purified boiler feed water, or on contract jobs where no purification plant is available, often are forced to use extremely poor water to feed into a boiler.



Parker Scale-Proof Locomotive Crane Boiler

The Industrial Works, Bay City, Mich., builders of the Industrial locomotive and wrecking cranes, are now building locomotive crane boilers equipped with an annular scale chamber placed between the tubes and the shell plate. The feed water is slowly passed through this scale chamber (at about 1/200 of the speed through the intake pipe) and attains a temperature at which the scale forming impurities will be liberated from solution without the use of any chemicals. The impurities are then carried in suspension and as the movement of the water is very slow these suspended precipitates settle down readily to the bottom of this chamber. This settling is accelerated by the decrease in density of the water as it is heated and by the decrease in its fluid friction.

The details of this design are fully indicated in the sectional view. The purifier consists of the annular scale chamber *A* extending completely around the tubes with a one-inch water space *B* between this chamber and the boiler shell. The outlet into the main portion of the boiler is the slot *C* guarded by the apron *D*. The feed water is admitted directly to the scale chamber *A* at a point farthest from the outlet slot.

It travels slowly around this chamber to the outlet and reaches approximately the boiler temperature before overflowing. The apron *D* keeps any floating impurities such as grease, oil, etc., from being discharged into the main boiler.

The sulphates of calcium are the hardest of the scale forming impurities to eliminate. They are precipitated at 280 deg. F., corresponding to the boiler temperature when holding the steam at only 35 lb. gage pressure. The carbonates and magnesia are precipitated at lower temperatures. These are all caught in the scale chamber together with mud, oil, and, in fact, all solids except common salt, for the first application of heat causes the liberation of these solids in the boiler over the crown sheet as well as in the scale chamber.

The scale forming impurities left in the scale chamber do not bake into scale as they do not come into contact with the hot furnace sheets, but they are left in the bottom of the scale chamber as soft mud, where they may be readily removed by blowing or washing out, quickly and easily, at the operator's convenience. It is stated that numerous tests have demonstrated the efficiency of this purifying device. In one test of a 42-in. diameter boiler of this type made at Paterson, N. J., a feed water naturally carrying 5 grains per gal. was loaded with 70 grains of calcium and 70 grains of earth, a total of 145 grains per gal. The feed water was taken from a barrel agitated with carbonic acid gas to form calcium carbonate. After about 1,200 gal. of this kind of water had been passed through the boiler, it was allowed to cool and the heating surfaces and lower mud ring were found to be perfectly clean and the mud was about six inches deep in the scale chamber. The blow-offs were both plugged so all impurities remained in the boiler. It was interesting to note that the presence of so much precipitated impurity in the scale chamber did not interfere with its operation.

This type of boiler was designed and patented in 1919 by Thomas T. Parker and has proved its value in utilizing all kinds of feedwater.

Redesigned Carbon Dioxide Recorders

Coincident with the present acute interest in fuel economy and more efficient boiler operation, the Uehling Instrument Company, New York, has introduced a new model CO_2 recording equipment, known as style U, which embodies important improvements over the superseded model. Chief among its advantages are remarkably quick action, greater accessibility and simplicity of parts, and the economy of combining in one machine means for determining CO_2 simultaneously from any number of boilers, up to a total of six.

A single unit equipment for one boiler consists of three principal parts: namely, the CO_2 meter proper, recorder and auxiliary boiler front indicator. The meter is placed wherever is most convenient and its function is to actuate the boiler front indicator and recorder in the engineer's office. The flue gas is analyzed, that is, the CO_2 is extracted, in the meter and the principle involved in the operation depends upon the change in pressure caused by a change in volume in a stream of gas flowing through two apertures. In the new model the gas travel is hastened by utilizing the exhaust from the main aspirators in an auxiliary aspirator, while the main aspirator draws the gas sample through the absorption chamber. This prevents lag in the travel of gas from the boiler up to the absorption chamber.

With each unit is included a preliminary filter which removes soot and dirt from the sample before it reaches the intermediate and final filters on the machine. This has been redesigned so that the filter chamber can be conveniently cleaned in a few seconds without interrupting operation of the machine.

Multiple equipments combine in a single outfit means for measuring CO_2 from two, three, four, five or six boilers independently and simultaneously. It is most economical to equip the boilers in batteries of six each, but this is not absolutely necessary, inasmuch as the CO_2 meters are now built on the unit plan and may be added to from time to time. With multiple unit machines, each boiler is equipped with its own recorder, auxiliary boiler front indicator, preliminary filter and absorbent chamber with necessary appurtenances, but the aspirator and other parts of the master unit serve all units in common.

The recorder operates on the hydrostatic principle, and thus all springs, levers and joint movements are avoided. It makes a continuous record of the per cent of CO_2, furnishing an autographic history of the operation of each boiler for every second of the day, showing when fires receive attention; when and how often furnace doors are opened, or how often stoker speed and fuel bed thickness are changed; fires broken and cleaned; effects of changes in damper regulation and methods of firing.

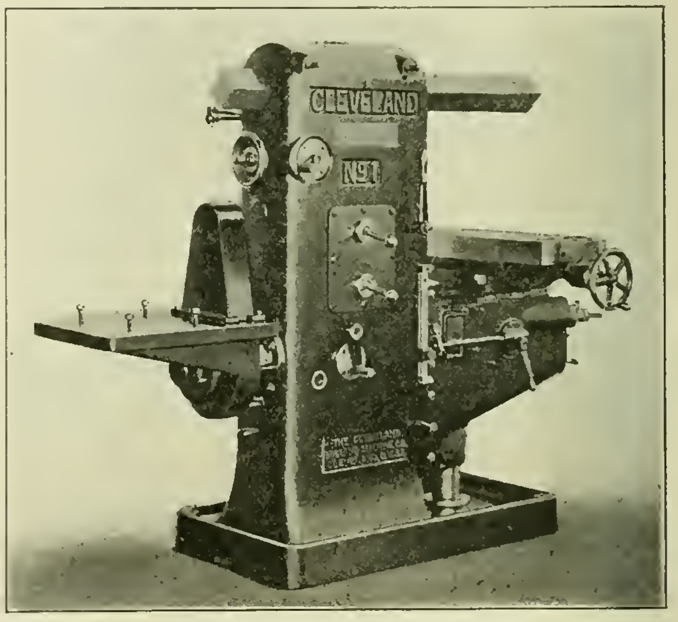
The boiler front indicator guides the fireman in supplying just the right amount of air to burn the fuel with the least loss of heat up the chimney. Uehling carbon dioxide equipment may also be combined with Uehling pyrometers to give continuous records of both carbon dioxide gas and stack temperature on the same shart.

Motor Drive for Milling Machines

ONE of the latest developments of the Clark-Mesker Company, Cleveland, Ohio, has been in applying mator drive to the Nos. 1 and 2 Cleveland milling machines. A friction clutch is provided in the drive between the sprockets and the chain, and the main drive shaft of the machine, which affords all the advantages of belt drive. The sprockets and chain run in oil and it is a simple matter to change over from the ordinary belt drive to electric motor drive by replacing the pulley housing with a bracket.

A constant speed motor is used running at about 1,200 r. p. m. The Morse chain used for the motor drive on the No. 1 machine is 2 in. wide and that on the No. 2 machine 2½ in. wide. The illustration shows that the motor is well up from the floor, away from dirt and chips, but not high enough to make the machine top heavy. An adjusting nut on the back of the motor drive housing is provided for adjusting the friction clutch for the main drive.

By this new development, all the advantages of individual electric motor drive are secured not only for users of new No. 1 and No. 2 Cleveland milling machines but for those already operating belt driven machines. The time and expense required for changing over will in many cases be far less important than the elimination of belt troubles and the more convenient placing of the machines.

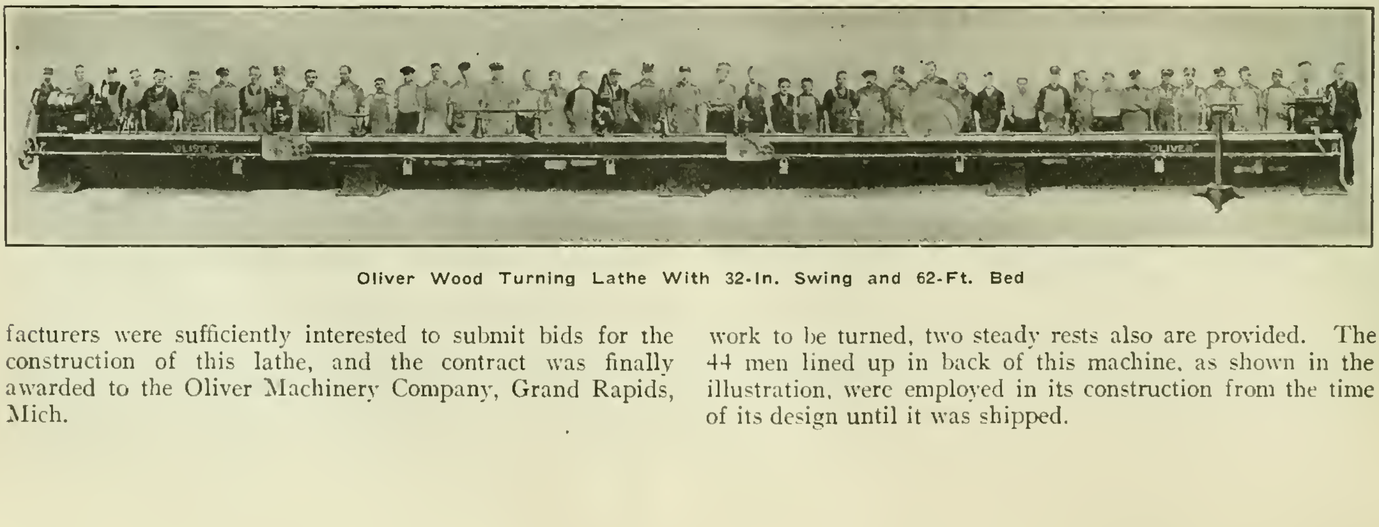


Milling Machine Arranged for Electric Motor Drive

Wood Turning Lathe of Unusual Length

THE wood turning lathe illustrated herewith was built in accordance with specifications written for the United States Government during the year 1919. The lathe was designed for the turning of spars or ship masts and has a swing of 32 in. and a bed 62 ft. long. Only two manufacturers were sufficiently interested to submit bids for the construction of this lathe, and the contract was finally awarded to the Oliver Machinery Company, Grand Rapids, Mich.

The bed of the lathe is cast in four sections, being supported upon five pedestals as indicated. Belt drive is secured from overhead shafting through four-step cone pulleys. Two power feeding carriages are provided; also several adjustable tool rests. In order to support the long and heavy work to be turned, two steady rests also are provided. The 44 men lined up in back of this machine, as shown in the illustration, were employed in its construction from the time of its design until it was shipped.

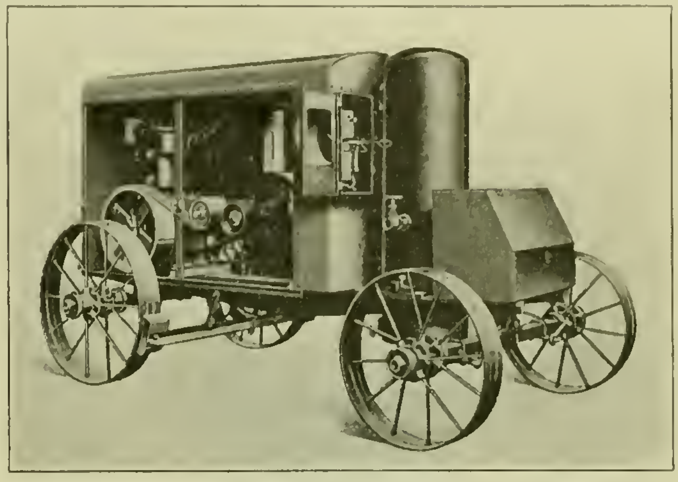


Oliver Wood Turning Lathe With 32-In. Swing and 62-Ft. Bed

Compact Portable Air Compressor Units

Users of compressed air who are located at a distance from the central power stations must avail themselves of some type of portable air compressor. The Imperial portable compressor made by the Ingersoll-Rand Company, New York, is designed to meet the needs of this class of service. For gasolene power, these units are driven by tractor type gasolene motors and are built in three sizes, with capacities of 45, 118 and 210 cu. ft. per min. For use where electricity is available as motive power, an electric motor driven Imperial compressor has been designed. This unit is of 118 cu. ft. capacity and weighs approximately 4,450 lb., depending upon the weight of the motor. As in the case of the corresponding gasolene motor driven compressor, this electric unit is of all-steel construction. Light steel doors, easily removed, and a sheet steel canopy completely house the entire unit, protecting it from the weather and preventing undue deterioration from rust.

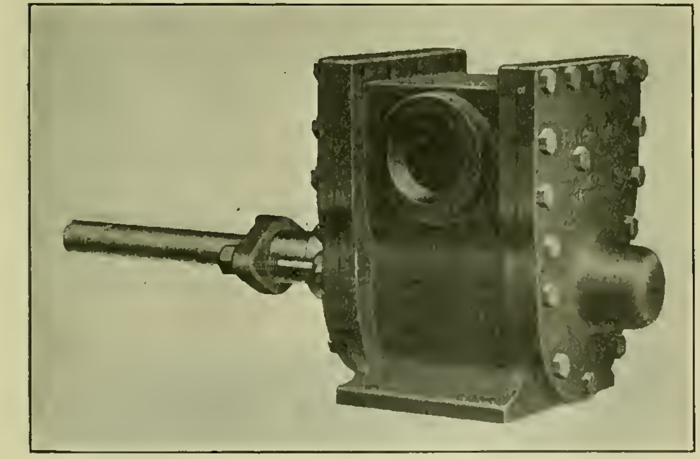
Either an alternating or a direct current motor can be furnished and a suitable intake unloader is provided, assuring efficient regulation. In any case, the motor control is in accordance with standard practice and specifications covering the type of motor used. Additional equipment includes an air receiver, safety valve, drain valves, pressure gage and service valves to which air hose lines may be connected.



Portable Air Compressor with Capacity of 118 Cu. Ft. per Min.

Efficient Rotary Piston Type Pump

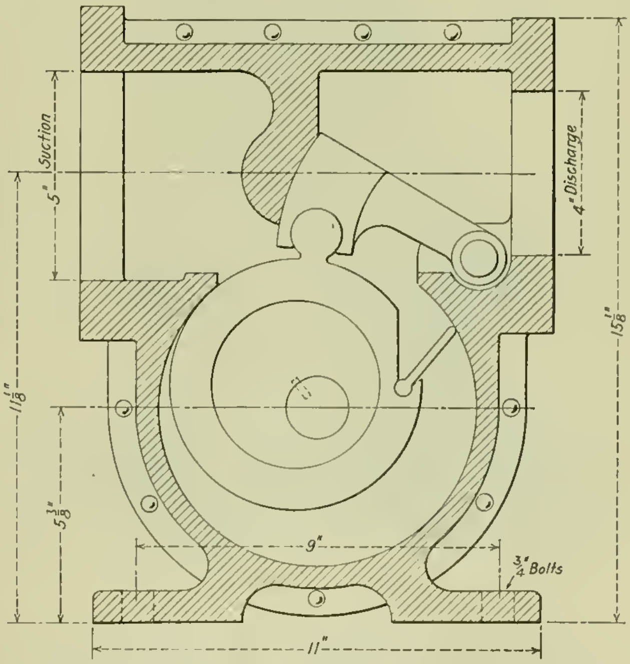
In the design of the rotary piston pump manufactured by the St. Louis Pump & Equipment Company, St. Louis, Mo., special attention has been given to the correction of weaknesses most common to pumping devices used for handling volatile and non-volatile liquids. The pump is simple, durable and stated to be unusually efficient; the best features of the rotary pump being combined with the best features of the piston pump.



St. Louis Rotary Piston Type Pump

There are only twelve major parts, consisting of a pump case with dividing partition, two end plates, a steel shaft with two eccentrics mounted thereon, two pistons, two rocker arms and two checks. Two chambers or cylinders are arranged, with a shaft passing through the center of each, two eccentrics, directly opposite in throw or 180 deg. apart, being mounted on the shaft. Surrounding these eccentrics and pivoted to the rocker arm are the two pump pistons. The arm serves to produce the reciprocating movement of the piston through the cam action of the eccentrics. Thus a composite reciprocating and rotary motion of the pump plunger or piston is obtained without actual contact of the piston and cylinder walls. The clearance, however, is small and a liquid seal results, giving vacuums up to 29 in.

The piston check is the only moving part touching the cylinder walls and this functions only at the point of transition at the end of the pumping suction movement or stroke to the beginning of a new stroke. The wear on this check is taken up automatically. The interval between the so-called strokes is so slight that an even impulse is imparted to the liquid handled. While the piston is discharging, it is acquiring fresh liquid on the opposite or suction side, and the piston in the opposite chamber is functioning conversely, thus giving balanced action.



Cross Section Showing Operating Parts

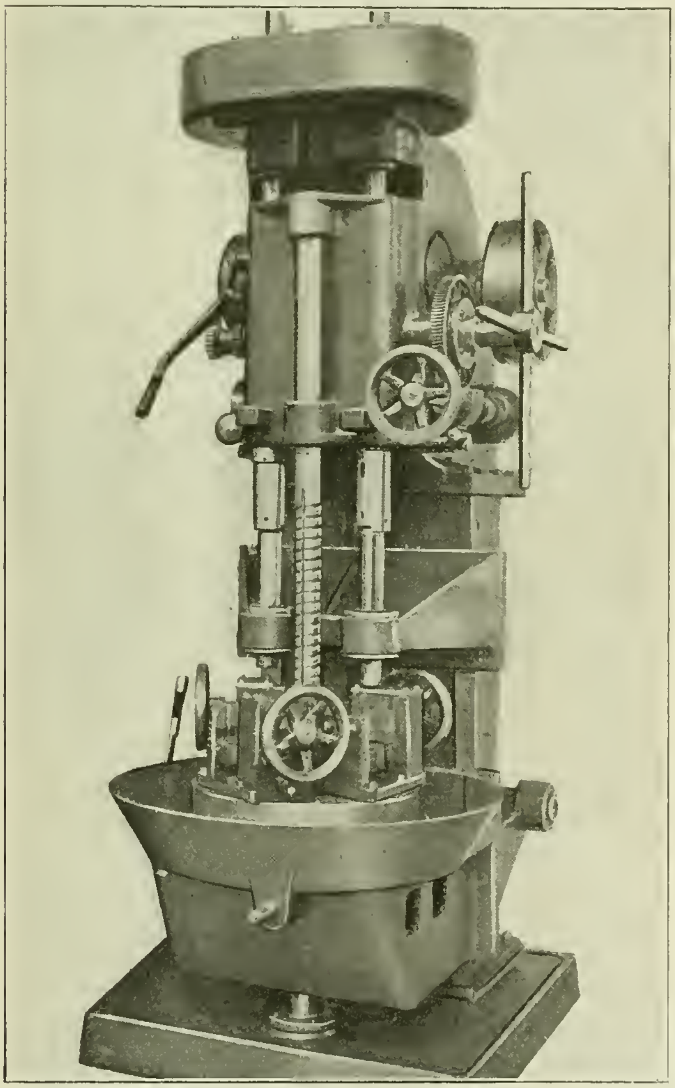
The construction is entirely of metal most suitable for the liquids handled, so arranged that no two similar metals are in contact at any bearing point. All wearing parts on the pump are rotative and at every point at which wear may be encountered even to a minor degree, self-lubricated bearings capable of long service are used.

The head at one end of pump case is blind; that is, the shaft does not extend through and this eliminates packing. At the other end, a gland which holds the packing material, is bolted to the head. The pump is compact, light in weight, practically free from vibration, durable and self-lubricating when handling either volatile or non-volatile oils or similar liquids.

Baker Boring and Drilling Machine

A TWO-SPINDLE machine designed especially for work having successive operations such as drilling, reaming, boring, counterboring, turning and facing, has been placed on the market by Baker Brothers, Toledo, Ohio. It consists of two spindles feeding simultaneously to work that is chucked on a circular indexing table. Three stations are provided so that the work is loaded and unloaded while the machine is in operation. Except for the very short indexing time, the machine is in constant operation and turning out work.

The spindles feed simultaneously but have independent speeds, thus driving each tool at its most efficient speed. Speed and feed changes are obtained by slip change gears, the drive being upon annular ball bearings. The principal specifications are: capacity, to drive 2-in. high speed drill; distance from center of spindle to face of column, 12¼ in.; distance from center of spindle to center of spindle, 10½ in.; length of feed, 12 in.



Baker Two-Spindle Drilling Machine

It seems probable that this machine would be adaptable to a variety of operations in railway machine shops, such as drilling and tapping nut blanks, drilling the many holes in brake hangers and rigging and many other similar operations.

Twenty-nine Passengers, 93 employees and six other persons were killed in train accidents during the second quarter of 1920 and 1,271 passengers, 690 employees and 23 other persons were injured; a total of 128 persons killed and 1,984 injured. Adding casualties in train service accidents—1,323 killed and 12,383 injured; and those in non-train accidents—112 killed and 25,398 injured—we have a total of 1,563 persons killed and 39,765 injured. The number of collisions reported in this quarter was 2,189 and of derailments 4,952. Adding miscellaneous accidents to trains we have a total of 7,883 accidents with total damage to cars and roadway of $7,762,500.

For the Good of Both the railways and the employees the thing most needed in the railroad field is an increase in the economy and efficiency of operation. The thing most needed to bring this about is an increase in the efficiency of labor. Probably nothing will contribute so much toward increasing the efficiency of labor as a better understanding by the managements and the men of one another's problems and points of view. The best way to bring about a better understanding will be for the officers and representatives of the employees of the various individual railways to get together and frankly talk over their mutual problems. Whether or not national agreements or national boards of adjustment exist under private operation, the efficiency and loyalty of the employees of the individual lines will depend largely upon the fairness and frankness with which the managements deal with them, and frequent conferences between the officers and representatives of the men can hardly fail to beget fairness and frankness on both sides.—*Railway Age.*

Subscriptions, including the eight daily editions of the Railway Age, published in June, in connection with the annual convention of the American Railway Association, Mechanical Division, payable in advance and postage free: United States, Canada and Mexico, $4.00 a year: elsewhere $5.00, or £1 5s. 0d a year. Foreign subscriptions may be paid through our London office, 34 Victoria street, S. W. 1., in £ s. d. Single copy, 35 cents.

WE GUARANTEE, that of this issue 10,300 copies were printed; that of these 10,300 copies 9,243 were mailed to regular paid subscribers, 9 were provided for counter and news company sales, 265 were mailed to advertisers, 32 were mailed to employees and correspondents, and 751 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 20,500, an average of 10,250 copies a week.

The *Railway Mechanical Engineer* is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.).

The directors of the American Railway Association, at a meeting in New York on January 6, elected Daniel Willard (B. & O.), chairman of the board and re-elected R. H. Aishton president of the association. W. G. Besler (C. of N. J.), was chosen first vice-president, in place of W. T. Tyler, and Hale Holden (C. B. & Q.), second vice-president, in place of E. H. Coapman. J. E. Fairbanks is general secretary and treasurer.

The total deficit for all the French railways for 1920 will be about $900,000,000, the operating ratio during the year being in the neighborhood of 125 per cent. The total number of employees has increased from 355,900 in January, 1914, to about 500,000; the amount of money paid out in wages meanwhile has increased 327 per cent. The greater part of the railways destroyed in northern France have been reconstructed and are now in operation.

The Chicago, Rock Island & Pacific has appointed a general reclamation committee, of which C. A. Morse, chief engineer, has been appointed chairman, and is conducting a campaign among its employees for the conservation of materials. The committee is not only urging employees to save on new materials, but also that all articles in need of repair be gathered up and shipped to the shops and that all scrap be moved as well. Under the direction of the committee the system has been placarded with posters advertising the drive.

The Chicago Safety Council recently organized a Steam Transportation Committee, which held its first meeting on December 21. At this meeting a general discussion took place as to the general activities which the committee would undertake. It was explained, however, that it was the intention that action should be taken as heretofore by individual roads regarding specific matters and an attempt be made to bring about the desired improvement or adjustment without referring matters to this committee for handling, except in special cases. C. L. Hinkle, general manager of the Chicago Great Western, is chairman of the committee, the personnel of which is representative of all the railroads in the city. Meetings of the committee are to be held once each month on the second Friday of the month at 12:30 p. m. in the Hotel Sherman, Chicago.

The pension list of the Philadelphia & Reading, established in 1902, now contains 485 names, of whom four have records of 57 years or more of service, and 72 others served 50 years or more. In the last issue of the "Roll of Honor," A. T. Dice, president of the road, expressed the management's appreciation of the long and faithful service these men had rendered. He said: "The prosperity which our company has enjoyed is due in no small part to your faithful service. Accordingly, it is just and right that you should share in that prosperity. You are entitled, also, in your retirement, to the satisfaction of knowing that by your work you have largely contributed to the upbuilding of the strong and important system of railroads we are now operating. The troublous times through which our country has passed since the beginning of the great war make clearer than ever before the value of efficient railroad service, and the vital interdependence of the country and the railroads."

Executive Committee Meeting of C. I. C. I. & C. F. Association

The Executive Committee of the Chief Interchange Car Inspectors' and Car Foremen's Association of America will meet at the Hotel Sherman, Chicago, on Thursday and Friday, March 3 and 4. The entire membership is invited to this meeting to suggest changes in the A. R. A. Rules of Interchange.

Engineering Council and A. S. M. E. to Meet in Syracuse

Herbert Hoover will be the principal speaker at a meeting in Syracuse, N. Y., on February 14, at which it is expected the plans of the American Engineering Council for dealing with industrial relations and, particularly, with the waste due to unemployment will be outlined. On the following day, February 15, the National Council of the American Society of Mechanical Engineers will meet.

Coal Production

The railways during 1920 transported the largest amount of bituminous coal ever handled by them in any calendar year except in 1918. The statistics of the United States Geological Survey regarding the amount of bituminous coal produced and transported up to December 18 of each of the last four years are as follows:

1917..............	536,288,000 tons	1919..............	441,592,000 tons
1918..............	566,349,000 tons	1920..............	537,555,000 tons

New Rolling Stock for New Zealand Railways

The government of New Zealand has signed a contract with the North British Locomotive Company for the delivery of 25 Pacific type locomotives at a price of $43,225 each. The weight of the locomotives will be 190,000 lb. in working order. Cammell Laird & Co. have received the contract for the delivery of 2,500 eight-ton freight cars at a price of $1,139.75 per car. In addition to the above, there are under construction in New Zealand, by Price Brothers, Thames, 20 locomotives of the Pacific type, similar in every respect to those to be supplied by the North British; also, ten of the same type to be built in the government's own workshops. The government is now calling for bids for 1,000 additional freight cars to be built in New Zealand.

The Pullman Company Wage Reduction

Conflicting reports resulting from an account of a so-called voluntary wage cut of 20 per cent by employees of the Pullman Company at Chicago, have simmered down to two or three authoritative outstanding facts.

In the first place, the suggestion of a wage cut was made by J. B. Weaver, vice-president in charge of construction of the Pullman Company, who advised the employees at the Pullman Car Works, which is an open shop employing 9,000 men, that a decrease in their pay was necessary. The matter of reductions in pay at the Pullman repair shop, which is unionized, has not yet been brought up.

At present, the company is restoring its men at the Pullman repair shop to the basis of a nine-hour day, as against the eight-hour day under which they have been working. The nine-hour day will apply five days a week, with a five-hour day on Saturday.

MEETINGS AND CONVENTIONS

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associotions and railroad clubs:

Air-Brake Association.—F. M. Nellis, Room 3014, 165 Broadway, New York City.

American Railway Association, Division V—Mechanical—V. R. Hawthorne, 431 South Dearborn St., Chicago. Next convention June 15-22, Atlantic City, N. J. Exhibit by Railway Supply Manufacturers' Association.

Division V.—Equipment Painting Division.—V. R. Hawthorne, Chicago.

American Railway Association, Division VI.—Purchases and Stores.—J. P. Murphy, N. Y. C., Collinwood, Ohio. Second annual meeting June 20-22, Atlantic City, N. J.

American Railroad Master Tinners', Coppersmiths' and Pipefitters' Association.—C. Borcherdt, 202 North Hamlin Ave., Chicago. Convention September 12, 13 and 14, Hotel Sherman, Chicago.

American Railway Tool Foremen's Association.—R. D. Fletcher, 1145 E. Marquette Road, Chicago.

American Society for Testing Materials.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.

American Society for Steel Treating.—W. H. Eiseman, 4600 Prospect Ave., Cleveland, O.

Association of Railway Electrical Engineers—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.

Canadian Railway Club.—W. A. Booth, 131 Charron St., Montreal, Que. Meeting second Tuesday in each month except June, July and August, at Windsor Hotel, Montreal, Que.

Car Foremen's Association of Chicago.—Aaron Kline, 626 N. Pine Ave., Chicago. Meeting second Monday in month, except June, July and August, New Morrison Hotel, Chicago.

Car Foremen's Association of St. Louis.—Thomas B. Koeneke, 604 Federal Reserve Bank Building, St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis.

Central Railway Club.—H. D. Vought, 95 Liberty St., New York. Meeting second Thursday in January, March, May, September and November.

Chief Interchange Car Inspectors' and Car Foremen's Association.—W. P. Elliott, T. R. R. A. of St. Louis, East St. Louis, Ill. Next meeting March 3 and 4, 1921, Hotel Sherman, Chicago.

Cincinnati Railway Club.—W. C. Cooder, Union Central Building, Cincinnati, Ohio. Next meeting February 8. Short addresses will be made by E. R. Oliven, G. F. A., Southern Railway; A. G. Olberding, American Brake Shoe Company, and R. C. Barnard, superintendent, Pennsylvania System. There will also be a musical entertainment.

Dixie Air Brake Club.—E. F. O'Connor, 10 West Grace St., Richmond, Va.

International Railroad Master Blacksmiths' Association.—W. J. Mayer, Michigan Central, 715 Clarke Ave., Detroit, Mich. Next meeting, August 16, 17 and 18, 1921, Hotel Sherman, Chicago.

International Railway Fuel Association.—J. G. Crawford, 702 East Fifty-first St., Chicago. Next annual meeting, May, 1921, Hotel Sherman, Chicago.

International Railway General Foremen's Association.—William Hall, 1061 W. Wabasha Ave., Winona, Minn. Convention, September 12, 13, 14 and 15, 1921, Hotel Sherman, Chicago.

Master Boilermakers' Association.—Harry D. Vought, 95 Liberty St., New York. Convention, May 23 to 26, 1921, inclusive, Planters' Hotel, St. Louis, Mo.

New England Railroad Club.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Next meeting February 8. Paper on Problem of Handling Material and Freight on Railroads will be presented by Charles N. Winter, Associate Editor, *Railway Mechanical Engineer.*

New York Railroad Club.—H. D. Vought, 95 Liberty St., New York. Next meeting, February 18. Paper on Operating Problems will be presented by J. J. Mantell, manager, New York Region, Erie Railroad.

Niagara Frontier Car Men's Association.—George A. J. Hochgrebe, 623 Brisbane Building, Buffalo, N. Y. Regular meetings, January, March, May, September and October.

Pacific Railway Club.—W. S. Wollner, 64 Pine St., San Francisco, Cal. Meetings second Thursday in month, alternately in San Francisco and Oakland, Cal.

Railway Club of Pittsburgh.—J. D. Conway, 515 Grandview Ave., Pittsburgh, Pa. Meetings fourth Thursday in month except June, July and August, Americus Club House, Pittsburgh.

St. Louis Railway Club.—B. W. Frauenthal, Union Station, St. Louis, Mo. Meetings second Friday in month except June, July and August.

Traveling Engineers' Association.—W. O. Thompson, N. Y. C. R. R., Buffalo, N. Y.

Western Railway Club.—Bruce V. Crandall, 14 E. Jackson Boulevard, Chicago. Next meeting, February 21. A paper on Modernizing Existing Locomotives will be presented by G. M. Basford.

PERSONAL MENTION

GENERAL

C. H. Temple, superintendent of motive power and car department of the Canadian Pacific, Western Lines, has been appointed chief of motive power and rolling stock, with headquarters at Montreal.

R, Preston, assistant superintendent of motive power of the Canadian Pacific, with headquarters at Winnipeg, Man., has been promoted to superintendent motive power and car department, Eastern Lines, with headquarters at Montreal.

W. L. Robinson, master mechanic of the Baltimore & Ohio, with headquarters at Washington, Ind., has been appointed superintendent fuel and locomotive performance, with headquarters at Baltimore Md., succeeding E. E. Ramey, who has been assigned to other duties.

H. H. Stephens, master mechanic of the Pecos division of the Atchison, Topeka & Santa Fe with headquarters at Clovis, N. M., has been promoted to mechanical superintendent of the Southern district with headquarters at Amarillo, Tex., succeeding W. D. Deveny, assigned to other duties. W. D. Hartley, general foreman, locomotive department, at Richmond, Cal., succeeds Mr. Stephens at Clovis.

R. A. Pyne, superintendent of the motive power and car department of the Canadian Pacific, Eastern Lines, with headquarters at Montreal, Que., has been transferred to Winnipeg, Man., succeeding C. H. Temple. A. Sturrock, master mechanic of the British Columbia district, with headquarters at Vancouver, B. C., has been promoted to assistant superintendent of motive power, with headquarters at Winnipeg, Man.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

J. W. Chandler has been appointed master mechanic of the Kansas City Southern, at Pittsburg, Kan., succeeding C. J. Burkholder, resigned to enter the service of another company. C. L Adair succeeds Mr. Chandler as master mechanic at Shreveport, La.

E. R. Woody

Edmund R. Woody, whose promotion to master mechanic on the Chesapeake & Ohio at Peru, Ind., was announced in the January issue, was born on September 10, 1880, at Richmond, Va. Mr. Woody entered the employ of the Chesapeake & Ohio on October 1, 1895, as a machinist apprentice and in 1900 was appointed erecting gang foreman. In 1909, he was transferred to the Newport News shops as assistant general foreman and in 1910 became general foreman at the Richmond Seventeenth street shops. In 1912 he was appointed assistant master mechanic in charge of the Fulton shops, Richmond, which position he held until his appointment as master mechanic at Peru.

Alexander Peers, who has been appointed master mechanic of the Canadian Pacific at Moose Jaw, Sask., Canada, was born in August, 1875, at Cheshire, England. Mr. Peers entered the service of the Canadian Pacific on July 16, 1901, at Winnipeg, as a machinist. From June 2, 1906, to June 12, 1906, he served as a draughtsman and from June 13, 1906, to August 6, 1906, served as relief locomotive foreman at Winnipeg, Fort William and Ignace. On August 7, 1906, he became locomotive foreman at

Souris, Brandon and Winnipeg. From April 24, 1914, until the time of his recent appointment, he was division master mechanic at Winnipeg and Moose Jaw.

G. M. Lawler, who has been appointed master mechanic on the Atchison, Topeka & Santa Fe at La Junta, Colo., as noted in the January issue, was born on July 12, 1888, at Albuquerque, N. M. Mr. Lawler attended a business college for two years at night and entered the employ of the Atchison, Topeka & Santa Fe as a machinist apprentice at Albuquerque on February 28, 1905. In 1910 he was promoted to gang foreman and in 1911 became roundhouse foreman. In 1914 he was transferred to Belen, N. M., as division foreman and in 1916 was transferred to Raton, N. M., as general roundhouse foreman, which position he held at the time of his recent appointment.

G. M. Lawler

CAR DEPARTMENT

W. J. Robider, general master car builder of the Canadian Pacific, has retired and the position has been abolished. The duties of general master car builder have been assumed by the assistant chief mechanical engineer.

SHOP AND ENGINEHOUSE

Ernest Ruick, a machinist, has been promoted to night roundhouse foreman of the Atchison, Topeka & Santa Fe at Strong City, Kan.

R. Tuck, roundhouse foreman of the Atchison, Topeka & Santa Fe at Richmond, Cal., has been transferred to Needles, Cal., as general foreman. E. F. Callaher, formerly roundhouse foreman at Richmond and transferred to Needles, has been returned to Richmond.

E. A. Murray, master mechanic of the Chesapeake & Ohio, with headquarters at Clifton Forge, Va., has been promoted to shop superintendent at Huntington, W. Va., succeeding H. M. Brown, resigned. C. B. Hitch succeeds Mr. Murray as master mechanic at Clifton Forge.

John Edward Garretson has been appointed general foreman on the Chesapeake & Ohio at Hinton, W. Va. Mr. Garretson was born on December 12, 1888, at Montgomery, W. Va. He attended the Hinton high school and in June, 1904, started to work as a call boy and a machinist's helper. In July, 1905, he entered the service of the Chesapeake & Ohio as a machinist apprentice at Hinton. After completing his apprenticeship, he worked as a machinist until 1912, when he was sent to Logan, W. Va. In May, 1914, he was promoted to day roundhouse foreman, and on December 1, 1916, became general foreman at Logan, which position he held until his recent appointment.

PURCHASING AND STOREKEEPING

Edmund T. Burnett has retired as general purchasing agent of the Norfolk & Western. Mr. Burnett was born in Philadelphia, Pa., and was educated at Saunders Institute. He was engaged in mercantile pursuits for several years after he had completed his schooling and first entered railway service in 1882 as chief clerk to the purchasing agent of the Norfolk & Western. In 1891 Mr. Burnett was appointed assistant purchasing agent, with headquarters at Roanoke, Va. In 1893 he was promoted to purchasing agent with headquarters at Philadelphia. When the road was reorganized in 1896 Mr. Burnett transferred his headquarters to Roanoke. When the government assumed the operation of the railroads Mr. Burnett was appointed, first, an associate member of the Eastern Regional Purchasing Committee and, later, regional purchasing agent for the Pocahontas region. When the roads were returned to their owners Mr. Burnett was appointed general purchasing agent of the Norfolk & Western.

SUPPLY TRADE NOTES

C. L. Mellor, manager of sales of the Barco Manufacturing Company, Chicago, has been elected secretary of this company. Mr. Mellor will continue his duties in charge of sales in addition to his duties as secretary.

John R. LeVally, formerly sales engineer of the Locomotive Superheater Company, at Chicago, has been appointed district sales manager of the company at Pittsburgh, Pa., with offices in the Union Arcade building.

Martin J. Root, formerly of the Fairbanks Company, New York, has been elected president of the United States High Speed Steel & Tool Corporation, which has been reorganized. The headquarters of the company are at 489 Fifth avenue, New York.

C. R. Weber has been elected treasurer of the Sherritt & Stoer Company, of Philadelphia, filling a vacancy made through the retirement of C. H. Stoer some time ago. Mr. Weber, previous to his appointment as treasurer, was in charge of the accounting department.

George S. Bigelow, formerly manager of the railway department of the Chicago Varnish Company, is now in charge of the railway department of the Mountain Varnish & Color Works, Inc., of Toledo, Ohio, with offices in the Railway Exchange building, Chicago.

Edmund H. Walker, first vice-president of the Standard Coupler Company, New York, has been elected president, succeeding George A. Post, who has retired. Mr. Walker has been connected with the company since February, 1905. Previous to his connection with the Standard Coupler Company he was engaged in railroad work with the Great Northern, the Atchison, Topeka & Santa Fe, the Chicago, Burlington & Quincy, and the Minneapolis, St. Paul & Sault Ste. Marie, in various departments. Mr. Walker has taken an active part in the work of the Railway Supply Manufacturers' Association and was three times elected president of the organization, serving in that capacity during the years 1917, 1918 and 1919.

E. H. Walker

C. E. Adams, vice-president of the Air Reduction Sales Company, New York, has been elected president to succeed A. F. Blagden, who has resigned to become associated with the American Dyewood Company, New York. John McHugh has been elected a director to succeed H. R. Hoyt, deceased.

The Hallidie Machinery Company, L. C. Smith building, Seattle, Wash., have been appointed representatives of the Conveyors Corporation of America, Chicago, formerly the American Steam Conveyor Corporation. They will handle the sales of the American steam conveyor and American trolley carrier in the states of Washington and Oregon.

The Whiting Foundry Equipment Company, Harvey, Ill., has announced that it has changed its name to the Whiting Corporation, increasing its authorized capital stock from $700,000 to $3,000,000. The Whiting Corporation remains under the same management and will continue the manufacture of cranes, foundry equipment and railway specialties as heretofore.

The Reade Manufacturing Company has moved from Hoboken, N. J., into its new factory at Jersey City, N. J., where additional facilities are available. Two new departments, a traffic department and a mechanical or service department, have been added to the organization, both of which are under the supervision of R. H. Vogle, sales manager of the railroad department.

At the annual election of the Union Railway Equipment Company, Chicago, the following officers were elected: W. B. Hall, president and treasurer; G. W. Clark, controller and secretary; A. F. O'Connor, mechanical engineer; E. S. Jubell, superintendent; H. O. Comstock, sales agent. Mr. Jubell was formerly in charge of the forge department for the Haskell & Barker Car Company. The company's new forging plant, located on the Indiana Harbor Belt, at Hammond, Ind., is now in operation.

R. W. Levenhagen, secretary of the Sherwin-Williams Company, Cleveland, Ohio, has been elected vice-president in charge of auxiliaries of the Glidden Company, Cleveland. Mr. Levenhagen has spent the greater part of his life in the paint and varnish industry, having started with the Sherwin-Williams Company 25 years ago. He held various positions in the service of the Sherwin-Williams Company and rose steadily until he became secretary, which position he held until his recent election as vice-president of the Glidden Company. Besides serving as secretary of the Sherwin-Williams Company, he was vice-president and general manager of the Detroit White Lead Works, Detroit, Mich., and vice-president of the Martin-Senour Company, Chicago, for a number of years.

Joseph Sinkler has resigned his position with the Franklin Railway Supply Company, Inc., to become general manager of the railway division of the Pilot Packing Company, Inc., with headquarters in the Peoples Gas building, Chicago, Ill. Mr. Sinkler was born at Scranton, Pa., and began his business life with the Dickson Locomotive Works in the same city. Three years later he entered the employ of the New York, Susquehanna & Western and the Delaware, Lackawanna & Western. On July 1, 1904, he became associated with the Franklin Railway Supply Company, and on January 1, 1916, was appointed western representative of the Economy Devices Corporation, Chicago. Resigning from this position on November 15, 1917, he accepted a position as special representative of the Perolin Railway Service Company, and on January 1, 1919, returned to the services of the Franklin Railway Supply Company, where he remained until his present appointment.

J. Sinkler

Howard C. Mull, manager of the sales department of the Verona Tool Works, Pittsburgh, Pa., with headquarters at Chicago, has been appointed manager of the railway department of the Reliance Manufacturing Company, of Massillon, Ohio, with offices at Chicago. Mr. Mull was born on July 13, 1889, at Cincinnati, Ohio, and entered railway service in the engineering department of the Cleveland, Cincinnati, Chicago & St. Louis in 1910. Two years later he was transferred to Cleveland, Ohio, and placed in charge of safety matters. In May, 1913, he entered the employ of the Verona Tool Works, and two years later was promoted to representative of sales, western territory, with headquarters at Chicago. In 1918 he was appointed manager of sales, with headquarters at Chicago, the position he occupied at the time of his recent appointment.

On January 1 the Chambers Valve Company, Inc., New York, was taken over by the Bradford Draft Gear Company, with offices at 23 West Forty-third street, New York; Munsey building, Washington, D. C., and McCormick building, Chicago. Frank H. Clark, formerly president of the Chambers Valve Company, becomes vice-president of the Bradford Draft Gear Company, with headquarters at New York, while the Washington office will be under the direction of Harry F. Lowman, vice-president.

R. F. Eissler has been appointed assistant to the vice-president of the Chicago Pneumatic Tool Company, New York, with headquarters in the company's new office building at 6 East Forty-fourth street, New York. W. C. Straub, formerly district manager of the New Orleans branch, has been appointed district manager of the Pittsburgh branch to succeed Mr. Eissler, and Ross Wyeth, formerly attached to the Pittsburgh branch, has been appointed district manager of the New Orleans branch to succeed Mr. Straub.

A. D. Graves, manager trade sales of Pratt & Lambert, Inc., Buffalo, N. Y., has been appointed general manager of the company. This position was formerly held by President J. H. McNulty. C. D. Sproule, sales manager, western division, at Chicago, has been appointed resident manager with office at Chicago. J. R. Mickle, railway sales representative at New York, has been appointed sales manager at New York, and H. M. Guisey, assistant resident manager at Buffalo, has been appointed assistant sales manager at New York. The company held a convention from January 10 to 13 in a publicity building which it has recently completed in Buffalo, N. Y. At this meeting there were a number of interesting addresses made by officers of the company and many papers were presented by the salesmen.

A. D. Graves

Mr. Graves is a native of Ohio, his boyhood having been spent in Columbus. He was a bookkeeper in a wholesale drygoods house for nearly five years previous to entering the employ of a concern manufacturing varnish. In 1908, he started as a salesman for Pratt & Lambert and spent the next ten years in developing trade in Philadelphia and vicinity, when he became manager trade sales. Mr. Graves is one of the successful twelve Pratt & Lambert men whose high percentage of sales won them a trip to Europe in the summer of 1914.

Harry R. Warnock, vice-president in charge of mechanical matters of the Standard Stoker Company, New York, and formerly general superintendent of motive power on the Chicago, Milwaukee & St. Paul, died suddenly of heart failure at Hagerstown, Md., on January 19. He was born at Newcastle, Pa., on July 16, 1870. He began railway work as a freight brakeman with the Pennsylvania Lines West of Pittsburgh in June, 1889, and in the same year went to the Pittsburgh & Lake Erie as a brakeman. In September, 1891, he was promoted to locomotive fireman and later was locomotive engineer, which position he held until May, 1900. From that date until July, 1904, he served consecutively as engine despatcher, roundhouse foreman and general foreman, resigning on the latter date to become master mechanic of the West Side Belt, Pittsburgh, Pa., where he remained until October, 1905, when he became master mechanic of the Monongahela Railroad. He remained in this position until September, 1913, when he was appointed superintendent of motive power of the Western Maryland, which

H. R. Warnock

position he held until December 15, 1917, when he was appointed general superintendent of motive power of the Chicago, Milwaukee & St. Paul. In July, 1920, he became associated with the Standard Stoker Company and at the time of his death was vice-president in charge of mechanical matters, as above noted.

E. W. Englebright

E. W. Englebright, who was engineer for the New York office of the Union Pacific until that office was merged recently with the organization of the assistant to the president at Omaha, Neb., where he has been located since that time, has resigned to become associated with the Elvin Mechanical Stoker Company, 50 Church street, New York. Mr. Englebright was born on January 12, 1885, at Oakland, Cal., and attended public schools until 1903 He then entered the employ of the Southern Pacific at Oakland, Cal., in its engineering department and served as rodman, levelman and transitman until 1905, when he entered the University of California, pursuing a course of civil engineer- until 1909. He then returned to the Southern Pacific and served as assistant engineer on the Shasta division at Dunsmuir, Cal., until 1910, when he was appointed assistant division engineer. In 1912 he served as roadmaster at Klamath Falls, Ore., remaining there until 1913, when he became assistant to E. E. Adams, then consulting engineer of the Union Pacific System for engineering, motive power and equipment standards, with headquarters at New York. Following the appointment, in 1918, of Mr. Adams as engineer for the Division of Capital Expenditures, at Washington, Mr. Englebright was appointed acting consulting engineer for the Union Pacific System corporations, with the added duties of purchasing the large number of locomotives and cars, orders for which were placed by the Union Pacific System prior to the termination of federal control. On the return of the railroads to private control he became engineer for the New York offices of the Union Pacific System, as noted above.

H. H. Marsh

Howard H. Marsh, for nearly eight years district manager of the *Railway Mechanical Engineer*, and the other publications of the Simmons-Boardman Publishing Company, at Cleveland, Ohio, has resigned to become president of the Victory Equipment Company, with office at 444 Maison Blanche Annex, New Orleans, La. As head of the Victory Equipment Company, he will handle the following accounts: McMyler-Interstate Company, Cleveland, locomotive cranes, pile drivers and material handling equipment; Ball Engine Company, Erie, Pa., steam shovels and railroad ditchers; Schaefer Equipment Company, Pittsburgh, Pa., truck lever connections, brake levers, brake rod jaws and stake pockets; and Equipment Manufacturing Company, Cleveland, trucks and trailers.

His education, business experience and wide acquaintance fit Mr. Marsh for his new undertaking. He is still a young man, having graduated at the University of Vermont in 1903, with the degree of B.S. in civil engineering. That same year he entered the employ of Engineering News (now Engineering News-Record), as assistant to the western manager, and stayed there until 1907, when he was appointed western representative of Engineering-Contracting, with headquarters in Chicago. He left the latter place to go to Cleveland as district manager of the Simmons-Boardman Publishing Company. Mr. Marsh's removal to New Orleans is due to his desire to be near his family, as it was necessary for Mrs. Marsh to take up her residence in the Southwest in order that her health might be restored. In addition to his other work, Mr. Marsh will continue to act as representative of the Simmons-Boardman Publishing Company in the southwestern territory.

D. E. Sawyer has been re-elected general sales manager of the Pollak Steel Company, Cincinnati, Ohio, with office at 120 Broadway, New York; S. K. Morrow, manager of operations, has been appointed manager of sales for its three plants, with office at the Cincinnati works; C. G. Talbott, assistant manager of operations, has been appointed manager of rolled products for the Marion plant; A. C. Weihl, superintendent of the Cincinnati plant, has been appointed general works manager in charge of operations and productions of the Cincinnati, the Chicago and the Marion plants, and V. W. Prather, cost auditor for the Cincinnati plant, has been appointed auditor of the three plants. R. A. Mitchell has succeeded Mr. Weihl as superintendent of the Cincinnati plant; J. H. Deickman has been appointed manager of materials and inspection of its three plants; W. P. Woods has been appointed auditor, and G. H. Tallaksen, superintendent of the Chicago plant. The company has recently distributed a unique souvenir; it is a pen made in the form of a miniature standard M. C. B. car axle, with machined wheel seat and journal and rough turned center.

Lima Locomotive Works Changes

Lewis A. Larsen, assistant to the president of the Lima Locomotive Works, Inc., has been elected vice-president and Waldo H. Marshall has been elected a director.

L. A. Larsen

Mr. Marshall was formerly president of the American Locomotive Company and later resigned to go with J. P. Morgan & Co.

Mr. Larsen was born at Ridgeway, Ia., in 1875. He received his early education in the public schools of Ridgeway and Decorah, Ia., and Upper Iowa University, Northwestern University and St. Paul College of Law. In November, 1897, he entered the service of the Chicago Great Western as clerk to the master mechanic. He held successively the position of chief clerk to the superintendent of motive power and chief clerk to the assistant general manager. In 1904 he resigned to accept the position of chief clerk to the superintendent of motive power of the Northern Pacific at St. Paul. In November, 1906, he became associated with W. H. S. Wright, railway supplies, representing the Railway Steel Spring Company, the Pittsburgh Forge & Iron Company and other companies, and in 1907 entered the service of the American Locomotive Company. In 1909 he was appointed assistant to the vice-president in charge of manufacturing, and July, 1917, was appointed assistant controller. For several years previous to 1917 Mr. Larsen was a special lecturer in the Alexander Hamilton Institute, New York. He has also contributed a number of papers to the railroad magazines. In December, 1917, he was appointed assistant to the president of the Lima Locomotive Works.

Millholland Sales and Engineering Company

W. K. Millholland and E. Millholland have sold out one part of their interest in the Millholland Machine Company and have started a new company, called the Millholland Sales and Engineering Company, with temporary offices at 304 Rauh building, Indianapolis, Ind. After March 1 the company will occupy the machinery store which Marshall & Huschuert have been occupying. This new company will handle a line of railroad and machine shop equipment, and also foundry equipment, and act as consulting engineers on manufacturing and designing problems.

W. K. Millholland, for the past six years president and general manager of the W. K. Millholland Machine Company, previous to taking over active management of the Millholland company, was sales engineer for several large machine tool companies, and also designer for a machine tool company. He is a member of the American Society of Mechanical Engineers.

E. Millholland has for the past ten years been vice-president and works manager of the Millholland Machine Company. During the past three years he was also sales engineer.

The Foote-Burt Company Completes New Plant

The Foote-Burt Company, Cleveland, Ohio, has recently completed a new plant at East One Hundred and Thirty-first street and St. Clair avenue, which increases considerably the company's manufacturing facilities. The total floor area of the new shop is over 131,000 sq. ft. The main factory building is of brick, concrete and steel construction, 507 ft. by 236 ft., exclusive of the addition which houses the shipping department. Separate buildings are provided for the boiler house and for chip storage.

The equipment in the main building is arranged for progressive manufacturing. All material is received in the rear main aisle and is distributed from this aisle to the manufacturing department in the center of the building. The parts move to the front main aisle from which they are distributed to the assembling department in the front of the building. By means of a monorail system, the completed machines are taken from the assembling department to the shipping department. The general offices are on the ground floor across the front of the building, with the factory office on the west side, adjacent to the dispensary and experimental department. A notable feature of the plant is the drawing room, which covers the entire second story of the front end of the building and is approximately 235 ft. long by 24 ft. wide.

American Brake Shoe & Foundry Company

William F. Cutler, president of the Southern Wheel Company, St. Louis, Mo., has been elected vice-president of the American Brake Shoe & Foundry Company, with headquarters at New York, and William B. Given, Jr.. assistant vice-president at New York, has also been elected a vice-president.

William F. Cutler was born on March 5, 1888, at Washington, D. C., and was educated at Hill School, Pottstown, Pa., and was in the class of 1909, at Sheffield Scientific School, Yale University. He began railway work as an apprentice in the Altoona (Pa.) shops of the Pennsylvania Railroad, and later served in the shops of the Hale & Kilburn Company, Philadelphia, Pa. In 1912 he entered the service of the American Brake Shoe & Foundry Company at New York, and subsequently held various positions until 1914, when he went to St. Louis as vice-president of the Southern Wheel Company, a subsidiary of the American Brake Shoe & Foundry Company. In 1917 he was elected president of the Southern Wheel Company, which position he still retains, in addition to his new position as vice-president of the American Brake Shoe & Foundry Company. He is a son of Otis H. Cutler, chairman of the board of the American Brake Shoe & Foundry Company.

William B. Given, Jr., was born on December 7, 1886, at Columbia, Pa., and was educated at Yale University. He has been in the service of the American Brake Shoe & Foundry Company since 1911, with the exception of two years, when he served in the United States Army. He held various positions with the American Brake Shoe & Foundry Company until 1915, when he was appointed assistant to president. From May, 1917, to May, 1919, he served as a captain of infantry in the Rainbow Division of the United States Army, and then returned to the American Brake Shoe & Foundry Company as assistant vice-president, which position he held until his recent election as vice-president of the same company as above noted.

TRADE PUBLICATIONS

Heaters.—The Ross Heater & Manufacturing Co., Inc., Buffalo, N. Y., has issued a 39-page book, Catalogue F, which illustrates and describes the various types of heaters, condensers, expansion joints, coolers and air-jector pumps which it manufactures.

Ladles.—The Whiting Corporation, Harvey, Ill., has issued catalogue No. 156 descriptive of their complete line of foundry ladles, including their new style helical worm geared crane ladle and a new style teapot spout ladle, having the spout inside of the bowl. The book is well illustrated.

Iron.—The Burden Iron Company at Troy, N. Y., have just issued a 30-page catalogue describing Burden iron products and their use in the railroad field. Clear cut illustrations show the various processes through which all Burden products must pass and particular attention has been given to various uses in locomotive and car construction. The booklet is well illustrated and very carefully written.

Riveting Machines.—Catalogue No. 4, entitled "Riveters," has been issued by the Hanna Engineering Works, Chicago, and includes 63 pages devoted to the description and illustration of various types of riveting machines. These machines include the common types of gap riveter, the boiler door ring riveter, pinch bug riveter, combination yoke riveter, forged nose riveter, boiler head riveter and others.

Radial Drills.—An unusually well illustrated and carefully prepared catalogue has been issued by the Western Machine Tool Works, Holland, Mich., devoted to a description of the Western low hung drive plain radial drill, designed for heavy duty. A general description and illustration of the machine is given in the front of the catalogue, accompanied by diagrams of the driving mechanism. A description also is included of a special tilting table.

The Melting Pot.—A monthly publication, known as The Melting Pot, containing much timely information regarding heat treatment, together with descriptions and illustrations of the use of Stewart furnaces, is being issued by the Chicago Flexible Shaft Company, Chicago. A large amount of information on annealing, carburizing and other heat treating subjects is included. In addition, there are many up-to-date and valuable notes on shop practice, particularly relating to heat treatment.

Screw and Ratchet Jacks.—The complete line of jacks made by the Duff Manufacturing Company, Pittsburgh, Pa., is described and illustrated in catalogue No. 104. Jacks of similar construction are grouped and a general description of the construction and operation is given, which is followed by a few short notes on the particular service for which each special type is best fitted. In the closing pages of the catalogue are shown illustrations of repair parts and tables to facilitate ordering material needed for repairs.

Vertical Surface Grinders.—A 40-page catalogue has been issued by the Blanchard Machine Company, Cambridge, Mass., containing in the foreword an interesting description of the development of the Blanchard vertical surface grinder. Illustrations are given showing the rigid construction and power of the machine. Special attention is called to the wheel mounting, spindle arrangement and direct motor drive; also the magnetic chuck. The reading pages of the catalogue are devoted to a description of the field for vertical surface grinding and the advantages of this method of machining are pointed out.

Lathe Chucks.—The 1921 catalogue of the Cushman Chuck Company, Hartford, Conn., is now ready for distribution and contains 50 pages, entirely rewritten and rearranged. Illustrations show the original Cushman workshop and the present plant. Each general style of chuck is fully described, and sizes and prices, together with code words, are quoted. Line drawings and tables also show the dimensions of detailed parts of the chuck. Useful information furnished in this catalogue includes directions for increasing the efficiency of lathe chucks, prolonging their life and instructions regarding the repair and replacement of parts.

An Incentive to Provide for Car Maintenance

A study of the probable effects of the adoption as a permanent policy of a scale of prices for labor and material expended in the maintenance of foreign freight cars in interchange, high enough to include a profit, reveals a wide range of possibilities, the ultimate result of which will all tend toward cheaper maintenance of equipment. One of the difficulties in the way of adequate maintenance of freight car equipment under heavy traffic conditions—when a large part of the work must be done—is the lack of adequate facilities. It is true that many railroads are adequately supplied with such facilities and it is only because of this fact that other railroads can continue to operate without making provision for the full share of repairs which the volume of their traffic should bear. For such roads there is little incentive to make the improvements needed so long as to the well equipped roads may be left a considerable measure of the responsibility for taking care of the equipment of the country, when it costs the poorly equipped roads less to pay for the work at M. C. B. rates than to do it themselves. The prices fixed at the present time are high enough to show a profit for those roads whose costs are considerably below the average. But if they were fixed with the deliberate intent of including an average profit of 10 or 15 per cent above the actual cost of labor, material and overhead, would there not be created a powerful incentive for those roads whose costs are high because of a lack of adequate modern facilities, to provide the needed facilities? Is it not reasonable to suppose that, once provided, these facilities would fully justify themselves by the reduction in unit costs, the immediate benefit of which would accrue to the roads making such investments?

The Foreman a Business Man

The lack of training which foremen are given to fit them for their responsibilities as leaders of men was forcefully brought to attention by G. M. Basford's paper before the February meeting of the Western Railway Club. Leadership is probably the most important function of the foreman, but the variety of ability and capacities the possession of which are advantageous both to the foreman and to the railroads, is almost endless. There are others than that of leadership which ought to be developed by training. One of these is the ability to visualize the job of running a shop or a roundhouse as a part of the business of furnishing transportation, in which money is spent to get certain results; and the ability to see the part these results play in the production and the cost of train miles. Conditions are such at the present time that the problem of leadership is paramount and it must be solved if satisfactory relationships are to be re-established on the railroads. The very necessity for concentrating on this one problem, however, entails the danger of a loss of breadth of view leading to the neglect of other factors affecting the cost of equipment maintenance and operation. Not only is it necessary to get production from labor, but it is necessary to take advantage of every device or plan whereby the need for depending on labor may be eliminated. Sometimes these things are beyond the authority of the foreman because of the capital investment involved. But the ability of the foreman on the ground to see the possibilities, even though his authority will not permit him to go ahead independently, is an asset the railroad should cultivate. A recommendation for many improvements of this nature must originate with the foremen and if the dollars and cents aspect—the business aspect—can be presented along with the more tangible advantages of convenience, an invaluable service has been rendered to the head of the department. Too frequently, however, when such ability shows itself among the foremen its exercise is discouraged, if not suppressed, by the executive officers of the department and until these officers not only learn to recognize its value but develop it themselves, it is unfair to expect much from the foremen.

Are Diesel Locomotives A Possibility?

Anyone reading the article regarding the Diesel engine in railroad service, which appears in this issue, cannot fail but be impressed with the prominent role this development has assumed in Sweden and with some of the claims advanced for the Diesel engine as a source of motive power in heavy traction. While the advocates of the oil engine are not laboring under any delusion as to the prospect of any immediate use of the Diesel motor in heavy traction, it is felt that as our higher grade fuel resources approach exhaustion the economic pressure upon large fuel users will be so great as to force the adoption of a more economical prime mover. It is argued that this applies with particular force to the railroads since they are the largest consumers of high grade fuels and are already feeling acutely the great increase in cost. While current fuel prices are expected to decline, no return to the prewar levels is anticipated, and there is bound to be a gradual appreciation in the price of any commodity as its supply diminishes. Sooner or later the law of supply and demand is going to work some tremendous changes in the conduct of our railroads. Just as we now realize that the railroads could not have held up under the war strain had it not been for other appliances contributing to the economy of the modern locomotive, so the day will come when some of the refinements that we are now reluctant or afraid to adopt will be regarded as equally vital. If electric traction is some day to figure prominently on railroads of dense traffic, is it altogether rash to predict the advent of the Diesel locomotive in sparsely populated districts remote from fuel producing centers? The Diesel engine underwent a remarkable development in submarine service during the war, and it is claimed that German manufacturers are now perfecting a transmission mechanism which will make it possible to use the same design Diesel motor in rail traction.

The Effect of a Seniority Ruling

The mutual welfare of railroad owners, managers, shop executives and shop employees is dependent on a just and common sense method of settling present disputed questions. It is impossible for one class to profit long at the expense of another and the best interests of all will be served by the early establishment of fair working conditions. One question about which there has been a wide diversity of opinion has been the rights of a workman due to his seniority or length of service. There can be no question but that in certain instances a seniority ruling will prevent injustice should there be partiality on the part of a foreman or should a man's ability for some reason be unknown. In by far the larger number of cases, however, experience has demonstrated that seniority does more harm than good, particularly as it prevents ambitious workmen from securing justified advancement. Moreover, the effect of this ruling is to encourage shiftlessness on the part of indifferent workmen who realize that they will be advanced according to length of service and irrespective of whether they turn out a fair day's work or not. This results in a decrease in shop production which is hard to estimate.

Another serious effect of the seniority ruling and one which should cause its abolition is the fact that a shop man may be allowed to try for a position for which he is entirely unfitted simply because he is the oldest man in length of service. A most forceful example of this occurred recently in a railroad shop where a young machinist, who had become thoroughly familiar with the operation of a piston rod grinding machine, was displaced by an older man who knew nothing about the machine. According to the National Agreement, the older man had three weeks in which to make good and for two weeks he struggled along with the machine. Production practically stopped and finally, lack of attention to lubrication caused the grinding wheel spindle bearings to melt and put the machine entirely out of commission. Men should not be tried out on work for which they are obviously unfitted and thoughtful shop workers, as well as managers, must realize that in the long run every one loses as the result of such wasteful practices.

Railroad Administration Draft Gear Tests

In this issue of the *Railway Mechanical Engineer,* there appears the first installment of a series of articles describing the tests of draft gears conducted by the Inspection and Test Section of the Railroad Administration. To those who have sought in vain for definite information among the many conflicting statements regarding draft gear performance that have been published in the past, these tests will be of incalculable value. The scope of the tests and the field of investigation remaining to be covered cannot be set forth more clearly than is done in the preface to the report by C. B. Young, under whose direction the work was conducted. In his introduction, Mr. Young states that when the Railroad Administration decided to build the standardized equipment, the Committee on Standards and the Purchasing Section were both embarrassed owing to a lack of definite and intelligent knowledge of the relative merits of the different gears as well as the relation between mechanical value and cost. Much information on the subject of draft gears was presented by the various manufacturers, but a comparison of the information offered soon developed the fact that each manufacturer had prepared his information on a basis of his own intellect, and that it was impossible to correlate or co-ordinate the various tests in any comparable manner. In the absence of definite information, the rivet shearing test was adopted, but results showed that the requirements of this specification were useless in judging the merits of the gears. The Inspection and Test Section was therefore requested to conduct a series of tests to determine the mechanical value of each make and type of friction draft gear then regularly offered for sale and these investigations are described in the report.

The information covering the tests which have been made on new gears is definite and final. To a limited degree, tests were made on gears which have seen considerable service, but the service tests and the train operation tests which the section had planned were not made because of lack of time. As Mr. Young points out, the report must be used as a whole in order to obtain accurate and definite information concerning the draft gear. The picking out and exploiting of an idea here or there which favors one or the other of the draft gears tested, is to be discouraged and those who use the report should guard themselves against errors of this kind. The report gives reliable, entirely comparable and unbiased values for new commercial gears of the various types and the values given should supplant the widely varying figures frequently given out in the past as a result of inaccurate, unscientific or incomparable tests.

Equalization of Weights on Locomotive Wheels

Locomotives built in recent years have usually been designed to carry loads on the driving wheels that are near the limit that the rails will bear. Furthermore, the heavy reciprocating parts add to the weight of the counterbalance and make the additional force due to the dynamic augment very great. The result is that heavy motive power imposes severe stresses on the track and lately there has been much discussion as to whether the loads are now greater than the track structure can withstand. Whether this is the case or not, it is certain that nothing should be done to increase the load on any of the wheels above its normal amount. Nevertheless this often occurs through improper distribution of the weights between wheels, either equalized together or in separate equalizing systems. Sometimes it is due to improper location of fulcrum pins or to reversing equalizers; in other cases the cause is not apparent. If locomotives were not designed with a high factor of safety, improper weight distribution would cause the overloaded parts to fail. Even if immediate failure does not occur, faulty equalization often causes much trouble. Hot bearings, broken springs and similar defects may be due to this condition when the cause is not suspected. If the weight on the leading truck or the front drivers is too low, these wheels may have a tendency to climb the rail. This is a troublesome feature of some designs of passenger engines.

To remedy the faulty conditions mentioned, the erection of the equalizing system should be done with care and the parts should be made to check with the blue print before they are applied. Even when this precaution is observed, some engines may leave the shop with the weight unequally distributed and for that reason scales for ascertaining the weight carried on each wheel should form part of the equipment of every large repair shop.

Why Build Firing-Up Sheds?

The judgment of master mechanics and shop superintendents in northern sections of the country who have taken the precaution to construct firing-up sheds for the protection of workmen while putting the finishing touches on locomotives just out of shops, was vindicated by the record-breaking snowfall in the latter part of February. There are almost always small, unfinished jobs to be done on locomotives when they leave the erecting pits, and in any case the trial runs develop work which must be done. The difficulty of getting mechanics and helpers to work effectively when exposed to severe or inclement weather and the resultant locomotive delays make some form of shelter necessary. Handling the work in the main shop is certain to hamper other operations. Some form of covered firing-up shed should be constructed in sections of the country subject to severe cold weather and provided with suitable heating and lighting arrangements. A steam line for blowers and an air line for pneumatic tools should be provided. In many cases it would also be advisable to have pits, inasmuch as these will greatly facilitate final inspection and repair work. In an actual case the cost of such a shed, substantially constructed, was only $3,500. This shed was large enough for a shop turning out not more than two locomotives a day. The interest at 6 per cent on $3,500 is $210, which represents the carrying charge on this investment. It is true that such a shed would not ordinarily be used more than half of the year, but it is equally evident that the saving due to accelerated locomotive movements and labor saving in even two or three spells of bad weather would more than equal the interest on the investment.

Straight vs. Coned Treads for Driving Wheels

New York.

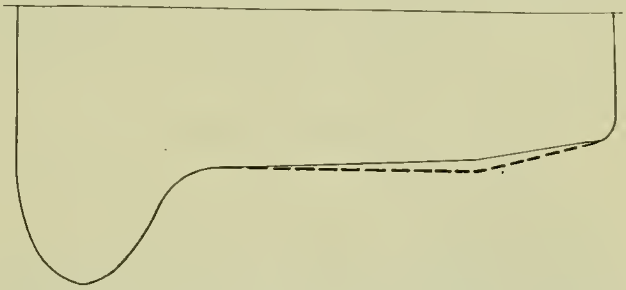
To the Editor:

The editorial relative to Sharp Tire Flanges in your issue of February, 1921, suggests the question: Why use cone-tread wheels in rigid wheel bases comprising two or more pairs of coupled wheels? The writer doubts the advisability of this practice under any circumstances other than with a single pair of wheels on a radial axle and is convinced that it is largely responsible for sharp flanges and poor tracking qualities.

Assume, for illustration, a locomotive with five pairs of coupled wheels and a rigid wheel base of 22 ft., with no provision for lateral movement other than 1/4 in. narrow tire setting on front and back wheels and the usual 1/4 in. total lateral play between wheel hubs and boxes, under which condition the maximum possible variation of alignment of flanges, is 1/4 in. between front and main, and main and back wheels. This is common practice on locomotives of the 2-10-2 type designed to traverse curves of 16 deg. deflection and a radius of 359 ft.

The middle ordinate of this curve on a 22 ft. chord is 2.02 in. and the quarter ordinates 1.51 in. Assuming the frames to be rigid the track must be laid 1.77 in. wider than standard gage to allow this locomotive to pass.

It may be seen that with the flanges of the front and back wheels in contact with the outer rail of this curve, those of the intermediate wheels will be 1.51 in. away from the outer rail and that of the main wheel will be 1.77 in. away from the outer rail.



Present Standard Tire Contour and Form Proposed for Driving Wheels

The taper of the tread of the American Railway Association standard tire section is 1 in 20, and the diameter changes 1/10 in. for each inch of tread. Thus it may be seen that the diameter of the intermediate wheels which run upon the outer rail are .151 in. (nearly 5/32) less than those of their mates which run upon the inner or shorter rail, while the diameter of the main wheel which runs upon the outer rail is .177 in., (over 11/64) less than that of its mate, which runs upon the inner or shorter rail. This condition of the smaller of pairs of wheels running upon the outer or longer rail is undoubtedly incorrect and just how much the lateral thrust of the front and back flanges is increased by the tendency of the intermediates to run toward the outer rail, over the pressure which would be had with wheels having straight treads, is very hard to estimate in view of varying conditions of rails, the use of sand, etc. It must be considerable, however, and no doubt causes more rapid flange wear than would be had with the straight treads.

It would seem that the use of tires with straight or parallel treads as shown in dotted lines on the accompanying diagram, on all wheels, would result beneficially. A good compromise would be to use A.R.A. treads on the front and back wheels and straight treads on all intermediates, although there are good and valid objections to this, as will be shown.

With cone-tread wheels on the wide gage track of sharp curves good flange lubrication is imperative and if cone treads must be used, it would appear that decided advantages would accrue from the use of some device which would allow lateral displacement of all but the main wheels, without sacrifice of stability. This applies not only to locomotives of the 2-10-2 type, but as well to any having coupled wheels.

Such a device should have only sufficient lateral resistance to permit the wheels to adjust themselves to any curve, which generally speaking, will be sufficient to return the wheels to the normal position on straight track and maintain stability in that position.

It is a well known fact that cone-tread wheels, when leaving the wide gage track of curves will seek to adjust themselves to correct diameters for straight track. In doing this several sidewise oscillations take place until the wheels find the true position. These oscillations have been known to spread the rails of poorly spiked and braced track, thereby causing derailments.

With coupled wheels of different diameters in the same wheel base on curves, some of the wheels must be slipped into correct relationship by the side rods. This no doubt causes rapid wear of rod bushings. With straight treads all diameters are alike and the only slipping necessary would be that due to the length of the rails traversed; this would produce only torsional stresses in the axles, which would not be detrimental to the rods.

While it is admitted that the cone tread is correct with one pair of wheels, it is herein suggested that straight treads have decided advantages in rigid wheel bases with coupled wheels. Chas F. Prescott.

Ball Bearings for Railway Cars

New York, N. Y.

To the Editor:

In the article on the use of ball bearings for railway cars, published on page 23 of the issue for January, 1921, there appeared a misleading statement, which I should like to have an opportunity to correct. The ball bearings on the Swedish State Railways, which were stated to have covered 240,000 kilometers and more, were repaired several times so that it was not really the same bearing which covered the total distance. This is best borne out by the fact that the Swedish State Railways have not made any further installations of ball bearings on passenger cars, but, on the other hand, have practically abandoned their use in this service. The maker of these ball bearings has made a request to be permitted to substitute roller bearings for his ball bearings.

As for the N. K. A. disk bearings, these have since been installed in additional express train equipment on the Swedish State Railways and are now being installed on "Stockholm, Wästeras, Bergslagens Järnvägar," Sweden, in express train service in France, and on the Danish State Railways. Disk bearings are also being applied in street car service in Copenhagen and Odense Sparvägar, Denmark, and are now in operation in Malmö, Sweden.

E. F. Maas.

(The statement regarding the service obtained from ball bearings was taken from a Consular report, which we had no method of verifying at the time. Apparently the report was misleading in this particular and we are glad of the opportunity to correct any erroneous impression that the article may have given rise to.) Editor.

NEW BOOKS

Developing Executive Ability. By Enoch Burton Gowin, 9 in. by 6 in., illustrated, bound in cloth. Published by The Ronald Press Company, 20 Vesey street, New York city.

While this book is designed primarily for the young executive, without particular reference to his attachment to railroad service, still there can be no question but that the subject is one which should be of keen interest to a very large number of railroad men. It is certainly the greatest personal and individual problem for every young man engaged in railroad service, as well as a problem of the greatest importance to many who have graduated into important executive officers with our railroads. Railroad officers are sometimes criticized on the ground that they do not handle their work with the same degree of precision and system practiced by executives in other business activities. The author, who is assistant professor of commerce, New York University School of Commerce, Accounts and Finance, has endeavored to show how the day's work may be so systematized that it can be cleared away with ease and precision, how the executive may utilize the time thus gained for constructive effort and for the development of mental vision, initiative and reasoning power, and show him how to develop and prepare himself for broader activities and greater responsibilities. The alert and ambitious railroad man, no matter what his relative position may be, will welcome any possible suggestions by means of which he can effect many economies of time, energy and money. The book is in no sense theoretical. It is simply a common sense analysis of those qualities which characterize executive ability and the means by which this ability may be obtained. It is more than interesting to note that in illustrating his point Professor Gowin has often referred to Harriman, Hill and Ripley, and it may be doubted whether the tremendous influence of the old school railroad executives on our modern business organization is even now fully appreciated. This is not only the kind of a book railroad men should read, but it is the kind of a book that they will want to read.

Powdered Coal as a Fuel. By C. F. Herington, 303 pages, 8 in. by 9 in., bound in cloth. Published by D. Van Nostrand Company, 8 Warren street, New York city.

This is the second edition of a book which made its appearance about two years ago, and represents both a revision and enlargement upon the original text, although at the time of its publication this book probably represented the best and most complete treatise upon this subject. Since that time it cannot be denied that powdered coal has assumed a wider field of usefulness and is now regarded as a most promising development. This applies particularly to industrial operation, as it has been demonstrated that the limitations imposed upon the locomotive in its present form make the successful application of this fuel to locomotive use decidedly problematical. However, it should be of particular interest to railroad engineers to know that one of the most successful installations of powdered coal under stationary boilers has been accomplished by the Missouri, Kansas & Texas Railroad at its Parsons, Kansas, shops. It should also be stated in this connection that the American Locomotive Company has met with considerable success in the use of powdered coal in its metallurgical furnaces at Schenectady. Both of these installations and other installations of similar character in industrial plants are described in detail. The author relies more upon descriptions of successful installations than upon theoretical analysis of the subject to demonstrate the possibilities of powdered coal. The book shows very completely just what is being done at the present time with powdered coal and may serve to convince many as to what can be accomplished with this fuel.

Mountain Type Features New Rock Island Power

Greater Steaming Capacity and Larger Driving Wheels Indicate Trend in Development of This Type

UPON return to private management, the Chicago, Rock Island & Pacific was one of the earliest to place large locomotive orders. These orders included 10 Mountain, 10 Mikado and 15 Santa Fe type locomotives all of which were purchased from the American Locomotive Company and constructed at their Dunkirk plant. None of these types is new to the Rock Island since this road has operated both Mikado and Santa Fe type locomotives of the same general design in freight service for several years and was one of the first railroads to adopt Mountain type locomotives for heavy passenger service.

The selection of these locomotives by a railroad that has had experience with each type is in itself significant and would indicate that the Mikado has made a place for itself which the advent of heavier power cannot usurp. It also serves to demonstrate that the Santa Fe type is here to stay and verifies the foresight of those who placed the Mountain type in passenger service on the Rock Island seven years ago.

When the first Mountain type locomotives were placed in service on the Chicago, Rock Island & Pacific, they enabled the consolidation of the St. Louis and the Chicago sections of the Colorado trains into one train west of Phillipsburg, Kansas, where maximum and ruling grades of 1.0 per cent are encountered. The trains hauled by these locomotives usually consisted of 10 or 11 all-steel cars weighing from 675 to 750 tons although as high as 1,175 tons in 19 cars have been handled successfully over a division of 140 miles.

Pioneer and New Mountain Types Compared

The policy of the Chicago, Rock Island & Pacific with respect to the design and equipment of new locomotives has been consistently directed toward obtaining maximum efficiency in operation and economy in maintenance. Therefore, a comparison between the pioneer and the new Mountain type locomotives affords an interesting commentary upon the development of this type practically since its initiation in passenger service.

It will be observed from the specifications which are submitted in connection with this article that the rated tractive effort of both locomotives is nearly identical, but that the weight of the new locomotives is considerably greater than that of the original Mountain type. The new locomotives weigh 29,000 lb. more on the drivers and are proportionately heavier throughout.

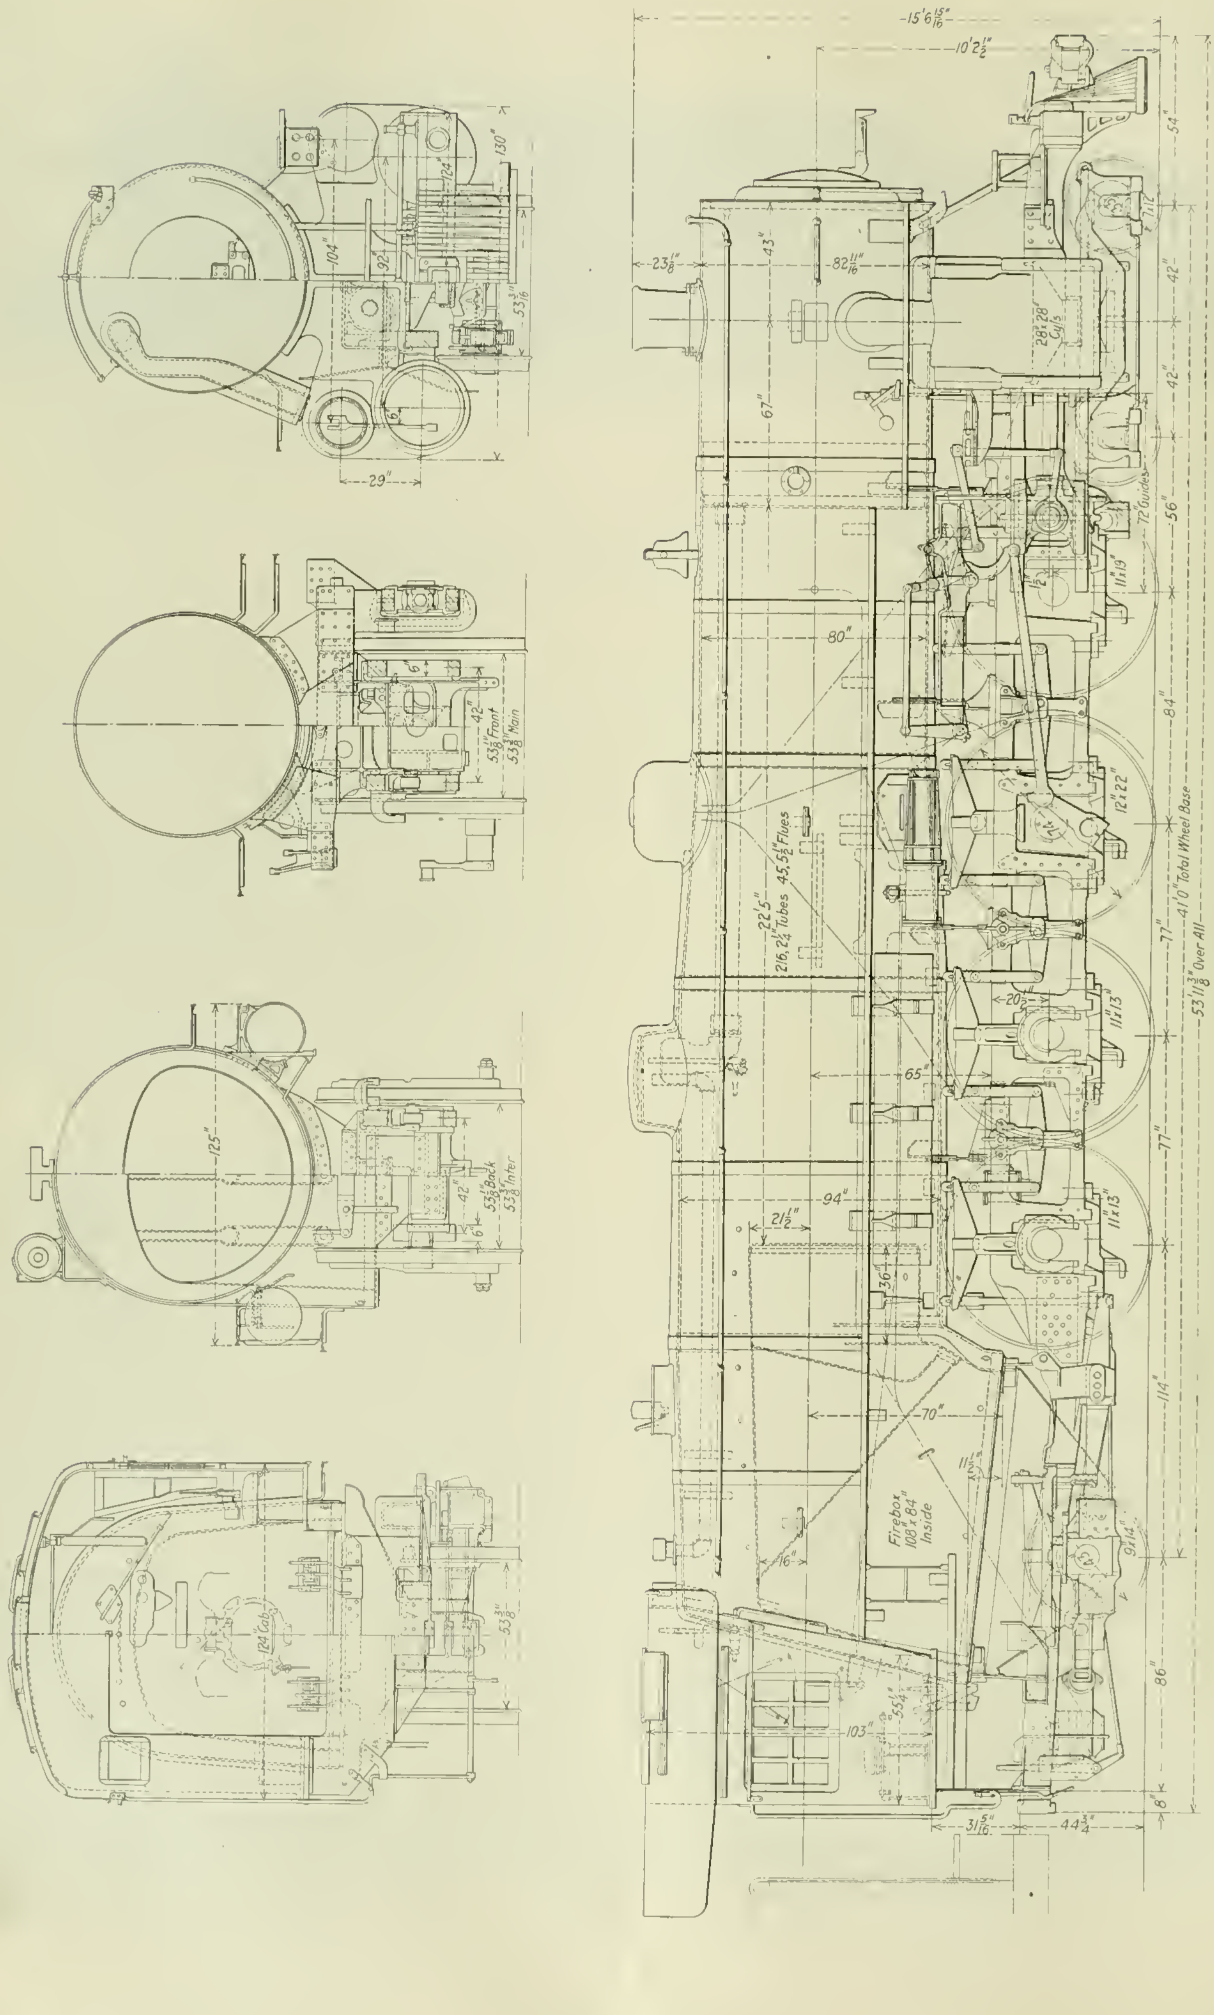
This increased weight is largely accounted for in the boiler dimensions as the total heating surface of the new locomotives, excluding the superheater, is nearly 600 sq. ft. greater. The greatest proportional increase occurs in the firebox heating surface of the new locomotives which is over 30 per cent greater than the firebox heating surface of the older locomotives. This increase is largely accounted for by the application of three thermic syphons to each locomotive as the other firebox dimensions, including the grate area, are practically the same.

The most striking difference in design, however, appears in the driving wheel dimensions, the new locomotives having 74 in. driving wheels as compared with the 69 in. wheels of the earlier locomotives. As the cylinder dimensions of the two locomotives are the same, it will be seen that the larger driving wheels tend to balance the larger boiler, which carries 200 lb. pressure as compared with 185 lb. on the original locomotives. These are the first Mountain type locomotives built with driving wheels as large as 74 in. and their ability to sustain high speeds with heavy trains will be watched with interest.

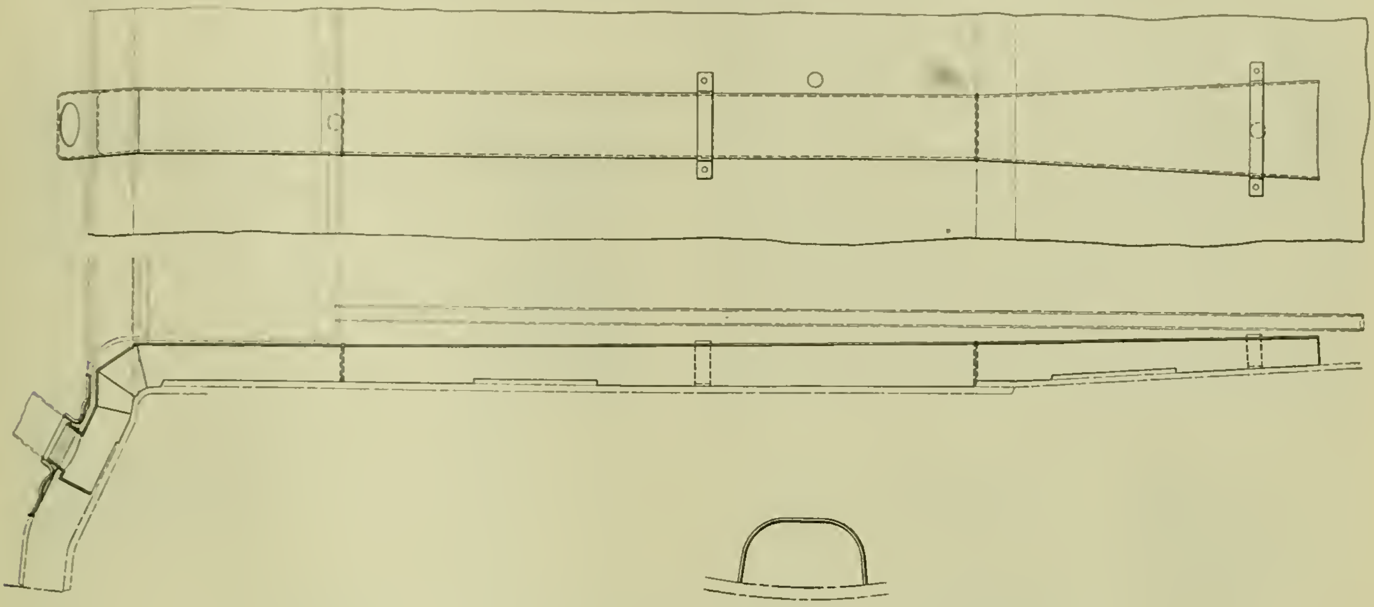
Special Features of the New Locomotives

Among the novel characteristics applying generally to all three classes of the new locomotives is the short slope of the cab front which permits all of the wrapper sheet staybolts to be outside of the cab so as to facilitate inspection and removal. All the piping is arranged so as to interfere as little as possible with inspection and minor repairs to staybolts. The location of cab appurtenances was given special attention in the design of these locomotives from the standpoint of both safety and accessibility. An outside steam turret is provided with extension handles to the valves so that all pipes having boiler pressure are located outside of the cab. The injectors also are located outside of the cab. The detached water column is specified in accordance with the recommendations of the mechanical standards committee of the Railroad Administration.

The tenders of these locomotives are of the Franklin type with unit draw-bar attachments and Commonwealth cast steel underframes. This is in distinction to the Vanderbilt type of tender which was constructed for the first Mountain type locomotives and has characterized the Rock Island locomotives for many years. It should be noted in this connection that the new tenders for the Mountain type locomotives have a water capacity of 10,000 gal. and carry 16 tons of coal in comparison to the tenders attached to the original Mountain type locomotives which had a maximum capacity of 8,500 gal. of water and 14 tons of coal. The locomotive tender has a low center of gravity with rounded bottom and corners

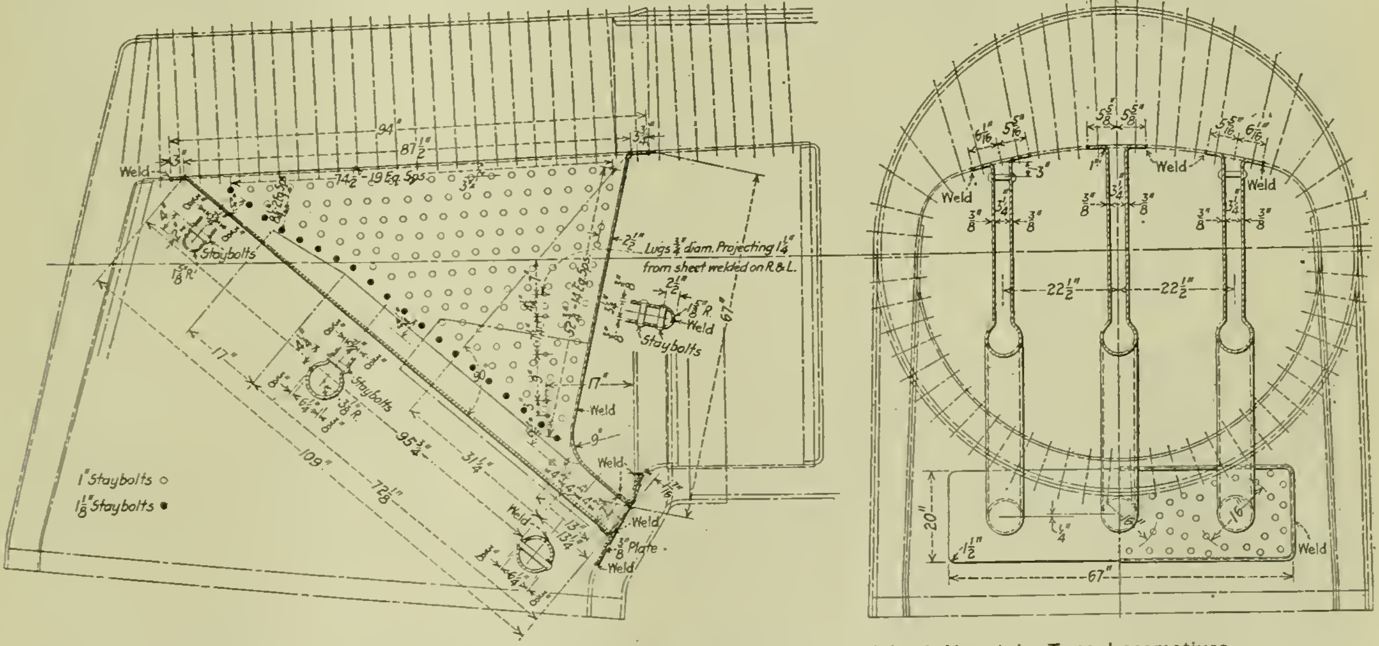


Elevation on Sectional Views of New Mountain Type Locomotives for Chicago, Rock Island and Pacific bringing the side and bottom sheet connection above the radius so as to eliminate the customary angle in the corners of the cistern to which the side and bottom sheet are attached and which usually give trouble on account of leakage.



Intake Channels for the Thermic Syphons Applied to New Rock Island Locomotives

We are indebted to W. J. Tollerton, general mechanical superintendent, for the following statement relating broadly to the principles governing the design of these locomotives:



Detailed View of the Nicholson Thermic Syphons as Applied to Rock Island Mountain Type Locomotives

"Many of the features on these locomotives were brought about by closely watching previous engines of similar design, and the idea has been to eliminate any weakness that may have developed; also the design is prepared with a view to the greatest possible reduction of possible future shop labor when the engine is overhauled, by easy accessibility of the different parts, and the idea of making each part, if possible, run from shopping to shopping without renewal. It must be appreciated now, more than ever, that anything that can possibly be done to increase mileage and get a quicker turn on the engine, both at the terminal and when passing through shop, should be anticipated at the time the design is made."

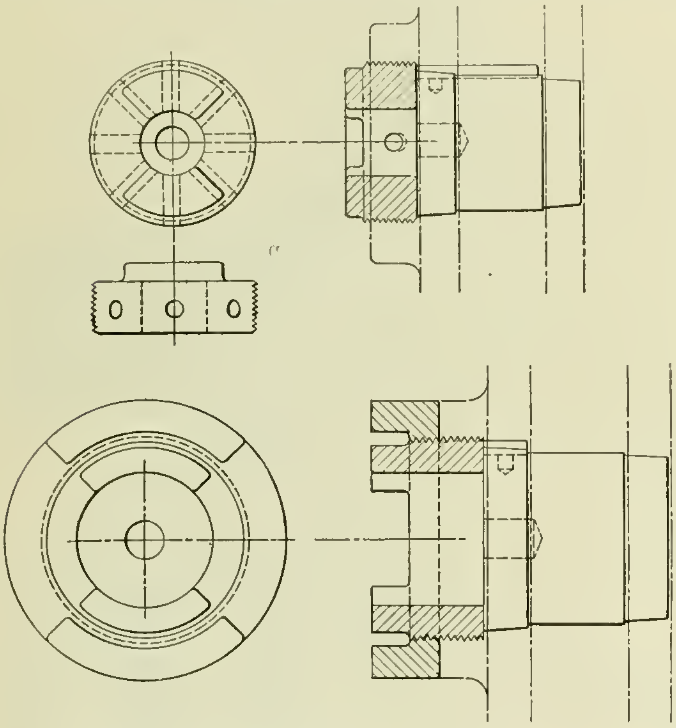
Special Equipment Applied to the New Locomotives

The most noteworthy addition to these new locomotives in the form of a specialty designed to increase economy and capacity is the Nicholson thermic syphon, the details of which are illustrated in connection with this article. While this device has been applied to locomotives on the Rock Island for over a year and is now giving satisfactory service on a number of other railroads, this is the first instance in which the syphons have been specified throughout on new orders of Mountain, Mikado and Santa Fe type locomotives. As will be observed from the specifications and drawings, the syphons add 141 sq. ft. of heating surface to the firebox and serve to support a brick arch in place of arch tubes. The purpose of the syphons is to increase the capacity of the locomotive by increasing the firebox heating surface as noted and to improve the circulation within the boiler resulting in a freer steaming and more economical locomotive.

Two other novel and interesting specialties applied to these locomotives are the wrist and knuckle pins, both of which are illustrated in detail. These designs are patented by the U. S. Metallic Packing Company and have the advantage of enabling the pins to be removed from the outside and the rods taken down irrespective of their position.

The new locomotives are all equipped with force feed lubricators, Barco flexible steam heat and air brake connections, Alco power reverse gears, Baker valve gear, the Woodward engine truck, oscillating front driving box, Franklin adjustable driving box shoes and wedges, hollow main crank pins with internal grease lubrication and adjustable hub plates by means of which the lateral can be taken up without dropping the wheels.

The locomotive smoke-box is equipped with the Unit spark arrester which is cylindrical in form and can be readily removed through the front door. Franklin grate shakers are applied to all of the locomotives but stokers of the Duplex type are applied only to the Santa Fe type locomotives as it has been found entirely practical to meet the maximum service requirements on Mountain and Mikado type locomotives by means of hand firing and it was thought that the application of syphons would further improve the free steaming qualities of these locomotives. However, the Mountain type locomotives are designed so that stokers may subsequently be applied if found necessary.



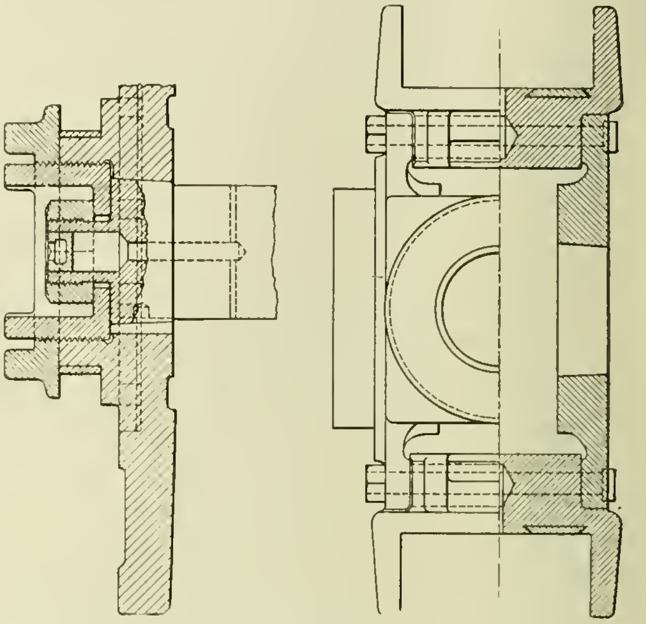
Removable Knuckle Pins Applied to New Rock Island Locomotives

In addition to the Alco standard drifting valve these locomotives are equipped with an auxiliary saturated steam line to the cylinder. A manually operated quick opening 1¼ in. starting valve is connected to a 1¼ in. pipe extending from the turret to the front end of the boiler. From this point, 1 in. branch pipes lead into each steam pipe. A copper pipe, having its own connection from the hydrostatic lubricator in the cab, is led to this steam line. A 1¼ in. tee is also inserted near the cab for emergency oiling of the piston valves by the engineman in case the force feed oil pump fails en route.

Mountain Type Locomotive Dimensions

The Mikado locomotives purchased by the Rock Island last year do not differ materially in design from locomotives of the same type which have been in service on the railroad for some years and the new Santa Fe type locomotives are substantially the same in design as the locomotives of this type built for this railroad in 1918 and described in the January, 1919, issue of the *Railway Mechanical Engineer*, page 41.

For convenience the principal dimensions of the Mountain type locomotives which were constructed for the Rock Island in 1913 and referred to in the foregoing are tabulated together with the dimensions of the new locomotives as follows:



Sectional Views of Crosshead, Showing Novel Wrist Pin Design

	Chicago, Rock Island and Pacific Mountain Type Locomotives	
General Data:	Built in 1913	Built in 1920
Tractive effort	50,000 lb.	50,400 lb.
Cylinders, diameter and stroke	28 in. by 28 in.	28 in. by 28 in.
Weight in working order	333,100 lb.	369,000 lb.
Weight on drivers	224.100 lb.	253,000 lb.
Weight on leading truck	57.500 lb.	57,000 lb.
Weight on trailing truck	51.500 lb.	59,000 lb.
Weight of engine and tender in working order	490,500 lb.	559,000 lb.
Wheel base, driving	18 ft. 0 in.	19 ft. 10 in.
Wheel base, total	38 ft. 11 in.	41 ft. 0 in.
Wheel base, engine and tender	70 ft. 2¼ in.	79 ft., ¾ in.
Ratios:		
Weight on drivers ÷ tractive effort	4.48	5.02
Total heating surface ÷ grate area	6.66	7.32
Total heating surface ÷ grate area	65.4	74.4
Per cent firebox heating surface to evaporative surface	7.50	8.66
Per cent superheating surface to evaporative surface	22.9	26.6
Total evaporative surface ÷ volume of cylinders	206	234
Grate area ÷ volume of cylinders	3.14	3.15
Wheels:		
Driving, diameter over tires	69 in.	74 in.
Driving thickness of tires	3½ in.	4 in.
Driving journals, main, diameter and length	11 in. by 22 in.	12 in. by 22 in.
Driving journals, others, diameter and length	11 in. by 13 in.	11 in. by 13 in.
Engine truck wheels, diameter	34 in.	33 in.
Engine truck journals, diameter and length	7 in. by 12 in.	7 in. by 12 in.
Trailing truck wheels, diameter	42 in.	43 in
Trailing truck journals, diameter and length	9 in. by 14 in.	9 in. by 14 in.
Boiler:		
Style.	Conical	Conical
Working pressure, pounds per sq. in	185 lb.	200 lb.
Outside diameter, first ring	78 in.	80 in.
Firebox, length and width	107½ in. by 84 in.	108 in. by 84 in.
Tubes, number and outside diameter	207—2¼ in.	216—2½ in.
Flues, number and outside diameter	36—5½ in.	45—5¼ in.
Tubes and flues, length	22 ft.	22 ft. 5 in.
Heating surface, tubes and flues	3,805 sq. ft.	4,283 sq. ft.
Heating surface, firebox	312 sq. ft.	406 sq. ft.
Heating surface, total	4,117 sq. ft.	4,689 sq. ft.
Superheating surface	944 sq. ft.	1,247 sq. ft
Grate area	62.7 sq. ft.	63 sq. ft.
Tender:		
Tank.	Cylindrical	Rectangular
Water capacity	8,500 gal.	10,000 gal.
Coal capacity	14 tons	16 tons

Getting Better Results From Railroad Organizations*

The Subordinate Officer Occupies a Strategic Position, but Is Not Properly Trained to Fill It

BY GEORGE M. BASFORD

DISCUSSIONS on reducing cost of transportation do not really begin before someone mentions the real key to the situation, which is effort of the individual all along the line to improve his production, to save. The next thing mentioned is the foreman and supervision. The foreman today is the most vital influence on the road.

Giving my conclusion first I am going to suggest what seems to me to be an absolutely unquestionable necessity on railroads today. I am going to suggest a foreman for a new job. The job is to take charge of the whole railroad organization as an organization, as a general foreman of personnel, but the man would have a title and standing that places him next to the chief executive of the road. This officer would supply a missing link in our troubled days. The chief executive was formerly so close to the small organization that he could know every man. Not only did he know every man, but he handed to them, by contact, his ideals, his desires and his inspiration. As organizations grew this link was lost. It must be found again. At this precise point in the development of railroads, and in the present complication of their problems there is nothing to be done that will net as much as securing the co-operation of the rank and file for increased production and the reduction of cost of transportation. The minute the men in the ranks, on the track, in the shops, yards, terminals, trains and engines center their minds to the fact that the best thing they can do for themselves, for the railroads, and for the public, is to get busy to save dollars, the railroads will be saved.

It is not enough that some should be striving or that some departments should be organized for effective effort of the individual. It is necessary that the effort should be general, bringing departments into combined efforts. Now we hear men say, "I should worry, the coal is not charged to my department." To answer this there must be some way for these men to learn the policy of the road with respect to coal, and the policy with respect to everything they use.

It Takes a Shock to Wake Us Up!

Is it radical, is it revolutionary to suggest a high officer for the exclusive administration of the organization as an organization, who will himself be a part of the policy of the company and whose duties are to see that everybody from himself down to unskilled labor understands that policy? Sometimes it takes a shock to wake us up. Right now we are having one. Until organization questions receive some sort of consistent attention we shall continue in trouble and in trouble that has a remedy.

How can anyone defend such a thing as this? An important department of one of our fine big railroads has not once in 30 years been presided over by an officer who grew up on that road and in that department, but in this time many importations have been made. All have been able officers but they came from "outside." Think this over!

Another big road recently had a narrow escape. A vacancy in a high position was about to be filled by an outsider when the president's attention was called to a man already in the service, who for years had been preparing for exactly that position. He was promoted. He has made good. Some say, "We need new blood." The answer is you already have it. Circulate it. Every time a stranger is imported to a high position notice is served on the entire organization that it is useless for the individual to exert himself. This is just what has happened on many of our railroads. When foremen and men see this why should the men desire to be foremen and why should foremen wish to go higher?

"Give me a bunch of good foremen and the yard will run itself," says the ship builder.

A Picture

Two years ago a large industrial organization started such a plan. It involves 15,000 men in a number of plants and includes a very large office and sales force in this country and abroad. A remarkable man was selected to manage personnel, training and promotion. He reports to the board of directors and works with the executive assistant to the president. Policies are established by conferences in which the personnel officer has a part. He carries these policies out through and with the organization, everybody knowing that he represents the highest authority. He has begun with recruiting, training and promotion questions, is developing co-operation such as is seldom seen and has made remarkable headway in better understanding among not only the different plants of the company but among the officers and men of individual plants.

To succeed the policies must be definite and the objects of the organization must be known. This officer is supplying through the organization itself that which was lost when great growth came. He is bridging the distance that was rapidly increasing between the executives and the men. He has established apprentice schools, workmen's schools and foremen's schools, which means that the foremen are studying men and methods of dealing with them and are becoming managers of men. The work he is doing is entirely applicable to the railroad, the small road as well as the large one. The railroad needs the facts he is collecting. Who have we got in our employ? What is he doing? What is he capable of doing when trained to do it? The roads need the job analysis he is making for his company and the system he is working out to find and fit men to the jobs.

Chief Clerk

Let us think a moment how chief clerks are selected. It is a personal matter with the officer. Chief clerks sign the officer's name, take action for him in his absence. I have seen over one hundred officers of a certain road in conference for several days at headquarters here in Chicago—while the chief clerks ran the road. Because this is personal service these men are selected with personal care and from men who have been through long periods of training. Naturally they make good. We should therefore think of two things in this case.

First, these men are often good material for promotion. Think of this—the chief clerk is close to his superior. He absorbs from his superior the things that made that superior successful. He grows by his contact with a bigger man. This is training, of the sort that we are talking about. Moreover, the chief clerk is in an exposed position where good work shows up quickly and clearly. Let us get the obscure men up into a brighter light and see what happens.

Second, every man on the road must and does act for the

---

*From an address before the February meeting of the Western Railway Club.

boss in his absence and should be selected with equal care and should be trained as well. Every man signs the name of the boss on every job he does and the railroad is about 150 ft. to 200 ft. wide and perhaps 2,000 miles long. The boss is necessarily away most of the time from most of his subordinates.

Biggest Job on the Road

Someone has said that "the foreman is the top sergeant of industry." Nothing is more true or more important in any industry than this. The character of an organization is up to the character, ability and progressiveness of the foreman. No matter who or what the captain is, the company is practically useless unless the top sergeant is right. If the foreman is a timeserver, as sometimes he has been taught to be, the men will be timeservers also and the result is well known. Who on a railroad ever gets shop foremen or yard foremen together to tell them how important their jobs are and to show them that to their men they represent the railroad? Are they encouraged to know the manhood, ability and possibilities of their men? Does the foreman look with his own eyes alone or does he look with the eyes of the management? Does he know his men when off the job? Is he their friend and advisor?

How is a new foreman selected when a foreman leaves? He may be most skilled with his hands and may be most proficient with his own work, but he must know how to manage and operate the most complicated, most delicate machine in the world—a human organization with intricate problems always present. Is he usually told about the management of men and is he helped and supported as he should be in that management?

Some big successful industries are getting to a point of appreciating what foremen can do and are already holding foremen's schools and foremen's meetings to bring these important men to see their own possibilities. Remarkable results are being obtained by leading the foremen to realize that they are really administrators of human affairs, that they require wisdom as well as ability, that an army is what its commander makes it, that the gang reflects the leader and that the leader must know and have the confidence of the men he leads.

In the question of shop foremen a new situation developed instantly when piecework was abolished. Is it not true that piecework furnished the incentive to the individual worker, whereas incentive in earlier days had been supplied by the foremen? Under piecework the foremen deteriorated, in some cases to the mere checking of work. Foremanship received a knockout when, by piecework, men received more than the foremen did. When piecework disappeared this left many roads with foremen who were not trained at all and did not know how to furnish the incentive to the men. This is not the fault of the foremen, but of the system of things which changed. It confirms the opinion that the loss of inspirational contact has been serious.

The Traveling Engineer

Is it possible that these vitally important men can get closer to the men on the engines and represent to them the ideals and the humanity of the wonderful organization of a railroad? There is no finer body of men than those who run our engines, but as a body what do they know, what do they see of the management? It is represented to them by rules, the breaking of which means trouble. These men can affect the treasurer's figures more than any other class of men on the road. For instance, they can improve ton-mile figures more than anyone else can. I believe that a 10 per cent saving in fuel lies in the hands of these men whenever the desire to save it is made an ideal with them and when the idea of saving is "sold" to them.

Roundhouse Foreman

Here is the man who must be the manager of his men. He is often isolated and must rely on himself and frequently faces great difficulties of weather, lack of facilities, even of conveniences, and without sufficient subordinate supervision in his work. His work is a continuous emergency. A big roundhouse job is as big as the head of the department had a generation ago.

The new officer we are talking about would give the roundhouse foreman great encouragement, would help him get the facilities he needs inside and outside of the roundhouse. This officer would be able in a short time to provide him with trained men. Here is a good place for a start to be made in reducing idle time of engines. Here is where industrial intelligence counts heavily. Co-operation counts most of all. Despatchers should understand the roundhouse. Traveling engineers should spend enough time there to understand how engines come in off the road.

Recruiting Officers

Without a systematic method for taking recruits into employment, without insisting that employing officers should work to a certain plan or system the character of recruiting will depend largely upon and will be limited by the ability, the personality and methods of those who do the hiring. Various manufacturing plants employ highly trained recruiting officers in employment offices. Some concerns go so far as to employ psychological tests, others use intelligence tests, means for selecting recruits having become a science. We may hold different opinions as to the tests suggested and used, but it seems decidedly necessary that greater care in some form should be exercised, especially in recruiting for permanence. Those who have made exhaustive study of employment officers and recruiting officers in industries say that there is no case on record of this work having been abandoned when once started.

Employment management in industry has become a profession, devoting itself to getting and keeping men through uniform, consistent policies.

Recruiting Along the Road

Let us select for various jobs young men and boys who are recommended because of character, physical ability and the necessary intellect. One way to select them is to enlist the aid of local officials along the line of road. Station and local officials of all departments may be asked to recommend those they know about or whose parents they know. The headmaster of the grade school or the principal of the high school, the clergy, and even the local judge may and will recommend the best material when they are interested to do so. Having in mind office boys, apprentices and young men it stands to reason that living along the line of the road they will already have an interest and an embryo undeveloped loyalty to the property from which the loyalty so greatly needed under present conditions may have promise of development. Wherever this is done the results have justified the plan and it seems worthy of consideration.

Labor Turnover

To engage new men, teach them their duties and launch them into service costs a lot of money. To engage, train and then lose them in large numbers is a very serious loss. It is one of the biggest leaks in industry. To hire and lose a skilled man costs from $250 to $300 in one industry which has been studied. It must cost railroads more than that because in many cases great damage is done by such men. I know of one large railroad shop which for three years in fairly busy times had not found it necessary to go beyond its own apprentice graduates to supply all the skilled talent needed and in that period no skilled workman was hired from outside.

Inspiration

A large majority of men take pleasure in accomplishment of a good piece of work. Making something, repairing something or making a good run over the road brings satisfaction and is in itself an inspiration. Praise is often in order but must be used with discretion, so also censure. Notice taken in either case indicates that the company cares whether work is done well or not and most men will respond.

A road had three shops far apart and a flue job at each. One of the flue gangs had made a record. The leaders of the gangs at the other shops were sent to investigate. They went back and beat the record. This was not all. All three flue jobs were overhauled, new machinery installed and a lot of money saved. Mere expression of interest inspired these men to do good work and they were happier for doing it. It is a part of training of men to show them that the job they are doing is of great importance to the road.

Friends

Everybody needs a friend. Every young man finds a turning point in his career, a point in his life when he wakes up to a realization of his responsibility and his opportunity. It may be that a word of advice, of caution, of recommendation given at the right time will make, and the absence of it will break a career. It is most fortunate if this friend is his employer or the representative of his employer, the foreman, the general foreman, the master mechanic, the train master, the chief despatcher. In older days when organizations were small it was the boss himself. In these days of big things it is the representative of the boss. The most important thing a big organization can do is to provide the thing that bigness has outgrown—personal contact with big unselfish minds, minds big enough to give a point of view to an individual. The employer is really the best friend of the employee. If this is not true in any case it must be made true. Then it must be understood by every officer and every workman. How shall this be done? It must be somebody's business to get it done.

Good Soldiers

Nobody ever wanted "good soldiers" as railroads want them now. Railroad men are good soldiers, but who are their leaders and why? Most men are followers, in fact everyone is a follower of some sort. We worship heroes and ideals. We follow leaders more able, capable or perhaps more dominant than ourselves. Shall we follow our superior? That depends upon their leadership and we are "company men" or "organization men" depending on the influences and their strength.

What is to be done about it when others lead our people away? Is there nothing we can do? Let us remember that the "old man" used to be the leader, and let us consider the possibility of regaining some of his leadership in the days that are to come. It will be needed. Men always have followed and always will follow those whom they think "get" them most. It is important to find a way to discover, recognize and reward individual ability.

Discussion

Talking things over brings co-operation. When people get together for discussion responsibility is necessarily forced upon those present and the natural tendency is to look at the question from the other man's point of view. This is the value of meetings, especially when the object is to reveal and develop the importance of the person who has a tendency to consider himself obscure and overlooked. Nothing in any organization helps so much as for this man and that man to stand up and tell in his own way what or who is holding him back. When the accused must answer the chances are that more complete understanding will be reached. The chief who is present is not the only one who will begin a liberal education from discussions with his foremen or his men.

Apprenticeship

I use the word apprenticeship with hesitation simply because to most people it suggests merely "trades." It really represents training, thorough training of the hands, of the mind and of the morals of the lad. What we need today is a modern up-to-date substitute which will fit the times and the change from an employer with one employee to the multiple employer with thousands of employees. The principles involved remain the same. Let me quote from a report of a Massachusetts Commission on industrial training:

"In many industries the processes of manufacture and construction are made more difficult and more expensive by a lack of skilled workmen. This lack is not chiefly a want of manual dexterity, though such a want is common, but a want of what may be called industrial intelligence. By that is meant mental power to see beyond the tasks which occupy the bench for the moment, to the operations which have preceded and to those which follow it—power to take in the whole process, knowledge of materials, ideas of cost, ideas of organization, business sense and a conscience which recognizes obligation."

Consider what the sort of training this suggests would mean in saving money for the railroads, applicable as it is to every department, every office, the track, the yard, the terminal, the roundhouse and of course the shop. Apprenticeship of this kind should not, by any means, be limited to the shops. Some roads, notably the Santa Fe, have faithfully developed apprenticeship and have enjoyed wonderful results. This road should be proud of the 1,506 graduates of its apprenticeship courses. What has been done with shop trades should now be extended to every department, every office and every job.

Selling an Idea

Experience in selling something to people who think they do not want it would help the leaders of big organizations more than they know. An organization must have ideals. To succeed these must be sold to those who are to carry out the principles—to the official staff and by them they must be sold to the rank and file. Is the ideal of reduced cost of transportation sold to the men in the ranks? Do many of the men say, "What do I care? There is more coal, more material, and more time where this came from." When the ideal that the roads are working for is sold to the men the present labor problem will be simplified. Foremen and subordinate officials can and I believe will accomplish this in the future, but selling necessarily involves something to sell—which in this case is not lacking—and ability to bring the purchaser's mind to the need to buy.

Looking Ahead

How are we to look ahead when we have so many troubles in hand? Troubles we shall always have and if years ago we had looked into the future on the personnel question our difficulties today would be less. If we do so now they will be less ten years from now.

In the development of railroads a lot has happened since the day when a road was so small that the superintendent was the only operating officer—when the master mechanic and everybody else, having to do with operation, reported to the superintendent. The old "Czar" system has gone. In that system the "Old Man" held everyone's job in the palm of his hand, hired and fired as he liked, rewarded and punished as the old-time head of the family rewarded and punished his children and there was no one to question him. In those days the captain of a ship held little more power than the railroad official.

There was something fine about the old method when the highest operating officer knew everybody. In spite of the faults of the system, which really was the best system for the time, it has left us some of the best traditions and has given transportation service some of the best of men. It gave co-operation. Co-operation had to be because there was someone on hand to enforce it. This effect of co-operation has probably done more than any other one thing to tie railroad men together and make so many of the old-time railroaders feel that any man in railroad service was, in a large sense, a member of his own family. This feeling is not as strong today, co-operation is not as common, but it is, and will remain, a factor that we cannot do without. It must be provided.

Another feature of old-time railroading was the training of men. I refer not only to apprenticeship, but to the careful training of every new man for his job. As a matter of course boys entering the shops were apprentices, so also were firemen, brakemen and switchmen and all the rest. In those days somebody had time to instruct new men. Whatever else we say of those days, certain features of the times indicate a thoroughness which we do not get today. In days of old, promotion was controlled by prejudice, by favoritism, sometimes by family ties, but with all the faults of the early days, men were seldom imported from other roads.

No one wants the old days back, but it is fitting to consider features of the old which should be provided with the new. Some of these are the careful selection and training of new recruits, the spirit of the railroad men of older days, co-operation and the intimate knowledge of the men in the ranks on the part of someone in authority. Of all the things we need to take out of the past and apply to the future, the things we need the most are the selection, the training and the knowledge of men. Railroads are too big, even departments are too big to permit the operating officers to know who are working for them, but some substitute for these features of old times must be found. A way must be found for foremen at least, or sub-foremen, thoroughly to know the men working for them, their personalities, their capacities, their abilities and their qualifications for promotion. This and the selection and training of men may be supplied under present conditions and may yet make railroad service as happy as it ever was, but to accomplish this requires a lot of thought, a lot of time and a definite plan which will enlist the co-operation of the men. It calls for a high officer whose job it is to see it done.

When specially trained men were wanted in 1918, C. R. Dooley and staff delivered 100,000 trained men to the army in six months and had 40,000 more nearly ready when the armistice was signed. About 70,000 of them went across, men trained in 67 different trades. These men were selected as well as trained. Nothing that lies before the railroads is as difficult as that. The report which outlines the problem, the plan, the organization and the execution will open the eyes of any man who does not know about modern training methods.

When railroads start in to tackle their production problem in as thorough a fashion and with as complete a plan, cost of transportation will come down. Nothing will influence the workers as a real plan will do it. When they understand the plan, its objects and the country's need of it the workers will want to do their part and without their earnest efforts in co-operation success is out of the question.

There is no other way. An enlightened mind is the greatest asset on earth.

Our high official in charge of personnel cannot be expected to change the atmosphere of the organization quickly. He will not himself attempt to make the change. He will not himself attempt personally to train everybody. He will see that everybody on the road is trained, that every officer trains his own successor. He will see to it that men are specified and treated as carefully as steel and iron are. He will use the entire organization and will inspire everyone in it by concentrated effort to bring out the best in every individual in the direction of enlightened team work.

Reducing the Fuel Consumption of Power Plants

BY WILLIAM N. ALLMAN

(Continued from the February Issue)

When it is considered that only about 57 per cent to 67 per cent of the coal that is consumed in the average plant is utilized for producing steam, it becomes clear that it is also quite an important matter to retain the heat in the steam and not allow it to escape through lack of proper insulation.

Heat is much more evasive than gas, it escapes through a boiler plate or pipe about like water through a sieve. When it is considered that steam carrying a pressure of only 100 lb. per sq. in. has a temperature of about 338 deg. F. and that on the hottest summer day 90 deg. to 100 deg. F. would be extremely hot, it will be readily observed that there is a tremendous waste due to leakage if proper insulation is not provided for.

The real object of insulation is to prevent the flow of heat from the container to the outside atmosphere. It has often been noted that great care is exercised in guarding against losses in electrical distribution and water leakage and also against undue loss in steam pressure between the source of power and the prime movers, and not until quite recently has there been the great care given to insulation that now manifests itself. The losses in heat units through poor insulation have now become a vital factor in power plant operation, and power plant engineers and managers are very busily engaged in determining where the losses may be reduced by insulation.

TABLE 1—TOTAL HEAT LOSS IN B. T. U.'S PER HOUR PER LINEAL FOOT OF BARE PIPE OF DIFFERENT SIZES AND AT VARIOUS TEMPERATURE DIFFERENCES AS GIVEN BELOW

HEAT LOSS IN B. T. U. PER LINEAL FT. PER HOUR

(For finding losses at temperatures between those shown, the B. T. U. Differences per Degree are given in Column between the Main Columns or Degree Columns)

Pipe size, in.	Area of pipe surface per lin. ft.	Temperature differences																		
		50°		100°		150°		200°		250°		300°		350°		400°		450°		500°

The following losses apply to flat as well as curved or cylindrical surfaces:																				
B. t. u. Lost per sq. ft. per hour.....		97.5	2.35	215.2	2.90	360.0	3.46	533.0	4.10	737.8	4.80	978.0	5.83	1269.4	6.89	1614.0	8.73	2050.6	10.8	2590.0

Inspection of Table No. 1 will readily convey the enormous loss in B. t. u.s from uninsulated or bare surfaces and it is a surprising fact that this condition has been allowed to exist so generally. It has been estimated that the loss of heat from a bare or poorly insulated surface represents a loss in fuel ranging from 25 per cent to 65 per cent and principally for the reason that the escaping heat is not visible this can hardly be realized. If on the other hand it were visible, it would be so perceptible that steps would very quickly be taken to correct this evil and prevent the loss.

The efficiency of an insulating material is expressed by the percentage of heat saved by using the insulation as compared to what would be lost if no insulation were used and the surface left bare or uninsulated.

The efficiency of all insulation varies according to the size of pipe to which it is applied and according to the difference in temperature between the steam in the pipe and the air surrounding the pipe, as well as according to the thickness of insulation. Therefore the rate of flow of heat through a certain thickness of material and at a certain difference in temperature, determines the conductivity of the material. The relative efficiencies of insulating materials are obtained by comparing their conductivities under similar conditions. Heat is also frequently wasted where sections of insulation are not properly joined or where fittings are exposed.

Table No. 2 shows what losses may be expected from uninsulated surface. The figures are conservative, as both the boiler efficiency and the heat value of the coal are high and a lesser boiler efficiency or inferior grade of coal would cause even a greater waste in pounds of coal.

Table 2—Heat Losses from Uninsulated Hot Surfaces
ordinary steam temperatures

Temperature of Surrounding Air 70 Deg. F.

Steam pressure (gage)	Steam temperature (deg. F.)	Difference between temperature of steam and surrounding air (deg. F.)	Loss per sq. ft. per hour (B. t. u.)	Waste of coal in lb. per sq ft. per year	Number of sq. ft. of surface that wastes a ton of coal in 1 year
0	212	142	334	293	6.82
10	240	170	425	372	5.38
25	267	197	522.5	458	4.37
50	298	228	644	564	3.55
75	320	250	737.5	646	3.10
100	338	268	820	718	2.79
150	366	296	960	840	2.38
200	388	318	1,079	945	2.12
250	406	336	1,184	1,036	1.93

Temperatures Lower Than 212 Deg. F.

Surface temperature (deg. F.)	Difference between surface temperature and surrounding air (deg. F.)	Heat loss per sq. ft. per hour (B.t.u.)	Waste of coal in lb. per sq. ft. per year	Number of sq. ft. of surface that wastes a ton of coal in 1 year
100	30	56.6	49.6	40.3
120	50	97.5	85.4	23.4
140	70	142	124.3	16.1
160	90	190	166.3	12.03
180	110	242	212	9.44
200	130	298.5	261.5	7.65

Table 3—Minimum Thicknesses of Steam Pipe Insulation That Should Be Used for Given Character of Service

Steam pressures	Steam temperatures	Thickness of insulation for pipes larger than 4" in size	Thickness of insulation for pipes 2" to 4" in size	Thickness of insulation for pipes ½" to 1½"
0 to 25 lb.	212° to 267° F.	1" or standard*	1" or standard*	1" or standard*
24 to 100 lb.	267° to 338° F.	1½"	1½"	1" or standard*
100 to 200 lb.	338° to 388° F.	2" or double standard	1½"	1½"
Higher pressures	388° to 500° F.	2½"	2" or double standard	1½"
or superheat	500° to 600° F.	3"	2½"	2" or double standard*

For higher temperatures obtain special recommendations.
*Standard and double standard thickness apply to 85% magnesia insulation only—other thicknesses apply to all types of insulation.
It is always preferable to apply insulation greater than 1½-inch thickness in two or more layers with all joints broken or staggered.

The selection of the proper insulating material with due reference to its insulating efficiency and durability should follow a careful analysis of the conditions and requirements of the case under consideration. The greatest savings, of course, are to be effected by the proper insulation of the high pressure and high temperature steam lines.

Not every pipe covering is a good insulator, under all conditions; some may be effective at low temperatures and comparatively worthless at high temperatures. Again some insulators are fairly good on the initial application but soon deteriorate with age and the subjection to constant heat.

In the selection of an efficient covering it is highly important to consider its heat resisting qualities, mechanical ability to withstand ordinary wear and tear, and the effect of expansion and contraction of the pipes. To obtain more horsepower from the coal pile is the chief aim of all power plant managers and engineers and certainly after all that has been said and written on this most important subject of fuel conservation, those places in the power plant that spell "loss" will not be passed up and remain unnoticed.

Another appliance, which no doubt is overlooked and perhaps not considered as a losing factor is the steam trap. The loss of steam through open pet cocks or through leaky traps is quite large. This loss may be attributed to certain defects in the device and it is therefore highly important that they receive frequent inspection. .

General Suggestions

The United States Fuel Administration made every effort to bring home to fuel users the gravity of the situation and the importance of coal and power economy, and only by the whole-hearted co-operation of all concerned in the operation of the plant can the desired savings be effected.

The call for men trained in combustion efficiency is now more insistent than ever before. Everywhere the cry is for greater fuel conservation, more efficient methods of firing and the elimination of waste. Therefore, the man whose training enables him to solve these problems scientifically is offered unlimited opportunities as well as setting a standard for his subordinate. The Fuel Administration during the war advocated keeping a record of the temperatures of the flue gases as they leave the boilers. It was stated that with this knowledge the engineer could find the highest working efficiency and immediately discover sources of waste, while without this knowledge operation is mere guesswork.

All chief engineers, operating engineers, and firemen know, or at least should know, that decreasing the temperature of chimney gases without wasteful excessive air admission minimizes coal consumption. The ending of the war has not changed the conditions of boiler operation. It is fully as imperative to save fuel now as it was while the war was on.

In summing up the whole matter of fuel conservation, it is highly important not to overlook what may appear to be the small matters, for example it has been found that scale only 1/50 in. thick on the boiler tubes often means a loss in heat transference of 9.4 per cent with the consequent additional cost for extra fuel. Again, the pressure continually dropping means only extra work for the fireman, sweating away with shovel and slice bar to hold the load, and perhaps a job cleaning the tubes every few days. To a trained observer, however, it may indicate conditions that no amount of tube cleaning will remedy, as hot gases short-circuiting through leaky baffle walls, cold air sweeping in through myriads of tiny cracks in the setting, clinker pitted, slowly cleaned fire boxes, condensation in the steam lines, improper manipulation of dampers, improper care and adjustment of heating systems. All these conditions can be corrected by giving them the attention they deserve.

The Diesel Engine in Railroad Service

May Soon Become an Important Factor
In Heavy as Well as Suburban Traction

THE following article comprises an account of the extensive service which Diesel engines are performing in suburban passenger service in Sweden and a short outline of the possibilities of this form of prime-mover in heavy traction. We are indebted to a translation from Le Genie Civil of October 16, 1920, for the following description of the Diesel-Electric cars designed for suburban passenger service in Sweden together with a report of tests which have been conducted indicating a very economical fuel performance for these cars.

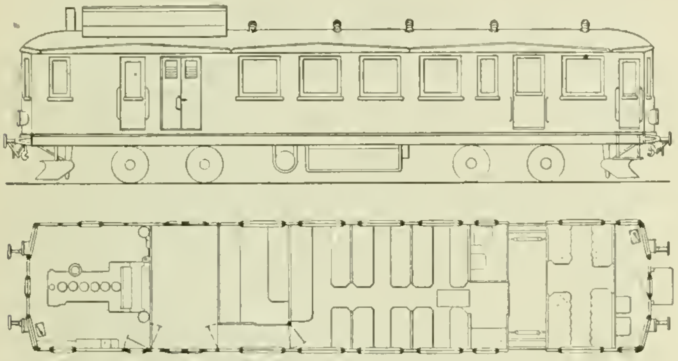

Fig. 1—Diesel Engine Composite Car

The second part of this article dealing with the broader phases of the Diesel locomotive as applied to heavy traction is contributed by Heinrich Schneider of Baden, Switzerland, who has made a close study of the Diesel locomotive for several years and has designed a number of improvements to this engine. In writing this part of the article it was the intention to outline briefly recent developments in the Diesel locomotive and draw particular attention to the great possibilities for the development of the Diesel locomotive in this country on account of its superior efficiency.

Diesel-Electric Cars on the Swedish Railways

Gasoline-Electric Motor engines have been studied for a certain number of years with a view to taking the place of motor engines or steam engines in surburban service. Although, up till now, this class of car is not widely distributed, it is nevertheless not without interest, especially in countries which are rich in liquid fuel, and its use may even be considered for traction on certain lines, like the trans-African lines, where coal and water are lacking and where electrification by means of overhead wire would incur expenses out of proportion to the traffic to be expected at the commencement.

Amongst the motors which may be installed on motor-engines of this class, with electrical transmission between them and the axles, the Diesel motors, which are today being extensively constructed in all industrial countries, offer the well known advantages of strength and economy which have caused them to be adopted on board submarines and numerous vessels. It is desirable, therefore, to give some consideration to various types of motor-engines of this kind, called for the sake of convenience "Diesel-electric," that have been running for some years on several lines of small Swedish railway companies.

There were no less than four different types, furnished with successive improvements, of these motor-engines working in Sweden between 1913 and 1917, which continued to run as long as it was possible to obtain the petroleum oils required for their motors. Moreover, they recommenced their service as soon as this period of scarcity was over. A statement of the characteristics of these cars will be found in the accompanying table. Each of these types includes a Diesel motor with six (or even eight) cylinders, direct connected to a dynamo which provides current for two motors mounted on the axles nearest the center of the car, or on those which are furthest from the Diesel motor.

In the first type, (Fig. 1), one end is arranged as an engine room with place for the engine-driver; then comes a baggage compartment, a postal compartment, a third class compartment (31 seats), a toilet, an entrance hall, a small second class compartment (10 seats), and finally a motorman's compartment for directing backward running. The second type differs little from the first, but it is lighter. Fig. 2 gives the plan of the third type, in which the Diesel motor is fitted in the middle of the car, while the two ends of the car are occupied by freight compartments or for postal service, and by the two motorman's compartments. Here the axles are independent, while the fourth type, in which the body of the car is similar to the foregoing, is mounted on two trucks, each of which carries a motor. The distribution of the loads is here symmetrical with reference to the center of the car. All the cars were supplied by the Générale Electric Company of Vasteras (Sweden) and the motors by the Atlas-Diesel Company. The following description specially concerns the third type, but the others only differ in the various disposal of the parts.

Diesel Motors

Some Diesel motors are 75, others 120 horse power. The first have six cylinders in line, the others six cylinders in V, and have speeds respectively of 550 and 500 revolutions per minute. Fig. 3 represents a 160 h.p. motor having eight cylinders. The crank shaft is completely enclosed in a gear-box which supports the two rows of cylinders inclined at 40 deg. The compressor for the injected air is worked by a crank at the end of the main shaft. The cylinders and yoke are cast in one piece. The valves are arranged in boxes which may be taken apart. The two opposite cylinders are slightly staggered in order to avoid the complication of forked connecting rods.

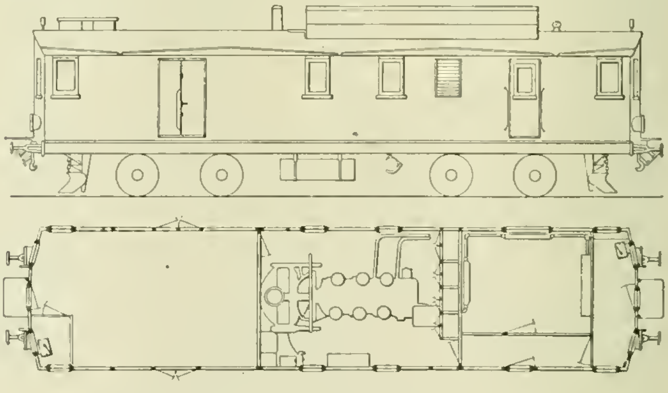

Fig. 2—Diesel Engine Express Car

The oil fuel is passed to the valves by a single pump, passing through distributors which allow any cylinder to be stopped. The regulation of the pump's output is effected by

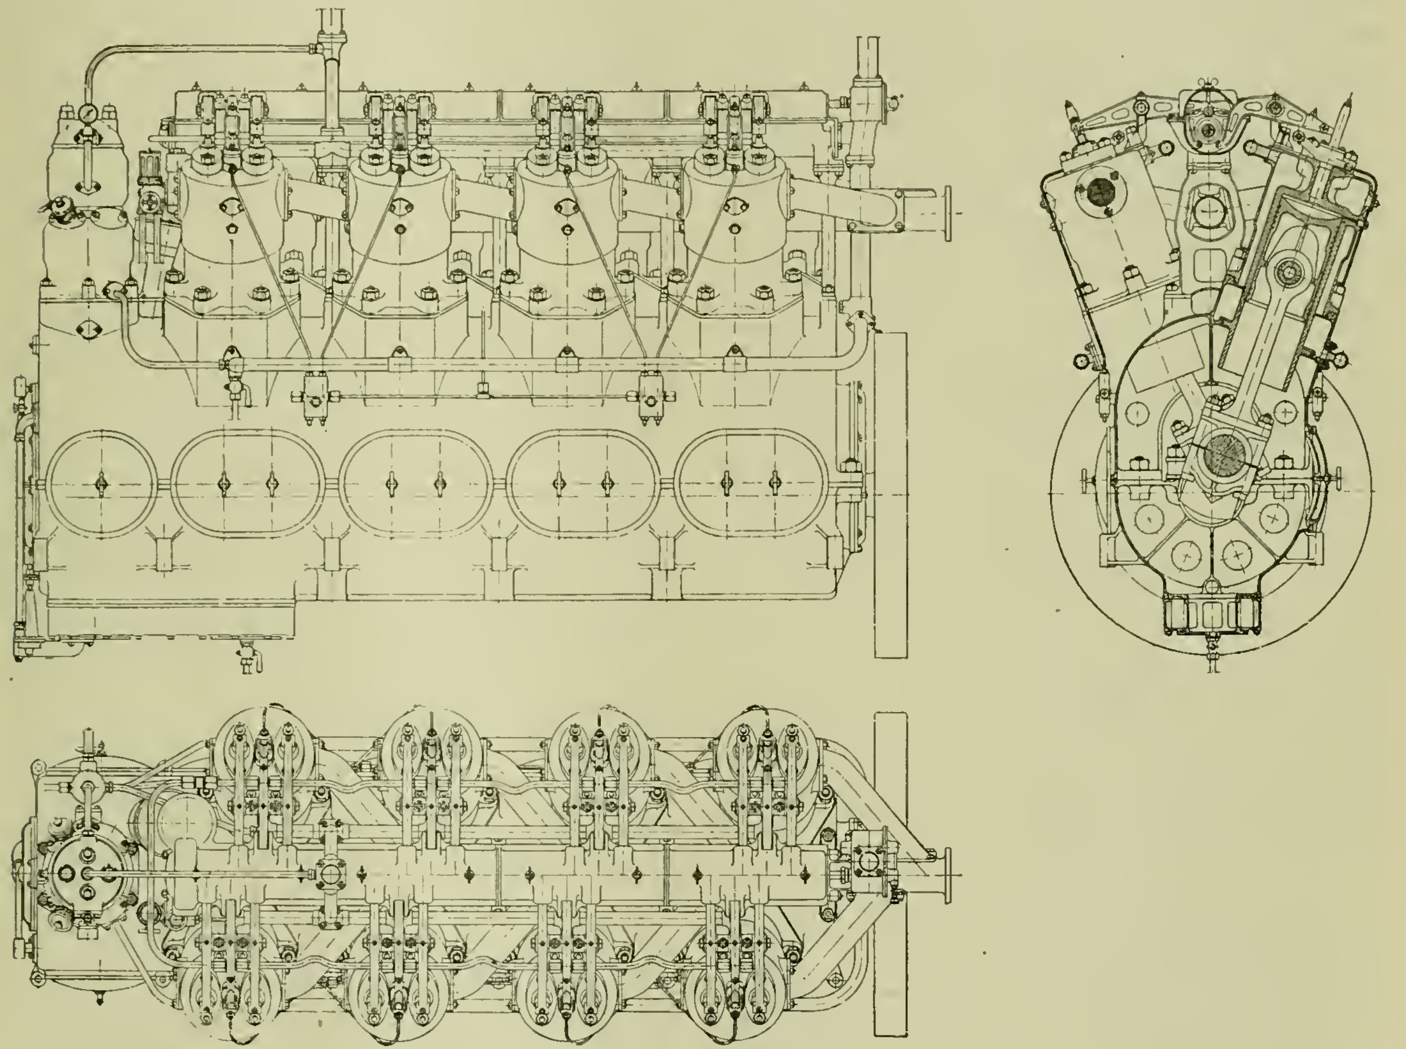

Fig. 3—160 H.P. Diesel Engine Designed for Railway Service

a regulator which acts on the pump. The fuel is injected by air compressed to about 60 atmospheres, furnished by the compressor. As this compressor does not give any air until after it is started, there are reservoirs of air which are filled automatically while the motor is in motion. The burnt gases are carried by a collector to an exhaust box and come out above the roof of the car. The cylinders and the compressor are cooled by water circulated by a pump mounted on the end of the distributing shaft. This water is cooled in a radiator placed on the roof. In order to prevent the water from getting too cold, a wooden frame may be placed around the radiator, on which a canvas is stretched. At each end of this frame doors are placed which can be opened from inside the car to regulate the temperature of the water. It is possible, also, in winter, to let the water pass into the radiators of the car, for heating purposes.

The motor is oiled by means of a pump which takes the oil under pressure to all the bearings. Before returning to the pump this oil passes through a filter with a radiator, placed under the car, in order to cool it. Reservoirs for the water and the oil fuel are fitted under the ceiling of the car. They are filled by means of outside joints and hand pumps placed in the engine room.

The motor is set in motion electrically, by means of a storage battery placed below the car. At this time the dynamo works as a motor, and all the necessary connections are made automatically by turning the handle of the controller in the driver's cabin. On the motor is fitted a small compressor which gives air at approximately six atmospheres for the brakes, signals and distribution of sand. The following are the results of trials of the motor of a car in 1916:

Bore of cylinder: 200 millimetres.
Stroke: 240 millimetres.
Fuel: Texas oil.

	Trial No. 1	Trial No. 2
Duration of trial (minutes)	44	44
Load	100 per cent	110 per cent
Revolutions per minute	500	495
Horse power	120	132
Consumption of oil:		
Total (grams)	16,900	
Per hour	23,040	
Per horse power hour	192	
Pressure of air injection (kg. per sq. cm.)	56	

Electrical Equipment

The direct connected dynamo delivers its power direct to motors mounted on the axle, so that the whole power of the motor can be utilized no matter what the speed of the car. The dynamo is mounted on the same frame as the Diesel motor and is driven by means of a flexible elastic coupling. The dynamo gives a continuous current, the tension of which varies between wide limits up to about 550 volts. It has eight poles, and is furnished with commutation poles with excitation shunt and series windings (the latter is only in circuit when the generator is working as a motor, for starting the Diesel motor by the storage batteries).

The two traction motors are series motors, with commutation poles. They drive the two center axles by means of spur wheels. Their frames are completely closed, and divided into two halves, the lower of which can be turned down on a hinge; in this way the interior of the motor can be examined without raising the car. The motors are fixed on one side by two bearings on the axle; on the other side the spring suspension allows the motors to follow the movements of the axles. In case of one motor breaking down, the driver can put it out of action from his seat and continue with the other.

Tests have shown that a 40-ton train hauled by a car of the first type, attains the following speeds:

On the level....................miles per hour	33
With a gradient of 0.3 per cent....................	24
With a gradient of 0.6 per cent....................	17
With a gradient of 1 per cent....................	12

With a car of the second type, with the same motor power, but on a narrow gage, rather higher speeds are obtained. Types 3 and 4 are furnished with motors which are more powerful and intended for heavier trains.

In the motorman's compartment are placed all the instruments necessary for driving, applying the brake on the car and controlling the machinery. The controllers have two drums, one to change the direction of running and the other to regulate the speed of the car. The direction is changed with the Diesel motor at rest. The drum for changing the speed controls the starting of the Diesel motor, the connecting of the electric motors, and the variations of speed.

Under these conditions, the car is easily driven. On starting, the handle for changing the direction is turned as desired; the safety knob is depressed, and the handle for changing the speed is turned to the first notch, at which moment the Diesel motor is set in motion. At the second notch the connections for setting the storage batteries in action are cut; at the third notch the car starts. By continuing to turn the handle the voltage of the dynamo is increased, and therefore the speed of the car. On stopping the safety knob is released in order to stop the Diesel motor, and then the handle is moved back to the starting position. When the motive power is not required, in going down hill for instance, or when the train is at rest, the Diesel motor does not revolve, but it starts instantly when necessary; this, of course, causes a saving of fuel and lubricating oil, diminishes the wear of the machinery and does away with vibrations while the car is standing still.

The constant voltage current required for starting the Diesel motor and for lighting, is furnished by a storage battery under the car. This battery charges itself automatically during the running; it can also be charged while the car is at rest, by proceeding in the same way as for starting, but after having placed the switch at "charge" the traction motors are, in this case, cut off.

Results of Tests

In February, 1919, the following figures were obtained on a train comprising a Diesel electric motor engine of Type III, a passenger car with two trucks and a passenger car with two axles. There were 139 passengers in the train:

Weight, motor car	32.8 tons
Weight, passenger car with trucks....................	23.8 tons
Weight, car with two axles....................	16.0 tons
Total	72.6 tons
Weight, 139 persons (at 165 lb.)....................	10.4 tons
Total	83.0 tons

	Stockholm-Vasteras	Vasteras-Stockholm
Distance ....(miles)	69	69
Number of stations stopped at....................	8	8
Time during which car was running..........	3 h. 1 m.	2 h. 55 m.
Time during which motor was running..........	1 h. 59 m.	2 h. 11 m.
Ratio of these times..........(per cent)	65.5	74.5
Average speed per hour..........(miles)	23	24
Total consumption of fuel..........(kilogr.)	47.5	46.5
Consumption of fuel per 1,000 ton-miles,	18.9	18.6
the average weight of the train being 83 tons ....(pounds)	18.9	18.6
Density of oil fuel....................	0.815	0.815

Consumption of fuel reported during two weeks' working:

	1st week	2nd week
Weight of train....................(tons)	61.5	81.0
Consumption of fuel per ton-kilometre....(grams)	6.11	5.38

Statistics from the service of six cars of 75 h.p., which were in use during the years 1913 to 1917, gives rather interesting information, as these statistics cover more than 650,000 kilom. In 1917, these cars were for the time being stopped on account of lack of fuel, but at the end of 1919 the distance covered was more than one million kilometres, which corresponds to a daily trip of more than 600 kilom. during four years and a half. The following are the results of these statistics:

Total distance covered....................(kilom.)	658,889
Number of days in use....................	4,380
Distance covered without trailer....................(kilom.)	395,664
Distance covered with trailer....................(kilom.)	263,225
Number of kilometres per day....................	150
Number of ton-kilometres....................	22,875,690
Average weight of train....................(tons)	34.8
Consumption of fuel per ton-kilometre..........(grams)	9.65
Consumption of lubricating oil per kilometre....(grams)	11.95

These results are very encouraging, especially if compared with those obtained with other oil-electric vehicles, by which the specific consumption was generally at least double. On account of the low over-all efficiency of steam engines and of the high price of coal in Sweden, it has been estimated that, under the same conditions, a Diesel-electric train only expended about 6 per cent as much in fuel as a steam train. This has led to the construction of motor-engines with motors of 160 and even 250 h.p. A 250 h.p. motor will draw a train carrying 300 passengers.

Direct Drive Needed for Heavy Traction

In the discussion of the Diesel locomotive contributed by Heinrich Schneider, the author advocates the adaptation of the submarine type engine for locomotive service, with direct drive. The following is an abstract of Dr. Schneider's views:

For the highest economy the Diesel locomotive will have to be given serious consideration in the near future. In Europe mechanical engineers are quietly, though indefatigably working at the perfection of this style of locomotive. Owing to the wear and tear, the destruction during the time of war and the falling off in the production which still continues in several countries, the world is faced with the necessity for great renewals in all rolling stock, particularly locomotives. The increase of wages as well as the high prices for coal and oil necessitate that materially greater attention be paid to the economic consumption of fuel by locomotives than has been heretofore required.

Each style of locomotive has its special field of activity, and none will predominate everywhere. For street cars nothing but electric propulsion can be considered. However, the steam locomotive will be chiefly employed in thinly populated and mining districts, while the Diesel locomotive will find its greatest sphere of activity in poor coal districts. There is an unlimited field of activity for the Diesel locomotive in those countries and parts of the world with long railroads, scattered stations and low traffic density, such as South America, Africa, Asia, as well as India, China, Russia, etc., which are not highly industrialized, sparsely populated and without large coal deposits.

In various countries there is at present the desire to electrify all railways. However, this is only recommended for countries which like Switzerland can utilize easily exploited water power. In other countries where electric power is to be generated from coal or oil, expensive electric power stations, collector installations, etc., and very expensive electric locomotives are required for the electric railway installations. Such installations, can, therefore, only be considered for countries of highly cultivated industry and large population as in Europe and parts of the United States, while for all other countries the building cost and working expenses of these installations are very extravagant. It is here that the Diesel locomotive will be found to be greatly superior to electric railway traction.

As with the automobile for which electric propulsion has answered in city traffic only, propulsion by combustion engines has proved far superior in all other departments.

The construction of the Diesel locomotive has been tried for many years. Diesel, himself, in describing his motor in 1897 pointed out the following advantages offered by the Diesel locomotive: "The concentration of great capacity in a locomotive requires, for economy, long and heavy trains. With the oil motor locomotive, however, the greatest economy would be obtained with short and frequent, as well as separate passenger, freight and goods trains." Scherl with his single rail railway, with frequent light and high speed trains points out the same thing.

No material progress has been made for the last 30 years in the development of the steam locomotive as to the utilization of heat. It is only by the insertion of the superheater that a nominal improvement has been achieved in the utilization of fuel. The rapidity with which all railway companies have seized upon this innovation shows their eagerness to improve the economy. The superheater increased the utilization of fuel by 10 to 20 per cent while the Diesel locomotive allows of an increase of the utilization of fuel of upwards of 200 per cent compared with the exhaust steam engine. There are, however, some firms in central Europe at present building experimental locomotives with steam turbine drive and condensation installation and this may bring improvement in the consumption of fuel compared with the exhaust steam locomotive engine.

If we but view the construction of marine engines and motor cars which likewise forms a part of the system of communication, we find that the progress of railways has conspicuously lagged. It is to be expected that in the course of some years a considerable development will occur in this field. About 12 years ago the first, and so far the only, Diesel locomotive was turned out in Europe, displaying on its trial trip, a capacity of about 1,000 h.p. and a speed of 100 km. (62 miles) per hour. Trial trips were made with this locomotive from Berlin, and it is to be regretted that nothing was published in regard to the result. For the purpose of starting there was an auxiliary compressor of ample capacity installed on this locomotive. However, it appears that the difficulties in starting were nevertheless so great as to have prevented the construction of further Diesel locomotives of this description. To overcome the starting difficulties arising out of the direct propulsion by the Diesel locomotive, electric transmission of the oil engine output to the driving shafts has been suggested. This arrangement, which was at first intended for narrow gage railways only, has found employment in benzol and oil dynamo motor cars, Important firms have of late developed this construction so far that it can already compete with the electric motor car and the steam locomotive.

In the matter of trunk line locomotives of highest capacity, however, there can be no talk of electric transmission since electric motors would assume such large space and weight as to require a whole motor car to themselves. The direct transmission of the Diesel engine is considerably cheaper and more simple.

The great possibilities of the Diesel locomotives have been recognized for a long time past, though almost unsurmountable difficulties have opposed their construction. These, however, may now be looked upon as having been overcome owing to the remarkable evolution of oil engines during recent years. The following are the conditions that must be met in the construction of reliable Diesel locomotives:

1—A reliable, reversible and high speed Diesel motor is required.

2—Ability to start the train by means of an oil motor, bearing in mind that oil motors will not start under load.

3—Special construction must be devised for the accommodation of the motors and driving mechanism.

It is one of the objects of this article to state what has been accomplished toward meeting these several requirements. In the approved engine of the submarine boat we find the actual construction of the locomotive driving engine ready for use. Cylinder dimensions, stroke, and rotation figures are almost the same. Both valve motion and governing apparatus remain the same, although the labor of adapting this to the railway service is not to be underrated. The starting difficulties have been solved by a number of recent inventions, only a portion of which have been made public.

The greatest difficulty in regard to starting has been overcome by the insertion of liquid gears of two different types. By the employment of liquid and mechanical gears the limit put upon the direct driven locomotive by the number of revolutions, the stroke and piston pressure is extended. A particularly hopeful design may be mentioned in which the starting apparatus consists of but one rotating part, so that a considerable increase in speed is possible. Furthermore, there is a design which with some slight alterations will make it possible to use the submarine boat engine for locomotives.

America, as the richest oil producing country in the world, with her highly cultivated industries, her great financial resources and her tremendous railway system is the very country for the Diesel locomotive. It is therefore difficult to realize why America has hitherto paid so little attention to the construction of oil engines. As we may presume that the reason for this lies in the fact that, until the transformation of the economic state of things brought about by the war, there was a superfluity of cheap fuel, so that the economical oil motor met with delayed consideration in America as compared with Europe where the high prices for combustibles gave rise to a much earlier search for a more economical engine.

At present strenuous efforts are being made in the states to replace the steam drive in shipbuilding by the oil motor drive for which the large marine oil engines must be developed. The steam locomotive is much less economical than the stationary or marine steam engine or turbine and yet these have been replaced by the oil engine for some time. If America wants to extend her dominating position in industry to the construction of heat engines, she will be obliged to take up the construction of Diesel motors and oil motor locomotives.

Central Europe engaged vigorously in the construction of the Diesel motor locomotive before the war but all such endeavors were interrupted by the outbreak of hostilities. Although Germany is economically overthrown, there are several influential German firms who are energetically pushing the construction of oil motor locomotives. Hence Germany appears to keep up the lead in the construction of combustion engines in spite of the breakdown she has suffered. It is high time to get rid of prejudices concerning the oil motor locomotive because of its apparently insurmountable difficulties, seeing how similar mistaken ideas were entertained for so many years about the Zeppelin airship. The oil motor with a capacity equal to that of the locomotive engine is already available. Owing to the issues of the war, the world enjoys the benefits of the experience with the construction of the submarine oil engine, so that America is now in a position to utilize this.

That the evolution of the Diesel locomotive engines will take years is considered a matter of course by every authority, but we should commence all the sooner with studies and preparatory labors for the oil motor locomotive engine puts the highest claims on the engineering art. The conclusion to be arrived at from these observations is that there are no longer any insurmountable technical obstacles in the way of the construction of the oil locomotive and that there is an economical necessity for substituting the far superior oil locomotive for the steam locomotive.

Controversy Before Labor Board Continues

Situation Forcefully Presented by Atterbury; Brotherhoods Fail to Secure President's Intervention

THE immediate abrogation of all national agreements, the remanding of the question of rules and working conditions to negotiation between each carrier and its own employees, the re-establishment of the agreements, rules and working conditions in effect on December 31, 1917, and the right to pay unskilled labor not less than the prevailing rate of wages in the various territories served by any carrier, were requested of the Railroad Labor Board on January 31 by General W. W. Atterbury, vice-president of the Pennsylvania and chairman of the Labor Committee of the Association of Railway Executives. The request was accompanied by a vigorous statement of the present precarious financial position of many of the carriers, General Atterbury predicting bankruptcy for many and a resulting financial panic unless steps are taken immediately to cut needlessly huge wage payments and thus bring operating expenses into proper relation to the operating revenues now accruing under increased freight and passenger rates.

At the close of General Atterbury's statement, which has been generally quoted in the press, H. T. Hunt, a member of the public group on the Board, and Judge R. M. Barton, chairman of the Board, suggested that representatives of the railroads and the employees meet to formulate means, if possible, to avert the disaster predicted by General Atterbury. To this suggestion the latter replied that negotiation would be futile because of the dissimilarity of the views of the executives and of the employees and because of the necessity for immediate action.

Chairman Barton then stated that the requests made by General Atterbury would have to be considered in executive session but, in reply to a question of B. M. Jewell, president of the Railway Employees' Department of the American Federation of Labor, he said that representatives of the employees would be heard before any action was taken by the Board. Mr. Jewell and other representatives of the employees present at the hearing declined to reply to Mr. Atterbury's requests or to make any statement at that time. Mr. Jewell, however, stated that he would prepare a reply on behalf of the employees to be presented to the Board later.

General Atterbury's statement was made after the Labor Committee of the Association of Railway Executives had been in session at Chicago for three days discussing the present labor situation and formulating plans for the restoration of conditions under which an honest day's work for an honest day's pay might be rendered by railway labor.

Various of the "independent" railway organizations have been fighting since the beginning of the present hearings for the right to present their views regarding national agreements independently. On February 2 the Board's decision on their petitions was made public, representatives of these organizations being granted the right to be heard in the present case despite the opposition of the larger brotherhoods who have maintained that the members of the independent organizations are adequately represented by them.

Appeal to President Wilson

The vigorous stand taken before the Railroad Labor Board by General W. W. Atterbury, vice-president of the Pennsylvania and chairman of the Labor Committee of the Association of Railway Executives, against the continuance of national agreements brought forth talk of general railroad strikes, charges and answers. The matter finally reached President Wilson, whom representatives of the labor organization petitioned for the presentation of the issues involved to Congress and representatives of the carriers followed with specific answers to the charges made by the labor leaders.

The executives of the brotherhoods filed long telegrams to the President, declaring that they did not believe that the carriers were in the financial condition outlined by General Atterbury and attacking the latter for "violating all decent proprieties, disregarding the Transportation Act and flouting existing agencies such as the Interstate Commerce Commission and even Congress itself."

"General Atterbury's policy," the telegram charged, "is to disrupt labor unions, turn public opinion against the employees and place wages on a previous basis so that railway profits might be enhanced when prosperity returned."

In support of these contentions, the telegrams reiterated the charges of mismanagement and control by a New York banking group which have been made repeatedly during the past month by various labor leaders and which are under investigation by the Interstate Commerce Commission.

The charges made in the employees' telegram were immediately answered by T. DeWitt Cuyler, chairman of the Association of Railway Executives, in a telegram to the President.

President Wilson on February 6 replied to the telegrams addressed to him by the railroad labor leaders and the railroad executives at Chicago last week, declining to interfere in any way, during the last month of his administration, in the controversy between the railroad executives and the labor leaders regarding the abrogation of the national agreements. The labor leaders had asked for a Congressional investigation of the railroad situation but the President in his reply indicated confidence that the case is now in the hands of the proper tribunal and he therefore referred the copies of the telegrams to the board and to the Interstate Commerce Commission for such action as they may deem wise. The President's action was taken on recommendations made to him by John Barton Payne, director general of railroads, to whom the telegrams were submitted on their receipt last week.

B. M. Jewell, president of the railroad department of the American Federation of Labor, declared that the president's message was a complete vindication of the stand taken by the unions in that it "makes it perfectly clear that the board should confine its jurisdiction strictly to the controversy as to wages and working conditions, leaving financial matters to the Interstate Commerce Commission."

Atterbury Replies to Jewell

W. W. Atterbury, Chairman of the Labor Committee of the Association of Railway Executives, issued a statement on Tuesday in reply to the assertion of B. M. Jewell, representing the employees, that President Wilson's reply meant that the Board would consider only wages and working conditions, and that financial questions would be considered by the Interstate Commerce Commission.

"His hope that the financial results of existing rules and working conditions can be hidden from either the Labor Board or the public will not be realized," said Mr. Atterbury's statement.

"He would maintain indefensible waste and inefficiency even at the cost of destroying the earning power of the railroads or of compelling them to go to the Interstate Commerce Commission for still higher rates.

"The producers and consumers of the country cannot support Mr. Jewell's program. It requires no conspiracy against union labor to explain their attitude or mine. The railroads are struggling to regain the reasonable productivity of a considerable part of their employees, now seriously impaired by the rules and working conditions coming over from the war. That conspiracy is the conspiracy of the entire country."

This reply was followed in turn by the issuance of two statements by General Atterbury in both of which he presented evidence to sustain his contentions made before the board on January 31.

While both the carriers and the employees were publicly defining their respective positions in this controversy, Mr. Jewell petitioned the Labor Board for additional time in which to prepare his reply to General Atterbury's requests. This petition was opposed by E. T. Whiter, who presented a letter on this subject written by General Atterbury and vigorously opposing any further extension of time. After consideration in executive session, however, the Board granted Mr. Jewell's request and February 10 was set as the date upon which he would be heard.

Mr. Jewell in the interval granted him to prepare a reply to General Atterbury, repaired to New York and retained Frank P. Walsh, the labor counsel, and W. Jett Lauck, economist, and a battery of publicity men to assist in bringing a conspiracy charge before the Board. Mr. Jewell planned to ask for postponement of consideration of the question of national agreements and for a hearing upon the evidence the unions wished to present in support of their charge that railway executives and financiers have conspired to re-establish autocratic control of the transportation industry.

Chairman Barton in opening the session on February 10 read a resolution passed by the Board which prohibited the presentation of such evidence and which pointed out that the Interstate Commerce Commission is the proper body before which to present such charges.

Board Denies Immediate Abrogation of National Agreement

The Board's resolution also denied General Atterbury's requests for immediate abrogation of the National Agreements and for the right to pay unskilled labor the prevailing rate in the territory where they are employed. The resolution, after reciting the history of the present case, stated that the Board must hear all of the evidence before ruling on the National Agreements and that it was powerless to grant General Atterbury's request regarding unskilled labor because the matter has not been brought before the Board according to the procedure outlined by the Transportation Act.

After a short recess Mr. Walsh began a presentation on behalf of the employees. He confined his remarks to replies to General Atterbury, attacking the Pennsylvania and charging that his statements are misleading. That the railroads are in a precarious financial condition was denied by Mr. Walsh, although the statement was not accompanied by proof.

B. M. Jewell, appearing before the Railroad Labor Board at Chicago on February 17 in the resumption of hearings in the controversy over National Agreements, asked that the Board take the following steps immediately:

"First: That the Board refer the National Agreements which are now before it to a joint conference of the representatives of the railroads and of the labor organizations with the recommendation that their disagreements be adjusted by negotiation as soon as possible—the Board agreeing to pass immediately upon any points of difference which may arise from the negotiations.

"Second: That the Board request the representatives of the railroads and representatives of the labor organizations to meet the Board in conference to consider the establishment of boards of adjustment as contemplated by the Transportation Act.

"Third: That in reply to Mr. Atterbury's notice to the Board and his subsequent letter to the chairman advising him that he contemplates filing a flood of individual complaints to reduce the wages of unskilled employees, the Board recommend to Mr. Atterbury that he meet in general conference with the representatives of the employees affected so that the existing General Agreements will not be impaired and the matter brought to the Board in the form of a single complaint."

Mr. Jewell declared his constructive proposals were brought forward with the following objects in view:

"1. To insist upon the fundamental principle of collective bargaining which is now the real issue before the Board in our pending cases.

"2. To expedite the cases which otherwise will absorb a vast amount of time and effort.

"3. And to restrain Mr. Atterbury and the railroads from preventing the proper functioning and destroying the effectiveness of this Board by flooding it with a large number of individual complaints which it cannot handle."

Mr. Jewell also asked that a conference be called immediately between the railroad labor chiefs in Chicago and the members of the Association of Railway Executives.

Executives Denounce Conference Plan

The Association of Railway Executives at a meeting on February 18 unanimously adopted the report of its labor committee and passed resolutions refusing to enter into national conferences suggested by the employees as a means of settling differences over wages of unskilled labor and working conditions.

The executives denounced the employees' proposed conferences as a plan by labor leaders to bring about nationalization of the railroads.

The committee report pointed out that the opposition made by the roads to the National Agreements and the position taken today was not to be construed as an attack on labor organizations themselves.

"The railroads are confronted with this situation—while endeavoring to escape from one set of rigid and uniform rules and working conditions inherited from the war they are met with a new demand, which, if acquiesced in by the Labor Board, would deprive individual carriers of direct negotiations with their own employees."

Replying to statements by labor leaders that the railroads' suggestion to abrogate the National Agreements was part of a plot originating in Wall street to break down the labor organizations, the report said:

"The record demonstrates that the railways have acted throughout independently, primarily in their own interest, but also in the interest of the shippers and farmers."

Atlanta, Birmingham & Atlantic Case

The efforts of the Atlanta, Birmingham & Atlantic to secure authority to reduce the wages of its employees below the rates set by the Board's decision of last July have attracted much attention, the case coming before the Board simultaneously with the introduction of General Atterbury's evidence in the National Agreements hearings outlining the precarious financial condition of many of the carriers. The case is also viewed with interest inasmuch as the rulings of the Board in this case will undoubtedly establish precedents which will serve to guide the Board, the carriers and the labor organizations in preparing, submitting and arguing future cases of this character. It is not, however, considered in the light of a test case by railway executives.

The Atlanta, Birmingham & Atlantic had ordered a cut in the wages of its employees effective on February 1 because of its inability to meet its operating expenses. Despite drastic reductions in working forces and in train service the carrier was losing about $100,000 a month. The employees objected to the wage cut and, when conferences were held between their representatives and representatives of the carrier, a controversy arose as to whether the wage reduction could be made effective, under the terms of the Transportation Act, pending a decision by the Labor Board. The representatives of the carrier held that the wage cut was unavoidable and would have to be made on the date announced even though the Board had not reached a decision on the employees' appeal. The employees held that the existing rates of pay should be continued until the Board had made its ruling.

When the case came before the Labor Board on January 25, the employees refused to present evidence in the case until the Board had instructed the carrier to rescind its wage cut order. The representatives of the carrier after presenting voluminous evidence showing the financial condition of the road, held that they had not violated the spirit or letter of the Transportation Act in cutting their wages first and then coming before the Board. Subsequently the Board passed a resolution upholding the employees' contention and ordering the carrier to rescind its wage cut order.

Following the precedent established in the Atlanta, Birmingham & Atlantic case the Board issued an order on February 14 directing the Erie to rescind its recent order reducing track laborers' wages, re-establishing the seven-day week for train despatchers and deducting the January 31 earnings of telegraphers. The order was to have been effective on February 1.

Fatal Gasoline Explosion at Memphis*

On January 24, 1921, vapors from a tank car of casinghead gasoline on the Union Railway spur on Front street, Memphis, Tenn., became ignited and resulted in a blast that killed 11 people and badly injured 19 others. Probably 40 or 50 men, women and children received slight injuries from falling debris or from burns. The explosion wrecked an oil plant, levelled a block of frame buildings and broke window panes within a radius of five blocks, the estimated loss being $200,000.

Shipments of casinghead gasoline began about 10 years ago and the records of the Bureau of Explosives show this disaster to be the sixteenth serious accident that has resulted from the removal of the dome cover while interior pressure exists in the tank.

The gasoline contained in the car was a volatile product known as absorption gasoline with a gravity of 81.5 deg. Baumé, initial boiling point of 80 deg. F. and end point of approximately 360 deg. F. The car was spotted on Saturday, January 22, and the following Monday morning, January 24, a negro workman at the plant opened the tank car without relieving the pressure within. The pressure of vapors that existed in the car is not known although it has been said that the relief valves had been giving off vapors previous to this time. This statement has not been verified but probably there was a pressure of nearly 25 lb., at which the valves popped. The removal of the dome cover resulted in the sudden relief of pressure and gasoline vapor and liquid gasoline boiled out of the dome head in large quantities. The wind from the west in carrying these vapors across the street, mixed them with air and formed readily ignitable mixtures. The vapor became ignited by open fires in the frame buildings on that side of the street and instantly there was a terrific explosion which demolished every house on the west half of that block, as well as destroying buildings in the blocks north and east. This explosion was followed by a second and more muffled one which was made by the flame flashing back to the tank car where vapors issuing from the dome caught fire and burned as they came out. The damage on the west side of the track in the oil plant itself was due largely to the fire that followed. This fire caused the destruction of a garage containing four automobiles, the ruin of a warehouse of sheet iron construction and the loss of several hundred barrels of oil and grease stored therein. These drums of oil caused several minor explosions and, upon breaking, burned with intense heat.

To add to the danger of the fire, there were seven 11,000-gal. tanks filled with gasoline and kerosene, which stood opposite the garage in the oil plant, and five more tanks elevated against a concrete wall at the west side. A second car of absorption gasoline, spotted at the same time as the one which exploded, was vented and the escaping vapors burned. The storage tanks also were vented at the top with nipples enclosing wire gauze and as vapors formed and passed out of these vents into the air, they burned quietly. Neither the second tank car nor any of the tanks were damaged in any way. It is interesting to note that after the fire had been extinguished, the car from which the explosion originated was still about half full of gasoline. The car was damaged only slightly and the wooden foot boards were only partly burned.

The investigation of the accident showed that the colored employee, Andrew McKinley, removed the dome cover without paying attention to the positive directions on the dome placards pasted over the dome cover joint and cautioning that the dome cover should not be removed until after release of all interior pressure in the tank. When he succeeded in unscrewing the cover it was thrown into the air by interior pressure in the tank and a column of gas and liquid was forced vertically upward to a height estimated by witnesses to be about 100 ft. The dome cover contains vent holes under the flange and above the threads, the object of which is to make it impossible to completely unscrew it without evidence of interior pressure furnished by the noise of vapor escaping through these vents. Witnesses 100 ft. or more away from the car testified that a hissing noise of growing intensity was heard while McKinley was engaged in unscrewing the cover. This warning as well as the warning of the dome placard was disregarded.

The serious results of this explosion demonstrate once more the need for ceaseless vigilance in handling tank cars of gasoline or other volatile liquids which may explode. In handling gasoline, the Interstate Commerce Commission regulations require that a car, when loaded, must have a certain voidance above the gasoline. This voidance is to take care of any expansion of the liquid which may occur if it becomes heated in transit. Safety valves are provided which will relieve any pressure above 25 lb. within the car. These valves should always be opened before the tank car is unloaded. In case pressure develops, the car can be sprayed with water and the resultant cooling will condense the greater part of these powerful vapors, thus reducing the pressure measurably.

Another way to relieve the pressure is by leaving the valve open and allowing the gas to dissipate slowly. In addition, there are in the dome cover several holes above the threads which will allow the escape of vapors before the cover is entirely removed, thus warning a man when there is pressure within. In no case should the dome cover be removed until this pressure is relieved.

"Only about 9 per cent of the country's factories are properly illuminated," says Industrial Power. "Thirty-five per cent of our factories have not changed their lighting systems in five years, notwithstanding that the lighting art has been revolutionized during this time. In other words, 35 per cent of America's industrial plants are five years behind the times in a matter that may affect their output anywhere up to 35 per cent."

---

*The account of this explosion is taken from a special bulletin issued by the Bureau of Explosives and the report of an investigation conducted by the Department of the Interior, Bureau of Mines.

Virginian Gondola Car of 120 Tons Capacity

120-Ton Cars Now in Service on the Virginian

Gross Load Behind Tender Increased from 7,950 to 13,200 Tons; First Application of New Six Wheel Truck

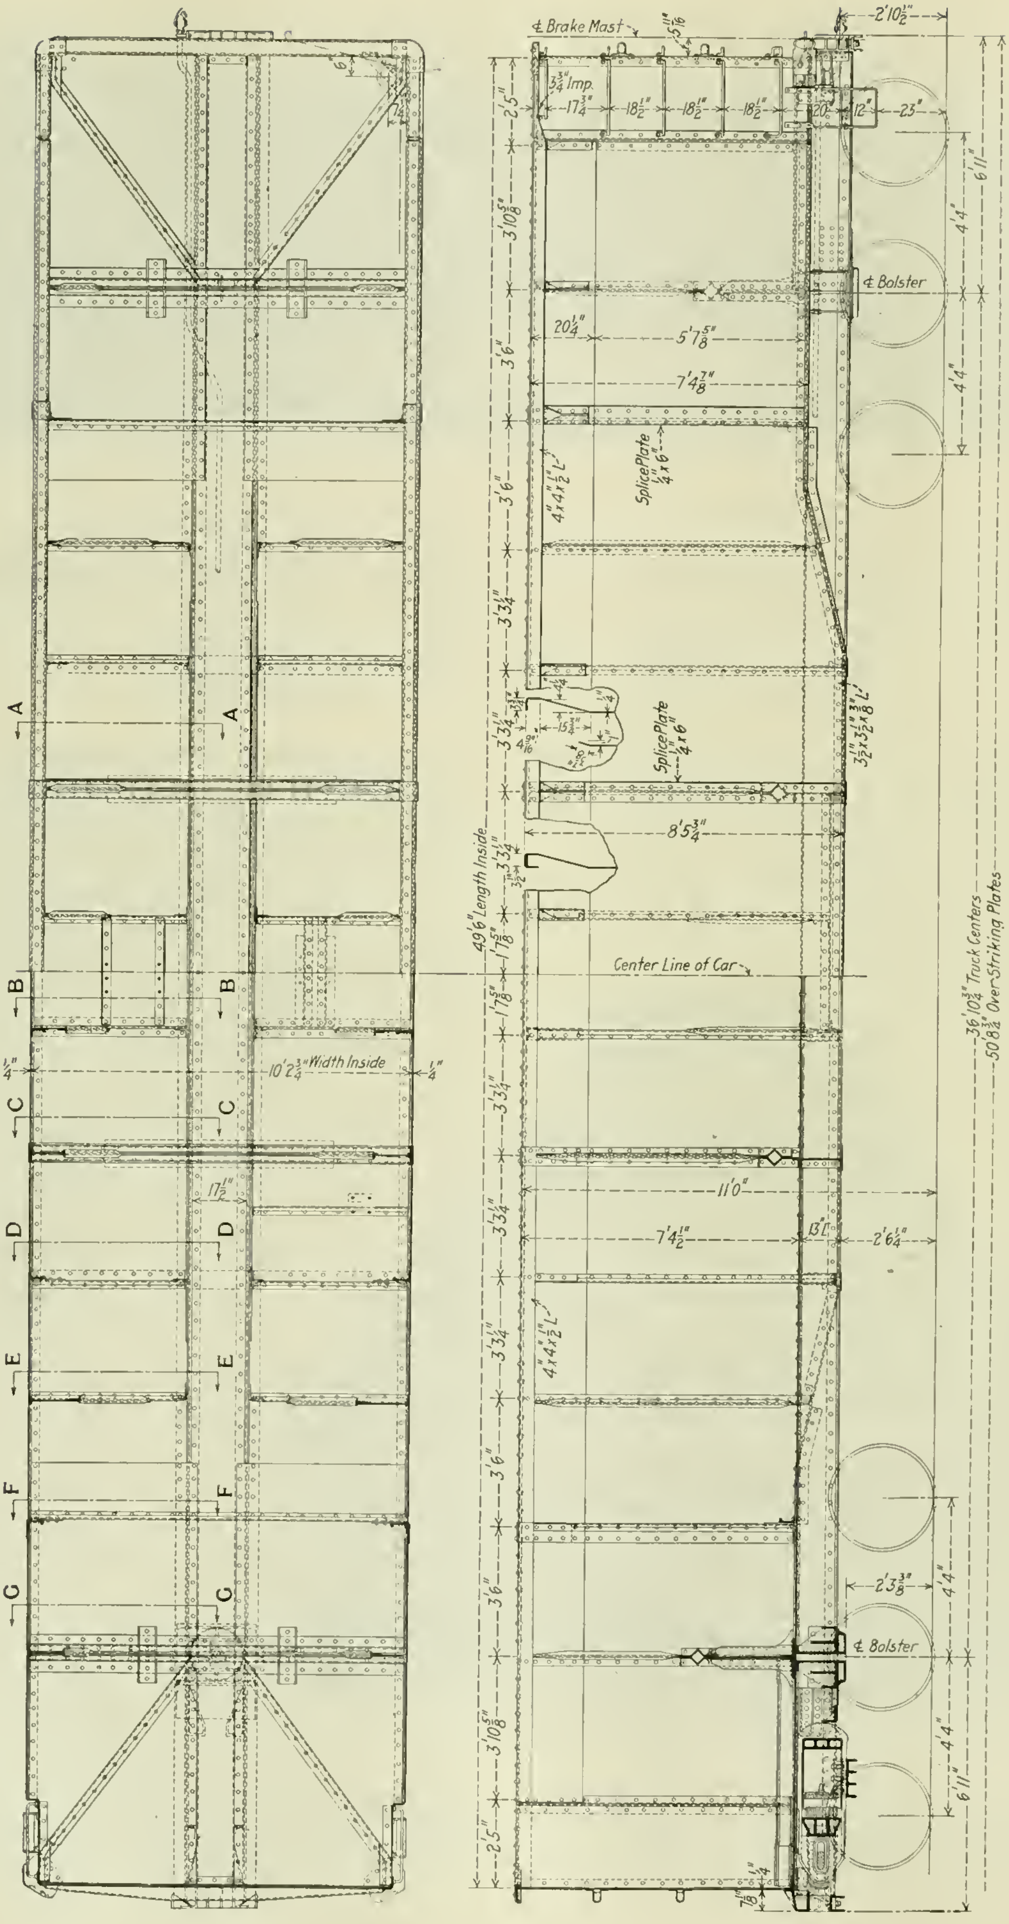
THE Virginian Railway has recently received from the Pressed Steel Car Company at Pittsburgh, 1,000 steel gondola coal cars of 120 tons capacity. This equipment is the heaviest in the history of transportation and is notable for two reasons: First, because it is the first instance where a large number of cars of such extremely high capacity have been placed in service, and, second, because the equipment has been developed especially to meet the operating conditions on the Virginian road.

Interior of the Car Body, Showing Gusset Side Stakes, Bolsters and Cross Bearers

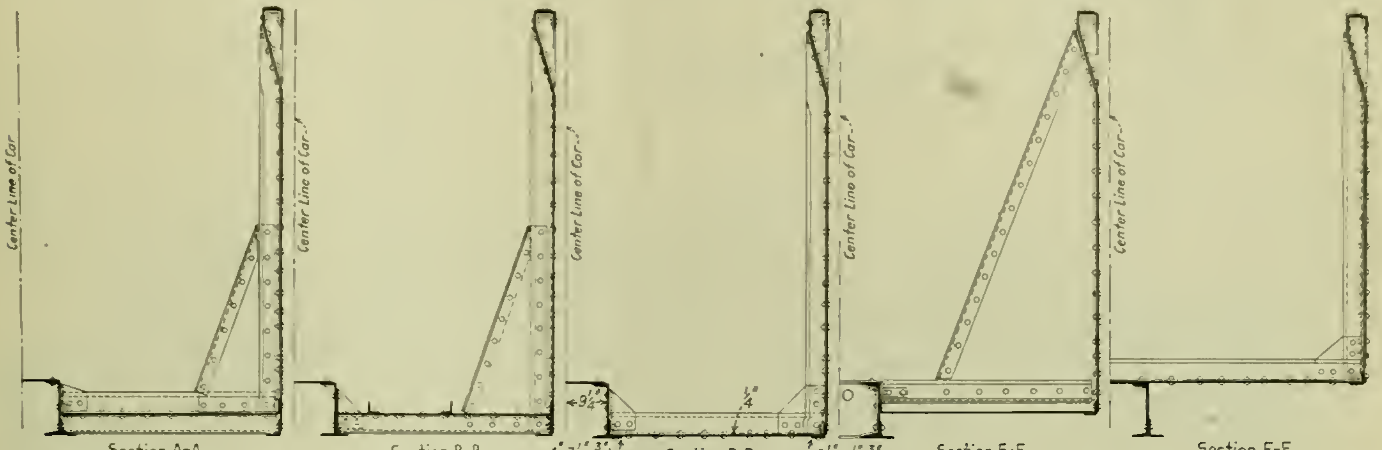
The circumstances that led the Virginian to go from the use of 55-ton cars to 120-ton cars are worthy of comment. Of the total traffic handled by the Virginian, 92 per cent is coal, moving to tidewater and inland points from mines west of Princeton, West Virginia, the greater portion of which moves to Sewalls Point pier, 342 miles from Princeton. The profile consists principally of slight descending grades; thus the tonnage that can be handled in a single train is limited over a large part of the line, not by the tractive capacity of the locomotive, but by the difficulty of securing proper operation of the air brakes in the handling of long trains on descending grades to avoid break-in-twos.

Since such a large proportion of the traffic consists of tidewater coal, the normal operation of the road depends upon the ability to dump cars promptly on arrival at the pier. In order to secure the maximum capacity of the pier duplicate unloading facilities have been provided. Two separate car dumpers, one handling a 55-ton car and the other two 55-ton cars, or one 120-ton car, dump into electrically operated conveyor cars. The conveyor cars from one dumper are drawn by a cable hauling system up an incline to the top of the pier, from which point they are moved by electricity to the proper chute and the coal dumped through by air pressure. The other dumper is served by an elevator that lifts the car to a track running over the pier pockets.

Under normal conditions the Virginian moves a large proportion of its traffic in its own equipment, consisting principally of gondola and hopper cars of 55 tons capacity and, latterly, 120 tons capacity. Two of the former cars can be handled on the two-car dumper, or one 120-ton car, from which it will be noted that the adoption of a car carrying

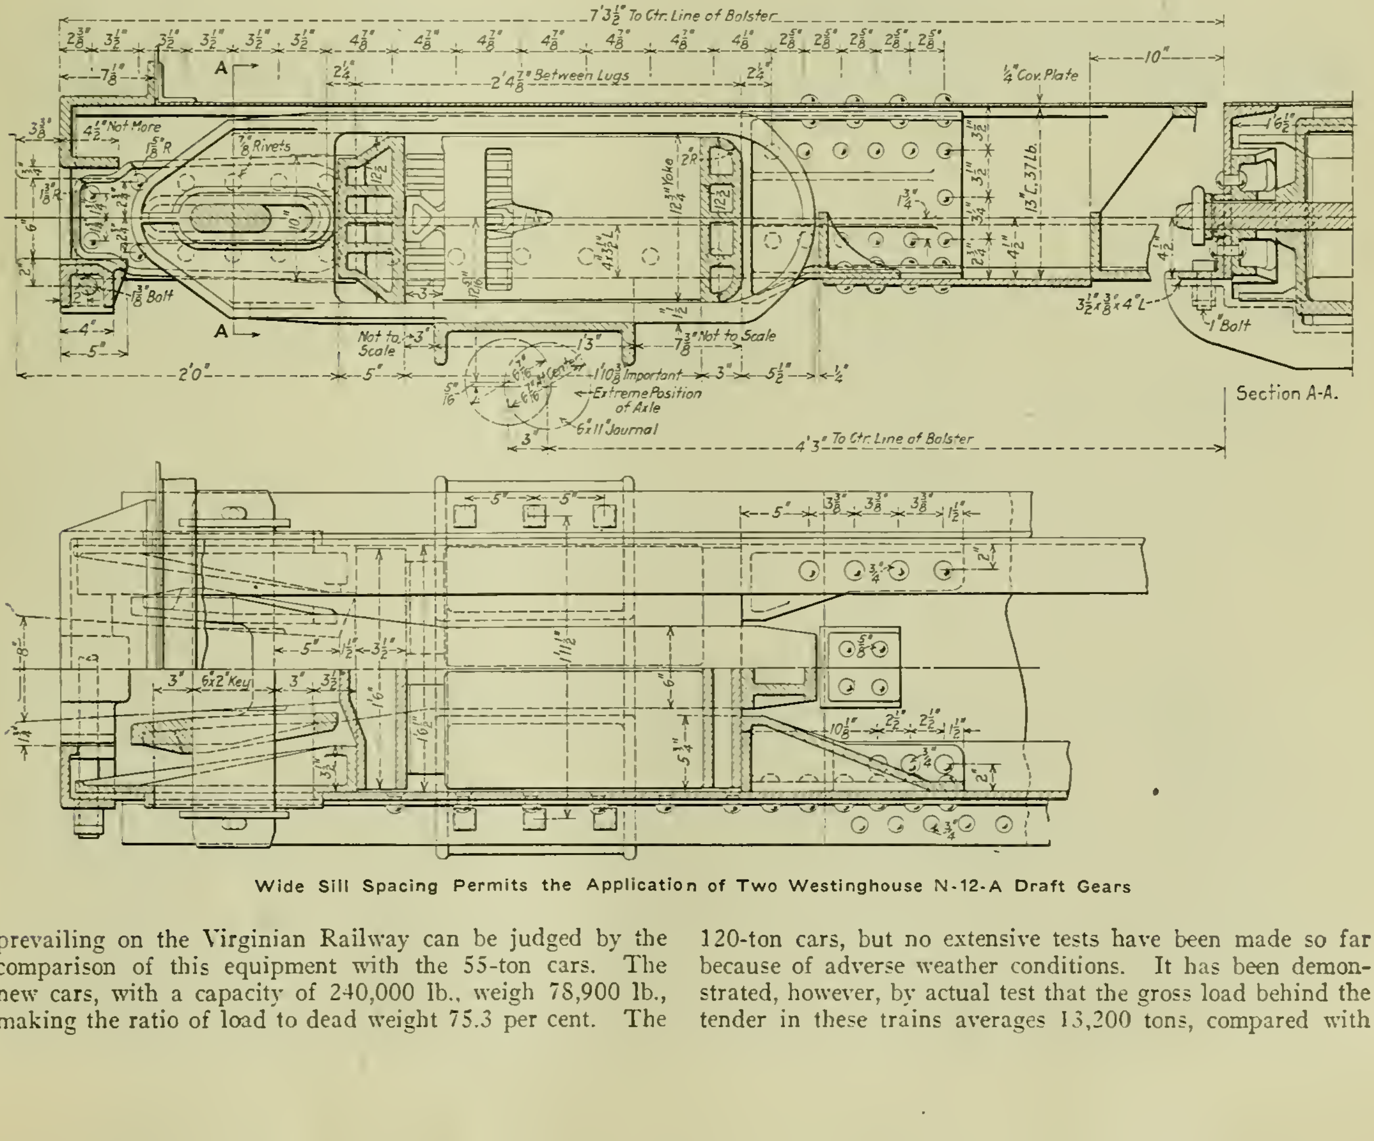


Plan and Side Elevation of the Body of the Virginian 120-Ton Car a less load would have the effect of reducing the capacity of the dumper and the efficiency of the pier. With this in mind, plans were made for the development of equipment having twice the gross weight of the 55-ton cars. In 1917 four sample 120-ton cars were placed in service to determine whether the use of such equipment would be practical and economical, and, as a result of these experiments, the order for 1,000 cars of this capacity was placed in the spring of 1920, immediately after the roads were turned over to the corporations.



Cross Sections of the Car Body

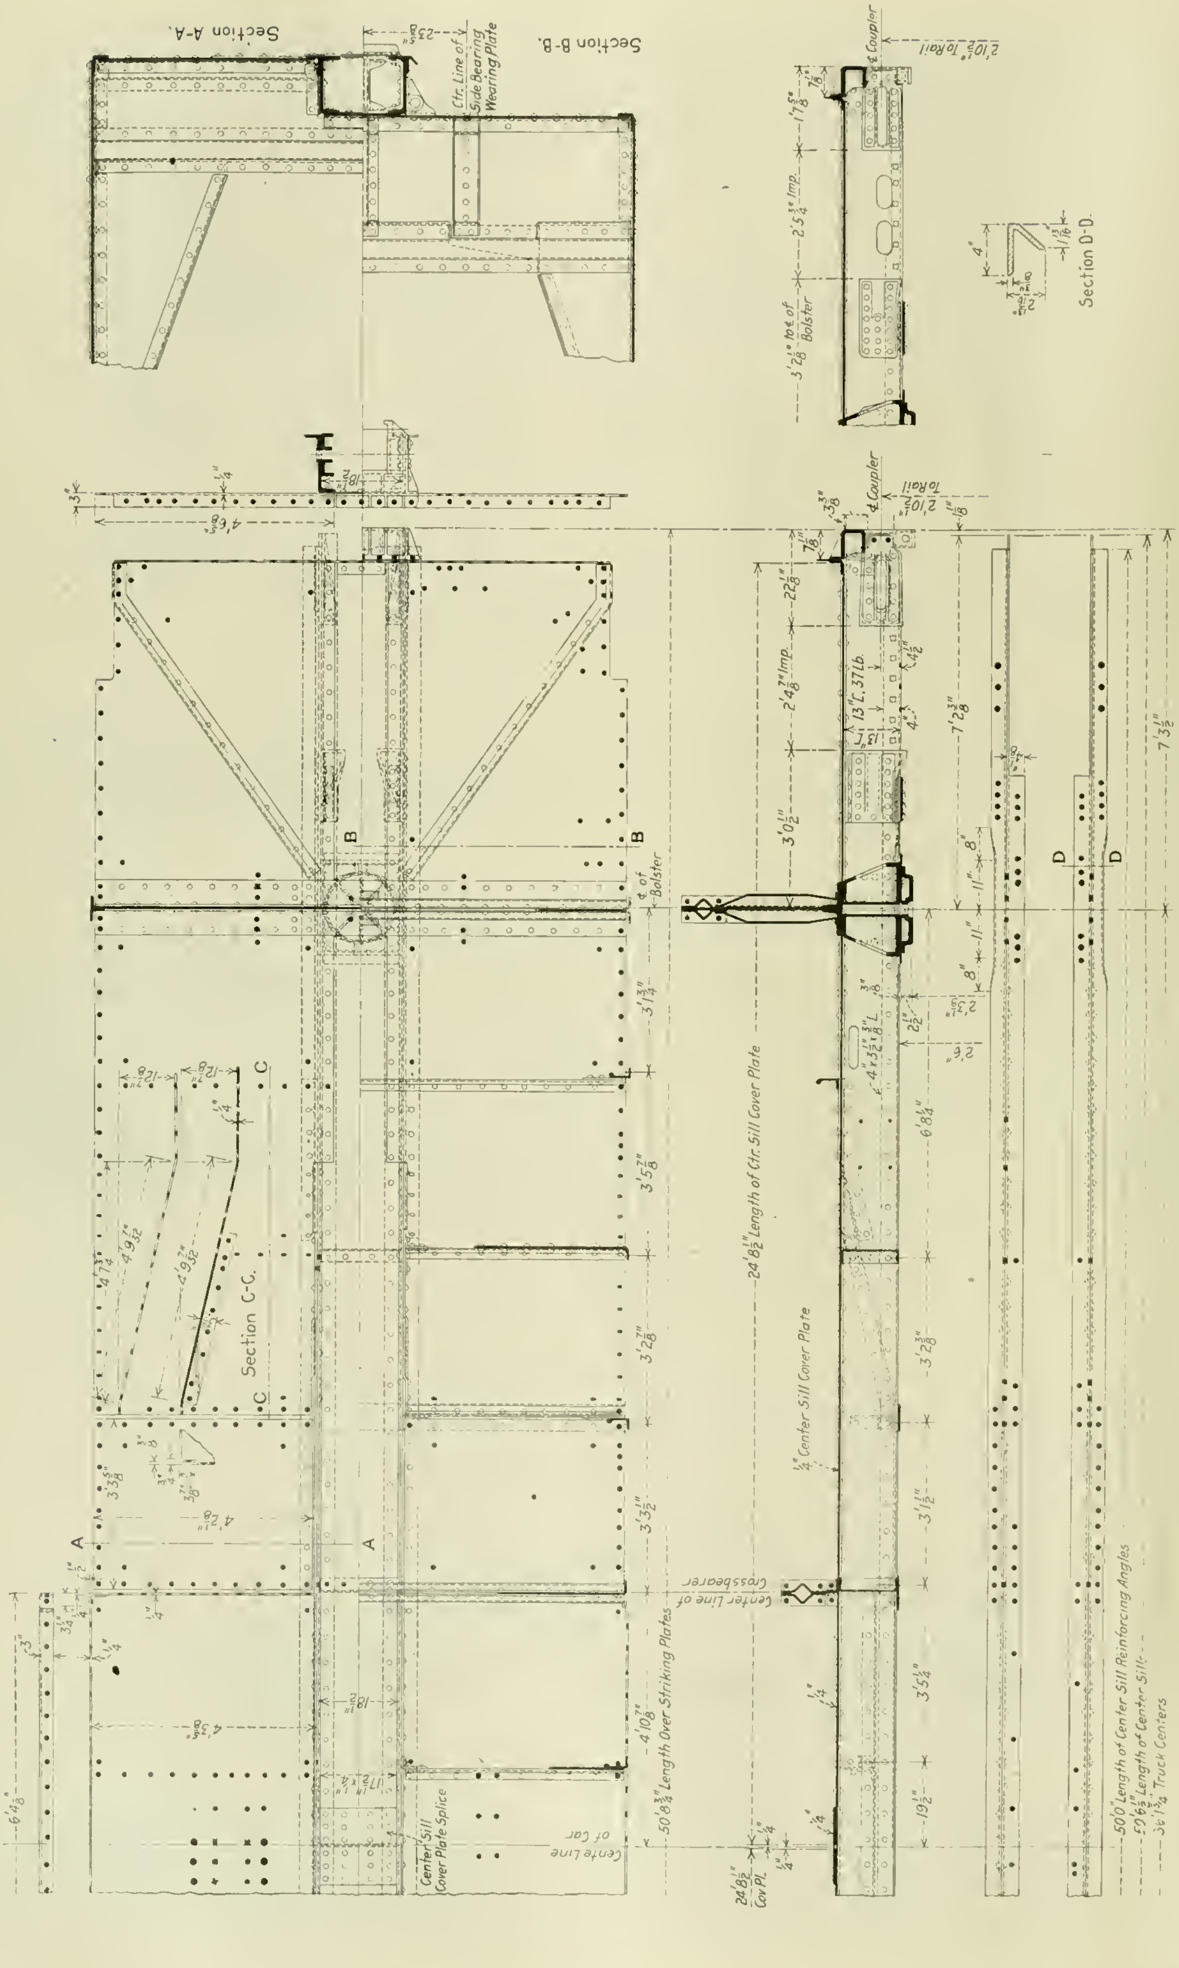
The advantages of the 120-ton car under the conditions prevailing on the Virginian Railway can be judged by the comparison of this equipment with the 55-ton cars. The new cars, with a capacity of 240,000 lb., weigh 78,900 lb., making the ratio of load to dead weight 75.3 per cent. The gondola and hopper cars, with a capacity of 60 tons, weigh 41,000 lb. and 44,000 lb., respectively, making the ratio 74.5 and 73.2 per cent.



Wide Sill Spacing Permits the Application of Two Westinghouse N-12-A Draft Gears

The 120-ton cars are 49 ft. 6 in. long inside, while the 55-ton hopper cars are 32 ft. 6 in. long and the gondolas 40 ft. long. Thus the gross weight per foot of length for the 120-ton cars is 61.7 per cent greater than for the 55-ton gondola, and 31.0 per cent greater than for the hopper. For a given length of train the net tonnage that can be handled in the larger cars is even greater.

It has been found entirely practical to handle trains of 120-ton cars, but no extensive tests have been made so far because of adverse weather conditions. It has been demonstrated, however, by actual test that the gross load behind the tender in these trains averages 13,200 tons, compared with



Details of the Underframe and Floor Construction, Showing Draft Arrangement for Westinghouse and Cardwell Gears

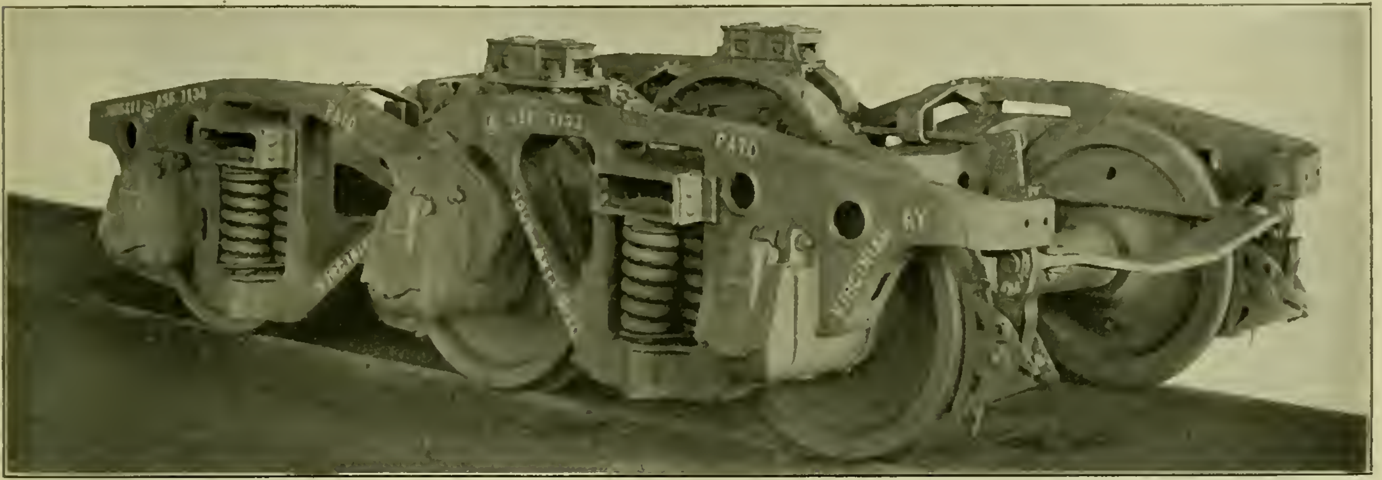
7,950 tons hauled with the smaller equipment. It is the opinion of the operating officials that with favorable weather conditions a train haul of 14,000 tons gross or 10,540 tons net load will be secured by the use of the 120-ton coal cars.

Construction of the Cars

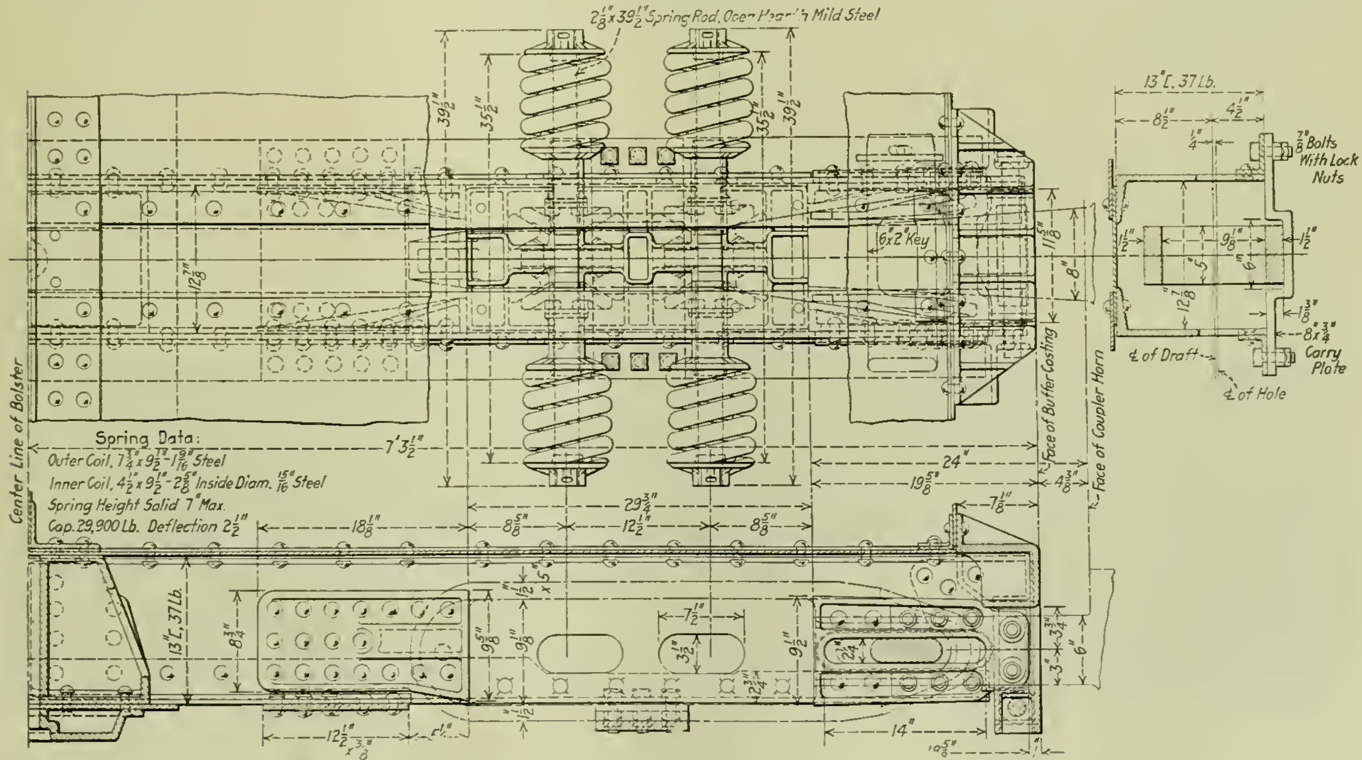
As already mentioned, these cars have been made extremely wide and high in order to keep down the length.

The car body is 49 ft. 6 in. long by 10 ft. 2¾ in. wide inside and has a depth at the center of 8 ft. 5⅛ in. and at the ends over trucks of 7 ft. 4¼ in. The cubical capacity is 3,850 cu. ft. level full or 4,450 cu. ft. with a 30 degree heap. This latter figure, with coal at 54 lb. per cu. ft., is equivalent to approximately 240,000 lb. The cars are stencilled 218,000 lb. capacity, but, adding a 10 per cent overload, brings the capacity to approximately 240,000 lb., the load which the car is designed to carry, both from the standpoint of strength and as to dimensions.

The size of the car, coupled with the fact that it is deeper at the center than at the end, gives it the general appearance of one of the modern quadruple hopper cars. However, it is not a hopper car, as it has no hoppers, drop doors or means of discharge other than from the top. It is to be operated solely on the lines of the Virginian and dumped only in car-dumping machines. These facts suggested the design finally adopted.



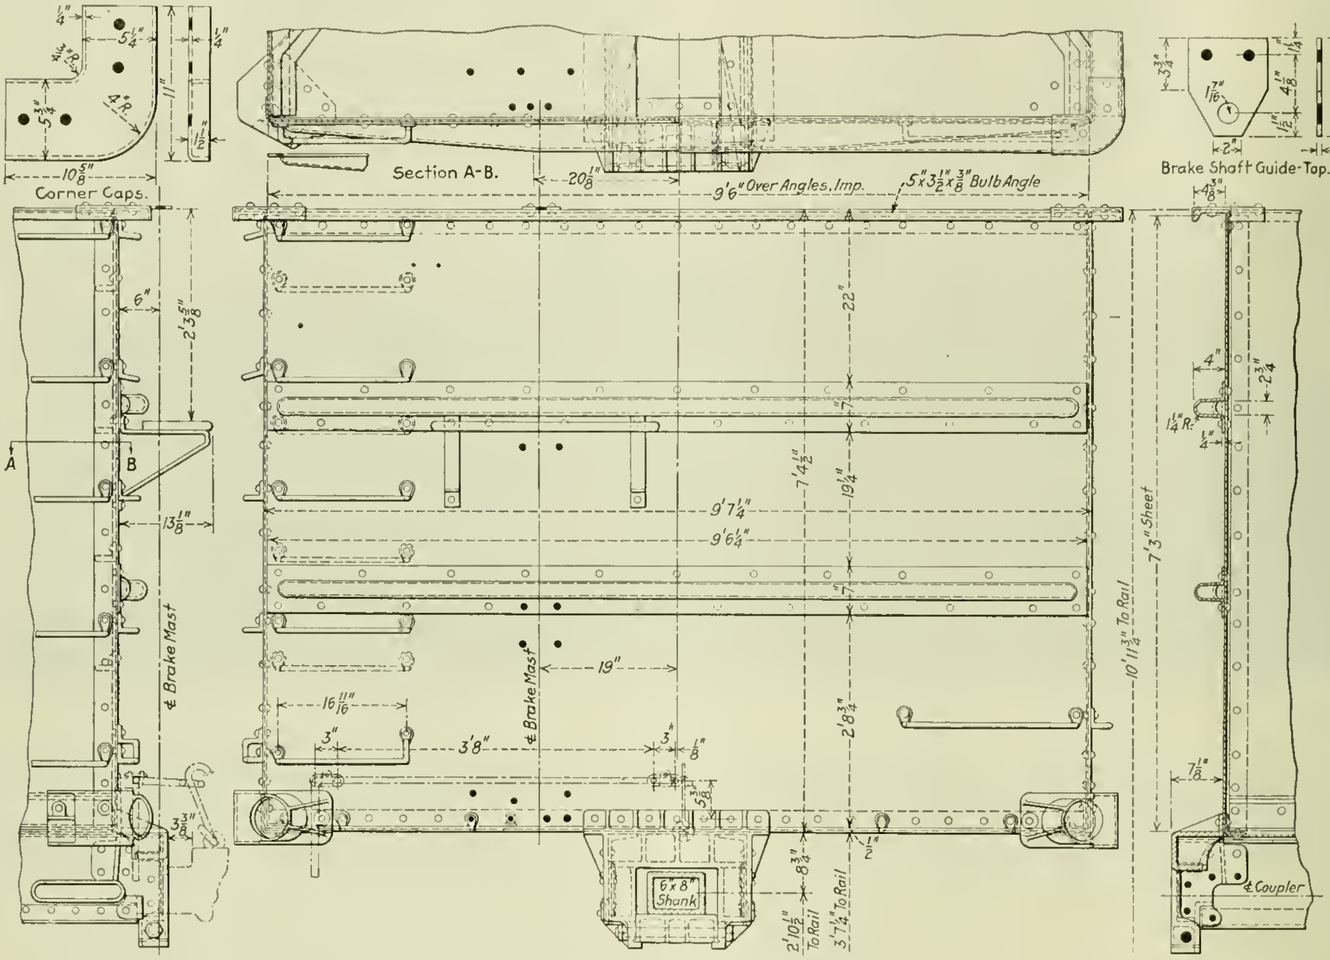
The Lewis Truck



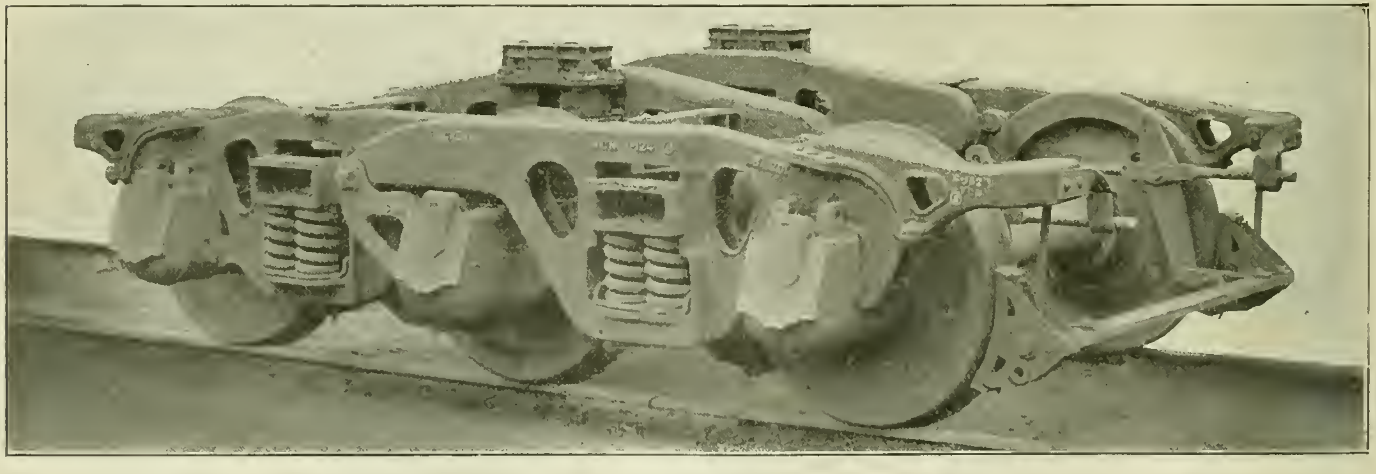
Arrangement of Cardwell Duplex Draft Gear

The sides, it will be noted, are entirely free from outside side stakes or other projections beyond the plane of the side sheets. The car presents a smooth, straight surface throughout the depth of the body at all points to engage the blocking and clamps in car dumpers, thus avoiding concentrated stresses on side stakes, top angles and other projections while the car is being dumped. This construction also admits of using practically all of the clearance width of the road for the inside or available loading width of the car and provides the required cubic capacity in a minimum length and height.

The sides are formed of ¼-in. plates sloped in near the top at an angle of approximately 15 degrees and then flanged out, overlapping the horizontal leg of the top angle to which they are riveted. The top angles are standard 4 in. by 4 in. by ½ in. rolled angles with the vertical flange outside in line with the plane of the side sheets. On the inside of the side construction 14 stakes are provided on each side and the connection between these stakes and the side top angle is effected through malleable iron castings, as is shown in the drawings of the car body. The side stakes consist of reinforced triangular gussets and 5-in. rolled bulb angles, all directly connected to bolsters, cross bearers and floor supports, all of which are located inside of the car body. Along the bottom the sides are reinforced by a 3½-in. by 3½-in. by ⅜-in. rolled angle, which also supports the floor. This angle extends to within approximately 2 ft. 4 in. from either end. At these points the plane of the side sheets is dropped back into the car to bring the ladders inside the clearance limits and also to afford these a certain amount of protection in car dumpers and elsewhere. The assembled side construction forms an efficient girder which will carry the entire weight of the lading as well as the dead weight of the car at a low fiber stress and leave the center sills to take care of the buffing stresses.

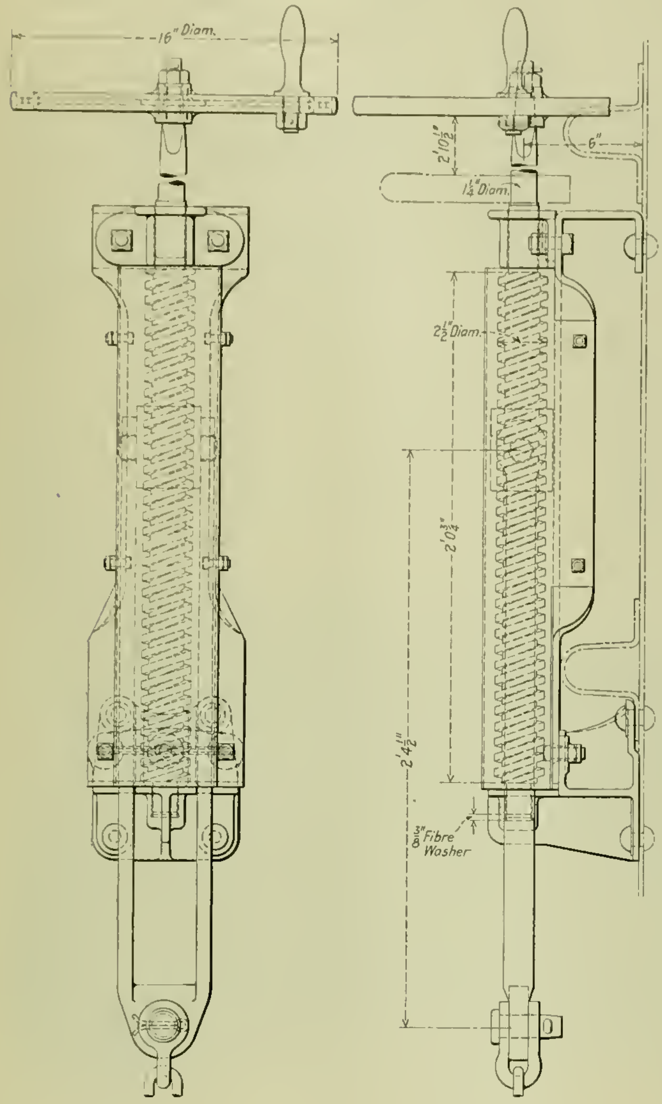


Details of the End of the Car Body



The Buckeye Six-Wheel Truck

The center sills are made up of two 13-in. 37-lb. standard rolled channels applied with the flanges toward each other and reinforced at the top by a cover plate and at the bottom by 4-in. by 3½-in. by ⅜-in. rolled angles. Five hundred cars are equipped with Westinghouse N-12-A draft gear and Lewis or Lamont trucks, being known as Class G-4 cars, while the remaining 500 cars have Cardwell duplex draft gear and Buckeye trucks. These are known as Class G-3 cars. On the Class G-4 cars the center sills are spaced 18½ in. apart and on the Class G-3 the standard 12⅞-in. spacing is employed. The center sills develop an effective buffing area of over 30 sq. in. and the ratio of stress to strain, figured according to A. R. A. practice, is below .05.



Details of the Screw Type Hand Brake

The ends are formed of ¼-in. plates reinforced at the top by a 5-in. by 3½-in. by ⅜-in. rolled bulb angle, intermediately by two pressed steel braces extending the full width of the car and at the bottom by the floor sheets, which are flanged up to engage the ends and are riveted thereto. The floor sheets are all ¼-in. plates and all floor supports, including bolsters and cross bearers, are of built-up construction.

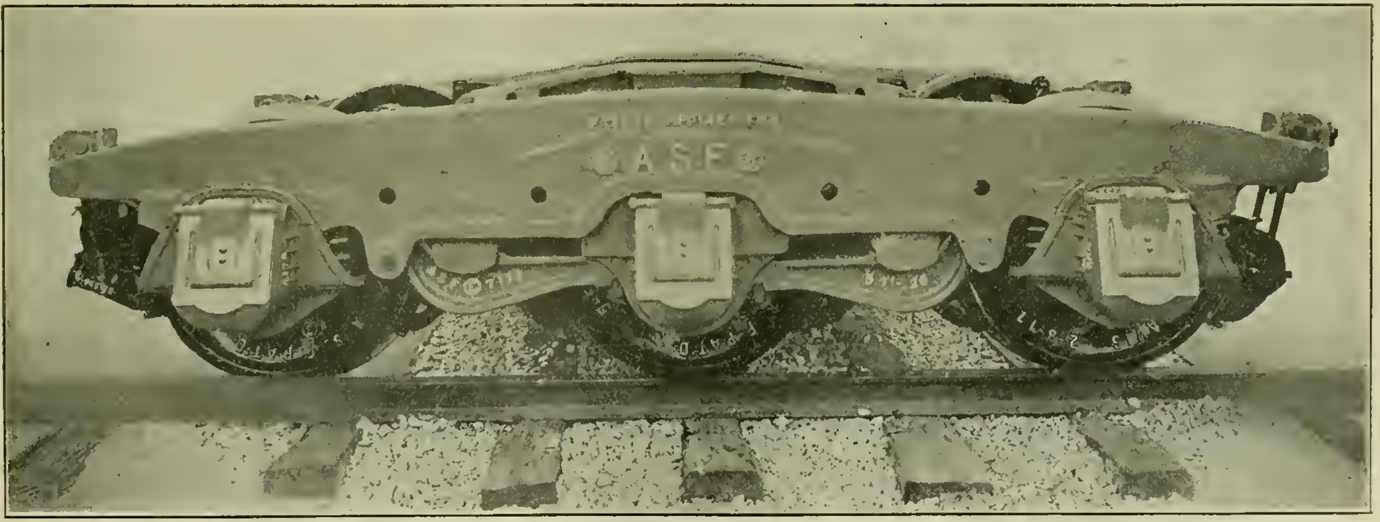
The trucks are of the six-wheel type with cast steel frames, two designs being used, as previously mentioned. They are equipped with A. R. A. standard 6-in. by 11-in. axles, 33-in. rolled steel wheels, Stucki side bearings and clasp brakes.

The Lamont Truck

The first application of the Lamont six-wheel truck, which has just been developed by the American Steel Foundries, has been made under ten of these cars. The outstanding features of this truck are its short wheel base of 8 ft. 3 in., the arrangement of the springs and equalizing system, and the three piece bolster which uniformly distributes the load over the four points of support.

The bolster is made up of a central or equalizing member and two cross bolsters. The central bolster carries the center plate and side bearings and at either end rests on the middle of one of the cross bolsters, the ends of which in turn are carried on the longitudinal equalizers under the side frames. The principal feature of the equalizing system is the location of the springs at the journal boxes instead of over the equalizer. The journal boxes are of special construction, in which seats are provided for coil springs on either side of each box, the truck frames resting directly on the springs of the end journal boxes. The springs at each of the middle journal boxes are spanned by a spring cap; on the middle of this cap bears an equalizer, from the ends of which are hung the inner ends of the main equalizers. The other ends of the latter are hung from the truck frames.

Westinghouse empty and load schedule KDE-4-10-16 brake equipment is used for the power brake and for braking the cars by hand, a special screw type of hand brake is provided, as the ordinary type would not be suitable for spotting these cars on dumpers and in handling them about the mines where, at points, it is necessary to drop them down steep grades after loading. The couplers are of a special design having A. R. A. type D heads and slots for connecting to



The First Application of the Lamont Truck Was Made on Ten of These Cars draft gear with 2-in. by 6-in. forged keys and cast steel yokes.

The completed cars are 10 ft. 11¾ in. high from rail to top of sides. The Class G-3 cars weigh 78,800 lb., of which 41,600 lb. represents the weight of the body and 37,200 lb. the weight of the Buckeye trucks. The Class G-4 cars weigh 78,900 lb., the body weighing 43,200 lb. and the Lewis trucks 35,700 lb. These dead weights make the ratio of revenue earning load to total weight hauled 75.3 per cent.

Tank Car Outlets and Other Projections

Colonel B. W. Dunn, Chief Inspector of the Bureau of Explosives, having received many letters protesting against the recent prohibition of nipples or other attachments to bottom outlet valves of tank cars, has issued a statement calling attention to the dangers incident to the transportation of gasoline.

The tank car committee of the American Railway Association finds the tank car and the locomotive tender, of all railroad equipment, the most liable to derailment; and in the case of the tank car, the breakage of the outlet chamber almost invariably follows the derailment and adds greatly to the danger of further damage.

The bottom outlets of tank cars have always given more trouble in connection with leakages and fires than any other cause. It is contrary to elementary principles of safety to make a hole in the bottom of a tank containing thousands of gallons of a dangerous inflammable liquid, and depend upon any device to keep it closed. On English railroads a bottom valve is not allowed in any "tank waggon" carrying inflammable liquids of the first class. Furthermore, such liquids as gasoline are not transported in "tank waggons" of any type.

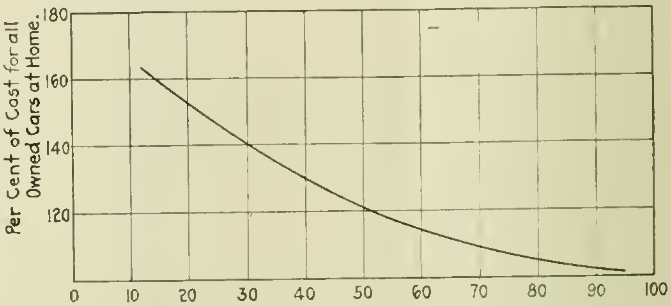
The Bureau of Explosives appreciates the difficulties. The desideratum is a car with valves which would not leak; but no valve has yet been placed in service which successfully accomplishes this result. The next best thing is to use a solid valve cap as a second defense against leakage at the bottom of the outlet chamber. If builders had made a serious effort years ago to make a really tight outlet, one might have been developed. It is hoped that some one of the experimental types now under service tests may prove satisfactory.

When extensions in the way of nipples and stop cocks are added to the outlet chamber the hazards are greatly increased. Valves extending below the bottom of the outlet chamber provide additional joints, each one of which is an additional possibility for leakage. These extensions are also liable to be struck and knocked off or ruptured by flying ballast or obstructions during transit. Consignees demanding these forget that the extensions increase the hazards while the car is moving. Gasoline is the most dangerous commodity transported on American railroads. The Bureau of Explosives' records show that from 1910 to the beginning of the present year, gasoline was responsible for 83 per cent of the deaths, 63 per cent of the personal injuries and over 49 per cent of the property damage occurring in the transportation of all classes of dangerous articles, exclusive of explosives. In the majority of the gasoline losses the bottom outlets started the trouble. So long as the railroads put up with this situation, just so long will improvement of the bottom outlet arrangement be delayed.

The action taken at the meeting of the tank car committee of the American Railway Association on June 4, 1920, against supplementary extensions, is believed to be a step in the right direction. It amended Section 7 of the Tank Car Specifications by adding sub-paragraph "c" providing that "No nipples, valves or other attachments, shall project below the bottom outlet cap except while car is being unloaded." This decision of the tank car committee was based principally upon the records of results in a large number of cases where this type of car was involved. The Bureau of Explosives heartily concurs in the action of the committee.

Effect on Cost of Repairs of Changes in the Percentage of Freight Cars at Home

In developing a method for arriving at allowances which should be made in the expenditures for maintenance of way and equipment in the application of test period amounts to guaranty period conditions in the settlement to be made between the railroads and the United States Government for the six months' guaranty period, following the return of the roads to private operation, a committee representing the railroads has made a study of the effect on the cost of maintenance of freight cars of variations in the proportions of home and foreign cars on the lines. The studies are based on information covering the test period received from 80 railroads owning 82 per cent of the freight car equipment of the country.



Change in Cost of Freight Car Repairs With Change In Per Cent of Cars at Home

The results of this study are shown graphically in the diagram, and the values from which the curves were plotted are given in the table. Starting with a cost of 100 per cent, or unity, for 100 per cent of owned cars at home, the cost increases at an accelerating rate as the per cent of owned cars on the home lines decreases. The cost shows an increase of 21.17 per cent when 50 per cent of owned cars are on home lines and with 25 per cent of the owned cars at home the cost of repairs is 45.56 per cent greater than the base figure. For 13 per cent owned cars at home, the smallest percentage covered by the actual observations, the cost of repairs is 61.21 per cent higher than the base figure, or over 33 per cent greater than when the normal proportion of half of the cars which the road owns are at home.

Effect on Cost of Repairs of Changes in Percentage of Freight Cars at Home

Change in Cost of Freight Train Car Repairs Due to Change in Percentage of Owned Cars on Home Line

Container Car in Express Service on N. Y. C. Lines

American Railway Express Company Operates Experimental Car Between New York and Chicago

THE container system of transporting materials has been given much attention in the past and considerable progress has been made in development work. These experiments have, however, been made only in freight service in an attempt to relieve the congestion of traffic due to delays in loading or unloading the present type of freight car, particularly when handling less-carload shipments. Many of the same difficulties and delays are also encountered in handling express matter and this has led to the application of the container idea to the railway express service.

A container car designed especially for express service has been placed in operation on the New York Central between New York and Chicago. This car left New York recently in an American Railway Express train and after delivering its cargo of merchandise for leading Chicago department stores at the South Water street terminal of the Michigan Central Railroad, was reloaded and made a return trip to New York.

A Nine-Section Express Car

The car is a nine-section express car, its sectional cargo space consisting of nine separate containers or steel boxes firmly secured on the car to prevent shifting during train movement. Each container is removable so that it may be transported by motor truck between stores or factories and the railroad.

This new equipment was built by The Merchants Despatch Transportation Company of East Rochester, N. Y. It consists of a modified low-side gondola car carrying nine containers which may be lifted on or off the car by means of a crane or other type of hoisting apparatus. The car is constructed along the lines of the New York Central standard 60 ft. baggage car and is mounted on two four-wheel trucks of the passenger type. It is equipped with passenger buffers and with air, steam, and signal line connections so that it may be operated in passenger train service. The underframe is of steel construction throughout having a deep center sill which is supplemented by the construction of the car sides. The superstructure consists of a low steel side framing—about 30 in. high—having side plates of steel which stiffen the car frame and also serve to prevent any sidewise movement of the containers. The sides are connected at each end of the car to a cast steel anti-telescoping end-frame which is approximately the same height and width as a passenger car, having much the same appearance as a blind-end baggage car.

The containers are designed so that they may readily be removed from the car and loaded upon automobile trucks. They are 9 ft. long by 6 ft. wide inside, have an inside clear height of 7 ft. 4 in. and a capacity of 6,000 lb. They are substantially built of structural steel and being entirely of metal will eliminate the losses due to damage from fire. A door is provided in one side of each container through which the material is loaded and the door then locked and sealed. The container is then placed upon the car where the side of the car which projects above the base of the door gives additional security to the contents as the door cannot be opened until the container is raised above the top of the side frame. This feature makes the pilfering of goods—now so prevalent—practically impossible. Besides the facility with which the container and its contents may be handled, this method of transportation is expected to eliminate much of the delay caused by the detailed billing and re-checking of small shipments.

On the initial trip of this express car, the handling of the loaded containers was accomplished with surprising speed. With no special station equipment—only a locomotive crane being available—the containers were transferred from motor trucks to their positions on the car in from 30 seconds to two minutes each. Under existing conditions, this nine-section express car could therefore be unloaded and reloaded ready to proceed within 40 minutes. No crew of handlers equipped with trucks could possibly equal this performance.

In addition to the nine-section steel container car now in passenger train express service, there are at the present time

New York Central Container Car Designed for Handling Express Matter, Equipped with Passenger Trucks and Buffers and with Air, Steam and Signal Line for Passenger Train Operation under construction at the plant of the Merchants Despatch Transportation Company other container cars for use in freight train service. These cars, which are 46 ft. long, are provided with steel underframe, wooden sills and floors, and steel sides and ends about 24 inches high for holding the containers in place. The cars will be equipped with standard freight car trucks and will be in every way suited for regular freight train service. The containers now under construction for use with these cars in freight service are 15 ft. long, and three containers will be used on each car. They are constructed with steel sides, ends, roofs and floor frames, wooden floors and sheathing and doors in one end only.

Other Container Cars Under Construction

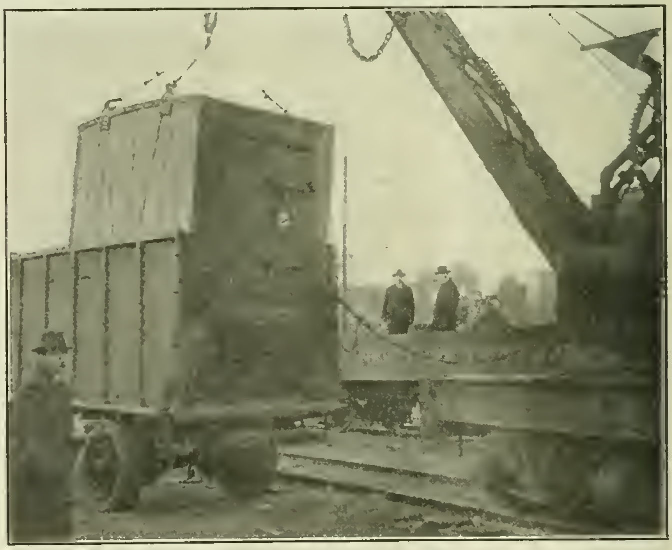
It is expected that this container car system will be expanded by the New York Central to completely co-ordinate the steam railroad, the motor truck and the electric railway. If it proves to be successful in actual service it will bring about a new system of handling less-carload freight and express matter between large centers of population. The New York Central primarily seeks greater security for shipments in transit, the losses to the railroads through the theft and damage of goods having increased alarmingly in recent years—the aggregate annual loss and damage claims paid by American railroads in 1920 having been increased about 300 per cent since 1914. Several other points of improvement in service are expected from the container car system of transportation. This system provides that the portable containers shall be loaded and locked on the shippers' premises and then conveyed by motor truck and lifted aboard the car. At destination the locked container is carried by motor truck direct to the consignee. All of the intermediate handling and checking processes are done away with.

Empty Container Showing Interior and Door Construction

Another advantage of the new system which is expected to prove most valuable is greatly increased use of rolling stock in actual service. This is particularly important when traffic expands to its "peak" and the prime need is to shorten lay-overs of cars in yards and stations for loading and unloading, and to limit their idleness through misuse for storage purposes. With ample supplies of the removable containers, which in their several classes will be of uniform size and interchangeable, one carload of the containers may be removed and sent with their loads to consignees, and another set immediately hoisted to their places and the car be ready to proceed within a matter of minutes. The containers may remain on station platforms or on the premises of shippers for loading or unloading at convenience, without tying up rolling stock at points where track capacity is limited.

Locomotive Crane Placing a Loaded Container on the Car

One of the difficulties that will be encountered in the operation of this system will be the lack of adequate lifting apparatus on the premises of many shippers, which will necessitate the tie-up of a motor truck while the container is unloaded and reloaded. Other difficulties that must be overcome are: the possibility of scattering the containers over too wide a territory and the probable lack of sufficient suitable traffic in one direction. These objections to such a system are, however, vastly outweighed by the advantages.



A Loaded Container Being Lifted From the Motor Truck

The performance of this first car in express service will be followed closely and it is expected that in a future issue, the readers of the *Railway Mechanical Engineer* will be given some very interesting operating data.

Draft Gear Tests of the Railroad Administration

First of a Series of Articles Describing Investigations Conducted by the Inspection and Test Section

THE draft gear tests of the United States Railroad Administration were originally undertaken at the request of the Committee on Standards for Locomotives and Cars and the Central Advisory Purchasing Committee for the purpose of determining the relative merits of the several commercial gears in order that mechanical excellence and costs might be evaluated. The Inspection and Test Section, as a preliminary to any work, carefully studied all of the common methods of testing draft gears. Letters on the general subject were also addressed by the section to all of the draft gear manufacturers and to a large number of prominent mechanical officers of the roads, the replies to which showed a wide difference of opinion, not only as to the proper method of testing draft gears, but as to what performance should be expected from a gear.

A comparison of the many test reports submitted showed an entire inconsistency in results, supposedly obtained under similar conditions. It became evident that a test of all gears under exactly the same conditions, removed from any proprietary influence, was essential, and also that the tests should be conducted in such a manner as not only to determine the comparative value of the several gears, but to obtain all the exact information possible with respect to draft gear action, and to extend the study as far as possible toward the ultimate determination of the ideal draft gear. With such a program in view, the co-operation of the A. R. A. Committee on Draft Gears was felt to be desirable, and upon invitation from this section, this committee has taken an active part in the test work and in analyzing and compiling the results.

The present report covers in a rather extensive manner the action and comparative merits of the various gears when considered from the viewpoint of impact and buffing. The opportunity for the investigation of draft gears in train starting and similar operations has not developed as was hoped for, so that it is impossible at this time to present definite information in this latter respect.

The full investigation of draft gears should include not only the laboratory and impact tests of the present report, but also a wide range of train operation tests and service tests, from the results of which should be determined:

1. The minimum amount of movement necessary between cars for starting trains, and whether this movement may be free slack, as between coupler knuckles, or whether it should be resisted movement.
2. Whether the beginning of draft gear compression should be an easy movement or a stiff movement, and whether there should be an initial compression to prevent movement from slight shocks.
3. The effects of recoil and what amount of release force is desirable.
4. The desired capacity, travel and ultimate resistance of the gear, as well as the shape of the curve representing draft gear resistance for both buffing and train starting.
5. The coupler horn and coupler shank clearance.
6. The life, together with the rate of wear and loss in gear capacity attending it, that should be expected from an acceptable draft gear, as well as the setting of a measure, either in time, mileage, or loss of capacity, when a draft gear should be removed from the car and be repaired or scrapped.

Draft Gear Testing

The following discussion on the general subject of draft gear testing is given for the benefit of any who may be called upon to do similar work in the future.

It is important to have a full knowledge of the condition of each test gear before putting it into a test. Check measurements should be made, such as spring heights, barrel or housing dimensions, initial spring compression, initial friction compression, absolute free height, absolute friction height, and solid height, keeping a record of possible travel at any of the previously mentioned gear heights. By having such a record it will later be possible to check up the gear conditions and to know whether any loss in travel is due to set of springs, wear of friction members or deformation of parts of the gear. Depreciation in any of these respects should be reported in equivalent loss in coupler or gear travel.

It is important to protect the friction surfaces of test gears from any grease, rust or moisture. Even the handling of the friction faces with bare hands may leave enough grease or moisture on them to lower the gear capacity.

In testing draft gears, the gear should not be loaded beyond the solid point. Few gears will stand much service beyond their normal capacities, especially under the drop machine. The determination of the solid point, however, is often quite difficult. The static test is best suited to accurately fix the limit of normal gear closure. In tests of other characters, such as the drop test, the gear should be closed only to the travel determined from the static cards as the limit of normal gear action.

All gears, irrespective of construction, should be set up and restrained in a suitable testing frame, corresponding in dimensions to the draft gear pocket in the car. The frame should be so designed that the influence of its yield will be minimized. The gear should rest in the frame upon pieces of metal corresponding to the stop faces of the gear draft lugs or other stop member. A striking plate of the same size as the coupler butt should be placed on top of the gear for receiving the blow. This will develop whether or not the gear construction is substantial enough to receive the coupler butt forces in service. Where followers are regularly used with a gear, they should, for comparative purposes, be set up with the gear in the testing frame. In all respects service conditions should be simulated in the testing frame, as in no other manner will the weak or strong points of a gear be shown. It is more convenient to test gears such as the Miner, Westinghouse and similar types without a frame, but a frame is necessary for some other gears, such as the Cardwell, and in any impact testing the yield of the frame, no matter how carefully constructed, may slightly increase the results. It is therefore only fair that all gears should be tested under similar conditions.

It is a noticeable fact, however, that if a friction gear is brought for testing from a cold place into a warm room, the capacity will be low; and if brought from a warm room to a colder outside atmosphere, the capacity will be higher. This is due to the deposit of moisture on the colder metal, or the abstraction of moisture from the friction surfaces of the warmer metal, as the case may be. In general the humidity of the air is a decided factor in testing, and an instance is known of a depreciation of 20 per cent in a gear which could be explained in no other manner.

Another point of interest is that when a gear is to be given a static test without a frame, and the free height of the gear is greater as set up than the pocket length in the car, the gear should first be compressed to slightly below the pocket dimension and then released to the exact pocket length. The compression test should then start from this released point.

In impact testing, where the load passing through the gear to the supporting device is measured or compared, the gear should never be tested beyond the closing point. This rule applies particularly to rivet shearing tests and car-impact tests. It should be remembered that after a gear goes solid its normal functioning ceases, and further testing is only of the gear housings or barrel. Hence in over-solid testing the greater deformation of a weaker gear barrel offers additional protection to the rivets for the time being, and also offers more yield in the car tests. Any considerable repetition of such over-solid blows would, however, shortly destroy the gear. On the other hand, a sturdy gear will usually shear the rivets at the first over-solid blow and will similarly produce a sudden change in car velocity, but the sturdy gear will not be so quickly destroyed. For a full knowledge of the functioning of a gear it is necessary to know only its capacity up to the point of closure and the character of its action within that capacity. Any yield or cushioning beyond the solid point is due to deformation or spring of the heads or barrel, and is obtained only at the expense of strength and life of the gear.

The suggestion is frequently made that all gears be tested to determine the point where a force of say 500,000 lb. is set up in the sills. On the face this would appear to be entirely reasonable and a proper test for the grading of gears. But for the same reasons as before, a premium would be placed upon a weak gear construction. Furthermore, it is a fundamental principle of mechanics that there can be no force set up in any structure greater than the resistance offered by the structure. It therefore follows that if a gear were constructed with an ultimate strength value of 400,000 lb. it would be physically impossible to apply 500,000 lb. through it to the car. Hence, the only over-solid draft gear tests that should be made are those that will discover the weakness of a gear rather than credit it with false merit. The destruction and endurance tests are the only over-solid draft gear tests known that will correctly rate the gears in this respect.

Another practice from which wrong conclusions are often drawn is that of testing gears against sills of different sizes and conditions. It is not fair to set up one gear on heavy channels and another on light channels, as again, the force developed will depend upon the yield and the resistance offered by the channels. Thus if a test were made upon 20-lb. channels it would be unreasonable to expect as high a force as upon 30 lb. or 40 lb. channels, for not only is there a greater yield of the channel, but the elastic limit of the material in the lighter channels might be reached and passed, which would preclude the possibility of reaching as high a force as might be shown in the heavier channels. In other words, it is impossible to put more load into the light channels than they will stand, as the force is limited by the resistance of the structure supporting the gear.

Test Program

The following general program was decided upon for the present tests as offering the best means of investigating the comparative action of the gears:

9,000 lb. Drop Tests—Solid Anvil.
  Closing gears by drops of 1 in. increments.
  Recoil tests.
  Investigation of influence of foreign material on friction surfaces.
  Investigation of rivet shearing tests.
  Destructive tests.
Static Tests.
  Closing gears at a rate of 1/8 in. per minute.
  Closing gears at a rate of 3/4 in. per minute.
  Closing gears at a rate of 3 in. per minute.
Car Impact Tests.
  Calibrated gear in one car only, solid buffer in another car.
  Calibrated gears in both cars.

In general three each of 18 different types of draft gears are embraced in the tests. The table of Fig. 1 has been prepared to identify the gears and to give other data of prime interest in connection with them. Fifty-nine gears in all were used because of gear failures developing during the progress of the various tests.

Description of Gears

In the report as presented, the gears used are described at some length. Since practically all of the types tested are in common use, these details will be omitted and the description will be confined principally to those features which differ from the usual practice.

Westinghouse Type D-3.—This is the well-known friction draft gear of the Westinghouse Air Brake Company. It has a nominal travel in the car of 2 7/16 in., the first 5/8 in. of which is spring travel, the remainder being friction travel.

Fig. 1—Gears Included in the Test Program

Westinghouse Type NA-1:—This is a new gear recently introduced by the Westinghouse Air Brake Company. A description of its construction will be found in the Railway Age, Daily Edition for June 14, 1920, page 1785. The nominal travel of the gear in service is 3 in.

Sessions Type K:—This is the type of gear manufactured by the Standard Coupler Company and used on 50,000 of the United States Railroad Administration cars. The gear has a nominal travel of 2 1/16 in., the first 1/8 in. of which is spring travel and the remainder friction travel.

Sessions Jumbo:—This is a heavier gear of 3 in. nominal travel recently developed by the Standard Coupler Company and is similar to the Type K gear.

Cardwell Type G-25-A:—This is the regular pattern of the Union Draft Gear Company's gear slightly modified to give a nominal travel of 2¾ in.

Cardwell Type G-18-A:—This is the regular Cardwell gear of the Union Draft Gear Company with 3 3/16 in. nominal travel.

Miner Type A-18-S:—This is a slightly modified arrangement of the well-known A-18 gear of W. H. Miner and is the design applied to United States Railroad Administration locomotive tenders. The gear has a nominal travel of 2½ in.

Miner Type A-2-S:—This is a slightly modified arrangement of the A-2 gear of W. H. Miner, the nominal travel being 2½ in.

National Type H-1:—This is a new gear of 2½ in. nominal travel, manufactured by the National Malleable Castings Company. A central friction column with four ways in it is cast integral with one follower of the gear. In these ways are four friction segments, or shoes. The other, or movable follower, is arranged to wedge these shoes inwardly into the ways of the column and, as the gear is closed, the longitudinal movement of the shoes is resisted by a single coil friction spring that surrounds the friction column below the wedges. Four independent corner posts of 1⅝ in. diameter steel are provided to receive the blow when the gear goes solid, so that this force is received on entirely different metal. An independent release spring surrounds each of these corner posts. The gear is held to any desired length and as a self-contained unit by means of two ¾ in. rods.

The friction members of this gear are made of electric steel, hardened. The corner posts are of tempered knuckle-pin steel.

National Type M-1:—This gear is similar in construction to the National Type H-1, the most notable difference being that but two release springs are used instead of four as in the H-1 gear. Otherwise the same description serves for both. The nominal gear travel is 2½ in.

National Type M-4:—This gear is of the same general construction as the two preceding National gears, but has three flutes in the center column with three friction shoes, and has no independent release spring. Otherwise, the design is the same as for the other National gears. The nominal travel is 2½ in.

Murray Type H-25:—This gear is of the regular Murray pattern without wear blocks as manufactured by the Keyoke Railway Equipment Company, but was specially designed to give a nominal travel of 2¾ in. for use on Railroad Administration cars.

Gould Type 175:—This is the original Gould friction draft gear, manufactured by the Gould Coupler Company. It has single angle friction wedges pressed outwardly against the friction faces of the barrel by two sets of half-elliptic springs. It has a nominal travel of 2½ in.

Bradford Type K:—This gear is of the rocker type and is manufactured by the Bradford Draft Gear Company. The nominal travel is 2½ in.

Waugh Plate Type:—This is the well-known plate gear of the Waugh Draft Gear Company. As included in the test, each gear was made up of four sets of plates in series, each set consisting of 15 steel plates, ¼ in. by 6 in. by 11⅞ in. The nominal travel is 2¼ in.

Christy Gear:—This gear, when tested, was under development by the American Car Roof Company. It has since been taken over by the Standard Forgings Company and, in a modified form, is now known as the Stanforge friction draft gear. A description of the gear in its present form can be found in the Railway Age, Daily Edition for June 14, 1920, page 1784. The nominal travel is 2½ in.

Harvey Friction Springs:—These are the regular interwound Harvey friction springs as manufactured by the Frost Railway Supply Company. Each gear, as included in the test, consisted of two of these springs set in twin fashion, side by side. The nominal travel was 1⅞ in.

A. R. A. Class G. Springs:—These are the regular A. R. A. draft springs of 8 in. diameter and 7⅞ in. high.

Selection and Condition of Test Gears

At the beginning of these tests the various manufacturers were asked to furnish gears for test purposes, so that the gears as tested were in each instance procured directly from the proprietor, with full knowledge on his part that they were for test purposes. Whether or not gears of average manufacture were furnished must be decided from previous or additional experience with the several gears and from a knowledge of the manufacturing practices of the concerns. Unless a definite statement to the contrary appears in this report it is to be understood that gear conditions and performances as developed during the tests are in accordance with what is believed to be average conditions.

Immediately upon receipt of a test gear it was given a test number and then taken apart. The parts were marked, and measured for comparison with the manufacturer's drawings and for later comparative tests measurements. The gears were reassembled with the parts in their original positions and were given a definite amount of preliminary drop test work to condition them for the regular tests.

Westinghouse D-3:—These gears as received were in good average condition and conformed very closely to the dimensions given on the manufacturer's drawings. The results obtained in the test agreed very well with the results obtained in other tests of the same gear.

Westinghouse NA-1:—The gears as received appeared to be in average condition and the results of the test in general are believed to be representative of the action of the average product.

Sessions K:—The gears as received represented average workmanship and condition and the results of the test in general are comparable with previous tests of the same gear.

Sessions Jumbo:—These gears as received represented average workmanship and condition. The results of the test are believed to be representative of the commercial gear.

Cardwell G-25-A:—These gears as received were in average condition as to workmanship. The springs furnished for the test gears were of excessive length, the average free length being 10 1/16 in., whereas the drawing dimension is 9½ in. With all the parts properly assembled on the spring rod, the springs from the drawings should be under 3/16 in. compression, while with the gears as furnished, the springs were under ⅝ in. compression. The average drop test results obtained from these gears are greater by slightly more than 4 in., than the average results obtained in routine acceptance tests of the same gear. The lowest capacity gear of this type in the present test is more than 3 in. greater than the highest capacity gear of the same type in the Railroad Administration's acceptance test. It is, therefore, believed that the results obtained from these test gears are not representative of what may be expected from the regular product as furnished commercially.

Cardwell G-18-A:—These gears were received in average condition as to workmanship and the parts conformed more closely to the drawings than in the case of the G-25-A, although they averaged above the drawings. The individual variations, however, would probably be accepted as within manufacturing limits. The averages are believed to more nearly represent the true value of the commercial gear than those obtained from the other Cardwell type.

Miner A-18-S:—These gears as received were in good average condition as to workmanship and material. The results obtained are in harmony with those of other tests and the gears are believed to be representative of the commercial product.

Miner A-2-S:—The condition of these gears as received correspond with that of the Miner A-18-S and the test gears are believed to be representative of the commercial gear.

National H-1:—These gears conform closely to the drawing dimensions. The results obtained are comparable with results obtained in other tests of this gear and are believed to be representative of the gears as furnished commercially.

National M-1 and M-4:—The condition of these gears corresponded with that of the other National gears and is believed to be representative of the commercial product.

Murray H-25:—These gears as received had probably been given more conditioning than any other gears in the test, yet the results are not believed to have been influenced especially as they are just slightly below the average routine acceptance test of the same type for Railroad Administration cars.

Gould 175:—These gears conformed with drawings and appeared in good average condition except for a coating of grease which was found in the interior. The manufacturer disclaimed all knowledge of this and the parts were cleaned and the gears placed in a satisfactory condition. The results of the test are believed to be representative of the action of the commercial product.

Bradford K:—The undeveloped state of this gear makes it impossible to compare the test gear with the commercial product. It is felt that avoidable defects in workmanship and design are responsible, at least in part, for the breakage of gear parts noted later in the report.

Christy Gear:—As this gear was undeveloped and had never been furnished commercially, comparisons are impossible. The test gears had all of the friction surfaces machined, although it is understood that the gears were designed to be furnished regularly of rough castings. Some of the parts did not correspond to the dimensions on the drawings and the gear travel was ⅜ in. less than the drawings called for.

Harvey Friction Springs:—The spring group constituting these gears conforms reasonably closely to the drawing dimensions and the results of the test are believed to be representative of the commercial product.

A. R. A. Class G Springs:—The springs used in this test were of ordinary carbon steel oil tempered, drawn from regular railroad stock conforming to A. R. A. specifications.

Table 1—Comparative Performance of Gears in Shop Tests

Application of Limit Gages and Progressive Sizes in Railway Machine Shops*

BY COL. H. E. O'BRIEN

Assistant Mechanical Engineer, Lancashire & Yorkshire, Horwich, England

The adoption of graduated sizes of pins and holes and the bushing of holes subject to wear are two valuable methods of effecting economies.

The parts to be handled in the machine shop usually associated with "General Repairs" are—motion, valves and cab details.

The Foreman and His Training

The foreman directs the efforts of a group of workers.

He is ordinarily selected from the ranks because of his reputation as a master workman; in that capacity, however, he has had little, if any, training or experience in managing other workers.

Obviously the prime responsibility of a foreman is to understand human nature and direct human beings—a very different sort of task from handling tools or operating machines.

What sort of training should a foreman receive before he enters upon his new task? Who will be responsible if he fails to make good? What do you think about it?

Motion

The motion is dismantled in the erecting shop, examined, and results of examination posted on to the machine shop, giving particulars of new parts required, which are replaced from a stock which is maintained and based upon past experience.

The parts requiring repair are dealt with in the following manner:

Motion Pins (*Limit Gage*) —The limit gage system on motion is on the pin basis (owing to push and running fits being on one pin of one diameter). Tolerance on motion pins is 0.0005 in., the high diameter being the nominal diameter, the low diameter being the nominal diameter minus tolerance.

The motion pins are manufactured in nine different sizes, the first five varying 0.005 in. each and the remaining four vary 0.010 in. each, and each size is identified by a letter as follows:

	J	K	L	M	N	P	Q	R	S
High	2"	2.005	2.01	2.015	2.02	2.03	2.040	2.05	2.06
Low	1.9995	2.0045	2.0095	2.0145	2.0195	2.0295	2.0395	2.0495	2.0595

The pins are turned on automatics with an allowance of 0.010 in. to 0.015 in. for grinding after case hardening.

Hollow Motion Pins.—When these pins are worn below minimum size they are annealed and expanded by means of a press and mandrils: these mandrils run in sizes from No. 1 to No. 9, each varying in diameter 0.005 in. They are then rehardened and ground to size required. A substantial economy has been effected by this means.

Holes.—All rods are bushed with case-hardened bushes in rapidly wearing holes, and when worn the bush is pressed out and the new one inserted and ground to diameter required, which is governed by the size of hole in which the pin is fixed.

Limits.—The minimum variation allowed between pin and hole is that demanded for running fits, i. e., 0.0025 in. The maximum variation is 0.005 in., thus giving a manufacturing tolerance of 0.0025 in.

Reversing Shaft.—The journals of the reversing shafts wear slightly, and when worn oval to the extent of 0.010 in. they are turned up in lathe to graduated sizes, each varying 0.015 in., and when worn to the minimum diameter a sleeve bush is shrunk on and returned to standard size. Standard size of journal is 5 in., the minimum diameter is 4¼ in.

Reversing Shaft Carrier Bracket.—The bracket is bored out to allow for the fitting in of a cast iron sleeve bush; this diameter remains constant. The internal diameter of these bushes is machined to graduated sizes to suit the shaft journals. Worn bushes are re-bored to the nearest graduated size.

Radius Links.—These links wear mostly in the centre owing to the notching up when running; this necessitates them being ground parallel, and the radius blocks fitted to suit.

Radius Blocks.—Radius blocks are machined to four sizes, varying 0.015 in. each. After the blocks are fitted in the links a special fixture is used to mark the blocks while in position in the shaft, which ensures the holes being in line with the center of the shaft.

CHART SIZES OF RUNNING AND PUSH FITS

Running Fits

	J	K	L	M	N	P	Q	R	S
High	2.0045	2.0095	2.0145	2.0195	2.0245	2.0345	2.0445	2.0545	2.0645
Low	2.0025	2.0075	2.0125	2.0175	2.0225	2.0325	2.0425	2.0525	2.0625

Push Fits

	J	K	L	M	N	P	Q	R	S
High	2.0005	2.0055	2.0105	2.0155	2.0205	2.0305	2.0405	2.0505	2.0605
Low	2"	2.005	2.010	2.015	2.020	2.030	2.040	2.050	2.060

Reversing Screws.—The reversing screws are made in two

---

*Taken from a paper on Management of a Locomotive Repair Shop, read before the Institution of Locomotive Engineers, England.

sizes, standard 2-in. diameter, and a 1/16-in. above. When these are worn thin on the thread they are scrapped.

Reversing Screw Nuts.—These are also made in two sides, standard and a 1/16-in. above. The reason for this is, when the standard nut has worn thin on the thread they are machined out a 1/16-in. larger in diameter, thus giving the nut another life.

Piston Rods.—Piston rods wear smaller in diameter at the middle than the ends, due to the friction of the packing. This necessitates them being ground to bring the rod parallel the whole of its length. They are ground in five graduated sizes, each varying 0.0312-in., standard size being 3-in. diameter, minimum diameter 2⅝ in. After the grinding operation the rod is then dealt with on the bench to have the crosshead and cotter fitted. Occasionally the crosshead has expanded leaving no cotter draw; in that case a crosshead is taken from stock and fitted, leaving a ⅛-in. draw. The old crosshead is placed in stock, and when new rods are being turned these crossheads are despatched to the lathe and the rods turned on cone to suit, thus getting the crosshead into service again.

Crosshead Gudgeon Pins (Effect).—Gudgeon pins are examined, and if worn more than 0.0312-in. on the little end or slide block bearing, they are renewed. These are made in two sizes on the slide block bearing, standard, and 1/16-in. above to give the slide block another life. They are manufactured on the automatics, case hardened and ground.

Piston Head.—The piston head, if found to have a clearance in the cylinder bore of 3/16-in., is condemned for that particular engine. Should the diameter of the head be over standard size, it is placed in stock and machined to suit the cylinder nearest to its diameter. The bore and cone portion for the piston rod bearing remains constant in all cases and is therefore interchangeable. Clearance allowed between cylinder bore and piston head for new or re-bored cylinder is 0.015-in.

Slide Blocks.—Slide blocks wear very slightly in the gudgeon pin hole; in cases where the wear exceeds 0.010-in. they are re-bored to 1/16-in. above standard size. This is sufficient to wear the block and flange to their minimum thickness.

Slide Valve Spindles.—The flat valve type of spindle, when in for repairs, is generally found to have expanded at the buckle, and if this expansion exceeds 0.015-in. above standard, it is sent to the smithy for closing, and there machined up to standard in the buckle. Should the spindle have worn below the minimum diameter a new end is welded on to the buckle and machined to the standard diameter.

The standard diameter of the spindle is 2⅛ in. As the spindle wears more in the center than at the end, due to the friction of the packing, this necessitates it being ground to bring the rod parallel the whole of its length.

They are ground to nine graduated sizes, varying 0.015-in. from 2⅛-in. diameter to 2-in.

Valve Spindle Crosshead.—The same remarks apply to fitting of crosshead to spindle as in the piston rod.

Valve Spindle and Piston Packing.—Packings are manufactured in graduated sizes in conformity with piston rod sizes.

Cab Details.—The injectors are stripped of all cones and plugs; scale removed from body and cones. Valve seatings and cones are re-faced and adjusted.

Steam Valve and Tappet Valve Seatings.—Due to the constant wear and repeated cuttings of the seatings, they rapidly become worn out. In order to increase the life of the body it is bored out and a bush fitted as a renewable seat.

Pipe Ends.—Occasionally the thread on pipe ends becomes stripped; these are restored to standard by turning the ends down and sweating on a sleeve bush, afterwards re-cutting the thread. After injectors are repaired they are tested for efficiency in lift and delivery.

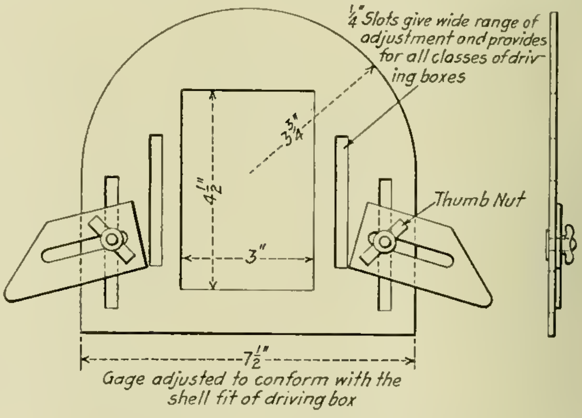
Ejectors.—The ejector is stripped of all plugs and cones, thoroughly cleaned and examined, and cones that have been cut due to action of the steam are re-turned and adjusted. In all wearing parts renewable seatings are fitted wherever possible. The disc plate requires turning up and facing to the driver's application handle. All glass gage cocks, lubricator cocks, etc., are stripped, examined and new plugs fitted where required. In cases of taper plugs they are ground only. Parallel plugs are ground and asbestos packed.

Driving Box Gage

BY A. W. C.

It is highly important that the crown brass of a driving box should be a good tight fit in the box, and this requires that the brass properly bears on the small angular surfaces as well as on the curved surface or back of the shell. If these requirements are not met, the brass will very easily work loose and become a source of trouble and annoyance. When an old brass has been removed, it is a rather difficult matter to measure the small angular surfaces, and their distance from the crown of the box, and then lay out these measurements on the shell. After being some years in service and having had various repairs made to them, driving boxes vary considerably, so that each brass must be made to fit its particular box, and the edges are not planed to any standard dimensions.

An expedient commonly resorted to in many repair shops and roundhouses, is to place the brass on end on the box, in a position as near as possible to that which it will occupy in the box; that is, with the back of the brass in line with the crown surface of the box. The outlines of the angular surfaces are then scribed on the brass, which is planed to these lines, and pressed into the box with somewhat doubtful results. A simple, adjustable gage, as illustrated, can be made easily and used for accurately transferring the outlines of the angular surfaces on the box to the brass.



Efficient Form of Driving Box Gage

The gage is made of ⅛ in. sheet steel to the dimensions shown. The two wings or blades are attached to the body of the gage by ¼ in. carriage bolts and wing nuts. In use, the curved portion of the gage is placed against the crown of the driving box, and the blades are adjusted to bear on the angular surfaces in the box, being secured in that position by tightening the thumb nuts. The gage is then placed on the end of the brass, with the curved portion flush with the back of the brass. The outlines of the blades are scribed on the brass, thus faithfully reproducing the dimensions of the driving box brass fit. It is obvious that this saves handling the heavy driving boxes and brasses now in use and affords a far better method for getting a good fit.

Notes on General Shop Practice at Du Bois

Production Is Increased and Unit Costs Decreased By Using Present Equipment to the Best Advantage

BY GEORGE W. ARMSTRONG

Many interesting and effective methods have been developed at the Du Bois shops of the Buffalo, Rochester & Pittsburgh, each one a real factor in increasing the efficiency of shop operation. Careful attention to details, elimination of much lost motion and the equipment of machines with time saving jigs and fixtures all help to increase shop output and reduce the unit costs of repair work.

The driving box equipment represents a good use of old tools for single purpose production. For machining crown brasses to fit driving boxes, a slotter (Fig. 1) has been equipped with the customary holding mandrel; the stroke has been lengthened to take brasses for extended main driving boxes and a simple, heavy feed suitable for brass cutting applied. Rapid finishing of the brasses is assured by these comparatively simple, inexpensive changes in the slotter.

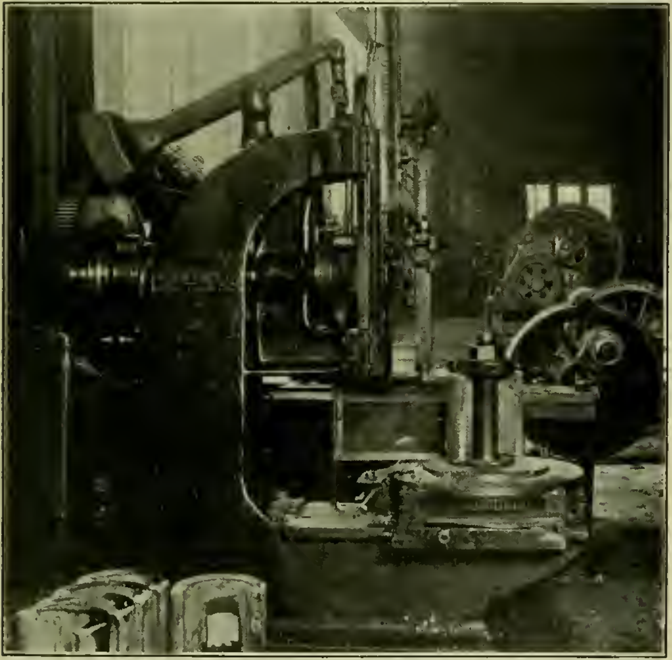


Fig. 1—Slotter Arranged for Rapid Machining of Crown Brasses

Driving boxes are bored and hub liners faced on a boring mill (Fig. 2) which has been equipped with a piloted boring bar to provide rigidity and permit the taking of heavy cuts. Hub liners are faced by the second head, thus performing two operations at one setting of the driving box and making sure that the hub face is at right angles to the bore of the box. Driving box shoe and wedge ways are kept a standard width by electric welding steel liners along the driving box flanges. The edges of the liners where they are welded to the driving box are beveled, an operation cheaply performed by planing a number of liners at the same time. They are held at the proper angle in a planer chuck using suitable beveled blocks and feeding the tool across all the liners at once. To assist in holding the liners six holes are punched for "tack-welding." After welding, the driving boxes are planed to the standard widths between shoe and wedge faces called for by the blue prints.

Washout plugs are quickly and accurately turned and threaded in an engine lathe (Fig. 3). Several sizes of castings are carried so as to reduce the amount of metal to be removed to an economical minimum, about 1/8 in. range being cared for by each casting. The small end of the plug is cored out to a bell shape to reduce the weight and permit quick center punching for the tail stock center.

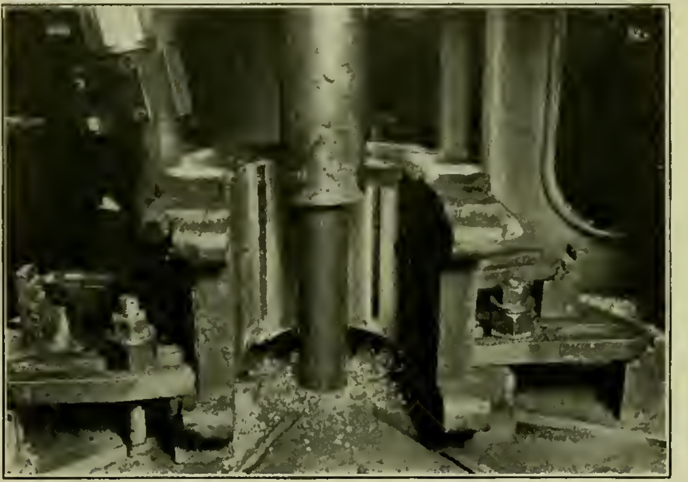

Fig. 2—Heavy Cuts Are Taken With a Piloted Boring Bar

The threading tool is a hobbed chaser (as shown on top of the tool post) held in a block fitted to take the place of the regular tool post. Grinding this tool at an angle furnishes a turning edge to precede the threading chaser. By means of an adjustable stop, the carriage travel can be regulated, permitting the taking of several cuts and yet maintaining the size where a number are made of the same size. The taper is obtained by setting over the tail stock, as this method has been found to give the best results. The strips, shown at an angle on the side of the tool block, have been provided to hold the hinged guard, protecting the workman from flying

Fig. 3—Method of Machining Washout Plugs

brass chips. The average production, working on a quantity shop order, is 100 plugs in eight hours.

An interesting method of solving a difficult shop problem is illustrated by the fixture for turning lift shaft bearings (Fig. 4). This is one of the troublesome jobs in the average shop, owing to the long arms requiring a large swing lathe to turn them. Such a lathe in many cases is not available and as a result, the bearings are filed, a lengthy operation that does not produce accurate work. The special fixture illustrated has been devised and is fastened to the lathe face plate. It consists of a sleeve carrying a turning tool, capable of sliding lengthwise and keyed to a center portion, which also has a live center. The lift shaft is placed between the center in the fixture and the lathe dead center. Both the lift shaft and the outer end of the fixture are held by steady rests. Turning up to a capacity of 6 in. in diameter by 16 in. in length can be done by moving the turning sleeve with the tool bit along the shaft; such traversing motion being caused by a lathe tool engaged in a slot in the sliding sleeve.

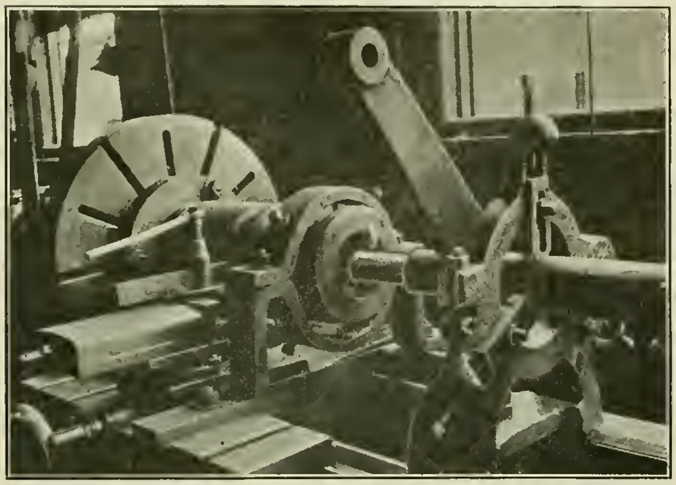

Fig. 4—Fixture for Turning Lift Shaft Bearings

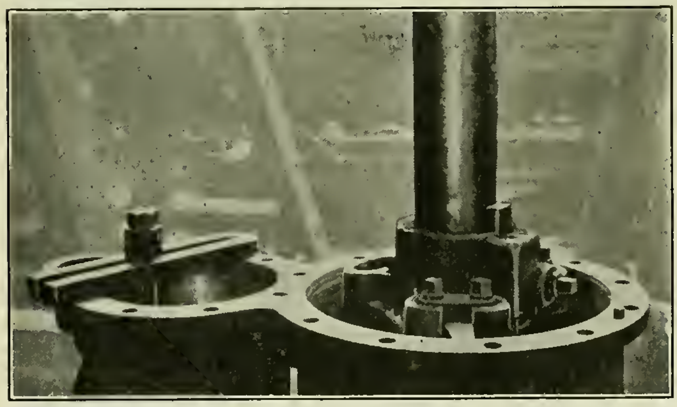

Fig. 5—Adjustable Head Used in Boring Air Compressor Cylinders

Fig. 6—Folding Screens are a Convenient and Effective Safety Device

Air compressor cylinders are accurately and quickly bored on a radial drill press (Fig. 5), the steam cylinder of an 8½ in. cross compound compressor being shown. A regular boring tool through the bar is used for the small bore cylinders, the adjustable boring head being used for the 14½ in. cylinders. The boring bar is maintained rigid by a pilot bracket bolted to the side of the drill press table. As illustrated, a clamping bolt and cross iron through one cylinder allows the other cylinder to be swung over the side of the drill press table and the boring bar extends through the cylinder to the pilot bracket. A roughing feed of .009 in. and finishing feed of .006 in. are used.

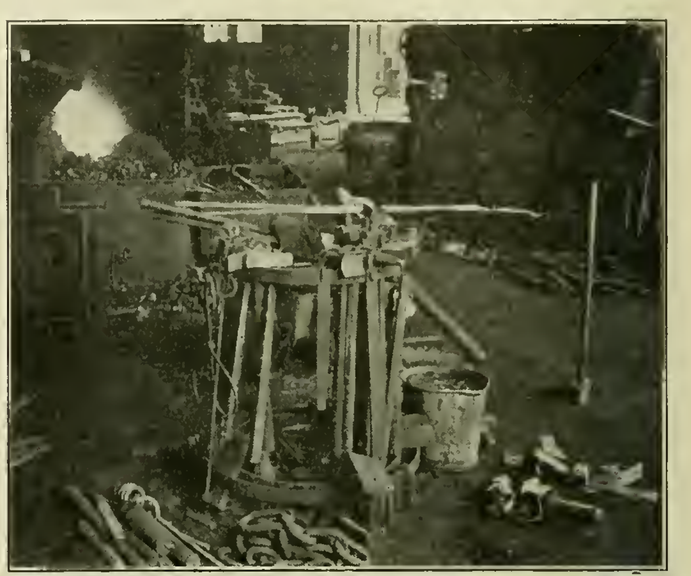

Fig. 7—Handy Tool Rack With Sheet Iron Drawer

Fig. 8—Fixture Used in Rolling Boilers

Safeguards are everywhere in evidence in the Du Bois shops, indicative of the vigilance of the men on the safety committee, who make a general inspection of the shop every other Saturday afternoon. One very simple and valuable safety device is the screen (Fig. 6) used around vises where much chipping and filing is done, especially in the rod department. These screens when not in use can readily be folded back out of the way.

A good blacksmith shop tool rack has been devised (Fig. 7) which keeps the tools readily available and near the anvil where wanted. It consists of two concentric circles of 1½ in. by ¼ in. iron separated as shown, one pair forming the top and the other the bottom of the tool rack. A sheet iron drawer is provided in the center for keeping orders, time books, etc. It is difficult to say just how many steps and how much time are saved each day by having tools and working implements right at hand ready for use.

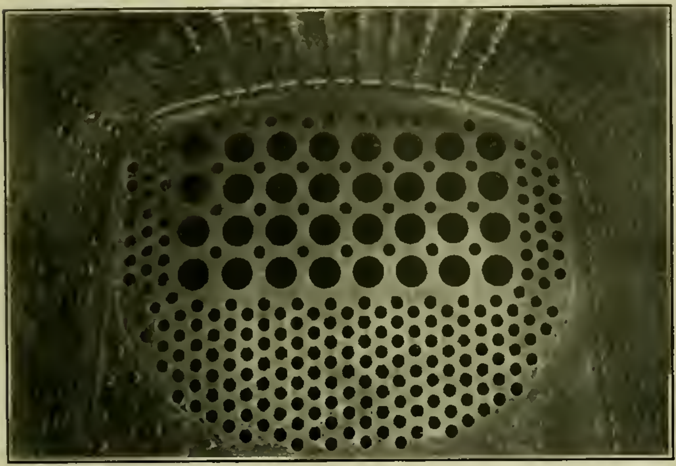

Fig. 9—Application of New Flue Hole Portion to Back Flue Sheet

Rolling boilers is quickly and easily accomplished by the fixture illustrated in Fig. 8. The boiler is slung from the main hoist hook with the steel shackle bar under the belly of the boiler. Turning to any desired position is accomplished by the cable attached to the auxiliary hoist hook.

The practice of electric welding has come into general use at Du Bois and shows excellent results, especially on boiler work. A large number of fireboxes have been applied with complete electric welded seams, except at the top of the back tube sheet, where it has been found more satisfactory to rivet to the crown sheet. Back heads are welded in completely, including the door holes. Where flue sheets require replacing solely because of cracked bridges or where a change is made from saturated to superheated steam, the flue hole portion is cut out by the torch and a new section welded in place (Fig. 9), thus requiring no renewal of staybolts or driving of mud ring rivets. Side sheets requiring renewal because of enlarged staybolt holes, or other causes except defective seams, are renewed by electrically welding a new section in place.

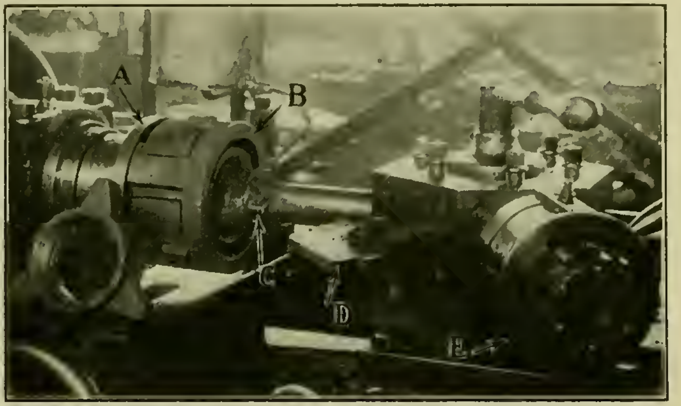
T. O. Edwards, auditor of the Southern Pacific, discovering that a number of employees of the road have lost Liberty Bond savings and other "nest eggs" through misrepresentation of unscrupulous promoters, has issued the following warning: "No matter how attractive the proposition may seem to be on the surface, employees, before investing their savings, should consult with some responsible banker in their community who will gladly give them frank and unbiased advice, whether they are a patron of the bank or not. There are many opportunities for sound and profitable investments at the present time, but attempts are being made every day to defraud the public and impose upon the credulous."

Chuck for Holding Hose Nuts

By J. M. Cairns
Assistant Foreman, Boston & Maine Shops, North Billerica, Mass.

In most railroad shops a large number of hose nuts have to be machined either for local use or for other points on the system. In the quantity production of hose nuts, as all other locomotive parts, a small amount of time saved on each one means a large total saving which is well worth while. The special chuck, illustrated and described in this article, is designed to save part of the time formerly spent truing up and centering hose nuts in ordinary chucks of either the independent or universal type.

The operation of the chuck is extremely simple. As shown in the illustration, it consists of a nut holder *A* arranged to screw on the lathe spindle and slotted to receive the lugs of the nut. The ring *B* is arranged to telescope the nut holder and a partial turn engages three shoulders which prevent its slipping off again.



Special Chuck and Turret Lathe Tooling Arrangement for Machining Hose Nuts

The lathe used is a well-known type of 18 in. brass turret lathe, equipped with an internal plunger, or spindle, controlled by a lever at the head end. In operation, the hose nut is put in place with the holding ring applied and turned in the locking position. The lever is pulled back, forcing the internal plunger against the back of the nut, thus automatically locking the ring and holding the nut in a firm grip.

Hose nuts are made of malleable iron in two sizes, 3¾ in., 8 thread, and 4 in., 8 thread. They are roughed out with the boring tool *C*, the finishing size being attained by a forming drill *D*. The final operation consists of tapping out with a collapsible tap *E*, thus reducing to a minimum the total time required for setting up and machining a hose nut.

Instructions for Grinding Chilled Cast Iron Car Wheels

The following instructions and the accompanying tables, embodying the Atchison, Topeka and Santa Fe practice in grinding chilled cast iron car wheels, are abstracted from the 1920 Proceedings of the American Railroad Association, Section III—Mechanical.

The original tape size of a chilled iron wheel is shown by the number of small lugs on the back of the wheel. Wheels sent in for grinding must be taped with the standard A. T. & S. F. tape, which has special graduations for measuring worn wheels which are smaller than a Tape 1 wheel, and the original tape size must also be noted. Then, by referring to the table under the original tape size, and reading across from the actual tape size of the wheel as measured, the diameter, circumference and depth of chill can be found. If the wheel is slid flat the flat spot must also be measured and under the column headed "Length of Flat Spot" will be found the diameter and tape to which the wheel must be ground. The depth of chill after grinding can be determined by referring to the chill corresponding to the reduced tape size.

Wheels with worn treads can be ground if the measured tape size is shown above the heavy line on the table for the original tape size of the wheel. Skidded wheels should have the greatest flat spot measured, and the wheel must then be ground the same as for a slid flat wheel as described above. In no case are slid flat wheels to be ground if the tape size and diameter necessary for grinding are under the heavy line in the table for the original size of the wheel. The flanges of wheels that have been ground must not exceed the maximum allowance of 1⅛ in. in height. If the flanges are over this limit they must be ground also.

Reference to the tables will show that X, X/1, X/2, X/3, etc., are markings on the standard Sante Fe tape, made for convenience in measuring worn wheels and corresponding to the definite diameters, 32⅞ in., 32 27/32 in., 32 51/64 in., 32 49/64 in., etc., respectively.

Examples

Slid Flat.—An original tape 2 wheel which measures X/3 and has a 3¼ in. flat spot must be ground to tape X/7, or 32 39/64 in. in diameter. The chill is 9/16 in., which is reduced by grinding to 31/64 in.

Tread Worn.—An original tape 3 wheel which measures X/2 on re-taping would grind to X/2 but could not be ground if the re-taped size fell below the minimum, or X/8.

Tables Used on the Atchison, Topeka & Sante Fe to Determine Whether Chilled Cast Iron Car Wheels Can Safely Be Ground

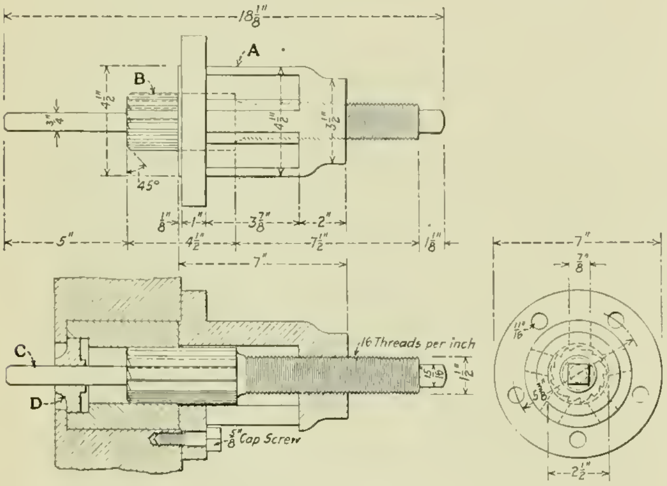
Reaming Reversing Valve Bushings

BY CHARLES W. SCHANE

Apprentice Instructor, Erie Repair Shops, Huntington, Ind.

The jig illustrated herewith has proved an effective device for reaming worn reversing valve bushings in the steam heads of New York air compressors. The bushings can be reamed without removing the compressor from the engine or taking off the steam head and on account of this feature, the device has proved of great value in saving time at roundhouses and reducing the number of air compressor failures. A pair of reversing valve bushings can be reamed and new packing rings fitted and applied in an hour's time by one machinist.

As shown in the illustration, the jig consists of a body *A* arranged to be fastened to the under side of the steam head in place of the reversing valve cap by means of five 5/8 in. cap screws. The reamer *B* is made in one solid piece with one end threaded to advance the reamer, the extreme end being squared for a wrench. The other end consists of a piloting stem 3/4 in. in diameter. In operation, the jig is attached to the under side of the steam head, being held securely in place by the cap screws. The reamer is guided by the piloting stem *C* which is a running fit in bushing *D*. As the reamer is turned, it advances into the bushing and when fed in the full distance, leaves a smooth, true hole to which the reversing valve packing rings may be fitted.



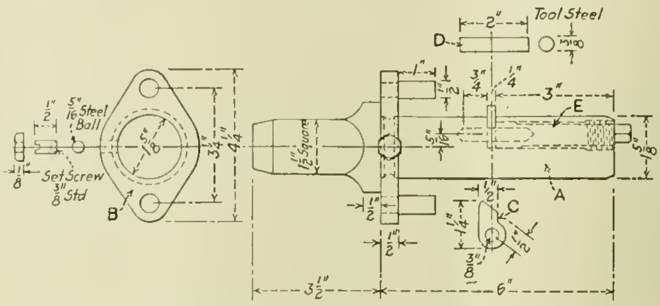
Device for Reaming Reversing Valve Bushings

On account of the reaming action being upward, the chips fall out of the valve chamber into the body of the jig and may be brushed away through the apertures shown. This prevents any possibility of chips getting into the valves of cylinders of the air compressor.

Liberty Flue Cutter

A device known as the Liberty flue cutter has given exceptionally satisfactory service in the Horton shops of the Chicago, Rock Island & Pacific for cutting out flues in front ends. Referring to the illustration, mandrel *A* is made of tool steel, slightly less than 1 5/8 in. in diameter and provided with a 1 1/2 in. square end for driving. Plate *B*, made of 1/2 in. stock, is arranged to turn freely on the mandrel and form a positive stop when the mandrel is inserted in the boiler flue. Plate *B* is held against the shoulder on the mandrel and allowed to turn freely by means of the steel ball, 3/8 in. set screw, and lock nut as shown, the steel ball rolling in a groove in the mandrel *A*.

The cutting knife *C* is made of carbon steel shaped as indicated with a shoulder to take the direct thrust and arranged to be held in the mandrel *A* by means of the steel pin *D*. The slight radius at the point of the knife *C* makes possible a shearing action which shears the thickness of the flue and width of the knife in one revolution from the time the knife begins to cut. Very little power is required for this operation. The steel pin *D* is held in place by means of pin holder *E* which is also made of tool steel. All wearing parts of the Liberty flue cutter are case hardened to increase their resistance to wear.



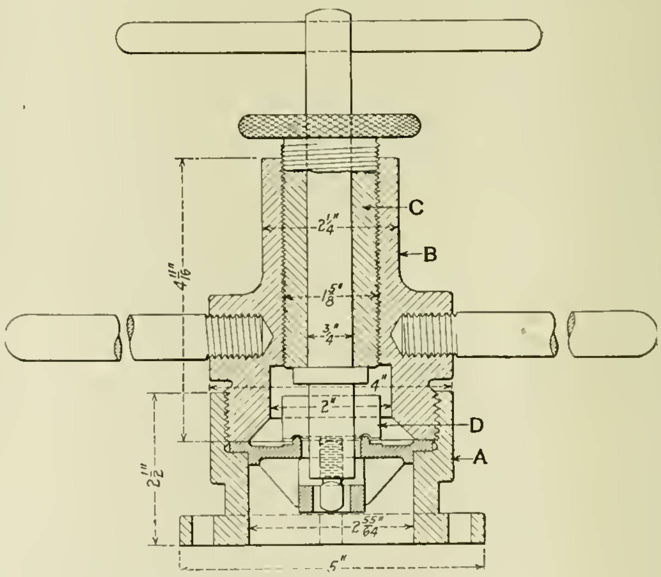
An Effective, Easily Made Flue Cutter

Emergency Seat Refacing Tool

BY JOHN FLINNER

Air Brake Inspector, Pittsburgh & Lake Erie, McKeesport, Pa.

A special tool designed to reface the brass seats of emergency valves applied to Westinghouse triple valves of either the passenger or freight type is shown in the illustration. The emergency valve seat is placed in the base *A* of the fixture as shown. Part *B*, provided with two handles, is arranged to turn into the base *A*, holding the brass emergency valve seat firmly in place. An adjusting screw *C* may be turned down by hand against a shoulder on the valve stem carrying the cutting tool *D*. This cutting tool is double acting, so ground as to give the required shape to the valve seat. It is held in place by means of a square-headed set screw as shown.



Tool for Refacing Emergency Valve Seats

This emergency valve seat refacing tool has been used with good results as it makes possible the refacing of valve seats that become worn or cut in service. In addition, old style valve seats may be refaced, giving them the improved semi-circular section shown, which has been found to give better service.

A Profitable Railroad Reclamation Project

170 Tons of Bar Iron a Month Rolled From Bundled Scrap at Beech Grove Shops of the "Big Four"

ESTABLISHED early in 1918 for the purpose of re-rolling bar scrap, the rolling mill at the Beech Grove (Indianapolis, Ind.) shops of the Cleveland, Cincinnati, Chicago & St. Louis has since been adapted to the reclamation of miscellaneous wrought iron scrap at a materially greater profit than was realized under the original re-rolling practice.

The rolling mill was placed in operation in April, 1918, at a time when materials of all kinds were exceedingly difficult to secure. The railroad had on hand a large accumulation of scrap, including considerable quantities of old truss rods, arch bars and other miscellaneous material of rectangular cross section, suitable for re-rolling into useful bar stock.

Rear View of the Mill Showing the Cooling Bed and the Jib Crane for Handling the Finished Bars

At the outset the mill was operated along conventional lines of re-rolling practice. Both the roughing and finishing rolls were fitted with the usual alternate oval and circular passes. Heating and re-rolling were the only operations performed on round iron, while flat sections were split before being rolled.

Several stages of development were passed through before the present practice was established. One of these was the use of splitting rolls on the roughing side of the mill, so that flat sections might be split hot and re-rolled at the same time. This practice, however, did not always eliminate the necessity of reheating half of the split material before it could be rolled and saved only the shearing operation. During the early history of the plant some attention was given to the production of rectangular sections in the rolls but considerably greater difficulties are encountered in the operation of the mill on rectangular work than in the production of circular sections. As the demand for round bar stock is great enough to keep the mill busy, its operation is now confined exclusively to the production of that class of material.

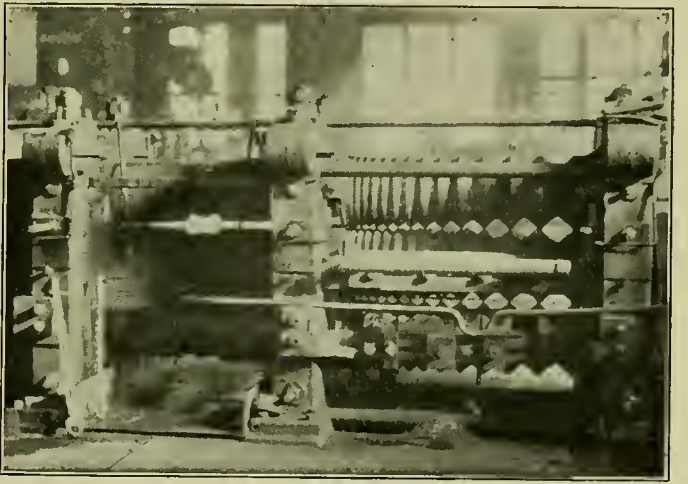
A careful study of the operation of the mill developed the fact that, under the local conditions, the profit was not large from strictly re-rolling operations. Under the present method of operation the rolling mill serves as a means of reclaiming practically all of the miscellaneous wrought iron scrap accumulating on the road. Scrap iron bars and trimmings of all sizes are sheared and bundled and then rolled into round bar stock ranging from ⅝ in. to 1½ in. in diameter, practically supplying the needs of the railroad for this class of material, at an average monthly net profit of over $3,500.

The Rolling Mill Equipment

The rolling mill is located in the blacksmith shop and occupies a total floor space of approximately 45 ft. by 120 ft. The equipment consists of an Ajax B, 14-in. mill driven by a 100-hp. motor, a shop built furnace with double heating chambers each measuring 7 ft. by 5 ft. 6 in. inside, hot tables for the roughing and finishing rolls on the furnace side of the mill, a metal floor and a straightening bed of old rails at the back side of the mill.

The furnace is 18 ft. in length and the two heating chambers are separated by a partition wall. Each chamber is heated by two oil burners, the two sets of burners being located at opposite ends of the structure. The four burners consume about 48 gal. of oil an hour. Each heating chamber is provided with two door openings and normally its charge consists of 12 bundles of scrap. Both ends of the furnace are used continuously; a fresh charge is heating in one end while that in the other is being rolled.

The present operation of the mill on bundled scrap was made possible by the adoption of the so-called Gothic roughing rolls. The characteristic form of the passes in these rolls is shown in one of the illustrations. The rolls were cast in a local steel foundry, of electric steel poured around cores of steel rails, and were machined in the railroad shops.



The Roughing Rolls, Showing the Form of the Gothic Passes

Operating Practice

For some time the rolling mill has normally been in operation 16 hours daily and a total complement of 19 men is required for the two shifts. Each shift is made up as follows:

One head roller (day shift only)
One roller (night shift only)
One heater
One heater helper
One rougher }
One finisher } (on the furnace side of the mill)
One catcher }
Two helpers } (on the turning floor side)
Three laborers piling scrap (day shift only)

The roller, heater, rougher finisher and catcher are rated as blacksmiths while the head roller receives a differential. The others receive the regular rates for helpers and laborers.

It is worthy of note that the head roller, in direct charge of the operation of the mill, is an experienced rolling mill operator, and to this fact may be attributed, in no small measure, the successful development of the present practice.

The scrap material comes to the rolling mill from two sources. The greater part of the round stock comes from the scrap yard, where radial stays, staybolts and other rod and bolt scrap accumulates from all points on the system. The long pieces, such as radial stays, tie rods, etc., are sheared to 24-in., 30-in., and 36-in. lengths so that they may be used as foundations for the piles. The greater part of the flat and square bar scrap is made up of trimmings which accumulate in the blacksmith shop itself. This material is collected from various locations in the shop and the accumulation moved by crane to a point adjoining the rolling mill. Here the pieces are trimmed to conform to the lateral dimensions of the bundles and the bundles assembled.

The bundles are made in lengths of 24 in., 30 in., and 36 in., depending on the size of the stock to be rolled. All are 4½ in. square and each bundle is bound by two No. 8 iron wires. The composition of the bundles is clearly shown in one of the illustrations. The foundation is a layer of round material, sheared to length and laid on the two binding wires, which are bent to shape. The pile is then built up of miscellaneous flat and short round pieces and finished at the top with another layer of round material laid longitudinally. The piles average in weight about 94 to 100 lb. for the 24-in., 115 lb. for the 30-in., and 140 lb. for the 36-in. length. The 24-in. piles are used for rolling ⅝-in., ¾-in., and ⅞-in. stock and the 30-in. pile is used for 1-in. to 1½-in. stock. These two sizes take care of by far the greater part of the output, although the 14-in. rolling mill is capable of handling up to 2-in. finished stock. For bars over 1½ in. in diameter the 36-in. piles are used.

The mill is operating with an average furnace loss not exceeding eight per cent. The piled scrap, as it comes from the furnace, is run directly through the largest pass on the roughing rolls. For bundles of the size used extensive ragging is unnecessary; a few small radial grooves chipped in their sides prevent slipping in the first roughing passes. The material is worked down through the roughing passes until only a few passes through the finishing rolls are necessary. On the 1-in. material the bars go through nine roughing and four finishing passes. The welding up of the piles is completed in the first three or four passes.

The straightening bed adjoins the center bay of the shop, which is served by a traveling crane. As the finished bars cool they are piled just back of the straightening bed as shown in one of the illustrations. When a pile, such as that shown, accumulates, one end is lifted and swung under the traveling crane by the post gib crane shown in the upper foreground of the photograph. The pile is then moved to the shears, located just across the shop, where the bars are cut up into bolt lengths for the forging machine furnaces.

In the usual re-rolling mill practice, alternate oval and circular passes are used throughout the process. The passes on the Gothic roughing rolls, however, are all of similar form, with the longitudinal diagonal longer than the vertical and the bar as it comes from each pass is given a quarter turn about its axis before entering the next smaller pass in the rolls.

The rolling mill itself is in actual operation about one-half of the time. The remainder is taken up in recharging the heating chambers following each run of twelve bars. Under normal operating conditions each eight-hour shift produces from five to eight tons of finished bar stock, depending on the length of the bundles and the diameter of the finished bars.

The original finishing rolls are still in operation and there has never been a failure of any part of the mill. The only repair which so far has been required was the renewal of one bearing.

In addition to the average furnace loss of eight per cent, an additional two per cent is lost in defective bars and waste in cutting up to bolt lengths. This loss, however, has been found to be less than the normal cropage encountered in cutting up merchant bars because of the more economical use that can be made of bars running from 40 to 60 ft. in length than is possible with the merchant bar lengths.

The quality of the material is excellent. Assuming that proper care is exercised in heating, the working over of the bundled scrap adds to the refinement of the iron and the comparatively loose structure of the bundles causes a more complete working of the material in the center than would take place in solid billets of the same size. The finished bars are homogeneous in structure and show good fractures. Tensile tests indicate that the material averages the following physical properties:

Bundled Iron Scrap Ready for the Furnace

Tensile strength, lb. per sq. in.	50,152
Yield point, lb. per sq. in.	33,539
Elongation, per cent in 2 in.	27
Reduction of area, per cent	43

Average of 25 tests. Slight admixture of steel obtained from common iron reclaimed.

A comparatively small proportion of reworked material enters into the scrap, most of which consists of flat sections with an appreciable percentage of staybolts. An inspection of the make-up of the piled scrap as shown in one of the illustrations, remembering that the mill rolls only bolt stock, shows that there is no danger of a deterioration in the quality of the rolling mill output due to repeated reworking of the same material.

Re-Rolling Steel Scrap

Although probably 90 to 95 per cent of the output of the rolling mill is wrought iron stock, an occasional accumulation of material such as steel arch bars and coupler yokes is run through the mill. Only re-rolling operations are employed on steel, but here also the Gothic roughing rolls have demonstrated their value.

Instead of splitting rectangular sections, such as arch bars, it is possible to rough down the full size sections through the Gothic rolls, thus eliminating the shearing operations and half of the rolling operations.

Accounting

In arriving at the cost of operation of the mill, it bears a portion of all fixed charges against the department of which the rolling mill forms a part. The mill occupies approximately 5,000 sq. ft. of floor space and employs 19 men. Interest at 6 per cent is charged against the mill operation on a portion of the cost of the building, bearing the same ratio to the total as the ratio of the floor space occupied by the rolling mill to the total floor space in the blacksmith shop building.

Report of Beech Grove Rolling Mill Operation for the Month of October, 1920

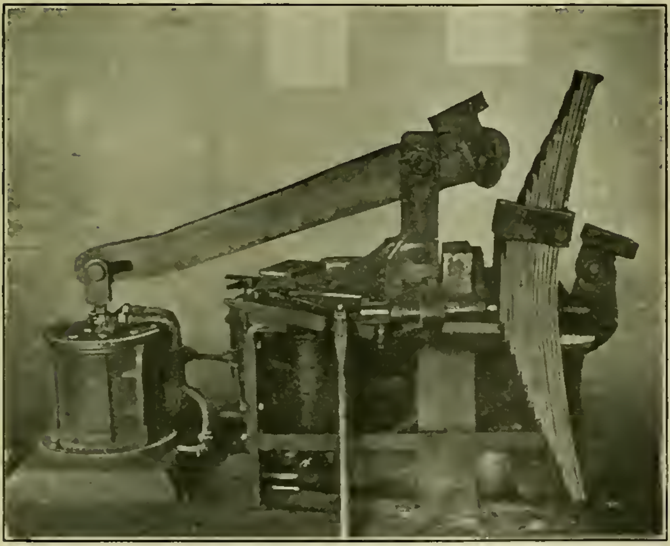
Scrap to furnace—		
370,720 lb. at $21.10 G. T.		$3,492.05
Fixed charges on mill and building for housing—		
Interest at 6 per cent rate per year	$168.71	
Depreciation	207.54	
Taxes at 1.8 per cent	47.45	
Insurance at .2 per cent	5.27	
Repairs at 3 per cent	83.33	
		512.30
Labor direct charge		2,655.66
398½ fuel hours at $1.86 per hour		741.21
398½ power hours at .30 per hour		209.55
26 days' supervision at $5 per day		130.00
		$7,740.77
Finished product—		
175,900 lb. ¾-in. rod iron at $3.35 cwt	$5,892.65	
118,940 lb. ⅞-in rod iron at $3.35 cwt	3,984.49	
50,300 lb. ⅝-in. rod iron at $3.40 cwt	1,710.20	
		11,587.34
Net profit for the month		$3,846.57
Net profit since April 11, 1918		36,225.87

In the same way a portion of the cost of the department's supervision is charged against the rolling mill operation bearing the same ratio to the total cost of supervision as the number of men employed in the rolling mill bears to the total number of men employed in the department. Interest at 6 per cent is also charged on the cost of the equipment and its installation and depreciation is charged at the rate of 5 per cent on the mill, 50 per cent on the furnace and 2 per cent on the floor space.

A statement showing the results of the operation of the mill for the month of October, 1920, is presented in the table.

Easily Made Spring Bander

For railway blacksmith shops handling a large amount of spring repair work, there is no question about the need for a modern, powerful spring banding machine. With sufficient springs to keep such a machine busy practically eight hours a day, enough time and money will be saved to pay a good return on the capital invested. For outlying points, however, where it is necessary to reband a spring occasionally for emergency work, some sort of inexpensive machine must be provided to perform the operation. The machine illustrated was designed for this purpose, using scrap air cylinders and reclaimed materials throughout, at a cost probably not exceeding $250.



Spring Banding Machine Suitable for Small Shops

As shown in the illustration, the device consists of a substantial base plate mounted upon an iron frame work with the two operating levers moved by means of air cylinders. The ratio of the arms is such that with 80 lb. air pressure in the cylinders, ample power is provided to compress the spring band. While the strokes are not adjustable, it is possible by means of blocks of different thicknesses to accommodate a spring of any standard size.

In operation, the spring leaves are assembled in the correct order in a horizontal position on the table of the machine. The jack screw, illustrated, is used to press the leaves firmly together; then the spring is swiveled to a vertical position and the heated band slipped in place. After this operation the spring is swiveled back to the horizontal position, the movable jaws swung into place, and suitable blocks applied depending upon the spring size. Pressure is applied to the air cylinders and the heated band firmly pressed around the spring leaves in the usual manner.

Crosshead Babbitting Devices Eliminate Machining

It is a general practice to take up wear and maintain crosshead gibs to standard dimensions by babbitting. In most cases a mandrel of some nature is used and sufficient babbitt is poured into the gib to permit of machining it to the proper width and thickness. This involves two distinct operations and requires considerably more time than would be needed if just the right amount of babbitt could be put on in the first place and no machining was necessary. In order to save the time ordinarily required for machining, a large railroad system has developed the series of interesting and ingenious jigs and mandrels described in this article.

	A-1	B-1	C-1
A	14"	12½"	17½"
B	16"	14½"	19½"
C	3' 5¾"	3' 2¾"	4' 0¾"
D	19½"	18"	23"
E	16"	14½"	19½"
F	1¾"	1¼"	2¾"
G	9¼"	8¼"	10¼"

Fig. 1—Details of Fixture Used in Babbitting Alligator Crosshead Gibs

Alligator Type Crosshead

Details of the fixture used for babbitting alligator crosshead gibs are shown in Fig. 1 and the actual operation of pouring in Fig. 2. Referring to Fig. 1, the operation of the device will be practically self-evident. Three fixtures are provided for three types of alligator crossheads of various widths of guides and distances between guides. The three classes have been designated A-1, B-1 and C-1 for purposes of identification.

The crossheads are preheated by lowering them into the molten babbitt. On removal from the babbitt, they are cleaned of all surplus babbitt and dirt, being placed on the mandrel ready to pour one gib. The crosshead is not keyed on the mandrel, but is driven firmly in place. The guide width is cared for by setting the taper gibs of the jig, these gibs also having been preheated at the same time as the crosshead. Side play is equalized by using small wedges between the crosshead gib and guide mandrel, as shown near the ladle in Fig. 2.

That the finished wearing surface will be parallel with the guide is assured by measuring with a gage, hooking under the bottom crosshead gib and measuring to the under side of the jig. A special clamp with a hand screw is used for bringing the crosshead and jig into alinement, if necessary. A common C-clamp is used to hold the taper gib in place after adjustment. Graduations shown on the taper gibs are so spaced that movement of the gibs the distance represented by one graduation will vary the total width 1/32 in. It is thus an easy matter to adjust for any width of guide.

Repeated tests have demonstrated that accurate babbitting of alligator crosshead gibs is possible with these jigs. Crossheads have been checked by laying two straight edges along the two wearing surfaces and measuring in front of the crossheads at a distance equal to the stroke. The straight edges were found to be parallel to within 1/64 in. or less.

Box Guide Suspended Type Crosshead

Arrangements for babbitting the four-guide, or box-guide, suspended type crosshead are made by means of the special jig illustrated in Fig. 3. In this case a somewhat more complicated problem is encountered since the crosshead must be removed in such a way as not to damage the babbitt. Consequently, the jig is made collapsible, and after the babbitt has been poured it is possible to remove the two lower plates illustrated and release the crosshead from the mandrel. The jig shown in Fig. 3 is adjustable and will accommodate two classes of crossheads as shown in the table. Longitudinal adjustment of the box can be made by loosening up two bolts, as shown, correct alinement being maintained by means of the tongue and groove arrangement indicated. Particular attention is called to the construction of the mandrel for holding the crosshead. It is made in three sections, being held on the taper pin by means of a 1 in. steel spring. The taper pin has one threaded end extending through the back plate and held by means of a 2 in. nut. Tightening this nut will, of course, expand the mandrel sections until they fit accurately and tightly the taper hole in the crosshead. It is possible by means of this jig to accurately aline a box guide suspended type crosshead and babbitt it so that no further machining is necessary.

Fig. 2—Pouring Babbitt in Alligator Crosshead Gib

Valve Stem Crosshead

To take up wear, valve stem crossheads also require babbitting and in most cases machining. A fixture designed to eliminate the necessity for this machining is illustrated in Fig. 4. As shown, the crosshead is supported on a mandrel, corresponding to the valve stem, securely bolted to the base plate. The sides of the base plate extend about half way up the sides of the crosshead, the other half being covered by means of the cover plate shown. The cover plate is held in accurate alinement by two 60 deg. shoulders as shown in the end view, Fig. 4. Two U-bolts, riveted in the base plate, extend through the cover plate and, in conjunction with two taper pins, provide for holding the cover plate firmly in place.

In operation, the fixture is up-ended with the crosshead in place and all small openings at the bottom are filled with clay. The babbitt is then poured. After cooling the cover plate is removed when the crosshead can be forced off by a taper key in the horizontal keyway shown.

Method for Squaring Walschaert Valve Gear

Changes Required in Various Parts May Be Determined by This Method with a Minimum of Time and Effort

BY W. J. DIXON
Assistant Master Mechanic, Baltimore & Ohio, Holloway, Ohio

BEFORE attempting to set the valves on a locomotive equipped with the Walschaert gear, a careful check should be made to determine whether such parts as the reach rod, tumbling shaft arms, radius rod hangers, union links, etc., are of the correct dimensions. After the above mentioned parts have been proved and the port openings correctly scribed on the valve stem, the engine should be run over, catching the dead centers in the usual way.

To determine the changes to make in the gear as based on the tram marks on the valve stem, an easy way is to proceed according to the following method:

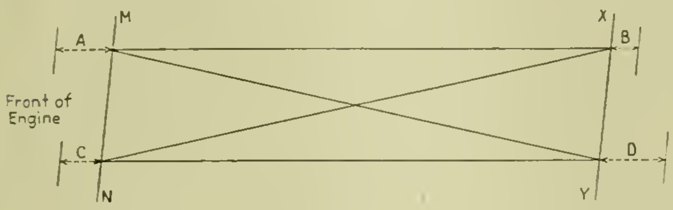

Fig. 1

Assume that lines *MN* and *XY*, in Fig. 1, represent the two port marks on the valve stem, and *A, B, C, D* are the tram measurements from the port marks:

Rule I:

$(A + C) - (B + D)$ divided by 4 = valve rod change.

Rule II:

$(A + D) - (B + C)$ divided by 4 = eccentric rod change, *at valve stem.*

Rule III:

$(A + B) - (C + D)$ divided by 4 = crank arm change, *at valve stem.*

In making the above computations it is understood the lesser is subtracted from the greater which might reverse the above combination. For example, to compute the valve rod change we might have $(B + D) - (A + C)$, etc.

Fig. 2

Fig. 3

Example 1

Taking a practical example, assume the diagram shown in Fig. 2 represents the valve stem reading. The numbers indicate the measurements from port marks in thirty-seconds of an inch. The forward motion is shown below, while the back motion appears above the center line, the front of the engine being at the left.

To obtain the valve rod changes using Rule I:

$$(4 + 24) - (8 + 12) = 8$$
8 divided by 4 = 2, or 1/16 in.

Therefore, the valve rod should be shortened 2/32 or 1/16 in., as there is a direct motion on this part. Making this change gives the valve stem reading as shown in Fig. 3.

Proving the above operations gives the following results:

$$(10 + 14) - (2 + 22) = 0$$

The next step is to determine the required change in the eccentric rod. Taking conditions after the valve rod alterations have been made as indicated in Fig. 3. and using Rule II:

$$(10 + 22) - (2 + 14) = 16$$
16 divided by 4 = 4, or 1/8 in.

From Fig. 3 it can be seen that the valve should move back 4/32 in. Referring to Fig. 1, this change would take 4/32 from *A* and *D* and at the same time add four each to *C* and *B*. This would produce readings on the valve stem as shown in Fig. 4. To prove the correctness of the operations we have:

$$(6 + 18) - (6 + 18) = 0$$

This shows that no further change is necessary for a balance of figures either for valve rod or eccentric rod. However, the change shown above is a result obtained at the valve stem. To bring about the change, it is necessary to make a greater alteration in the eccentric rod. This is determined by multiplying the valve stem change by a factor determined by dividing the travel of the valve in full gear into the throw of the eccentric arm. For example, if the travel of the valve is 6 in. and the throw of the eccentric arm is 18 in., 18 divided by 6 = 3. Referring to the 4/32 in. used in Fig. 4, 4 multiplied by 3 = 12, or 3/8 in., the amount which the eccentric rod should be shortened to obtain the results shown in Fig. 4. In determining whether to lengthen or shorten the eccentric rod it should be borne in mind that when the link block is located at the bottom of the link, a direct motion exists from the eccentric crank arm pin to the valve itself. Therefore, lengthening the eccentric rod adds to *D* and *A* (Fig. 1), while *B* and *C* are diminished an equal amount. Shortening the rod has an opposite effect throughout.

Fig. 4

Fig. 5

Referring to Fig. 4, it will be noted that having made alterations to the valve and eccentric rods, the valve is square in both forward and back motions, but has more lead in the forward motion. To correct this proceed as follows, applying Rule III:

$$(18 + 18) - (6 + 6) = 24$$
24 divided by 4 = 6

A 3/16-in. change in lead is needed at the valve stem. This would require a crank arm change on the main pin sufficient to give 3/16 in. more lead in the back motion. In doing this, 3/16 in. lead would automatically be taken from the forward motion, producing the results shown in Fig. 5.

Example II

Should the tram marks on the valve stem measure up as shown in Fig. 6, it is necessary to proceed as follows, using

Rule I to obtain the valve rod change:

(8 + 16) — (24—4) = (8 + 16 + 4) — 24 = 4
4 divided by 4 = 1

Therefore the valve rod should be lengthened 1/32 in.

This alteration gives the diagram shown in Fig. 7. It should be borne in mind that when a tram mark on the valve stem shows blind, the measurement is negative and should be so considered when computing the change.

The eccentric rod change to correct Fig. 7 is made by applying Rule II as follows:

(7 + 25) — (15 — 3) = (7 + 25 + 3) — 15 = 20
20 divided by 4 = 5, or 5/32 in.

The eccentric rod should therefore be shortened to produce 5/32 in. change on the valve stem. Making this change gives results as shown in Fig. 8.

To find the necessary change in the lead and the movement of the crank arm position correcting Fig. 8, Rule III is applied as follows:

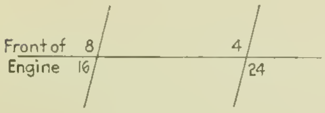

Fig. 6

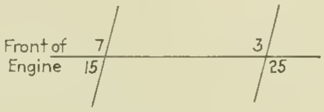

Fig. 7

(20 + 20) — (2 + 2) = 36
36 divided by 4 = 9, or 9/32 in.

The crank arm should be moved back on the main pin to produce the above change of 9/32 in. on the valve stem. Making this change produces results as shown in Fig. 9.

Referring to Figs. 5 and 9, it is seen that the valve has been squared with equal distributions in forward and back motions. By the above outlined method, it is possible to prove each operation so that the mechanic may always be sure that he is making correct changes. The three changes may be made in any order: for instance, the eccentric or crank arm alterations may be given consideration first if desired.

Fig. 8

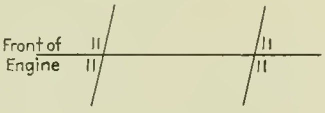

Fig. 9

In closing it may be well to call attention again to the first paragraph of this article. In order to obtain satisfactory results, the parts mentioned must be to all practical purposes perfect. Otherwise it might be possible to obtain correct readings on each valve stem separately and yet not have square valves on the locomotive.

The method of squaring valves explained above is also applicable to the Baker valve gear. It should be borne in mind that the factor used to determine the eccentric rod change always is a constant of four regardless of the valve travel and throw of the eccentric arm.

A Large Plant installed an electrical thermometer system to detect any increase in temperature in its coal pile, the pyrometer being in the engineer's office. Machinery further says:

"A temperature of 250 deg. F. was considered the safe internal temperature. Portable receptacles for thermo-couples were constructed of one-inch wrought iron pipe, welded to a point at the end entering the coal pile, and the exposed end was fitted with a self-closing cap. The switches in the engineer's office were numbered and lettered to correspond with these receptacles. The engineer was thus enabled to observe the temperature readings of the coal at the different points, and to detect dangerous increases of temperature."

The Effect of Relative Humidity on Leather Belting*

By F. W. Roys,
Worcester Polytechnic Institute

Any one who has ever had anything to do with leather belting knows that an ordinary oak tanned leather belt, not waterproofed or weather proofed, changes its characteristics considerably with the weather conditions, and it was because no information was available regarding these effects that experiments were undertaken, the conclusions from which are quoted.

All of the experiments were made on a single specimen of belting, and it will not be contended that the results are applicable, directly, to any other belt. However, it is assumed that if consistent results have been obtained for this particular sample, other belts of the same sort of material will show similar characteristics, the same in kind, if not in amount.

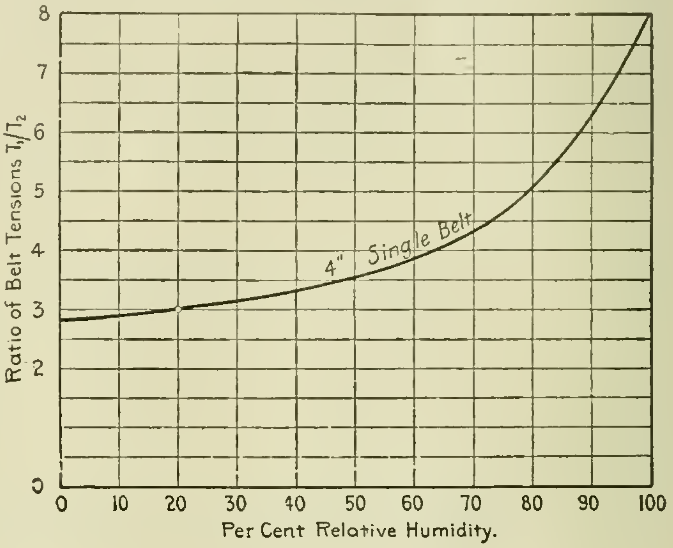

Fig. 1—Effect of Increasing Humidity; Horse Power Constant

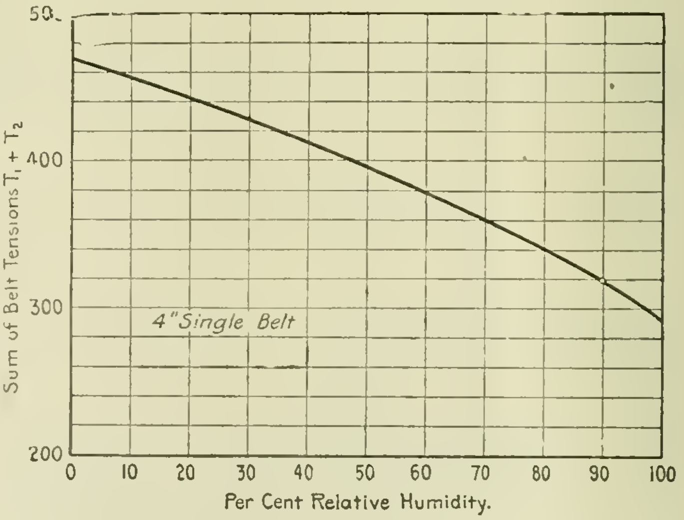

Fig. 2—Effect of Decreasing Humidity; Horse Power Constant

In a general way it may be stated that the effect of a change in the relative humidity is greater at high humidities than at low; that the effect is shown more rapidly in single

---

*From a paper read before the National Association of Leather Belting Manufacturers, November 17th, 1920.

than in double belts; that an increase in the humidity shows practically immediate results, while a decrease in the humidity takes a longer time to be effective.

Much more attention should be paid to the effect of the relative humidity than is ordinarily the case. Suppose that a plant engineer who is supposed to see that belts are kept tight and working at the proper tensions, pays no attention to the weather conditions, but has the belt tightened to a tension which he calls standard.

If such an adjustment was made when the relative humidity was 20 per cent and a subsequent change in the weather conditions produced a relative humidity of 90 per cent, while the power to be transmitted remained the same, the sum of the belt tensions $T_1 + T_2$ must decrease. Since the difference in tensions remains the same while the sum decreases, it is evident that the ratio T_1/T_2 must increase. Fig. 1 shows this variation quite clearly, and at the higher humidities this ratio reaches a value where the belt is in great danger of slipping.

On the other hand, suppose that the belt was set to standard conditions when the relative humidity was 90 per cent and subsequently the atmosphere dried. The belt would then become far too tight, not only working at too high a stress, but also producing excessive pressure on the bearings. Fig. 2 shows this effect very clearly.

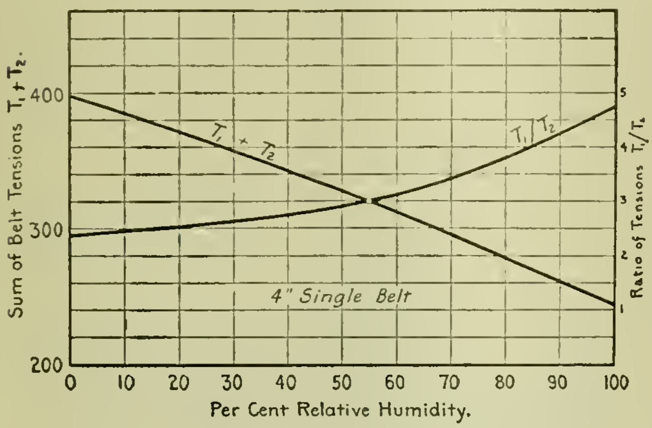

Fig. 3—Effect of Change of Humidity from 55 Per Cent; Horse Power Constant

If care were taken to allow for the effect of a change of the relative humidity, or if the adjustment were made when the humidity was 55 per cent, then no change of humidity that would occur would either tighten or slacken the belt in a degree that would be likely to give any trouble. Fig. 3 shows the effect on both the ratio and the sum of the tensions.

All of the preceding tests were made at a temperature of 70 deg. F., and it should be noted that the higher humidities are apt to occur at temperatures above 70 deg. F. and the lower humidities below 70 deg. F.

In conclusion, it may be stated that if a belt drive can be fitted with a spring or gravity tightener, so called, a load probably 50 per cent greater can be carried without danger of stretching the belt, slipping or excessive pressure on the bearings.

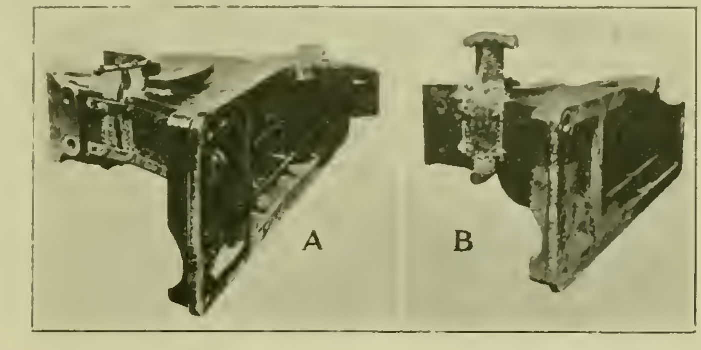
Casting Locomotive Frames in Small Units.—In order to overcome the difficulties of casting locomotive frames of unusual length and other long sections, the Metal & Thermit Corporation, New York, recommends that these be cast in shorter units and these units thermit welded together. By using this method small foundries can undertake the work. The number of parts to be welded will depend on the size of the foundry and available mold and pattern facilities.

An Air Compressor Repair

The connecting-rod of an air compressor, one of two units operated at the Erie Railroad shops, Susquehanna, Pa., for supplying air pressure to the pneumatic tools, recently snapped in two, causing one end of the rod to fly around into a wedged position and exerting such a strain on the machine that the hollow cast-iron back frame of the bed plate broke off.

The cross section of the hollow casting at the point of fracture measured about 8 in. by 6 in., the thickness of two opposite walls being 3 in. and the other two opposite walls only ⅞ in.

A new bed plate was ordered, but it was impossible to get it delivered in less than 60 days. As the idleness of this air compressor cut down the compressed air supply over all the shops 50 per cent, the operators decided to make a Thermit weld. In welding the casting, the bed plate was laid on its side and the broken sections were lined up by means of bolted straps, as shown at *A* in the illustration. These straps were left on and welded in with the metal comprising the weld. Three hundred pounds of cast-iron Thermit were used and the welded bed plate was returned to service. The appearance of the plate immediately after welding is shown at *B*.



Air Compressor Bed Plate Before and After Welding

Locomotive Cylinder Welding*

One of the most costly repair jobs on locomotives is replacing broken cylinders. A locomotive cylinder is a complicated core casting, weighing two or three tons, which requires careful fitting to the boiler, frame and opposing cylinder to insure alinement. If so badly cracked by any cause that replacement is required, the job involves not only a new cylinder but fitting in place, which work may keep the locomotive out of use for several weeks. Thus, the loss of service in a busy period may be a greater item than the actual cost of the new cylinder and the labor. Hence the importance of a process which enables a broken cylinder to be restored to service in the shortest possible time. This the railway shops have in oxy-acetylene welding.

A common cause of cylinder fracture is carelessness in closing the cylinder cocks and trapping water between the piston and the head. A slug of water is practically incompressible and when caught between the advancing piston and the head something must give way. Often the cylinder head is broken into fragments and the flanges ripped off. Breaking piston rods also wreck cylinders frequently. Another cause less frequent, but from which many locomotives suffer in cold weather, is freezing of water in the cylinders which crack by the expansion of the ice or are fractured when the attempt is made to move the locomotive. Head-on collisions add their quota of cylinder repair work.

The secrets of successful cylinder repair with the oxy-acetylene torch are proper preparation, preheating and slow

---

*Abstracted from the January, 1921, issue of Autogenous Welding.

cooling. There seems to be almost no limit to what can be done in restoring broken parts if care is taken to preheat to redness and to cool slowly when the job is finished. Even if the fracture is one that requires the cylinder to be removed in order to work the molten metal in a level position the saving is still substantial as the time needed for the welding and replacement is much less than that required to supply a new cylinder and to fit it in place.

In the course of cylinder welding, James Causey, cylinder repairman at the Wabash shops, Decatur, Ill., has developed a method of preheating which is a departure from the methods commonly used. Mr. Causey formerly followed the practice of building a firebrick wall around the cylinder to be welded, but in succeeding jobs such parts of the wall as could be dispensed with were removed. The result is, that at the present, no firebrick whatever is used for heat retaining. Asbestos paper extending entirely around the side walls or above the cylinder is employed instead. A large wire basket is placed below the cylinder to hold charcoal, and to the end of each cylinder, extending half way up, is bolted a thin plate to act as a retaining wall for the charcoal within the cylinder. The charcoal in the basket and cylinder are fired and more is added from time to time as it burns away until the desired degree of preheating is obtained. Then the cylinder plates are removed and the burning fuel hoed out. After the welds are made the plates are replaced and the charcoal is also added in quantities sufficient to retain the heat in the cylinder.

Driving Box Grooving Device

Grease grooves in driving boxes are ordinarily cored or chipped but there are disadvantages to either of these methods. Cored grooves may sometimes contain foreign matter which will cut the journal and, if not, the grooves may be greatly reduced in size or entirely eliminated due to wear and reboring of the boxes. Chipping, on the other hand, is an operation which requires considerable time and gives more or less unsatisfactory grooves due to irregularity and lack of sufficient depth.

A device for milling oil grooves in driving box crown bearings has been developed and used with considerable success for this work. A general view of the device is shown in Fig. 1, and details of construction in Fig. 2. Referring to Fig. 2, the device consists of a base plate *B* into which is firmly fastened the hollow vertical post *C* which has two large portions of its cylindrical surface cut away as shown. The moving part of the fixture consists of a right angle gear driving an end mill and guided by means of master plate *D* and control pin *E*.

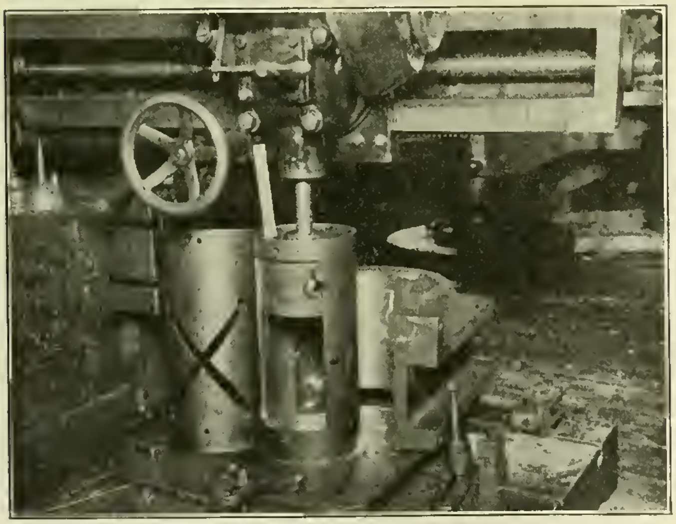


Fig. 1—Grooving Device with Master Plate Removed

In operation, the mechanism is clamped to the base of a radial drill which furnishes power to revolve the end mill *M* through the arbor *F*, bevel gears *G* and *H* and shaft *N*. Pinion *I* and gear *J*, arranged to mesh with rack *K*, control the feed of the tool in to the required depth. It is held at that depth by a ratchet arrangement on flange *L* (not shown). Since the end mill is guided entirely by the master plate, it is evident that grease grooves in any desired size of driving box can be milled by providing the necessary master plate. In setting up, the driving box is slid onto the base plate and clamped so that the axis of the grooving device coincides with the center of bore of the box.

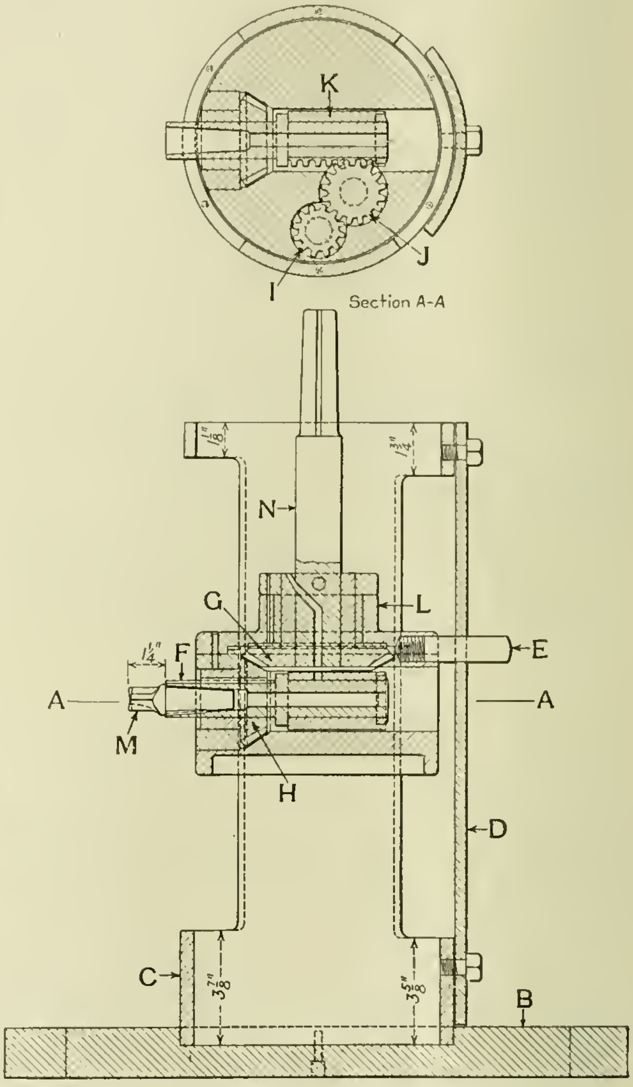

Fig. 2—Details of Driving Box Grooving Device

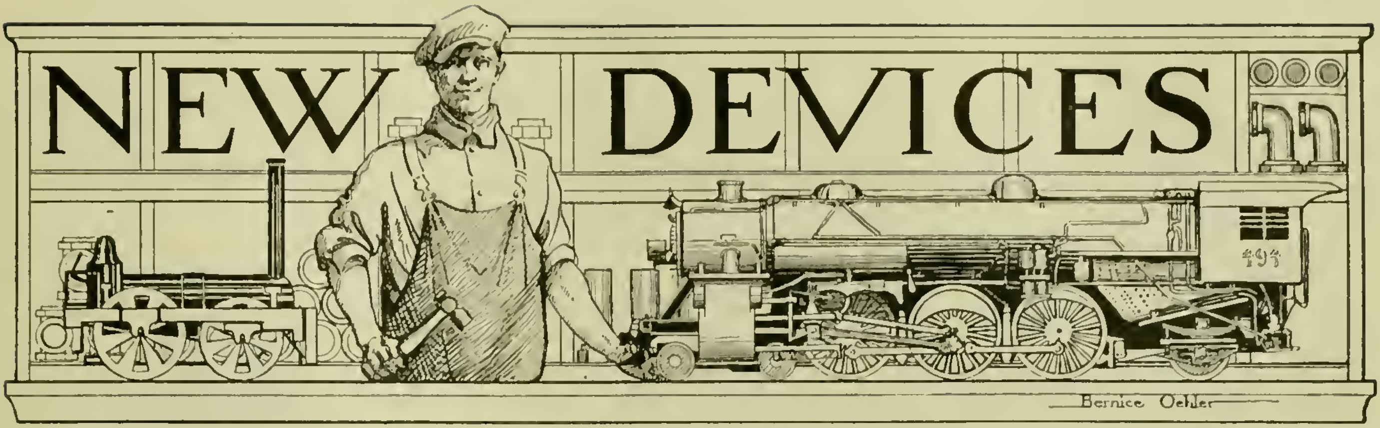
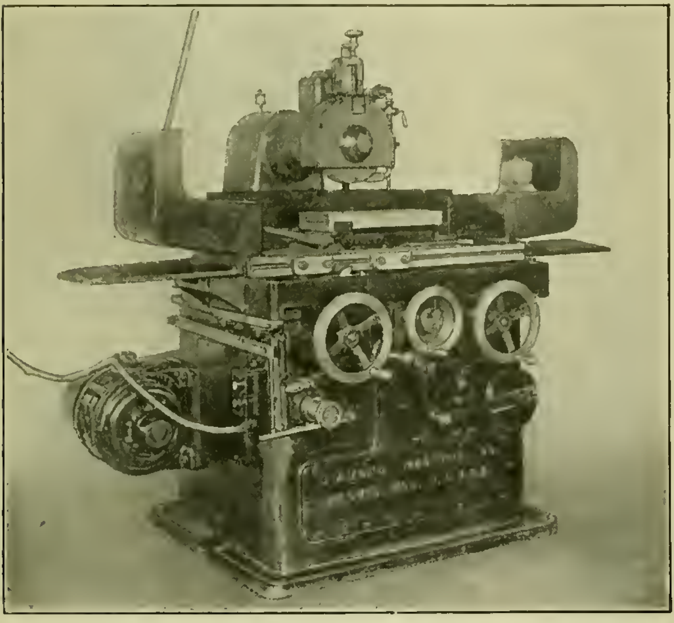
To summarize briefly, the device consists of a right angle gear box driving an end mill and guided by a master plate while the spindle of the drill is fed down. Starting at the top of the slot, the end mill is fed down, care being taken to guide it over the crossing of the slots. Then returning to the center, it is fed up and down to complete the diagonal slots.

The Allegation that railroad managers sent engines and cars for repair to outside shops in order to put "honest graft" into pockets of personal friends is proved by facts and figures to be totally false. If railway shop employees would do more work they would get more work.—*Forbes Magazine* (N. Y.)



Small High Duty Surface Grinder

RIGIDITY of construction and ability to remove metal quickly are features of the new Type C surface grinder, made by the Diamond Machine Company, Providence, R. I. Work 10 in. wide, 24 in. long and 8 in. high can be ground. One of the unusual features of this grinder is the casting of the wheel spindle head integral with the vertical column. The combined column and head rather than the head alone is adjusted up and down for different thicknesses of work. The mass of this large column added to that of the head itself is responsible for much of the improvement in the quality of the work produced.

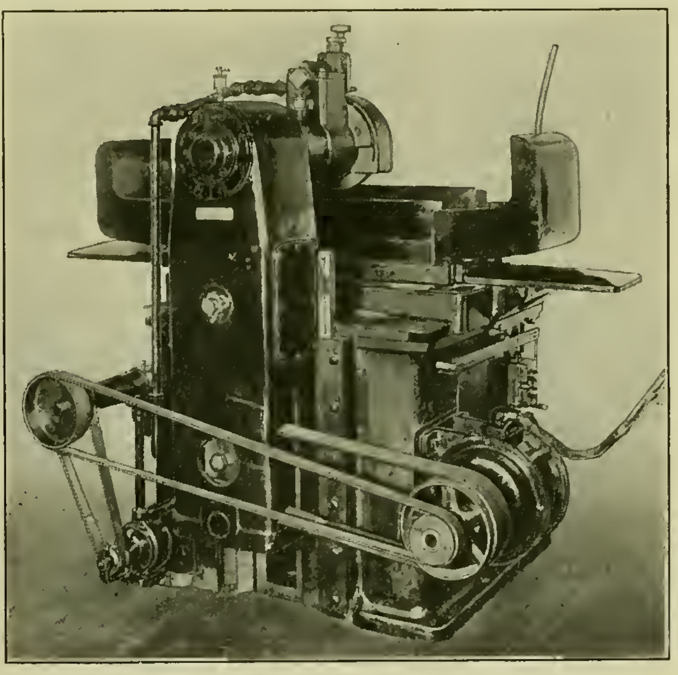


Diamond Type C High Duty Surface Grinder

Another feature closely connected with the above is the construction of the main spindle bearing nearer the grinding wheel. This is a composite ball and plain bearing which combines the advantages of both types without the defects of either. The rear end of the spindle is also provided with a ball bearing. The driving pulley is between the two spindle bearings and nearer the rear bearing so that any vibration of the driving belt cannot produce corresponding vibrations in the spindle itself. Moreover, the spindle between bearings is 2¼ in. in diameter so that flexure vibrations are avoided entirely.

The hand wheels for the three adjustments are arranged side by side at the top and front of the base and are placed symmetrically with reference to the center line of the machine. The left hand wheel for longitudinal travel moves the table about 2 in. per rev.; the center wheel moves the table transversely (in or out) .500 in. per rev., and the right hand wheel raises or lowers the wheel head (with column) .100 in. per rev. The outer edges of the rims of the two latter wheels have graduations for each thousandth of an inch so widely spaced that the operator can readily split the thousandths into tenths. Ball thrust bearings are used on both the horizontal and vertical adjusting screws. Careful arrangements of piping, guards and troughs assure an ample supply of coolant which stays where needed and does not spatter over the machine and floor.

The ways for all three directions of travel are completely covered by metal guards to prevent injury from abrasive dust or gritty water. Longitudinal travel of the table is accomplished by a train of belt driven gears and reversal is effected by a single shifting belt. A simple though novel device insures a complete shifting of the belt at each end of the stroke. A "stop trigger" is provided and a momentary pressure of the finger upon this trigger will stop the table at the completion of any stroke already begun. A clutch connected



Rear View of Grinder Showing Drive Arrangement

with the left hand wheel will stop the table instantly at intermediate points.

The transverse of "in and out" table feed is automatic and adjustable from .001 in. to .020 in. The feed takes place at both ends of the table travel and can be adjusted to move in either direction. There is an automatic stop for this feed which prevents overtravel and can be set to disengage at any desired point.

With the Type C grinder, the usual sliding toothed clutch for reversing has been eliminated which makes possible heavier cuts. A cut .234 in. deep and 1/16 in. wide, or a total cross section of .0150 sq. in., has been taken. It is stated that a pound of metal per minute can be removed with this machine. This high rate of cutting makes this grinder well adapted for production work on parts up to the maximum size that can be handled.

Regulating Valve for Liquid Fuels

THERE are many types of liquid fuels and each type is found in an almost indefinite number of grades, nor do these various grades run absolutely uniform. It is, therefore, necessary to use some sort of regulating valve which will compensate for the wide difference in liquid fuels and deliver to the burner a constant flow of fuel of varying viscosity and only in sufficient quantity to secure complete combustion. A valve designed for this purpose and known as the Rigby liquid fuel regulating valve has been placed on the market recently by Baily-Lewis, Inc., Pittsburgh, Pa. This valve has been tested and used with good success during the last two years at the Farrell Works of the Carnegie Steel Company.

As shown by the cross-sectional view, the fuel enters at the opening *12* and passes down through the stop-cock *3* into the trap *8*, where any sediment or heavy particles of fuel settle. The fuel then passes easily through the triangular opening in the valve seat *21* to the nozzle or burner.

The vital feature of the valve is the triangular aperture in the valve seat beveled back from the face and the sliding, shearing valve running in a groove cut in the face of the seat. A top view of the valve seat and triangular opening and a sectional view through the valve seat *20*, triangular opening *21* and valve are included in the illustration *4*. From these the manner in which the valve slides across the triangular opening, 1 in. long by ⅛ in. at its greatest width, will be apparent. This movement regulates the flow by opening and closing the aperture.

The area of a ⅛-in. orifice is .0123 sq. in., being approximately equivalent to a ½-in. needle valve open just 1/100 in. The impossibility of passing liquid fuel through a 1/100-in. opening is apparent. The superiority of the Rigby valve is due to the triangular shaped opening in the valve seat. This shaped orifice can have an opening of ½ in. against a 1/100-in. opening on a needle valve to give the same approximate orifice area, as shown in the table. Moreover, a needle valve has a wide seat which allows sediment or particles passing through the valve to impinge on the seat, thereby completely clogging the valve. The Rigby valve has its smallest aperture at the seat where the fuel enters the triangular opening and is beveled off as shown at *30*, so that when fuel passes through the aperture it must pass into the outlet for burning; it cannot stop as the beveled opening gives no opportunity for impingement.

TABLE OF AREAS OF RIGBY VALVE OPENINGS

Travel of Valve	Area
⅛-in.	.00097 sq. in.
¼-in.	.0039 sq. in.
⅜-in.	.0087 sq. in.
½-in.	.0156 sq. in.
⅝-in.	.0243 sq. in.
¾-in.	.0351 sq. in.
⅞-in.	.0477 sq. in.
1-in.	.0625 sq. in.

If sediment should lodge in the opening on the seat, it can be cleaned off by turning the handle of the valve *7*, thus closing the valve. The stem of the valve is threaded so that one complete turn of the handle moves the valve 1/16 in. This operation immediately shears off the particle of sediment and pushes that part above the seat into trap *8*, the balance of the particle immediately passing through the triangular opening when the valve is again opened. This operation can be accomplished in a few seconds and the valve can be reset to give the same opening.

The trap *8* can be cleaned in a few minutes without stopping the flow of fuel through the valve, by turning stop-cock *3* and removing the plug *9*.

The lock-nut arrangement makes it possible to set the valve for any required quantity of fuel necessary. It also provides a guarantee against waste of fuel. The installation of the valve from a safety point of view is highly important, as explosions due to leakage are almost an impossibility. It is stated that savings of five to 15 per cent are possible by using the Rigby regulating valve. The valve is manufactured in sizes suitable for various conditions, with two standard sizes; namely: type "A" with 1-in. valve travel; and type "B" with ½-in. travel.

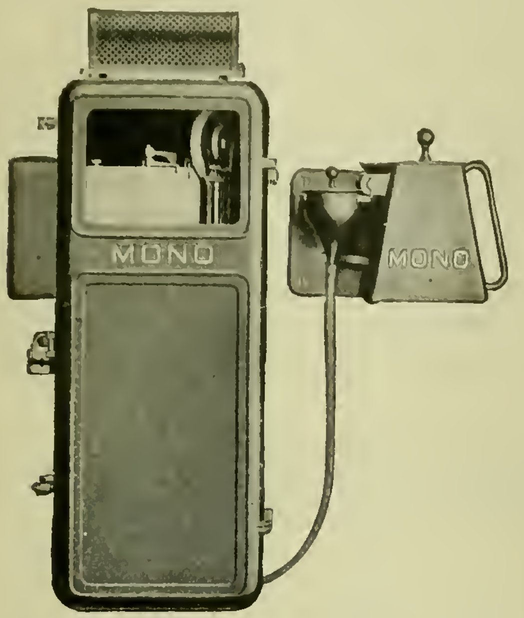
Details of Rigby Liquid Fuel Regulating Valve

Duplex Mono Flue Gas Analyzer

A new type of instrument designed to make automatic analyses of flue gases and to record both CO_2 and combustible gases has been developed by the Mono Corporation of America, Buffalo, N. Y. The instrument, which is known as the Duplex Mono Gas Analyzer, is intended to give a more reliable indication of the efficiency of combustion than can be obtained by the use of an instrument recording CO_2 alone. To show the necessity for greater refinement in flue gas analysis, it is pointed out that an increase of one per cent in the combustible gases may decrease the efficiency of combustion over six per cent. The percentage of CO_2 at which combustible gases begin to form, varies considerably from time to time, even in the same furnace. Occasional tests with hand instruments to determine the presence of CO do not give sufficient data to insure proper combustion conditions, and effective combustion control can be established only by continuously recording the percentage of CO_2 as an indicator of the amount of excess air present and also detecting and recording the presence of combustible gases, either CO, CH_4 or H_2.



Automatic Analyzer for Recording CO_2 and Combustible Gases

The Duplex Mono is designed to detect the presence of combustible gases in the flues immediately upon their appearance and to record accurately the percentage of CO_2 at that particular time. The chart shown herewith is a diagram made by one of these double recording instruments. The lower contour of the diagram represents the percentages of CO_2 present at all times. The lighter areas indicate the presence of combustible gases. The height of the lighter areas indicates roughly the proportion of combustible gases present, but is not intended as a measure of the actual percentage and is on a larger scale than the CO_2 record.

The apparatus which is shown in the illustration is driven by water pressure of about 10 lb. per sq. in. Before entering the instrument, the gas samples from the flue are pulled through a filtering system, which removes all soot and dirt. They are then drawn into and forced through the apparatus by a mercury piston. There are no mechanical valves, such functions as these ordinarily fulfil being performed by various kinds of mercury seals, traps and similar arrangements.

Samples of gas are forced alternately through two routes, one leading directly through a caustic potash tank where CO_2 is absorbed, and the other first through an electrically heated furnace wherein the combustible gases are oxidized to CO_2 and H_2O, and then through the caustic potash tank. Samples that are forced through the caustic potash tank only give the readings for CO_2. Those that are first forced through the electrically heated furnace and then through the caustic potash tank give readings of CO_2 plus combustible gases. The difference between any two successive readings is proportional to the amount of the combustible gases present at the time the analyses are made.

In the electrically heated furnace, the oxygen necessary to oxidize the combustible gases, CO, CH_4, and H_2 to form CO_2 (which is later absorbed in the caustic potash tank) and water (which is condensed) is usually taken from the air which is almost invariably present in flue gases, even when combustible gases are present. When such free oxygen is not available, oxygen is taken from copper oxide provided in the furnace for that purpose. The copper oxide, however, probably seldom acts as anything but a catalytic agent and need never be renewed.

Should any of the copper oxide be reduced to plain copper to oxidize combustible gases in the process of analysis, it is reoxidized by oxygen present in the flue gas samples passing through the electric furnace later.

To diminish the lag between the time when the gas leaves the flue and the analysis is recorded on the chart, small communicating tubes are used. The lag between the time that the sample is taken from the flue to the time that it is recorded by the instrument is about three minutes where the distance between the instrument and the point where the flue is tapped is about 60 ft. and the instrument is making about 40 analyses per hour.

These instruments are made to produce records covering a range of either 20, 25 or 40 per cent, according to the purpose for which they are intended. The apparatus is practically dustproof and requires only a slight amount of attention, which consists in winding the clock once a week, replacing the caustic potash solution two or three times a month, replenishing the ink supply twice a month, and putting in new rolls of recording paper once every two months.

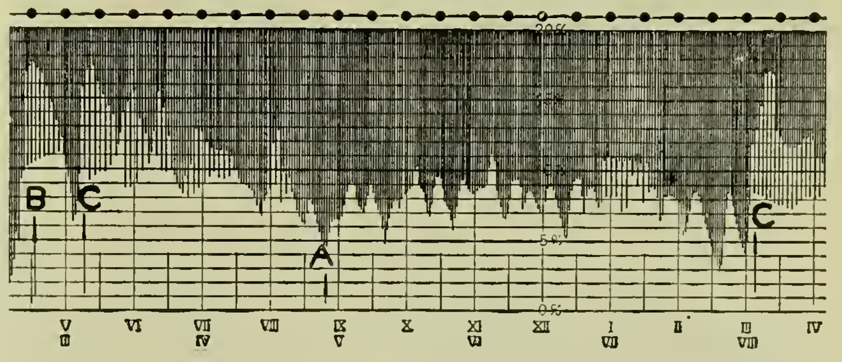


Chart from Duplex Mono Analyzer Indicating Presence of Combustible Gases

The readings indicating the presence of combustible gases are exaggerated, if anything, by the Duplex Mono. This is quite an advantage in a danger signal. The losses due to the appearance of combustible gases are much greater than the savings due to an equivalent increase in CO_2 as registered on the chart, and an exaggerated record of their presence on the chart has a favorable effect on the fireman. Since it is aimed never to have combustible gases present at any time, there would be no object in having exact records of the percentage present when they do appear. An approximate, and preferably an exaggerated record, as made by this instrument, is all that is necessary. The CO_2 records of the machine are invariably accurate.

The utmost efficiency of combustion is attained with the highest percentage of CO_2 that can be reached in a given furnace without having combustible gases begin to appear. The higher it can be raised, the more economical is the process of combustion. Knowing its maximum from the records of the instrument, the fireman can always tell the degree to which he is approaching ideal conditions. Should combustible gases appear at a point below the critical point, he knows that his dampers, fire doors, or the fire itself needs immediate attention, which experience soon teaches him to give to the best advantage. The record is equally valuable for the plant executive.

Safety Locomotive Cold Water Sprinkler

ONE positive advantage and three negative advantages are claimed for the locomotive cold water sprinkler, recently invented by George Dittman, roundhouse foreman of the Pittsburgh & Lake Erie, at McKee's Rocks, and placed on the market by the McKee Company, Pittsburgh, Pa. An abundant supply of water at a usable temperature is provided and the device will not discharge steam or hot water, cannot freeze and will not interfere with any other device on the locomotive.

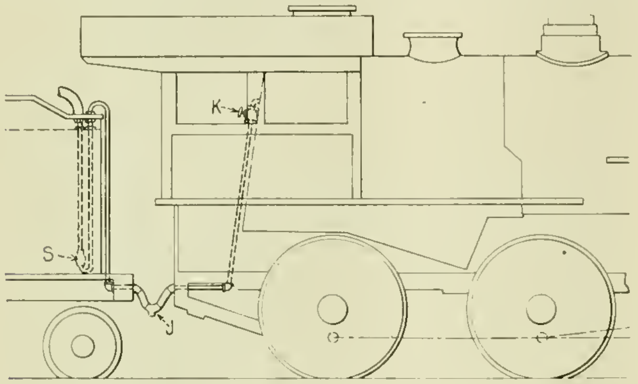

Fig. 1—General Arrangement of Dittman Cold Water Sprinkler

The general arrangement of the sprinkler on a locomotive and tender is shown in Fig. 1, which indicates the ease of applying or removing it without draining the tank. Referring to Fig. 1, *K* is the steam control valve, *J* the automatic drain fittings and *S* the sprinkler valve proper. Valve *S* is shown more in detail at *A*, Fig. 2. When the operating valve is open, steam passes through the piping to the underside of the sprinkler valve, expanding through the nozzle and drawing water through the small holes indicated. Part of the velocity of the steam is imparted to the water which is delivered in a continuous stream to the sprinkler hose. The location of the valve in the bottom of the tank assures an ample supply of cold water and eliminates danger of discharging steam or hot water and scalding the fireman.

The automatic bronze drain valve shown at *B*, Fig. 2, is placed at the lowest point in the steam supply pipe or hose and, as shown in the illustration, remains open except when steam pressure is applied, thus preventing freezing.

The application of the Dittman cold water sprinkler is easily made. A hole 1¾ in. by 3½ in. is cut in the top of the tank at a convenient point; two ⅝ in. bolt holes, spaced 5 in. on centers, being drilled to receive the studs. Referring to *A*, Fig. 2, a return bend is made in a piece of ⅜ in. pipe long enough to reach to the bottom of the tank. The sprinkler valve and cover plate are applied as shown with the return bend secured to the cover plate by lock nuts at the top and bottom. Application of the studs holds the device firmly in place. The installation is completed by applying a steam valve *K* at a convenient point on the back head and inserting the drain valve at the lowest point in the connecting piping.

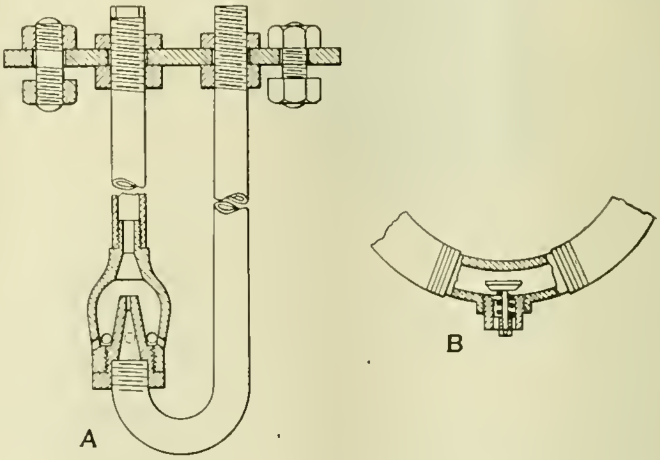

Fig. 2—Details of Sprinkler and Drain Valve

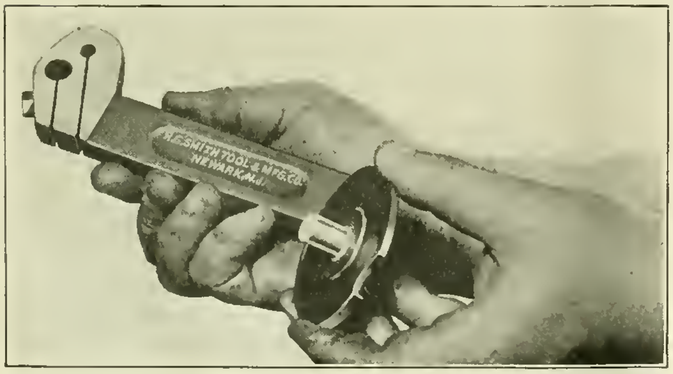
A Long Life Cutting-Off Tool



Cutting-Off Tool With Long Cutting Circumference

A NOVEL cutting-off tool with a cutting circumference of over 300 deg. has been developed by the R. G. Smith Tool and Manufacturing Company, Newark, N. J. This cutting-off tool, as shown in the illustration, is made so that clearance is maintained throughout the entire cutting circumference by gradually tapering down the thickness of the cutting edge. This gives the tool ample side clearance rake, the other clearance being secured by grinding when sharpening.

This tool is used in the patented Smith tool holder, being held firmly in place by tightening up the set screw shown with a small hexagonal wrench. On account of the ease of sharpening and long life of this cutting-off tool, it is adaptable to use in automatic screw machines and turret lathes, as well as in hand lathes.

Centrifugal Pump for Cooling Compounds

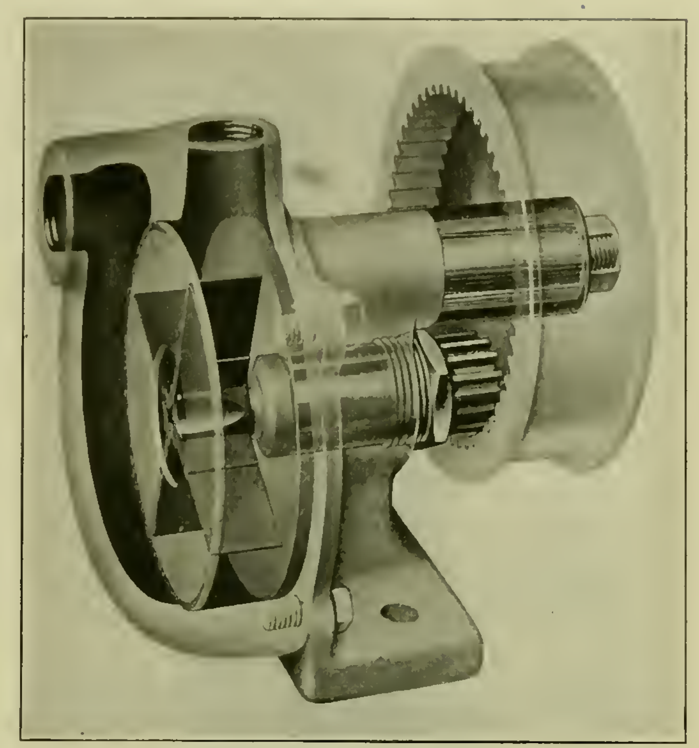
FOR delivering oil or water to drill presses, lathes, tapping machines, centering machines, screw machines, etc., whether the machines are running forward or in reverse, a two-way centrifugal pump, as illustrated, has been developed by the Ross Manufacturing Company, Cleveland, Ohio.

The Ross pump is designed to deliver a flow of liquid from the same outlet regardless of the direction of rotation of the impeller blades and from this ability to reverse instantly comes the name "two-way" pump. With machines which run in both directions such as screw machines, the pump must work in two ways, otherwise the machine will be without cooling compound when running in one direction. Where a battery of machines is cared for by a single pump, a reservoir is placed in the main distributing line with an overflow, thereby providing gravity feed for normal use, and where pressure is required the overflow is plugged.

The Ross pump is light, compact and neat, and is said to give a large and constant volume of any liquid, bringing the stream to the work without pressure. If pressure is required, however, the outlet nozzle is reduced in size and the pump speeded up. No priming is needed after the first time.

The pump is constructed with oilless bearings and graphite-asbestos packing and no bearings or gears come in contact with the cooling compound. This feature is important as steel chips are bound to mix with the compound and the bearings or gears cannot be expected to last long with steel chips being constantly ground through them.

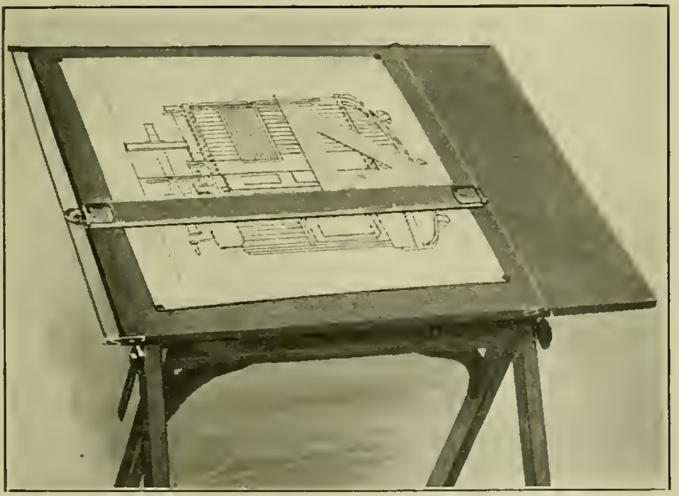
The impeller is composed of four light pieces of vanadium spring steel and the design is such that there is no end thrust. The pump can be mounted with the base in any one of four positions and is assembled with four hexagon-head cap screws, which simplifies disassembling. The gear ratio is four to one, giving a high impelled speed when belted to a slow pulley.



Ross Two-Way Centrifugal Pump

Precise Parallel Ruling Attachment

MANY advantageous features are combined in the parallel ruling attachment developed recently by the New York Blue Print Paper Company, New York. This device may be applied to any drawing board, large or small, and there are no cords or wires on the surface of the board to interfere with the work. In addition, all cords on the under side of the board are eliminated and metal parts are so designed that the drawing board can rest on a table or other piece of furniture and be moved from place to place without scratching the surface.



Precise Parallel Ruling Attachment

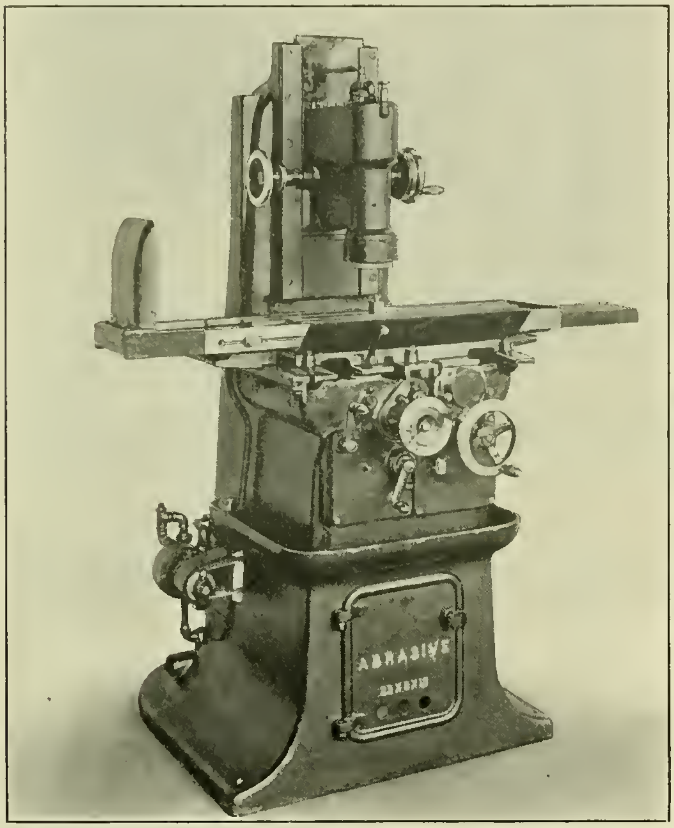
All metal parts of the attachment are made of aluminum and will not rust. Two plates are provided, one with a double pulley and the other with two small pulleys, to be applied to the ends of the straight edge. Four metal brackets are applied to the corners of the drawing board and a small metal grip is provided to hold the cord which guides the straight edge firmly.

The straight edge may be of any length desired, regardless of the size of the board, as shown in the illustration. In this case, tools, ink, etc., may be placed on the board at the right of the attachment without interfering with its operation. The double pulley acts as a T-square head since it is provided with a shoulder for that purpose and the cords running parallel are hidden in the straight edge. The pulleys are firmly and accurately attached to the straight edge and are given a careful test at the factory before shipment to insure perfect alinement.

An additional advantage of the Precise parallel ruling attachment lies in the fact that the straight edge can be simply and quickly adjusted to any angle desired. The attachment is stated to be accurate in every detail, convenient to manipulate and an efficient device for drawing room work. It is furnished complete in lengths varying from 24 to 60 in. and can be fitted with straight edges having crystalloid transparent lined, mahogany lined, and hardwood lined edges for various classes of work.

Vertical Spindle Surface Grinding Machine

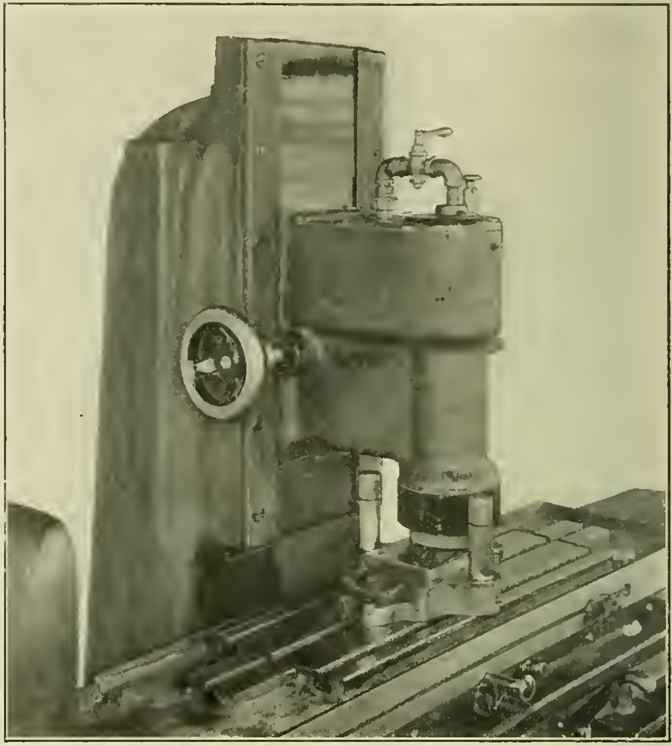
For several years there has been a demand for a small but sensitive vertical spindle surface grinding machine, not only for tool room use but for certain classes of production work, as for instance the squaring of shaft ends on centres, surfacing of small pieces held by magnetic chucks and re-sharpening pilot dies. Heretofore, the grinding of pilot dies has necessitated the use of a much larger machine of the horizontal spindle type in order to secure the large wheel diameter required to clear the pilots. By using the cupped wheel the cutting edges of the die are left sharp, whereas, with the disc style of wheel these edges are more or less "dubbed" over. The grinding time is also materially reduced.



Sensitive Vertical Spindle Surface Grinder

The machine illustrated has a capacity of 22 in. longitudinal feed, 8 in. transverse feed, both automatic, and 10 in. hand vertical adjustment. The wheel spindle is massive and carried on radio-thrust ball bearings. All of the high speed shafts are likewise carried on ball bearings. Wheels up to 5 in. in diameter can be used.

The adjustment of the wheel head is by means of a screw which is actuated by a worm and wheel. Two hand wheels are provided, one for fine feed being graduated to .00025 in. and one for rapid movements having an acceleration of 3 to 1. The gear case for the operating table and cross feed is a self-contained unit in which the gears and clutches run in a bath of oil.



Grinder Used for Sharpening Pilot Die

All belts are enclosed, also all dangerous moving parts, so that the safety of the operator is assured. All bearings are carefully guarded against the admission of dust or water. The machine, which is made by the Abrasive Machine Tool Company, East Providence, R. I., can be equipped with countershaft or concealed motor drive. Ample provision is made for use of water or a cooling compound.

Pilot Bar and Drill Press Chucks

The pilot bar type of chuck illustrated, which was developed recently by the Frontier Chuck & Tool Company, Inc., Buffalo, N. Y., was especially designed for work requiring piloted tools. Referring to Fig. 1, it will be seen that the air cylinder and the chuck are one complete unit and that the air source is at the back of the outer tube, the air being piped through the spindle of the machine on which the chuck is mounted. A revolving air box on the rear end of the spindle makes an ideal connection to the air valve. A tube is screwed into the piston which allows a pilot bar of any desired length to enter without interfering with any other part of the chuck.

Wedge spindles of the circular type and with flat inclined surfaces, which rest against the ends of the levers are held in place but free to revolve on the face of the piston by special nuts. The wedges, one for each jaw, rest against a similarly tapered surface on the end of the lever that is pivoted at the opposite end and pinned to a jaw at the center. Therefore, when the air is admitted to the cylinder the piston and the wedge spindles are forced forward, causing the levers to swivel on their fulcrums and bringing the jaws toward the center of the chuck. When the air is turned off, springs force the piston and jaws back to their original positions. It will be noted that the pilot bar is guided by the pilot bushing which is screwed into the face of this chuck and that the outer pilot tube has no movement whatever.

The drill press chuck, shown in Fig. 2, was developed for application on drilling machines and other machines where the chuck does not revolve. The chuck is provided with holes for bolting to the table of the machine. Its operation is similar to that previously described with the exception that the air is admitted at one side of the cylinder instead of the back. Due to the opening running clear through the center, danger of chips working into the operating mechanism is eliminated. Also, the base is raised on four legs about one inch high which allows the operator to rake out any chips that might accumulate by falling through the opening in the center. Both chucks are made with either two or three jaws, manufacturing or adjustable type, and in sizes, 10 in., 12 in., 15 in. and 18 in.

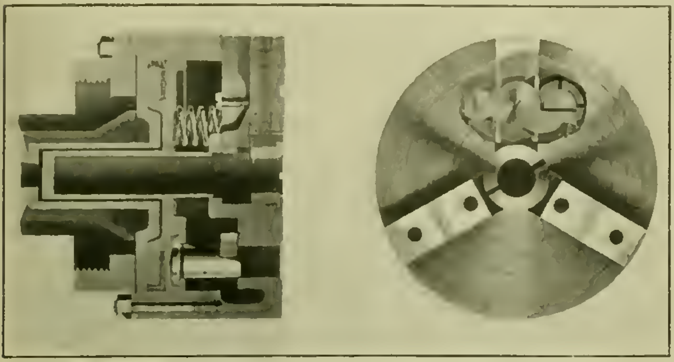


Fig. 1—Lavoie Pilot Bar Pneumatic Chuck

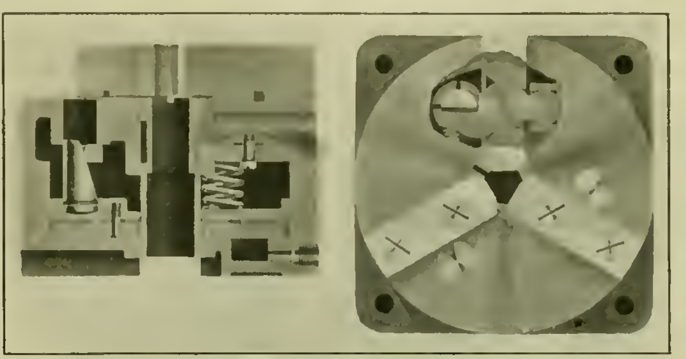

Fig. 2—Pneumatic Chuck Used on Drilling Machines

Die Heads for Railroad Shop Use

ALTHOUGH on the general market for several years, it is only recently that H & G automatic self-opening die heads, manufactured by the Eastern Machine Screw Corporation, New Haven, Conn., have been introduced for use in railroad machine shops. The range of sizes of die heads has been extended to cover the requirements of this work and two styles are provided designed to handle almost any threading job in the railroad field. Style *A*, a phantom view of which is shown in Fig. 1, is of the rotating type for use on automatic screw machines and bolt threaders. Style *C*, illustrated in Fig. 2, is of the stationary type for use on turret lathes, hand screw machines, etc.

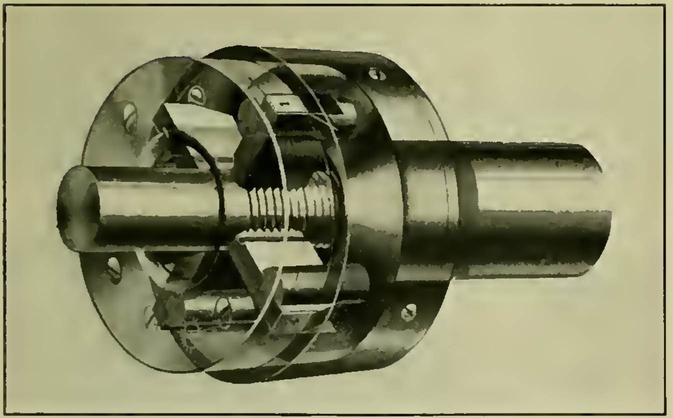

Fig. 1—Phantom View of Style A, H & G Die Head for Use on Automatics

The working parts of the die head are plainly illustrated and the same general working principle applies to both styles. The chasers slide in slots that are accurately ground and fitted. Sliding cams hold the chasers rigidly to the exact diameter desired and practically eliminate the possibility of faulty threads. In the design of these die heads every effort has been made to secure a high degree of workmanship, assuring parallelism and accuracy of leads in all threads cut.

All parts of the die heads are hardened, thus providing increased strength and greater wearing qualities. The heads are easily adjusted to accurate dimensions and each size will cut threads of various diameters and pitches with a change of chasers. The style *A* H & G die head is made in nine sizes for cutting threads up to 3 in. in diameter and the style *C* is made in six sizes for cutting threads up to the same size. Style *CC* is a special model made for Cleveland automatic screw machines and can be furnished in three sizes, having a maximum capacity of 1½ in.

Referring to the phantom view, the chasers are operated by cams having a positive bearing directly over the cutting edge. There are no springs used in closing the head. The cams are solidly supported by the body and the entire construction is characterized by simplicity. The chasers are hobbed, causing the threads to run true to leads and micrometer measurements. The chasers are made from specially selected high speed tool steel hardened to assure toughness, durability and long life. The chasers are interchangeable and may be used in any H & G die head of the same size, irrespective of style or date of manufacture. This feature allows a large number of sets to be carried in stock ready for prompt shipment.

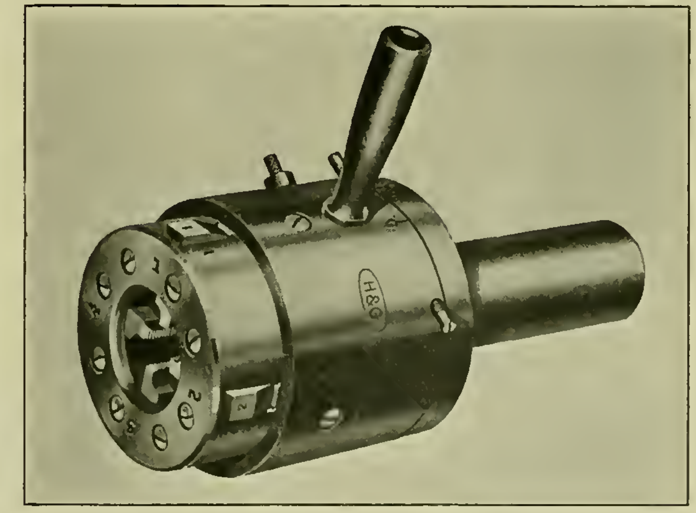

Fig. 2—Style C Die Head for Use on Turret Lathes, Hand Screw Machines, Etc.

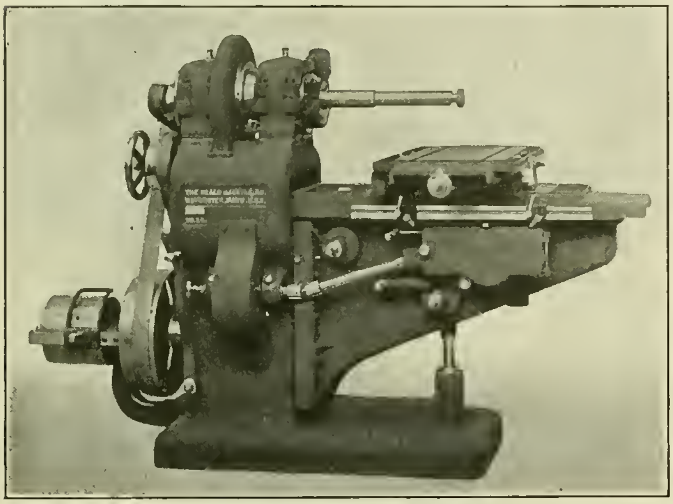
Self-Contained Internal Grinder

THE Heald Machine Company, Worcester, Mass., has developed recently a new cylinder grinder known as style No. 55, for the re-grinding of cylinders and other internal grinding repair work. This machine differs from the Heald style 60 machine commonly used in railroad repair shops by the elimination of certain speed boxes and other expensive units. These are replaced by a drive from a single shaft on the rear of the machine. The machine is self-contained and a countershaft therefore is unnecessary. This is also an advantage since the machine may be belted directly from the main line drive and no time is required in setting up a countershaft.



Heald No. 55 Internal Grinder

In addition to simplifying the style 60 grinder, the new machine is provided with increased width for the knee and main table so that when grinding the extreme hole at either end in the larger castings, there is no undue overhang on either side. Also, the distance between the center line of the grinding spindle and the top of the cross slide table has been increased. On the style 60 machine, this dimension ranged from 4¼ in. to 7½ in. and on the style 55 machine, 7 in. is the minimum and 9½ in. the maximum. This feature is especially convenient when the machine is used for grinding holes in large castings, as is often necessary in railway shop work.

The eccentric and spindle arrangement on the style 55 machine is the same as on the style 60. As regular equipment, an arm is provided which grinds holes 2⅜ in. in diameter and over by 11 in. long; also holes 3 in. in diameter and over by 18 in. long. This arm is particularly desirable for certain classes of repair work and may be furnished in other sizes if desired. The advantages of the new style 55 Heald grinder may be summed up in the facts that it is self-contained, comparatively simple in construction and possesses a larger range and greater capacity than the style 60 machine. All of these advantages are particularly valuable for miscellaneous internal grinding work.

A Handy Forge for Heating Rivets

A LIGHT weight, portable rivet heating forge, which is stated to be economical and efficient in operation, has been placed on the market recently by the Norton Manufacturing Company, Boston, Mass. The forge may be readily moved from place to place by means of two folding handles. Two hooks are provided, as shown in the illustration, in case it should be desired to lift the forge by means of a crane to a scaffolding or other point adjacent to the work.

Reference to the illustration shows that the spent gases are vented through an opening in the top of the forge and pass upward away from the operator. This eliminates the necessity for the customary air curtain and is said to save in the neighborhood of 8 to 20 cu. ft. of compressed air per min. Rivets are manipulated through the top opening without discomfort to the operator and are always in plain view. No direct blast touches the rivets which are, therefore, subject to minimum oxidation. The forge may be regulated to provide only a mild soaking heat or the flame may be adjusted to keep rivets at a white heat.

A valuable safety feature results from the fact that no air pressure is required in the oil tank of this forge. A special vacuum burner is used which draws the oil from the tank, thus preventing leakage from all pipes and fittings due to pressure. The burner is simple in construction and operation, so designed as to burn low grade fuel oil or kerosene with an accurately controlled temperature. Standard fire brick are used in the forge and, therefore, it may be relined quickly and at a minimum of expense.

Starting with a cold forge, it is possible to heat rivets white hot in five minutes. The No. 2 Norton forge, illustrated, weighs 190 lb. and is 24 in. in height. It has a capacity to heat 350 ¾ in. by 3 in. rivets per hour. The oil tank has a capacity of 10 gal. In operation this forge is said to have shown an oil consumption of less than one gallon per hour and an air consumption of less than 4½ cu. ft. per min. On account of the fact that rivet forges are operated almost continuously, it is important that they should be economical in the use of fuel and air.

No. 2 Norton Rivet Heating Forge

Radial Drill Stand and Removable Drill

FOR bench drilling operations, particularly in railway tool rooms, the Hisey-Wolf Machine Company, Cincinnati, Ohio, has recently developed a tool which will be of special value. As shown in Fig. 1, the standard Hisey-Wolf portable drill of 1¼ in. capacity, which may be furnished in either the single or two-speed type, is mounted in a special head attached to a radial drill stand. The drill is held firmly in place by suitable clamps and is capable of adjustments, vertically and horizontally, as shown in the illustration. In addition, the drill holding head may be tilted at an angle with the base of the stand by means of the small hand wheel shown. A graduated collar facilitates setting the drill at any required angle. After necessary adjustments are made, the drill may be clamped firmly in the desired position and operation of a trigger starts the motor.

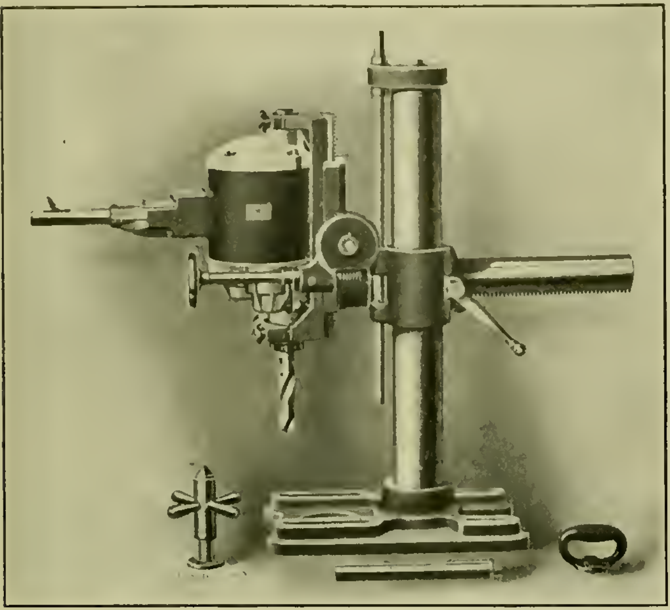


Fig. 1—Hisey-Wolf No. 3 Radial Drill Stand

The portable drill removed from the stand is shown in Fig. 2. It is evident that the field of usefulness of this drill is greatly increased since it may be used either as a portable or radial drill. Suitable slots provided in the base of the drill stand may be used to bolt it to a bench or table as desired. Dimensions of the No. 3 radial drill stand correspond to types "NM" and "NNA" radial drills manufactured by this company. When the No. 3 radial drill stand is ordered separately, the full name plate markings of the make of the machine, for which the drill stand is wanted, should be given.

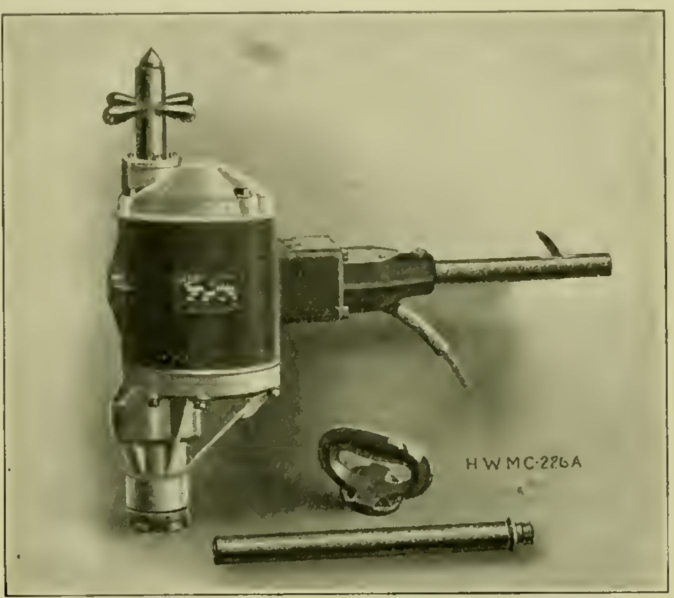

Fig. 2—Portable Drill Before Application to Stand

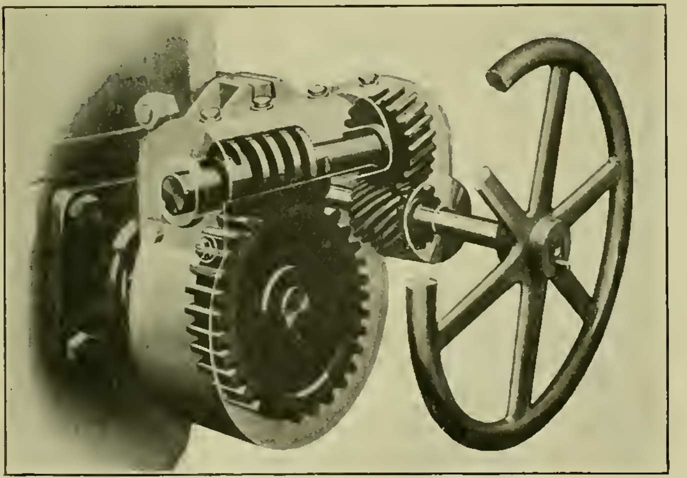
Helical Worm-Geared Crane Ladle

THE distinguishing feature of a new ladle designed by the Whiting Corporation, Harvey, Ill., is the fact that the gearing is mounted on the trunnion instead of on the bail. Consequently any distortion of the bail or bowl will not interfere with the alinement of the gears. The manner in which the gear bracket engages the bail is clearly shown in the illustration. A further advantage of this arrangement is that the gear alinement is not affected by wear on the trunnion journals.



Whiting Crane Ladle Tilting Mechanism

This gear combination, as illustrated in the phantom view, has the self-locking feature of worm gearing but by virtue of the balanced thrust obtained through the helical gears and the efficiency of the gearing being much higher than that of the ordinary worm gearing, the power required to rotate the ladle is considerably less. The helical gear on the hand wheel shaft meshes with a helical gear on the worm shaft. The work shaft is placed at an angle so that the worm will properly mesh with the large straight-toothed gear keyed to the trunnion. The latter gear is of cast steel; the worm and helical gears being made of forged steel. All gears have machine cut teeth. The construction of the gear case is such that it will accommodate several different ratios of helical gears, depending on the speed desired.

This new style of gearing is completely enclosed in a dust proof cover, yet is readily accessible for inspection. Small oil cups with spring caps provide ample lubrication. Crane ladles of this type are made in various sizes for both iron and steel.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

Subscriptions, including the eight daily editions of the Railway Age, published in June, in connection with the annual convention of the American Railway Association, Mechanical Division, payable in advance and postage free: United States, Canada and Mexico, $4.00 a year; elsewhere $5.00, or £1 5s. 0d a year. Foreign subscriptions may be paid through our London office, 34 Victoria street, S. W. 1., in £ s. d. Single copy, 35 cents.

WE GUARANTEE, that of this issue 10,500 copies were printed; that of these 10,500 copies, 9,460 were mailed to regular paid subscribers, 9 were provided for counter and news company sales, 266 were mailed to advertisers, 32 were mailed to employees and correspondents, and 733 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 31,000, an average of 10.333 copies a week.

The *Railway Mechanical Engineer* is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.).

The piece-work system has been restored in two departments of the foundry of the Pennsylvania Railroad at Altoona—the cleaning room and the wheel foundry.

The Landis Tool Company, Waynesboro, Pa., has announced its intention of reducing prices, commencing March 1, 1921, on all machines, with the exception of crankshaft grinding machines. The reduction on other types will average 15 to 20 per cent.

By a fire at the Pullman repair works at one hundred and eighth street and Langley avenue, Chicago, on the morning of January 27, a freight car shop was destroyed at a loss of about $450,000. Seven new refrigerator cars and 12 Pullman sleepers were also destroyed. The fire was the result of spontaneous combustion in one of the tool rooms.

W. J. Tollerton, general mechanical superintendent of the Chicago, Rock Island & Pacific, and chairman of the Mechanical Division of the American Railway Association, has been designated as American reporter to the International Railway Congress to be held at Rome, Italy, in April, 1922, on question No. VII—Passenger Carriages.

The United States Civil Service Commission announces an open competitive examination for senior mechanical engineers, Grade 1, salaries $3,000 to $5,000. A vacancy in the Bureau of Locomotive Inspection and vacancies in positions requiring similar qualifications at salaries ranging from $3,000 to $5,000, will be filled from this examination. Applications should be made on Forms 1312, which must be filed with the Civil Service Commission, Washington, D. C., not later than March 29.

Sir Robert Hadfield, inventor of manganese steel and a leader in the British steel industry, has been awarded the John Fritz gold medal for notable scientific and industrial achievement. Manganese steel, non-magnetic, was used in the manufacture of millions of helmets worn during the war by American, British and Belgian soldiers. Award of the medal was voted unanimously by the sixteen members of the committee representing the American organizations of civil, mechanical, mining, metallurgical and electrical engineers.

Freight Cars

The Delaware, Lackawanna & Western has ordered 40 caboose cars from the Mt. Vernon Car Manufacturing Company.

The Louisville & Nashville has ordered 1,500 box cars, and 100 40-ton stock cars from the American Car & Foundry Company; 500 box cars from the Mt. Vernon Car Manufacturing Company; 300 40-ton coke cars, and 300 55-ton gondola cars from the Chickasaw Shipbuilding Company.

Shop Construction

ATCHISON, TOPEKA & SANTA FE.—This company has awarded a contract for the construction of a one-story brick addition to its machine shop at Argentine, Kan., to Jerome Moss, Chicago, at an approximate cost of $45,000. The dimensions of the addition will be 102 feet by 115 feet, and the improvements to be undertaken include the construction of an office, tool room, engine pits and drop pits.

A. R. A. Names Executive Committee

The secretary of the American Railway Association, J. E. Fairbanks, has announced the personnel of the executive committee for the calendar year 1921 as follows: Division I, Operating, General W. W. Atterbury; Division II, Transportation, E. J. Pearson; Division III, Traffic, C. H. Markham; Division IV, Engineering, H. G. Kelley; Division V, Mechanical, W. B. Storey; Division VI, Purchasing and Stores, W. G. Besler; Division VII, Freight Claims, N. D. Maher.

Safety Appliances for Cars of Special Construction

The Interstate Commerce Commission at a conference held on December 6 adopted the following ruling regarding the application of safety appliances on cars of special construction:

Cars of special construction, as contemplated by the commission's order of March 13, 1911, are cars which cannot be equipped with safety appliances as prescribed in the order for any specified classes enumerated therein. In the construction of new equipment which does not conform to the specified classes designated in the order, plans shall be submitted to the commission prior to construction of such cars for the purpose of determining the location and application thereto of all safety appliances required by statute and the order of the commission of March 13, 1911.

Research Graduate Assistantships at the University of Illinois

To assist in the conduct of engineering research and to extend and strengthen the field of its graduate work in engineering, the University of Illinois maintains fourteen Research Graduate Assistantships in the Engineering Experiment Station. Two other such assistantships have been established under the patronage of the Illinois Gas Association. Each assistantship carries an annual stipend of $600 and freedom from all fees except the matriculation and diploma fees. There will be thirteen vacancies in addition to two in gas engineering to be filled at the close of the current academic year. The positions are open to graduates of approved American and foreign universities and technical schools who are prepared to undertake graduate study in engineering, physics, or applied chemistry. Nominations are made from applications received by the director of the Engineering Experiment Station each year not later than the first day of March and become effective the first day of the following September. Additional information may be obtained from the director of the Engineering Experiment Station, University of Illinois, Urbana, Ill.

MEETINGS AND CONVENTIONS

American Society of Mechanical Engineers.—The spring meeting of the American Society of Mechanical Engineers will be held at the Congress Hotel, Chicago, May 23 to 26. Sessions are planned by the professional sections on aeronautics, fuel, management, material handling, machine shop, power, forest products and railroads, the details of which will be made public later.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations and railroad clubs:

Air-Brake Association.—F. M. Nellis, Room 3014, 165 Broadway, New York City. Annual convention May 3 to 6 inclusive, Hotel Sherman, Chicago.

American Railway Association, Division V—Mechanical.—V. R. Hawthorne, 431 South Dearborn St., Chicago. Next convention June 15-22, Atlantic City, N. J. Exhibit by Railway Supply Manufacturers' Association.

Division V—Equipment Painting Division.—V. R. Hawthorne, Chicago.

American Railway Association, Division VI—Purchases and Stores.—J. P. Murphy, N. Y. C., Collinwood, Ohio. Second annual meeting June 20-22, Atlantic City, N. J.

American Railroad Master Tinners', Coppersmiths' and Pipefitters' Association.—C. Borcherdt, 202 North Hamlin Ave., Chicago.

American Railway Tool Foremen's Association.—R. D. Fletcher, 1145 E. Marquette Road, Chicago.

American Society for Testing Materials.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. Thirty-ninth St., New York. Spring meeting May 23 to 26 inclusive, Congress Hotel, Chicago.

American Society for Steel Treating.—W. H. Eiseman, 4600 Prospect Ave., Cleveland, Ohio.

Association of Railway Electrical Engineers.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.

Canadian Railway Club.—W. A. Booth, 131 Charron St., Montreal, Que. Next meeting March 8. Paper on "The Repairing of Steel Freight Cars" will be presented by Samuel Lynn, M. C. B., Fittsburgh & Lake Erie Railway Company, together with stereopticon views.

Car Foremen's Association of Chicago.—Aaron Kline, 626 N. Pine Ave., Chicago. Meeting second Monday in month, except June, July and August, New Morrison Hotel, Chicago.

Car Foremen's Association of St. Louis.—Thomas B. Koeneke, 604 Federal Reserve Bank Building, St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis.

Central Railway Club.—H. D. Vought, 95 Liberty St., New York. Next meeting March 11. Paper on "Engine Terminal Layout" will be presented by H. E. Stitt, chief engineer, Austin Company, Cleveland.

Chief Interchange Car Inspectors' and Car Foremen's Association.—W. P. Elliott, T. R. R. A. of St. Louis, East St. Louis, Ill. Next meeting March 3 and 4, 1921, Hotel Sherman, Chicago.

Cincinnati Railway Club.—W. C. Cooder, Union Central Building, Cincinnati, Ohio. Meeting second Tuesday of February, May, September and November, Hotel Sinton, Cincinnati, Ohio.

Dixie Air Brake Club.—E. F. O'Connor, 10 West Grace St., Richmond, Va.

International Railroad Master Blacksmiths' Association.—W. J. Mayer, Michigan Central, 715 Clarke Ave., Detroit, Mich. Next meeting August 16, 17 and 18, 1921, Hotel Sherman, Chicago.

International Railway Fuel Association.—J. G. Crawford, 702 East Fifty-first St., Chicago. Next annual meeting, May 24-26, 1921, Hotel Sherman, Chicago.

International Railway General Foremen's Association.—William Hall, 1061 W. Wabasha Ave., Winona, Minn. Convention, September 12, 13, 14 and 15, 1921, Hotel Sherman, Chicago.

Master Boilermakers' Association.—Harry D. Vought, 95 Liberty St., New York. Convention, May 23 to 26, 1921, inclusive, Planters' Hotel, St. Louis, Mo.

New England Railroad Club.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Next meeting March 8. Election of officers, together with annual entertainment.

New York Railroad Club.—H. D. Vought, 95 Liberty St., New York. Next meeting March 18. Paper on "Safety of Passengers in Steel Cars" will be presented by F. M. Brinckerhoff.

Niagara Frontier Car Men's Association.—George A. J. Hochgrebe 623 Brisbane Building, Buffalo, N. Y.

Pacific Railway Club.—W. S. Wollner, 64 Fine St., San Francisco, Cal. Annual meeting Thursday, March 10, at 8 p. m. Election of officers.

Railway Club of Pittsburgh.—J. D. Conway, 515 Grandview Ave., Pittsburgh, Pa. Meetings fourth Thursday in month except June, July and August, Americus Club House, Pittsburgh.

St. Louis Railway Club.—B. W. Frauenthal, Union Station, St. Louis, Mo. Meetings second Friday in month except June, July and August.

Traveling Engineers' Association.—W. O. Thompson, N. Y. C. R. R., Buffalo, N. Y.

Western Railway Club.—Bruce V. Crandall, 14 E. Jackson Boulevard, Chicago. Meeting third Monday each month except June, July and August.

PERSONAL MENTION

GENERAL

D. G. McCormick has been appointed mechanical engineer of the Mobile & Ohio, with headquarters at St. Louis, Mo.

C. J. Sevier has been appointed assistant to the superintendent maintenance of equipment of the Western Maryland, with headquarters at Hagerstown, Md.

O. C. Cromwell has been appointed assistant to the chief of motive power and equipment of the Baltimore & Ohio, with headquarters at Baltimore, Md.

H. W. Salmon, Jr., has been appointed acting fuel agent on the Missouri Pacific, with headquarters at St. Louis, Mo., succeeding W. P. Hawkins, who has resigned.

G. S. Goodwin, corporate mechanical engineer of the Chicago, Rock Island & Pacific, has been appointed mechanical engineer of the Rock Island System, with headquarters at Chicago.

J. W. Sasser, superintendent of motive power of the Norfolk Southern, has resigned to become superintendent of motive power of the Virginian, with headquarters at Princeton, W. Va., succeeding R. E. Jackson, resigned.

J. C. Garden, superintendent of motive power on the Grand Trunk Railway at Stratford, Ont., has been appointed acting general superintendent of the motive power and car departments of the lines east of the Detroit and St. Clair rivers, and consulting engineer of the motive power and car departments of the Grand Trunk Western Lines, succeeding W. H. Sample, retired. John Roberts, general foreman, has been appointed acting superintendent of motive power, with headquarters at Stratford, succeeding Mr. Garden.

P. O. Wood, superintendent of the St. Louis-San Francisco, with headquarters at Memphis, Tenn., has been appointed assistant superintendent of motive power with headquarters at Springfield, Mo. Mr. Wood was born at Memphis, Tenn., in 1877. He entered the service of the Kansas City, Memphis & Birmingham (now a part of the Frisco) in 1891 as a machinist apprentice in the Memphis shops. After completing his apprenticeship he served as a machinist and air brake repairman until 1904, when he became a locomotive fireman. In 1907 he was promoted to engineman and, in 1913, to assistant superintendent of locomotive performance. In 1916 another promotion made him assistant general superintendent of motive power. In 1917 he became division superintendent at Memphis and remained in that position until his recent appointment.

A. Sturrock, whose promotion to assistant superintendent of motive power on the Canadian Pacific, with headquarters at Winnipeg, Man., was announced in the February *Railway Mechanical Engineer*, was born on July 27, 1883, at Dundas, Ont. He entered railway service in 1901 as a machinist in the Stratford, Ont., shops of the Grand Trunk. After a year's service with the Grand Trunk, Mr. Sturrock came to the United States and was employed as a machinist, first on the Atchison, Topeka & Santa Fe, and later on the Denver & Rio Grande. His service with the Canadian Pacific began in July, 1904, when he was employed as a machinist in the company's shops at Winnipeg. He was promoted to locomotive foreman in 1911, with headquarters at Fort William, Ont., a position which he held until 1913, when he was transferred to Vancouver, B. C. In April, 1914, he was again promoted, being made general locomotive foreman of the shops of the Canadian Pacific at Ogden, Alta. A year and a half later Mr. Sturrock was made division master mechanic, with headquarters at Cranbrook, B. C., and in January, 1915, was promoted to general master mechanic of the Alberta district, with headquarters at Calgary, Alta. At the time of his recent promotion he was serving as general master mechanic of the British Columbia district at Vancouver.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

R. J. Rheaume has been appointed assistant master mechanic of the Canadian National Railways Hornepayne, Ont.

Eugene Schull has been appointed master mechanic on the Frisco System, with headquarters at Sapulpa, Okla., succeeding C. F. Coffman, resigned.

C. E. McGann has been appointed master mechanic of the Pittsburgh division of the Baltimore & Ohio, with headquarters at Glenwood, Pa., succeeding W. C. Burel, resigned.

A. J. Flowers, assistant master mechanic on the Central of Georgia at Macon, Ga., has been appointed master mechanic, with headquarters at Columbus, Ga., succeeding E. G. Gross, resigned.

H. M. Allen, locomotive foreman on the Canadian Pacific, with headquarters at Alyth, Alta., has been promoted to master mechanic, on the Kenora Division, with headquarters at Kenora, Ont.

A. G. Fischer has been appointed master mechanic on the Frisco System at Memphis, Tenn., succeeding G. R. Wilcox, who has resigned. William Henry succeeds Mr. Fischer as assistant master mechanic at Monett, Mo.

A. Devine has been appointed assistant master mechanic of the Canadian National Railways at Campbellton, N. B., succeeding F. F. Carey, who has been appointed assistant master mechanic of the St. Maurice division, at Quebec, Canada.

J. E. Gould, master mechanic of the Charlotte Harbor & Northern, with headquarters at Arcadia, Fla., has been appointed master mechanic of the Cumberland & Manchester, with headquarters at Barbourville, Ky. F. S. Market has succeeded Mr. Gould at Arcadia.

W. J. Denix, master mechanic on the Canadian Pacific at Moose Jaw, Sask., has been appointed master mechanic at Vancouver, B. C., succeeding A. Sturrock, who has been promoted to assistant superintendent of motive power at Winnipeg, Man.

J. Gibson, locomotive foreman on the Canadian Pacific, with headquarters at Sutherland, Sask., has been promoted to master mechanic, with headquarters at Moose Jaw, Sask., succeeding A. Peers, whose appointment as master mechanic was announced in the February issue.

G. W. Ray, master mechanic on the Western division of the Chicago & Alton, with headquarters at Slater, Mo., has been transferred to the Northern and Southern divisions, with headquarters at Bloomington, Ill., succeeding M. J. McGraw, who has resigned. F. Stone succeeds Mr. Ray.

H. A. Amy, locomotive foreman on the Canadian Pacific, with headquarters at North Bay, Ont., has been promoted to division master mechanic, with headquarters at Ottawa, Ont. E. G. Freeman, locomotive foreman, with headquarters at Cartier, Ont., has been transferred, succeeding Mr. Amy.

W. D. Hartley, whose appointment as master mechanic on the Atchison, Topeka & Santa Fe at Clovis, N. M., was announced in the February issue of the *Railway Mechanical Engineer*, was born on August 14, 1886, at Albuquerque, N. M. He was graduated from the high school at Las Vegas, N. M., in 1903, and in May of the same year entered the employ of the Atchison, Topeka & Santa Fe, serving as a machinist apprentice and machinist until September, 1909, when he became roundhouse foreman at Richmond, Cal. From October, 1914, to February, 1918, he was division foreman at Barstow, Cal., and from February, 1918, until his recent transfer as master mechanic, was general foreman at Richmond.

CAR DEPARTMENT

O. J. Greenwell has been appointed master car repairer on the Tuscon division of the Southern Pacific, with headquarters at Tucson, Ariz., succeeding A. G. Saunders, who has resigned.

A. J. Krueger, shop inspector of the New York, Chicago & St. Louis, with headquarters at Cleveland, Ohio, has been promoted to master car builder, with the same headquarters, succeeding R. W. Miller, deceased.

SHOP AND ENGINEHOUSE

W. T. Abington has been appointed night roundhouse foreman on the Rock Island at Herington, Kan., succeeding S. L. Hamilton, resigned.

SUPPLY TRADE NOTES

L. A. Lenhart, plant manager of the General American Tank Car Corporation, East Chicago, Ind., has resigned to become vice-president of the Youngstown Steel Car Company, Niles, Ohio.

The Atlas Valve Company, Newark, N. J., has secured the sole patents and rights to manufacture the Ideal automatic pump governor, by purchase from the Ideal Automatic Manufacturing Company, New York.

E. R. Lewis, editor of the Maintenance of Way Cyclopedia, one of the publications of the Simmons-Boardman Publishing Company, has been appointed officer engineer of the Michigan Central with headquarters at Detroit, Mich.

John L. Bacon has been appointed manager of the service and inspection department of the Franklin Railway Supply Company, with headquarters in New York. Mr. Bacon was formerly district manager of the Cleveland office of the same company.

The Black & Decker Manufacturing Company, Baltimore, Md., has opened a new branch office and service station at 75 Fremont street, San Francisco, Cal. This office has jurisdiction of the company's affairs over the entire Pacific coast territory and is in charge of F. A. Johnson.

B. A. Bell, railway specialist for the Western Electric Company, has been appointed railway representative of this company at Atlanta, Ga., succeeding J. W. Smith. Before taking up the duties of railway specialist Mr. Bell was general salesman for the Western Electric Company.

Theodore L. Dodd has been elected vice-president and a member of the board of directors of the Allegheny Steel & Tube Company, with headquarters at Chicago. Mr. Dodd will have jurisdiction over the sales in the Middle West, extending to the Pacific coast.

The Chicago Flexible Shaft Company opened an office at Detroit on February 1 for the sale and distribution of Stewart furnaces and to extend direct service in heat treating problems to customers in that territory. The new office is located at 601 Kerr building, and is in charge of George P. Beck.

A. T. Kuehner has been appointed mechanical engineer of the Standard Stoker Company, Inc., New York. Mr. Kuehner is the inventor of the Keener journal box for locomotive drivers and trucks. This device will be manufactured and placed on the market by the Standard Stoker Company. Mr. Kuehner, until his recent appointment, was on the staff of C. A. Gill, superintendent of motive power of the Baltimore & Ohio.

Max Grant, who has been associated with the Tropical Paint & Oil Company, Cleveland, Ohio, has been appointed manager of technical railway sales, of the Glidden Company, Cleveland, and M. F. Emrich, formerly vice-president and general manager of the Campbell Paint & Varnish Company, St. Louis, a subsidiary of the Glidden Company, has been appointed general sales manager of the industrial division of the Glidden Company, with headquarters at Cleveland.

Alba B. Johnson, formerly president of the Baldwin Locomotive Works, has resigned from the board of that company and also as a director of the Standard Steel Works, Philadelphia, Pa. John M. Hansen, president of the Standard Steel Car Company, Pittsburgh, has been elected a director and member of the executive committee of the Baldwin Locomotive Works and W. L. Austin, vice-chairman of the board of directors of the Baldwin Locomotive Works, has been elected a director of the Standard Steel Works, Philadelphia, to succeed Mr. Johnson.

Louis B. Rhodes, southeastern sales representative of the Vapor Car Heating Company, Inc., with headquarters at Richmond, Va., died of heart failure on January 25, at Nashville, Tenn. Mr. Rhodes was formerly master mechanic on the Georgia Southern

& Florida and had served as superintendent of motive power of the Virginian. Later he was with the Ward Equipment Company. He was in the service of the Standard Heat & Ventilation Company at the time when the latter company was consolidated with the Chicago Car Heating Company in the organization of the Vapor Car Heating Company.

The Brown & Sharpe Manufacturing Company has recently prepared a list of graduate apprentices who have completed the company's training courses during the seventy or more years that the apprenticeship system has been in use in the plant. In the Brown & Sharpe organization, the executives, with few exceptions, were formerly Brown & Sharpe apprentices. This list, though incomplete, contains the names of many now holding important positions and serves to prove that the apprenticeship course lays the foundation on which to build broadly and progressively. The company is sending these booklets to any former Brown & Sharpe graduate apprentice or to others who are interested in training courses and desires to add as many names as possible to the next edition.

The executive, sales, purchasing and accounting departments of the Reed-Prentice Company, the Becker Milling Machine Company and the Whitcomb-Blaisdell Machine Tool Company, 53 Franklin street, Boston, will be located on and after February 21 at the Reed-Prentice plant, 677 Cambridge street, Worcester, Mass. On account of present business conditions, the Becker plant at Hyde Park, Boston, is operating with reduced force, production to be increased as soon as conditions warrant. The Becker cutter department business showed a marked increase in volume during January and it is expected to be running full capacity shortly. The Worcester plants of the Reed-Prentice and Whitcomb-Blaisdell Machine Tool Company are completing orders on hand, and are also building machines to be placed in stock.

The Toledo Crane Company, Bucyrus, Ohio, successors to The Toledo Bridge & Crane Company, Toledo, builders of Toledo cranes, has been chartered under the laws of Ohio, with the following officers: C. F. Michael, president; W. F. Billingsley, vice-president and general manager; A. G. Stoltz, treasurer, and C. Gallinger, secretary. The officers with C. H. Dexheimer are the stockholders and directors. All stock has been subscribed and paid in and none will be offered for public subscription. The main office is at Bucyrus with sales offices in New York City, Boston, Philadelphia, Pittsburgh, Buffalo, Cleveland, Cincinnati, Chicago, St. Louis, Kansas City, Seattle, Salt Lake City, San Francisco, Birmingham and Minneapolis. The company will have completed by March 15 a building 120 ft. by 320 ft., to be used for erecting and assembly, with a machine shop 60 ft. by 300 ft., a structural shop 90 ft. by 300 ft., a pattern shop 60 ft. by 140 ft., and a forge shop 40 ft. by 100 ft., all to be equipped with modern tools.

Clifford J. Ellis, district manager of sales for the Midvale Steel & Ordnance Company and the Cambria Steel Company, with headquarters at Chicago, Ill., died at his home in Evanston, Ill., on January 31. Mr. Ellis had been district manager of sales for more than 30 years and for 37 years had been in the service of the Cambria Steel Company at Chicago. He was born on November 25, 1860, and when 19 years of age entered the employ of Wood Morrell & Co., Johnstown, Pa., who controlled the Cambria Iron Company. Not long thereafter he became assistant to the treasurer and in 1883 he was transferred to Chicago, entering the sales department of the company, where he had served up to the time of his death.

C. J. Ellis

Harry M. Evans, eastern sales manager of the Franklin Railway Supply Company, Inc., has been elected vice-president of the company, with offices at 30 Church street, New York. Mr. Evans was born at Meadville, Pa., and was educated in the public schools at that place. He began railroad work as a call boy on the Erie, and served in various positions in the mechanical, transportation and traffic departments of that road. He entered the mechanical department of the Franklin Railway Supply Company in October, 1908, as traveling representative. In August, 1916, he became assistant western sales manager, and in January, 1917, was appointed eastern sales manager, which position he was holding at the time of his recent election.

Harry M. Evans

E. Emery, formerly manager of the R. H. Blackall Company, Pittsburgh, Pa., has opened offices in the Oliver building, Pittsburgh, under the firm name of the Emery Sales Company, handling railway supplies. Mr. Emery will serve as special representative, reporting to the Pittsburgh office of the Schaefer Equipment Company, handling its full line of foundation brake details in a defined territory. He will also have charge of sales in the Pittsburgh district of the Mason Packing Company, Pittsburgh, which manufactures the Mason semi-metallic packing for locomotive air pumps, and will represent the Standard Horsenail Company, New Brighton, Pa., handling its line of taper pins, shaft keys and channel pins. Mr. Emery was graduated from the Chicago Manual Training School in 1899, after which he was connected for two years with the F. B. Reddington Company, Chicago, in an engineering capacity. He was for eight years with A. Sorge, Jr., & Company, Chicago, handling a steam specialty line. He was engaged in sales and engineering work for a time and later was with the Parker Boiler Company, Philadelphia, Pa., for one year as general sales manager. Mr. Emery was then assistant sales manager of the Rust Boiler Company, Pittsburgh, and when that business was sold to other interests he joined the R. H. Blackall Company.

E. Emery

Locomotive Superheater Company Takes Over Locomotive Feed Water Heater

The Locomotive Superheater Company, New York, has acquired the patents and business of the Locomotive Feed Water Heater Company, also of New York. Feed water heating and superheating have many factors in common, and logically the former can best be perfected by a combined organization broadly experienced and trained in this field. During the past few years remarkable progress has been made in successfully adapting feed water heaters to locomotives, and if the thermal efficiency of the locomotive is to be further increased, the development of the feed water heater should be conducted with a full knowledge of the engineering features of the superheater.

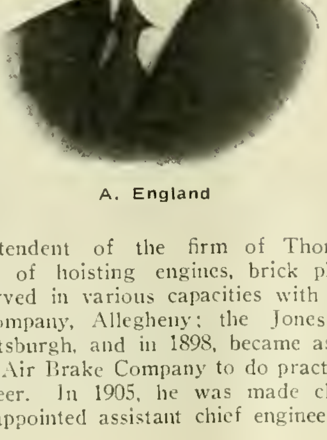
The Locomotive Superheater Company will conduct the further application of the apparatus for preheating feed water through its regular engineering, inspection and service organizations, to which has been added the operating organization of the Locomotive Feed Water Heater Company. This consolidation of resources and effort promises more intensified development and better service to the railroads.

Westinghouse Air Brake Company

S. W. Dudley, chief engineer of the Westinghouse Air Brake Company, Wilmerding, Pa., retired on February 1 to accept a professorship of mechanical engineering at Yale University.

S. W. Dudley

Mr. Dudley, who is a graduate of Yale University, had been associated with the air brake company for 17 years. He spent the summers of the years 1903 and 1904 in the plant as a special apprentice, returning to school to complete a post graduate course during the other seasons. In 1905, he established permanent connections with the Westinghouse Air Brake Company and assisted in and compiled much of the data pertaining to the tests of the Type R triple valve on the Pennsylvania, and the ET equipment and the Type R passenger triple valve on the New York Central. In 1906 he was assigned to the New York office to follow the installation, operation and maintenance of new air brake equipment that was placed in service on electric locomotives and motor cars during the inauguration of the New York Central's terminal electrification and, in 1907, returned to Wilmerding to take charge of the air brake publicity department. From 1909 until his appointment as chief engineer in 1914, he served as assistant mechanical engineer and assistant chief engineer (in charge of operation).



A. England

Alexander England, who has been appointed chief engineer to succeed Mr. Dudley, has been a member of the air brake organization for the past 22 years and, since 1914, has served as assistant chief engineer. He was born in Dundee, Scotland, and at an early age entered the employ of the Scotch firm of Pierce Brothers, engineers and shipbuilders, to serve an apprenticeship and finished a course of study that earned him a diploma in mechanical engineering from the City and Guilds of London Technical Institute, he entered the service of the Mercantile Steamship Company of London as an engineer in the Mediterranean and Black Sea trade. In 1887 he left the marine service and went to Pittsburgh, Pa., where he took a position as assistant superintendent of the firm of Thomas Carlin's Sons, manufacturers of hoisting engines, brick plant machinery, etc. Later he served in various capacities with the Specialty Manufacturing Company, Allegheny; the Jones & Laughlin Steel Company, Pittsburgh, and in 1898, became associated with the Westinghouse Air Brake Company to do practical work under the chief engineer. In 1905, he was made chief draftsman, and in 1914 was appointed assistant chief engineer.

TRADE PUBLICATIONS

Hand and Machine Tools.—The McCrosky Tool Corporation, Meadville, Pa., has issued a 64-page illustrated catalogue descriptive of their various types of tools, such as reamers, chucks, lathes, milling machines, etc. The catalogue is divided into several sections, each section being devoted to a detailed description of a particular tool. Prices and specifications are also given.

Locomotive Cranes.—A catalogue of detailed parts of Brownhoist locomotive cranes has recently been issued by the Brown Hoisting Machinery Company, Cleveland, Ohio. All the parts are shown in photographs in which each detail is clearly numbered to facilitate identification for ordering. The book also contains illustrated directions for erecting and operating these locomotive cranes.

Belting.—"A Saving for Every User of Belting" is the title of a new and interesting catalogue published by the Stanley Belting Corporation, Chicago, Ill. Aside from the general features of a well-worked out descriptive book, it gives valuable instructive points and considerations for every user of belting. The results of a test of Stanley belting are given and several typical installations are shown.

Wrought Iron and Steel.—The Reading Iron Company, Reading, Pa., has issued Bulletin No. 2 in which the structural differences between wrought iron and steel and their relation to the field of welded pipe have been described in a simple way. Photomicrographs of wrought iron and steel are shown and the structure of the two materials is discussed in a manner that is of interest to the layman as well as the engineer.

Gate, Globe, Angle, and Check Valves.—The Walworth Manufacturing Company, Boston, Mass., has issued a six-page folder which illustrates the diversified line of brass valves which this company manufactures. A list is included showing the sizes in which the various types are manufactured and giving a list of prices. The circular calls attention to the fact that the Walworth Manufacturing Company has been making valves since 1842.

Radial Flow Heater.—Catalogue F, issued recently by the Ross Heater & Manufacturing Company, Inc., Buffalo, N. Y., contains 39 pages devoted to the description and illustration of the two general types of Ross heaters. One of these types is the radial flow instantaneous heater, in which the liquid is heated as it is used. The other type is the storage heater, which, as the name implies, has a storage capacity to be drawn on in emergency. Several examples of each type of heater are given.

Injectors.—The new 1920 catalogue, issued by William Sellers & Co., Inc., Philadelphia, Pa., is a well arranged and fully illustrated book. It is divided into six sections, the first section being devoted to a description of the various classes of injectors. Main check and stop valves are described in section two; steam valves, in section three, and locomotive feed water strainers, ejectors, etc., in section four. A table and diagrams of tests are given in section five. Hints for the maintenance and repair of injectors are also included.

Transveyors.—A new edition of the Transveyor Picture Book has been issued recently by the Cowan Truck Company, Holyoke, Mass. This presents in an attractive book form the advantages and many possible uses of the Cowan transveyor. The photographs were taken at random from a great variety of industries and tell a forceful story without many words. Present models and specifications of the Cowan transveyor are given, and a two-page diagrammatic chart showing structural features and advantages is included.

Performance of Steam Boiler Plants.—Brownlie & Green, Ltd., Manchester, England, have recently reprinted an article by David Brownlie entitled "Exact Data on the Performance of Steam Boiler Plants. Average Figures for the Performance of Some Different Types of Steam Boilers." The author points out that the figures usually taken in practice are entirely erroneous and presents data obtained as a result of investigations during ten years on nearly 500 boiler plants, giving the average figures for different types of boilers.

Are Wage Reductions Necessary?

The most momentous question of the day on the railroads is readjustment of working rules and wages. At present the question promises to revolve into a heated controversy. In discussing this matter it may be enlightening to depart somewhat from the evidence presented at Chicago and consider for a moment the existing economic conditions to determine whether they indicate that a reduction in wages is justifiable or not.

No one will deny that there has been a serious slump in business all over the country. Factories are working intermittently; millions are idle. The number of cars loaded weekly has declined to 70 per cent of what it was last fall. For the week ending February 23 there were 423,193 cars standing idle. Economists are generally agreed as to the cause of the present depression. The international situation caused a sharp decline in the prices of farm products. Other prices did not drop at the same time. Therefore, after the decline the farmers' goods would purchase relatively a much smaller amount of other commodities. In other words, the purchasing power of the farmer had declined. Farmers form a very large proportion of the population and it is natural that when they curtail purchases, business should be bad. There are economic forces which, if allowed to operate normally, work out a natural balance between industries and occupations. That balance must be sustained in order that the products or services of each group may be absorbed by all the other groups. When the balance is lost, unemployment results and continues until a redistribution is worked out so that everyone is at work and all products are absorbed.

The secret of prosperity is in balanced industry with the production of every branch of industry in proportion to the wants and buying power of the people in all other occupations. The number of people that can be employed in any industry depends on the demand for the product, which in turn depends on the price. If the price of a commodity is increased, the consumers will have to curtail their purchases of it, or of something else. Individuals or groups may fix prices or wages, but they cannot govern the effect their action will have upon sales. This is made very plain by present conditions. Dealers object to cutting prices and labor organizations object to reductions in wages. They have been successful in holding out, but their prices are too high for the farmers and business is stagnant because the adjustments necessary to restore equilibrium are not made. It is shortsighted to think that wages can be fixed under all conditions by agreement between employer and employee. There is a relationship between each industry and all other industries that must be taken into account. What is needed now is a readjustment of the relationship of prices of farm products with other prices and wages. It would be difficult, if not impossible, to control the international conditions that govern the prices of farm products in order to cause these prices to rise. The only other course that will restore the balance of industry is to bring other prices and wages down.

This is not an argument for reducing the wages of railroad employees only. Other wages and prices must come down also. Neither is it the intention to propose that the reduction should be of the same magnitude as the drop in farm products. Nevertheless, it is worse than foolish—it is futile—for any group of employees to oppose a moderate reduction of wage rates. As the cost of living is declining a reduction at this time will be more apparent than real.

The modern industrial organization is dependent upon intelligent, voluntary and harmonious co-operation on the part of all the people. It requires that the people shall distribute themselves in the various industries and so direct their individual policies as to keep the industries in balance and effect a ready exchange of products. If through mistaken ideas of self-interest they organize themselves into groups and become so intent upon forwarding group interests that they lose sight of the necessity for general co-operation, the whole modern system of highly developed and highly specialized industry will break down.

What Is the Other Fellow Doing?

It is well known that a country cannot expand commercially without adequate means of transportation. It is equally true that the industries of a country cannot grow in efficiency and economy without some method of spreading general knowledge regarding improved machinery and methods which have demonstrated their value. While in some respects railroad shops are decidedly different from manufacturing plants and are confronted by different problems, certain fundamental conditions and problems are the same. Among these is the absolute necessity of keeping in touch with late developments and practices which have proved big time and money savers. Mechanical department officers on the whole are awake to this necessity, and no new railroad repair shop is now constructed without first making a careful and detailed study of existing plants with the idea of incorporating all possible good features and avoidi ngbad ones. The annual June convention of the American Railway Association, Division 5—Mechanical—offers a wonderful opportunity for railroad men to interchange ideas and benefit by the inspiration which comes from contact with capable, experienced officers who daily meet the difficult problems arising in the repair and maintenance of cars and locomotives in a serviceable condition. The technical papers also afford a fine opportunity for careful readers to keep abreast of the times and in touch with the most modern, approved shop practices.

One avenue of information has been sadly neglected, however, due to the short-sighted policy of some roads in not allowing their gang leaders and foremen to visit other shops and attend conventions. For example, the leading tool maker of a large railroad shop desired to attend the convention of the American Society for Steel Treating held at Philadelphia last year. This man's service with the railroad had been entirely satisfactory and he desired to profit by the wealth of information on the heat treatment of high speed tool steel available at the convention. He was told that no expense money could be allowed but in spite of this fact attended the convention for two days, and returned to his position with definite information, the actual cash value of which to his company would be hard to estimate. It is true that this tool maker was furnished with transportation to and from the convention, but his hotel expenses were paid out of his own pocket and he was required to lose two days' pay for the time he was absent from the shop. Can there be any excuse for such a penny wise and pound foolish policy? It is recognized that owing to the magnitude of the railroad industry, indiscriminate traveling cannot be tolerated. There is no reason, however, why the prohibition of educational trips should be so hard and fast that ambitious workmen or foremen must be at a financial loss in acquiring information which may well mean thousands of dollars annual saving for the railroads with which they are connected.

Machine Tool Obsolescence

The word obsolescence is defined as "the state of being out of date; disused." Unfortunately a large amount of the machinery and equipment used in railroad shops is obsolete to the extent that it has gone out of date and can no longer be efficiently operated. Even more unfortunate, however, is the fact that the second part of the definition does not apply since this machinery is now being used, no matter how uneconomically, and at a considerable cost for labor and delayed repair work. It may be dangerous to draw comparisons, but a prominent automobile manufacturer stated recently that he could not afford to operate machine tools, for example, after they are two years old. In this length of time they have earned their cost many times over and if not readily salable as second-hand tools, they are scrapped in favor of more efficient, productive types. Admitting the fundamental difference between railroad shops with diversified repair work and automobile plants manufacturing standard products, there is no reason why railroad shops should swing to the other extreme and be required to operate with machines indefinitely old. Two years is an extremely low estimate of the useful life of machine tools, but some reasonable period, as for example 10 years, should be decided on and used as a basis in accounting for depreciation. Developments in the design and improvement of machine tools are so rapid that most machines 10 years old are hopelessly out of date as production tools and can no longer be used economically in shops handling any considerable amount of work. Especially in the centralized production departments of railroad shops is it necessary and good economy to employ only modern, high capacity machines. Old machines should be retired and this can be accomplished by setting aside annually an amount of money equal to 10 per cent of the value of railway machine shop tools, charging it to the depreciation account. Then, at the end of the 10 years, it will be possible for the shops to benefit by the installation of new and improved machinery which is not held up due to difficulty in obtaining the necessary capital. The high cost of labor and the high cost of equipment held out of service, combined, make it imperative that obsolete machinery and shop tools be replaced as fast as possible by modern productive machinery.

Save Time in Valve Setting

There is one operation in setting locomotive valve gears which may be materially speeded up, especially in some shops, without in any way reducing the quality or accuracy of the work. The operation referred to is revolving the main driving wheels in valve setting to obtain the dead centers, lead, cut-off and travel marks. In many shops the driving wheels are now revolved at a considerable expense of time and physical effort, the common method being to relieve the spring weight on the wheels as much as possible, apply rolls beneath them and draw the rolls together until the wheels just clear the rail. Hand operation of the rolls by a long handled ratchet revolves the wheels. The difficulty with this method is in the large amount of physical effort required to turn the rolls, which in many cases slip and do not make the wheels revolve. A considerable proportion, possibly 35 per cent, of the time required to set valves is now spent turning the driving wheels, and the remedy for this condition is rapid power revolution of the driving wheels in valve setting. In some cases, air motors have been applied to the rolls, thereby reducing materially the labor involved, but the results with this method have not been wholly satisfactory due to continued sticking and slipping of the wheels. Some device of greater power should be provided. It is possible to design a set of power driven rolls of rugged construction, sufficiently large in diameter to eliminate practically all slipping between the rolls and the driving wheels. An efficient form of drive for such a mechanism has already been devised in the application of an electric motor to a four-wheel truck, connected to the rolls by a powerful, universal joint. With the weight relieved from the main driving boxes and a sufficiently powerful motor to drive the rolls, no difficulty will be found in revolving the driving wheels. The time saved by rapid power revolution of driving wheels in valve setting is doubly important because it occurs during the last day or two the locomotive is held in the shop for repairs. The reduction of this time by one day for one locomotive would more than pay the cost of a set of new power rolls.

An Eye to the Future

It would be difficult to conceive of circumstances more trying to the men in the car department than exist at this time. Ever since 1917 the problem of keeping equipment in condition has been a difficult one. The percentage of bad order cars has been high and freight cars have been used so intensively that little progress has been made in getting them repaired, except during a few short periods of light traffic. Now that cars are being returned to the owning roads and large numbers are idle, the conditions are favorable for doing a good deal of repair work, but the critical financial situation of many of the railroads makes this impossible. Cars reaching the home road are merely being set aside and bad orders are steadily increasing. The number of unserviceable cars on March 23 was 459,411, the highest figure ever recorded.

There is no question that immediate economies are called for, but it would be a mistake to allow this to interfere with the problem of future repairs. The cost of almost any work can be materially reduced if it is carefully planned in advance. In car work there has been too much of a tendency to leave the decision as to how to handle the job to the repairman. This has resulted in costly methods of doing work without efficient specialized equipment. Furthermore, it has led to waste through repeated replacement in kind of parts that should have been strengthened. This is an opportune time to lay plans for correcting wrong conditions. As cars are bad ordered, they should be carefully inspected with the ideas mentioned above in mind. If a large number of one class need heavy repairs, a schedule for handling the work can be outlined. By obtaining material in advance and systematizing the operations, work can be greatly expedited.

Some classes of cars are continual sources of trouble, and under normal conditions would have been retired without question. There has developed in recent years a practice of keeping cars in service almost irrespective of the amount of repairs required, though this is in many cases the costliest policy that could be followed. The old equipment of low capacity often shows a high repair cost per car. If the figure is changed to the cost per ton of capacity, it is still higher, and if it could be ascertained on the basis of the ton mile, it would probably be startling. This is the measure that should be applied when deciding what cars are not economical to repair. Traffic is certain to increase again, and when that time comes the roads cannot afford to put up with the interruptions to traffic and the handicap to the shops that would result from keeping a large number of old, weak cars in service.

The Temperature at Which carburizing should be carried out should be just above the critical temperature of the steel, or 1650 deg. F., generally speaking. To operate at a lower temperature will decrease the rate of penetration, thus increasing the cost, and to operate at a very much higher temperature will not only produce a very high carbon surface with its tendency to crack and peel, but may burn the pieces beyond reclaiming. Correct known temperatures are essential to success.—*The Melting Pot.*

Selecting Foremen

Washington, D. C.

To the Editor:

In the March number of the *Railway Mechanical Engineer*, views are asked as to what training a foreman should have. When this was read a man of wide railroad experience happened to be near and he was asked the question as to what is necessary to make a good foreman. The answer came, quick as a flash, "They can't be made." "You mean they have to be born?" "Yes," was the answer.

This question of foremen is one that all of us have given considerable thought ever since the day we were trying to determine the requisites in order to qualify ourselves for a foreman's job. There is more truth than poetry in the statement that foremen have to be born, but it is really only a half truth, as numbers of men have been made, some actually hand-molded. What, then, is necessary—can the points be defined—is it possible to take a man's measure and determine accurately whether he is a potential official?

In the "box" calling for views on this subject, the statement is made that as a rule the best mechanics are selected for minor officials. If this rule were followed blindly, we would soon be shipwrecked, as it has nothing whatever to do with a man's capacity to accept and profit by advancement and should be only incidental.

It is necessary to study a man for some time to determine his capabilities. First, is he honest in every way? Second, is he substantial, that is, dependable in an all around and general way? Next, is he subject to the influence of other men in the shop; is he prejudiced or narrow-minded? Who are his associates and what does he do with his spare time? Is he ambitious and does he feel that railroading offers ample opportunities to make him anxious to make it his life work? Does or can he exert good influence over men, and can he talk forcibly—to the point and with conviction when necessary? Will he study his job and endeavor to perfect himself in the profession, realizing that there are many angles to it and many units that go to make up the whole? Last but not least, can he control himself and thus permit his mind to function properly in times of dire stress or emergency?

Human nature is the same yesterday, today and tomorrow, but there is too much loose talk going the rounds about men having no ambition and about it being well nigh impossible to recruit the quota of minor officials. Because you "happen" to pick out four or five men and ask them how they would like to take Jim Jones' place and they state that they would prefer to remain in the ranks, it does not follow that such a conclusion is correct. The trouble is really with the management, for a live organization will assure itself at all times of sufficient potential officials, as otherwise it will deteriorate and eventually fail. We anticipate our needs on other scores and must do so for future foremen. It has been truly said many times and in many ways that the foreman is the life blood, if not the mechanical department itself, to all intent and purposes.

If a higher official asks a master mechanic for a man to go to another division for promotion and he has none available, it is an admission on his part that he is not anticipating or planning for the future, and therefore that little can be expected from him as far as better results are concerned. He should be glad, if it were possible, to train men for the whole system and take pride in and profit by their success. It is worth while to be able to pick a winner and the best training obtainable is by teaching others.

The master mechanic dictates the policy of his shop, his subordinates execute it, therefore the most important item of all—choosing and making the subordinates—should be the master mechanic's particular duty. The general foreman should, of course, be consulted, but he should not select the men alone. This is a tedious operation requiring the highest skill, and the highest official, who is supposed to be the most skilled, should perform the task. Letting general foremen and roundhouse foremen select their subordinates invariably tends to stabilize or deteriorate the quality of the foremen, whereas if the higher official selects them, the quality should be persistently improved. From another angle, where various men handle this operation uniformity is not secured, while if the master mechanic selects them all, by and with the advice of his subordinates, uniform results will be obtained, mistakes in analysis can be more readily determined and guarded against.

As a concrete example the master mechanic says, "Mr. General Foreman, I want you to consult your subordinates, study and observe the workmen and give me the names of four men for prospective machine shop foremen, four for roundhouse foremen, two for boiler foremen and two for general foremen. I will then acquaint myself with these men in order to determine if they will prepare themselves, in anticipation of promotion. Give this matter mature thought for I will not approve your recommendations without personal investigation in each case and I am determined to have sufficient supervisory material in the making to fill all needs." A little talk with these men, after due deliberation and observation, should encourage them to make ready for promotion, and if their enthusiasm is aroused they will make good. Impress upon these men the required fundamentals, get them to thinking and planning and enthusing, tell them that their ability must grow if they expect it to bring more money each year, encourage them to consult with and study their superiors and invite them to attend a staff meeting from time to time. They can use their imagination and be acquiring skill as a supervisor so that there will be no question about their making good when their time for promotion comes.

John Mitchell.

NEW BOOKS

The Welding Encyclopedia. Compiled and edited by L. B. MacKenzie and H. S. Card, editors of the Welding Engineer, 336 pages, 6 in. by 9 in., illustrated. Bound in cloth. Published by the Welding Engineer Publishing Company, 608 South Dearborn street, Chicago.

The development of fusion welding processes and the rapid extension of their application in industry during the past decade has created a field which is now becoming highly specialized. Although several books have been published dealing with various phases of welding, the greater part of the literature on the subject is not available to the practical welder for the reason that it is widely scattered through periodical publications dealing primarily with other matters. The Welding Encyclopedia brings together in one volume a wide range of knowledge concerning welding practice, equipment and auxiliary appliances for all classes of work. About one-third of the subject matter is an illustrated definition section in which all words, terms, and trade names used in the welding trade are defined. Short treatises are included in this section on a number of the more important topics and it also serves as an index to the subject matter in the special chapters on the oxy-acetylene, electric arc, electric resistance and Thermit processes, the use and care of equipment, boiler welding, and the heat treatment of steels, which follow the definition section. A valuable feature of the book is the section on Rules and Regulations, which contains a compilation of the various codes of rules applying to fusion welding. These include the A. S. M. E. boiler code, the regulations of the Department of Commerce Steamboat Inspection Service, Lloyd's Register of Shipping, the Underwriters' Laboratory, the National Board of Fire Underwriters, the American Railway Association (M. C. B.), and the Interstate Commerce Commission specifications for gas shipping containers. The status of welding regulations in the various states is briefly summarized and where specific regulations have been developed these are given. There is also a catalogue section in which are described equipment, materials and supplies sold commercially for use in welding. The book forms a valuable reference work from which the practical welder may obtain much fundamental knowledge of correct practices for a wide range of work, and to which the general reader may refer for the meaning of terms and for a knowledge of the status of the different branches of the art.

Steam Locomotives of the Present Time (Die Dampflokomotiven der Gegenwart). By Robert Garbe, 7½ in. by 10½ in., illustrated. Volume 1, 859 pages; volume 2, 54 lithographed tables and drawings. Published by Julius Springer, Linkstrasse 23, Berlin W. 9, Germany.

This is a second edition of this well-known work originally published in 1907. The text has been brought up to date and an attempt has been made to present the same well-rounded survey of locomotive development in all countries that was given in the earlier work. Apparently the war interfered with the compilation of data and some parts of the book are unfortunately incomplete.

The book opens with an historical sketch of the use of highly superheated steam in locomotives and a discussion of the essential progress in locomotive building in the past 20 years. The first chapter deals with superheat as a working medium, the question being discussed largely from the theoretical viewpoint. The succeeding chapters are devoted to the calculation of the main dimensions of superheated steam locomotives, two-cylinder and multi-cylinder locomotives with simple and double expansion and the uniflow engine of which a rather extended discussion is given. Various types of superheaters are described and noteworthy structural details of more recent locomotives are discussed. A section is devoted to the latest developments in feed water heating. The superheated steam locomotives of the Prussian State Railways are described and the section following is devoted to superheated locomotives of various railroads in countries other than Germany. The American locomotives are described in this and in a previous chapter but the types shown cannot be classed as typical examples of the latest developments in motive power in this country. The results of numerous tests of superheated steam locomotives, principally in Germany, are set forth and it is notable that these are nearly all from seven to ten years old. The concluding chapters deal with details of design and operating methods.

Apparently the principal shortcoming of the book is the lack of complete and up-to-date information concerning the locomotives built by the allied countries. This, however, is not of primary importance as American readers would be chiefly interested in the book for the information they might obtain regarding the progress that has been made in Germany in the years during which communication was interrupted. Apparently the descriptions of German motive power have been given painstaking attention and the work of German designers during and since the war, is here presented for inspection for the first time.

In Boring Sheet Brass it is a good idea to place a piece of hard wood behind the piece being drilled.—*The Melting Pot.*

Delaware & Hudson Heavy Consolidation Locomotive

Notes on the Comparison of Locomotive Dimensions

Significance of the Principal Factors, Their Application in Designing and Values for Various Types

BY LAWFORD H. FRY

Standard Steel Works Co.

For a number of years past the Railway Mechanical Engineer has published lists of dimensions, weights and ratios in connection with the descriptions of new locomotives. It is felt that in view of the many new developments in recent years, the data furnished does not meet the present requirements. It has been decided to revise the form of tabulation hitherto used and in order that the new form should represent the best practice, suggestions have been invited from a number of authorities on locomotive design. The paper by Mr. Fry, presented below, is the first contribution on this subject. Others will appear in later issues.—EDITOR.

IN passing judgment on a locomotive design, attention must be given not only to the dimensions but to the proportion in which these stand to each other. These proportions are conveniently measured by the factors discussed below. Before entering the discussion it is well to note that the proportion between the dimensions is more conveniently expressed as a "factor" than as a "ratio." It must be remembered that a ratio must be expressed as the relation of one number to another and not as a single number. For example, if a locomotive with 202,000 lb. on drivers has a rated tractive effort of 45,000 lb. we may say that the ratio of adhesion is 4.1 to 1 or that the factor of adhesion is 4.1. The latter form of expression is the more convenient.

It is also convenient to give each factor a name and to designate each by a definite letter; thus (A) for the Factor of Adhesion, (B) for the Boiler Factor, and so on, as shown below.

Factors

The most important factors in common use are:

$$\text{A} = \text{Factor of Adhesion} = \frac{\text{adhesive weight}}{\text{rated tractive effort}}$$

$$\text{B} = \text{Boiler Factor} = \frac{\text{rated tractive effort}}{\text{evaporative heating surface}}$$

$$\text{C} = \text{Combustion Factor} = \frac{\text{evaporative heating surface}}{\text{grate area}}$$

$$\text{BD} = \text{Boiler Demand Factor} = \frac{\text{rated tractive effort} \times \text{driving wheel diameter}}{\text{evaporative heating surface}}$$

$$\text{E} = \text{Factor of Efficiency of Design} \quad \frac{\text{total weight}}{\text{evaporative heating surface}}$$

Sh/S = Superheater surface as percent of evaporative heating surface.

Before considering the factors in detail two of the dimensions entering into them require attention. These are the tractive effort and the heating surface. The rated tractive effort (R.T.E.) is computed from the well known formula R.T.E. $= \left(\frac{0.85 d^2 s P}{D}\right)$ where d is the cylinder diameter, s the stroke and D the driving wheel diameter, all in inches, while P is the boiler pressure in pounds per square inch. The force thus computed is the maximum tractive force deliverable by the cylinders at the rim of the drivers if the cut-off is long enough to give 92 per cent of the boiler pressure as mean effective pressure, and if the machine friction absorbs about 8 per cent of the indicated cylinder power (0.92 x 0.92 = 0.85 nearly). Even though these assumptions do not hold exactly, it is desirable to use the factor 0.85 in all cases so that the rated tractive effort is a definite measure of those dimensions of the cylinders, drivers and steam pressure which determine the tractive force.

The heating surface used in computing the factors is the total evaporative heating surface made up of the firebox, tube and flue heating surfaces, the superheating surface being left for separate consideration. Considerable use has been made of the so-called "equivalent heating surface" which is taken to be the evaporative surface plus 1.5 times the superheating surface. This is, however, a purely arbitrary figure and has little in its favor. The operation of a locomotive is primarily dependent on the steam produced by the evaporative surface. The addition of a certain amount of superheating surface enables the steam to work with greater efficiency and thus gives greater boiler power, but a continued increase in superheater surface would not give a continued increase in boiler power in the manner indicated by the "equivalent heating surface." To secure satisfactory comparisons for the steam producing capacity of the boiler and also for the added efficiency due to superheating, it is desirable to base the boiler factors on the evaporative surface and then to express the superheating surface as a percentage of the evaporative surface.

Table 7...	2-10-2	Suph.	1920	12	4.2	15.0	920	78	24.0

Average values of the various factors are given in Table 1. These represent 161 locomotives of the types most in use at present for main line service. The values given under date of 1910 are taken from an earlier compilation made by the writer (The Engineer, Oct. 13, 1911), while those under date of 1920 are from Tables 2 to 7 herewith. The latter are all modern locomotives, the majority having been put into service between 1915 and 1920, and all use superheated steam.

Factor of Adhesion

$$A = \frac{\text{Adhesive Weight}}{\text{Rated Tractive Effort}}$$

The value of this factor shows the weight holding the wheels to the rail for each pound of average force tending to rotate them, and therefore measures the ability of the engine to start without slipping. In considering this it must be remembered that the force developed by the cylinders varies throughout the stroke, the value given by the formula for rated tractive effort being the average value, while the maximum value is about 20 per cent higher. With a clean dry rail slippage will not be likely to occur so long as this maximum value of the tractive force does not exceed 30 per cent of the weight on drivers, that is so long as the average value, the rated tractive effort, does not exceed 25 per cent of the weight on drivers. In other words, if A, the Factor of Adhesion, has a value of 4.0 or more the locomotive is not likely to be slippery on starting.

Column 6 of Table 1 shows average values of the factor A for various types of locomotives. It will be seen that the modern locomotives are quite uniform in having values from 4.1 to 4.3 on the average. The tendency is for the heavy drag types such as the 2-8-2 and 2-10-2 to have the lower values; that is, for these engines to have cylinders of a size to fully utilize all of the adhesive weight.

Boiler Factor

$$B = \frac{\text{Rated Tractive Effort}}{\text{Evaporative Heating Surface}}$$

This factor measures the pounds of rated tractive effort to be developed by each square foot of heating surface, when the engine is working in full gear. In the case of two locomotives at the same speed in miles per hour the horse-power of each is proportional to the tractive effort. (The formula is $\text{H.P.} = \frac{\text{T.V.}}{375}$, where V is the velocity in miles per hour.) Therefore under these conditions the horse-power required from each square foot of heating surface is proportional in each case to the value of the factor B. If one engine has $B = 10$ and the other $B = 12$ the latter is calling for 20 per cent more power from each square foot of heating surface.

It may be taken that at slow speeds with engines in full gear, a horse-power can be developed from 3.0 sq. ft. of heating surface in a saturated steam locomotive and from 2.5 sq. ft. in a superheated locomotive. On this basis the maximum speed in miles per hour at which the full rated tractive effort can be developed will be $V = \frac{125}{B}$ for saturated and $V = \frac{150}{B}$ for superheated locomotives.

Boiler Demand Factor

$$BD = \frac{\text{Rated Tractive Effort} \times \text{Driving Wheel Diameter}}{\text{Evaporative Heating Surface}}$$

This is simply the boiler factor B multiplied by the driving wheel diameter, D. With the engine in full gear, the factor BD is proportional to the foot-pounds of work done during each revolution for each square foot of heating surface. It is evident that both the B factor and the BD factor measure the relation between the cylinder and boiler dimensions, that is between the steam consuming and the steam producing parts of the locomotive. The difference between the two factors is shown in the following definitions:

When two locomotives are both developing their full rated tractive effort, or are both developing the same percentage of their rated tractive effort, the amount of horse-power to be supplied by each square foot of heating surface is proportional, for each locomotive, to the factor B when the speeds are the same in miles per hour, and is proportional to the factor BD when the speeds are the same in revolutions per minute. It is obvious that if two engines have the same driving wheel diameter, they will show the same relationship whether compared by their B or by their BD factors. The difference comes when two engines of the same type and designed for the same number of revolutions per minute are intended to work at different speeds in miles per hour and have driving wheel diameters in proportion to these working speeds. If both locomotives are well proportioned they will have approximately the same value of BD, while the slower speed engine will have a correspondingly larger value of B. The BD factor is therefore a better measure of the basic proportions of the locomotive.

Values of the factors B and BD from columns 7 and 8 of Table 1 show the following average values for modern superheater locomotives:

Type	B	BD	D
4–6–2	11.5	840	73 in.
4–8–2	12.6	860	68 in.
2–8–2	14.1	870	62 in.
2–10–2	15.0	920	62 in.
2–8–0	17.8	1015	57 in.

These figures show that the 4-6-2, 4-8-2 and 2-8-2 types have very similar values of BD, the averages running from 840 to 870, while the values of the factor B increase as the driving wheel diameter is decreased. With the 2-10-2 and 2-8-0 types the tractive power stands in a larger proportion to the heating surface, as shown by the larger values of BD. The fact of course is, that these types having a large proportion of their weight on driving wheels, offer more opportunity for providing large cylinders and less for providing heating surface. The larger values of *BD* show that they are adapted for lower speeds in revolutions per minute, while the proportionately still larger values of *B* (due to smaller driver diameters) indicate considerably lower speeds in miles per hour.

For a comparison between saturated and superheated steam the following figures are taken from Table 1 for the Pacific type (4-6-2) and the Consolidation (2-8-0) which are the only two classes appearing in the older saturated class and also among the more modern superheaters.

	B	BD	D
4-6-2 Superheated	11.5	860	73 in.
4-6-2 Saturated	9.0	620	69 in.
Difference as percent of value for superheated engine	22 per cent	28 per cent	
2-8-0 Superheated	17.8	1015	57 in.
2-8-0 Saturated	13.7	800	58 in.
Difference as percent of value for superheated engine	23 per cent	21 per cent	

The indication is that when saturated steam is used the boiler

factors should be 20 to 25 per cent lower than with superheated steam.

Combustion Factor

$$C = \frac{\text{Heating Surface}}{\text{Grate Area}}$$

The value to be given this factor is determined by the quality of the fuel to be used. For this reason no averages have been struck, as there is no meaning in an average based on varying grades of fuel. The individual figures show that the roads using anthracite aim at having a value of about 35 to 40, while the soft coal roads aim at about 55 to 60, for superheater locomotives. In saturated steam locomotives the necessity for greater heating surface tends to increase these figures from 10 to 20 per cent.

Factor of Efficiency of Design

$$E = \frac{\text{Total Weight}}{\text{Heating Surface}}$$

This gives the pounds of total weight per square foot of heating surface. Strictly speaking, this factor is an inverse measure of the efficiency of design, for the larger the factor the greater the weight the designer has required to secure the heating surface which is the source of power.

Values taken from Table 1 show average values for modern superheater locomotives as given herewith.

	Factor E
4-6-2	76
4-8-2	80
2-8-2	75
2-10-2	78
2-8-0	82

For saturated steam locomotives the values will be increased by from 15 to 20 per cent.

Superheater Surface as a Percentage of Evaporative Heating Surface

The meaning and value of this factor require little explanation. It is evident from Table 1 that the average value for all types is very close to 23 per cent, and it will be seen in the other tables that the variation of the individual values from the average is considerably less than for the other factors. This is natural as the same amount of superheat is desired irrespective of the locomotive type. The uniformity is also partly due to the design of the superheaters being largely in the hands of a single concern.

Use of Factors in Design

The factors which have been discussed afford a complete basis for a preliminary estimate of the general dimensions of a locomotive to fulfill any given conditions of service. Take for example the following problem:

Required the general dimensions of a Pacific type locomotive, to have drivers 70 in. in diam., to burn bituminous coal, and to be capable of developing a running tractive effort of 17,750 lb. at the rim of the drivers, at a speed of 40 miles per hour.

This means that $\frac{17{,}750 \times 40}{375} = 2{,}000$ horse-power must be developed. Assuming that 1.7 sq. ft. of heating surface are required for each horse-power, we find that 3,400 sq. ft. are required for 2,000 horse-power. The remaining dimensions follow at once if the various factors are given the average values taken from Table 1, viz.:

$$A = \frac{\text{Wt. on drivers}}{\text{Rated Tract. Effort}} = 4.3$$

$$BD = \frac{\text{Rated Tract. Eff.} \times \text{Dr. diam.}}{\text{Heating surface}} = 840$$

$$C = \frac{\text{Heating Surface}}{\text{Grate Area}} = 55$$

$$E = \frac{\text{Total Weight}}{\text{Heating Surface}} = 76$$

Superheater Surface = 23 per cent of Heating Surface.

The results obtained are:

Total Weight	258,000 lb.
Wt. on Drivers	176,000 lb.
Rated Tract. Eff.	40,800 lb.
Heating Surface	3,400 sq. ft.
Superheater Surface	780 sq. ft.
Grate Area	60 sq. ft.

A preliminary lay-out of the general dimensions in this way is of great use to the designer, or in consideration of new power. It is of course to be understood that the dimensions correspond to average values and can be modified to suit the details of design and service.

Other Factors

There has been a practice of using some other factors for the same purpose as those discussed above. An examination of them will show, however, that they merely duplicate the information given by the preceding factors and throw no additional light on the proportions or performance of the locomotive. Among these factors are the following:

Total Weight Divided by Tractive Effort.—This is not an important comparison to make, as the connection between total weight and tractive effort is only secondary. The tractive effort has a direct connection with the weight on drivers which provides adhesion, and again with the heating surface which furnishes the steam. The total weight has a direct connection with the heating surface, as it represents the expenditure necessary to obtain the steam production. The relation of tractive power to total weight is indirect, the factor connecting them depending first, on the heating surface provided for the tractive effort which is governed by the speed required, and second, on the total weight required to provide each unit of heating surface, which is governed by the methods of the designer. It, therefore, follows that a comparison based on the relation between total weight and tractive effort is meaningless unless we know the relation between tractive effort and heating surface, and also that between heating surface and total weight. These latter relations are measured respectively by the factors *B* and *E*, and if they are known we gain nothing by computing a factor to show the relation between total weight and tractive effort.

Weight on Drivers Divided by Heating Surface.—This again is a secondary relation which has no meaning unless we know the relation between weight on drivers and tractive effort (factor *A*) and the relation between tractive effort and heating surface (factor *B*). When these two relations are known our useful knowledge is not increased by finding the combined relation between the weight on drivers and the heating surface.

Cylinder Volume in Relation to Heating Surface.—The volume of steam used per revolution at a given cut-off is proportional to the volume of the cylinders. Consequently the relation of the cylinder volume to the heating surface may be taken as a measure of the relation of steam requirement to steam supply. So long as the boiler pressure is the same, the comparison will be similar to that obtained from the *BD* factor. The cylinder volume relation, however, takes no account of the boiler pressure, and consequently in the case of two similar locomotives one with 160 and the other with 200 lb. per sq. in. boiler pressure, it would show no difference in the relation of steam consumption to steam production. Actually, although the volume of steam used is the same for both, the weight of the steam is approximately 21 percent greater for the locomotive with 200 lb. per sq. in. boiler pressure. The *BD* factor brings the boiler pressure into account, and shows the effect of the greater steam consumption and greater power due to higher boiler pressure. Comparisons made on the basis of the *BD* factor are therefore more representative of actual conditions than those made on the basis of cylinder volume.

Table of Dimensions of Modern Locomotives

Tables 2 to 7 give for 97 modern superheater locomotives, particulars of the general dimensions and of factors based on these dimensions. The average values of the factors for modern locomotives which are given in Table 1 are drawn from these tables. The individual figures need no further comment, but are of interest, both as giving the actual sizes of the locomotives, and as showing the deviations of the individual values of the factors from the average values.

Stoker Fired Locomotive Makes Continuous Run Over Three Divisions

To demonstrate the fact that a trip for a locomotive need not necessarily be limited to one division of approximately 100 miles as has been generally the fixed practice on railroads for many years past, the Erie Railroad recently planned a test run by which one of its through New York-Chicago passenger trains would be hauled over three divisions, by one engine alone instead of using three engines for the three divisions as is the practice at the present time.

This test was based on the belief that the superior firing service of the modern mechanical stoker on heavy locomotives and long runs would render fire cleaning unnecessary at the end of each division. Continuous operation over the three divisions would be advantageous as it would eliminate the costs of terminal handling, such as changing engines, cleaning fires, coaling, turn table and roundhouse service, time consumed, etc. It was believed these charges could be divided by three.

Accordingly on February 24, heavy Pacific type engine No. 2926 equipped with a Duplex stoker attached to Erie train No. 3, consisting of one mail car, one express car, two coaches, two Pullman cars and one dining car left Jersey City at 12.18 p. m., for a continuous trip over the New York, Delaware and Susquehanna divisions, a total distance of 332.3 miles. The train arrived at Hornell, the final terminal at 11.28 p. m. on time, having covered this distance without incident in 9 hours and 13 minutes.

On the return trip, February 25, the same engine left Hornell at 10.57 a. m., one hour and one minute late, with train No. 4 consisting of one mail car, one express car, two coaches, two Pullman cars and one dining car, arriving at Jersey City at 7.00 p. m. on time. There was no hand firing done nor was the rake used during the round trip of 664.6 miles.

The fire was clean on arrival at Jersey City terminal, the ash pan being reasonably free from ash and not in any way clogged; and insofar as the condition of the engine was concerned, it could have been placed on another train and returned to Susquehanna over two divisions, a distance of 192 miles. This trip demonstrated decisively the practicability of one engine covering three divisions, and this was only made possible by this Pacific type engine being mechanically fired.

Design of an Improved Locomotive Throttle Valve

New Type Developed on Buffalo, Rochester and Pittsburgh, Has Many Advantages for Large Power

BY W. J. KNOX
Mechanical Engineer, Buffalo, Rochester and Pittsburgh

THE mounting cost of labor and materials, the lack of money with which to provide terminal facilities and to increase rolling stock have all made insistent demands for more intensive operation and more refined and economical appliances and methods. Every department of the railroads has labored to better operation. The mechanical department, with the others, has made earnest efforts in this direction and while there have been very few radical or basic improvements in the steam locomotive for some years, there has been a constant and steady rejuvenation and improvement of old and existing appliances and methods, and a constant development of new ones. Many of these aim at fuel saving through numberless channels, some at labor saving, others to promote safety and security, all with the common desire to improve economy and increase capacity. One of the steps recently accomplished in this direction by the mechanical department of the Buffalo, Rochester & Pittsburgh is described in the following.

General Arrangement of Throttle Valve

Problem of the Throttle Valve

For locomotives of maximum capacity to generate sufficient steam, the boiler must be extremely large. The limitations of clearances so restrict the height of the dome that the throttle standpipe is quite short and the distance above the water level, with three gages of water, to the steam admission level is small. To prevent priming it is essential, therefore, that steam be admitted to the throttle on these large engines at as high a level as possible.

In American practice, the throttle valve is almost invariably a single valve of the poppet type, generally arranged for double admission with two seats or with single admission and a dash pot or piston to balance the single valve. In either case, especially when of the single admission form, to provide sufficient passageway without excess lift the valve must be very large in diameter and of great weight. If of the double admission type, it is difficult to so balance the valve that it can be operated without resorting to much compounding of the leverage and long travel of the throttle lever, or the pull required at the lever handle must be very great. Valves of the single admission type with balancing pistons, while more easily operated, have developed numerous faults in service.

The valves are cold when ground in and even though the work is well done and tested before steam is raised in the boiler, the large disc, when heated to the temperature of the steam at working pressure, becomes distorted and the valve cannot be kept tight. A further objection to the valve of large diameter is that when the engine is working light and a limited steam supply is admitted to the dry pipe, the large valve will be opened a mere crack. This results in wire drawing the steam between the joint face of the valve and seat, quickly cutting these joint faces and causing the valve to leak.

Leaking throttle valves have always been a source of trouble, annoyance and much waste of fuel, but with the introduction of the superheater other causes of fuel waste, shop expense and danger have been introduced, not before so apparent. When working with a throttle design permitting admission of steam at a low level much priming results and the superheater units must serve to evaporate the excess moisture, consequently reducing the resulting temperature and efficiency. From a leaking throttle and the results of evaporation in the units, courses of scale are built up in the header at the discharge ends of the units until the openings are almost or entirely closed. This prevents or retards circulation and the ends of the units next the fire become heated, are swelled spherically by the pressure and burst, a real source of danger and very expensive to repair. This is not a hypothetical case, but happens repeatedly after a few months' service, and the trouble has been cured or at least greatly improved by using the design illustrated.

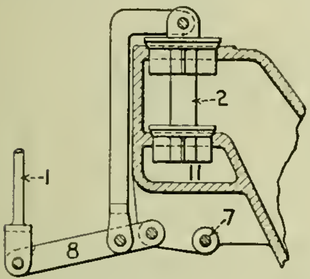

Fig. 5

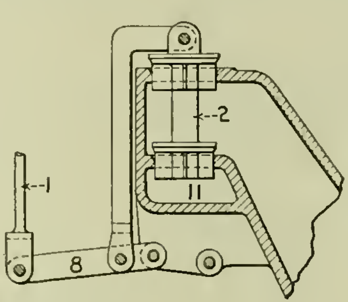

Fig. 7
Operation of Valve "A"

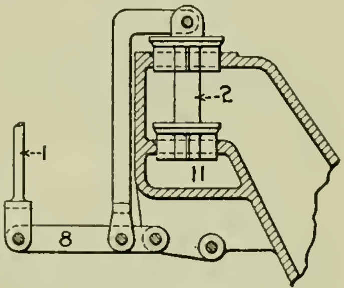

Fig. 9

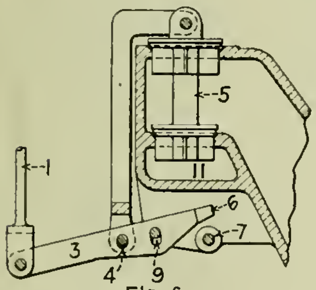

Fig. 6

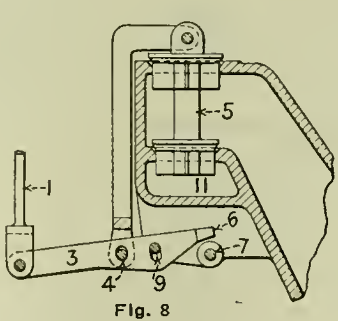

Fig. 8
Operation of Valve "B"

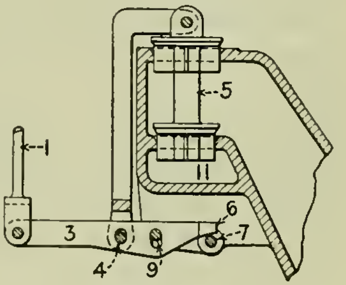

Fig. 10

Details of the Operating Mechanism

Operation of the Improved Valve

In the operation of the throttle valve the upward movement of the connecting rod, 1, from the position indicated in Fig. 5 first moves the valve member, 2, as shown in Fig. 7 and at the same time moves the lever, 3, to the position of Fig. 8, thus taking up the lost motion in the elongated pivot opening, 4, without causing any movement of the valve member, 5. A further upward movement of the connecting rod, 1, brings the parts to the positions indicated in Figs. 9 and 10, the valve member, 2, being opened still farther and the opening movement of the valve member, 5, starting. The lever, 3, is now moved so that its end, 6, engages the transverse rod, 7, this rod constituting the fulcrum for the lever during its further movement.

As the connecting rod is moved upward still further the valve members are opened simultaneously, the opening movement of the member 5 being more rapid due to the fact that the right hand end of the lever arm, 3, is longer than the corresponding end of the lever arm, 8. This movement of the lever arm, 3, is permitted by reason of the clearance in the elongated pivot opening, 9. At full travel both valves are open an equal amount. All the steam passing the throttle valve is admitted at the highest point possible, at the top level of the pipe. For the top seats the steam enters directly from the dome at the level of the seats. For admission through the bottom seats, steam is supplied by the ports, 10, to chamber, 11, below the valves as shown in the general arrangement, Figs. 3 and 4.

The opening provided by one valve before the second commences to lift is ample to pass the steam required by the locomotive when working light and can be graduated to meet the requirements when drifting much better than by so-called drifting throttles and special drifting appliances. The two valves are each one-half the diameter of a single valve and as they are arranged to open in sequence the lifting force required is only sufficient to overcome the unbalanced area of one small valve or is only one-half as much as for the large valve. The two small valves weigh less than the single large valve. The small valves are more easily machined, are much easier to grind in and experience has shown that they are tight when first applied and remain tight in service. Frequent regrinding is not necessary.

Advantages of the New Design

Among other advantages claimed for this design of throttle valve is the fact that the waste from escaping steam is avoided and the danger from the locomotive moving, if not blocked, does not exist. Scale does not build up in the header, stop up the discharge openings from the units and prevent circulation. The danger from bursting and leaking superheater units is reduced to a minimum.

The heavy expense and lost time incident to taking out the units and welding or applying new return bends is thus avoided and the efficiency of the superheater is not impaired. Most important of all, the locomotive is not held out of service so frequently and is in safe condition to handle traffic economically.

A New Rod Design

In April, 1917, the Erie applied main and side rods of an unusual design as shown in the accompanying drawing to a ten-wheel locomotive which has since been operating out of Jersey City in heavy suburban passenger service. The change in design was accomplished by lengthening the main crank pin to accommodate the back connecting rod bushing outside of the main rod bushing. The crank pin on the rear driver was lengthened to correspond with the main pin and the cross section considerably increased to withstand the additional stress.

As will be observed in the drawing, this arrangement at once eliminates the customary clevis pin and bushing which serve to connect the forward and back side rods and renders each of these rods interchangeable on a locomotive of this type where the driving wheel centers are an equal distance apart and the bearings of the same dimensions.

The *Railway Mechanical Engineer* is indebted to William Schlafge, mechanical manager of the Erie, for the following information concerning this special design of main and side rods:

"By referring to the accompanying drawing illustrating the details and manner of application of these rods, the difference between them and the usual type of connecting rods applied to ten-wheel locomotives will be readily observed. These rods were applied to locomotive 916 in April, 1917. Since that date only one complete set of new bushings has been applied. This is an exceptional performance. Moreover, we have not had a case of a hot pin on this locomotive since these rods were applied."

The simplicity of the design together with the interchangeability of the forward and back rods is also a feature of importance on a ten-wheel locomotive and there appears to be no reason why the same design could not be applied in principle to other types of locomotives having a greater number of driving wheels. Under certain conditions, the simplicity of design taken into consideration with the excellent results being obtained in use on the Erie would seem to recommend the design to more general consideration.

Kunze-Knorr Air Brake.—The final trials of the Kunze-Knorr air brake, preceding their adoption on the railways of Sweden, were made on the Ange-Braecke Line, which has an almost continuous 1 per cent grade, 20 kilometers long. The special freight train used in the test weighed 1,300 tons, and had a length of nearly 700 meters, being made up of 57 cars with 132 axles. Traveling at 45 kilometers per hour, with 8 brake vans, the train was stopped within 70 sec. in 605 meters. At a speed of 20 kilometers per hour, the corresponding figures were 38 sec. and 145 meters. The brakes are reported to have given full satisfaction for regulating the speed of the train.

Railway Executives Testify Before Labor Board

Labor Unions Present a "Bill of Rights"; Roads Request Conferences to Discuss Wage Reductions

THE principal development in the hearings before the Labor Board during the past month was the summoning and cross-examination of several railway executives. B. M. Jewell, president of the Railway Employees Department of the American Federation of Labor, on March 5 asked the Labor Board to subpœna the members of the labor committee of the Association of Railway Executives, which was abolished, to appear as witnesses when he resumed his reply to the presentation made on behalf of the carriers in the national agreements controversy. The request was filed by Mr. Jewell as an answer to the action of the Association in abolishing the committee.

Several days previous Mr. Jewell filed a letter with the Board charging that the railway executives are in a state of dissension over the question of abrogating national working agreements. He urged that before proceeding further with the cases now pending the Board should rule on the request of the unions for a national conference with the railway managements over the agreements.

The letter charged that a year ago a majority of the railroad executives were in full accord with the union leaders on the question of establishing bipartisan boards of adjustment and declared that Gen. W. W. Atterbury as a "minority of one had ridden roughshod" over the other executives.

"He prepared a minority report," the letter states, "and presumably because of the support which he was able to secure from the financiers who dominate the transportation industry, was able to thwart the will of the other executives, prevent the establishment of the national boards of adjustment, and refuse any conferences on national agreements."

After a delay of two weeks, granted by the Board to Mr. Jewell to prepare his rebuttal statement to the presentation which had already been made on behalf of the carriers, Mr. Walsh and Mr. Jewell appeared before the board on March 14, stating in substance that "it will be impossible for us to proceed with the presentation of our case until the witnesses we have called for have been subpœnaed and have presented themselves for examination."

During the course of Mr. Walsh's opening remarks it developed that in reply to the employees' request for subpœnas, the Board, before taking action, had requested them to state what they expected to prove from the testimony of these witnesses. In reply to this Mr. Walsh stated that the employees expected to establish:

(1) What led to the carriers' decision to have National Agreements abrogated; (2) why the carriers have refused to meet representatives of the employees on this subject; (3) whether the executives are fundamentally interested in doing away with the waste and extravagance chargeable to the National Agreements; and (4), whether these executives really believe that National Agreements are unworkable, unjust and unreasonable.

In addressing the Board on March 14, Mr. Walsh said in part:

"My clients are in no sense responsible for the delays in these proceedings, nor will they remain silent under any such imputation. We have been ready from the outset to go forward in an orderly way to a speedy determination of the issues involved in this controversy, and we submit that the whole matter could have been disposed of weeks if not months ago, if we had been granted the conferences which we asked of the railroad executives, or if this board had taken steps to bring about such conferences.

"The delay has been both disturbing and costly to the general public. It has contributed largely to the uneasiness and uncertainty in all business and in all industry which have prevented that return to normal activity and productivity in which we are all so vitally concerned. It has recruited thousands upon thousands to the army of the unemployed. I, for one, am apprehensive of the economic and political consequences that may ensue when we have a horde of hungry men, women and children in this country."

On the insistent demand of Mr. Walsh and Mr. Jewell, Robert S. Binkerd, assistant to the chairman of the Association of Railway Executives; General W. W. Atterbury, vice-president of the Pennsylvania and chairman of the association's disbanded labor committee; Carl R. Gray, president of the Union Pacific, and a member of the labor committee before its abolishment, and Thomas DeWitt Cuyler, chairman of the association, were summoned by the Railroad Labor Board to appear before it on March 18.

In addition, members of either the old labor committee or the Conference Committee of Managers of the Association, were notified to hold themselves in readiness for a similar call. Mr. Binkerd was requested to bring with him the minutes, letters, recommendations and other records having to do with the proceedings of the association and its labor committee with reference to the dispute now before the Board.

These developments were brought about by the adoption of resolutions by the Board on March 14 after Mr. Walsh and Mr. Jewell had maneuvred for additional delay and again declined to meet the issue, namely, the justness and reasonableness of the National Agreements now in effect.

B. M. Jewell Presents a "Bill of Rights"

When this part of the hearings opened on March 18, Mr. Jewell read a "bill of rights," outlining the basic principles upon which he said the National Agreements are founded and for which the employees' representatives are fighting. This statement outlined in general the plan of attack later followed by Mr. Walsh in his examination of the various witnesses.

After stating that representatives of the employees have repeatedly attempted to have this controversy remanded to joint conferences and that "an aggressive and misguided minority of railroad executives has seized upon the question of National Agreements as the means of misrepresentation of the railway employees before the public and as the occasion for an attack on labor organizations," Mr. Jewell said:

"The fundamentals which are the basis of the National Agreement are as follows:

Eight hours as the recognized measure of the standard work day with an adequate hourly wage.

Payment for time worked in excess of the regular eight hours at proper over-time rates for the various characters of service required.

The beginning and ending of working shifts to be so arranged as to permit of reasonable living arrangements by employees and their families.

Reasonable rules for the protection of health and safety of employees.

Clear and concise definition of the work of each craft to be performed by mechanics and helpers.

The formulation of apprenticeship rules so as to develop sufficient, competent and efficient mechanics.

Applicants for employment as mechanics to be required to show that they have served an apprenticeship of four years or performed mechanics' work for a similar period and they not to be denied employment, when their services are needed, for any reason other than their inability to perform the work for which they are making application for employment.

The right of majority in each craft to determine what organization shall represent them. This organization to have the right to make an agreement which shall apply to all workers in each craft.

The right of the majority of each craft on each railroad to select a committee or representatives who shall handle all grievances which may arise affecting all employees of the craft in accordance with the provisions of the agreement.

Craft, point seniority, limiting seniority to the local shops or points and not permitting interchange of seniority with other shops, crafts, or departments of railroads.

The right to organize and the protection of employees against discrimination because of membership in labor organizations or for any other reason.

"These fundamentals constitute the irreducible minimum in labor's bill of rights," he continued. "If machinery is to be successfully established for the peaceable settlement of the disputes between management and employees on the railroads these fundamental principles are an absolutely necessary preliminary."

As a result of the carriers' recognition of thése principles, Mr. Jewell said that "well rounded and smooth running machinery would now be in operation and peace on railroads and good-will between management and employees would prevail where now exist growing distrust, dissension, dissatisfaction, and increasing rumblings of a fast approaching, costly and vicious conflict, such as existed in the railroad industry prior to December 31, 1917.

"If it is proper, and we admit it is," he continued, "for railroad management of all railroads to have a national union of management, then, by the same line of reasoning, it must be admitted that the employees are entitled to the same. Railroad management is willingly accepting all the benefits of the Transportation Act, and just as willingly and determinedly is it endeavoring to escape its burdens. The law itself is not being given the fair test which it should be given.

"The facts are, there is at present and for years past there has been no individual and independent railroad management with which the employees could bargain collectively. Railroad managements' labor policy is practically dictated by and through a small committee. Railroad managements' policy thus dictated is then sought to be imposed upon a local railroad craft organization of employees by and through the national union of railroad management. Railroad labor's organizations and policy are formulated in order that it may hope to successfully cope with the compactly and nationally organized union of railroad managements."

Cross Examination of Railroad Executives

Following the presentation of this statement Mr. Walsh called Mr. Binkerd, Mr. Cuyler, Mr. Gray and General Atterbury to the stand.

By the testimony of these witnesses Mr. Walsh attempted to prove:

1—That national boards of adjustment and National Agreements are inseparable.

2—That railway executives are divided on the question of national boards of adjustment and therefore on National Agreements.

3—That Mr. Cuyler and General Atterbury, alleged representatives of capital, have exerted a powerful influence in opposition to National Agreements as part of a general attack upon labor organizations.

4—That the carriers are organized nationally to treat labor and other problems and they therefore should treat with the employees nationally.

5—That the basic principles of the National Agreements are just and reasonable even when applied nationally.

6—That the railroads are unfairly moulding public opinion to influence the Labor Board.

7—That the labor policy of the railroads is dictated by a handful of executives.

8—That the Association of Railway Executives and its officers wield more than an advisory power.

From Mr. Binkerd, Mr. Walsh elicited information regarding the history, purposes, organization and powers of the Association of Railway Executives and detailed information regarding the files of that organization which he presented in accord with the order of the Board. From Mr. Cuyler, Mr. Walsh obtained information regarding his position and influence in the Association and the extent to which publicity work has been carried and by whom. Mr. Gray proved a distinct disappointment to the labor leaders, for he outlined in unmistakable terms the opposition of the executives toward continuation of National Agreements, and met every attack on their position with opinion and evidence gained through many years of railroad experience in every part of the country. Mr. Walsh retired from the examination after a short time, leaving the interrogation of Mr. Gray to counsel for the carriers.

General Atterbury completed the wreck of the hypothetical case as visioned by Mr. Walsh. He was not only not content to take the defensive, but at times took a hand in the questioning and backed up his contentions with proof.

It had been confidently expected by the labor leaders that, through the testimony of Mr. Gray, it would be possible to establish the existence of a difference of opinion among railway executives as to the justness and reasonableness of National Agreements, and thus materially weaken the carriers' case. However, the dispatch with which Mr. Gray killed this plan led Mr. Walsh, after a short time, to retire from the examination. Counsel for the railroads, however, asked Mr. Gray to present testimony as to the reasonableness or unreasonableness of National Agreements. To this Mr. Gray stated that the varied conditions existing in different parts of the country makes it practically impossible to devise rules which can be applied justly and reasonably over the whole country.

The "bill of rights," previously presented to the board by Mr. Jewell, was then brought to Mr. Gray's attention, and the manner in which these rules worked out in actual practice when applied universally, was quickly pointed out.

Cross Examination of General Atterbury

On March 21 General Atterbury took the witness stand, and, in response to questioning, outlined his connection with the Pennsylvania, the Association, its Labor Committee and other railroad organizations. This led Mr. Walsh to submit a long list of organizations of executives and subordinate officials, which, he maintained, treated railroad problems nationally, and inferred that questions in which the employees were interested should be treated on the same scale.

In answer to a question regarding the importance of the abrogation of National Agreements, General Atterbury said: "The abrogation of National Agreements is the most important thing before the country today."

During the progress of the examination, Mr. Walsh attempted to point out a difference in the positions taken by General Atterbury and Mr. Whiter's committee.

In reply to Mr. Walsh's request that he add something to Mr. Whiter's presentation, General Atterbury read a statement which said in part:

"No more serious question (National Agreements) confronts the American people today. We have come to a parting of the ways. One road leads to government ownership, nationalization, Plumb Plan-ism, and Syndicalism,—the other road, to industrial peace, and the continuation of that individual initiative, energy and responsibility which is peculiarly American. The issue is in your hands. The signboard on one road is: National Agreements. The signboard on the other is: Negotiate directly with your own employees.

"The following quotations from the Official Circular No. 107 of the Railway Employees Department of the American Federation of Labor, which circular as an interesting coincidence. is headed 'Yours for Government Ownership of Railroads'—are illuminating.

> We are the first class of railway employees to force the understanding that the Railway Administration would negotiate and sign a National Agreement.
>
> * * * it was up to him, the Director General, to settle with us and further * * * the entire proposition would be submitted to our membership at once for a strike vote.

"The other road I have indicated leads to industrial peace. I can quote no better testimony advocating following the signboard—'Negotiate with your own employees' than the following, taken from the Report of Industrial Conference called by the President, of which William B. Wilson, Secretary of Labor, was chairman, and Herbert Hoover, vice-chairman.

> The right relationship between employer and employee can be best promoted by the deliberate organization of that relationship. That organization should begin with the plant itself. * * *
>
> Industrial problems vary not only with each industry, but in each establishment. Therefore, the strategic place to begin battle with misunderstanding is within the industrial plant itself. Primarily the settlement must come from the bottom, not from the top.

"My views as to what the employees should not do, are as follows: (1) undermine discipline; (2) limit production; (3) demand pay for which there is no equivalent production; and (4) force the 'closed union shop.'

"I have no fight with organized labor as such. I have every desire to see its existence healthy and normal. Within reasonable limits, it is a healthy spur to bring about fair conditions as between employer and employee.

"My views as to what the employee has the right to expect and the employer should provide, are as follows: (1) as steady employment as possible; (2) a good wage; (3) time for recreation; (4) opportunity to elevate himself in his employment; (5) a voice in determining the rules and regulations under which he should work; and (6) the right to be, or not to be, a union man. But to apply these principles, the 'dog collar' of National Agreements must be removed.

"An agreement to be properly binding must be equitable, and entered into freely by both parties; and in order that it may be intelligible and properly carried out, it is necessary that there be a common understanding. But a common understanding can only come from free discussion and negotiation.

"The so-called National Agreements were put in force on the Pennsylvania by order of the Director General. No discussion whatever was held between the employees who would work under these agreements, and the officers who necessarily would have to administer them. Nor have the employees who work under these agreements been permitted by their leaders to discuss them with their own railroad officers, or modify them as a result of such discussion."

After calling attention to the hurried effort on the part of the leaders of the shop crafts to make the question of National Agreements an issue before the Board, General Atterbury continued:

"Confusion, misunderstanding and bitterness between the officers and the employees were bound to, and did follow, and are bound to continue until the so-called National Agreements are wiped out, and the officers and employees now working under them on the Pennsylvania sit down together and work out their own set of working rules to meet their own conditions. You may fairly ask what justification I may have for this statement I have just made. Your Board some time ago very wisely decided that it had no jurisdiction over the question of national boards of adjustment. That decision took that 'dog collar' off. What followed on the Pennsylvania with our men in train and engine service is typical and convinces me of the possibilities in this direction with all classes of employees. There are no cases before the Labor Board from our men in train and engine service involving grievances as a result of the train and engine service rules and working conditions on the Pennsylvania. Our men and our officers are settling them between themselves. Understand that there were in existence seven separate schedules, covering different parts of the system and you must recognize that we have varying conditions incident to serving a territory with agricultural, industrial, and climatic differences, that stretches from the straits of Mackinaw to the Chesapeake Bay, and from the Atlantic Ocean to the Mississippi river and the waters of Lake Michigan.

"Each railroad negotiating its schedules with its own employees is the road to industrial peace."

There followed an interesting controversy between General Atterbury and Mr. Walsh as to the formation of the various National Agreements. General Atterbury vigorously maintained that these agreements were obtained from the Director General by coercion and stated, in support of this contention, that Director General Hines "took strike threats too seriously; his experience in handling labor matters had been too limited."

The next move in the examination was openly announced by Mr. Walsh when he said: "I will now try to prove that some universal rules are necessary." Following this he introduced considerable evidence regarding the legislation designed to safeguard railroad workers, various uniform rules promulgated by the Interstate Commerce Commission, etc. He then took up the rules contained in the National Agreements, and immediately found that, instead of examining the witness and directing the trend of the testimony, he was in turn being examined, and that the trend of testimony was being directed by General Atterbury. The first rule of the Shop Crafts Agreement was presented for General Atterbury's approval. It brought forth the reply:

"The eight-hour day is a perfect farce. It is merely a means for getting more money. The rule typifies the whole business. Why doesn't the rule say 'eight hours' work shall constitute a day,' instead of 'eight hours shall constitute a day's work.' "

General Atterbury then continued to bring out defects in the universal application of rules, stating again and again in discussing the applicability of the eight-hour day to railroad service that "the length of the working day should be gaged by the character of the service rendered." The remainder of the morning session was devoted to efforts on the part of Mr. Walsh and Mr. Wharton of the board to get General Atterbury to commit himself against the basic eight-hour day, but these efforts were without avail. In discussing other rules of National Agreements, General Atterbury took and consistently maintained the position that "no rule is a good rule unless it is agreed to by the officers who apply it and men who work under it."

Inadvertently, perhaps, Mr. Walsh then mentioned the relative merits of piecework as compared with the hourly wage system. This led to vigorous defence of piecework by General Atterbury, who said: "The abolition of piecework has been made a bone of contention by men who would level all good Americans."

General Atterbury said: "I would negotiate agreements with our men right now if their leaders would let go." To this Mr. Walsh replied that he, General Atterbury, could legally negotiate agreements with his own men at the present time. The latter was evidently waiting for this opporunity, for he immediately produced two communications from the Railway Employees' Department of the American Federation of Labor to members of the shop crafts, telling them, in substance, not to negotiate any agreements except the complete National Agreement. Furthermore, General Atterbury took this opportunity to substantiate his term for the National Agreement—"dog collars." This expression, he said, originated in a cartoon contained in a bulletin issued by the Railway Employees' Department of the American Federation of Labor, portraying labor handing railroad management a small dog collar labeled "National Agreement." Railroad management is saying, "It won't fit." Labor is replying, "We'll make it fit." How the "dog collar" was made to fit was explained by General Atterbury by reading portions of the communication below the cartoon.

The result was both serious and amusing. Mr. Walsh, aided by Mr. Wharton, attempted to draw different conclusions from labor's statement, "We'll make it fit," but their attempts were not successful, and the course of the examination was quietly but quickly changed; however, not before General Atterbury had vigorously stated, "The leaders of the American Federation of Labor are throttling the employees and the National Agreements are throttling both the employees and the management. I don't want to take anything from the employee. I want only a fair day's work for a fair day's pay." In answer to a question by Mr. H. T. Hunt, a public member of the board, Mr. Atterbury said: "You cut the 'dog collar' off and see how quickly the Pennsylvania will negotiate agreements with its men."

On continuing this line of examination, General Atterbury exclaimed that the "whole object of National Agreements is to employ more men." Objections to this statement elicited the reply: "I am a better friend of the men than their own representatives at this table. I maintain, in fact, that the men are not being represented."

The remainder of the day's testimony was of a similar character, Mr. Walsh endeavoring to obtain General Atterbury's approval of the principles of various rules of the Shop Crafts Agreement, and General Atterbury consistently maintaining his position as has already been outlined.

The morning session on March 22 found General Atterbury still on the stand with the cross examination proceeding without results for the employees' case. The necessity for classification rules was first brought up by Mr. Walsh only to be denied in substance. Regarding this, General Atterbury testified: "I take it that this Board is to quiet not foment trouble. If it were to write standard rules instead of pouring oil on the waters it would be throwing rocks into it. The Board can't write standard rules."

Mr. Walsh stated that there have been but 175 disputes in a year under the National Agreements, and upon asking General Atterbury if that would not indicate harmony under these rules, the latter replied: "No. The boards at Washington have already given the men everything they have asked for. There is nothing more to request."

The apprentice rules in the Shop Crafts Agreement were next taken up, Mr. Walsh attempting to justify their existence by reference to so-called "abuses" which took place prior to their creation. This discussion ended when General Atterbury said: "I can find restricted production under every rule of the National Agreement, and this rule is no exception. You men are trying to get more money for the men; I am trying to get an honest day's work for that pay."

Regarding the representation of employees, General Atterbury maintained through a long series of questions that the principle of representation by men elected by the majority is not fair to the minority who have a right to be represented by men of their own choosing. Following this, General Atterbury outlined his definition of and views upon the "closed shop," stating in substance that he deprecates the closed non-union shop as well as the closed union shop. Furthermore, he read a circular issued by the Railway Employees' Department of the American Federation of Labor showing that that department has issued orders which establish closed shops.

The testimony during the afternoon session of the same day continued the same. Various of the rules were brought up by Mr. Walsh, and General Atterbury as strenuously objected to their application nationally.

Mr. Walsh attempted to capitalize the evidence that the Pennsylvania had maintained prior to General Atterbury's departure for France "an extensive espionage system among its employees" and had "little arsenals" at various plants. After lengthy discussion of the charges of coercion on the part of both the Pennsylvania and the employees, the subject finally dropped upon a promise by Mr. Hunt to read General Atterbury's complete report from which the charges were taken. Just prior to the closing of the morning session, Mr. Walsh produced a letter alleged to have been written by I. W. Geer, general manager of the Pennsylvania, southwestern region, to supervisory employees, in which he charged the supervisory employees to defame the labor organizations if necessary to obtain certain information. This letter was later declared to be a fake by General Atterbury and Mr. Whiter after they had communicated with Mr. Geer.

Mr. Walsh later turned to apparent discrepancies in statements as to the cost of the National Agreements. General Atterbury immediately produced a statement which Mr. Walsh tried to keep from the record. This statement, which was filed with the Board, showed by figures of the Interstate Commerce Commission that the estimated saving of $300,000,000 was far below the actual saving possible.

A long series of questions regarding Master Car Builders' rules, etc., and their necessity followed, but throughout the session General Atterbury maintained consistently the stand which he had already taken on this subject. This completed the examination of witnesses summoned so far, and the Board adjourned until March 24, when Mr. Jewell began presentation of a long statement in reply to General Atterbury's stand before the Board.

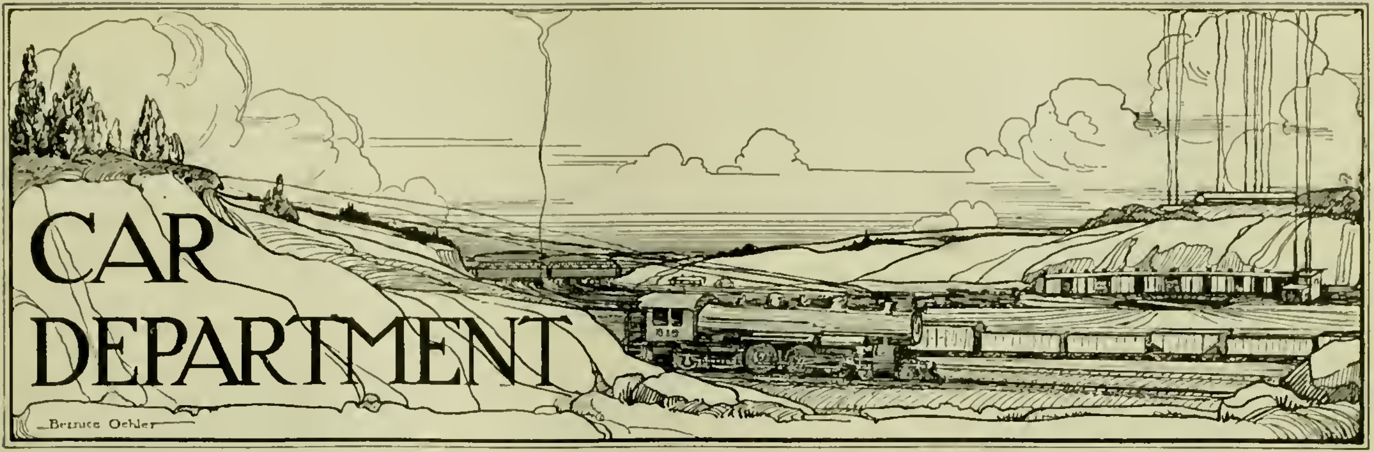
Developments so far have not indicated when or how the labor leaders will attempt to answer Mr. Whiter's presentation, but from their present tactics it is assumed that this will not be presented until the Board has decided that the case has been delayed long enough.

Developments in Other Hearings

On March 1 representatives of the Brotherhood of Railway and Steamship Clerks, Freight Handlers, Express and Station Employees appeared before the Board to justify the agreements made with the clerks and present their rebuttal statements. Statements were also made by representatives of the signalmen and the Brotherhood of Maintenance of Way Employees and Railway Shop Laborers.

Wage Reductions Proposed on Many Roads

During the past month many roads have held conferences with their employees to discuss decreases in the wage scale. In a great majority of cases the men are not disposed to accept any reductions without action by the Labor Board. While the earlier conferences were confined principally to unskilled laborers, later developments include proposals to reduce wages of all classes of officers and employees.

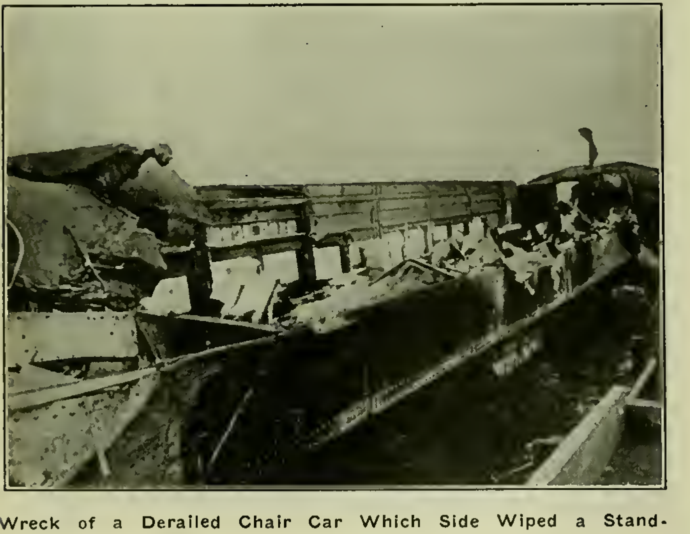


The Safety of Passengers in Steel Railway Cars*

A Discussion of the Action of Cars in Accidents and Methods Which Will Avoid Telescoping

BY FRANK M. BRINCKERHOFF

THE general adoption of steel in place of wood in the construction of passenger train cars some 15 years ago marked a distinct advance in the art of car building. Various problems arose during the change, and many have been successfully met. The two most important problems to be solved were and still are: safety of passengers and weight of complete car.



Wreck of a Derailed Chair Car Which Side Wiped a Standing Locomotive

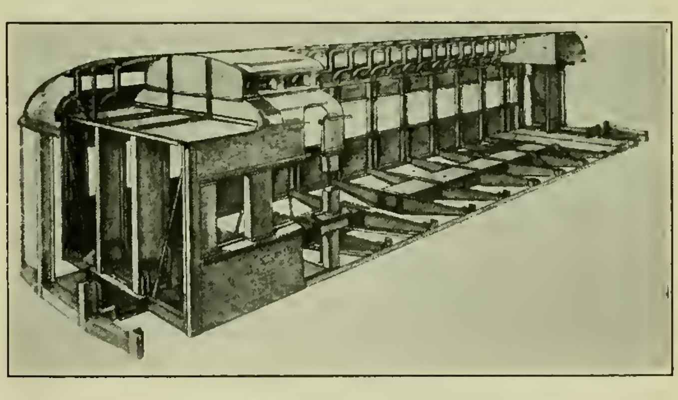
To successfully defend the passenger space against invasion in side wiping collisions and derailments, strong sideposts must extend from side sill to roof and all the side frame members must be co-ordinated to ward off the colliding body.

That some steel passenger cars are heavier than the wooden ones which they displace in service, seems to be indicated by the significant fact that the adoption of steel passenger train cars was frequently accompanied or closely followed by the purchase of heavier locomotives to handle the new passenger equipment.

It is not the intention at this time to discuss the economic consequences of the increased weight of steel passenger train cars, though that aspect is, of course, very important.

With regard to the problem of safety of passengers, I wish to present in a condensed form the results of an extended investigation of the behavior of passenger train cars when derailed or in collision, and to point out that, while the steel structure affords much greater safety to passengers than did wooden car bodies, modifications can be made in the superstructures of steel cars which will greatly increase their ability to resist destructive shock.

The data and some of the illustrations from which this paper is compiled can be found in the printed reports of accidents investigated by the Bureau of Safety, Interstate Commerce Commission, which are available to all; other illustrations are from photographs taken by various pictorial news bureaus and have appeared in the daily press, and a few are from our office files.



Framework of Passenger Car

Showing collision diaphragm and bulkhead with high-girder side walls.

In making our collection many hundred prints were examined and only those were selected which are of interest to car designers. It is greatly to be regretted that frequently the only available photographs of a wreck were taken as general views of the accident. Many valuable photographic studies of structural failures could have been made by an expert on the spot.

It was natural that the early designs of steel car structures should follow conventional lines and that the evolution from

---

*From a paper presented before the New York Railroad Club, March 18, 1921.

the all-wood car to the all-steel car should be gradual. It is now possible, however, to examine the photographic records of typical accidents to passenger trains and profit by past experience when designing and building new equipment.

For the purpose of analysis the illustrations have been divided into two groups: derailments and collisions. The records of the Bureau of Safety show that by far the greater number of accidents are in the derailment class though the loss of life and injury to passengers and equipment is greatest in the collisions.

Derailments

Examining first the large derailment class it is found that a considerable portion of the momentum of the train is gradually expended in plowing up the roadbed and in tossing about the car bodies. Therefore, the violence of impact between the individual derailed cars is not comparable to the shock experienced in a rear end collision between a moving and a standing train wherein the momentum of the combined units of the moving mass, led by the locomotive, is concentrated in an impact upon the rear units of the standing train. This reduction in the degree of violence of impact is, however, somewhat offset by the fact that when cars are derailed the heavy underframe of one car is frequently projected against the relatively weak superstructure of an adjoining car with more or less disastrous results. Furthermore in derailments the cars are sometimes overturned or fall upon a neighboring car; in such cases the superstructure of the car is subjected to extremely severe stresses.

Examination of many illustrations of accidents of the derailment and side wiping class, led us to the conclusion that distribution of metal which would strengthen the superstructure of the car as compared to the strength of the underframe was highly desirable. During the last 10 years or more, 315 cars have been built according to a system evolved, with the purpose constantly in mind, to produce a car body structure of great strength, but still of a weight not in excess of wooden car bodies of similar size and equipment. I wish to introduce at this point a short description of this system which affords unusual protection to the passenger space when cars are derailed or side wiped.

A Car Body Structure of Greater Strength

The sideframe members of these cars are organized in the form of a girder extending from the side sill to the side plate at the roof line, a height of 7 ft. 6 in. or more. The underframe of this system includes centersills adequate to sustain the shocks of collision, draft, etc., but instead of being of the fish belly type, designed to be self-supporting between truck centers, as is the usual custom, the centersills of this system are uniform in section throughout their length and are supported approximately every six feet by heavy cross bearers between the high girder side frames. The centersills, being thus supported, have no measurable deflection and are, therefore, superior in capacity to resist end shock to those of much greater weight and depth which are self-supporting between bolsters. By this co-operation between side frames and centersills a great reduction in weight per car is accomplished and yet a much stronger body structure results.

The ends of the bodies of these cars are reinforced against the stresses of impact to an extent considered appropriate to the service in which the cars are employed, some of these cars being electrically operated in tunnel service, others in suburban steam and suburban electric service, others in through line steam service at high speeds and in heavy trains. The system of end reinforcement is, of course, carried to the greatest extent in the cars in the latter service where the greatest momentum is to be dealt with in case of accident.

This system of reinforcement of the ends of the car body co-ordinates the body end walls with the members of the high girder side frame and roof in the form of a rectangular tube with ends barred to prevent penetration by an impacting body. This is accomplished in the through line cars by the introduction of two new members:

1. An anti-telescoping tie plate extending across the car from side plate to side plate and lengthwise of the car for about six feet forming a flat ceiling for the lavatory, passageway and saloon and being securely riveted to the plate of the high girder side frame.

2. Special deep piers forming the posts for the door in the end of the car body. These piers are approximately 21 in. deep and as in some classes of accident they may be subjected to tension. The web plates of these piers pass through the upper tie plate and also through to the underframe and are, together with their flanges, securely riveted to each of these members. The corner posts and the adjacent side posts of the car body are also specially designed to withstand the shock of cornering collision.

First Stage of Telescoping of Steel Cars

The body of the chair car has overridden the buffer sill of the coach.

The car structure thus formed is illustrated in the perspective drawing shown, from examination of which it will be seen that the compression member of the high girder side frame effectively braces this reinforced body end at the roof line.

The extent to which the high girder side frame and body end reinforcement of passenger car bodies will protect the passenger space when in collision or derailment can be somewhat gaged by examination of the damage to steel baggage cars after being involved in accidents of these classes. Baggage cars, because of the typical arrangement of their side doors, windows, etc., have in effect high side frames, with the elements of plate girders, extending from side sills to roof line at the car body ends. The high girder side frame and body end reinforcement of passenger cars, above described, co-ordinates all the strength elements of the car structure even more effectively than does the form of plate girder side walls of the usual baggage car, and in addition the body of the passenger car will be protected to a certain degree by the wreckage of its vestibule which, when in collision, will be forced back against the reinforced body end. Comparatively little damage results to baggage cars with high side walls when colliding with coaches of the usual low frame construction, thus demonstrating the advantage of the high structure when subjected to end shock.

End View of Coach Shown in Previous Illustration

The chair car has commenced to exert a bursting stress upon the body of the coach.

Rear Collisions

Considering next the illustrations of typical rear collisions, it is interesting to note that, where cars with steel underframes are involved, the penetration by the locomotive into the rear car seldom exceeds the depth of the vestibule and that the greatest damage occurs where one car overrides another. The pilot of the locomotive usually underruns the rear car until the buffer sills of the car come in contact with the heavy frame of the locomotive, where further progress is arrested and the penetration of the vestibule structure by the locomotive boiler or smoke box ceases.

When one car overrides another the penetration is in some instances complete, the entire length of the invaded car being practically destroyed. Careful analysis of typical photographic records of railway wrecks will lead to the following conclusions:

1. The underframe of the modern steel passenger car is adequate to withstand the shock of the most violent collision.
2. The underframe of the invading car overrides the underframe of the invaded car and wedges its side walls apart, the point of impact being a foot or more above the floor according to the upward angle assumed by the overriding underframe.
3. The superstructures of steel cars fail to protect the passenger space, when overridden in collision by a car having a steel underframe, because of the relative weakness of the invaded superstructure as compared with the heavy underframe of the invading body.
4. The joints connecting the side walls, hood and roof are subjected to tension because the invading body having penetrated between the side walls, exerts a bursting stress on the invaded structure. The members composing the roof are always light in section and the joints connecting them to the sides inadequate to resist the heavy tension stress of collision.
5. The structure of the invading car is subjected to compression, and as the joints connecting its members are better able to resist compression, than the invaded car structure is to resist tension, the invading car body is seldom seriously damaged.

Accurate computation of the force expended in a collision between trains is practically impossible. Two reactions, however, occur in all rear end collisions, which can be used to roughly gage the violence of the shock, namely:

1. Depth of penetration by the invading car, and
2. The distance the standing train is driven ahead by the force of the collision.

These reactions are complements of each other and roughly indicate the energy expended.

With these reactions in mind it seems highly desirable that the invading car be restrained from penetration by some device which will cushion the impact shock and impart motion to the standing train, thus diverting the force from the work of destruction to the work of moving the mass.

It is obvious that in a train collision the points of impact will be more or less damaged. It is impossible to build a car structure that will successfully resist all damage by an overriding car. The problem is to provide means to arrest the progress of an invading car before it penetrates deep into the invaded structure, meantime transmitting the force of the collision to the standing train to set it in motion.

The Second Stage of Telescoping

When telescoping has reached this stage the structure can offer but little resistance to further penetration by the invading body.

The essence of this problem is the element of *time.* The structure best adapted to solve the problem must contain members which will act to resist penetration at the vestibule end and interpose a rapidly increasing resistance to the progress of the invading car.

The essential characteristics of a member best suited to accomplish the above ends are: *Flexibility* to avoid shearing; *elasticity* to avoid abrupt stressing; *high ultimate strength* in tension to resist bursting stress exerted by an invading car.

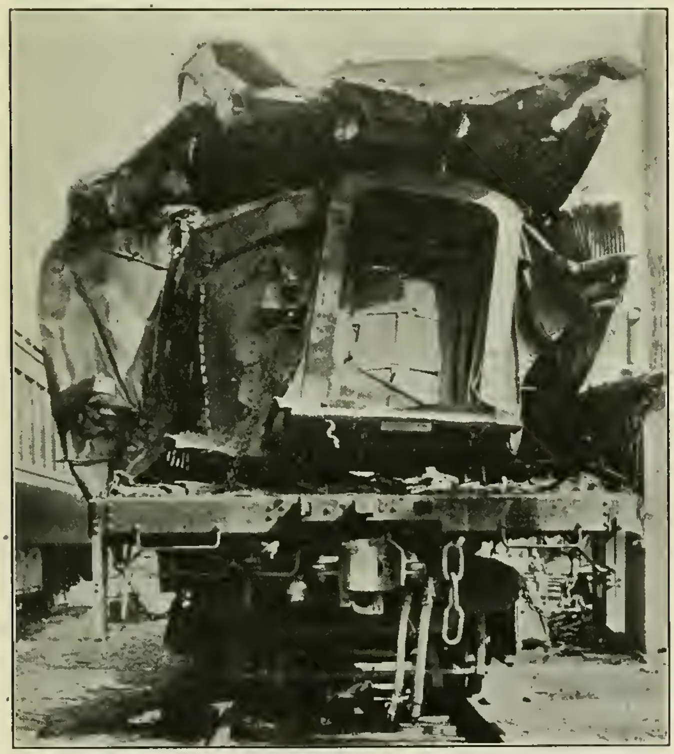
Use of Wire Cable Proposed as Remedy

Manifestly the material best adapted to meet the above requirements is *wire cable.* The manner of introducing the wire cable in a car structure may vary considerably. One form may be described as follows:

A wire cable anchored to the underframe of the car, passing through the vestibule buffer sill, up through the vestibule corner post, across the hood, down the opposite corner post, through the buffer sill to the anchorage point at the underframe.

The loop is thus distended in such a manner that the vestibule end of an invading car will penetrate within the loop. The initial shock of collision will be met as now by the vestibule end posts. When the resistance of these end posts is overcome and as the invading body progresses, the cable loop, together with the members of the invaded vestibule will be drawn in and down against the vestibule of the invading body crushing both within the confines of the loop.

The more resistant the structures thus crushed, the greater will be the energy absorbed and the greater will be the pull exerted by the cable, through its anchorage in the underframe, to impart motion to the mass.



End View of the Car Shown in the Last Illustration

The design further provides for a second group of cables, imbedded in the body corner posts and body end frame, to act as a second line of defence against the invading car. Should the force of the collision be not completely dissipated through the resistance of the vestibule end posts and the cable in the vestibule end, the invading car body will next encounter the high resistance of the body end wall, and the second group of cables will come into action upon being encountered by the invader. The second group of cables being also anchored to the underframe and distended in loop form will also draw the structure of the invaded car down and in upon the invader and similarly impart motion to the mass. This second group of cables will also act to draw downward and inward the roof and sides of the invader.

The size and number of the cables and the number of groups or lines of defence can be increased until all reasonable doubt of their collective ability to arrest an invading car disappears.

In the absence of the wire cables, a corresponding collision would result in wedging apart the invaded structure with comparatively little dissipation of energy and imparting but little motion to the standing cars, because the energy expended in wedging aside the members of the structure is exerted at almost right angles to the direction of the invading body and consequently, results in but little forward thrust.

The arrangement of the cables is purposely such that it is impossible to bring an abrupt stress on them. They are distended in an approximately rectangular loop by members which, when subjected to collision shock, are bent and distorted by the cable which is of superior strength to any member with which it is associated except only the centersill to which it is anchored. For example the combined tensile strength of the cable loops shown in the illustration is 2,000,000 lb., and therefore equivalent to the ultimate strength of centersills having a cross section of approximately 50 sq. in. Consequently when a car body protected by cables is invaded, the vestibule of the invader will be crushed down and the zone of destruction in the invaded car will be limited to the area enclosed by the cable loops engaged.

The Final Stage of Telescoping

The complete separation of the side walls of the invaded car indicates the desirability of incorporating strong tension members in the superstructure.

Length of Path of Resistance

Thrust will be imparted to the centersills of the car in which the cables are incorporated, from the moment of impact upon the vestibule end and in a gradually increasing degree until all the cable loops are drawn in and down to a position of rest against the crumpled structure of the invading car. This prolonged and steep path of resistance is of the utmost importance.

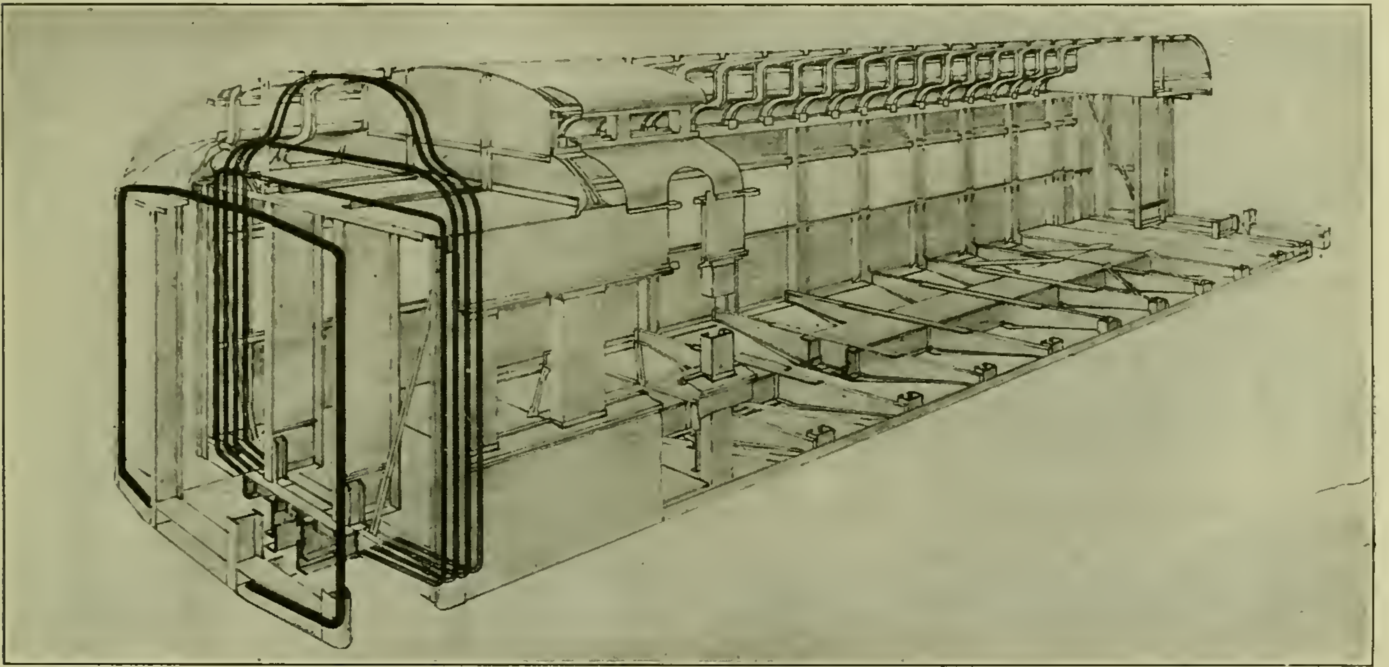
In the illustration the cable loops are shown in combination with a high girder side frame and body end reinforcement as first described. This we consider the strongest form of car body construction in use today. When completely equipped with cable loops, this design provides the following path of resistance to penetration by an invading body:

1. A rigid vestibule end wall having as high initial resistance as practicable.
2. Cable loop, enclosing the vestibule end wall and acting to retain the structural members in the path of the invading body, upon the failure of the initial resistance of the vestibule end wall.

3. A rigid body end wall including the strong piers at the doorway and the deep body end reinforcing plate, collectively over five times the section of the vestibule end.

4. The second group of cables which will act to prevent disruption of the body end wall structure and any further penetration.

The resistance effected by the cable loops is accumulative and the ultimate resistance will not be reached until the wreckage of both vestibules is compressed in a tangled mass within the confines of the loops engaged. The crumpling of the structural members within the cable loops will act to cushion the shock. The resistance will increase rapidly in a series of steps beginning with the resistance afforded by the rigid vestibule end posts and reaching a peak equal to the accumulated resistance of the four stages in the path of resistance above described. The body end structure being of much greater strength than the vestibule end structure will insure that the vestibule structure must be practically destroyed before the initial resistance of the body end structure is overcome, and the second group of cables called upon to resist further penetration. I believe that only in cases of the utmost violence will the body end of the invaded car be crushed in and the ultimate resistance of the main cables be developed. For example, in some of the complete telescoping cases illustrated the initial resistance offered by the vestibule and the body end construction of the invaded car was inadequate to prevent penetration. The secondary resistance offered by the roof structure and the interior fittings was negligible as compared to that which would have been afforded by wire cables of 2,000,000 lb. (1,000 tons) capacity which would have checked the invader at or near the point of entrance. It is my opinion, that in cases of extreme violence, and before the vestibule structures have been completely compressed, the thrust transmitted to the underframe of the invaded car, through the medium of the cables, will be sufficient to impart motion to the standing train and thus dissipate a large proportion of the energy of the collision.



Reinforced Body End with Cable Loops

We are all familiar with shock absorbers in daily use, such as rubber heels, pneumatic tires, truck springs, buffing devices, draft gear, etc. All these devices introduce a time element, or path of resistance, commencing at the instant of impact and increasing in resistance until the shock is absorbed or the device becomes solid. The introduction of the strong cable loops in the car structure, produces a collision shock absorber which may be compared to a buffing device in which the maximum length of path of resistance, or travel, is only limited to the confines of the loops engaged instead of limited to a few inches travel. Time will not permit of entering into details of the method of incorporating the cable loops in the car structure. It is the intention, however, that all the structural members be retained by the cable loops within the path of the invading body to make resistance to penetration during the time the loops are being drawn down as great as possible.

In the foregoing description of a car adapted to resist the shocks experienced in sidewiping, derailments and collisions we have naturally illustrated and described the design of car which we have ourselves evolved while guided by a close study of the collection of photographic records of accidents which we have been accumulating for a number of years. Manifestly the cable system of reinforcement can be incorporated in any adequate design of vestibule end and body end construction. I, however, believe that a car embodying the strong superstructure, with strong vestibule and body end construction as outlined above is particularly well protected against damage in accidents of the derailment and sidewiping class and further that such a car fitted with the limiting loop of wire cables as described will be as safe against invasion by a telescoping body as now seems possible.

Adjustment of Brake Power on Tank Cars

Some confusion has arisen as to the provisions of circular S. III-11, issued in May, 1919, by the American Railroad Association, Section III-Mechanical, specifying the adjustment of brake power on tank cars.. The mechanical division of the American Railway Association has issued Circular S III-193 revising the original instructions.

The original circular states that the minimum average power brake equipment should be 60 per cent of the light weight of the car, based on a cylinder pressure of 50 lb. per sq. in. In order to eliminate the confusion which has been caused by the use of the word "minimum" in connection with the 60 per cent braking power, causing some to believe there is no limit to the maximum percentage of braking power that may be employed, the paragraph in question has been changed to read as follows:

> The recommended practice of the association provides that the air brake power for freight equipment should be 60 per cent of the light weight of the car, based on the cylinder pressure of 50 lb. per sq. in.

The sketches shown in Circular S III-11 specifying the methods of making end brake connections at the cylinder lever, did not clearly indicate that the brake chain should be connected at the top of the drum on the lower end of the brake staff. In the revised circular sketches of the brake chain connections have been shown in which the proper attachment of the chain to the top of the drum or barrel is clearly indicated, and a paragraph clearly specifying this location has been added to the instructions.

Some car owners have endeavored to provide the hand brake power specified by lengthening the piston ends of the live cylinder lever to provide a hand brake connection (instead of by the method specified in Circular S III-11 and the specifications for tank cars, regardless of the fact that by so doing the equalization of the hand brake power on the two trucks is seriously disturbed. In order to cover this point clearly the following paragraph has been added:

> Cars are not in accordance with the requirements if (a) the hand brake connection is made to an extension at piston end of live cylinder instead of to the push rod as shown in Figs. 1, 2 and 3, of Circular S III-11; (b) unless the body and truck levers are properly proportioned for the percentage of brake power specified for the air brake, or (c) on which the percentage of brake power for the hand and air brake is not equal on both trucks.

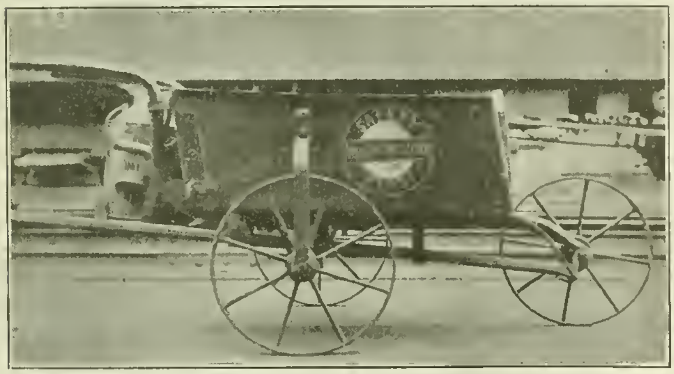
The two sentences in the first paragraph under "Adjustment of Hand Brake Power" in Circular S III-11 have been confused to the extent of considering the second sentence without regard to the preceding one, cases having been reported in which the brake power for the air brake system was less than 27 per cent of the empty car weight. To make these instructions clear this paragraph has been changed to read:

> With the body and truck lever properly proportioned to 60 per cent braking power on each truck, as specified in the foregoing, and based on the formulae and diagrams shown herein, the hand brake wheel or the hand brake ratchet lever, brake staff and chain, and the hand brake leverage between brake staff and cylinder shall be so proportioned that a force of 125 lb. at the rim of the brake wheel or 3 in. from the outer end of hand brake ratchet lever will develop an equivalent load *W* at the brake cylinder piston of not less than 2,500 lb. and 3,900 lb. respectively, for cars having 8-in. and 10-in. cylinders.

Emergency Truck for Car Repairs

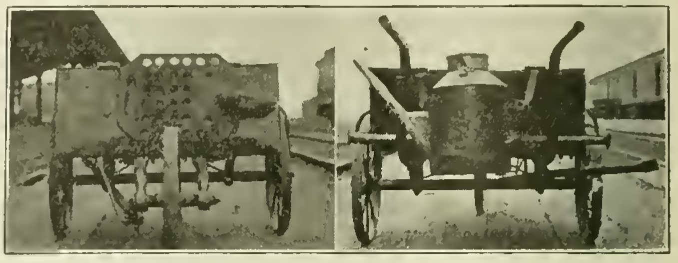
BY E. A. AUSTIN

A truck for carrying the materials and tools necessary for making light repairs is a handy device for use at passenger stations. Such devices are not widely used although they have proved a great help in expediting work. The type shown in the illustration herewith is used at Milwaukee on the Chicago & North Western. One of the advantages of the design is that it is built low enough to pass underneath cars, being only 27 in. high. This saves the time ordinarily wasted in running around the train in case the work must be done on the opposite side from that on which the truck happens to be.



A Side View of the Repair Truck

As shown in the rear view, a large oil can is carried between the handles of the truck. In the front of the body, there is a jack plate with a goose neck that catches the rim of the wheel and holds it on the rail when jacking up the box to change brasses. The long bar resting on brackets at the side of the truck answers for two purposes. One end is square for driving in wedges and the other has a point shaped like a parrot bill for throwing over the lateral of the axle or for removing the wedge in case it binds when the car is jacked up.



A Jacking Plate and An Oil Can Are Carried on the Front and Back of the Truck

The interior of the truck has five compartments. Two are used for buckets of prepared packing, one for the journal jack, one for brasses and one for blocking. It is customary to carry one block 3 in. by 10 in. by 24 in., one 1½ in. by 10 in. by 24 in., and an iron plate ½ in. by 8 in. by 12 in., which is convenient to use where there is not sufficient space to get a thicker block under the jack.

Virginian 120-Ton Cars

Among the illustrations accompanying the description of the 120-ton coal cars for the Virginian, published in the March issue, there is a plan and side elevation of the body, which appeared on page 164. Several incorrect dimensions are shown on this drawing. The distance from the center line of the body bolster to the striking plate, should be 7 ft. 3½ in., instead of 6 ft. 11 in. The distance between truck centers should be 36 ft. 1¾ in. and not 36 ft. 10¾ in. Both these dimensions are correctly given in the details of the underframe and draft gear on pages 165, 166 and 167. The wheel base of the truck is shown on the drawing of the car body as 8 ft. 8 in., whereas the wheel base of the Buckeye truck used was 8 ft. 6 in., of the Lewis truck 9 ft., and of the Lamont truck, 8 ft. 3 in.

Strikes on Southern Roads.—A strike was ordered by the labor organization on the Missouri & North Arkansas on February 27, when enginemen, trainmen, telegraphers and station agents left their work. An attempt was made to resume service, but after a time C. A. Phelan, receiver and general manager, issued a statement to the effect that service would be suspended because depredations which had been committed would endanger the lives of passengers and employees.

The Atlanta, Birmingham & Atlantic was placed in the hands of a receiver by Judge Sibley of the United States District Court, Atlanta, Ga., on February 25. Later Judge Sibley signed an order putting into effect the schedule of reductions which Mr. Bugg, president, and later receiver of the road, had urged before the Labor Board. On March 5 a strike was authorized and about 1,500 men walked out. The places of the striking employees were filled as rapidly as possible, and local passenger and freight service was resumed after a short interruption.

Draft Gear Tests of the Railroad Administration

Second of the Series of Articles Describing Investigations Conducted by the Inspection and Test Section

After measuring the test gears and reassembling them with their parts in their original positions, the 9,000 lb. drop tests were made. Except for a few gears that were added at a later date, the original series of drop tests was made at the Mt. Clare shops of the Baltimore & Ohio Railroad. After the car-impact tests at Rochester, the same gears were submitted to a second series of drop tests under the Pennsylvania Railroad machine at Altoona for check purposes.

The drop tests were in all instances made with the gears supported upon a solid anvil. Before beginning the drop tests of either of the above series each gear was given a certain amount of preliminary work to insure the proper seating of the parts. The uniform practice was followed of first determining the drop test value of each gear, by dropping the weight from 1 in. free fall and then increasing the fall by 1 in. increments, until the closing point was reached. The gear was then given 10 blows from 1 in. below the solid height, which usually resulted in building up the capacity of the gear slightly. After this preliminary work the regular drop tests were made, the tup being again dropped through heights increasing by 1 in. increments until the closing point was reached. In the case of gears such as the Harvey springs the solid point was previously determined from a preliminary static test and this point worked to in the drop test.

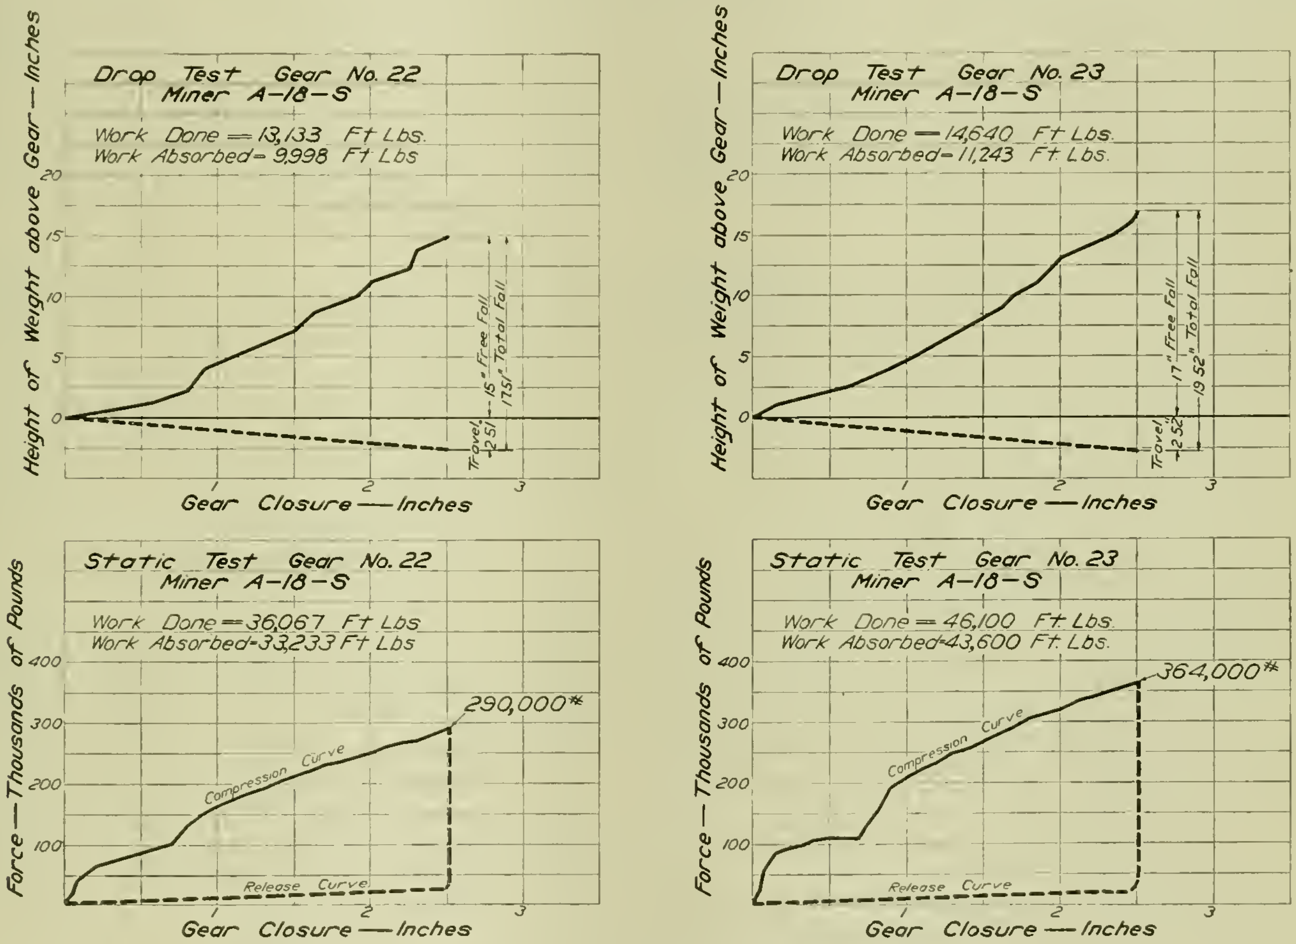


Fig. 2—Typical Drop Test and Static Test Diagrams, Miner A-18-S Gears

The information for plotting drop test diagrams was obtained during the first series of drop tests by causing the tup to drive a nail into the end of a wooden post, the penetration of the nail denoting gear closure for each successive drop. The diagrams have been plotted to the exact points recorded, with no averaging or smoothing up of the curves. The regularity of gear action can thus be seen and in such a test this is of as much, if not more interest than the general trend of the line.

Some of the drop test figures obtained in these tests are higher than usually reported for gears of the same type. The care taken to have all surfaces in good condition and the uniformity of testing conditions insures that the present results are comparable with each other. In general throughout this report the drop tests are reported in terms of "total fall," this being the free fall plus the penetration or actual travel of the gear. Some confusion has existed heretofore in this respect but it is proper to express these results in total fall rather than free fall if the true drop test capacities are to be compared.

The recoil of the 9,000 lb. weight was also measured by means of a special slide on the side of the drop machine. The quantities as tabulated are for the total recoil of the weight above the lowest point reached by it in closing the gear. The drop test capacity, foot pounds of work done, is accordingly represented by the potential energy in the weight at a height corresponding to the total fall required to close the gear. The energy given out by the gear upon release is denoted by the amount of recoil of the weight. The work absorbed is found by subtracting the energy of recoil from the "work done," or the total energy required to close the gear.

A discussion of the individual performance of the gears in the drop test follows:

Westinghouse D-3:—The action of these gears under the drop was entirely satisfactory. The initial flatness of the curves shows the result of the preliminary spring action and the curves as a whole indicate that the gear action is reasonably consistent throughout the entire range. The average total fall of the 9,000 lb. tup required to close a new gear of this type, when in good condition, is taken at 19.8 in., and the total recoil of the weight at 3.8 in. These figures are arrived at by averaging all of the drop test results for these gears, the same practice having been followed for each gear unless a statement to the contrary appears.

Westinghouse NA-1:—The drop test results on these gears are not quite so regular as on the older Westinghouse D-3 gear, but while the diagrams are more irregular, the action in general is good. The results also are considerably higher, hence it cannot be expected to find as regular action as in the lighter gear. No breakage or failure of any kind occurred during these drop tests.

Sessions K:—The drop test diagrams for these gears, while not so smooth, are yet good for a gear of such short travel. In two gears the spring barrels began to scale before the gears went solid. Failure of the gears had, therefore, begun before closure and hence the tests are not satisfactory.

Sessions Jumbo:—This gear showed considerably more capacity and at the same time more uniform action under the drop test than the previous Sessions K gear. The spring barrel of one gear developed a crack during this test.

Cardwell G-25-A:—The action of these gears under the drop was good, the diagrams being especially smooth and regular. The cast iron friction blocks formed decided depressions in the malleable iron heads, however, and a crack developed at one corner of one of the friction blocks, while in the final drop tests at Altoona one of the side friction members was broken in halves. The average drop for the test gears of this type is 21.1 in., but as heretofore explained, it is believed that these test gears are not representative, the average drop test results obtained in United States Railroad Administration acceptance tests being 16.6 in. The gear is, therefore, credited with a value midway between these figures, or 18.9 in. total fall required to close an average new gear when in good condition. The average total recoil to be expected is taken at 2.8 in.

Cardwell G-18-A:—This gear showed smooth and regular action under the drop, and the diagrams are entirely satisfactory. The springs of one gear took a slight set during the drop tests.

Miner A-18-S:—The drop tests of these gears were satisfactory and the diagrams denote especially uniform gear action for all ranges. This is particularly noticeable because of the fact that the gear has a travel of but 2½ in.

Miner A-2-S:—These gears did not show so regular under the drop as the previous Miner gears but the diagrams are good. The drop capacity, however, is low. In one gear the main spring went solid during this test.

National H-1:—This gear developed an unusually high capacity under the drop and while the diagrams are not entirely smooth, yet, considering the amount of fall and the short travel of 2½ in., the gear action is good.

National M-1:—The drop tests of these gears did not produce diagrams proportionally as smooth as those of the previous National gears, considering their lower capacity. The diagrams, however, show reasonably uniform gear action.

National M-4:—The action of this gear under the drop was very similar to that of the National M-1 just described.

Murray H-25:—These gears, while not of high capacity, showed the most regular action of any friction gear tested. The diagrams are unusually smooth and indicate consistent action throughout the full range of the gear. Considerable chafing and wear occurred during the closures under the drop. Unquestionably, this wear would soon deteriorate the gear.

Gould 175:—These gears showed good action under the drop except for the fact that in each instance the plates of the friction spring took a slight permanent set. The gears showed high recoil and because of this feature it was difficult to keep them in position on the anvil.

Bradford K:—The drop testing of these gears was difficult and unsatisfactory. The springs went solid before the heads of the gears came together and two gears failed by splitting the heads. The failures were undoubtedly due to this spring condition, as extremely high forces are set up in this, as in most friction gears, if the springs go solid before the gear is closed. One gear also developed a cracked head during the drop test. It is noticeable that the portion of the head immediately back of the coupler butt, in buffing, is not properly supported. Another serious point is that in several instances the heads pinched and stuck in the frame on release. These gears showed low capacity and high recoil under the drop, their action being very little different from that of a spring gear.

Waugh Plate Type:—These gears gave reasonably smooth diagrams in the drop test but in each instance the plates took a permanent set. The drop capacity is low and the recoil high. The gear is of especially easy movement at the beginning of its travel.

Christy:—This gear was very erratic under the drop, and the action is not at all satisfactory. The gears as tested were shorter than the pocket dimension and this clearance allowed the wedge roller to get out of position upon recoil. The total fall required to close the test gears ranges from 14.3 in. to 26.3 in. It is therefore difficult to set an average value, but in the absence of better uniformity the three results have been averaged.

Harvey 8 in. by 8 in. Springs:—Each of these gears as tested consisted of two Harvey 8 in. by 8 in. springs, set side by side upon the anvil. The gears showed but little capacity under the drop, although the action was regular. In the case of one gear the springs took a slight permanent set.

A. R. A. Class G Springs:—Each of these gears as tested consisted of two A. R. A. Class G springs, set side by side upon the anvil. The springs showed low capacity in the drop test, but the action was smooth throughout the range of the springs. A summary of the data obtained in the drop tests is shown in Table I.

Static Tests

Immediately upon the completion of the drop tests the same two gears of each type were closed in a testing machine at a speed of ⅛ in. per minute. Readings were taken for each 1/10 in. of compression, the closure being continuous, with no stops except where sudden changes in load occurred.

In many gears, when being closed at a slow speed, the resistance will build up at an abnormal rate, and shortly, from some reason such as the elasticity of the parts, a sudden readjustment will occur. In many instances this is accompanied by a loud report that may be best described by use of the word "bombardment." Invariably such readjustment results in a sudden reduction of the load. When a bombardment occurred during the tests, the machine was stopped until a full record of the conditions could be obtained. In plotting the static test diagrams the actual results have been used, all bombardment actions being shown, and no curves having been averaged or smoothed out, as is frequently done in plotting such diagrams. No gear should be condemned, however, solely because of the presence of bombardments or irregular action in the static tests, for some gears, while showing very irregular static diagrams, and even total failure in this slow test will yet show excellent results in both the drop test and the car-impact tests. Bombardments are conceded to be a normal action of many types of gears in slow static testing.

Table II—Comparative Ultimate Resistance of Gears in Static, Drop and Car Impact Tests

The car-impact tests show that when cars are coupled at a velocity of four miles per hour, each of the two opposing draft gears begins to close at a rate of 2112 in. per minute (176 ft. per min.) and that the closing rate gradually falls off until it is zero at the point of maximum gear closure, this corresponding with the point where both cars are of equal velocity. The average rate of closure at four miles per hour impact is approximately 1400 in. per minute; the static test rate of ⅛ in. per minute exists for less than 1/100 in. of gear movement. Results of slow static tests cannot, therefore, be compared with service or impact tests. The static is the simplest and the easiest draft gear test to make, and it is probably understood by the average mechanical man better than any other. It is unfortunate, therefore, that it is not more reliable, but as will be seen as the various tests are discussed, it is usually misleading and cannot be employed for comparing the merits of different draft gears.

The practice of rating gears upon a supposed ultimate resistance such as, for example, "a 200,000 lb. gear" or "a 350,000 lb. gear," is to be discouraged. Due to the limited travel of draft gears it is necessary that the ultimate resistance of the gear be high if cars are to be handled at switching speeds above two miles per hour. The manner in which this ultimate resistance is reached is of great importance. It will be seen in some of the static cards that while the ultimate resistance is high, yet at the beginning of the diagram it is extremely low and becomes really effective only during the last quarter of the diagram. This means not only that the gear is of low capacity for its ultimate resistance, but that the final rate of building up the force is too high and will set up undesirable vibrations in the car structure. The ultimate resistance of a gear cannot, therefore, be wholly indicative either of capacity or of cushioning value, capacity being a product of the average force and travel, and cushioning being dependent upon the rate of building up of the force as well as the magnitude of the force itself.

Static test diagrams were plotted for closures at the rate of ⅛ in. per minute. The same gears were also partially closed at the rate of ¾ in. per minute and at an average rate of 3 in. per minute, for comparison. These three closures were made in immediate succession so that the condition of the gear had not changed.

Because of the fact that the results of static tests are not indicative of the action of the gear under service conditions, the discussion of the individual performance of the gears in the static test, which was included in the report, will be omitted. The results of the tests are given in Table II. For comparison there are shown also the results obtained in the drop test and later in the car-impact tests. Part of this table requires some explanation.

Column 3 gives, for a closing speed averaging 3 in. per minute, the ultimate or maximum resistance of the gear at the point where the gears just closed or where normal gear action ceased. Columns 4 and 5 give the ultimate resistance, at closing speeds of ¾ in. and ⅛ in. per minute. An asterisk (*) in any of these columns denotes that the maximum resistance as tabled was developed before the gear was closed, a bombardment or other cause reducing the resistance at the point of closure. It will be understood that the capacity of the testing machine would not admit of complete closures at the 3 in. and ¾ in. speeds. The results have been extended proportionately, however, so that the tabulated results represent complete gear closures.

Table III—Performance of Gears with Coateo Friction Surfaces (Drop Test)

		Total fall in inches of 9,000 lb. weight to close

Column 10 gives a computed resistance for the drop test. This figure has been obtained by proportioning the resistances to the foot-pounds of work done in these two tests. Thus in gear No. 1, the static test at ⅛ in. per minute gave an ultimate resistance of 190,000 lb. with 18,434 ft. lb. of work done. In the drop test the work done was 13,875 ft. lb.; hence on the same basis the ultimate gear resistance is 143,000 lb. The figures in this column, therefore, although purely hypothetical, are of interest. If the static card is indicative of the dynamic force curve, then the results in Column 10 are approximately correct, for inasmuch as the one leg (gear travel) is the same in both diagrams, the other leg (resistance) should be roughly proportional to the area, or work done.

The resistance figures given in this table represent a variety of speeds and conditions of gear closure, the static closures being at a constant speed and the drop and car-impact closures beginning at a high speed, which gradually reduces to zero at the point of maximum closure. In the car-impact tests, with a gear in each car, the gears begin to close at a speed not less than 1056 in. per minute at two miles per hour impact, or 2112 in. per minute at 4 M.P.H. impact. In the drop test, with a 15 in. free fall, the gears begin to close at a speed of 6458 in. per minute or 9130 in. per minute at 30 in. free fall.

9,000 Lb. Drop Tests—Friction Surfaces Coated with Foreign Material

It has been repeatedly noticed when taking down gears in car repair yards that the friction surfaces, while usually worn to a good bearing contact, are not in the same clean and perfect condition as that of protected test gears. On the contrary, there is frequently found an actual coating or glazing of hard, black material that can sometimes be scraped off with a knife. This is probably an accumulation of particles of metal, coal dust and rust.

In order to obtain some knowledge of the effect of foreign material upon the friction surfaces, one of each type of gear was taken apart, after completing the original drop and static tests, and the friction surfaces were dampened and sprinkled with a mixture of pulverized coal and iron rust. The gears were then reassembled with the parts in their original positions and the dampness allowed to dry out. Each gear was then put under the 9,000 lb. drop and the closing point determined in as few blows as possible, and the gear then given 12 blows at or just below the closing point.

The gear was then taken apart and the free material wiped off with clean waste. In almost every instance the friction faces were now found to be covered with a hard, glazed coating similar to that found in service. This was removed with clean, sharp sandpaper and the surfaces again wiped off with clean waste. This in every instance left the friction surfaces in as perfect looking condition as could be desired. The action of the gears immediately after this is therefore especially interesting, as in almost every case the careful cleaning of the surfaces did not increase the capacity, and quite a number of blows were required to restore the gears to their original capacities. In several instances it was impossible to entirely restore the gears. Any gear might by this method be made to show an extremely low capacity, even though all parts of the gear were of full size and to gage and the friction surfaces apparently in perfect condition. At the same time, an inferior gear could be in apparently no better or more favored condition and yet show decidedly higher results. Table III. has been prepared to show the results of this test.

Car Inspectors and Foremen Propose Changes in Rules

Members Recommend Revisions in Interchange Code for Consideration of A. R. A., Division V.

At a meeting of the Executive Committee of the Chief Interchange Car Inspectors' and Car Foremen's Association of America, held at the Hotel Sherman, Chicago, March 3 and 4, proposed changes in the A. R. A. rules of interchange were taken up, thoroughly discussed and many of them approved for the consideration of the proper committees of the Mechanical Division of the American Railway Association. At the annual meetings of the Executive Committee, held for the purpose of discussing and recommending changes in the interchange rules, it has been customary for members of the Executive Committee only to vote. This meeting, however, was attended by about 100 members of the association, and a motion was adopted that all members be permitted to vote. The meeting was called to order by J. J. Gainey (Southern), chairman of the Executive Committee, who presided at all the sessions.

Elimination of Delivering Line Defects

One of the outstanding features of the meeting was the resolution presented by C. J. Wymer, superintendent car department, C. & E. I., recommending that the rules of interchange be revised to eliminate all delivering line defects, making the owner responsible for all repairs except those due to accident; that the standard prices for labor and material be fixed high enough to afford the repairing line a substantial profit, and a per diem or rental charge be fixed high enough to reimburse the owner for his investment and the cost of maintenance.

Mr. Wymer's resolution, which was offered at the beginning of the first session, after being discussed at length, was revised by a committee, and finally lost by a vote of 32 to 16. The resolution, as revised by the committee, is as follows:

> Whereas, The present interchange code of rules of Mechanical Division V of the A. R. A. in our opinion does not meet present day requirements for handling and maintenance of equipments, and does not sufficiently facilitate the movement of traffic; be it therefore
>
> Resolved, That these rules should be revised, eliminating all delivering line defects, making all necessary repairs chargeable to car owners, except badly damaged cars due to accident on which a limit of repairs chargeable to owners should be provided. A limit to the cost of repairs due to owner's defect should be maintained, owner to advise disposition of car within a specified time, this time to be determined.
>
> Resolved, That the prices for labor and material should be sufficient to afford the repairing line a substantial profit.
>
> Resolved, That if the changes recommended are adopted, the per diem or rental charge should be sufficient to insure the car owner a fair return on investment, which would include interest, taxes, insurance and depreciation. Per diem or rental should include cost of maintenance.

The motion to adopt the resolution was seconded.

A. Herbster (N. Y. C.): This will automatically do away with defect carding. It will eliminate a whole lot of our troubles that we have had in the past. I have not heard anything from Mr. Wymer regarding fire damage, and nothing has been brought up regarding cars being in a flood. On the whole, I think his resolution is a very good one.

A. Kipp (N. Y. O. & W.): It looks to me as if there is altogether too much money involved at the present time to have the railroads of this country adopt any such system. We have not gotten to the point yet where the car owner wants to be, and will be, entirely responsible for the repairs to his cars. Until that time arrives or our equipment is in different shape than it is today, I do not think that a resolution of this kind would be considered by the Arbitration Committee.

F. H. Hanson (N. Y. C.): I think it is a move in the right direction, although probably we are a little hasty in recommending to the extent that Mr. Wymer has suggested. I believe certain modifications should be made in order that our superiors and the Arbitration Committee may sit up and take notice, because there seems to be a tendency now instead of changing a rule now and then each year and making the car owner responsible for more defects to do the pounding all at one time.

J. J. O'Brien (T. R. R. A.): Mr. Wymer, no doubt, has given consideration first to Rule 1, which we all know in the mechanical department no railroad in this country is living up to. Without conforming to that rule, all of the other rules do not fit in. It is very unfortunate that rules which have been gotten up by the Master Car Builders' Association, with good intentions and a spirit to carry them out, cannot be lived up to because of the lack of men and facilities necessary to keep the equipment up.

We have to take another point into consideration. The Car Service Section has formulated rules on the theory that Mechanical Division rules are not going to be conformed with, and, as a result, there is a conflict and always will be. The Car Service Section imagines that all cars are fit for service, and, in reality, approximately 75 per cent are defective and not fit for the commodity for which they were built.

Probably some modification could be made to that resolution, but the intent is good, and it is food for thought for the Arbitration Committee.

C. J. Wymer: It will be observed that the third section of this resolution provides a per diem or rental charge sufficient to protect the car owner which should remove the objection made by some of the members who have spoken. The first section would have the effect of saving an immense amount of stationery, time of car inspectors, time of clerks and time of officers which is required in carrying out the present provisions of our rules and in settling the controversies which arise under them. This labor could be expended in more substantial ways, and the officers, as well as clerks, could give their time to more important duties; the car inspectors could devote their time to repairing more defects and looking for defects which are vital. In interchange the car inspector is more interested in finding the defects which may penalize his railroad with a defect card than he is in finding the things which might cause an accident on your railroad. I believe the inspection should be confined to providing for the safety to train men, safe handling of the equipment and protection to the commodity. No doubt much of the time of inspection could be eliminated. Forces could be reduced because of the time now consumed in making all of these records for protection purposes.

The portion of the resolution relative to the charge for labor and material being sufficient to provide a substantial profit for the repairing line would effect better maintenance of equipment. The owning road would be interested in keeping its cars in repair and thereby preventing the expense which would be involved if repaired on foreign lines. On the other hand, it would be an incentive for the railroad which had a foreign car on its line needing repairs, to make the necessary repairs in order that it might avail itself of the profit. It would also have a tendency to improve the construction of equipment so that it might be maintained at the minimum cost.

The provision for the per diem charge is an absolutely necessary feature in order to protect the company owning the cars. Otherwise there would be no incentive to own cars; it would be profitable to operate with the other man's cars, and it would work a material hardship on the large car owner who would necessarily have to be protected in a regular charge. I brought out in the resolution that the private ownership of cars should be equally protected in the way of return for the use of their money.

A. Kipp: Mr. Wymer speaks of the rental or per diem charge reimbursing the car owner for these repairs that he is going to make the car owner responsible for. At the same time he speaks in his resolution of the price for labor and material, encouraging the foreign line to make repairs. If the per diem is sufficient to take care of all of that for the owner, I cannot see where the incentive is for a road to take its neighbor's car into its shop and thoroughly repair it. While the car is being repaired, the repairing line is paying the owner a rental charge sufficient to take care of any repairs that may be made. Today the roads of the country are pretty generally trying to get rid of the foreign cars on account of that per diem charge. If a road pays that $1.10 per day for 100 or 150 days and then makes $100 or $150 worth of repairs to the car, I can not see where the repairing line is going to get very much out of it.

F. W. Trapnell (Kansas City, Mo.): The railroad without any cars would fare mighty well against one that had a lot of cars. It seems to me in order to go into a deal of this character, it would be necessary to equalize the equipment of the country between all lines. Parts of our country have more business than they have cars to handle, and the roads are using everybody's cars. It seems to me that if everything was made the owner's responsibility and, covered in a per diem charge, it would be hard for those roads to do business.

J. P. Carney (M. & C.): I favor the idea personally, but I think we should go at it more moderately. I think the day is coming when all of the repairs will be thrown into a pool and pro-rated on the basis of the number of cars owned by the different railroads. As a matter of fact, we are all spending a lot of money, and when we get through one hand washes the other if we are honest in the matter. I would be in favor of making everything the owner's defects with the exception of Rule 32.

C. J. Wymer: Mr. Kipp mentioned this incentive. I am not surprised at that point being raised, but the two departments are separate, and I believe the mechanical department would take advantage of the opportunity of repairing cars at a profit. As to the great stock of material, I do not think that affects the matter any more than at present. The change in the rules does not obligate a railroad to carry such stock any more than they do now.

Mr. Trapnell seems to have overlooked the fact that the per diem or rental charge would pertain to large car owners, which I intimated was absolutely necessary to be provided along with this change in the interchange rules.

Mr. Koeneke (Indiahoma Refining Company): What does this committee expect to do with privately owned equipment under a report of this kind. You speak of per diem while a private car moves under mileage.

H. W. L. Porth (Swift & Co.): The resolution embodies the word "rental" which would mean mileage.

The motion to adopt Mr. Wymer's resolution was lost.

M. W. Halbert (Chief Inspector, St. Louis, Mo.): The following recommendation for changes in A. R. A. rules, Mechanical Section III, was adopted at the meeting of the St. Louis Car Foremen's Association on Tuesday, March 1:

Rule 2, Paragraph 2—Change to read as follows:

"Empty cars offered in interchange for loading must be accepted if in safe and serviceable condition, receiving road to be the judge. Owners must receive their own cars when offered home for repairs at any point on their line, and foreign cars previously delivered by them at the points where originally delivered, subject to the provisions of these rules."

Eliminate paragraphs F to G, inclusive.

Reasons: It is felt by an investigation of actual conditions that by placing responsibility for transfer on the receiving line, many less cars will be transferred and more cars will be repaired under load without the necessity for transferring.

Eliminate paragraphs I and J.

Reasons: Unnecessary if recommended change in second paragraph is adopted.

A motion to recommend the proposed changes in Rule 2 was made and seconded.

A. Herbster: The chief joint inspector has this proposition under his thumb. If he does not want a car transferred he makes the receiving line repair. I do not believe the change of this rule will eliminate any transferring.

M. W. Halbert: I am not putting these rules up from the chief inspector's standpoint; I am putting them up for the Car Foremen's Association of St. Louis. The recommendations will eliminate a whole lot of trouble that you are having at large interchange points.

J. P. Carney: I would like to ask what that trouble is.

M. W. Halbert: As long as you pay a man for transferring a car, he can transfer for most any technical defect that could be repaired under this resolution.

J. J. O'Brien: We all know that inspection of cars is not made prior to delivery as it is upon receipt. Every one figures he will pass it to his neighbor regardless of the condition. Penalization has never accomplished anything, and the Master Car Builders, as the years have gone by, have decreased the penalization until they have gotten to the point now that the principal penalization is like Rule 32 and the transfer.

This transfer system in vogue at present has decreased the repairs to equipment and placed the responsibility mostly on the traffic or transportation department. The methods generally pursued of transferring rather than attempting to repair has resulted in less facilities and less men engaged in repairing. If the transfer of cars was placed under the jurisdiction of the mechanical department we know that the mechanical department, before it would transfer a car, would exercise good judgment and repair at least seventy-five per cent of the cars being transferred today. I know of a line that has reduced its transfers by placing them under the Mechanical Department, from fifty to seventy-five per cent. I am heartily in favor of this proposed resolution.

J. P. Carney: I agree with Mr. Halbert, but I believe there ought to be something more in the proposed change. We are paying a lot of money for interchange inspection and supervision that some roads are ignoring entirely. You deliver an empty car that a chief joint inspector says is all right and another road will return it. We have delivered cars for a certain load and have called in an outside party who said the cars were all right and the receiving roads have said they were in bad order and have returned them. We ought to change that rule to read so that we can get the chief joint inspector or his assistants to decide whether that car should be returned to the delivering road.

A. Herbster: If we figure on this change in the rule the A. R. A. will have to change Car Service Rule 14. They are the ones that place the responsibility for cost, not the mechanical department. The mechanical rules only tell us when we can transfer a car, therefore I do not believe that the resolution is in order.

Secretary Elliott: The mechanical division tells us when we can transfer a car and get paid for it, not when we can transfer it. That resolution takes out the feature of getting paid for it. If you want to transfer it, that is your own business.

M. W. Halbert: A great amount of money is expended every year on claims. Every time you transfer a car, no matter what commodity it is loaded with, you have a claim. I have heard it said that there were over $105,000,000 worth of claims paid in 1919. Why not make the necessary repairs if possible and let the car go forward instead of transferring it and getting the claim presented against you, or holding the car up and making the delay?

C. M. Hitch (B. & O.): Nothing has been said so far relative to the loading line loading rotten cars to offer to his connection. When you make the receiving line responsible for the cost of transfer it is more an incentive to cause a bad car to be loaded and imposed on the receiving line than it is to have the delivering line responsible for the transfer. I do not agree with the move to make the receiving line responsible for the cost of transfer; neither do I agree with Mr. Carney's suggestion to change Rule 2 to give the joint inspector sole authority to return empty cars. I believe the A. R. A. will continue to have the receiving line the judge as to what it will accept and run over its railroad.

A. Kipp: I heartily agree with Mr. Hitch so far as the delivering line is responsible for the transfer. Mr. O'Brien said that if the mechanical department was responsible and made to transfer the cars it would make fewer transfers. That is one of the arguments that our operating department put up to the motive power department. After quite a fight they put the transfer of cars over onto the motive power department. We are keeping a very accurate account of the transfers and find now that we are transferring even more cars than we were when the operating department was transferring. The rules strictly specify what defect shall be repaired under load and the A. R. A.'s tell us for what we can transfer and have the delivering line pay the transfer. We should cut down the transfers as low as they can possibly be cut down. That is what we are doing on the road I am with. We are not transferring anything that can be repaired under load, whether it is a reparable defect under load or not. We pay no attention to that whatever. Our foremen all have instructions that if the car can be repaired under load to repair it.

J. J. O'Brien: There should be more cooperation between traffic and mechanical departments. All of the loaded cars originated through traffic and solicitation, on the theory that the cars will move to destination. If the car passes through a territory where they have good facilities and men to keep it in repair, it proceeds. If, however, the car goes along a line where they have no facilities or men, it is transferred. The railroads today are willing to accept freight in a wheelbarrow or by wagon load; when they get it by the car-load, simply because they haven't the facilities to make repairs, they want to transfer.

A. Herbster: I think Mr. O'Brien is putting the mechanical department in the wrong light. We all know that some cars must be transferred because they cannot reasonably be repaired under load, and that will go on as long as the railroads run. But I do not believe any road is doing the transferring on a wholesale order. I know it is not done on any point with which I come in contact. If we come up against a localized condition, that ought to be remedied at the point where it is happening. I cannot see that the change of this rule will change anything.

W. K. Gonnerman (B. & O.): The railroads are equipped at various points to handle the repairs under load. I know we are and I believe each railroad is in the same position. I am opposed to eliminating the penalties for transferring.

P. M. Kilroy: I am in favor of the change recommended by Mr. Halbert: It is true that the matter is under the chief interchange inspectors at all of the large interchange points, but you would be surprised if you were to follow up each one of those points and see just what a variation there is. Every car transferred at the present time is an absolute waste. Even the railroad that gets paid for the transfer is losing money, especially if that railroad is letting their transfers out on contract.

I have tabulated the number of cars transferred at the large interchange points during the last six months of 1920 and it is astounding to see the difference. Some points exceed others by over 2,000 per cent. At one interchange point, I am glad to say there were only forty cars transferred and those forty cars represented twenty-eight different railroads, so the rotten condition of the equipment that has been loaded is not confined to any particular railroad, to any particular section of the country or to any particular type of car. At least one of the cars that was transferred was built during the Railroad Administration period. Out of 25,000 cars interchanged at one point under load, there were 24 transferred. Out of 22,500 interchanged at another large point, there were 40 transferred. Out of 25,000 at another very large interchange point, there were 394 transferred and some 76 or 78 adjustments. They were all handled under the same ruling. The cars moved practically toward the same points. There are a great many railroads at the present time that are transferring cars to save per diem.

At least two cases that came under my observation within the last month will bear repeating. One car was transferred at the St. Louis gateway and the road doing the transferring had to pay a claim of $118 for damage to the freight they transferred. There was another case which you might think was caused by carelessness. The railroad doing the transferring was presented with a claim for $1,550.

If this change proposed by the Car Foremen's Association of St. Louis will make for uniformity and tend to eliminate any of the things that I have mentioned, it is a step in the right direction.

C. M. Hitch: I have had experience where we had so-called repair transfer at receiving line's expense and it did not lessen the transfer at the particular points involved, but increased and encouraged the loading of undesirable equipments. I am not in favor and never have been in favor of imposing on receiving line the cost of transfer for the reason that I do not feel they are transferring cars for fun. I do not see that they make a dollar in transferring cars; it is for the protection of the property at stake.

P. M. Kilroy: Unquestionably nobody wants to tell any railroad what it shall handle. The receiving line should be the judge of what it shall run. But I most certainly do know that transfers are not being made from a safety standpoint only. If you want to go on the ground yourself and look into it, you will know that the transfers are being made on purely technical grounds to avoid the running of the other fellow's cars. Let us assume that the receiving line takes a car and moves it up to one of their repair tracks and they find that the draft bolts are broken. They have either got to transfer that load or apply the draft bolts. If they apply the draft bolts, they get paid for it; the owner is responsible. But doesn't the line handling that car also reimburse for removing and replacing the load to apply the draft bolts? They are sending those cars back at the interchange point and a great many of them are doing this transferring for the reason that they have no facilities for making the repairs and they are taking advantage of the transfer rules to get those cars off their rails.

Mr. Owen (C. I. I., Peoria, Ill.): We have a small interchange at Peoria and we have a special agreement that the receiving line is responsible for repairs that can be made within twenty-four hours of A. R. A. labor. I believe that would be a good thing to incorporate in the A. R. A. rules. We are not having any trouble and we are transferring only for safety.

H. W. L. Porth (Swift & Co.): It seems to me the elimination of paragraphs F to G inclusive is a radical move. Possibly parts of those paragraphs should be eliminated but the elimination, for instance, of the first two clauses of paragraph F would be rather drastic. The elimination of clauses four, five, six and seven will be also.

M. W. Halbert: If the resolution is adopted, of what benefit would paragraphs F to G be? Eliminate the whole business.

C. J. Wymer: The thing I fear in this resolution is the lack of attention given to the condition of cars before loading. We might find that our transfers would increase rather than diminish.

The first sentence in paragraph 2 of the rule is changed by the insertion of "for loading." I do not see that that improves it in the least as they must be accepted now whether they are loaded or empty. This only provides for the acceptance of an empty car for loading and there is nothing said about the car that might not be for loading.

Secretary Elliott: The Car Service Rules take care of the good cars; we are only legislating for the bad order cars. That would be taken care of under the Car Service Rules.

Chairman Gainey: Mr. Hitch says that this allows for the loading of bad order cars and the giving of them to the other men. We are not going to load bad order cars and haul them over your own lines to give them to somebody else. I want you to bear that in mind before you vote. The man that is loading a car is for safety first all of the time if he is living up to what he should do for his country.

C. M. Hitch: I wish that I could feel that all lines would do that, but they do not.

T. P. Carney: There are a lot of roads that get cars that do not want to run a foreign car and they won't do it. If they have a draft bolt broken they call on the chief interchange inspector to give them a transfer and he has to do it under the rules. How can he get out of it?

W. J. Stoll (C. I. I., Toledo, Ohio): In Mr. Halbert's resolution he said that empty cars that have previously been delivered must be received back, subject to the provision of the rules. I do not believe in that. If you give the delivering line a chance to load the cars in bad order, then try to compel the receiving line to run it, he cannot get rid of it until it is empty. I am opposed to that part of the resolution.

P. M. Kilroy: I do not like the insinuation, either implied or direct, that anybody here is going to operate a car over their railroad that is liable to cause an accident. Some of us know that there are a great many transfers that are unnecessary. The railroad that I represent has a record of loading a car and moving it into St. Louis, taking it South, loading it and moving it back as many as five different times and it had five transfers issued against it. I think the car is still running. Would you call that necessary? I am trying to look at this thing from a revenue standpoint.

A. S. Sternberg (Belt Ry. of Chicago): Cars are in bad condition and it is generally conceded that there is occasionally a bad car sent in, but cars placed in industries are inspected very thoroughly. I know they are on our railroad and I believe they are on all railroads in the city of Chicago. None is loaded unless it is fit to carry the load. Why is it that a car will pass over two or three different railroads with a little defect, possibly with a split center sill with draft bolts good. go on another road without any trouble, the defect not being any worse than it was when it originated, and then be transferred against the delivering line? There are a lot of those transfers every day. The change proposed by the Car Foremen's Association of St. Louis will eliminate all such trouble. I believe there are more cars transferred today than during Government control, when the receiving lines did the transferring at their own expense.

A. Kipp: I do not believe that anybody is transferring cars that ought not to be transferred or that are safe to move over their lines. In all of the argument that I have listened to, this condition seems to exist at one particular point and that seems to be St. Louis. I do not see what we have to do with this transfer cost anyway. If we did anything, we should simply modify Rule 2 and say that we can make more repairs under load. The A. R. A. says who will be responsible for the transfer of the load after we tell them what defects we can repair under load. If we have not enumerated enough defects reparable under load, let us add some more.

I move that this resolution be laid on the table until our next regular meeting for discussion.

The motion was seconded.

H. W. L. Porth: There possibly may be trouble, not only in St. Louis, but in a lot of other points where railroads are transferring cars where they have no license to. I personally know that it is being done. But I agree with Mr. Kipp that they should increase rather than decrease the defects that should be repaired under load. If you eliminate paragraph F, aren't you going to decrease rather than increase them?

M. W. Halbert: If the receiving line were responsible for the transferring of the load, of what benefit would paragraphs F to G inclusive be to the receiving line? It is optional with the receiving line to make those repairs or any repairs they can possibly make without the transfer.

Chairman Gainey: I was on a committee for a week that checked up a terminal—every road in that terminal. There were fifty per cent of the cars sent in at the transfer that should not have been transferred. In one of the terminals which I visit, our transfers will run about fifty cars a month, with just as many if not more railroads than another terminal that I visit where we have eight and nine hundred transfers a month. There is something wrong when you get from fifty to nine hundred cars, with more railroads in the terminal with fifty transfers than there are where the nine hundred are transferred.

M. E. Fitzgerald (C. & E. I.): I cannot yet see how any money is going to be saved for the companies by adopting this rule. It will be a matter of education by the representatives of the various lines after you pass the resolution; they will tell their inspectors that we are now responsible for the transfer of cars and they will have to run certain cars because the transfers will not be permitted under the rule. That can be done just as well now. Tell your men that you will not transfer a car for draft bolts or certain other defects. If this resolution is adopted, there is still no instruction in the book to the inspector on what he will do.

The motion to lay on the table was lost.

The motion to adopt the proposed change in Rule 2 was lost.

J. J. O'Brien: I think the right method to use in handling this would be for this body to appoint a committee large enough to be representative of the different sections of the country, to come back this afternoon or tomorrow with recommendations of whatever corrections are necessary in this rule. I do not believe that it is proper to accept that resolution as a whole and present it as the recommendation of this body, but there are very many good points in it and there are some that have not been discussed.

One of them is right in the first paragraph of Rule 2 which outlines the delivery of a foreign car by a railroad to a connecting carrier. That has not been discussed except by Mr. Stoll.

Mr. Owen: The second paragraph of Rule 2 covers the return of cars to the delivering line after transfer or unloading if in the same general condition. If I would deliver you a car and it was necessary to transfer it and you did further damage or smashed the car up, why should I be obliged to take that car back if it is not in the same general condition? My facilities for repairing might not be as good as yours and I believe that the second paragraph of Rule 2 should stand.

On motion, a committee of 14 members was appointed to consider what changes in Rule 2 should be recommended, and report at the afternoon session.

The committee reported unfavorably on the recommendations of the St. Louis Car Foremen's Association, but, by a vote of two to one, with only three members voting, proposed that a limit of 24 man hours be placed on the repairs for which no transfer should be made at the expense of the delivering line.

F. W. Trapnell: The 24 man hours was not to include any of the cast steel parts that had to be repaired, such as bolsters or truck sides. Those will not take any part of the 24 one man hours.

Mr. Jameson (Southern): I would like to know what the committee means by 24 man hours; does it mean on the M. C. B. schedule, or does it mean in a man's judgment that he can repair in 24 hours?

C. M. Hitch: As the motion was put in the committee it was understood that the 24 man hours would be based on Rule 107.

J. J. O'Brien: The object of submitting that proposition to this body was to encourage repairs to equipment and discourage the transfer of cars that could be repaired within a limited time, and it is felt that it is the duty of the mechanical departments of railroads to assist in the movement of traffic by exerting a certain amount of hours in repairs to equipment rather than to transfer, in which they spend more than the ordinary 24 hours.

Mr. Armstrong (C. I. I., Atlanta, Ga.): Who is going to determine whether the car can be repaired within the 24-hour limit? Isn't it going to be left up to the judgment of the men who inspect the cars for transferring?

P. M. Kilroy: I believe any man in the room pretty nearly knows before he starts just how many hours he is going to get under the rules for such work.

President Pendleton: Does Rule 107 allow for repairs? If the car is under load you get an additional charge for removing the load. At points where I have been we did not consider the additional hour; we took the 24 hours as under Rule 107, but did not count the additional hour for removal of the load.

C. M. Hitch: Our chief interchange inspector and his assistants would undoubtedly have to become familiar with Rule 107 to enable him immediately to issue his transfer orders.

M. W. Halbert: We have had the 24-hour clause in effect in St. Louis and we had no trouble in handling it. If a rule like that were adopted now, all you would have to do would be to familiarize yourselves with the working hours and the cost.

A. Herbster: I do not think the proposition is understood as a whole. If I understand this rightly, any car cannot be transferred, or they will not get paid for the transfer, if the repairs consume 24 man hours or less, according to Rule 107. You cannot necessarily repair a car under the load even though the M. C. B. hours are less than 24; then what are you going to do?

A. Kipp: Suppose that it took 30 hours to repair some car and the next car we repaired in 15 hours; one hand washes the other. If you could save the transfer of a car by getting paid for 24 hours labor and you do not lose more than six hours labor on the job, it seems to me that you are ahead of the game with all of the claims that you may expect when cars are transferred. If the commodity in the car is of any particular value, there are not many instances of transfer but what there is a claim made and I believe the railroads would be ahead if they would put in even more than 30 hours.

On motion, the recommendation of the committee was adopted.

F. H. Hanson: I move that the following change in Rule 2, second paragraph, be recommended:

> After the word "defects" in the sixth line, add: "With the exception of cars having defects as enumerated under paragraph F."

The reason for recommending this change is that defects enumerated under paragraph F, Rule 2, tell us what repairs must be made under load. If that car is taken into a yard or shop and is made empty, you can take the same car out and compel the delivering line to accept the car back with those defects that the rules tell you must be repaired under load. We can see no reason why the defects that can be repaired under load should not be repaired by the handling line when the car is made empty, instead of returning it to the delivery line.

The motion was seconded.

M. E. Fitzgerald: You will have to take into consideration paragraphs I and J of Rule 2 which cover the movement of the car that is properly protected by return when empty card. Assume you run a car to its destination, you may return it if it is properly protected by the return when empty card. I think that the entire paragraph referred to in Rule 2 is out of place. It is properly taken care of in I and J.

The motion was lost.

H. W. L. Porth: Going back to paragraph F, article 3, it seems to me that ought to be changed. I think there are a good many trunk lines that pay no attention to that, even now, but this article was put into the rules at a time when cast steel truck bolsters and cast steel truck sides were an innovation. It is a standard or recommended practice now of the American Railway Association. It seems as if cars traveling under loads with defects to truck sides and truck bolsters should be repaired under loads the same as wheels. I move that it be the sense of this Association that article 3 be changed accordingly.

Chairman Gainey: There seems to be no second.

Rules 4 and 32.

Mr. Pellien (Asst. C. I. I., Buffalo, N. Y.): Rule 4, second paragraph and Rule 32, last paragraph, carding of slight damage not requiring shopping of car: In order to bring about uniform handling of defect cards for defects of this nature, this rule should be clarified or the wording modified, as at present it does not seem to be interpreted uniformly throughout the country. The word "immediate" should be placed before the word "shopping" and the words "before reloading" should be changed to "except when loaded." This would bring about uniform handling and would very much clarify the rule, making it read as follows:

> Defect cards shall not be required for any damage so slight that no repairs are required, nor for raked or cornered sheathing, roof boards, fascia, or bent or cornered end sills, not necessitating the immediate shopping of the car except when loaded, the receiving line to be the judge.

I move that that be accepted.

The motion was seconded.

M. E. Fitzgerald: Could that be construed to mean, if you had an opportunity to move a badly damaged foreign car home to the owner over your line—an intermediary line—that it would prohibit you from moving it to the owner and make you assume responsibility to the owner? You would not be entitled to a defect card unless you shopped the car.

Secretary Elliott: In that case you would card the car before you offered it home to the owner.

M. E. Fitzgerald: I must assume that the owner will shop the car, but many cars are not shopped. The cars are being carded and then reloaded. The rule should be changed but not, in my opinion, in the manner suggested.

Mr. Owen (Peoria, Ill.): The rule is not very plain. At our little point we aim to card everything that we figure has got to be renewed. There is a great difference in the judgment of the inspector whether it has to be shopped, whether it will be shopped when it gets on the home line or whether it will be loaded again. Something definite that would be thoroughly understood by inspectors of small points as well as big interchange points should be incorporated in the rule.

M. E. Fitzgerald: There should be a limit stating specifically a certain payment of damage before the car could be carded, or there should be a limit placed on the time in which handling lines would be entitled to collect on a card issued. For example, a car is carded in Chicago under load, moving South. The average car is loaded and unloaded in a certain limited time. That has been figured out. At the expiration of that time if the handling lines have not seen fit to repair that defect or found it necessary, the rule has been violated. The car should never have been carded and that card should be made obsolete. The road handling should assume responsibility.

A. S. Sternberg: There would be a bad order card attached to the car signifying that the car must be placed on the repair track. The hardship that rule brings out is something like this: We will say that the C. & N. W. might deliver a car to the C. & E. I. The latter will deliver it home to St. Louis, and will be penalized because the owner puts it in his shop and repairs it. The C. & E. I. is in no way responsible for the damage. The damage was on the car when it came from the Northwestern. I cannot see that the paragraph in itself is so misleading but there is so much difference in the opinion of car inspectors that it would be better if it were out of the rule entirely.

[An abstract of the remainder of the proceedings will appear in the May issue.—Editor.]

Relative Effect of Time and Service on Car Deterioration

During 1917 a detailed study of the conditions of rolling stock undergoing repairs was made by a western railroad system to determine the relative importance of "time and elements" and actual service as causes for the deterioration of equipment. The study included both passenger cars and freight cars. It was found that 24 per cent of the expenditure for passenger car repairs and 30 per cent of the expenditure for freight car repairs was made necessary by the effects of "time and elements."

Passenger Cars

In making detailed inspections of passenger cars undergoing repairs, the work was divided into two classes, shop and terminal or running repairs. The shop repairs were studied at the principal coach repair shop on the system by actual inspection of the conditions while the cars were undergoing repairs. A total of 83 cars were inspected while going through the shop.

In gathering data for the running repairs, the work done at two of the principal terminal points on the system, was checked during the period of one month at each place. During the two months the actual number of passenger cars receiving repairs at these two terminals was 4,492.

These two independent studies provided sufficient data from which to determine the average relationship of the various sources of deterioration, so far as each class of work was concerned independently. In order to arrive at a proper classification for all repairs it was necessary to determine the ratio of the total cost of running repairs to the total cost of shop repairs. In order to determine this the total annual cost of shop repairs at the three principal shop points where all heavy repairs to passenger cars are made, was subtracted from the total amount of the passenger car repair account. This determined the expenditure for running repairs. Dividing the total amount thus obtained for each of the two classes of repairs by the average cost per car as determined by the detailed studies, figures were determined representing the number of cars receiving each class of repairs. From these data it was determined that 10,452 cars represented the number receiving running repairs to properly balance the total of 83 cars actually checked while undergoing shop repairs. The two classes of repairs were, therefore, combined in this ratio to obtain the proper relationship of the various causes of deterioration in their overall effect.

The causes of deterioration are classified as "time and elements," starting, stopping and switching, and running. This applies fully to the draft gears, trucks and air brakes, but for the body no subdivision is made of the effects of actual service. Thus subdividing all repair expenditures, 24.1 per cent is attributed to "time and elements," 41.4 per cent to the effect of service on the car body, 16.4 per cent is due to running and 18.1 per cent to starting, stopping and switching. Of expenditures for terminal repairs alone, 1.5 per cent are due to "time and elements," 51.3 per cent to the effect of service on the car body, 26.2 per cent to the effect of running and 21 per cent to stopping, starting and switching. "Time and elements" accounts for 37.9 per cent of the cost of shop repairs, the effect of service on the car body for 38.2 per cent, running for 8.6 per cent and starting, stopping and switching for 15.3 per cent.

The table shows in detail the relative effect of these sources of deterioration on various parts of the equipment. Grouped by parts of the equipment, it is found that 64.9 per cent of all repair expenditures are for work done on the car body, 27.6 per cent for draft gear and truck repairs and 7.5 per cent for the air brake. Considering terminal and shop repairs separately, the car body receives 51.6 per cent of the terminal repairs, the draft gears and trucks receive 33.6 per cent and the air brake 14.8 per cent while of the shop repairs the body receives 76 per cent, the draft gears and trucks 21.8 per cent and the air brake 2.2 per cent.

Percentage Distribution of Cost of Passenger Car Repairs to Source of Deterioration

		Terminal repairs	Shop repairs	Weighted totals
Body—				
Inside fittings	Time and elements...	.01	6.80	4.20
	Service	21.60	25.60	21.20
Body proper	Time and elements...	0.25	31.00	19.30
	Service	29.70	12.60	20.20
Draft gear and trucks—				
Running		26.2	8.60	16.40
Time and elements..................		.....	.....	.....
Starting, stopping and switching.......		7.44	13.20	11.20
Air brakes—				
Stopping and switching................		13.6	2.10	6.90
Time and elements.....................		1.2	0.10	0.60
		100.00	100.00	100.00

Freight Cars

The sources of deterioration of freight cars were similarly classified as starting, stopping and switching, running, "time and elements," and loading and unloading, the latter applying only to the car body. The data for freight cars were gathered in the same manner as for passenger cars, the work being done at the principal shop and repair track point. A total of 487 cars was inspected in the proportion of one general, three heavy, seven medium and 38 light. The table shows the detailed classification of expenditures on a percentage basis according to the cause of deterioration, still further subdivided as between the car body, the draft gears and the air brakes. Grouped by causes, 45.7 per cent of all expenditures were required because of the effect of stopping, starting and switching, 17.1 per cent was made necessary by the running of the cars, 30.1 per cent by "time and elements" and 7.1 per cent by loading and unloading. Grouped by parts of the car, 59 per cent of the repairs were made to the body, 9.2 per cent to the draft gears, 26.2 per cent to the trucks and 5.2 per cent to the air brakes.

Percentage Distribution of Cost of Freight Car Repairs to Sources of Deterioration

Body—	
Starting, stopping and switching......................	16.8
Running	6.5
Time and elements..................................	28.6
Loading and unloading..............................	7.1
Draft gears—	
Starting, stopping and switching......................	7.9
Running	1.2
Time and elements..................................	0.1

Trucks—	
Starting, stopping and switching	17.5
Running	8.7

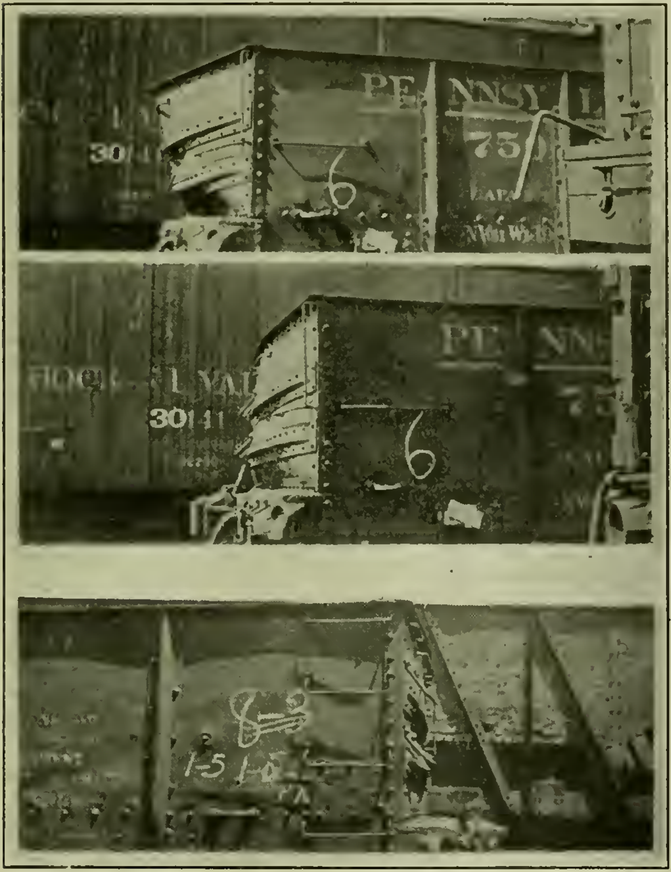
Straightening Car Ends with a Pull Jack

BY A. H. ANDERSON

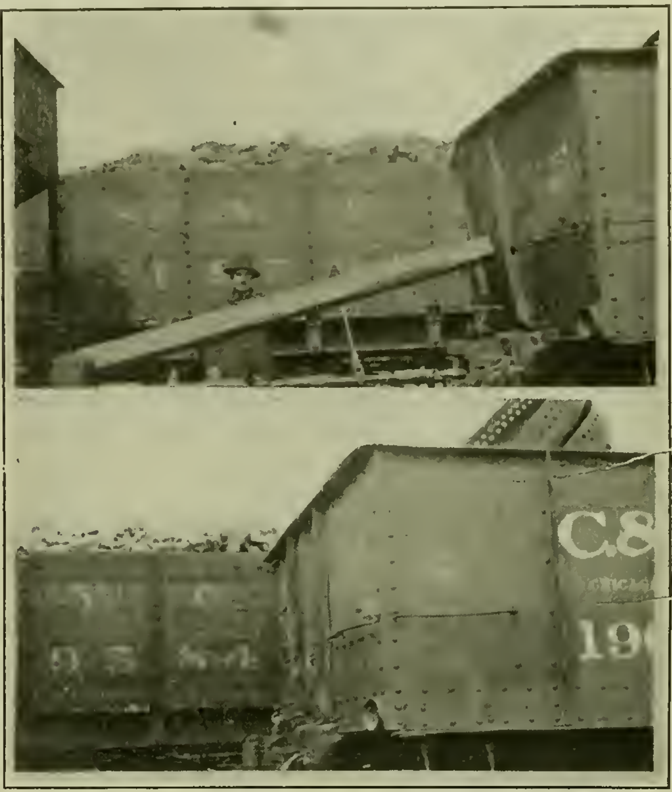
It is not generally realized that pull jacks furnish a simple and effective means of straightening steel ends without removing them from the car. Where the ends are bulged out so that they interfere with the end clearance or the efficient operation of the brake staff, particularly on cars which have the staff passing through an outside end sill, it is a simple matter to straighten them. This device can also be used for jacking in and fastening the ends on any class of car with wood or composite ends, whether loaded or empty. It is also applicable for trimming loads that are shifted over the end of the car and many other items that are taken care of on the repair tracks.



Pull Jacks Facilitate Handling Jobs Such As This

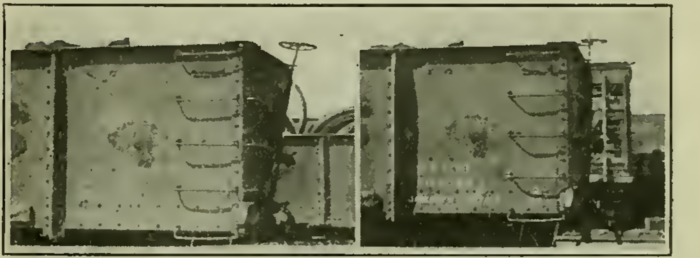
All that is needed for this class of work is a pull jack of ten tons capacity or even lighter. It is convenient to have two jacks for use when a long push is desired. In using the jacks, the knuckles are removed from the couplers on each car and the hooks of the pull jacks are placed around the knuckle pin. An oak timber of good quality, about 6 in. by 6 in., is used for pushing the end of the car, one end of the timber being placed against the bulged end as near the center as possible, or on the end brace if there is one, while the other end rests against the end sill of the other car. If the second car is loaded, the timber may be placed directly against the end. By drawing the pull jacks together, the end is forced back into place. The timber can be reset from time to time on different points until the ends are entirely straightened.

Only two men are required for this class of work. By using a ⅝-in. chain about 10 ft. long with grab hooks on both ends, it is usually possible to avoid pinching cars together and the same length timber can be used for various jobs. This method is especially useful for repairing steel ends at small repair points where there are no facilities for cutting down the parts and riveting them in place again.



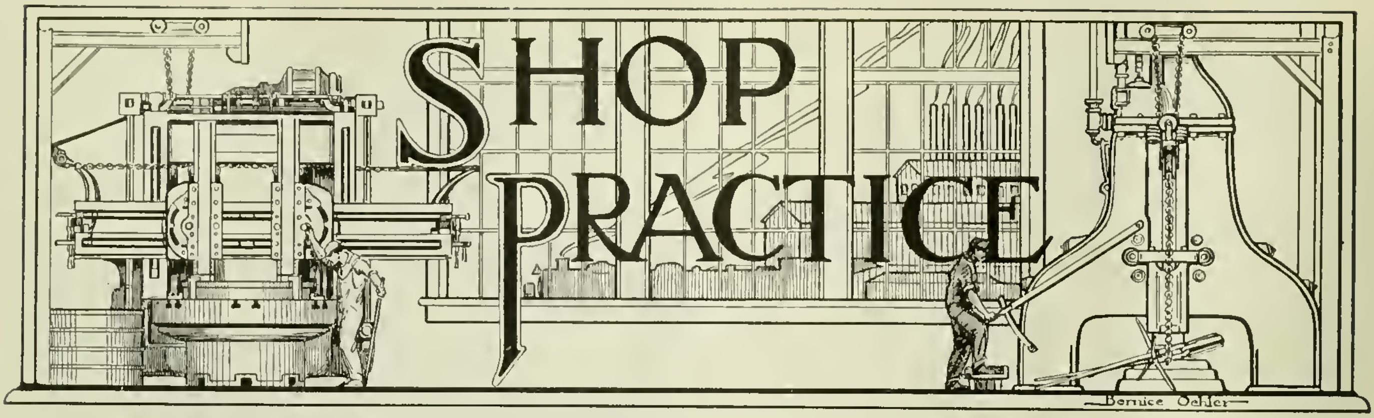
A Loaded Gondola Car Straightened Without Shifting the Lading

A few typical jobs done with this equipment are shown in the illustrations. The car in Fig. 1 was loaded with steel bars, 30 ft. long, to within 18 in. of the top. The lading was against the end of the car. By the use of the pull jack, the end was straightened to the position shown in the second view, when it was necessary to shift the load with an engine. The third view shows the end completely straightened after shifting the load. The total time required for this job was six hours for two men.



A Bulged End Repaired by Two Men in 20 Minutes

The second car shown carried a load of tank heads, 10 ft. in diameter, which were resting against the end. As shown, the end was bulged out 1 ft. at the top. The lading was pushed back as the end was straightened and all work on the car was completed by two men in 30 minutes. The third illustration shows another typical job of straightening, this being completed by two men in only 20 minutes.



Progressive Failure or Fatigue of Metals Under Repeated Stress*

BY H. F. MOORE†

If a freight car axle is subjected to a heavy overload, the ductility of the steel of which it is made allows it to bend. The axle is distorted, but actual rupture of the metal will not take place. Consider now the case when the loaded freight car is running. For every revolution of the wheels there is on every longitudinal fibre of the axle a complete reversal from tension, pulling action, to compression, crushing action. If failure occurs after the car has run many thousand miles, the action is entirely different from the bending action under a single heavy overload. Almost without warning the car axle snaps short off, and the steel behaves as if it were a brittle material rather than a ductile material. Such sudden failure under repeated loading is said to be due to the fatigue of metals, and occasionally occurs in shafting, automobile parts, airplane parts, wire ropes, band-saws, steam and gas engine parts, and other parts of rapidly moving machinery.

The Foreman and His Outlook

You are working for a large organization. You have jurisdiction over one comparatively small section of one of the several departments of that organization.

What do you know about your road—its extent, its policies, its financial condition, its operating problems, its traffic interests, its relations to the public, etc., etc.?

You say these things do not concern you! Are you sure of this? How can you co-operate intelligently with other departments if you know so little about the railroad as a whole?

Your department is not isolated; it is not an end in itself. It is one small member of the greater body all of whose parts must work in harmony and unison if effective work is to be done.

Explanations of Fatigue Failures

The apparent change in the nature of metal which fails under repeated stress gave rise to the theory that under repeated stress some profound change took place in the very nature of metal, changing ductile to brittle metal. This change was spoken of as crystallization, and it was supposed that under repeated stress, metal changed its structure from fibrous to crystalline, and as evidence the sharp crystal appearance in the fracture under repeated stress was brought forward.

In the latter years of the last century, various metallurgists began to use the microscope as a means of studying the internal structure of metals, and their work, especially that of the English metallurgists Ewing, Rosenhain and Humfrey, showed that the structure of metals is always crystalline either before or after repeated applications of load. They showed that the fracture under repeated stress was due to the spread of minute cracks, called by them slip lines, which extended completely through the crystals of the metal and which, spreading and uniting into large cracks, acted similar to minute hacksaw cuts, gradually reducing the cross section of a machine part until it could no longer carry its load and suddenly snapped off, very much as a piece of iron falls off when cut almost in two by a power hacksaw.

The starting point for one of these minute slip lines may well be some point in the metal where a minute flaw exists, either in the shape of a flaw within the metal, or in the shape of a notch or sharp scratch on the surface. We think commonly that our mathematical formulas for figuring the strength of machine parts are exact, because they involve exact mathematical processes; as a matter of fact these formulas neglect thousands of minute actions which tend to destroy material. For example, they take no account of a cutting action where a shaft rests on the edge of a bearing. Under a single load, these minute actions are of no importance; their effect is so localized that no appreciable effect is produced on the deflection of a piece. If, however, the loading is repeated thousands or millions of times, then such a microscopic cutting action may start a crack, which under repeated stress will spread to causing final failure.

Any sharp discontinuity in metal, due either to a surface defect or to an internal flaw, greatly increases the stress in the metal over a microscopic area around it. This fact has been verified both by experiment and by mathematical analysis. As an example, it may be cited that the localized stress at the edge of a rivet hole may be as high as three times an average internal stress in the metal of a plate; the stress near the bottom of a sharp notch may be five or six times as high as a stress a few hundredths of an inch away from the notch. At the danger of wearisome repetition it seems worth while again to emphasize that these localized stresses are of negligible account for structural and machine parts subjected to few loadings, but may be of the greatest importance

---

*A paper prepared under the auspices of the Engineering Foundation, the National Research Council, the General Electric Company, Schenectady, N. Y., and the University of Illinois Engineering Experiment Station, Champaign, Ill.

†Professor of engineering materials, University of Illinois, Champaign, Ill., and in charge of joint investigation of fatigue of metals.

in the case of parts subjected to many thousands of loadings.

The problem of the designer and the metallurgist is to determine limiting conditions so that this progressive failure will not occur. The usual method is to make sure that no fiber in any part of a machine member is loaded beyond the elastic limit of the material by any load which will come upon it. The difficulty of applying this rule is twofold. In the first place, the determination of the true elastic limit of metal is a matter of a great deal of uncertainty. Delicate methods of measurement of stretch and careful methods of computation give an elastic limit lower, sometimes much lower than the value given by the ordinary commercial test. Some doubt exists as to whether actual material is perfectly elastic under any stress, no matter how small that stress is. Here again it should be noted that a slight inelastic action is of no account for a structure loaded but a few times. But under load repeated many thousands of times any damage due to slight inelastic action is cumulative and actually may cause final failure. In the second place it practically is impossible to figure all the small localized stresses in a machine member, especially in an irregularly shaped machine member. Sharp shoulders or notches may cause localized stresses many times those which would be given by the ordinary formulas of mechanics.

This progressive spread of small cracks is offered as an explanation of the occasional failure of springs while under the action of light loads. At some time in its history a spring is subjected to a few heavy loads. These heavy loads start microscopic cracks and are not repeated often enough to cause them to spread far. However, these microscopic cracks are in themselves very sharp notches, and cause high localized stress under subsequent light loads with consequent spreading of the cracks and final failure. For a machine part subjected to repeated stress it may be necessary to know its history as well as the properties of the material in order to judge of its safety.

Machine for Making Fatigue Tests

At the present time the most satisfactory method to determine the ability of material to resist repeated stress is to make actual tests of it under a great many repetitions. Over a year ago the joint investigation of fatigue of metals was organized by the National Research Council under the auspices of the Engineering Foundation, University of Illinois Experiment Station, and National Research Council and was given as its main problem, the study of the behavior of a number of common kinds of steel under repeated stress. Tests are carried for several specimens of each kind of steel to one hundred million complete reversals of stress.

The machine used for the greater part of the testing is, in principle, a car axle placed upside down. A circular specimen rotates in bearings and is driven by a motor; weights are hung on it at two symmetrical points along its length. The bearings used are all ball bearing so that friction is reduced to a minimum. The suspended weights set up bending in the specimen; compression along the top side of the specimen and tension along the bottom. When the specimen rotates 180 degrees, any given longitudinal fiber changes from compression to tension, a complete reversal of stress. A revolution counter gives the number of cycles of stress. The machine runs at 1,500 revolutions per minute and operates day and night. A battery of 15 such machines now is in operation. In testing any kind of steel or other metal, tests are made on such a machine, using various weights. In this manner the number of reversals required to cause rupture is noted. It is found that there seems to be a fairly sharp limit of stress below which failure does not occur at one hundred million repetitions. Moreover, a curve plotted with stress as ordinates and numbers of repetitions for failure abscissas seems to be horizontal for this limiting stress. This stress is called the endurance limit of the metal, and is considered an index of the ability of the metal to resist repeated stress.

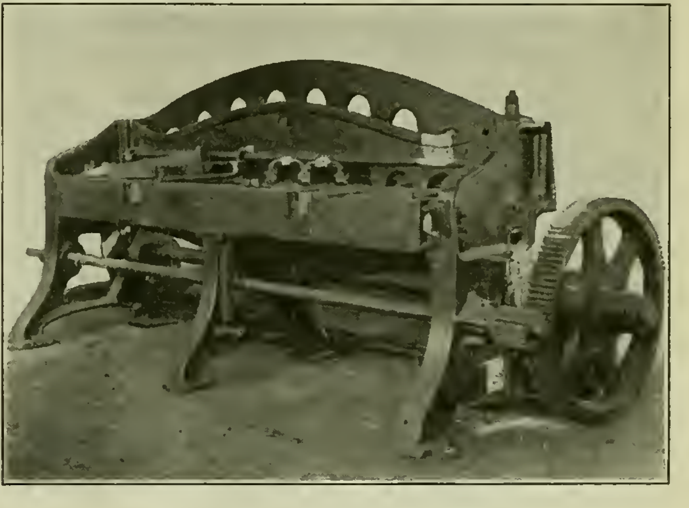
Factors in Fatigue Resisting Strength of Metals

The quantitative statement of factors affecting the fatigue resisting strength of a metal cannot be given at this time, but certain qualitative indications may be noted. Those fatigue resisting strength of metal depends upon: (1) Its elastic strength; (2) its ductility; (3) probably the amount of initial stress left in it by heat treatment; and (4) its homogeneity of structure. Possibly still other factors enter. It is evident that high elastic strength would tend to increase the fatigue resisting qualities of a metal. The effect of ductility may be explained by the fact that at a small flaw in a piece of ductile material some stretching would be found with a consequent tendency to distribute the stress over more material than in the case of a brittle material. Initial stress would, of course, tend to start microflaws when a slight additional working stress was given. It might be noted that if an ordinary testing machine test is made of a piece of steel containing initial stress, the measurement of stretch would be taken over a considerable length of the specimen and there would be a tendency for the positive and negative initial stresses present at different parts of the cross section to neutralize each other and thus to mask the first point of yielding of the specimen. This neutralizing tendency would not, however, prevent any initial stress from starting a crack when it was reinforced by a slight additional working stress. Inhomogeneity of a material is a source of weakness under repeated stress in that it permits the stresses to break down, because of the already started microflaws.

Probably many cases of fatigue failure of machine parts are blamed on the material used, when they should have been blamed on the shape of the piece or on the surface finish. In conclusion, it is desired again to call attention to the great danger of starting microflaws at the root of sharp shoulders, notches, or rough tool marks on a piece. Good surface finish and generous fillets at shoulders are vitally necessary in a design of parts to be subjected to repeated stress.

Wrecked Shear Reclaimed by Oxy-Acetylene Welding

The $3,000 metal shear shown in the illustration was broken in thirteen different places. In common parlance it was a "total wreck," and not many years ago would have been worthless except for a nominal value as scrap. In this day of modern welding, however, broken machinery of all



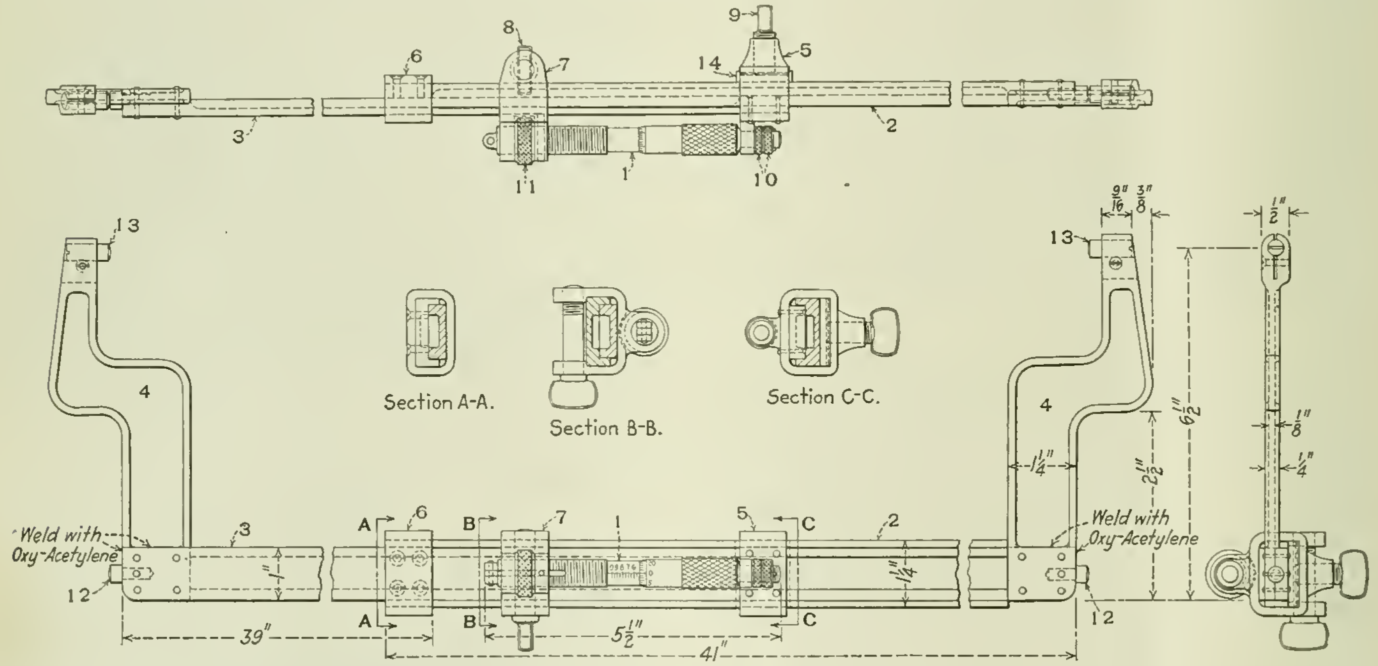
Heavy Shear Repaired by Welding

kinds can be repaired so cheaply and satisfactorily that the first thought is always for reclamation. In this instance the big shear was repaired by welding by the Oxweld Acetylene Company, Newark, N. J. No unusual features were encountered, and the job is cited only as being typical of what has now become everyday welding practice.

Gage for Calipering Driving Wheels and Tires

BY E. A. MILLER

For the accurate calipering of driving wheel tires, wheel centers and particularly the inside diameters of tires when allowing for shrinkage fits the gage illustrated has demonstrated its value. The frame of the gage is made in two parts sliding on each other, the micrometer *1* being provided to adjust the gage the required number of thousandths allowed for tire shrinkage. Parts *2* and *3* are made of axle steel to the dimensions shown, each being milled on one side to reduce the weight of the gage and provide stiffness. Part *3* is accurately planed to slide in part *2* without side motion. Two, offset, drop forged arms *4* are provided, one being riveted to part *2* and the other to part *3*. These arms are rigidly held against rocking by ⅛ in. tapered rivets in reamed holes.



Inside and Outside Driving Wheel Tire Callipers

Parts *5* and *6* are made of brass and act simply as guides for the ends of parts *3* and *2* respectively, being held in place by four ⅛-in. machine screws each. Part *5* is provided with a gib *14*, which slides along *2* and a thumb screw *9* for tightening the gage. The lug projecting on the side opposite the thumb screw is drilled to receive the 5/16-in. threaded end of the micrometer. There are two knurled, 5/16-in. nuts *10* on the end of the micrometer, a small pin preventing danger of loosening.

Part *7* is also made of brass and fits over parts *2* and *3* as is perhaps best shown in section *BB*. The thumb screw *8* is used to tighten part *7*. A ⅜-in. slot in *7* is arranged to receive the knurled nut *11* which turns on the ½-in. threaded end of the micrometer, as shown. This ½-in. end of the micrometer is split, as shown in the lower view and a ⅛-in. pin prevents turning when the knurled nut is turned. Before being split, the end of the micrometer is turned down to ⅜ in. and drilled for a 1/16-in. rivet which is applied after the gage is assembled. This prevents the knurled nut *11* from working off in use or due to any accidental turning.

Two contact points *12* which form the inside calipers are made of hardened tool steel, shaped as indicated, and turned into ¼-in. threaded holes in the respective ends of the gage. It will be observed that after the contact or gage points *12* were applied, a ⅛-in. tapered rivet was put through each to hold it against the possibility of working out. Contact or gage points *13* also are made of hardened tool steel, held in the drop forged arms *4* and forming the outside calipers. Contact points *13* are threaded and adjustable in or out, being held firmly in any desired position by means of the ⅛-in. machine screws shown.

Before proceeding to use this gage it is absolutely essential that contact points *13* be adjusted until the distance between them is exactly equal to the distance between contact points *12*. Should it be desired to bore a driving wheel tire for application to a wheel center and making the necessary allowance for shrinkage, the wheel center will first be calipered, using contact points *13*. With thumb screws *8* and *9* loose, the gage is adjusted to the approximate diameter of the wheel center. Tightening thumb screw *8*, adjustments can be made by turning nut *11* and fine adjustments by turning the micrometer sleeve. This will give the correct diameter of the wheel center. By means of the micrometer, contact points *13* can then be brought together the required numbers of thousandths allowed for shrinkage, tightening the thumb screw *9* which holds the two parts of the gage firmly together. But the distance between contact points *13* has already been adjusted equal to the distance between contact points *12*. Therefore, these latter points may be used as the inside calipers to which the tire should be turned.

Contacts points *13* can, of course, be used as outside calipers for calipering driving wheel tires whenever this may be necessary. In turning a wheel center to fit a tire which has already been bored, the operation described above is simply reversed. It is particularly important that the drop forged arms be immovable on the gage frame and as an additional precaution it has been considered best to provide oxy-acetylene welded fillets, as shown. The construction of this gage requires considerable time and accurate workmanship which, however, will be repaid many times over by the more accurate fitting of tires to driving wheel centers and the resultant elimination of trouble due to tires working loose.

A Locomotive Repair Shop Scheduling System

Foremen Are Relieved of Details and Shop Output Is Increased by Applying the Locomotive Schedule in Railroad Shops

BY GRANT GIBSON

LACK of progress in systematizing work in railroad repair shops is often due to failure on the part of mechanical department supervisors from gang foremen to superintendents of motive power to appreciate records and shop schedule systems. This is a rather pointed statement, but nevertheless true. The lack of appreciation of the man trained to keep records is ever present among railroad men and until such time as shop supervisors recognize the value of records in marking progress, warning of past mistakes and indicating possible future improvements, one avenue of increased shop output will remain closed.

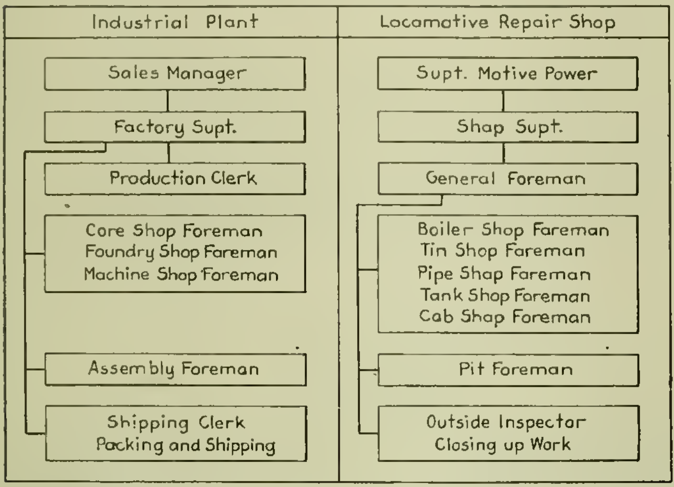


Fig. 1—Chart Showing Comparative Organizations. The Parallel Is Not Complete Until a Production Clerk Is Added Under the General Foreman

One of the thoughts that first came to the writer upon undertaking industrial work (after fifteen years in railroad mechanical departments) was the similarity of railroad and industrial organizations and four years as superintendent of a manufacturing plant has served to make this thought sink deeper. There is absolutely no reason why the same systems that have increased the efficiency of manufacturing plants should not provide greater railroad repair shop output. The contention that "due to the diversity of railroad work" these systems cannot be installed is prejudiced error; they can and will eventually be installed. What railroad shop has a wider diversity of work than exists in the plants of the International Harvester Company for example? This company repairs and builds a thousand types of machines; the average railroad may have fifteen or twenty types of locomotives.

The shop man should realize the similarity in organization referred to which is plainly shown in Fig. 1. The dissimilarity lies in the fact that the manufacturing plant has a production clerk to route and follow up the work while in most cases the railroads use their general foremen for this purpose. Put a production man under each general foreman—a man who will follow the work through—and the general, shop and gang foremen will have a great deal more time to plan department work and install improved methods.

An editorial entitled, "Systematizing Management in Railroad Shops," which appears in the November issue of the *Railway Mechanical Engineer*, incorporates three important factors in shop output:

1. Time Study.
2. Cost Records and Accounting.
3. Shop Scheduling and Follow-Up System.

The time study and cost records are really secondary in importance to the third factor, shop schedule and follow-up system, and it is the object of the writer to describe briefly in this article a method that will systematize railroad repair work, relieve the foremen of details and provide considerable increases in shop output.

Simplicity must be the keynote as any system involving an army of clerks is top-heavy and liable to break under its own weight. While there is a decided lack of system in the handling of repairs to passenger and freight cars, it is not as apparent as with locomotives, therefore, this article will be confined to the scheduling of locomotive repairs.

Duties and Records of Engine Clerk

The engine clerk of the superintendent of motive power is the chief dispatcher of locomotive repairs. His duties are to maintain all locomotive records including mileage, assignment, cost of maintenance, etc. The mileage is reported to him by the general superintendent of transportation; the cost of repairs by the shop superintendent or master mechanic. Form 1 is suggested for the purpose of maintaining this record. Incorporated therein are all the essentials, the left side of the form reflecting repairs and the right the miles made on the various divisions. One card is provided for each locomotive and is made to cover a three-year period.

Form 1, Showing Mileage and Locomotive Repair Data

It is poor policy to wait for a locomotive to go to pieces before repairing it and the practice should be to schedule the repairs according to mileage except in the case of wrecks. In applying the new system, the superintendent of motive power should first take into consideration the condition of power, right-of-way, past performance of the locomotives in passenger, freight, switch and work train service, arbitrarily setting up a maximum mileage between repairs for these classes, as for example:

Passenger locomotives, 120,000 miles.
Freight locomotives, 85,000 miles.
Switch locomotives, 65,000 miles.
Work-train locomotives, 70,000 miles.

Form 2.

———————1920.

Mr.——————
Shop Sup't.,
Master Mechanic——————

Dear Sir:

According to my records, Engine ———— is due for {heavy / light} repairs ———— 1920. This locomotive has made ———— miles since last heavy repairs and ———— miles since last light repairs. You will find attached hereto, for your guidance Form 3, describing in detail these repairs.

You will arrange for immediate inspection of this locomotive, to determine what repairs are necessary. Give your storekeeper a list of material needed in order that he may have same on hand when engine is held. (If engine is to be sent to another shop for repairs forward this information to the Master Mechanic or Shop Sup't in charge in order that he may have an opportunity to get his material together.)

This engine is to be repaired in ———— Shop and upon completion of repairs, Form 3 should be sent me giving in detail all repairs made and the cost.

Yours truly,
——————
Supt. Motive Power.

……………………………………………

Mr.——————
General Foreman.

Dear Sir:

Please note the above and with return of this communication filled out in every detail please send me Form 5.

You may retain Form 3 for your guidance.

Yours truly,
——————
Shop Supt.—Master Mechanic.

Form 2 is Sent Out by the Engine Clerk

Summary Appearing on the Back of Form 3

The next step is to determine the length of time required to segregate in the storehouse the materials needed for repairs. It would be ideal if the stores department could carry sufficient stock at all times to protect itself, but this is impracticable from a financial standpoint. Assume that two months is required for this segregation of material. Two and one-half months before an engine is due for repairs, the engine clerk sends out Form 2.

The time for sending out Form 2 is readily determined by subtracting from the maximum desired locomotive mileage between shoppings, two and one-half times the average monthly mileage. Form 2 is two-fold, the upper half being directed to the shop superintendent or master mechanic and the lower half to the general foreman. Form 2 is accompanied by Form No. 3, "Details of Repairs," which will be explained later.

Upon receipt of Form 2 at the shop the figures shown thereon are transferred to the upper parts of six forms, 4a, b, c, d, e, and f, covering detailed work in the boiler, machine, blacksmith, tin, pipe and tender shops respectively. Partial Form 4a, as illustrated for the boiler shop, is typical of the others.

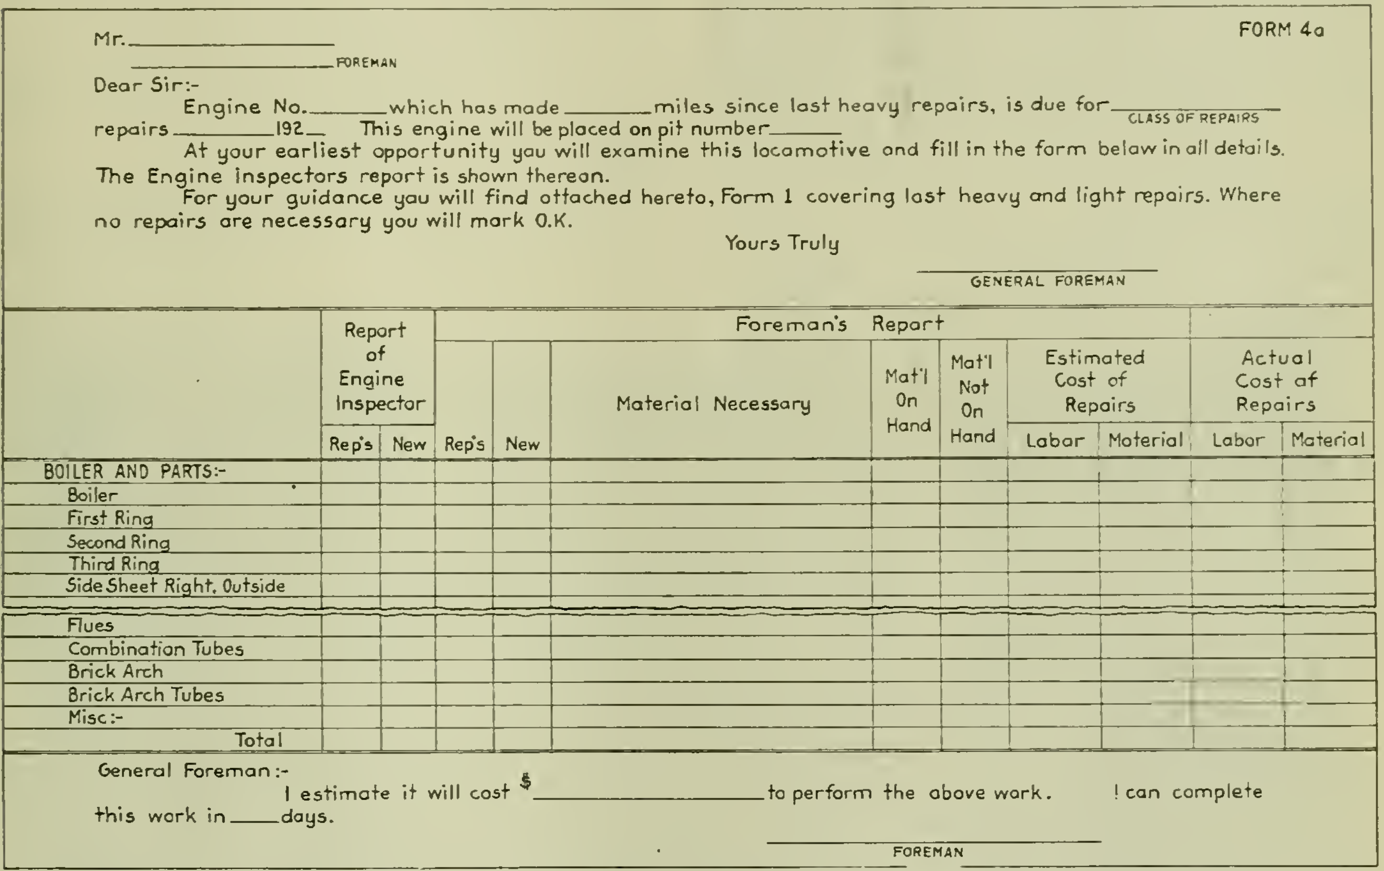
To allow for carbon copies, two each of Forms 4 are turned over to the roundhouse engine inspectors (boiler and machinery) who fill in the column "Report of Engine Inspector," after they have looked over the locomotive. They will report the repairs or replacements which develop under their observation and this information is a guide to the shop foreman who subsequently makes a more thorough examination. After the engine inspectors complete their report, the forms are returned to the general foreman, who gives them to his respective department heads. The general foreman also arranges with the roundhouse foreman to hold the engine for a thorough inspection, this being two and one-half months before the shopping is due. The roundhouse foreman knocks out the fire at the first opportunity and advises the several foremen when they may inspect.

The shop foremen (with engine inspectors if necessary) make an examination and very carefully fill in the several columns on Forms 4 under the heading "Foreman's Report."

Extreme care should be exercised by foremen in filling in the "Foreman's Report" as it is through this medium that the production clerk gets his line-up for scheduling. If, for example, the boiler shop foreman shows on the form that the front tube sheet merely needs repairs and subsequently it is discovered that a new sheet is needed, considerable delay will be incurred if there is no material on hand with which to make up the sheet.

Estimated and Actual Repair Costs

It will be noted that two columns are provided on Form 4a covering "Estimated Cost of Repairs" and "Actual Cost of Repairs." The sole idea in having the foreman fill in the first is to actually commit him as to the probable cost. If he declares the work will cost $8,000, he will make an effort to come within that amount. The production clerk will procure from the accounting department the actual cost of repairs after their completion and the discrepancies should be called to the foreman's attention by the general foreman. Each foreman, upon completion of his report, will sign in the space below and return one copy to the general foreman, retaining one for his file.



Mr.________ FORM 4a

________FOREMAN

Dear Sir:-

Engine No.______which has made ______miles since last heavy repairs, is due for ________ CLASS OF REPAIRS repairs______192__ This engine will be placed on pit number______

At your earliest opportunity you will examine this locomotive and fill in the form below in all details. The Engine Inspectors report is shown thereon.

For your guidance you will find attached hereto, Form 1 covering last heavy and light repairs. Where no repairs are necessary you will mark O.K.

Yours Truly

____
FOREMAN

Form 4a Is Made to Include All Details of Repairs to Boilers and Parts and Is Typical of Forms 4b, c, d, e, and f, Covering the Other Shop Departments.

Forms 4 provide the information called for on Form 5 which is forwarded to the shop superintendent or master mechanic, who in turn forwards it to the superintendent of motive power. Forms 4 are given by the general foreman to the production clerk.

Duties of the Production Clerk

A first-class production clerk saves his salary many times over each year by keeping the stock of finished parts at a minimum. He must not have an excess of any materials on hand; he cannot guess at his stock; he must *know* and his only method of knowing is through the medium of records. The production clerk in the industrial field is not a man of the trades; he is a clerk and must be a brainy one at that.

Again drawing a comparison between the industrial and railroad fields: the superintendent of motive power is the customer who orders engine number so-and-so in for repairs. Figuratively speaking, he pays for these repairs as his success is measured by his cost of maintenance per locomotive mile.

Second, the shop superintendent or master mechanic is the manufacturer and he is in the same position as an industrial manager. If the price, delivery and quality of work turned out by a manufacturer is not up to requirements, the purchasing agent will not give this manufacturer another order, but will let out the business to a competitor. If the cost, quality and speed of locomotive repair work done under the direction of a master mechanic or shop superintendent is not up to the expectations of the superintendent of motive power, the business will be switched, not to another concern, but to another man.

Third, there is the gap in the railroad line-up, as illustrated in Fig. 1, where the general foreman is the production clerk. By creating an additional position at a nominal salary, the general foreman can be relieved of a hundred small, annoying details that come up daily in the locomotive repair shop. Instead of worrying over these infinitesimal things, he can concentrate on the big things.

It has been stated before that the engine clerk in the superintendent of motive power's office instituted Form 2 two and one-half months before the locomotive was due to be shopped. It has probably taken ten days or two weeks to collect information required on Forms 4 and 5; therefore two months are left in which to prepare for the repairs.

The first thing to do is to arrange for the necessary material. Form 6, which is self-explanatory, is filled in by the production clerk and forwarded to the storekeeper after being approved by the general foreman.

It is the duty of the storekeeper to check his stock immediately and if he finds certain items missing, to order them at once. The production clerk should check up with the storekeeper from time to time to see if the material ordered is being received.

Developing a Shop Schedule

By way of illustrating the preparation of a shop schedule it will be assumed that engine 2001 is to be held for general repairs on May 2, and placed on pit 5. A review of Forms 4a, b, c, d, e, and f reflects that the following repairs will be necessary:

Put in new crown sheet.
Patch front flue sheet.
125 new flues.
General repairs to machinery.
Renew one main driving wheel (cracked).
Repair front section frame, right side.
Renew branch pipe.
Renew jacket in cab.
Apply two pair wheels, back tender truck, etc.

The general foreman should call the production clerk and his shop foremen in conference and set up chronologically the repair program for the locomotive. The general foreman has promised on Form 5 that it will take 40 working days to complete the repairs, this schedule being based on the detailed Forms 4. Each detail of the work is discussed and a promise given by the respective shop foremen as to dates of completion, the production clerk making notes as to these dates.

Form 5.
————————1920.

Mr.————————————
Shop Supt.—Master Mechanic.

Dear Sir:

Complying with request contained in the attached form number three, I estimate the cost of repairs to locomotive —————, as follows:

	Labor	Material	Total
Machine shop			
Boiler shop			
Blacksmith shop			
Tin shop			
Tender shop			
Cab shop			
Total			

I figure on placing this engine on Pit Number ——— and estimate it will require about ——— days to complete these repairs.

I have forwarded a list of material needed to the Storekeeper.

Yours truly,

————————————
General Foreman.

....

Mr.————————————
Sup't of Motive Power.

Dear Sir:

Please note the above. This for your information.

Yours truly,

————————————
Shop Supt.—Master Mechanic.

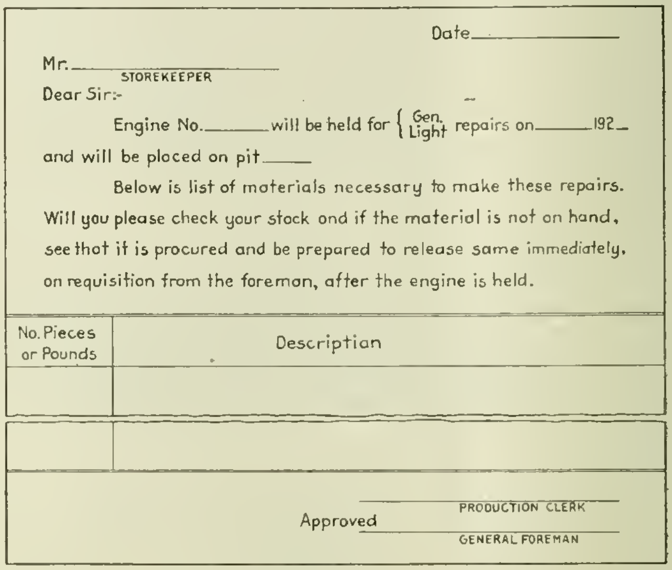
Form 5 Sums up Information on Forms 4 a, b, c, d, e, and f

From the information procured, the production clerk will set up data in a form similar to the following:

May 2—
Engine placed on pit. Tender sent to tank shop.
Stripping gang should start at 1.30 p. m.
May 3—
Stripping gang continues.
Start cutting staybolts for new crown sheet.
Start laying out new crown sheet.
Starts removing old flues and getting new flues made up and cut off.
May 4—
Stripping completed.
Drop driving wheels for removal of broken frame.
Send pair of defective drivers to wheel gang.
May 24—
Boiler shop to complete crown sheet.
May 25—
Frame weld to be completed.
Boiler shop to start applying crown sheet.
May 26—
Repairs to motion work, driving wheels and boxes completed.
June 13—
Shoes and wedges lined.
June 14—
Engine wheeled.
June 15—
Boiler shop work completed.
Valves to be set.
Tender repairs to be completed.
June 16—
Hydrostatic test to be applied and pops set.
June 17—
Tender out of shop ready for coupling up.
Engine out of shop ready for trial trip.

The foregoing gives a brief idea of the schedule which may appear complicated but can be made up in an hour after the first or second trial.

It is the duty of the production clerk to follow up the promises incorporated in his notes, making rounds through the plant twice daily to determine the progress. He should have no authority to criticize the foremen for falling behind but should make notes of any failures to live up to the schedule, reporting this information to the general foreman who will take the matter up with the foremen. The big idea is to get promises from the foremen who will usually do their level best to live up to them. A true sense of co-operation between the general foreman and the production clerk will be of inestimable value to the general foreman and to the operation of the plan.



Date————————

Mr.————————
STOREKEEPER

Dear Sir:-

Engine No.———— will be held for { Gen. / Light } repairs on———— 192—

and will be placed on pit————

Below is list of materials necessary to make these repairs. Will you please check your stock and if the material is not on hand, see that it is procured and be prepared to release same immediately, on requisition from the foreman, after the engine is held.

No. Pieces or Pounds	Description

————————
PRODUCTION CLERK

Approved————————
GENERAL FOREMAN

Form 6 Indicates to the Storekeeper What Materials Will Be Required for Repairs

Upon completion of repairs, Form 3 is made out by the production clerk. The information he has procured from Forms 4 and his chronological schedule will enable him to fill out this form with a few additional questions put to the foremen.

Value of Form 3 for Future Reference

Form 3 is an historical record of what actually happened while the engine was under repairs. It shows the parts repaired and renewed. It also shows special information on some details such as, diameter of wheels and size of journal on engine truck, kind of crank pins, location and make, etc. Should any of these special parts fail, it is merely necessary to refer to Form 3 to see when and where applied, kind of material, size, etc.

On the back of Form 3 is a summary of the cost of repairs set opposite the estimated cost which is reflected in the beginning by Form 5. There is also a space to explain the cause of over-running the estimate. The probable explanation will be some additional work discovered after the engine was stripped that could not be discerned at the time Forms 4 originated. On the other hand, it is possible that the foremen underestimated or that the job took too long.

Injecting the cost features in this system has considerable moral effect on the entire organization. It literally puts them on their toes as they know that their expenditures are being watched. The production clerk procures the cost data from the shop accounting department which already keeps individual costs on locomotives so this will entail no additional work. Form 3 should be made in triplicate; one copy to be retained by the production clerk and two to be forwarded to the superintendent of motive power.

An Appeal for the Shop Schedule

The foregoing incorporates the fundamentals of a shop schedule system, which will assist throughout the entire department. Don't let the bugaboo "diversity of work" deter you from endeavoring to institute some of the big ideas that have placed manufacturing companies years ahead of railroads in efficiency. Don't throttle your general foreman by making him follow up the short ends in his department. Give him a production clerk to dispatch his work and keep the main line open. Don't wait until the management on your railroad decides to install some high class efficiency system which often proves too cumbersome. Beat them to it by developing a simple shop schedule in charge of a live schedule man or production clerk. See that every one co-operates and watch results.

Welding Locomotive Cylinders

BY C. E. FARLEY

General Locomotive Foreman, Horton Shops, Chicago, Rock Island & Pacific

It is a well-known fact that badly broken cylinders are being welded in many railroad shops throughout the country at the present time with gratifying success. Figs. 1 and 2 show the repair of an unusual break in the right cylinder on a Mikado type locomotive. The entire front end of this cylinder was gone, including the division between the steam chest and cylinder. The cylinder had been patched previously, but when a piston head flew off, carrying with it the front cylinder flange, these patches were damaged. Their removal was also necessary in order to get at the broken parts conveniently for welding.

The entire casting was prepared and welded to the cylinder wall all in one piece (previously built up in the welding shop) except the outer wall of the steam chest, which was left open to allow the welding of the dividing wall between the exhaust and admission ports. The usual method of preheating was used, building a brick furnace enclosing the entire cylinder, using charcoal for preheating. The fire was started at 12 o'clock midnight, and the welding started at 7.30 A. M. Using two torches when possible, 16 blowpipe hours were required to complete the job.

The cylinder, welded and ready for the boring bar, is shown in Fig. 2. It will be noted that only one bushing was removed from the valve chamber, the cylinder bushing and the back chamber bushing being left in place. The valve chamber was bored in the front end for reapplying the bushing, the front joints on both valve chamber and cylinder being faced. It was not necessary even to bore the cylinder. All that was required on the by-pass valve chamber was to ream the seat as it lined up perfectly with the back end chamber.

A great deal was saved by not having to remove the bushing, as is the general practice where a heavy job of welding is to be performed. The operation, as described, has been proved practicable by a number of other cylinders that were welded without removing the bushing and are giving good service. The total cost of the welding was approximately $300 for labor and material, making a saving of not less than $700 on the entire job.

The opposite cylinder on this same engine was welded, as shown in Fig. 3, the flange that holds the cylinder to the frame being entirely broken off. The cylinder was removed, turned up at an angle of 90 deg., and the flange welded in place, as illustrated. It will be observed that the cylinder is supported by a chain, and the broken flange, which rests on top, must be welded at the back and the four bridges. The cylinder was reapplied to the engine, all splice bolts being saved and used over again, thus making the cost of this job very reasonable. In all, the two jobs of cylinder welding on this engine cost less than one cylinder in the rough. The welding operations were performed by a local machinist welder, assisted by representatives of the Oxweld Railroad Service Company.

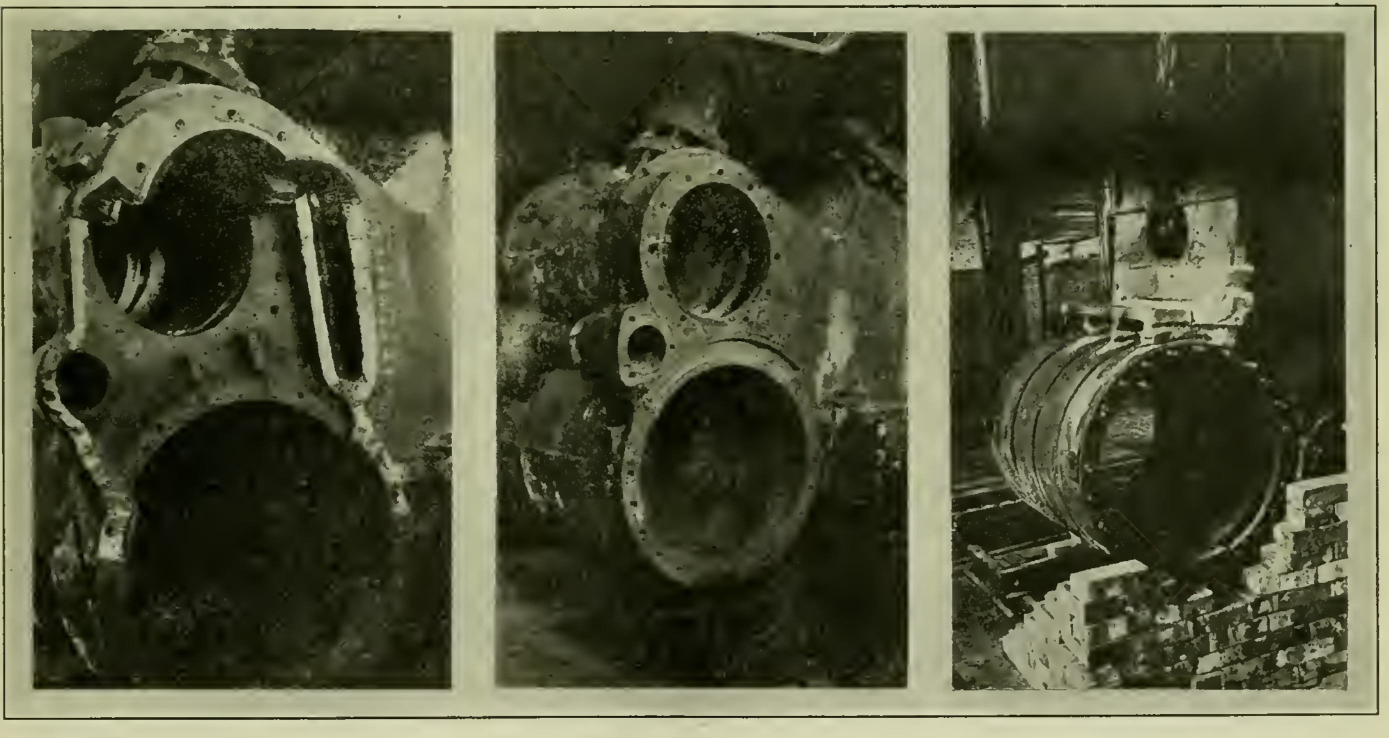


Fig. 1 Fig. 2 Fig. 3

Examples of Difficult Locomotive Cylinder Welding

Application of Shoe and Wedge Liners to Driving Boxes

On almost no question regarding the proper maintenance of locomotives has there been a wider diversity of opinion than regarding the best method of compensating for wear in the driving box shoe and wedgeways. Liners have been applied and held in place by short countersunk head brass screws. In some cases brass liners have been cast in place being held by means of diagonal undercut grooves. Under the severe hammering which driving boxes receive in service, however, liners applied by these methods tend to work loose and require frequent renewal.

To overcome this difficulty, many railroads have adopted the practice of tack-welding steel shoe and wedge liners in place and have thereby greatly reduced the number of liners working loose. Even in applying plates by welding, a considerable divergence of practice has been found, but the method illustrated has shown good results.

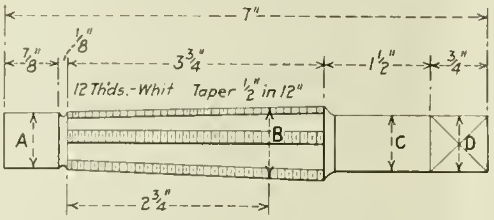
Driving Box Shoe and Wedge Liner Tack-Welded in Place

These shoe and wedge liners are made of steel and beveled on the edges by planing, a number of liners being held at the proper angle in a planer chuck and planed at the same time. The liners are welded to the driving box shoe and wedge ways at the edges and, to assist in holding the liners, six holes are punched in them for tack welding as shown.

Tapping Radial Holes in Boiler Shells

The difficulty which inexperienced workmen find in tapping holes in boiler shells so that studs applied in these holes will be on radial lines, is well known. For example, most air compressor brackets are supported on the barrel of the boiler by means of six studs. The brackets range from 2 to 3 ft. long and the studs are about that distance apart. If tapped into the boiler on radial lines the studs will not be parallel, but many times an attempt is made to have them parallel and the result is undue strain on the stud to say nothing of an unworkmanlike looking job.

In order to overcome this condition and facilitate the application of boiler studs along radial lines, the tap illustrated has been devised. The end of the tap is extended as shown at *A* in a cylindrical surface equal in diameter to the smallest diameter of the thread. With care in drilling the boiler shell on a radial line (the diameter of the hole being slightly larger than *A*) the tap will obviously start in the direction of the drilled hole and, as a result, the hole will be tapped along a radial line. The proportions of *A*, *B*, *C*, and *D* are shown in the table for seven different sizes of taps. The use of this tap will also aid in tapping a hole at right angles to a given plain surface, following the direction of the drilled hole as previously described.



D	C	B	A
1/2"	5/8"	5/8"	1/2"
9/16"	3/4"	3/4"	5/8"

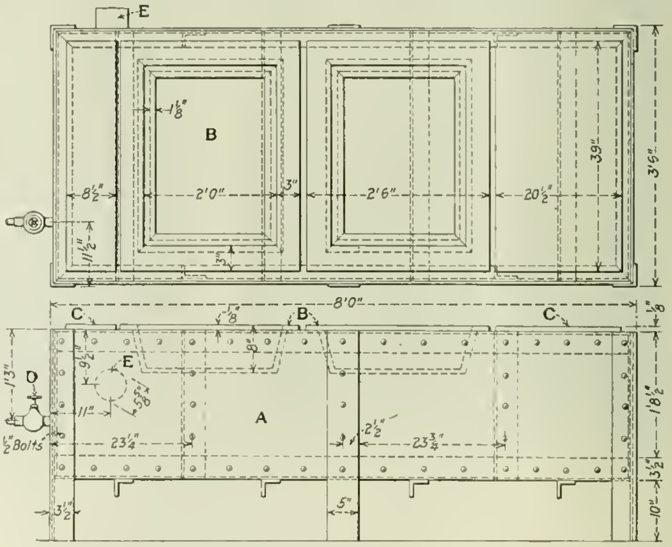
Tap Developed for Tapping Radial Holes

An Easily Made Babbitting Furnace

BY E. A. MILLER

For babbitting driving boxes, crossheads and other miscellaneous locomotive parts, the babbitting furnace shown has given exceptionally good service. The furnace *A* is supported by four ½ in. by 3½ in. by 3½ angle irons and ½ in. by 5 in. plates centrally located on each side. The furnace is made of 5/16 in. sheet iron, both sides and ends being stiffened all around by 5/16 in. by 3½ in. plates riveted to all the vertical supports. The side sheets and bottom are stiffened by four 5/16 in. by 3 in. angles. There is also a reinforcing angle iron all around the top which supports two cast iron babbitt containing pans *B* and two cast iron plates *C*.

The bottom and sides of the furnace are lined with 3 in. fire bricks covered with fire clay. A burner *D* for crude oil is provided; also a vent *E*. The cast iron pans are 1⅛ in. thick and 6⅞ in. deep inside. Removing one or both of the cast iron plates *C* will tend to cool off the furnace as desired, and they can also be used to preheat certain parts, such as rod brasses, etc. This furnace has given satisfactory service and a number similar in construction are now in use.



Babbitting Furnace of Simple Design

Making a Drill Live Up to Its Reputation

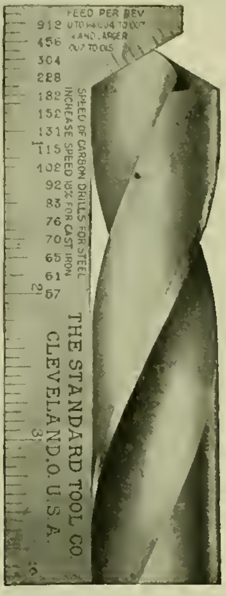
Satisfactory Results in the Use of Twist Drills Can Be Secured in One Way Only—by Correct Grinding

BY H. WILLS
The Standard Tool Company, Cleveland, Ohio

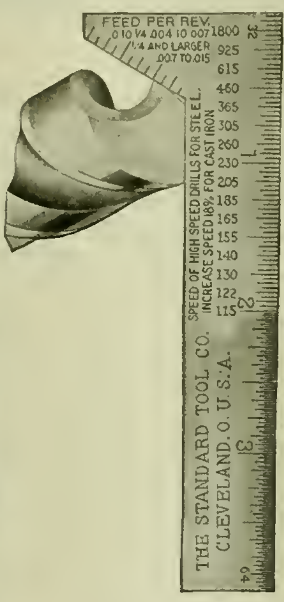
WHEN considering the almost human mechanical appliances employed in making standard types of twist drills and the precautions taken in the various operations from the laboratory tests of the steel bars to the final inspection, it is a fairly safe conjecture that if a drill gives trouble, some of the conditions surrounding its use are not right.

Twist drills will stand more strain in proportion to their size than almost any other tool and a large percentage of drill troubles could be eliminated with proper attention given to grinding the points. The form of the drill point controls the rate of production, accuracy of the hole, frequency of necessary grinding and the life of the drill. In fact, the most carefully made drill can be spoiled by poor grinding.

In testing a drill to determine whether or not it is properly ground, the first requirement is some form of twist drill grinding gage chart and scale, as illustrated. Two methods of holding the scale while measuring the length and angle of the cutting lip, also when estimating the approximate center angle, are shown. Although the included angle of the gage is only 118 deg., a close estimate on the recommended center angle of 130 deg. can be made.



Measuring Length and Angle of Cutting Lip



Estimating Approximate Center Angle

Twist drills must be properly ground and run at the correct speeds and feeds in order to do their work efficiently and with the aid of the gage illustrated, any skilled workmen can obtain these best results in increased drilling production. The gage is ground to an angle of 118 deg. and is graduated in thirty-seconds and sixty-fourths on one side and sixteenths on the other. The gage indicates the proper angle and length of lip to which the drills should be ground. It also shows the speeds and feeds recommended for drilling steel and cast iron, one side when carbon steel drills are used and the other when high speed drills are used. Opposite each 1/8-in. mark is a number showing the proper speed at which to run a drill of corresponding diameter.

Correct and Incorrect Grinding

Both cutting lips must be inclined at the same angle with the axis of the drill and must be of equal length. The point angle of 59 deg. (Fig. 1) has been universally adopted as best suited for average conditions. The drill point must have the proper clearance or contour of surface back of the cutting edges and this clearance must be identical on both sides. Approximately a 12 deg. clearance angle (Fig. 2), combined with the center angle of 130 deg. which will give a constantly increasing clearance toward the center, has proved best for average conditions.

Some of the undesirable conditions resulting from drill points improperly ground are illustrated. If both lips are not ground at the same angle with the axis (Fig. 3), one lip will fail to counteract the tendency of the other to spring away from the cut; consequently, one lip will do more work than the other, which will result in its becoming dull more rapidly than if both lips were cutting equally. In addition, it will be subjected to an abnormal torsional strain.

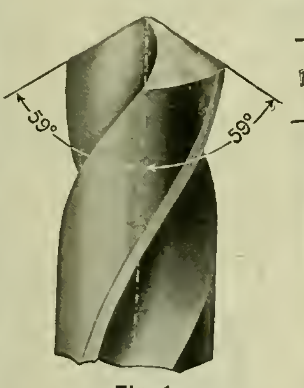


Fig. 1

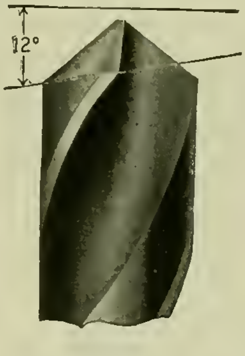

Fig. 2

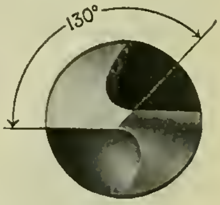

Fig. 2a

When the cutting lips of a drill have the same point angle, but are of different lengths (Fig. 4), the point of the drill will be "off center" or eccentric. As a result, the hole will be oversized to an extent equal to double the amount of this eccentricity. If the drill point is ground with both lips at different angles and of different lengths (Fig. 6), there will be a combination of the undesirable results described in the last two paragraphs.

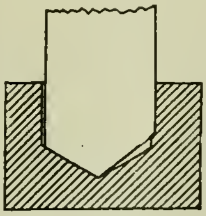

Fig. 3

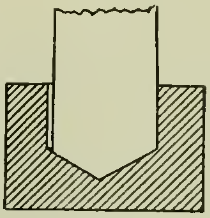

Fig. 4

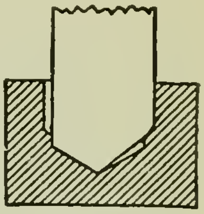

Fig. 5

The side and end views of a drill with the proper point angle (59 deg.) and the proper angle of clearance at the periphery (12 deg.), but with insufficient clearance at the point or center, are shown in Fig. 6.

A drill with insufficient clearance both at the periphery and at the center is illustrated in Fig. 8. The line *ABC* is at an angle of 12 deg., but there is no clearance immediately back of the cutting edges *BC* and the excess of clearance at the heel *AB* is of no benefit. The common result of grinding a drill with insufficient clearance is plainly shown in Fig. 8, and this splitting is almost sure to follow any attempt to obtain maximum production.

A drill with the proper clearance angle of 12 deg. is shown in Fig. 9, but it does not have the proper contour back of the cutting edges. This manner of grinding leaves the cutting edges thin and weak, causing them to crumble away under heavy speeds.

Maintaining Standard Web Thickness

Most twist drills are made with a gradual increase in the thickness of the web or center of the drill toward the shank. As the drill becomes shorter and the web thicker, greater force is required to drive it. To overcome this condition, it is good practice to thin the web to the original dimensions. This grinding must not extend too far up the flute of the drill and care must be exercised that the cutting lips are not injured; also that the same amount is ground out of each groove. Fig. 10 shows a drill with the web properly thinned. In Fig. 11, the grinding is excessive, leaving the web entirely too thin and liable to crumble. When this happens, a split drill is practically inevitable.

Incorrect grinding is usually the cause of drills splitting up the center, and no manufacturer should be called upon to replace a split drill, unless a flaw is evident in the steel.

General Precautions to Observe

Twist drills are made with a slight taper from point to shank, so that the largest diameter is always across the corners of the cutting lips. This prevents the drills from binding in the work, when they are sharp. If the outer corners are allowed to become badly worn, the drills will bind and cannot perform satisfactorily. Whenever the outer corners of the cutting lips show wear, the drills should be re-ground and every particle of worn surface removed, or the drills will continue to bind and very quickly be damaged beyond repair.

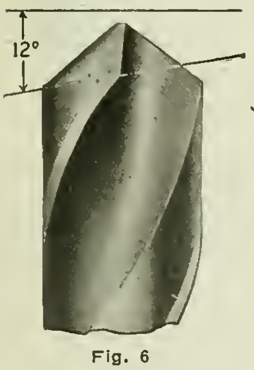

Fig. 6

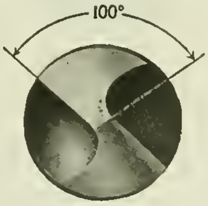

Fig. 6a

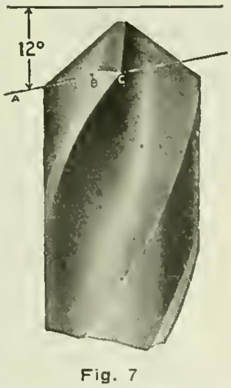

Fig. 7

In grinding high speed drills, care should be taken not to overheat them, and when heated they should never be plunged into cold water. Doing so is likely to cause small surface cracks which reduce the efficiency of the drill and may result in serious damage to it. Forcing the grinding on a wet grinder may also bring about the same condition.

If the suggestions for grinding drill points contained herein are followed and drills are run at the proper speeds and feeds, satisfactory results are practically assured. It is, however, hardly possible to do this grinding as accurately by hand as by using a good twist drill grinding machine, of which there are several on the market, and their use is earnestly recommended.

Broken or damaged tangs of drills are generally the result of an imperfect fit of the drill shank in its socket, which may be caused by a worn-out socket, dirt or chips accumulating in the socket, or bruises on the shank of the drill. In either case the driving power of the taper is reduced or destroyed, resulting in an abnormal strain being put upon the tang.

A drill of either carbon or high speed steel that can be filed is not necessarily too soft for service; in fact, if drills were tempered so that a good file would make no impression, they would be entirely too hard for general use. Any doubt regarding the temper can be checked by trying the drills in actual service.

Fig. 8

Fig. 9

Fig. 10

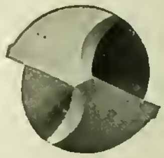

Fig. 11

Speeds and Feeds

There are so many conditions affecting drilling operations that it is extremely difficult to establish hard and fast rules for speeds and feeds. Published tables can be safely followed when drilling in commercial materials and experience will enable the operator to determine what changes, if any, can be made from them. Assuming that a drill is properly ground, when the corners of the cutting lips wear away rapidly, it is an indication that the speed is too great. If the cutting edges roughen or break out in minute particles it indicates that the feed is too great. A word of caution will not be amiss regarding the use of very small drills. It is seldom that these are run at more than a fraction of the speed necessary to obtain the best results, and excessive breakage is inevitable. These small drills are delicate tools; be sure they run true and that the cutting edges are kept sharp. A fine grade emery stone is best suited for this purpose.

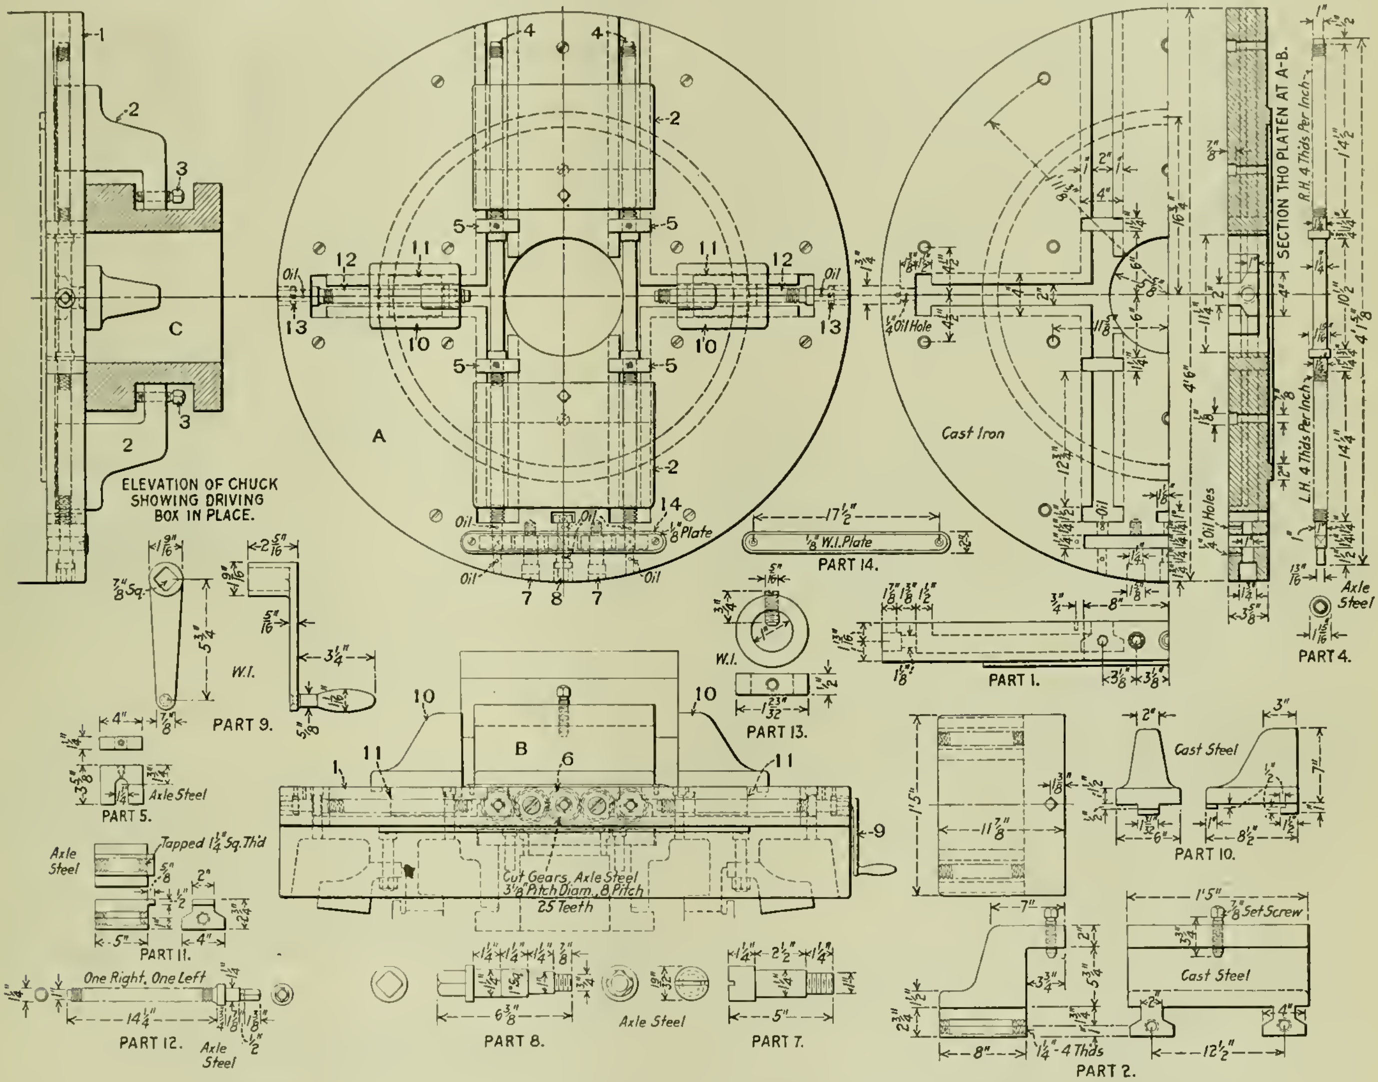
Driving Box Chuck

BY E. A. MILLER

A driving box has been developed, as shown in the illustration, for application to 54 in. boring mills, and its use will result in a considerable saving in the time ordinarily required to set up driving boxes preliminary to the operation of boring crown brasses. Referring to the illustration, *A*, *B* and *C* are the plan, front and side elevations of the assembled driving box chuck. Details of the individual chuck parts also are shown, and will aid in a full understanding of the operation of the chuck.

The base plate *1* is made of cast iron 3⅝ in. thick and provided on the under side with a ring which fits in a corresponding groove in the boring mill table. The chuck is secured to the table by means of fifteen ⅞-in. bolts, with round, slotted heads flush with the top surface. The base of the plate *1* is slotted, as shown in the detailed view, to receive the working parts of the chuck. Two large jaws *2*, which are provided to center the driving box, work together, one being drilled and tapped with four right-hand square threads per inch, the other jaw being tapped with four left-hand square threads per inch. Two long screws *4*, provided with right and left-hand threads are arranged to screw into the movable jaw *2*. Any rotation of the screws, therefore, causes the jaws to move together or apart depending upon the direction of rotation.

Care must be taken in assembling to see that the long screws are started in the jaws at the same time so the jaws will centralize. Four axle steel pieces *5* are arranged to fit corresponding slots in the base and by contact with shoulders on the long screws as shown, prevent longitudinal movement of the screws. Five eight-pitch gears with 25 teeth each are arranged in a train as shown. The middle and outside gears are provided with square holes for application to the long screws and the operating pin *8*; the other two gears are idlers mounted on pins *7*. Pins *7* are provided with 1 in. threads on the ends and make into corresponding tapped holes in the platen. Pin *8* is held in place by a ¾ in. nut on the end and a cotter to prevent it from working off. It is evident that, through the train of gears, the turning of pin *8* by means of handle *9* will turn the long screws in the same direction and move the jaws *2* together or apart as may be desired. Movement of the jaws is simultaneous.



Driving Box Chuck as Applied to 54-In. Boring Mill

The small jaws *10*, like the larger ones, are of cast steel but are not tapped out for the 1¼ in. square threads (four threads per inch). Two additional parts *11* are arranged to fit grooves in the platen and threaded to receive the 1¼ in. short screws *12*. The detailed views of parts *10* and *11* will indicate how they fit together and how turning one of the short screws will cause movement of the small jaw in or out, depending upon the direction of rotation. The two parts *11* are tapped, one with a right, and the other with a left-hand thread. These parts and the short screws have to be assembled before the long screws and main jaws are put in place. Two collars *13* are provided for application to the short screws after they are in place and prevent their longitudinal movement. A set screw in each collar provides for its adjustment on the short screw and for tightening in the desired position. A gear guard *14* is provided to cover the five gears and keep them free from chips. The 11¼ in. hole in the center of the platen allows all chips to drop through and prevents interference with the boring bar. Oil holes are provided throughout to lubricate moving parts. As an additional precaution to insure accurate work, two set screws *3* are provided in the large jaws *2*. Tightening these set screws after the centering jaws have closed against the driving box, will hold the box firmly to the platen and prevent any tendency to tip up on one side. For the rapid, accurate machining of driving boxes this chuck has demonstrated its value.

Curing Troublesome Frame Failures

BY FRANK ROBERTS

In going over the records for the past four years, it was found that 205 broken frames had been welded at the principal repair shop of a road having about 350 locomotives. Attention was especially attracted to the number of failures at the foot of the pedestals, shown at *A*, Fig. 1. By actual count there were 86 cases where the break was at one pedestal; seven cases where two pedestals were broken on the same locomotive and one case where three were broken on one locomotive. Altogether 103 pedestals were welded. All the rest of the frames broken in various places totaled 102. It has been found that 50 per cent of our frame failures occur at the pedestal foot.

This proves conclusively that the design of this part of the frame should be changed and it is a simple matter to increase the section sufficiently to insure against such failures. Fig. 1 shows the location of typical failures. There is usually so little difference between dimension *B* and the depth of the binder slot that the binder comes up very close to the frame, making it necessary to cut a fairly sharp corner at *C*. A sharp corner is always a weak point and dimension *B* should be made ½ in. or ¾ in. longer to leave a good protecting fillet at *C*.

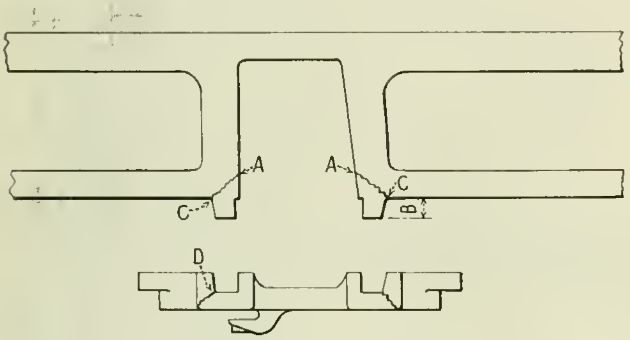


Fig. 1—Sketch Showing Location of Frame and Binder Failures

As a measure of increased strength the foot should be carried back along the frame about two inches further as shown in Fig. 2. This alteration will strengthen the pedestal foot and eliminate breaking at this point. Any man familiar with shop or enginehouse troubles is fully aware of the extent and expense of the above failures and the engineering department will at once appreciate the reasons for making the change as well as the effectiveness of the proposed change in design.

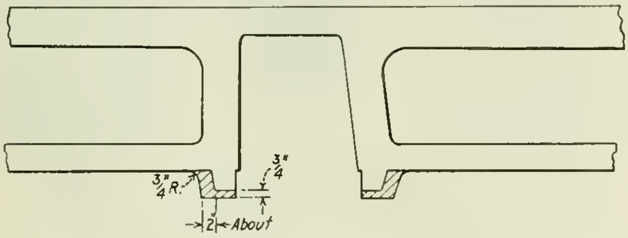

Fig. 2—Proposed Method of Strengthening Pedestal Foot

Considerable trouble has been experienced also through the failure of pedestal binders. The breakage occurred at point *D* in Fig. 1 and the design of the binder was changed, making a ¼-in. fillet at the bottom of the opening, thereby stopping the trouble. The whole fit of the binder on the pedestal had to be redesigned for the new pedestal, making arrangement for a good fit with no bearing on the fillets.

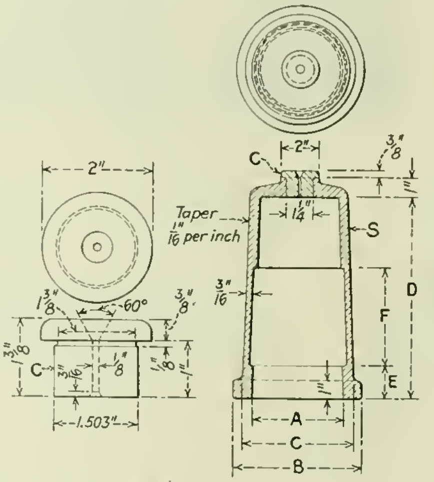
It is desirable to so design locomotive frames that the weakest link will be the part that can be most easily repaired. Certainly the pedestal foot is a hard part to repair and if breakage must take place, it is much better to have it in the binder than in the frame. The present improvement in strengthening the frame should place the advantage on the side of the frame.

Piston Rod Centering Sleeve

BY E. A. MILLER

If often happens that the end of a piston rod becomes battered in disconnecting the crosshead and in some cases the center is so badly damaged that it is exceedingly difficult to true the piston rod in the lathe or grinding machine. To overcome this difficulty, a special centering sleeve has been devised as shown in the illustration.

The sleeve *S* is made of axle steel, being reamed to the standard gage for the tapered piston rod end. Dimensions are shown for six different sizes of centering sleeves, arranged to fit practically all classes of piston rods received for repairs. It will be noted that the inside taper fit of the sleeve is relieved for at least half of the fit and this allows easy application or removal of the sleeve without impairing its accuracy. The outside of the sleeve *S* is tapered 1/16 in. per inch. A tool center *C* is made to the shape and dimensions shown, being hardened all over and ground, with an allowance of .003 in. for the shrink fit in the sleeve.



A	B	C	D	E	F
5 13/16"	6 15/16"	6"	11"	1 3/4"	5 3/8"
4 5/8"	6 3/8"	5 3/8"	10"	1 5/8"	4 7/8"
4 1/2"	6 1/4"	5 1/4"	10"	1 1/2"	4 3/4"
3 9/16"	5 5/16"	4 5/16"	8 1/4"	7/8"	4 1/2"
3 59/64"	5 43/64"	4 11/16"	8 3/4"	1 1/8"	4 3/8"
5"	6 3/4"	5 3/4"	11"	1 3/4"	4 7/8"

Centering Sleeve for Piston Rods with Damaged Centers

The application of this centering sleeve gives the same results as the original center in the piston rod, and will be found to save a large amount of time in truing up piston rods with damaged centers.

Hardening Hammer Die Blocks*

BY R. B. KERR

Since the introduction of the modern drop forging hammer, the problem of producing and successfully heat treating large dies to get the maximum of service with a minimum of loss, has engaged the attention of steelmakers and steel treaters alike.

Early in the game it was found that the percentage of loss from hardening from various causes was heavy. Flaws or pipes in the interior of the blocks resulting from improper casting or forging; steel of too high or irregular a carbon content; and more especially inadequate tempering room equipment, are among the chief causes of failure. The un-

---

*Abstract of a paper presented by title by R. B. Kerr, foreman, heat treating department, John Deere Harvester Works, East Moline, Ill., before the Philadelphia convention of the American Society for Steel Treating.

fortunate hardener too often is made the goat for the sins, mostly of omission, of both the steelmaker and the shop foreman.

Directions for Heating

While die blocks can be heated successfully in either coke or oil furnaces or even in the smith's forge, a gas heated furnace of the oven type is by far the most convenient and satisfactory for this work. Coke makes a nice clear fire of fairly simple regulation, and with a skillful heater in charge, good results can be obtained. An objection to its use is the frequent presence of impurities, particularly sulphur.

When heating dies the considerable air pressure required to burn fuel oil, makes necessary the most extreme care to prevent scaling or surface decarburization in the parts to be treated. The furnace, therefore, should be of the muffle type, the heating chamber completely inclosed, or if this is not available, the die should for protection be packed face down in a gas tight box of suitable size half filled with charcoal, and the whole thing heated up.

It might be said in passing that this method of pack hardening is excellent for heating dies and tools of nearly all descriptions. The parts come out of the packing box uniformly heated with a surface perfectly free from scale and in the best possible condition for hardening. The process is an old and successful way of heating steel and deserves to be more widely known and practiced.

Whatever the type of furnace used or the means employed the all important thing is to get a good heat on the die (a thorough slow soaking, uniform heat) for upon that depends to a great extent the success or failure of the operation. Particularly for the benefit of the younger steel treaters it may be said that thorough careful heating, more especially when handling comparatively large blocks of steel, is most essential.

For heating, a gas-fired, oven furnace of ample capacity should be used as being most convenient and suitable for the job. If the oven is already hot so much the better, if not, it should be brought up pretty well before putting in the work. Dies of any description should not be put into a cold furnace. Nothing is gained in time, and besides some chances of surface decarburization are offered with a too rapid increase in temperature.

Place the die in the furnace face down, unless the nature of the impressions makes this impossible, in which event it is good practice to protect the surface from possible gases by laying a closely fitting piece of asbestos or sheet steel on top while heating. As another precaution, if the die is of considerable size and the impressions are deep or irregular, it is well to bring it up to a dull red heat, about 1300 deg. F., and let it partly cool off in the furnace before taking the hardening heat.

Heat slowly and regularly. The time required will vary in proportion to the heating area of the furnace and the size and shape of the piece to be treated. Usually three to five hours are required for drop forging dies of average size. The most important point is to get a uniform heat throughout the piece, and one of the most valuable assets a steel treater can have is the ability to judge or sense correctly when a large block of steel is heated properly throughout. The average grade of hammer die steel will harden nicely at around 1450 deg. F. and the heat always should be held stationary for at least 15 minutes before removing the die from the fire. This insures a uniform temperature throughout the entire die.

Quenching and Drawing

The quenching tank should be of ample size and the water supply arranged so that it can be forced upward against the face of the die with considerable force and volume, using an overflow pipe of sufficient size to take it away. In most cases clean fresh water is all that is necessary, but if extreme hardness is required or if the water is soft or muddy, the addition of a little salt will sharpen it. Place a resting rack across the top of the tank, arranged at a sufficient depth so that the impressions on the face of the die will be well covered with water when the die is laid on it. On flat surfaced dies or on dies in which the impressions are shallow, a depth of from 1 to 1½ in. is about right.

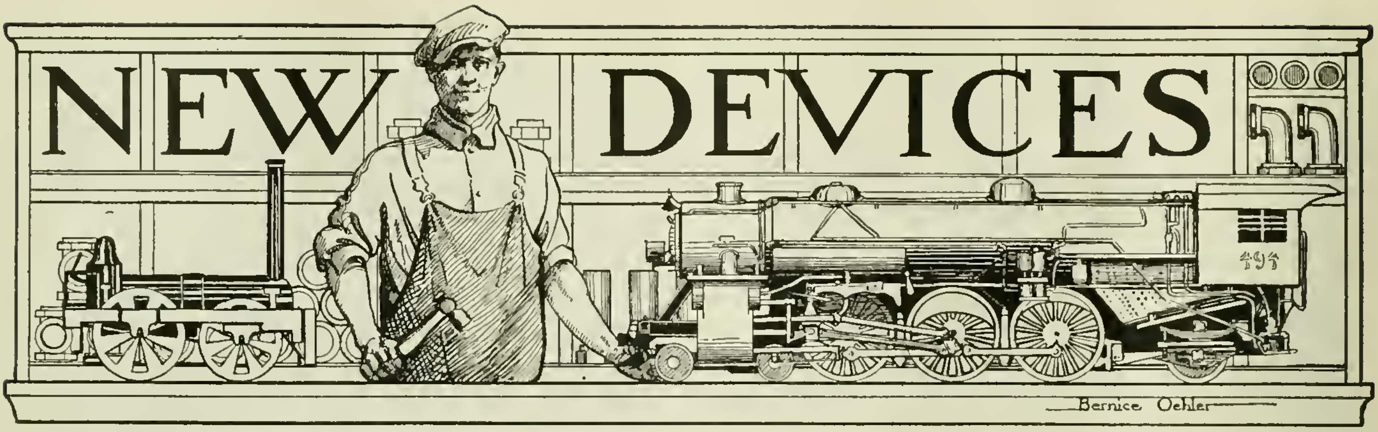
When all is ready get the piece out of the fire. If there are any dangerous looking corners or sharp projections that do not need to be hard, partly cool them off with a water jet or piece of water soaked waste to prevent chipping. Place the die on the resting rack face down and turn on the water. If the piece is wide or flat, prevent warping or crowning by keeping the back slightly cooled off; just enough water and no more. Run the hand over the face frequently to find how it is cooling off.

The temper should be drawn slightly on all hammer dies, both to relieve strains and to give them resiliency or spring, as well as for better wearing qualities, and the drawing should be begun immediately, even before the die is quite cooled off. If there is an oil tempering furnace at hand large enough, get the piece into it. Raise the temperature to around 400 deg. F., and hold it there for an hour or so. If for any reason this method cannot be used, swab the die with light machine oil and place it in a furnace partly cooled off. Leave it there until the oil begins to flash, then remove and allow it to cool off in the air.

Danger Due to Internal Friction

A die should never cool off entirely in the water. When a mass of steel at the hardening temperature is plunged into cold water, the grains in its outer surface immediately become set and rigid. A certain amount of contraction and shrinkage also takes place, partly because of the change from high to low temperature, and also because of the hardening of the metal. The amount of this shrinkage is in exact proportion to the surface area of the mass being treated; the greater the area the more the shrinkage. If this change took place all the way through there would be no trouble; but it does not. In the first place the interior of the piece cools off much more slowly than the outside, and, secondly, the setting of the grains, due to hardening, extends in a depth of from only ¼ to ½ in. at the most. This suddenly chilled outer layer is consequently being forced against the softer mass inside with an enormous pressure, causing distortion and strains which become more marked as the piece cools off. When the temperature recedes to a certain stage, governed partly by the temperature of the quenching water and the air, a violent action takes place. This is the danger point. The friction created by the molecules striving to adjust themselves to the new conditions generates heat inside. Heat means expansion, and unless this condition is offset promptly by heat applied to the outside to relieve the strains, the die, particularly if a large one, has about an even chance of bursting open. Whether it does or does not, the strains are there and are just as liable to manifest themselves in service later on with possibly more serious effects than if they appear immediately after hardening.

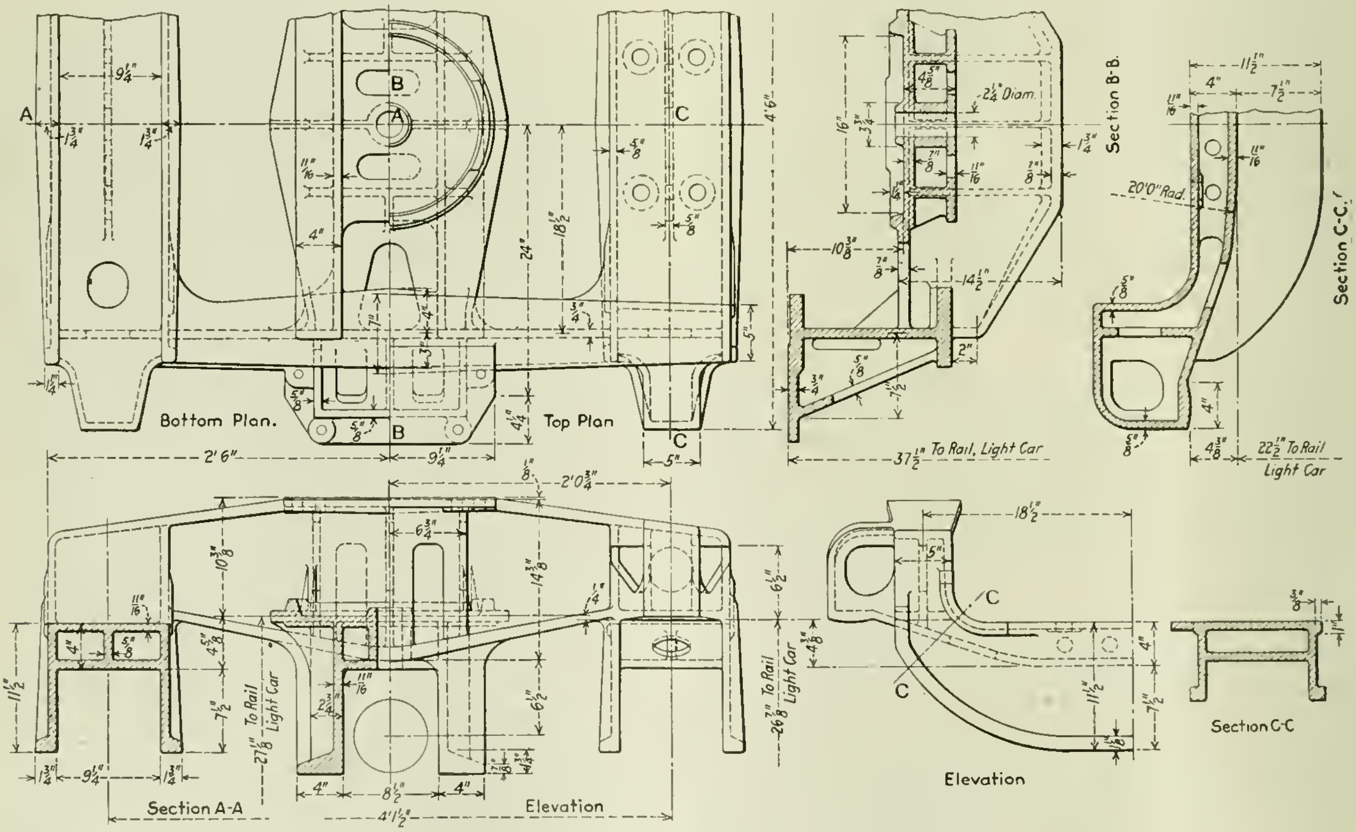
Allowing the dies to remain in the water too long and failure to draw the temper promptly after hardening is responsible for considerable breakage. This is partly due to the lack of proper equipment, and also to the fact that the principles involved are not so generally understood as they might be even among steel hardeners. This heat generation by friction, or as some might call it, molecular reaction inside of a body of steel, is no pet theory, but the author has noted its effects during many years of close observation and practice in the heat treating of steel, and believes it will be found in line with the natural laws governing cooling bodies.



Lamont Six-Wheel Truck for Freight Cars

A NUMBER of designs of equalizing six-wheel trucks have been developed for freight cars varying in capacity from 90 tons to 120 tons. The Lamont truck, the most recently developed of this type, has been brought out by the American Steel Foundries, Chicago, and has received its first installation under several of the new 120-ton coal cars built for the Virginian.

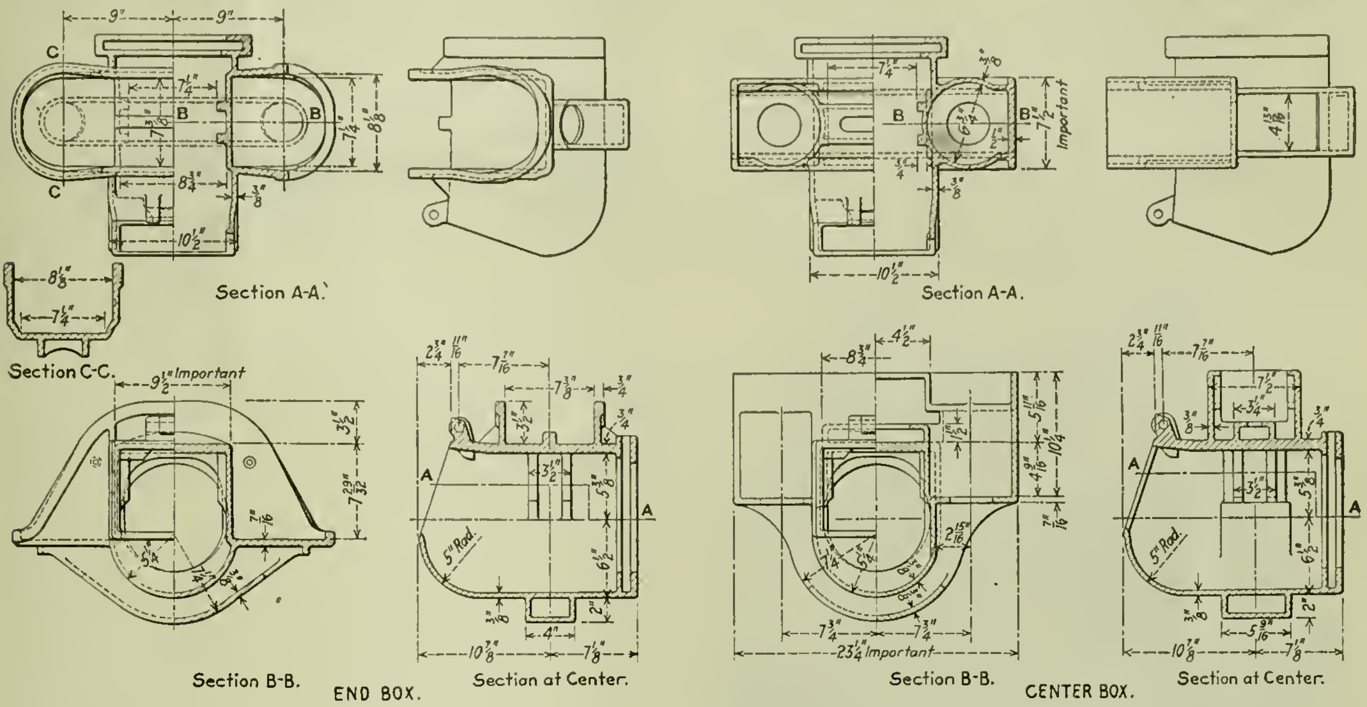
This truck differs from other six-wheel trucks for freight cars in bolster construction, the method of equalizing and the arrangement of the springs. The feature of the bolster design is its three-part construction, which provides for cross equalization of the load distribution to the four points of delivery to the longitudinal equalizing mechanism. The equalizing mechanism permits a symmetrical location of the bolster ends between the wheels, thus making possible a short wheel base and a simple arrangement of the brake rigging.



Details of the Equalizing Bolster

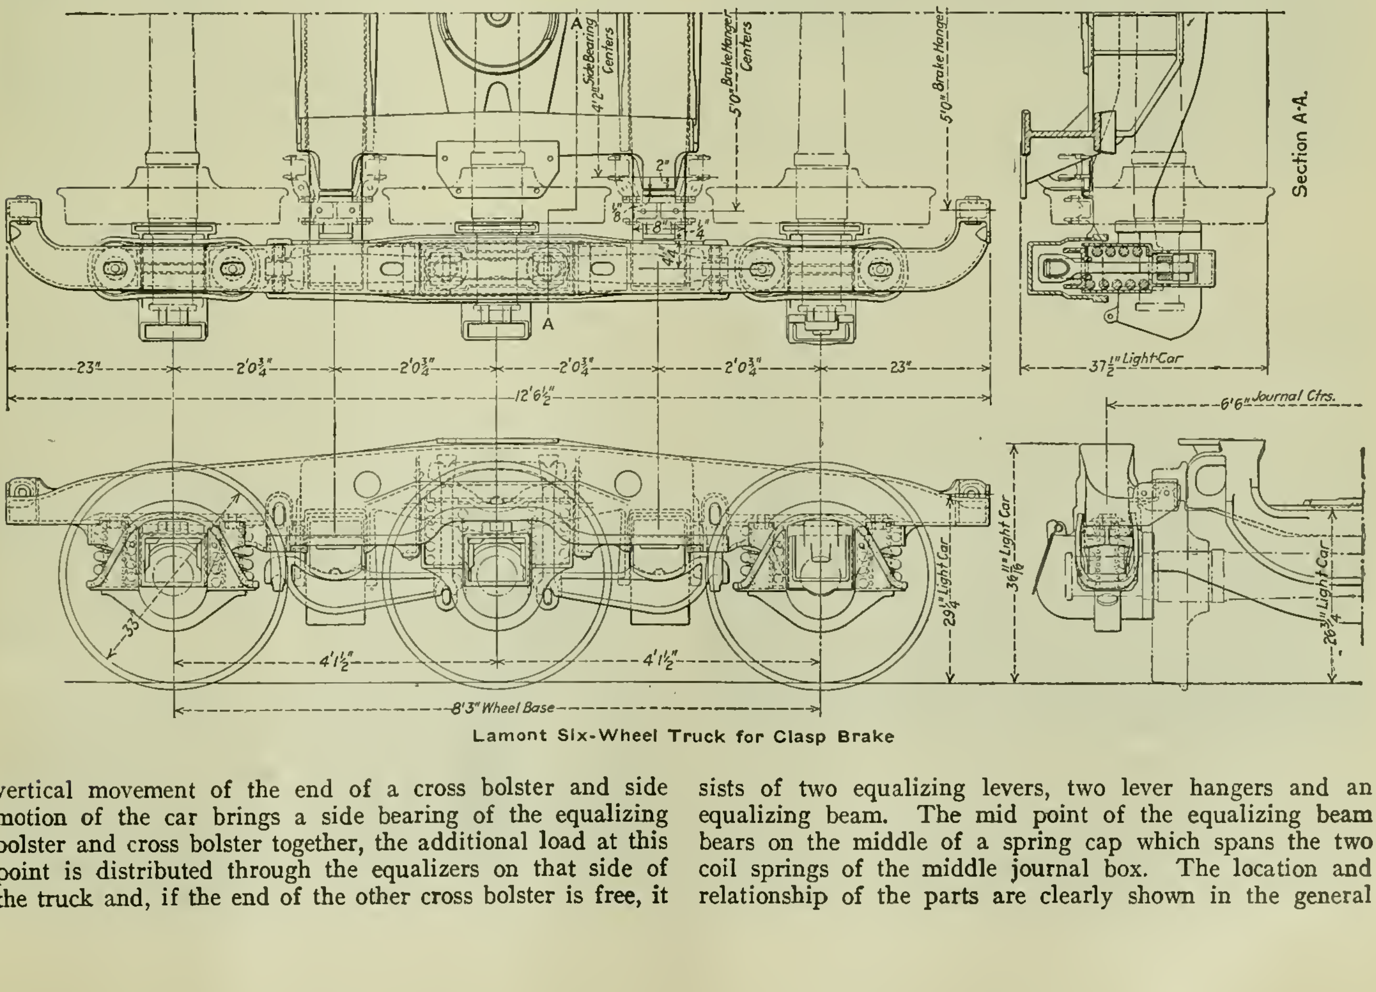
The springs are placed directly over the journal boxes and coil springs are used throughout.

The bolster consists of three parts: two cross bolsters and one equalizing bolster. The ends of the cross bolsters rest on the equalizing levers, and the equalizing bolster, which carries the center plate and truck side bearings, bears at the center of the cross bolsters with a clearance of ¼ in. at the side bearings when the car is riding level. The construction of the equalizing bolster is shown in one of the drawings, from which it will be seen that the center plate load is delivered to the side members of the equalizing bolster and through these to end portions which, taken separately, are inverted U-shaped bolsters designed to bear at the center of the cross bolster and nominally take one-quarter of the center plate load at each end. The bearing surfaces of these end portions of the equalizing bolster are curved to a radius of 20 ft. This permits a rocking movement of the equalizing bolster on the cross bolsters, and also provides for a limited amount of upward or downward movement of the ends of the cross bolsters as the wheels pass over inequalities in the surface of the track.



Details of the Journal Boxes

Under average track conditions this insures an equal distribution of the center plate load over the four points of delivery to the equalizing system. When a combination of vertical movement of the end of a cross bolster and side motion of the car brings a side bearing of the equalizing bolster and cross bolster together, the additional load at this point is distributed through the equalizers on that side of the truck and, if the end of the other cross bolster is free, it may be partially carried back across the truck to the other equalizing system.

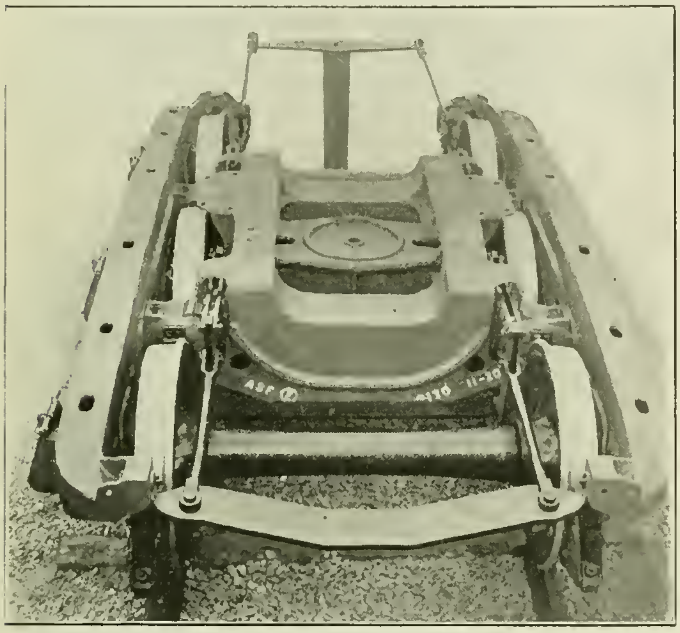


Lamont Six-Wheel Truck for Clasp Brake

Because of the clearance provided between the side bearings of the equalizing bolster and the cross bolster, very little clearance, if any, is necessary between the car body side bearings and the roller side bearings attached to the equalizing bolster.

The equalizing mechanism on each side of the truck consists of two equalizing levers, two lever hangers and an equalizing beam. The mid point of the equalizing beam bears on the middle of a spring cap which spans the two coil springs of the middle journal box. The location and relationship of the parts are clearly shown in the general drawing of the truck. The load delivered to either end of an equalizing bolster is taken up by an equalizing lever and delivered in the ratio of two to one, to the end and middle journals, respectively—to the end journal indirectly through the side frame, springs and journal box and to the middle journal through the lever hanger, equalizing beam, springs and journal box.

The journal boxes are of special design in which pockets have been provided on either side to receive the coil springs. Thus located, the springs support the maximum amount of dead load, they are protected through the equalizing mechanism against overloads and are in the best position to take up shocks from the individual wheels without passing them on to the equalizing system.



A Top View of the Truck, Showing Arrangement of Bolsters and Brake Rigging

Double coil springs are used on the end journal boxes and single coils on the middle journal boxes. The inner coils used on the end journal boxes have a free height 2¼ in. greater than the heavy outside coils. They are compressed to the height of the outer coils under the light weight of the car, and with this compression exert a force on each of the end journals of approximately 1,750 lb. The heavy coils are the same on both the end and middle boxes and are necessarily of high capacity, compressing only about ⅛ in. under the light weight of the car. Because of this comparative lack of resiliency under the weight of the empty car the inner coils have been provided at the end journals as a protection against possible derailment. The middle wheels being free to act through the flexible equalizing mechanism, do not require the protection of the inner coil springs, and only the heavy coils are used.

The middle journal boxes are guided by the side frames on their ends only. Clearance is provided between the upper portion of the boxes and the side walls of the frames to permit freedom of lateral movement of the middle pair of wheels on curves. When the middle journal boxes move laterally, an inverted pendulum motion takes place in the equalizing lever hangers, suitable provisions for this movement being made in the bearing surfaces of the hangers, keys and connecting parts.

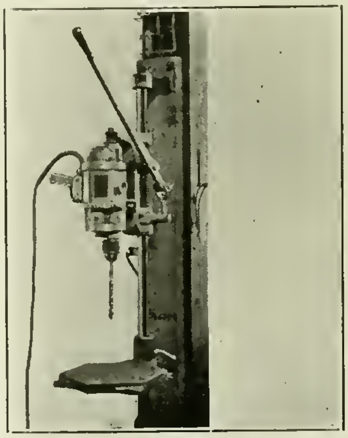
This truck has a wheel base 8 ft. 3 in., which is the shortest of any six-wheel truck yet developed. This has been an important factor in keeping down the weight of the trucks which, with the three-part bolster construction and clasp brakes, is 36,300 lb. per car. All parts of the truck are designed to carry a center plate load of 140,000 lb. and a 50 per cent overload on the side bearings without exceeding a fibre stress of 12,000 lb. per sq. in. All surfaces of contact between the journal boxes and the side frames are protected against wear by 3/16-in. hard steel liners. On the end journal boxes these liners are shaped to fit the top and sides of the boxes as well as the vertical flanges. For the middle journal boxes the liners are attached to the frame surfaces.

The truck has been designed for either clasp or single brakes. The trucks furnished for single brakes differ from those designed for the clasp brake rigging only in the shape of the side frames. For the single brake rigging the frames terminate at the outside spring pockets for the end journal boxes.

Adaptability Secured in New Post Drill

DETAILS of an application of Black & Becker portable electric drills to bench drill stands were given on page 740 of the November *Railway Mechanical Engineer*. Since that time the idea of the bench drill stand has been extended to make the stand attachable to a post or wall, whichever is more convenient. Standard portable electric drills of capacities from ⅜ in. to ⅞ in. are used in the new post or wall drill, and the principal change from the bench stand, previously described, has been to increase the length of the 1⅞ in. steel shaft and to arrange for holding it rigidly to the post by means of heavy brackets at the top and bottom. One other change has been in the arrangement for raising, lowering or swinging the table. All adjustments of the table are secured by means of the clamping screw shown in the illustration.

Attachment of the drill to the stand may be easily and quickly accomplished. As shown in the illustration, the brackets carrying the drill can be raised, lowered or swung around on the vertical column and secured in any desired position by means of a split collar and clamping screw. A strong spiral spring returns the drill to the high position when the feed lever is released. As both the drill brackets and drilling table have horizontal and vertical adjustments, the wall drill is an unusually flexible outfit, and for this reason is adaptable to a great variety of uses. It is made by the Black & Becker Manufacturing Co., Towson Heights, Baltimore, Md.



Black and Decker Post Drill

Specifications for the new post drill call for a column length of 46 in., vertical adjustment of drill 25¼ in., drilling radius 7 in., horizontal adjustment of drill 180 deg., feed by lever, 4½ in., and net weight 80 lb.

The extra long feed lever, illustrated, gives a feed ratio of approximately six to one, or in other words, a pressure of 80 lb. applied to the handle feeds the drill under 480 lb. pressure.

Rotary Wire Brush for Cleaning Operations

A ROTARY wire brush has been designed by the Independent Pneumatic Tool Co., Chicago, for use with the No. 71 Thor pneumatic grinder. It is interchangeable with the grinding wheel, an arrangement which in reality provides two tools in one, since the machine may be used either as a pneumatic grinder with a 4 in. emery wheel, or as a rotary wire brush for cleaning operations.

Thor Rotary Wire Brush Designed for Cleaning Operations

The face of the brush is 5 in. in diameter and, as shown in the illustration, all wires are of equal length, being hairpin shaped and made of specially treated steel. The concave back allows the wires to bend under pressure without breaking. By using this brush a large amount of time can be saved over that required by hand for the removal of paint, rust, scale, grit, etc. It is particularly useful on steel cars, tanks, frames, castings, sheet metal and other materials.

Duplex Compensating Suspension for Tractors

THE Baker R & L Company, Cleveland, Ohio, announces its new series C models of electric industrial tractors and trucks replacing the series B machines produced during the past three and one-half years. An important feature of the new machines is the ingenious manner in which the heavy thrusts of the axle and the driving and braking strains are resisted through what is known as the duplex compensating suspension. This suspension positively resists all torque and driving strain, provides for free spring action and maintains accurate alinement at all times between the axle and the frame.

Referring to Fig. 1, it will be seen that the axle is suspended by means of two V-shaped yokes through large ball and socket joints on the axle and trunnion bearings on the truck frame. The horizontal or driving yoke *A* transmits the driving power from the axle to the frame while the vertical or torque yoke *C* resists "torque" or the tendency of the axle to rotate and also has a slight forward and backward motion when compensating for the angular movement of the driving yoke.

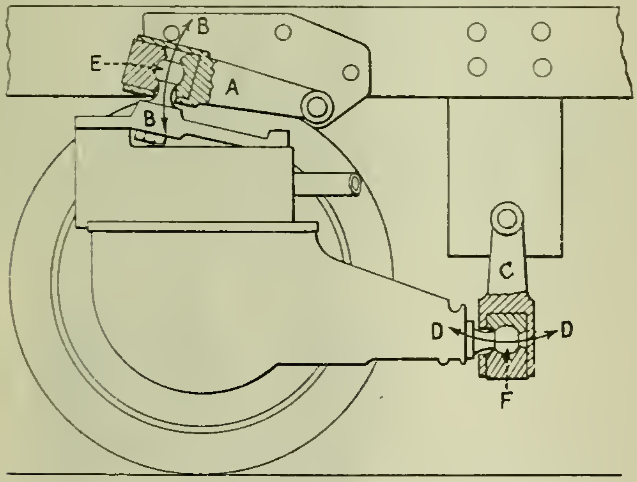


Fig. 1—Line Drawing of Duplex Compensating Suspension

The double concentric helical springs (not shown on the drawing) support only the truck load. They are loosely seated in the frame and axle members which are tied together against rebound with spring bolts, swiveling in their sockets. The flexibility provided by this construction permits the driving axle to negotiate either smooth or rough road surfaces, increasing traction without loss of power efficiency or clamping or binding the parts. Of equal importance is the elimination of maintenance expense, looseness and rattling when torque reactions are taken through sliding surfaces used in conventional constructions. The large, lubricated, trunnion bearings and adjustable ball and socket joints insure durability of parts for the life of the machine. A phantom view of the mechanism is shown in Fig. 2.

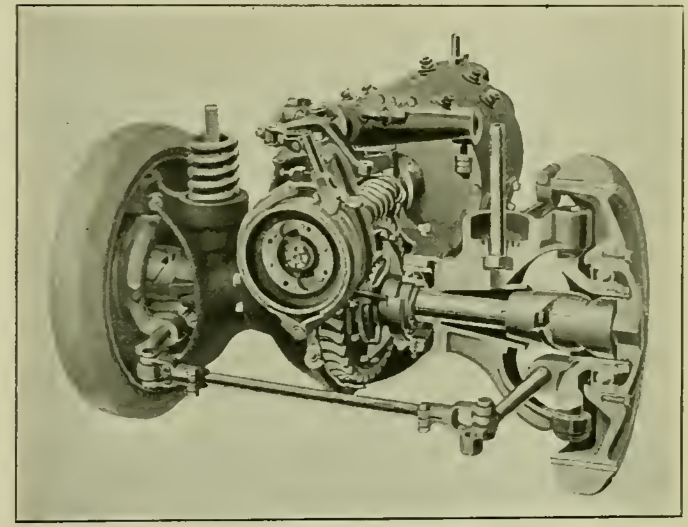

Fig. 2.—Driving Axle Equipped with Duplex Compensating Suspension

Emphasis is laid on the importance of the duplex compensating suspension because machines of the industrial truck type are subjected to extremely severe torque stresses. Although operated at slow speed they are frequently bumped into heavy objects and throughout their life must resist the

Fig. 3.—View Showing Method of Making Impact Tests

strains coming from abrupt starting and stopping. In fact, many operators change abruptly from full speed ahead to full speed reverse, subjecting the machine to heavier strains than are ever encountered in other vehicle work.

Sample machines incorporating this new feature were subjected to some unusual tests of a spectacular nature and stood up satisfactorily under strains which would easily have caused failure to trucks equipped with a less rugged and flexible type of spring suspension. In one of the tests a tractor, shown in Fig. 3, equipped with duplex compensating suspension was operated down a 12½ per cent ramp at 10 miles per hour as an impact test. The tractor struck a blow of 46 tons against the bumping post without damage to the spring suspension or other parts.

Automatic Valves Reduce Boiler Shut Downs

Modern power plants with their batteries of boilers, headers and many branch steam pipes, are susceptible to disastrous accidents and expensive shutdowns in the case of bursting boiler tubes or steam pipes. As a safety feature, the Golden-Anderson Valve Specialty Co., Pittsburgh, Pa., has developed an automatic, double-cushioned, triple acting, non-return valve for application in the main steam lines. The valve is entirely automatic in action, and in case of a split boiler tube or broken steam pipe, a reduction of pressure of 1 lb. or more below the pressure of the other boilers will cause the valve to close and isolate the boiler involved, thus allowing the other boilers to give uninterrupted service.

Should a break occur in a header or steam line, the valve on every boiler will instantly close, thus eliminating the havoc which would occur were the live steam from all the boilers permitted to escape through the break. It is also maintained that this valve equalizes the load between all the boilers automatically and makes possible the immediate location of a lagging or sluggish boiler.

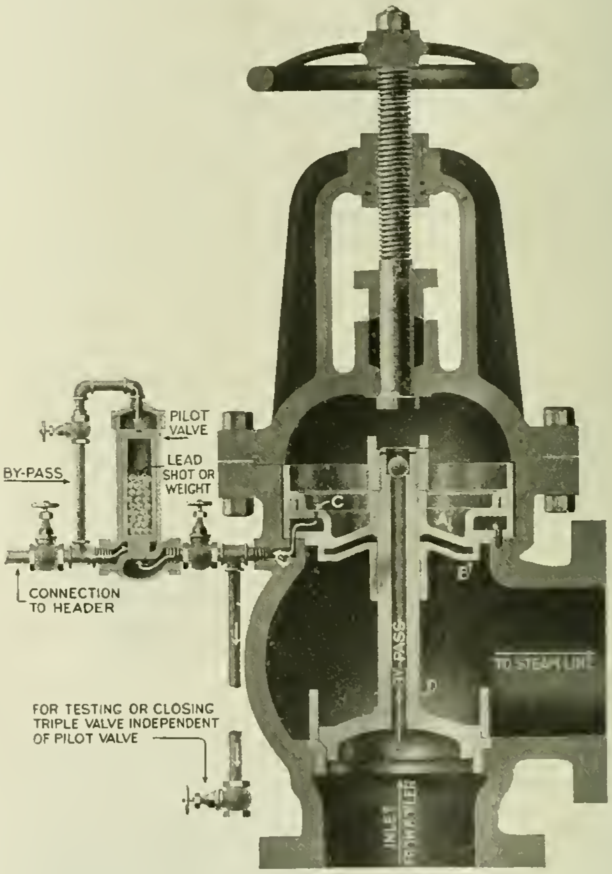
There is no need for hand operation as the valve automatically cuts in the boiler or cuts it out as the pressure equals or becomes less than the other boilers. If the steam gage should become defective and inaccurate the boiler cannot be cut in prematurely, as may happen with ordinary hand stop globe valves. At any time while in service under pressure the valve may be instantly tested or closed from the boiler room floor or other remote point.

The valve is fitted with special dash pots which provide against any hammering, pounding or spinning, and this feature assures smooth and durable operation. In the design of the valve. particular attention has been paid to provide adequate strength for the constant strain and vibration of a piping system. Perfect alignment is secured at all times and this prevents the binding and sticking commonly encountered.

Referring to the sectional view of the valve, it will be noted that the outside dash pot *B* is securely anchored to a shoulder of the valve body by numerous cap bolts. This dash pot acts as a cylinder for the inside dash pot *A* which is firmly fastened to valve disk *D* by a large lock nut. The design of the two dash pots affords a primary and a secondary cushioning (double cushion) effect which positively prevents any hammering or pounding. In case of an accident causing sudden closure of the valve, the double cushion allows an instantaneous drop of the valve to within ⅛ in. of the seat and then it closes smoothly under the control of the secondary cushion, preventing disastrous closure.

Automatic valves are usually placed on top of the boiler nozzle or installed in the steam line leading from the boiler; also in branch lines leading from the header. The automatic shot pilot valve is located adjacent to the main valve and piped into the header at about 15 ft. from the main valve on its outlet side. The automatic testing feature is connected between the pilot and main valve and extended to the boiler room floor. Boiler pressure is applied underneath the disk *D* and the valve, being balanced, will open automatically wheneven the pressure underneath the disk equals that above it. On reverse steam flow, as a result of less pressure beneath the disk *D* than above it, the valve will operate within 1 lb. variation.

In the case of a broken steam line or header with the valve working at 150 lb. pressure and the pilot valve set for 8 lb. differential, the instant pressure above the main valve disk drops to 142 lb. or less, it will permit the pilot valve to open and release the steam from between the dash pots. The main valve will then be instantly closed by the boiler pressure accumulating above dash pot *A* through by-pass in valve disk *D*, thereby shutting off all steam flow through the valve. The differential pressure may be decreased or increased by changing the weight of shot in the pilot valve. An 8 lb. differential is usually maintained which prevents premature closing or tripping on unusual steam requirements.



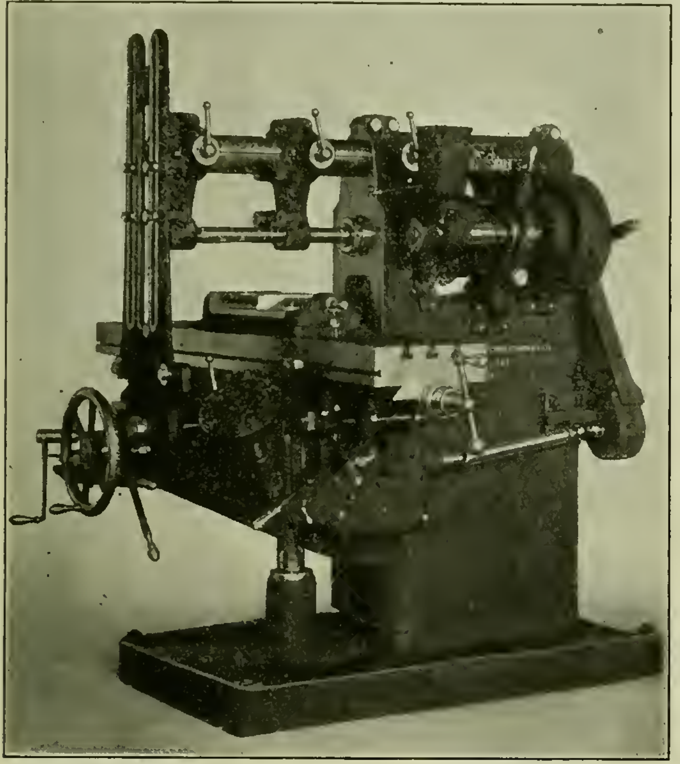
Golden-Anderson Automatic, Non Return Valve

The valve is equipped with a hand wheel and may be closed at any time like an ordinary stop valve. It will be noted, however, that the stem is not connected to the disk, but merely bears against it. Therefore, when testing a boiler hydrostatically the automatic valve can be left in automatic position, which allows it to float during the test and avoids strain on its parts.

An automatic valve should be tested automatically. By means of the automatic testing feature of this valve, it is possible to exhaust the steam between the dash pots at any time and determine whether the valve will close or not. The Golden-Anderson automatic valves are made in different sizes and several different patterns, including the angle pattern, globe pattern, vertical discharge elbow pattern, downward discharge elbow pattern, cross pattern, globe pattern for use where head room is limited, and others.

Cone Drive Plain Milling Machine

A NEW No. 4 plain milling machine with cone type drive has been developed recently by the Ford-Smith Machine Company, Ltd., Hamilton, Canada. As in the usual milling machine construction, special attention has been given to locating control handles for all movements of the knee and table within easy reach of the operator. In addition, rapid power traverse in all directions is secured, together with safety clips. An exceptional feed range, varying from .006 in. to 1.56 in. per revolution of the spindle, is provided. Rigidity of the knee is secured by eliminating holes in either the top or sides. A narrow guide is provided for the saddle on the knee. As shown in the illustration, a feed dial at the operator's hand indicates all feeds. Power feeds and automatic trips are arranged in all directions.



Ford-Smith No. 4 Plain Miller Equipped With Cone Drive

Special attention is called to the positive locking of the arbor supports on the overarm and of the overarm in the column. The column is of box section construction with heavy walls and bars for supporting the knee and bearings. Micrometer adjustments by means of graduated collars reading to 1/1000 in. are provided for the table screw, cross screw and elevating screw. The table is unusually stiff with wide bearings and great depth. The feed box is not carried on the column in the usual manner, but is bolted to an extension of the saddle on the knee. This construction makes possible the arrangement of the dial feed hand wheel, handy to the operator, at the working position at the front of the knee.

Twelve changes of speed are obtained from the dial which, in conjunction with the coarse feed handle at the side of the column, gives 24 changes when the back gear is in mesh. For ordinary work the feed is driven from the feed pinion geared to the spindle, but when the back gears are engaged the feed may be driven from the cone pinion, which speeds up the whole feed mechanism 3 to 1, or 10.8 to 1, according to the ratio of the back gear engaged, thus making possible exceptionally coarse feeds.

The rapid power lever must be held in position by hand while the rapid power is engaged, making the mechanism practically fool proof. As an extra precaution, however, a safety trip device is provided should the rapid power or feed overrun at any time. The countershaft is of the two-speed, friction type with self-oiling bearings. Friction clutches are of an improved expanding type carefully balanced with means of taking up wear.

Specifications for the Ford-Smith No. 4 miller call for a table working surface 71 in. by 14¼ in. Three ¾ in. T-slots are provided. The longitudinal, cross and vertical traverse are 42 in., 12 in. and 20 in., respectively. The distance from the face of the column to the base is 30 in. Eighteen spindle speeds, ranging from 14 to 450 r.p.m., are provided. The overarm diameter is 4¾ in., and the distance from the center of the arbor to the underside of the arm is 7¼ in. Twenty-four speeds are provided with the back gear in and 12 without the back gear. The feeds per revolution of spindle range from .002 in. to .39 in. for the cross and elevation. Rapid power traverse for the longitudinal, cross and vertical movements are at the rates of 130, 33 and 11 in. per min., respectively.

Gap Crane Saves Erecting Shop Headroom

ONE of the most formidable problems imposed in the design of modern locomotive repair shops is to provide a traveling crane capable of lifting a complete locomotive high enough so that it may be carried over the tops of other engines in the shop to be set down at some other point. With the rapid increase in the length and weight of locomotives, so that 90-ft. cranes are now common, this utility has added greatly to the cost of erecting shops. One feature that has been especially troublesome is the great headroom required. Thus, with adequate allowance made for clearance, the height of a locomotive on the floor, plus that of another one being passed over the top of it, plus the depth of the traveling crane and its trolley, gives a total height of 54 to 56 ft. or more from the floor to the underside of the roof trusses. This height is obviously a source of great expense in construction and is also a disadvantage in the operation of the shop because of the waste of heat, inefficient illumination and disadvantageous height to which the crane operator is removed from the floor.

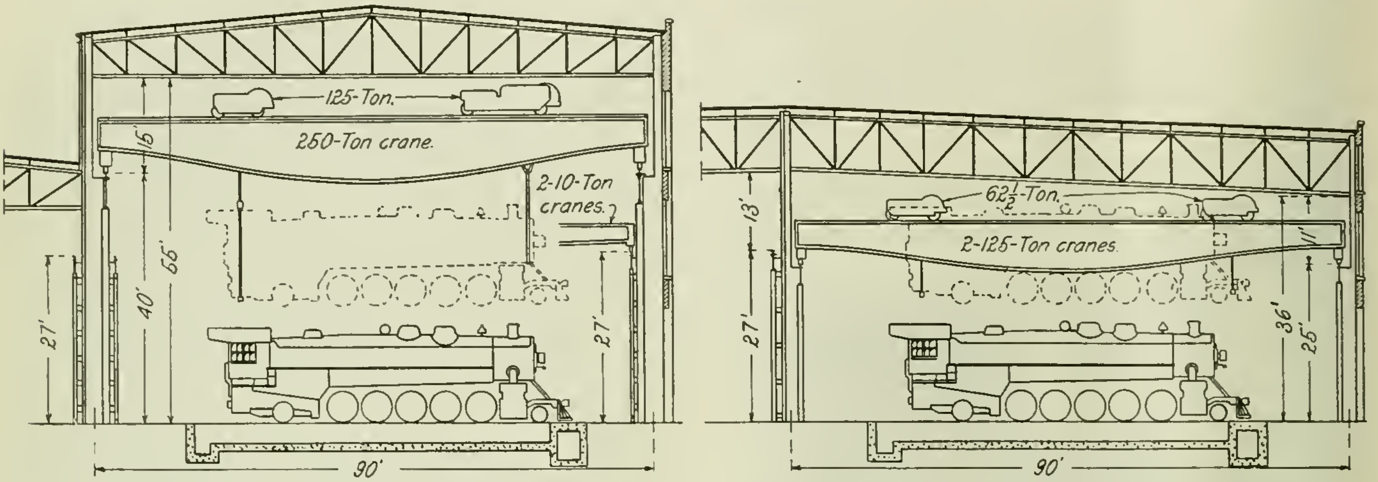
An appreciation of these shortcomings of the prevailing arrangement of shop structures has led to the development of the "gap crane" erecting shop by which from 15 to 18 ft. of the vertical height of the shop building may be saved. The idea is simple. The girders of the crane are spread apart a sufficient distance to permit the locomotive to be lifted up between them. As a consequence the crane may occupy the same vertical position as the locomotive, and the vertical height between the floor and the underside of the roof trusses consists of the height of the locomotive on the floor, plus the height of the locomotive in the air, plus the necessary clearance. The idea will be understood more clearly after an examination of the illustrations.

The gap crane is made up of four girders arranged in pairs with the two pairs separated a sufficient distance to allow the entire locomotive to be lifted up between them. Four trolleys of 62½ tons capacity each are used in pairs with the hooks or lifting devices at the ends of the fall lines attached to lifting beams which engage the front and rear ends of the locomotive. The lifting beam at the front end may be placed either under the extended sills or side frames which support the pilot truck or may be provided with adjustable saddle blocks and placed under the front end of the boiler, thus giving the same advantages as the sling rig but with greater resistance against overturning, a safety feature of importance.

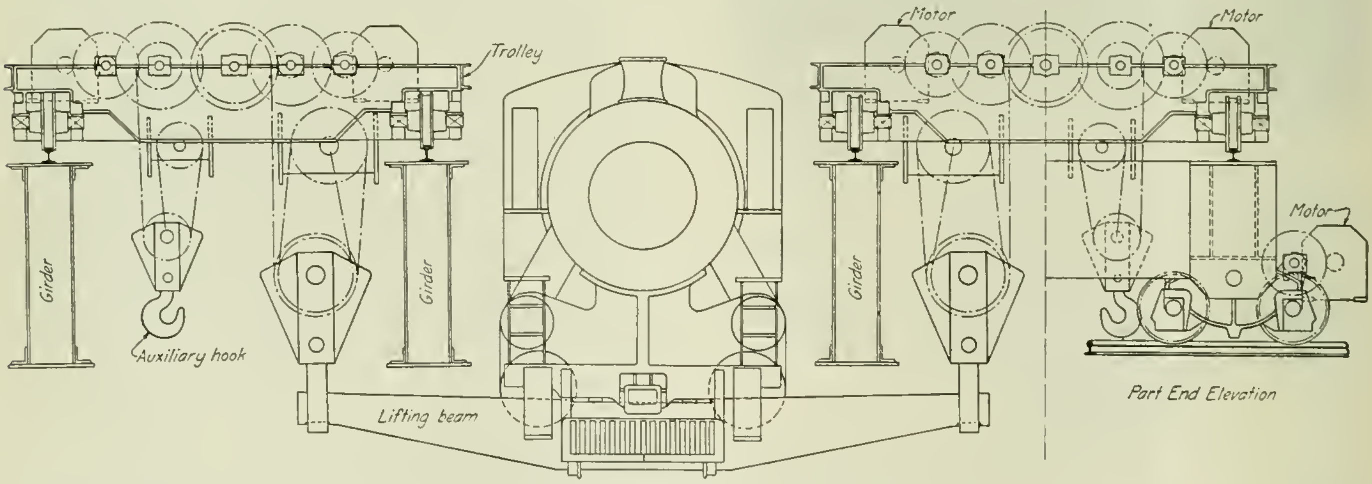
The gap crane may be constructed as a single unit or the two pairs of girders may be arranged to serve as independent "twin" cranes with provision for multiple unit control when they are used together for lifting a locomotive. Another feature of this development is the facility it offers for adaptation to old shops equipped with a crane of limited capacity. Thus, if a shop is equipped with a traveling crane of 120 or 125 tons capacity, a second crane of the same capacity may be provided and the two arranged to serve as twin cranes.

One point not to be overlooked in considering this development is the need in any modern shop of auxiliary or messenger cranes of 10 to 20 tons capacity. In the modern shop where high headroom has had to be provided for the lift-over operations, the auxiliary cranes have been usually operated on a separate runway about 27 ft. above the floor and therefore from 12 to 16 ft. below the runway upon which the large capacity crane is supported and thus the small cranes are enabled to operate without any appreciable interference with the large cranes. With the use of the gap crane in shops of 10 to 12 pits in erecting aisles, it is believed that the use of a single crane runway for both the heavy and light capacity cranes will work out very satisfactorily. With larger shops than this a more satisfactory arrangement would be to have the heavy cranes operated on a runway at an elevation of 24 to 27 ft. above the floor level and the light cranes mounted on a runway sufficiently high to enable them to operate over the tops of the heavy cranes. While this would involve some loss of the headroom saved by the use of the gap crane, it would accomplish a considerable saving in the cost of the steel frame of the building as compared with the case where the heavy section columns must be extended to the height necessary to support the heavy crane at the high elevation.

The idea of the "gap crane" erecting shop was conceived by Harvey Shoemaker, formerly superintendent of motive power of the Bangor & Aroostook, and construction work will be carried out by the H. K. Ferguson Co., Cleveland, Ohio.



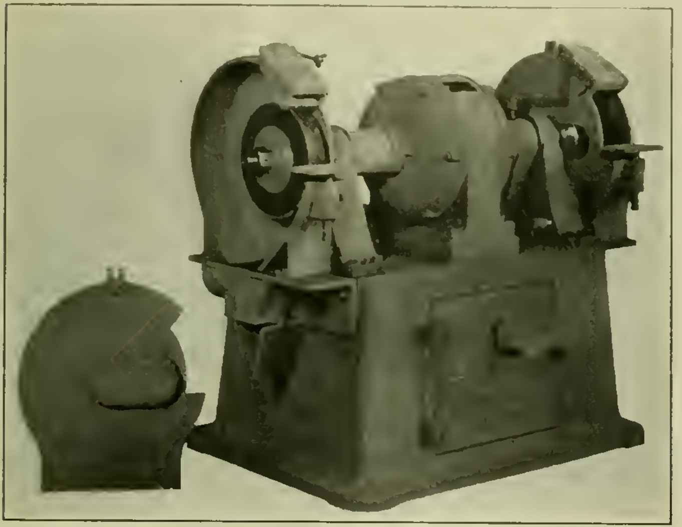
How a Gap Crane Reduces the Required Headroom in an Engine Shop



Cross Sectional Elevation of a Gap Crane

Heavy Duty Ball Bearing Dry Grinder

The Marschke Manufacturing Co., Indianapolis, Ind., has developed recently a No. 18 heavy duty, ball-bearing grinder, having four bearings. The machine is designed to swing either 18 in. or 20 in. by 3 in. wheels for dry grinding. The hood is adjustable, always bringing the wheel to the front of the hood, and an automatic control, spark plate adjustment is provided. The spark plate adjusts itself to the wheel as the steady rest is adjusted to the wheel by moving the hood. This is done by one hand wheel, no tools being required.



Marschke No. 18 Ball Bearing, Dry Grinder

The machine, illustrated, is provided with an exhaust fan, mounted inside the base. The fan operates on S. K. F. ball bearings and runs by means of a silent, high speed chain, all parts being enclosed in a housing kept free from dust and grit. The machine is equipped with or without an exhaust fan, as may be desired. The starter is mounted on the back of the door and opens with the door, permitting access to the blower. The machine is furnished with either a handle or push button starter. The hood support, which is also the outer ell for the exhaust, is equipped with an opening directly underneath the hood and answers for several purposes. It is used as a clean-out, and, when grinding brass, can be opened, the heavy brass particles being collected in a container underneath. This construction enables the brass particles to be saved and sold with other brass scrap.

Specifications for the new 18-in. dry grinder call for a 7½ hp. motor drive. The distance from the floor to the center of the arbor is 34 in. and the floor space required is 32 in. by 64 in. The speed of the motor under no load is 1,200 r.p.m.; under full load, approximately 1,160 r.p.m. When direct current motor drive is desired, a B. F. Sturtevant motor is applied and when alternating current is desired a Marschke motor, designed especially for this work, is used.

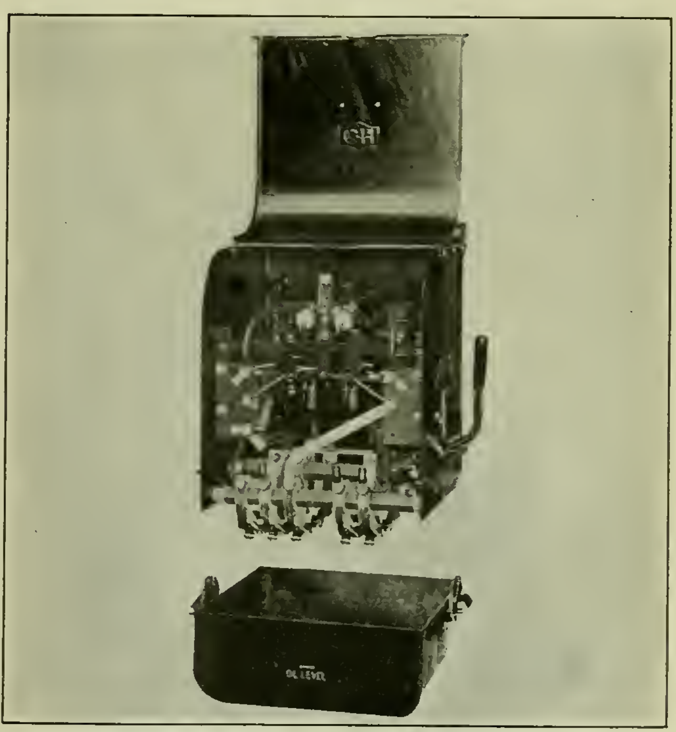
Rigidly Constructed Auto-Transformer Starter

The engineering department of The Cutler-Hammer Mfg. Co., Milwaukee, Wis., has devised an auto-transformer starter of unusually rigid construction to meet the severe requirements of the large industrial plant and mine, as well as that of the small mill and factory. The simple steel construction—using no wood or castings whatsoever—the absence of flexible moving leads, and the ease of inspection of the contacts and adjustments of the relays, enable this starter to give continuous and satisfactory service at a low upkeep cost. This starter, which is shown in the illustration, consists of two auto-transformers, commutating mechanism, low voltage release and duplex overload relay, all enclosed in a sheet metal case with the operating lever outside. The case is strongly reinforced with angle iron, and has a hinged cover which can be lifted to expose the transformers and relay. The transformers and case are carried directly on the supporting brackets and may be readily mounted on the wall, switchboard, or any post or pedestal.

The starter is operated by moving the operating lever forward to the starting position and then backward to the running position, where it is held in place by the low-voltage mechanism. Interlocks prevent moving the lever directly to the running position. If released in the first or starting position, the lever is returned to neutral by a spring. Locked in the neutral position it prevents unauthorized operation.

Two auto-transformers connected in open delta are used for both two and three phase service. The special construction of the transformer core allows either coil to be easily and quickly replaced. Each coil is provided with three accessible taps which give 50, 65 and 80 per cent of full line voltage.

The low-voltage mechanism is mounted inside the case on the right-hand side. A wire from the armature of the release coil extends through the case near the operating handle and is bent to form a hook, a slight pull on which releases the starter and returns the handle to neutral. Remote control of stopping may be obtained by inserting one or more normally closed pushbutton switches in the low-voltage circuit. Any push button will release the starter mechanism.



Starter With Oil Tank Lowered and Cover Thrown Back

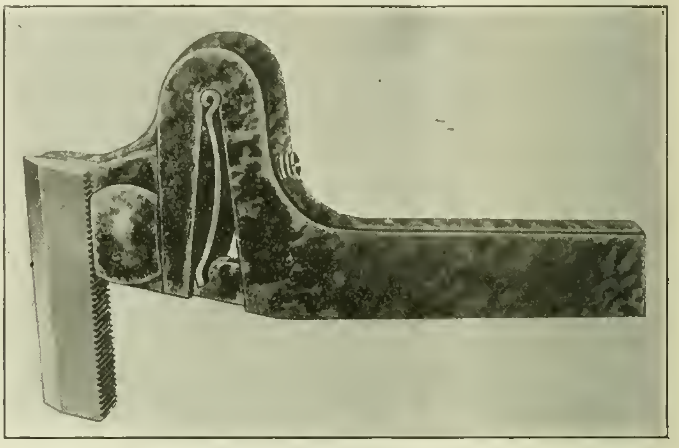
A duplex overload relay with a true inverse time limit movement is mounted inside the case on the transformer assembly in such a position that adjustments for time and current values can be readily made. This duplex relay is equivalent to two overload relays, each in series with one of two phases. The underwriters' rules do not require the installation of a disconnecting knife switch or circuit breaker ahead of this starter when thus equipped, because the starter completely disconnects the motor from the supply line when released by an overload.

These starters are made in various sizes for the operation of two or three phase induction motors rated between 5 and 100 hp. on standard commercial voltages between 110 and 2,200 and at frequencies of 60, 50, 33 and 25 cycles per sec.

Spring Threading Tool of New Design

THE old goose neck principle is incorporated in a new threading tool made by the Ready Tool Company, Bridgeport, Conn., for the purpose of eliminating chatter and to enable the operator to cut smooth threads on all lathe work. The cutter is held at an angle of 15 deg. and the side angles are accurately ground so as to cut a practically perfect 60 deg. thread. The cutter, being held on the left side of the holder, enables the operator to work close up to a shoulder. The spring allows threaded work to be finished smoothly and as only high speed cutters are provided threading can be done at high speeds.

Notched teeth are cut in the back of the cutter and in the front of the dog, the two being clamped together with a bolt holding the dog to the tool holder, which overcomes any possibility of the cutter slipping. An auxiliary spring with a set screw is incorporated in the holder and by increasing the pressure, heavy pitches, such as four, six and eight, can be cut just as smoothly as the finer ones, in which latter case the auxiliary spring is released.

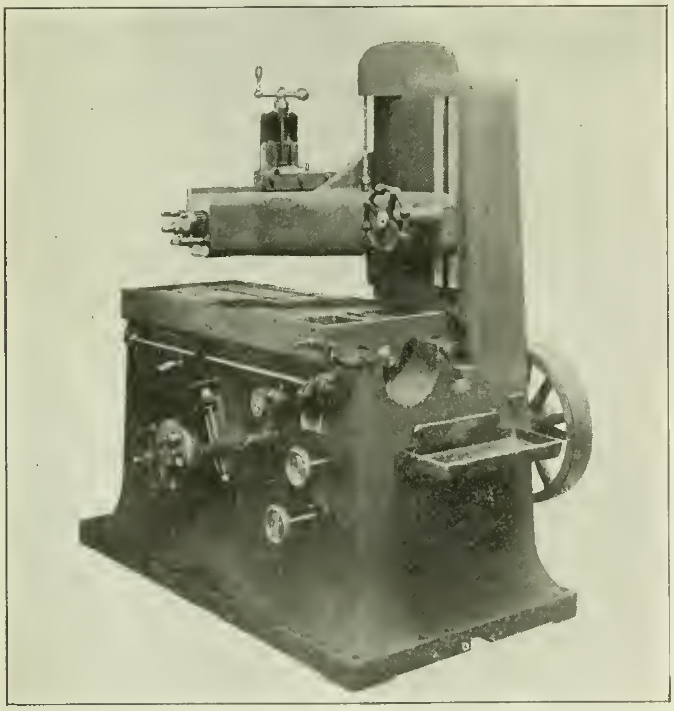


Ready Spring Threading Tool

Only the top surface of the cutter requires to be ground, thus assuring long life for the tool and accurate threads. A Woodruff key in the bottom overcomes any possible side thrust. "V" cutters as well as U. S. standard pitches and chasers are carried in stock for immediate delivery. This tool is made in right hand offsets, size ½ by 1 by 7 in.

Combination Clutch Brake for Shaping Planer

THE latest type of Coulter shaping planer, built by the Automatic Machine Co., Bridgeport, Conn., is shown in the illustration, and a noteworthy feature in its construction is the combination clutch brake mechanism. This is operated from the front of the machine, and enables the table to be stopped and started instantly without changing the motor or countershaft speeds. In fact, with this arrangement, no countershaft is necessary on the belt-driven model, as it can be belted directly to the main line shaft, thereby saving space where head room is limited. A length of stroke indicator is also provided together with clamps for clamping the down feed while the cross feed is working, or vice versa. These features are especially desirable for many tool room machine operations.



Coulter Shaping Planer Equipped With Clutch Brake

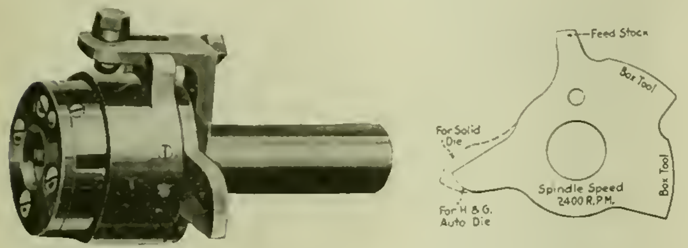
The clutch brake mechanism consists of a raybestos lined brake and a main driving pulley made up of two concentric wheels, the inside rim of one and the outside rim of the other being bevelled at an angle which by repeated tests has been shown to be most satisfactory for the purpose. Movement of the operating handle to throw out the clutch applies the brake simultaneously. There is a split nut on the driving shaft so that the amount of friction in the clutch can be adjusted. The large bearing surface and large diameter result in a minimum of wear, maximum torque for a given pressure and absence of appreciable heating. The whole arrangement is simple, with few parts to get out of order, a valuable feature for any machine in railroad shop use.

Other features, making the new Coulter planer of especial interest, are the shaper advantages of quick return stroke, variable speeds and ability to cut to a shoulder, with planer accuracy and table capacity. The maximum stroke can be taken with the same accuracy as a shorter one, and this maximum stroke can be taken anywhere on the table by merely positioning it under the tool without disturbing the work.

Redesigned Trip Levers for Die Heads

THE Eastern Machine Screw Corporation, New Haven, Conn., has developed a new self-opening die head for use on Brown & Sharpe automatics, which is said to practically double the production of button dies. The principle by which the chasers are held and operated with the positive bearing directly over the cutting edge is the same as in all H. & G. die heads, but changes have been made in the method of drive and in the design of the trip lever, as shown in the illustration.

Previously the head was kept from turning in the floating shank by a pin through the shank proper engaging and traveling in diametrically opposite slots in the floating shank. As redesigned, this is accomplished by an extension on the shell of the head which engages both sides of the arm of the floating shank that overhangs the body. This brings the drive further from the axis of the die head and decreases the friction to a negligible quantity, with the result that the coarsest pitch which the machine will pull is threaded without friction or cramp in the head.



Style D. H. & G. Die Head with New Method of Drive and Trip Lever

At the same time the design of the trip lever has been changed to make it sensitive for the finest threads up to 90 per in. These changes make it a simple matter to install the new heads on any Brown & Sharpe automatic.

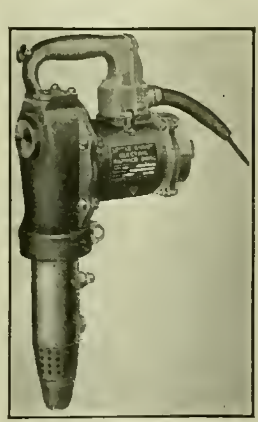
The layout of the cams is much simplified, inasmuch as they do not have to conform to the lead of the screw either on the advance or reverse, simply starting the thread and advancing the turret somewhat less than the amount of the lead, after which the die head pulls out and trips at the proper point.

The adjustment for length of thread is accurately made by an adjusting screw which brings the tripping button to the proper point. With this head it is possible to cut to a shoulder or a given point with great precision and simple adjustment is provided for the depth of cut which can be controlled to less than .0005 in. By the use of these die heads, it is possible to obtain an additional speed, inasmuch as the reverse belt can be used for forward driving at a more favorable speed.

The illustration shows a cam outline and compares the solid die cam with the self-opening die cam, showing that the change is very simple. This particular cam is threading at 2,400 r.p.m. One cam can be used for threading many different pitch screws. High speed steel chasers, provided with the proper clearances, produce straight, smooth threads at extremely high speeds.

Electric Hammer Drill of Novel Design

A HAMMER DRILL, driven by an electric motor instead of compressed air, is being manufactured by the Chicago Pneumatic Tool Company, New York. The drill is known as the Little Giant electric hammer drill, and is said to be particularly adapted for drilling concrete, soft stone and for light chipping of metals. The hammer blow, which is delivered by a piston on the drill steel or chisel, is produced by pneumatic impact. At the instant the blow is struck, the piston is running free of all mechanical parts and very little shock or vibration is transmitted to the electrical parts of the tool. The tool is so balanced that when held loosely in the hand, the line of center of gravity falls between the third and middle fingers of the hand and lies within the barrel of the tool, causing the tool to hang vertically and be easily controlled. The switch is located in the handle. All bearings are of the ball type and provision is made for the lubrication of all revolving and reciprocating parts. The gears and other portions of the moving parts subject to wear are all hardened. A universal type of motor is used which will operate either on direct or alternating current and motors will be supplied for either 110 or 220 volts



Electric Hammer Drill

A special feature of this drill is a live air device for clearing the hole of the cutting while drilling. The purpose of this device is to keep the hole clear, so that when holes are drilled in stone or concrete in a downward position the air will dispose of powdered cuttings which absorb and waste much of the force of the blow and tend to choke up the hole. This makes it possible not only to deliver the full force of the blow on the stone or concrete, but makes it easy to get the drill bit out of the hole. Hollow steels or bits are furnished for this purpose.

The efficiency and convenience of electric operated tools are well known and the Little Giant hammer drill marks one of the first attempts to operate a hammer by electricity.

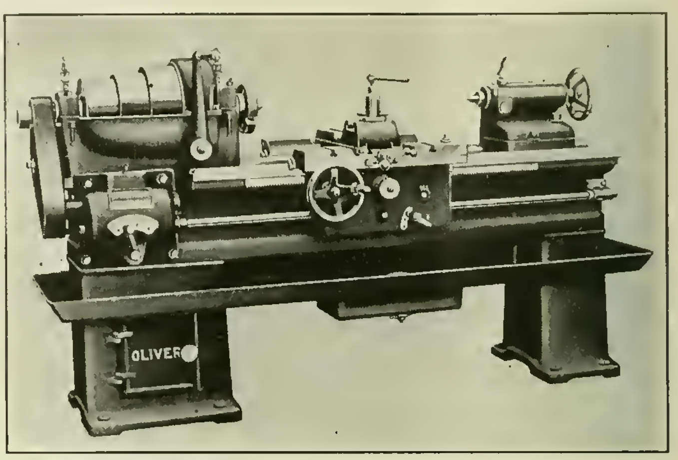
Fibrous Metallic Packing for General Use

FOR packing reciprocating, or revolving rods, glands, cocks and valves of all kinds, a metallic packing known as "Red Seal" has been introduced to the American market by General Engineering Accessories, Ltd., London. The feature of particular interest about this packing is its physical composition. It is a plastic metallic composition, "a fibrous mass, composed of 88 per cent impalpable powder of special alloy so fine as to pass through a sieve with 10,000 meshes per square inch." The packing is readily broken up by hand and can be kneaded, a characteristic which enables it to be packed into a gland of any shape and be distributed evenly. Tightening the gland compresses the packing together until it becomes a metallic ring, stated to be practically as impervious as a collar of steel. At the same time, due to the exceeding fineness and structure of the alloy, it cannot score the rod or stem which it surrounds. The use of a small quantity of cylinder oil mixed with the packing will facilitate packing inverted glands or glands in awkward positions.

Advantages claimed for Red Seal Packing are that it never scores or tapers a rod, never burns or gets hot, is equally efficient for superheated steam, hot or cold water, tar or ammonia, requires no skill to apply, does not harden, is self-lubricating and obviates the necessity of keeping a range of sizes in stock. It is being sold in this country by John Simmons Company, New York.

Simplicity Features New Oliver Lathe

After working on its design for several years, the Oliver Machinery Co., Grand Rapids, Mich., has developed a new 16-in. rapid production lathe, of which perhaps the most notable feature is its comparatively simple construction. By the elimination of more or less non-essential working parts and by strengthening the lathe at points subject to heavy working stress, a high production tool has been developed, which is now giving satisfactory service in several plants.

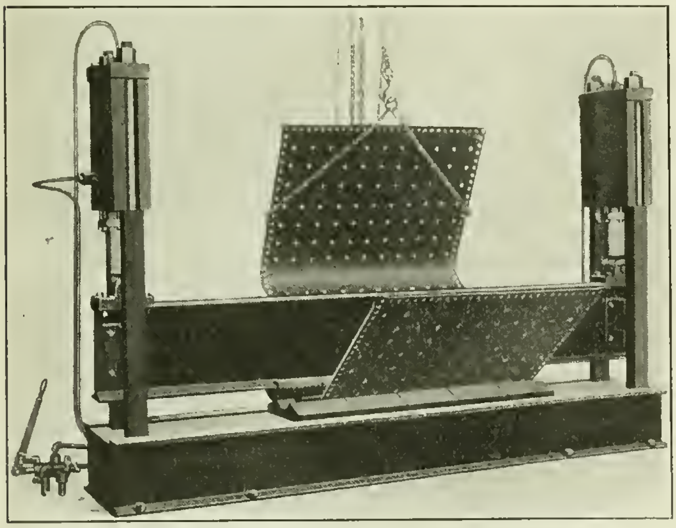


Oliver 16-In. Production Lathe

The simplest form of the lathe with a 3-step cone pulley headstock is shown in the illustration. The driving cone is large in diameter and each step of the cone is wide. This allows for a powerful drive at comparatively high speed. The large lever shown in the front of the headstock operates the starting and stopping clutch. The efficiency of this clutch and the ease of operating the lever are important elements in securing rapid production. The headstock may be furnished with double back gears or with single back gears, as desired. Four feeds are provided through the quick change gear box. The tool post is mounted on a carriage of substantial construction, as shown. Provision is made for a continuous flow of cutting compound at the cutting point. All working parts are carefully guarded.

Plate Press With Sectional Dies

A plate press designed for use with sectional dies has been developed by the Houston, Stanwood & Gamble Co., Cincinnati, Ohio. The machine consists of a simple arrangement of cross-beam, connected to rams at each end by bearings, having swivel pins which give the beam flexibility, and allows it to adjust itself to any unevenness of the work. The frame consists of heavy uprights, bolted through substantial cylinders at the top, and bolted through a heavy reinforced base casting at the bottom. The upper sectional dies are placed on the beam of the machine in a simple manner. A bar extended through a hole in each die enables it to be lifted by two men and slipped on at the end of the beam. It is then moved along to any position which may be desired.



Sectional Dies Produce Accurate, Interchangeable Work

The lower sectional dies are placed on the bed of the machine and aligned with the upper dies by means of the side channels which reinforce the bed. These side channels extend above the heavy base casting for that purpose. The operating lever for controlling both working and return stroke is conveniently located and is always within easy reach of the operator. The entire upper part of the machine is flexible to a necessary degree which takes care of any uneven strains and stresses during the working stroke.

The operation of bending a wrapper sheet is shown in the illustration, and the press is particularly adapted for this class of work, the work possessing the added advantage of interchangeability. The machine is built in various sizes and capacities, and is designed to operate by hydraulic or compressed air pressure.

Headlight Combines Strength and Lightness

The American Metal Products Company, Brooklyn, N. Y., has put on the market under the trade name "Ampro" a new electric headlight cast from a specially strong non-corrosive metal. The headlight weighs complete with mirror glass reflector 45 lb. On account of its light weight one man can install the "Ampro" without the use of tackle or special rigging.

Some of the features claimed for this new lightweight headlight are its weather tight and air tight construction; interchangeable straight and angle side number doors; improved latches which keep the doors intact under severe vibration; 14-in. mirror glass reflectors giving the maximum illumination required by the Interstate Commerce Commission; a new improved positive focusing device so constructed as to insure against breaking or bending of wires; and a specially designed positive electrical contact block which, when once wired, stays wired.

The "Ampro" headlight is readily fastened to the bracket on the smoke box door, or wherever it may be located, by means of four bolts through the legs.

Improvements in Twist Drill Grinder

The original New Yankee twist drill grinder, as made by the Wilmarth & Morman Co., Grand Rapids, Mich., was an improvement over previous types because preliminary calipering was eliminated, and positioning of the drill made entirely automatic. The only adjustment required was the setting of the tailstock for the various lengths of drills. This style of drill grinder, adapted to the grinding of straight shank drills only, remained standard with the Wilmarth & Morman Co. until the advent of taper and collared shank drills made a special attachment necessary.

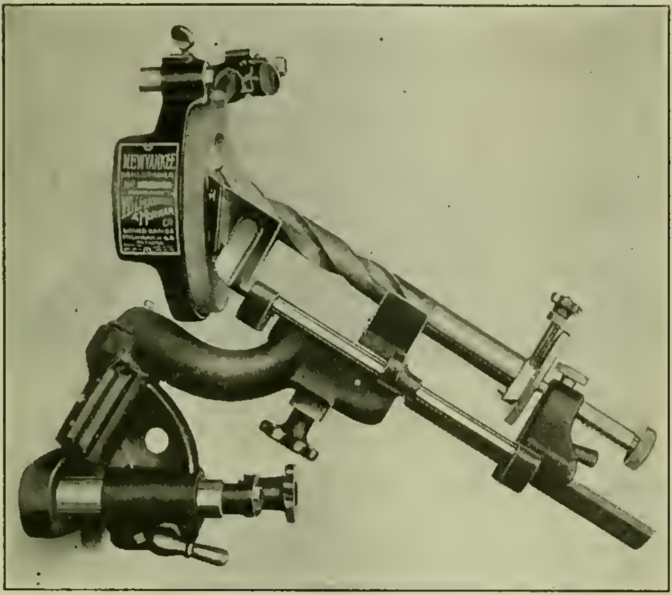


Fig. 1—Method of Holding Long Straight Shank Drill

The recently improved New Yankee drill grinder is provided with a new attachment by means of which straight and taper shank drills can be readily ground without any time consuming adjustments. The operation of the grinder is shown in the illustrations. Figs. 1 and 2 illustrate how long, straight and taper, collared shank drills, respectively, are positioned. When the body of taper and collared shank drills becomes too short to be supported by the sliding V block, Fig. 2, this part is thrown out and the shank of the drill is supported by a center detail in the elevating tailstock. Fig. 3 shows how a short, straight shank drill is positioned in the holder for grinding.

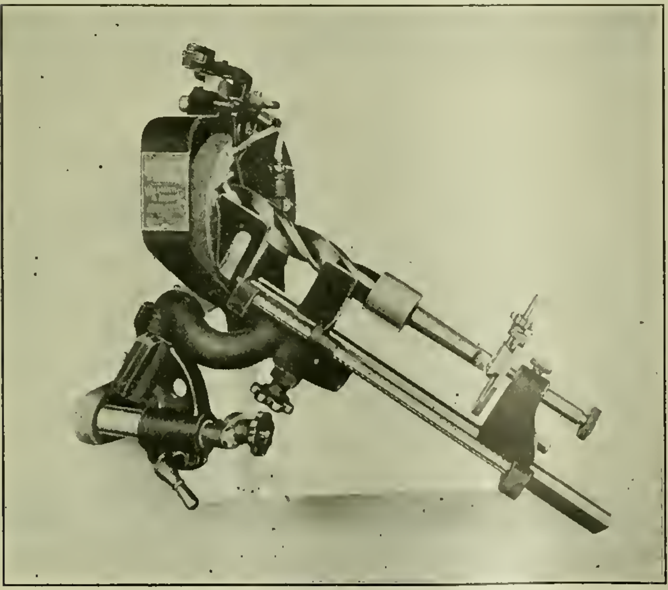

Fig. 2—Grinding a Taper, Collared Shank Drill

Nine belt and eight motor-driven styles of twist drill grinder are offered. These are made up in different combinations from four holders having the following capacities: No. 52 to ⅝ in., 3/32 to 1½ in., ¼ to 2½ in., and ½ to 4 in. Each machine is equipped with means for obtaining different clearance angles and includes a built-in wheel truing device.

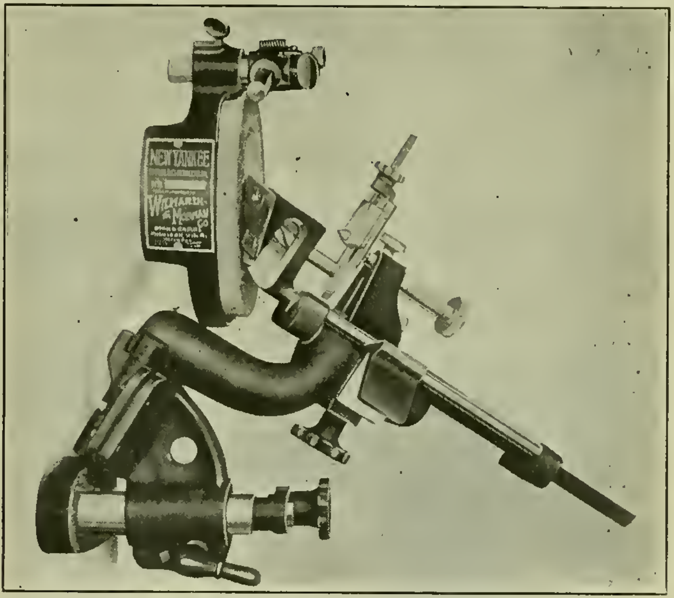

Fig. 3—Grinding a Short Straight Shank Drill

On account of the voluminous amount of drilling work in railway shops, twist drill grinders are an essential part of the toolroom equipment. The shop managements should not be content, however, to operate old style grinders when grinders with improved attachments are available. Especially when these attachments make possible a more accurate grinding of drills or when they allow for the grinding of short taper, or collared shank drills which would otherwise have to be ground by hand they should be installed. The aggregate saving due to their use will in the long run pay big dividends on the money invested.

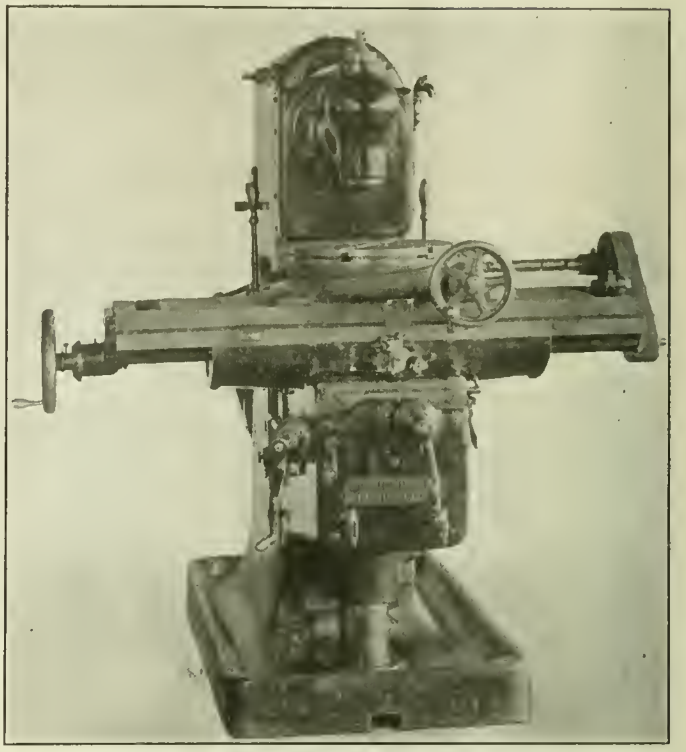
It is obvious that a shop or roundhouse so small as to require only the occasional use of twist drills could not afford the installation of a twist drill grinder, but in most cases the drilling requirements are large. Many drills of all different kinds and sizes have to be maintained in good working condition and, with the obvious inefficiency of hand grinding, the use of modern, improved twist drill grinders is advisable.

Rotary Table for Milling Machines

The rotary table as designed for Cleveland milling machines, made by the Clark-Mesker Company, Cleveland, Ohio, can be operated either by hand or power feed. There are sixteen changes of feed, controlled from the front of the knee in the same way as the other feed movements of the table. The direction of rotation may be reversed by using the feed reverse lever in front of the knee. The feed drive is taken from the table feed drive gear, connected by telescopic sleeves to a gear case on the end of the table. From this point a shaft extends and drives a pair of bevel gears which drive the work shaft. The worm is cut with a coarse pitch and runs in oil. The end thrust is taken care of both ways by large ball thrust bearings and means are provided for taking up the wear.

The worm wheel is accurately cut and is made sufficiently large to allow heavy cuts to be taken on the circumference of the table. The rotary table is liberally provided with T-slots of the same size as those in the milling machine table. An automatic trip for releasing the power feed at any desired point is provided. The circumference of the table is graduated in degrees for obtaining angular settings. The table has a tapered center hole to accommodate a short taper arbor for centering gears and other work as well as for clamping the work.

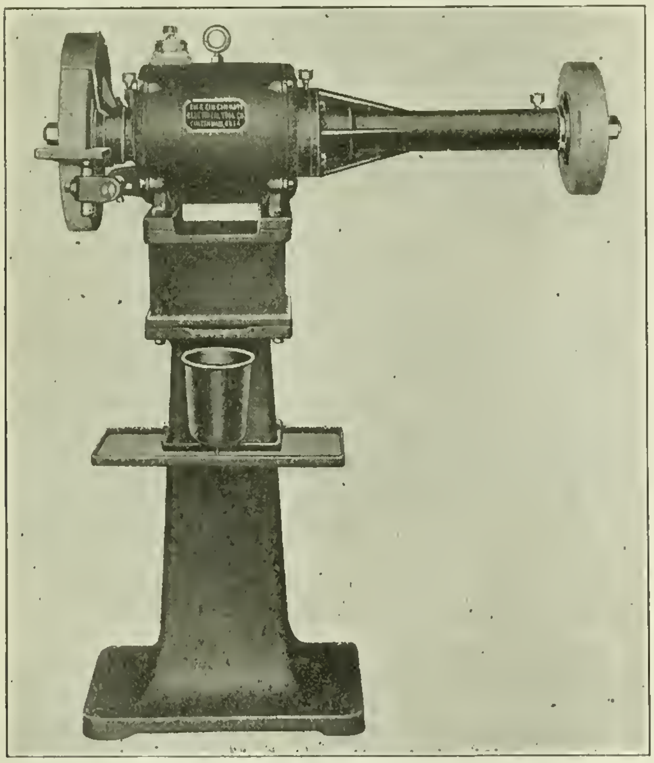
This rotary table attachment may be used for cutting large gears, sprockets, etc., or it may be used for dividing, when furnished with a crank and index plates. Index plates and crank, however, are not regularly furnished with the attachment.



Rotary Table Applied to Cleveland Milling Machine

Combination Grinding and Buffing Machine

A combination floor grinder and buffer which permits interchangeable buffing and grinding without the common delay of changing wheels, is the latest product of the Cincinnati Electrical Tool Company, Cincinnati, Ohio. The new machine is arranged with both grinding and buffing wheels, the grinding wheel being adapted to tool grinding and general grinding on all kinds of miscellaneous work.



Cincinnati Combination Grinder and Buffer

The motor windings are fully enclosed and protected and spindles are carefully ground. Annular ball bearings are fitted on both ends of the armature spindle, as well as the end of the extension spindle. Dust caps, fitted to the spindle, protect the bearings and windings from emery dust and dirt, thereby increasing the life of the machine.

The grinders are fully equipped, including tool board and water pot, and can be furnished without floor pedestal if desired.

The motors are made for direct or alternating current in ½, 1, 2 and 3 h.p. capacity to carry wheels from 8 to 14 in. in diameter.

Change in Safe End Taper

The Coleman tube safe end, as described on page 127 of the February *Railway Mechanical Engineer*, is shown to be held against movement towards the firebox by a square shoulder and against movement in the other direction by a taper end, beaded over. The taper, indicated, was 2¼ in. per ft. but experience shows that this amount is greater than necessary and a taper of 1½ in. per ft. has been adopted as standard.

Attention is also called to the statement on page 128 that the Coleman safe end requires about 10 per cent less working than the prossered safe end. In reality this should read 90 *per cent less* since the original statement was that Coleman safe ends require about 10 per cent *of* the working necessary with prossered safe ends.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

Subscriptions, including the eight daily editions of the Railway Age, published in June, in connection with the annual convention of the American Railway Association, Mechanical Division, payable in advance and postage free: United States, Canada and Mexico, $4.00 a year; elsewhere $5.00, or £1 5s. 0d a year. Foreign subscriptions may be paid through our London office, 34 Victoria street, S. W. 1, in £ s. d. Single copy, 35 cents.

WE GUARANTEE, that of this issue 9,200 copies were printed; that of these 9,200 copies, 8,253 were mailed to regular paid subscribers, 8 were provided for counter and news company sales, 265 were mailed to advertisers, 32 were mailed to employees and correspondents, and 642 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 40,200, an average of 10,050 copies a week.

The *Railway Mechanical Engineer* is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.)

Fire, early on the morning of February 16, destroyed a two-story shop building of the Missouri Pacific at St. Louis, Mo.; estimated loss, $100,000.

Senator Cummins, chairman of the Senate committee on interstate commerce, announces that he proposes to introduce at the beginning of the next session of Congress a bill providing for the compulsory consolidation of the railroads into 14 to 18 systems.

Eight thousand is the number of members of the National Safety Council who own or operate shops or other industrial plants; and the officers of the council propose to proprietors to conduct intensive campaigns, for some particular feature of safety, in all of these plants during one month throughout the year; a month to each feature. January was devoted to special efforts to prevent ladder accidents; February to infections arising from minor injuries, and March to unsafe clothing. For April the program is horse play.

Senator La Follette's speech in the Senate on February 21 and 22 in opposition to the passage of the Winslow bill has just been published in the Congressional Record, and, with the appendices, takes 64 pages, mainly in small type. The appendices consist largely of charts showing interlocking directorates and various statements presented by the labor leaders to the Railroad Labor Board at Chicago in connection with their charges that railroads have paid extravagant prices for car and locomotive repairs in outside shops.

A bulletin issued by the Bureau of Labor Statistics of the United States Department of Labor on employment in selected industries in January, 1921, summarizes reports from 46 car building and repairing establishments which in January, 1921, had on their payrolls 44,613 employees, or 5½ per cent less than for January, 1920. The amount of the payroll in January, 1921, however, was $3,125,082, or 9.6 per cent greater than that for January, 1920. A similar comparison for January, 1921, and December, 1920, is given for 45 establishments, which shows a decrease of 12.4 per cent in the number of employees on the payroll and a decrease of 20.2 per cent in the amount of the payroll. The bulletin states that the industry reports that in order to reduce expenses and on account of the general business conditions the number of employees was reduced. The per capita earnings for the period in January were 8.9 per cent lower than for the December payroll period.

R. V. Massey, chairman of the newly organized joint reviewing committee of the Pennsylvania Railroad, says that the committee already has successfully disposed of, to the satisfaction of both sides, eight controversies which have been pending a long time, one of them since 1914. To emphasize the fact that the committee is a united non-partisan body for the judicial and impartial settlement of differences and not a mere conference between representatives of opposing sides, it has been decided that at the meetings no two representatives of the management or of the employees shall be seated together, but that they shall be alternated around the table. Mr. Massey is "confident that every member of the committee, whether representing the men or the management, is keenly alive to the responsibility resting upon him; and equally confident that not one of the committee has the slightest doubt of the ability of this body to adjust on a fair and friendly basis any differences which may arise affecting the employees represented."

Inspection of Railway Stationary Boilers in Canada

The Board of Railway Commissioners for Canada has ordered that the railway companies subject to its jurisdiction put in force not later than June 1, 1921, regulations promulgated by the board for the inspection of railway steam boilers other than locomotive boilers. The orders cover the design and construction of the boiler and appurtenances and provide for periodical inspection.

Boiler Inspection Act Does Not Apply to Locomotive Cab

The New York Appellate Division holds that the Federal Boiler Inspection Act, requiring locomotive boilers and appurtenances to be kept safe, does not apply to a locomotive cab, so that sections 3 and 4 of the Employers' Liability Act, precluding the defenses of contributory negligence and assumed risk, where a safety act is violated, do not deprive the railroad of these defenses in an action for injuries caused by a depression in the floor of the cab. A cab is not appurtenant to a boiler, and the intention of the act was to guard against accidents peculiar to boilers.—Brown *v.* L. V., 191 App. Div. 691, 181 N. Y. Supp. 800.

No Exhibits at June Conventions

The Railway Supply Manufacturers' Association at a meeting of its executive committee at Pittsburgh, Pa., voted against having an exhibit at the convention of the American Railway Association, Division V—Mechanical—in June.

Further details relative to this decision are given in a letter sent to members of the association, dated March 10 and signed by J. D. Conway, secretary, and J. F. Schurch, president. The letter follows:

> After a thorough canvass and study of the entire situation, both among the manufacturers composing this organization and the railroad executives, your executive committee has unanimously decided it the part of wisdom

> and good business judgment to postpone the June, 1921, R. S. M. A. exhibit at Atlantic City for the following reasons:
>
> 1. We are all familiar with the present depression in railroad and general business and the attendant desire and demand to curtail expenditures in every possible direction to strengthen the existing financial situation with the prime motive of developing greater economy and efficiency in operation.
>
> 2. In the opinion of men of mature judgment in the manufacturing as well as the railroad fields we are confronted today with the serious situation of not knowing with any degree of certainty as to just when business conditions will improve. Many manufacturing concerns engaged in the production of railroad devices and specialties are either shut down or running at an unusually low rate of operation.
>
> While we realize this action is drastic, we feel that present conditions demand it. We are confident, however, that it will meet with the full approval of the business interests of the country, and we further believe that the future will warrant our resuming plans at a later date for the 1922 exhibit as in former years.

The executive committee also decided that it would not be necessary, in view of the cancellation of the exhibit and the annual meeting, to send representatives to such meetings of the Railroad, Mechanical and Purchases and Stores divisions, A. R. A., as may be held. The wisdom of cancelling hotel reservations was also suggested.

Mechanical Division of A. R. A. to Meet in Chicago

The General Committee of the Mechanical Division of the American Railway Association at a meeting in New York on March 30 decided to hold a business session at the Hotel Drake, Chicago, on June 15 and 16 instead of the convention that was to have occurred at Atlantic City. The program has been modified and reports will be presented only by the committees on the following subjects: Prices for Labor and Material, Car Construction, Loading Rules, Brake Shoe and Brake Beam Equipment, Train Brake and Signal Equipment, Specifications and Tests for Materials, Tank Cars and Standard Methods of Packing Journal Boxes. Both morning and afternoon sessions will be held while the division is meeting.

Locomotives to Be Built in Poland

It is stated by the Warsaw correspondent of the London Times that with the object of encouraging home industries the Polish government has recently signed contracts with a number of manufacturers in Poland for the delivery of large quantities of rolling stock for the Polish railways within the next 10 years. The firms chiefly concerned are the Polish Locomotive Works, Sosnowice, which has received an order for 1,100 locomotives; Lilpop, Rau & Lowenstein, Warsaw, which has received an order for 1,000 locomotives, 20,000 freight cars and 3,000 passenger cars; and the Ostrow Wagon Works, which has received an order for 18,000 freight cars and 2,800 passenger cars. None of these firms are in a position to carry out these orders with their present plants. The Polish Locomotive Works does not at present build complete locomotives, although it manufactures locomotive boilers. Neither has the Lilpop, Rau & Lowenstein plant built locomotives previously. The Ostrow Works is an entirely new enterprise and its factory is still in course of construction. Obviously these firms will need foreign capital and machinery to enable them to complete their orders.

Charges of Shop Unions Renewed

Five additional organizations of shop employees and the Railway Employees Department of the American Federation of Labor have joined with the International Association of Machinists in the complaint filed with the Interstate Commerce Commission requesting an investigation of railroad car and locomotive repair work. The original complaint was filed January 8, 1921, by W. Jett Lauck, representing William H. Johnston, president of the machinists. The press notice, just issued by way of keeping the subject alive, says that since the filing of the original complaint additional investigations have been made and the employees now claim to be prepared to fully substantiate all the charges made. The union heads who have joined with the Machinists' Association in the complaint, and the organizations which they represent, are as follows: B. M. Jewell, president of the Railway Employees Department, American Federation of Labor; J. J. Hynes, international president of the Amalgamated Sheet Metal Workers' International Alliance; Martin F. Ryan, general president of the Brotherhood of Railway Carmen of America; James P. Noonan, international president of the International Brotherhood of Electrical Workers; J. W. Kline, president of the International Brotherhood of Blacksmiths, Drop Forgers and Helpers of America; J. A. Franklin, president of the International Brotherhood of Boilermakers and Iron Shipbuilders.

Employee Educational Work on the Great Northern

To meet a desire expressed by a number of employees, particularly in the engineering department, for an opportunity to acquire a broader knowledge of railroading than comes to them through the routine work of their own departments, the Great Northern is developing a course of study to be taken up at bi-monthly meetings, in St. Paul, of a class of several hundred employees. The course is designed to cover a period of about six months and the class is open to employees of all departments who are interested.

The extent of the interest is indicated by the fact that over 400 employees responded to the call for the first meeting. Interest in the plan is also developing among employees at outlying points and consideration is being given to means of extending it. This work had its inception among employees and officers at the headquarters of the road at St. Paul. Consideration is also being given to the development of a course of study that will meet the special requirements of interested employees in the mechanical department.

Retrenchment

Further extensive reductions of forces by the Pennsylvania Railroad were reported on February 26, at Altoona, Pittsburgh and other points. The operation of the Pittsburgh Terminal as a separate division is to be discontinued and the old division boundaries will, in general, be restored.

The Delaware, Lackawanna & Western has ordered further reductions in forces at the Scranton shops. The Union Pacific on February 26 ordered further extensive reductions in its shops. On the New York Central, large numbers of men returned to work in the shops at Collinwood, Ohio; Elkhart, Ind., and other points, after forced vacations of one or more weeks.

The Canadian National, following the severe falling off in business throughout large sections of Canada, has taken off some passenger trains in New Brunswick, including trains No. 31 and No. 32 between Moncton and Levis. In the western part of Ontario considerable numbers of men have been dismissed and two divisions have been consolidated into one.

Two hundred men in the shops of the New York, Ontario & Western at Middletown, N. Y., resumed work on March 1 after a layoff of a month.

Freight Cars

The Louisiana & Arkansas has ordered 25 Hart convertible dump cars from the American Car & Foundry Co.

The Tientsin-Pukow has ordered 300 40-ton all-steel gondola cars through Mitsui & Co., 65 Broadway, New York, from the American Car & Foundry Co.

Locomotives

The Imperial Japanese Government Railways is having 30 locomotives built in Japan.

The Peking-Hankow has ordered 30 Prairie type locomotives from the Baldwin Locomotive Works.

The Louisville & Nashville will build 34 locomotives, including 16 Mikado type locomotives, in its own shops.

Shop Construction

Live Oak, Perry & Gulf.—This company has begun the reconstruction of its blacksmith and car shops at Live Oak, Fla. The buildings will be of frame construction, 50 ft. by 60 ft. and 60 ft. by 150 ft., respectively. The following new machinery will be purchased: planer, shaper, drill press and wheel press.

Louisville & Nashville.—This company has awarded a contract to H. W. Hancock, Louisville, Ky., for the construction of a roundhouse and shops at Loyall, Ky., at an approximate cost of $150,000.

Ann Arbor.—This company will replace its woodworking shop at Owosso, Mich., recently destroyed by fire, with a steel fabricated building.

Northwestern Pacific.—This company will erect temporary structures to replace the machine shop, wood working mill, car repair shop and minor buildings which were destroyed by fire at

Tiburon, Cal., as definite decision has not been made as to whether a modern shop will be constructed at that point, or some more advantageous location along the line.

Atchison, Topeka & Santa Fe.—This company has authorized the construction of a blacksmith shop at San Bernardino, Cal., with dimensions of 80 ft. by 306 ft., to cost $107,000. The company will also build a lavatory building at Needles, Cal., to cost $22,500.

MEETINGS AND CONVENTIONS

The American Railway Tool Foremen's Association will hold its eleventh annual convention at the Hotel Sherman, Chicago, on August 9, 10 and 11.

The American Society for Steel Treating will hold its 1921 convention and exhibition at Indianapolis, Ind., on September 19 to 24 inclusive. The exhibition will be in the Manufacturers' building at the State Fair Grounds which will provide a floor space of 76,800 sq. ft., and the meetings will be held at the Women's building, which is located a short distance from the exhibition hall, where three or four large rooms will make it possible to hold sectional meetings simultaneously.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations and railroad clubs:

Air-Brake Association.—F. M. Nellis, Room 3014, 165 Broadway, New York City. Annual convention May 3 to 6 inclusive, Hotel Sherman, Chicago.

American Railway Association, Division V—Mechanical.—V. R. Hawthorne, 431 South Dearborn St., Chicago. Next meeting June 15 and 16, Hotel Drake, Chicago, Ill.

Division V—Equipment Painting Division.—V. R. Hawthorne, Chicago.

American Railway Association, Division VI—Furchases and Stores.—J. P. Murphy, N. Y. C., Collinwood, Ohio. Second annual meeting June 20-22, Atlantic City, N. J.

American Railroad Master Tinners', Coppersmiths' and Pipefitters' Association.—C. Borcherdt, 202 North Hamlin Ave., Chicago. Convention September 12-14, Hotel Sherman, Chicago.

American Railway Tool Foremen's Association.—R. D. Fletcher, 1145 E. Marquette Road, Chicago. Convention August 9, 10 and 11, Hotel Sherman, Chicago.

American Society for Testing Materials.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.

American Societv of Mechanical Engineers.—Calvin W. Rice, 29 W. Thirty-ninth St., New York. Spring meeting May 23 to 26 inclusive, Congress Hotel, Chicago.

American Society for Steel Treating.—W. H. Eiseman, 4600 Prospect Ave., Cleveland, Ohio. Annual convention September 19-24, Indianapolis, Ind.

Association of Railway Electrical Engineers.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.

Canadian Railway Club.—W. A. Booth, 131 Charron St., Montreal, Que. Next meeting April 12. A paper on Some Side Light on Railway Time Tables will be presented by A. Hatton, general superintendent transportation, Canadian Pacific, Montreal.

Car Foremen's Association of Chicago.—Aaron Kline, 626 N. Fine Ave., Chicago. Meeting second Monday in month, except June, July and August, New Morrison Hotel, Chicago.

Car Foremen's Association of St. Louis.—Thomas B. Koeneke, 604 Federal Reserve Bank Building, St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis.

Central Railway Club.—H. D. Vought, 95 Liberty St., New York.

Chief Interchange Car Inspectors' and Car Foremen's Association.—W. P. Elliott, T. R. R. A. of St. Louis, East St. Louis, Ill.

Cincinnati Railway Club.—W. C. Cooder, Union Centrat Building, Cincinnati, Ohio. Meeting second Tuesday of February, May, September and November, Hotel Sinton, Cincinnati, Ohio.

Dixie Air Brake Club.—E. F. O'Connor, 10 West Grace St., Richmond, Va.

International Railroad Master Blacksmiths' Association.—W. J. Mayer, Michigan Central, 715 Clarke Ave., Detroit, Mich. Next meeting August 16, 17 and 18, 1921, Hotel Sherman, Chicago.

International Railway Fuel Association.—J. G. Crawford, 702 East Fifty-first St., Chicago. Next annual meeting, May 24-26, 1921, Hotel Sherman, Chicago.

International Railway General Foremen's Association.—William Halt, 1061 W. Wabasha Ave., Winona, Minn. Convention, September 12, 13, 14 and 15, 1921, Hotel Sherman, Chicago.

Master Boilermakers' Association.—Harry D. Vought, 95 Liberty St., New York. Convention, May 23 to 26, 1921, inclusive, Flanters' Hotel, St. Louis, Mo.

New England Railroad Club.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Next meeting April 12. Paper on Freight Claims—Their Cause and Prevention, will be presented by Charles M. MacDonald, freight claim agent, Boston & Maine.

New York Railroad Club.—H. D. Vought, 95 Liberty St., New York.

Niagara Frontier Car Men's Association.—George A. J. Hochgrebe, 623 Brisbane Building, Buffalo, N. Y.

Pacific Railway Club.—W. S. Wollner, 64 Pine St., San Francisco, Cal. Meeting second Thursday in month, alternately in San Francisco and Oakland, Cal.

Railway Club of Pittsburgh.—J. D. Conway, 515 Grandview Ave., Pittsburgh, Pa. Meetings fourth Thursday in month except June, July and August, Americus Club House, Pittsburgh.

St. Louis Railway Club.—B. W. Frauenthal Union Station, St. Louis, Mo. Meetings second Friday in month, except June, July and August.

Traveling Engineers' Association.—W. O. Thompson, N. Y. C. R. R., Buffalo, N. Y.

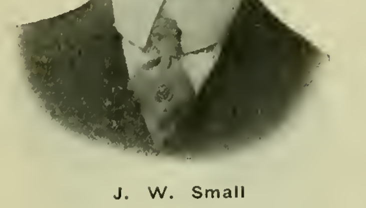
Western Railway Club.—Bruce V. Crandall, 14 E. Jackson Boulevard, Chicago. Meeting third Monday each month except June, July and August.

PERSONAL MENTION

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

F. G. Fischer

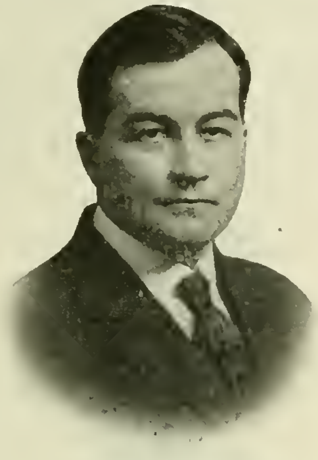
Frank G. Fischer, whose appointment as master mechanic on the Southern division of the St. Louis-San Francisco at Memphis, Tenn., was announced in the March issue of the *Railway Mechanical Engineer*, was born on October 19, 1878, at Richmond, Va. He received a common school education and entered the employ of the Chesapeake & Ohio on February 1, 1895, as a machinist apprentice. After working at various places on the Chesapeake & Ohio and the Baltimore & Ohio Southwestern as a machinist and roundhouse foreman until July, 1903, Mr. Fischer was employed in the roundhouse of the St. Louis-San Francisco at St. Louis, Mo. He then served successively as general foreman at Chaffee, Mo.; general foreman at Memphis; general foreman at St. Louis, and until his recent appointment was assistant master mechanic at Monett, Mo.



J. W. Small

J. W. Small, formerly superintendent of motive power of the Seaboard Air Line, has been appointed superintendent of motive power and shops of the Cuba Railroad with headquarters at Camaguey, Cuba, succeeding M. B. McPartland, resigned to accept service with another company. Mr. Small was born on September 24, 1870, at Chatham, Ont., and was educated in the high schools of that city and at the Collegiate Institute. He entered railway service in 1887 as a machinist apprentice on the Northern Pacific. In 1892 he went to Pocatello, Idaho, as a machinist on the Oregon Short Line. The following year he went to Tacoma, Wash., as a machinist for the Northern Pacific. During the same year he entered the service of the Southern Pacific as a machinist and served subsequently as gang foreman, roundhouse foreman, assistant master mechanic and master mechanic for that company. In 1906 he became superintendent of motive power of the Mexican lines of the Southern Pacific. In 1910 he went to the Kansas City Southern in a similar capacity and the following year became superintendent of motive power for the Missouri Pacific. The same year he went with the Sunset Central Lines (Galveston, Harrisburg & San Antonio, Houston & Texas Central, Morgan's Louisiana & Texas, Texas & New Orleans, etc.) as assistant general manager. In 1913 he was appointed superintendent of motive power of the Seaboard Air Line. During federal control Mr. Small served first as mechanical assistant to the regional director, Southern region, and later as mechanical staff officer to the regional director of the same region.

Harry M. Allan, whose appointment as master mechanic on the Canadian Pacific with headquarters at Kenora, Ont., was announced in the March issue of the *Railway Mechanical Engineer*, was born on July 26, 1886, at Balderson, Ont., and attended the Balderson public schools and the Perth high school. In October, 1906, after serving his apprenticeship with the Canadian Atlantic at Ottawa, Mr. Allan entered the employ of the Algoma Central at Sault Ste. Marie, Ont., and in March, 1907, resigned, and went from Fort William to Winnipeg and on to Moose Jaw, Sask., where he worked as a machinist for the Canadian Pacific. In 1910, he was promoted to shop foreman and from 1913 until his appointment as mentioned above, he was locomotive foreman in the Alyth roundhouse at Calgary, Alta.



H. M. Allan

CAR DEPARTMENT

Andy J. Litwin, car foreman on the Northern Pacific at Paradise, Mont., has been transferred to Staples, Minn., succeeding F. M. Weseman, deceased.

SHOP AND ENGINEHOUSE

W. Arthur Birch, freight gang foreman on the Atchison, Topeka & Santa Fe, at Needles, Cal., has been transferred to Barstow, Cal., to succeed E. O. Faulkner as roundhouse foreman.

H. D. Eddy, roundhouse foreman on the Atchison, Topeka & Santa Fe, at Needles, Cal., has been transferred to Bakersfield, Cal.

E. A. Murray, whose appointment as shop superintendent on the Chesapeake & Ohio, at Huntington, W. Va., was announced in the February issue of the *Railway Mechanical Engineer*, was born on September 1, 1876, at Staunton, Va. He received a public school education and on December 11, 1891, entered the employ of the Chesapeake & Ohio as a machinist apprentice. After completing his apprenticeship, he served successively as a machinist, locomotive fireman and gang foreman until 1903, when he was appointed general foreman. From 1909, until his recent promotion as above noted, Mr. Murray was master mechanic at Clifton Forge, Va.

E. A. Murray

George F. Heise has been promoted to the position of toolroom foreman of the El Paso & Southwestern shops at El Paso, Tex.

PURCHASING AND STOREKEEPING

J. E. Wharton, division storekeeper on the Pennsylvania, with headquarters at Toledo, Ohio, has been appointed storekeeper, maintenance of equipment department, with the same headquarters. The position of division storekeeper has been abolished.

SUPPLY TRADE NOTES

The R. G. Smith Tool & Mfg. Co. has moved from 315 Market street, into their larger factory at 245 N. J. R. R. avenue, Newark, N. J.

The H. K. Ferguson Company, southern department, has removed its offices to Room 218, Healey building, Atlanta, Ga. Richard W. Alger is the manager.

The Independent Pneumatic Tool Company, Chicago, has removed its Pittsburgh, Pa., office from 1208 Farmers Bank building, to 718 Bessemer building, corner of Fort and Duquesne Way.

Manning, Maxwell & Moore, Inc., New York, on May 1, will take over the merchandise and good-will of Patterson, Gottfried & Hunter, 211 Center street, New York. This firm handles mill and factory supplies.

Carl W. Bettcher has been appointed sales manager of the Eastern Machine Screw Corporation, New Haven, Conn. Mr. Bettcher was born on May 7, 1887, and graduated from the Boardman Manual Training School in 1904. He is also a graduate of Yale University, having completed the Sheffield Scientific course in 1907. The following two years he spent on the students' course at the General Electric Company at Lynn, Mass., doing principally testing work. He then entered the sales department of the Edison Lamp Works at Harrison, N. J., and after eight years of service with this company, became a captain of artillery in the United States Army and, for nine months of two years, was in active service in France. For the past two years he has been in the employ of the Eastern Machine Screw Corporation and will now specialize principally in the expansion of the sale of the H. & G. self-opening die heads.

Carl W. Bettcher

H. M. Pratt, manager of the branch office of the Southern Iron and Equipment Company at New Orleans, La., has been appointed general sales manager with headquarters at Atlanta, Ga. A. C. Wood succeeds Mr. Pratt at New Orleans.

The O'Malley-Beare Valve Company of Chicago has been appointed exclusive agent for the Chapman Valve Manufacturing Company of Indian Orchard, Mass., and will have charge of the sale of the Chapman lines of valves in the railway field in the United States.

The Southwark Foundry & Machine Company, Philadelphia, Pa., has opened a district office at 804 Swetland building, Cleveland, Ohio, under the management of its representative, Stewart Bolling, who has served for seven years as engineering salesman for this company.

The National Malleable Castings Company, Cleveland, Ohio, has bought the draft gear business, assets and good-will of the Butler Drawbar Attachment Company, Cleveland. The business of the latter company has been transacted for many years through the National Malleable Castings Company.

Harry L. Oviatt has been appointed traveling representative of the Armstrong Manufacturing Company, Bridgeport, Conn., manufacturers of pipe threading tools and taps. Mr. Oviatt has been with the Bullard Machine Tool Company, Bridgeport, for the past 13 years and during the last 3 years has been connected with the advertising department.

The Commonwealth Steel Company, St. Louis, Mo., has recently established an employees' benefit association, which provides insurance against sickness, accident or death for the employees. The company has offered to each member of its force a life insurance policy, varying in amounts from $500 to $2,000, depending on the length of service.

William C. Wilson, formerly connected with the Taylor-Wharton Iron & Steel Company and William Wharton, Jr., Company, in the capacity of manager of sales, northeastern territory, has become associated with the Pittsburgh Screw & Bolt Company, Pittsburgh, Pa. He will be located at its New York Office, 50 East Forty-second street.

The Power Equipment Company, 131 State street, Boston, Mass., has been appointed New England representative of the Conveyors Corporation of America, Chicago, for the sale of its American trolley carrier monorail conveying equipment, and Colwell & McMullin, 79 Milk street, Boston, are the New England representatives for its American steam ash conveyor.

The American Mason Safety Tread Company, 480 Lexington avenue, New York, has consolidated its general sales office for the New England States, New York State and New Jersey with the local New York City office, under the supervision of J. W. Scott. L. H. Devoe will continue to serve the trade in this territory as in the past, with headquarters at New York.

W. J. Roehl, formerly assistant purchasing agent of the Missouri Pacific, has been appointed sales representative in the St. Louis district for A. M. Castle & Co., Chicago, and has opened offices at 1946 Railway Exchange building, St. Louis. Mr. Roehl entered railroad business on May 4, 1906, as a clerk in the office of the supply agent of the Missouri Pacific and in May, 1910, was promoted to chief clerk. On March 1, 1913, he was promoted to chief clerk to the general purchasing agent and on June 1, 1918, became assistant purchasing agent.

W. J. Roehl

A. M. Castle & Co., in addition to their warehouse business in Chicago, are general distributors for the Rome Iron Mills' staybolt iron, the Lukens Steel Company's locomotive, flange and fire box steel; and the Detroit Seamless Steel Tubes Company's locomotive seamless boiler tubes.

The Liberty Car & Equipment Company and the Illinois Car & Manufacturing Company, both of Hammond, Ind., have been consolidated under the name of the Illinois Car & Manufacturing Company, with general offices at Hammond, Ind. The officers of the consolidated company are: P. H. Joyce, president; J. W. O'Leary, vice-president; J. F. Farrell, vice-president; J. E. Fitzgerald, treasurer, and O. R. Shearman, secretary. The plant at Chicago Heights is now known as the Liberty plant and the one at Hammond as the Hammond plant.

The Equitable Equipment Company, 411 Whitney Central building, New Orleans, La., has completed its organization for the purpose of handling locomotives, cars, railroad equipment, rails and rail accessories, machinery of all kinds, contractors' equipment and second hand machinery and equipment. This new company is taking over the equipment, rail and machinery business of A. Marx & Sons, Southern Scrap Material Company and the Ship Supply Company. The new firm will be under the direct management of O. D. Cleveland, who has been the manager of the New Orleans branch of the General Equipment Company.

Superheater Company

The election of three new vice-presidents is announced by the Superheater Company, New York, formerly the Locomotive Superheater Company. Gilbert E. Ryder, in charge of the service department, has been elected vice-president in charge of sales, with office at New York; Henry B. Oatley, chief engineer, has been elected vice-president in charge of engineering, with office at New York, and Charles H. True, works manager, has been elected vice-president in charge of production, with office at East Chicago, Ind.

Gilbert E. Ryder, vice-president in charge of sales, was born at Minneapolis, Minn., in 1880, and studied engineering at the University of Wisconsin, and also at the University of Illinois. His railroad experience began with an apprenticeship on the Chicago, Milwaukee & St. Paul, and included service as a journeyman in the mechanical department of that road at Dubuque, Ia.; Ottumwa, Ia., and West Milwaukee, covering five years. His engineering experience followed in the fuel testing bureau of the Technologic Branch of the United States Geological Survey. He later served the city of Chicago as deputy smoke inspector in charge of locomotives, which placed him again in contact with the locomotive fuel conservation problem. This was followed by editorship of the Railway Review at Chicago, after which he entered the service of the Superheater Company ten years ago. He became a member of the service department and later took charge of that department. He also developed and had charge of the publicity department. Mr. Ryder takes responsibility of the sales of the company (railroad, stationary and marine), with an unusual preparation in wide and very valuable engineering and practical experience.

G. E. Ryder

Henry B. Oatley, vice-president in charge of engineering, was born at Rochester, N. Y., and attended the public schools at that place. He received his engineering education at the University of Rochester and the University of Vermont, graduating from the latter in 1900 with the degree of mechanical engineer. He then entered the service of the Schenectady Locomotive Works, his experience while on this work embracing locomotive design and shop testing. He was associated with F. W. Cole in the early development of the superheater for locomotives by that company. In 1910, upon the formation of the superheater company, he was appointed mechanical engineer, and in 1916 he was appointed chief engineer for the company, which position he held at the time of his election, as above noted. In April, 1917, he was granted a leave of absence and served as an officer in the U. S. Navy on the battleships Ohio and Indiana. He entered service with the 1st N. Y. Naval Militia, which was the first body of armed troops to move after the declaration of war with Germany. Mr. Oatley is a recognized authority on superheating and has been an active factor in its development. He is, in a large measure, responsible for putting superheater design upon a practical

H. B. Oatley

operating and manufacturing basis in locomotive, marine and stationary practice, and, without sacrifice of efficiency, has developed uniformity of sizes and design.

Charles H. True, vice-president in charge of production, was born in Boston, Mass., and was educated at the public schools of Schuyler, Neb., and the University of Nebraska, graduating in 1898 with the degree of electrical engineer. Immediately upon graduation he entered the service of the Union Pacific at Omaha, and served in both the locomotive and car shops. In 1902 he became roundhouse foreman at Grand Island, Neb., and in 1903 resigned from the Union Pacific to take a similar position at Trenton, Mo., with the Chicago, Rock Island & Pacific. In October of the same year he was transferred to the Silvis shops as assistant superintendent of shops. In 1905 he was appointed mechanical engineer with the Railway Materials Company, at Chicago, and was engaged in the design of metallurgical furnaces for blacksmith shops and boiler shops, and in 1910 he refitted and took charge of the Phoenixville, Pa., plant of this company. Two years later Mr. True resigned his position with the Railway Materials Company to become works manager of the Superheater Company at East Chicago, which position he held until his election as vice-president, as above noted.

C. H. True

The Richmond, Va., office of the Vapor Car Heating Company, Inc., has been discontinued and all future business from the Southeastern territory will be handled from the offices of the company in Washington, D. C. The Washington office is in charge of Harry F. Lowman, who is assisted by L. B. Rhodes, Jr., previously connected with the sales department of the U. S. Light & Signal Corp. Mr. Rhodes, Jr., has been assigned to the Southeastern territory formerly handled by his father, L. B. Rhodes.

J. Brookes Spencer, assistant to first vice-president of the Southern Wheel Company, St. Louis, Mo., has been elected vice-president of the same company with headquarters at St. Louis. Mr. Spencer was born in St. Louis on January 15, 1888. He was educated at the Hill School, Pottstown, Pa., and was graduated from Yale University in the class of 1910. In 1917 he entered the service of the Southern Wheel Company at St. Louis and has been with the company since that time with the exception of a year when he served in the United States Army.

Keith J. Evans, advertising manager Joseph T. Ryerson & Son, was elected president of the Engineering Advertisers' Association at the annual meeting at Chicago on March 8. Mr. Evans has been with the Ryerson company for eight years, all of that time in the advertising department. Just prior to the entry of the United States in the war, Mr. Evans co-operated with Donald Ryerson, vice-president of the Ryerson company, who organized the "Four Minute Men" as a lobby in favor of military training. When war was declared, the organization was turned over to the Government and became a division of the Committee on Public Information. Mr. Evans was appointed national business manager, with headquarters at Washington, D. C., and served in that capacity until the organization was well under way, when he entered the army, becoming a second lieutenant in the field artillery. As advertising manager of the Ryerson company, Mr. Evans originated the 450-page loose leaf Ryerson steel service book, a very complete and handy current data book covering specifications and prices.

TRADE PUBLICATIONS

Gas Producer.—"The Automatic Gas Producer" is the title of a 10-page booklet, illustrating and describing the construction and operation of automatic gas producers made by R. D. Wood & Co., Philadelphia, Pa.

Cupola Users.—The Whiting Corporation, Harvey, Ill., has issued Bulletin No. 155, being a list of cupola users, arranged geographically and alphabetically under the various sizes of cupola. This bulletin supersedes No. 152.

Filters.—A 7-page bulletin, descriptive of the G-R multiscreen filter, has been issued by the Griscom-Russell Company, New York. This filter is a redesign of the well-known Reilly multiscreen feed water filter and grease extractor.

Machine Tools.—George Swift & Sons, Halifax, England, have issued a general catalogue of machine tools, illustrating and describing the line of radial drills, lathes, slotters, shapers and planers which are included in the regular line manufactured by this company.

Pneumatic Tools.—Circular No. 41, representing the latest achievements in the development of the pneumatic tool industry has been issued recently by the Keller Pneumatic Tool Company, Grand Haven, Mich. Specifications and a list of Keller made products are included.

Iron and Steel Workers' Machinery.—A representative type of each of the tools manufactured by the Scully Steel & Iron Company, Chicago, is shown in a 128-page catalogue which they have recently issued. A few details as to the size and capacity of each machine are given.

Dust Collecting and Conveying.—Two 4-page bulletins, Nos. 12 and 501, have been issued recently by the Dust Recovering & Conveying Co., Cleveland, Ohio. These bulletins illustrate and describe the development of dust collecting equipment and pneumatic conveying respectively.

Portable Electrical Drills and Grinders.—The Cincinnati Electrical Tool Company, Cincinnati, Ohio, have recently issued a new catalogue covering their complete line of portable electrical drills, grinders and buffers, including several new type machines which they have recently brought out.

Tap Drill Sizes.—A table of tap drill sizes for S.A.E. or A.S.M.E. machine tool standards has been prepared in pocket form by the Greenfield Tap & Die Corporation, Greenfield, Mass. Larger charts containing similar data and suitable for hanging in the shop for ready reference by the workmen, have also been brought out.

Sanitation and Welfare.—Bulletin No. 8 has been issued by the Bureau of Safety and Sanitation and Welfare of the United States Steel Corporation, New York, and contains 95, 8 in. by 10 in. pages devoted mostly to illustrations showing some of the things that have been done by the corporation and its subsidiary companies to improve the living and working conditions of employees.

Repair Parts.—The Roberts & Schaefer Company, Chicago, has prepared a book illustrating all of their modern equipment for coal, sand and cinder handling on locomotives. Each unit of each machine is numbered according to the reference kept in the office of the company, making it comparatively easy for one to order spare or repair parts for mechanical devices for coal, sand and cinder handling.

Tool Book.—The Goodell-Pratt Company, Greenfield, Mass., has recently issued tool book No. 14 containing 464 pages, 6 in. by 9 in. A detailed index of the fifteen hundred tools manufactured by this company is included in the front of the book, together with general information regarding design, making and inspection. List prices given in this catalogue were effective on January 1, 1920, and are subject to change without notice. For the convenience of mechanics and others who find the 6 in. by 9 in. book inconvenient to carry, a pocket edition with 3½ in. by 5½ in. pages is available.

Simple Common Sense

If the railroads are to give adequate service to the public which pays the bills, it will be absolutely necessary for the men and the managements to get together. Someone has said, "Figures don't lie, but liars figure." Some of the testimony recently introduced before the Railroad Labor Board is an insult to the intelligence of that Board and would seem to offer sufficient reason to adjudge those who gave it in contempt.

If the real reason for the long drawn-out and misleading exhibits which have been presented to the Board is to delay decisions on the part of the Board, then those who are giving the testimony should at least make a bluff at being in earnest and should talk to the point in controversy. As it is now the recent testimony of Lauck and Jewell is absurd and will react against the interests of the men these leaders are supposed to represent.

The wages of the shop crafts were increased to the present high standard for one reason only—to meet the highest cost of living recorded in recent years. We believe in paying good wages to railroad workers—wages that will enable the men to live well and that will attract the most desirable men to railroad service; but the cost of living has decreased considerably since wages were adjusted. We believe also in furnishing the public with a high grade of service at a reasonable cost, thus insuring the continued prosperity and development of the country and incidentally giving the men in railroad service steady employment. We believe also in giving the investors a fair return upon their money; if this is not done the large amount of capital necessary to improve the railroads will not be forthcoming, and incidentally the railroad employees will suffer because of business stagnation, since general business prosperity goes hand in hand with the prosperity of the railroads.

The interests of the employees, the managements, the public and the investors are so intimately associated and so dependent one upon the other, that they must work together, shoulder to shoulder, in the common interest. They must have a mutual understanding of each other's problems—this means a lot of educational work. Unless this co-operation can be brought about, sure disaster lies ahead. This is simple common sense.

The Business Situation

The latest report available as we go to press of the number of cars loaded with revenue freight is that for the week of April 16. There were 703,896 cars loaded, which is the largest number, with one exception, since the week of January 15, when 709,888 cars were loaded; the cars loaded for the week of March 5 totaled 712,822. Averaging the figures for the four weeks reported each month for the first quarter we find that the average weekly loading in January was 679,580, in February 683,088, and in March 698,627. In general coal loadings have fallen off, while merchandise, l. c. l. and miscellaneous loadings have steadily increased.

The indications are that the average weekly loading for April will be about the same as for March, although it may be larger. There are five weeks ending in April; the first week (April 2)—most of the days were in March—showed an abnormally low figure, 666,642, the lowest this year except for the week of January 1. If this first week is disregarded, April will undoubtedly make an excellent showing compared with the earlier months of the year. The average number of cars loaded with revenue freight for the first 15 weeks of 1921 was 687,296; this compares with 798,212 for the similar period in 1920 and 698,146 in 1919. Meanwhile the money market is easier and the prices of securities are higher than for some time. The car surplus has also shown a slight decline for the first time in months. Let us hope that the worst of the depression has passed!

One Effect of Seniority Rules

One apparently unfair and certainly costly result of seniority rules has come to our attention recently in their application to apprentices. An apprentice who had just completed a four-year course and developed into a valuable man for a certain railroad was outranked in point of seniority by a mechanic who had been employed but a short time before. The result was that when a reduction in forces was made at this point, according to the seniority rule, the apprentice was allowed to go and the mechanic was retained. Furthermore when it eventually becomes necessary to re-employ men the mechanic will have to be hired back again before the apprentice. This ruling certainly seems unfair from the standpoint of the apprentice and is a costly one to the railroad. There can be no question as to the relative value of a bright apprentice who has served four years with a railroad, becoming accustomed to its equipment and standards of operation, as compared to the value of a new mechanic who has just been employed. The latter in many cases simply calls himself a mechanic and has in reality had a limited experience.

The Importance of Checking Cut-Offs

An article on "Fuel Economy by Accurate Valve Setting" in this issue points out the possibilities of saving coal by setting locomotive valves more carefully, particularly as relates to equalizing and squaring the cut-offs. There are three common methods of squaring valves on locomotives with outside valve gears, of which the first and simplest is to equalize the valve travels. In this method the crank arms are set approximately correctly by a gage and, with the portmarks scribed on the valve stems, the travels can be readily found by trailing the engine, adjustments being made to equalize them. The objection to this method is that no check is made of the important points of steam admission and cut-off. In the second and more common method the engine is put on rolls and the leads, or port openings at the dead centers, checked, being squared in the full gear. This method is the one more commonly used and gives reasonably satisfactory results, the main objection to it being that no attention is paid to points of cut-off. It is no more necessary that steam ports open at the same instant than that they stay open the same length of time. In fact, from the standpoint of fuel economy, the second consideration is the more important. The third method of squaring valves, therefore, takes into account the cut-offs and differs from the second method only in carrying it a step further. The reverse lever is "hooked up" to bring the cut-offs at about 25 per cent of the piston stroke and the engine is run over, measuring the piston travel at the points of cut-off. Adjustments are then made to equalize the cut-offs, front and back, right and left. It has been demonstrated that valve events do not occur in regular order and because the valves are square in the leads is no indication that they will be square in the cut-offs. It is explained in the article that unequal cut-offs cause fuel waste due to the fact that the locomotive must be operated with the reverse lever unnecessarily near the corner. This means a larger consumption of steam and consequently of coal as has been demonstrated not only theoretically but by practical tests as well. The possibilities and great need of fuel economy are such as to warrant the most careful attention to setting valves and especially as regards equalizing the cut-offs.

The Future of the Steam Locomotive

The papers to be presented before the Spring meeting of the American Society of Mechanical Engineers which are published in this issue are notable because they represent an attempt to outline in a comprehensive way the direction that future progess will, or should, take. When an attempt is made to look forward it seems that the growth in motive power during the past 20 years has been easy because it was attained principally by increasing the size of individual engines. This statement should not be construed to mean that there have not been notable refinements in design during that period. The history of locomotive construction records occasional examples of extremely heavy power that were built prematurely and proved a total failure. These isolated instances show clearly that changes from the former practices were necessary before a satisfactory design of large locomotive could be evolved. There have been remarkable improvements in design during the last two decades, yet the principal development has been in increasing the size of the power.

It is doubtful whether development of the locomotive can proceed much further along these lines. The cylinders on heavy engines have now reached the clearance limits and the boiler is as high as it can be made. Although locomotives with six pairs of coupled wheels have been built in Europe, it would seem that the rigid wheel base of five coupled pairs of wheels is the maximum that can be operated over curves on the majority of roads in this country.

This does not mean that further progress in locomotive development must stop. If the limit of size has been reached, designers still have it in their power to make locomotives more efficient by refinement in design. In the past the majority of American roads have adhered to locomotives of the simplest possible types. Now there is need for more critical attention to the details of the machinery. It may be necessary to sacrifice simplicity and deliberately adopt features that will increase maintenance costs in order to reduce the fuel consumption of the engines and increase their capacity. The true measure of the efficiency of the mechanical department is not in the cost of repairs per locomotive or per car, but in the overall expense of fuel, wages and repairs for handling passengers and freight.

Notable Innovation In Freight Car Design

The common type of freight car truck, carrying the load on the center bearing, is one of the oldest features of car construction in general use, having been first applied in 1831. The very fact that this design has been perpetuated so long is conclusive evidence that it possesses merit. The flexibility of the structure is well suited for uneven track and the equalizing system minimizes the stresses that are transmitted to the car body. The clearance at the side bearings permits operation over tracks that are not in a true plane without imposing twisting stresses on the body and the small radius of the center bearing permits the truck to follow curves with little pressure on the wheel flanges.

Few designers have attempted to depart from the basic principles outlined above. Some trucks have been built which carry the load on the side bearings, but all have retained the transverse bolster as an essential feature. The new 100-ton coal cars of the Norfolk & Western described in this issue are noteworthy because of the fact that the load is carried on the side of the trucks and the center pin is used only to hold the truck in the proper position. By the use of longitudinal beams over the side frames the truck bolster is eliminated, being replaced by a light spider which holds the side frames square. This is especially noteworthy because six-wheel trucks usually require extremely heavy bolsters. The saving in weight by this method of supporting the load is not confined to the trucks. The body bolster likewise can be made lighter because instead of carrying the load to the center line, it is only necessary to carry it to the plane of the side frames, thus reducing the bending movement on this member materially.

Since the car is carried on four points of support, the question of the stresses set up when these points are not in the same plane becomes very important. The tests conducted on the first car built show that uneven track causes only slight variations in the load on each group of springs and does not result in excessive distortion of the car body.

Aside from the interest attached to the new design, the cars are notable for the high ratio of load to gross weight. Unnecessary dead weight in freight cars is costly to haul and light equipment offers opportunities for materially reducing operating expenses. The satisfactory performance of these cars since they were placed in service indicates that no unusual difficulties will be experienced in their operation or maintenance, and the results will fully justify the bold step which the mechanical department officers of the Norfolk & Western have taken in departing from conventional design.

An Old Friend

Probably the most familiar piece of machinery or equipment in railroad shops and roundhouses is the wheel lathe—familiar in many cases because the same old lathe has stood in the same place for so many years. Wheel lathes may be divided roughly into three groups, the first of which includes those not operated at all. Railroad men would probably be surprised to know the number of wheel lathes that simply occupy floor space (mostly in roundhouses) and never turn a tire. The second group includes wheel lathes which are operated but never ought to be. Perhaps they are underpowered and can hardly carry a one-quarter inch cut with one-eighth inch feed; sometimes their capacity is limited and large tires must be removed and turned on a boring mill, or shipped to another shop; in other cases the driving gears and mechanisms are so badly worn that the lathes cannot be operated even under medium cuts without seeming to tear themselves apart. The third group, to which fortunately a majority of wheel lathes belong, includes those modern productive machines which can, under average conditions, turn a pair of the largest tires in an hour or an hour and a half. Our point is that there are not enough machines of the third group in shops and roundhouses and that certainly there can be no excuse for longer retaining lathes in the first group.

It is said that the money for new wheel lathes is not available; also, that a roundhouse does not warrant the installation of a high priced special machine like a wheel lathe. Granting that in many cases the first statement is true and that the second holds for the smaller roundhouses, the only logical solution is to ship driving wheels to back shops where modern, productive wheel lathes are installed. Taking into account transportation charges and other elements, the tires will be turned quicker, better and cheaper. The examples of inefficient, worn-out wheel lathes are too numerous to mention and the only suitable place for obsolete and inefficient machines is the scrap heap.

New axle lathes also are needed badly in both roundhouses and repair shops. A great deal of credit is due to roundhouse and shop foremen for their ingenuity and determination in accomplishing results with inadequate equipment. At the same time the methods which they are sometimes compelled to use are very costly. The amount of waste effort on American railroads in a year due to the removal of tires for turning or pressing out axles to true up the journals is far too great. It is earnestly hoped in the present reorganization and attempt to place railroad finances on a firm basis once more that capital will be available to provide the shop machinery and equipment so badly needed for efficient, economical shop and roundhouse operation.

Apprenticeship in France

Elsewhere in this issue is an interesting article on apprenticeship as developed by the Paris-Orleans during the war. The principles which served as a basis for reorganizing apprentice courses are outlined in the article which explains the difficulties encountered and the results accomplished. The French have always realized the importance of training apprentices and workmen and in 1891 seven important railway systems had flourishing apprenticeship organizations. These systems differed in one essential. One group distributed the apprentices throughout the workshops and the other required their segregation in specially assigned buildings. These conditions continued from 1891 to 1900. On March 30, 1900, a law went into effect which forbade apprentices working in buildings where men were employed for more than ten hours a day. The effect of this law was practically to kill apprenticeship on some roads and to cause a notable falling off on others. At the beginning of the war, in spite of the high wages paid in ammunition factories and the consequent difficulty of securing apprentices, the Paris-Orleans reorganized its apprentice courses as explained in the article. Apprentice centers were formed in repair shops and roundhouses directly in opposition to the act of March 30, 1900, but the adoption of the eight-hour day in 1919 solved all difficulties in this connection.

The first principle of reorganization was recognized as the need for holding the interest of apprentices and paying them as much as possible by reducing the amount of unprofitable work to a minimum. The second principle developed was the importance of showing boys coming from a primary school just how and why practical work is done, as explained. An apprentice placed singly in a gang of workmen follows bad examples more quickly than good ones and in order that good habits of practice, discipline and self-reliance should be acquired, it was found best to group apprentices under the direction of capable instructors. One of the particular difficulties encountered was in the selection and training of these instructors. It was fairly easy to obtain good, practical workmen but they did not always have the mental requirements necessary for teachers. The recruiting of theoretical instructors also presented difficulties, perhaps the greatest trouble being to find instructors who would not confine themselves too closely to theoretical instructions difficult for the pupils to assimilate. The general conclusion seems to be that the quality and quantity of work performed by apprentices in the third year at least offsets their under-production in the first year and that the improvement of facilities for recruiting and developing capable shop employees and foremen is a clear profit.

It is interesting to note that apprenticeship centers are maintained at important roundhouses in France to afford preliminary training for engine drivers. In this way a man becomes a mechanic before he is a fireman or engine driver and the result is that most French enginemen are of mature years, thoroughly familiar with the detailed construction of practically all locomotive parts and are therefore able to give them the most intelligent and careful attention. French railroad men as a whole were astounded at the comparative youth of Americans assigned to drive the heavy American

Consolidation locomotives sent to France with the A. E. F. While these locomotives hauled an immense amount of traffic without serious accident, the American engine drivers could undoubtedly have taken lessons from their older French brothers in fuel economy and getting mileage between shoppings.

NEW BOOKS

Cams, Elementary and Advanced. By Frank De Ronde Furman. 224 pages, 6 in. by 9 in., bound in cloth. Published by John Wiley & Sons, Inc., New York City.

The chief original features of this book include the development and use of logarithmic, cube, circular, tangential and involute base curves, the establishing of cam factors and the demonstration that the logarithmic base curve gives the smallest possible cam for given data. The material given includes also the comparisons of the characteristic results obtained from all base curves in which the relative size of each cam, and the relative velocity and acceleration produced by each, is shown graphically in one combined group of illustrations. This enables the designer to glance over the entire field of theoretical cam design and quickly select the type that is best adapted for the work in hand. From these diagrams it is possible to note which form of cam is best adapted for gravity, spring or positive return, which is best for fast or slow velocities at various points in the stroke and which ones are apt to develop "hard spots" in running. Cam constructions best suited for heavy work in one or both directions are also described. All of the material is fully and clearly presented, the processes of design being mostly graphical and readily followed by practical shop men and draftsmen as well as by technical students.

Simple Superheated Steam Locomotives (Heissdampf Lokomotiven mit Einfacher Dehnung des Dampfes). By Eugene Brückmann. 600 pages, 11 plates, 7½ in. by 10½ in., illustrated. Bound in cloth. Published by C. W. Kreidel, Berlin, W. 9, Germany.

This volume is the third edition of a book which forms part of a cyclopedia on railroad practice. Being restricted to the most important type of motive power in use today, it covers the field comprehensively, treating the subject historically as well as on the basis of present practice.

The book opens with a history of superheated steam locomotives and describes many old patents as well as notable constructions of more recent date. A short chapter is devoted to the qualities of superheated steam, and this is followed by an analysis of the possible saving in water and fuel by the application of superheat. The increase of tractive effort at the drawbar and at the tender is analyzed for various pressures, for high and low speeds, compared with dry steam and with steam containing 20 per cent water. The limitations of steam pressure and superheat are also discussed.

The chapters on the locomotive boiler discuss the production of superheated steam, combustion in the locomotive and the theory of the locomotive boiler and superheater. The general discussion is followed by the computation of a saturated and a superheated steam boiler for the comparison of their performance and capacity. Rules for the calculation of boilers are given and materials for the construction of superheaters are discussed. The section on the types of construction and development of superheaters is very complete. A chapter is devoted to the calculation of the details of machinery for superheated locomotives which is followed by a discussion of the development of the superheated steam locomotive, instructions for handling locomotives in service, and descriptions of some of the newest types constructed. Tabulations of dimensions and drawings showing the general design complete the volume.

COMMUNICATIONS

Are American Roads Prejudiced Against Compounds?

Heath, Mass.

To the Editor:

It would be interesting to know the number of compound locomotives, exclusive of Mallets, still operated by railroads in this country and the results obtained. Many railroad men would no doubt feel that such information would be of no interest as the utility of compounds in the United States is definitely settled. Is this not largely a matter of prejudice? We read now and then of cross-compounds converted into superheated simple engines and of the economies effected, but why not retain the compound arrangement and add superheat as has been done successfully in Europe as well as in the case of American Mallets? Some statements regarding compound locomotives give the impression that intercepting valves are difficult to maintain. This argument does not appear sound for in the last decade devices have been added to the locomotive which require as much, if not more, attention than an intercepting valve.

An analogy in prejudice may be cited in marine engineering. Many of the latest ships will be found to be without superheaters and yet the idea of a marine engineer building a non-compound engine would be considered as absurd as building a large locomotive without a superheater.

In view of the success of Mallets in such cases, it is strange that economy cannot be effected by the use of compounds on divisions of a suitable nature.

W. G. Landon.

Right Kind of Foremen's Courses.—American business is finding it profitable to train plant foremen in the elements of good foremanship. Courses of instruction, conducted in the plants and designed to train foremen to cope with the problems that present themselves each working day, not only are developing better foremen, but are bringing returns in the form of increased morale, lower labor turnover, reduced costs and greater production.

The purpose of foremanship training, says an authority on the subject in *Forbes Magazine* (N. Y.), is to increase production and decrease costs. It is easily understood that those two things naturally follow when foremen are developed into real leaders and man handlers, thoroughly conversant and proficient in all phases of their jobs. A well organized course, therefore, will have these general functions:

1. To view the foremanship job in the perspective.
2. To analyze its responsibilities.
3. To develop intelligent performance of these responsibilities.
4. To develop team work.
5. To develop correct interpretation of policies.
6. To develop constructive thinking.
7. To develop analytical ability.
8. To develop leadership and subordinate driving methods.

The course itself, he adds, must be planned specifically around the first four items. The rest is more or less the general result of the discussions and follow up. Any foremanship course that performs these functions, even to a limited degree, is serving its purpose.

Locomotive Building in France.—The French output of locomotives at the end of the year 1922 will be 1,300 per annum. As its normal home consumption will not be more than 600, France will, states the Times (London) Commercial Supplement, become an important rival in foreign countries.

Problems in Design and Operation of Large Locomotives

Necessity for Improvement to Secure Maximum Service, Reduced Maintenance Costs and Increased Earning Power To Be Discussed at Railroad Section of A. S. M. E.

THE design and operation of large locomotives is the general subject which will be discussed at the railroad session of the Spring meeting of the American Society of Mechanical Engineers, to be held at the Congress Hotel, Chicago, May 26, 1921. Three papers, each covering a different phase of the question, are to be presented. The detailed design of large locomotives will be treated by M. H. Haig, mechanical engineer of the Atchison, Topeka & Santa Fe. H. W. Snyder, mechanical engineer of the Lima Locomotive Works, will have a paper on the Necessity for Improvement in the Design and Operation of Present Day Locomotives, while the need for the 2-10-2 and other heavy freight locomotives for road service will be discussed by A. F. Stuebing, managing editor of the *Railway Mechanical Engineer.* Abstracts of the papers by Mr. Haig and Mr. Snyder are given below. The third paper will be published in the June issue.

The Design of Large Locomotives

BY M. H. HAIG

Mechanical Engineer, Atchison, Topeka & Santa Fe

THE design of a large locomotive depends on the service to which it is to be assigned. The service varies with the weight of the train to be hauled and the number of cars in the train, and is affected by the topography of territory on which it is to operate, ruling grades in each direction, length of grades, average speed between terminals, method of dispatching, whether single or double track between terminals, etc. This information being available, it is a reasonably simple matter to determine upon the leading features of a locomotive to meet the requirements.

Restrictions and Limitations Imposed

For a locomotive to give practically 100 per cent service, its design and construction must not be restricted by personal opinion or by physical limitations of the road. If the weight needed for adhesion in starting a given train is restricted by an opinion that certain wheel loads should not be exceeded or because bridges and track are not capable of carrying the necessary weight, then the capacity of the locomotive is restricted and the train must be adjusted to the locomotive, instead of the locomotive being built to suit the train. This in turn has a tendency to limit a division or a railroad as a whole. Limitations such as these, together with clearances of bridges and structures, obstructions along the right of way, etc., affect the locomotive design and construction. The locomotive as a whole is dwarfed, or some of its vital or essential parts are so dwarfed as to cripple the machine as a whole.

A railroad is a plant, establishment or organization for manufacturing transportation. The locomotive is a very important part of the plant and is one of the most direct earners of revenue from which the transportation-manufacturing plant obtains its income. As such, it is a matter of business and economical principle to adjust some of the physical conditions of the road to meet the requirements of the locomotive, to prevent dwarfing it and to prevent sacrificing its power. Meeting these requirements of the locomotive amounts to meeting the necessary requirements of traffic. No turntable installed at a principal roundhouse should be less than 100 ft. long, and in many cases the length should be 125 ft. The distance between the walls of a modern roundhouse should be great enough to permit closing the door behind the tender of a Santa Fe or Mikado type locomotive and have ample room for trucking between the locomotive pilot and the outer wall of the roundhouse. Passing tracks should be long enough to take trains justified by the business and traffic of the division or territory. Bridges, rail and roadbed should be capable of carrying a static wheel load of at least 65,000 lb. per pair and of permitting the additional stresses resulting from a freight speed of at least 45 miles per hour. In meeting the requirements of rail stresses particular attention should be given to the employment of heavy rails on curves.

Unless these physical conditions are provided, a locomotive cannot be designed and constructed without restriction and proper power cannot be furnished to meet requirements. The only governing factors should be the size of train and the traffic of the territory.

Leading Features of Locomotive Construction

Leading features of locomotive construction such as relative size of cylinders, length of stroke, total heating surface, superheating surface, grate area, etc., have been well covered by handbooks and pamphlets issued by locomotive builders and by reports to the various associations, as well as by articles in the technical press. Tables of principal dimensions of large locomotives are obtainable from the same sources, together with detailed descriptions of features of design and construction which have met with general favor and some which have been short-lived. A discussion or comment on these features would therefore be largely a repetition of facts already presented and easily available.

Features which have not been so generally discussed and exploited are those which keep a locomotive in service a maximum length of time, reduce engine failures to a minimum, reduce cost of maintenance and repairs, and increase revenue-earning power. Among these, durability of material and accessibility of parts are important factors. The latter implies arrangements by which a locomotive is made free from complications in construction, inexpensive to repair, easy to maintain, and so put together that needed repairs can be made handily and quickly.

Almost as important as providing a locomotive that will meet the requirements of trains to be hauled and traffic conditions, is providing one that requires minimum repairs—a locomotive that after one trip is ready to be turned for the next trip.

A locomotive is in revenue-earning service only when it is hauling trains. Any road can make a study and determine what proportion of its locomotives are unserviceable and what percentage of the time its serviceable locomotives are on the road. Such information will show what percentage of the time its engines are earning revenue.

To maintain the advantages of designs already existing and to develop these still further requires the unlimited co-operation not only of the mechanical, civil-engineering and operating forces of the railroads, but also of the locomotive builders, and particularly of the manufacturers of material.

The necessity for unlimited co-operation by manufacturers of material is evident from the study of failures of parts both large and small. On the principle of encouraging further consideration of such co-operation by all concerned and for the purpose of arousing interest in those details of locomotive construction which are not always given the attention to which they are entitled, a number of details which seldom appear among "leading dimensions" will be discussed.

Counterbalance

Important among such details and one which is affected particularly by designers and manufacturers of material, is the counterbalance. The blow from the counterbalance is caused by the difference between the weight of the revolving parts carried by the pins and the total weight in the wheel to balance both the revolving and reciprocating weights. In other words, it is the weight in the wheel to balance reciprocating weight that causes the hammer blow.

Weight of reciprocating parts therefore affects hammer blow of driving wheels, riding qualities of locomotives, possible damage to track and bridges and total weight of locomotive. It is particularly essential to make these parts as light as possible, and to make them light the material must be durable.

Due to the increase in weight of locomotives and to the hammer blow on rails when reciprocating parts are heavy, the 1915 Committee of the American Railway Master Mechanics' Association made the following recommendation:

> Keep total weight of reciprocating parts on each side of locomotive below $^1/_{100}$ part of total weight of locomotive in working order and then balance ½ weight of reciprocating parts.

An attempt to counterbalance large locomotives in both freight and passenger service according to this recommendation has demonstrated its merit, but has further demonstrated that the durability of both cast and forged steel must be improved if the method is to be continued.

Crossheads

The Laird type of crosshead is lighter than several other designs, its performance is very satisfactory in service, and it therefore has advantages in designing for light reciprocating parts. A crosshead of this type used interchangeably on large freight and passenger locomotives is shown in Fig. 1.

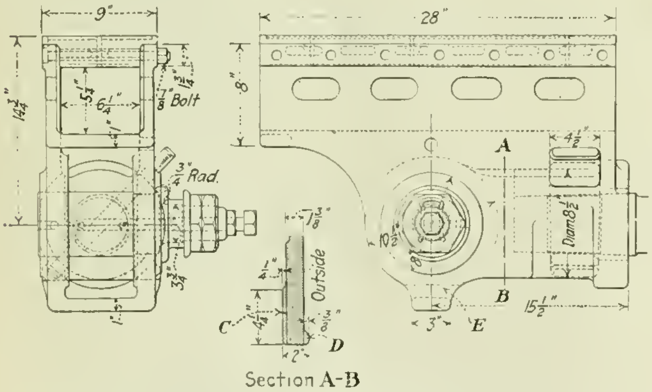

Fig. 1—Laird Crosshead Used on Various Types of Large Locomotives

The construction originally employed is shown by the figure, with the exception of later reinforcement at *C*, *D* and *E*. After about a year's service these crossheads began to break, the weakness appearing in the relatively thin wall between the hub around the piston rod and the lighter hub around the crosshead pin. The same weakness developed in crossheads of similar general design among locomotives of three or four different classes. The defects which proved common to these different crossheads are shown in Fig. 2.

By breaking up these crossheads in order to investigate the nature of the metal, it was found that in most cases each fracture had its origin in a shrinkage crack. The metal in most of the broken crossheads was found to be porous and to contain blowholes or gas holes, or shrinkage cracks, cold shuts or pipes. In some cases all of these defects were present.

Fig. 2 shows very clearly the difference in cross-section of the metal at and near the break. This difference is no doubt largely responsible for the defects in the metal which have caused an epidemic of failures. Crossheads of this general design have been used for many years, and as it appears impossible to modify the shape to advantage, the question, then, is whether foundries can adjust their practices to cast such irregular sections without blowholes, shrinkage cracks and other defects. This is one of the opportunities for manufacturers of material to co-operate with the locomotive designer.

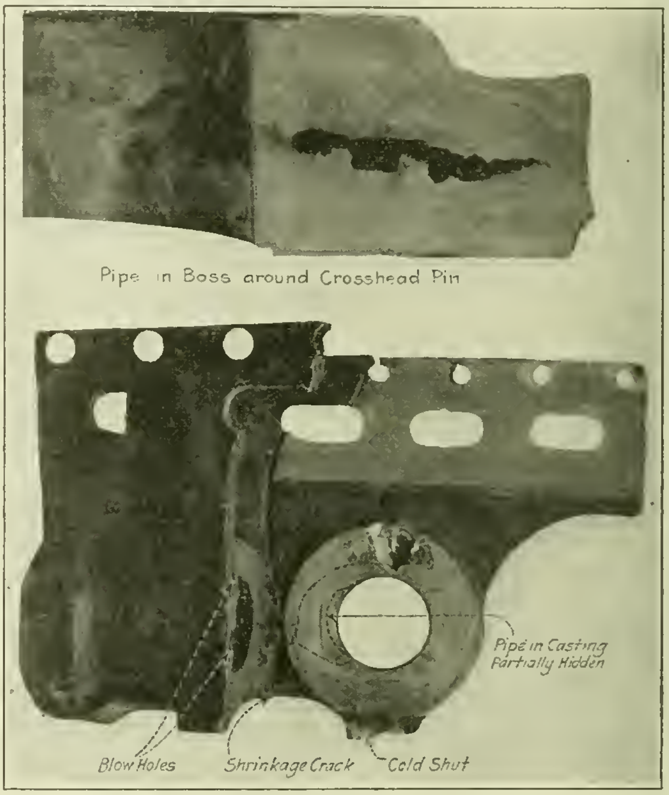

Fig. 2—Location and Nature of Defects in a Poorly Cast Crosshead

Driving Wheels

Another irregular section which causes shrinkage cracks is the cast-steel driving-wheel center. Rims and spokes are of much lighter section than the hub and counterbalance, and shrinkage cracks are not unusual at the juncture of these light and heavy sections. Foundries which cast locomotive parts have these conditions to meet and it is believed that foundry practices can be adjusted to meet them.

Crosshead Pins

In the development of locomotive construction within recent years the union link of outside valve gears has been connected direct to the crosshead pin. This reduces weight by eliminating the crosshead arm and by shortening the length of the combination lever, thus lessening reciprocating as well as total weight. A further advantage is in eliminating the bolted connection between the crosshead and arm.

In eliminating the crosshead arm the duty of the crosshead pin is increased. A broken crosshead pin is more serious than a broken crosshead arm. When a pin breaks there is a possibility of something else being broken and a very great probability of a cylinder head being knocked out and carrying a part of the cylinder wall with it. It is therefore absolutely necessary that the material in the crosshead pin shall be of a good quality, and the steel used should contain about 0.50 per cent carbon and have a tensile strength of 80,000 lb. per sq. in.

By reference to Fig. 1 it will be observed that the diameter of the union link shank of the crosshead pin is 3¾ in. This is believed to be considerably larger than usual in locomotive design. Even though the stresses in the crosshead pin are low, this large size appears to be a necessary precaution against the uncertainty in quality of material. As a further precaution there is a fillet of ¾-in. radius at the end of the shank.

Piston Rods

The greater number of breaks in piston rods of at least one railroad have been through the keyway. Next in order is the location in the crosshead fit adjacent to the collar. Breaks in the body are usually adjacent to the collar at the crosshead fit and occasionally at the collar adjacent to the piston-head fit.

The mechanical fit between the rod and the crosshead is often responsible for the breakage of the former. If there is not a good bearing throughout the length of the fit or at both ends of it, there is opportunity for a slight movement of the rod in the crosshead. This starts a crack which gradually progresses into a fracture. To facilitate making a good bearing at both ends of a piston-rod fit in a crosshead, the diameter is reduced 1/16 in. for a length a little greater than the keyway and about midway between ends of the fit. To prevent cracks starting in sharp corners at edges of the keyway, these edges are chamfered at both ends of the keyway and entirely around.

Rods with comparatively low stresses sometimes fail in such a manner that it is difficult to attribute a cause unless quality of material is responsible. This is true of rods of ordinary carbon steel as well as those of specially refined steel and of alloy steels. In this is another opportunity for the assistance and co-operation of manufacturers of material.

Cylinders

Failures of parts such as those described in preceding paragraphs, quality of material, uncertainty of cylinder cocks being operated, extreme variation in temperature due to use of superheated steam, foundry practices, etc., all affect the design of cylinders. Consideration of these and other features has resulted in the development of the design shown in Fig. 3, which is that of the cylinder of a Mikado locomotive. Except for modifications in dimensions this represents cylinders used also on Santa Fe, Mountain, Pacific and other locomotive types. The principal features of this cylinder are:

Simplicity in construction.

Uniform thickness of metal.

Absence of heavy metal sections at junctions of walls.

Walls and parts of ample thickness for strength, well ribbed, well braced and arranged with easy curves and generous fillets.

Uniform sectional area throughout length of steam and exhaust passages.

Short steam ports.

Small steam clearance.

Sections of metal, fillets and other features arranged to eliminate internal stresses set up in metal when cooling.

Double row of splice bolts holding halves of cylinder saddle together.

Double row of bolts at smoke arch.

Triple row of horizontal bolts securing cylinder casting to frame.

Depth of saddle casting directly above frame forming a box section and providing strength where shallow castings used with double-frame rail failed in the past.

Location of valve close to cylinder, permitting short ports, straight valve gear without offsets, and application of nearly straight steam pipe.

Large openings to cylinder cocks.

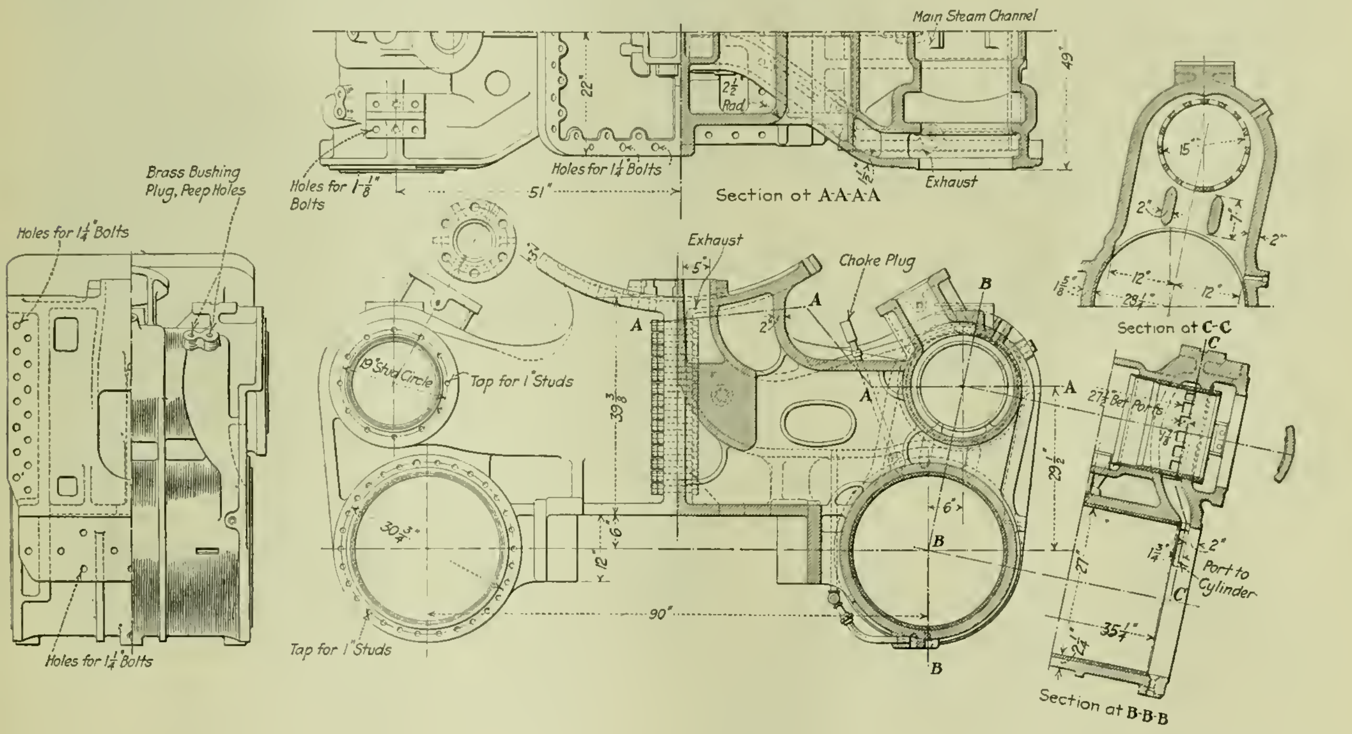

Fig. 3—Cylinder for Large Locomotive

The steam and exhaust channels are free from obstructions and restrictions which will interfere with free flow of steam. The exhaust channels are gradually reduced in area from valve bushing to base of exhaust pipe in such a manner that the cross-sectional area of any point in the channel is not larger than any area through which exhaust steam has previously passed.

A weakness in castings of some large cylinders has been in the wall around the live-steam port. As shown in Fig. 3, this wall is made 2 in. thick and the distance across the port below the valve bushing is 24 in. To reduce stresses in this wall it has been made thicker than most other walls of the casting and, compared with former practice, width across port has been reduced about 4 in. The bridges in the live-steam port are 2 in. thick. They were formerly but 1 in. in thickness and it was not unusual to find them cracked clear through. The change was made to increase the cross-section of the bridges in relation to the adjacent walls and thereby reduce tendency to shrinkage cracks.

To obtain a good cylinder casting from any design, it is necessary to have proper co-operation of the pattern shop and the foundry. Patterns must be well built and carefully checked. The checker should exercise especial care to see that patternmakers apply all the fillets called for. The foundry should so arrange the mold as to obtain uniform sections of metal. To insure this, careful measurements should be taken when cores are being set and a drop light should be let down into the mold when taking measurements.

Frame Braces

Locomotive frames are subjected to repeated lateral and twisting stresses, as well as to various other stresses, which will gradually break a single frame, but which can be withstood indefinitely by the application of substantial braces. An example of a pair of strong frames substantially braced is shown in Fig. 4, the arrangement illustrated being for a Santa Fe type locomotive. Bracing in the manner shown has been used for a number of years very successfully, and with very little modification is applicable to any locomotive class with outside valve gear.

Braces must be bolted to frames securely. Where braces or castings of other parts are bolted to a frame, the bolts should be applied with the head end bearing in these parts and not the thread end. This will provide for bearing on the bolt through the full thickness of the part bolted to the frame.

Boiler Cracks

In using the boiler to supplement the frames in forming a backbone or foundation from which to brace machinery parts, the boiler shell is subjected to additional stresses which result in cracks in the sheets. The most frequent causes of these cracks are guide-yoke braces, valve-motion braces and the ordinary belly braces to frames. Guide-yoke and valve-motion braces are often very stiff and are bolted securely to the frames and studded to the boiler. When the boiler expands the braces and connections are held rigidly by the frame and there is a tendency for the boiler to tear itself loose from these fastenings. This sets up strains in the metal which are aggravated by the vibration and pounding to which braces are subjected.

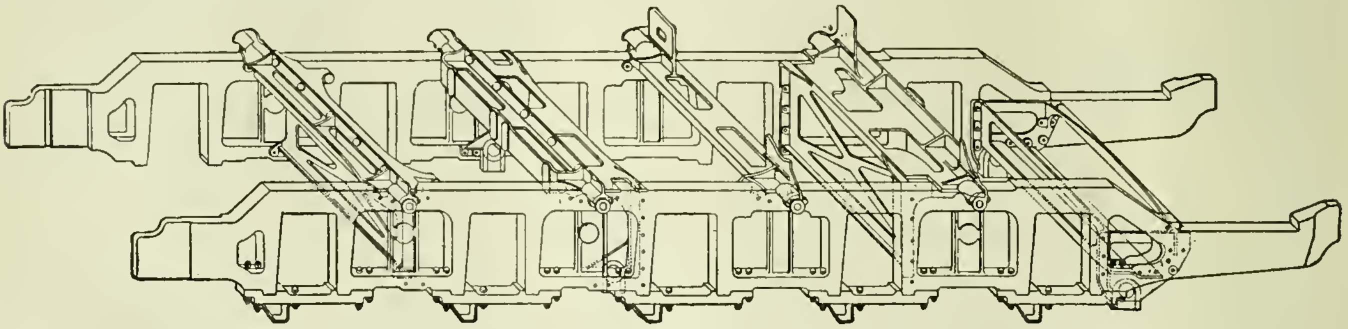

Fig. 4—Frames and Frame Bracing of a Large Locomotive

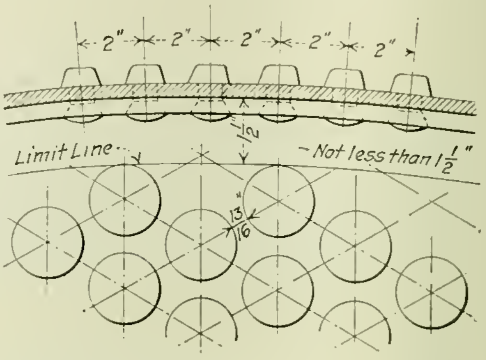
In an effort to overcome these cracks, outside welt plates have been riveted to the boiler to reinforce it where the brace pads are studded on. Experiments have been made with flexible, or partially flexible, braces, some of which have so far been successful.

On engines where breakage of braces has occurred, some of them are being replaced by braces with a pin connection at the lower as well as upper end. Where the use of pins is not favored, however, a thin plate in connection with a cast-steel brace should provide sufficient flexibility for expansion of the boiler and proper stiffness for bracing machinery parts.

The Back Flue Sheet

Boiler back flue sheets of large locomotives are renewed and patched more frequently on account of cracks in the knuckle near the top flange than from any other cause. On at least one road the average life of flue-sheet knuckles is three years and three months, the maximum and minimum varying within rather a large range.

A minimum limit of distance of top flue holes from top of flue sheet that is considered practical is shown in Fig. 5 To omit flues near the top of the flue sheet sacrifices heating surface. To raise the top of the flue sheet above the usual location of flues increases the weight in the firebox, adds to the amount of water necessary to cover the crown sheet, and by requiring increase in diameter of boiler to maintain steam space above the crown sheet, increases the weight of the boiler and consequently the weight of the locomotive as a whole.



NOTE:—Limit line to be increased to 2 in. in designing new boilers where this increase can be made without reducing number of flues, and without reducing bridge below desirable limit

Fig. 5—Minimum Distance Between Top Row of Flues and Flange of Back Flue Sheet

Considering the stresses and the peculiar punishment to which flue-sheet knuckles are subjected, it is important to specify this material carefully. The following limits have been demonstrated by experience as practical:

Tensile strength, 52,000 to 60,000 lb. per sq. in.
Elongation, not less than 25 per cent.
Carbon, 0.12 to 0.25 per cent.
Sulphur, not over 0.025 per cent.

The Ashpan

Various details at the rear of a locomotive should be arranged to permit a large ashpan with smooth slope sheets at an angle that will permit cinders to fall to the hopper without obstruction, and its design should be decided on before the designs of surrounding parts have progressed too far. Equally as important is area between the ashpan and mud ring or through parts of the pan, to admit air to support combustion. This area should be at least equal to the area through the boiler flues, and preferably a little greater.

The Grate Rigging

The place for grate rods, which operate the grates, is near the center of the grates and above the deep portion of the ashpan. On locomotives without stokers this arrangement is not difficult to provide for. With some stokers, however, grate rods in this position are interfered with, and this has resulted in some grate rods being located along the sides of pans, in certain cases very close to the flat portion or shelf of the pan under the mud ring. In this position the rods collect cinders close to the air openings and obstruct the admission of air for combustion. With steam grate-shaker equipment and stoker the grate rods can be located near the center of grates by applying a set of intermediate rockers.

Water Columns

A very thorough investigation into conditions affecting the performance of water columns indicates that the most satisfactory service is obtained with a column and connections conforming with the following specifications:

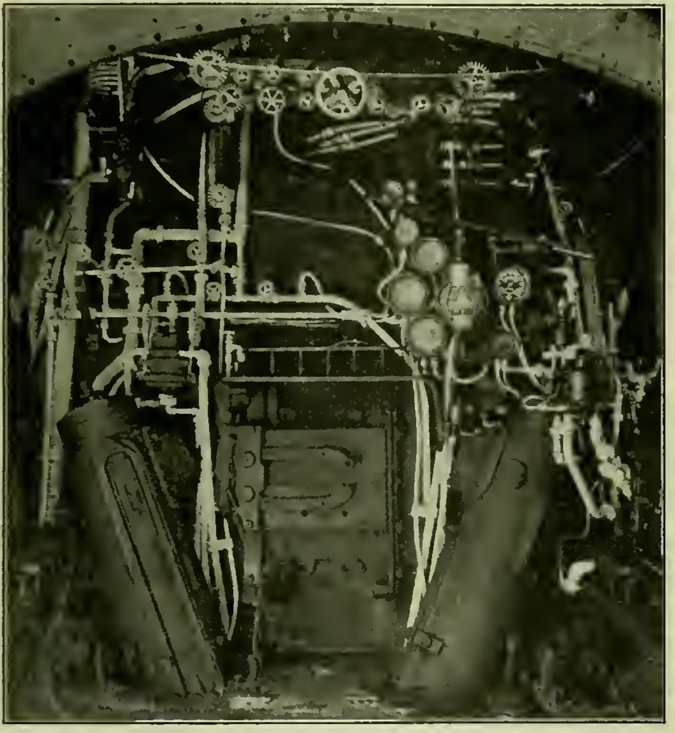


Fig. 6—Location of Boiler Back Head Fixtures in Large Locomotive

Inside diameter of water column, 3½ in.

Inside diameter of top steam pipe, 2 in.

Inside diameter of connection of column to top steam pipe, not less than 2 in.

Inside diameter of bottom connection to boiler, ¾ in.

Top steam pipe as short as possible consistent with required location forward of boiler back head flange.

Minimum number of bends in top steam pipe to column. This pipe to be lagged.

No valves between water column and boiler either in top steam pipe or in bottom connection.

Water-column bottom connection should extend into boiler far enough to clear nearby T-irons or other obstructions, approximately 4½ in. from inside of sheet.

Cab Equipment

The back wall of the cab should be far enough away from the boiler back head to give room for a satisfactory seat, for the application of the required equipment, and for a man to pull the throttle open without striking his arm against it. A distance of 46 in. from the face of back head at the center of fire door to the back wall of cab will meet these requirements.

Engineers' and firemen's seats should be located where the men can see ahead and their vision should not be obstructed by air pumps located too high, classification lamps misplaced, running boards too high at the front, or other obstructions that might interfere with their seeing semaphores, switch stands, etc.

Blow-off cock handles should be so located that they can be operated by a man in position where he can see the water glass, and preferably without leaving his seat. The water glass, steam gage, air gages, etc., should be so located that they can be seen by the engineer when in usual position on his seat.

The throttle lever, power reverse lever, cylinder-cock lever, sander valves, brake valves, etc., should be located where the engineer can reach them handily when sitting in usual position on his seat or sitting with his head out of the window. It appears like a small detail, but it is a worth-while one to locate the straight air valve where it can be reached easily by an engineer when in such a position that he can see a man at the back of the tank giving signals for coupling to a train.

The lubricator must be at such a height that a man can see the feeds, and it must be high enough to avoid pockets in the oil pipes. It must be far enough below the cab roof to be filled easily.

Cab equipment requires careful study and it is difficult to locate the various appliances by drawing, but it has been done. A cab with a large amount of equipment on the boiler back head, yet which is regarded as being reasonably convenient, is shown in Fig. 6.

The use of clear-vision windows has made it somewhat difficult to arrange the seats so that either seat or window will be a height to suit different men. This problem, however, has been solved for one road by its motive-power department chief, who has developed an adjustable seat made of steel and having a spring cushion and an upholstered back. The back being secured to the seat and independent of the back of the cab prevents any vibrations resulting from shaking of the cab wall.

Tender Capacity

Tender capacity should be arranged so as to reduce to a minimum the time a locomotive is detained from the productive work of hauling trains for the purpose of taking water and fuel. This implies large fuel and water capacities, but in arranging for suitable tender capacity care must be taken to avoid unnecessary weight, as any increase in the weight of the tender produces an equal decrease in the weight of train that can be hauled behind the tender.

Tender fuel space should be arranged so as to enable the locomotive to handle a full train with as few stops for fuel as may be feasible.

On territories equipped for water to be taken on the run or when stops for purposes other than taking fuel or water are made regularly at stations where water may be taken. the water capacity should be only sufficient to supply the locomotive when handling a full train, between water stations, with a moderate surplus for unusual delays.

On territories handling a large percentage of through trains with few stops, tenders of large capacity are desirable as they permit keeping locomotives more continuously at work. Where water is scarce and the supply has to be hauled to water tanks, tenders of large capacity are desirable as they reduce the number of water stations that must be maintained as well as the number of locomotives, cars, and men employed in hauling and handling water at these stations.

In addition to reducing time consumed by trains on the road, together with overtime pay to train and engine crews, large-capacity tenders effect a substantial saving by reducing the fuel consumed in starting and accelerating trains as well as the damage to locomotive machinery, draft rigging, tires and rail which frequently results from stopping and starting long freight trains. Train dispatching is simplified and the movements of superior and opposing trains are expedited, as a train which keeps moving interferes less with the movements of other trains than one which must stop frequently, thereby introducing uncertainty as to how long it will be detained.

Necessity for Improvement in the Design and Operation of Present-Day Locomotives

BY H. W. SNYDER
Mechanical Engineer, Lima Locomotive Works

No one, it is believed, will dispute the fact that present-day operation of high-power locomotives is one of the most vital questions with which our railroads are concerned. The demands of constantly increasing passenger and freight traffic have brought about a constant increase in size and power of our locomotives.

In view of the rapid strides that have taken place in increasing the size and power of locomotives within the last few years, it seems rather out of place to predict that the maximum has been reached. It is also true that the use of improved devices has made possible the satisfactory operation of the large locomotives of today. Everything seems to indicate that we have not reached the maximum capacity of the locomotive even within the present limits of clearance and rail load, and we may expect to see these same engines made far more powerful and economical by the application of devices which are now available or which are already being given serious attention.

In view of the foregoing, the most vital matter which confronts locomotive designers and operating officials is that of increasing the capacity as well as the efficiency of the locomotives which we have today. In many ways these problems have already been attacked and great improvements are continually being made.

In the following paragraphs an attempt will be made to bring to attention some of the problems which our present day locomotives bring forth and upon the proper solution of which depends their success.

Combustion and Steam Generation

In order that large engines may operate properly, it is of course necessary that a sufficient supply of steam be furnished to cylinders so that they can be made to produce their maximum horsepower. It is not enough to provide a given number of square feet of heating surface in the firebox and the tubes so that we may be reasonably certain that sufficient water will be evaporated to supply the cylinders. It is, however, necessary that we take into account proper construction of the boiler, necessary firebox volume to produce the best possible combustion of fuel, and the design of grates so that fuel will be economically burned to such an extent only as required by the maximum evaporation of the boiler.

In producing heavy motive power it has been necessary on account of prohibitive axle loads to apply a sufficient number of axles under the engine to reduce the individual axle load to within reasonable limitations. This has lengthened out the engine to such an extent that boiler design and maintenance has become a serious problem. In the first place, it is necessary to design a boiler that will properly function with the other vital parts of a locomotive. At the same time the length has become such that the use of combustion chambers is a necessity to avoid a prohibitive length of tube. Large engines have been constructed with a tube length of 25 ft. and it seems that no definite rule has been established as to what the limit of length of tube of a given size should be. Experiments have been made on this subject and it has been said that the maximum length in inches of a tube of a given size should be approximately 100 times its diameter in inches. It would seem that this is as nearly correct as any general rule which has been devised and one which can be readily followed.

The author does not feel that any definite rule should be made in regard to length of tubes, for this might bring about a condition whereby other vital features of the engine would be involved in order to abide strictly to the length as noted above. Tubes 2 or 2¼ in. in diameter in excess of 20 ft. in length are questionable, and this feature should be looked into carefully before a decision is reached.

The advent of long combustion chambers has brought along with it the necessity for increased attention to boilers. The application of a long combustion chamber requires a large number of additional staybolts and it would naturally be expected that a boiler of this kind would require more staybolt attention. For this reason, if for nothing else, there is no doubt that a proper installation of flexible stays in the firebox and combustion chamber will prevent a great deal of the staybolt trouble which has been experienced in the past. Although long combustion chambers require more attention in maintenance this will be offset by the increased firebox volume and the resulting better combustion.

On account of height limitations, the height of the dome as well as the steam space in the boiler has been reduced to such an extent that difficulties are being encountered with the proper life and maintenance of superheater equipment, because too much water is drawn over through the throttle into the superheater. This is a question requiring experiment to determine as nearly as possible the minimum steam space which should be provided for boilers working on various grades. Consideration should also be given to the height of the throttle above the water line as well as to the steam space in the boiler. Considerable development on this subject is now well under way and we can confidently expect results of value in the near future.

Increased Capacity Needed Without Increase in Size

As noted above, it seems that we have about reached the limit of size of cylinders and size of boiler due to road clearances. To undertake to provide additional road clearance on practically all of the main lines today would mean a total expenditure of money, entirely out of proportion to the benefits that would accrue.

On account of the apparent limitations of piston thrust and road clearances the greatest problem with large locomotives today is to increase their capacity without exceeding greatly present sizes. Anything to increase the hauling capacity of the locomotive without increasing the height and width limitations under which the locomotive must work might be called an essential capacity-increasing device. A few of these with which we are most familiar and which have proved beyond doubt their desirability are the superheater, the brick arch and the mechanical stoker. There are possibilities of still increasing the efficiency of the superheater without increasing the size of the boiler in which it must operate. There are also possibilities and constant improvements in the design of brick arches which lend to higher evaporation and better combustion of fuel. It has been stated that when a locomotive requires as much as 6,000 lb. of coal per hour it has gone beyond the limits of the ordinary fireman. Automatic stokers have been in use so long that their dependability for heavy power is no longer in question. Many men are studying this particular feature of locomotive design and operation and we may confidently expect in the future a gradual increase in the efficiency of these mechanisms. As they stand today they are an unqualified success, and time and study will bring about the necessary refinements so that better combustion and less coal per horsepower will be used.

We have not as yet gone very extensively into the use of feedwater heaters. It has been proved without a doubt in foreign countries that the feedwater heater is an essential capacity-increasing device as well as an economical addition to the locomotive. In this respect, then, it would seem that we are somewhat behind the Europeans, and there is no doubt that in the near future when the economies that can be effected by the use of feedwater heater are realized it will become almost as general as the superheater today.

Another small item which has received only passing attention in this country is the variable exhaust. As is well known, a variable exhaust that can be properly operated and which will not require much maintenance attention will have a great tendency to relieve high back pressure at high speeds, and its operation will also provide the necessary draft at slow speeds. It is one of the small things that deserves consideration and study and something which it is felt will be worked out satisfactorily for the future.

The Engine Proper

There have been no radical changes in the general design of cylinders. The use of outside steam pipes has resulted in advantages both from a casting and maintenance standpoint. It would seem well worth while to consider a design of cylinder by means of which the weight could be reduced to a great extent, permitting of additional weight of other parts, and thereby increasing the capacity of the locomotive.

The design of valve gears has received a great amount of attention and many accepted types are now available. In all of these every effort has been to better the steam distribution. In maintenance we are far ahead of engines used twenty years ago. There is yet, however, much to be desired in steam-distribution and this subject will bear as careful study in the future as it has in the past.

Power Transmission

When we consider that as much as 150,000 lb. piston thrust is being transferred through a single main rod and from this into the driving wheels of a locomotive, it is not difficult to understand why troubles are experienced with main crankpins and particularly side rod bearings at the main pin. In order to provide the proper strength to take care of this tremendous piston thrust it has been necessary to design extremely heavy main and side rods. The piston thrust is not the only consideration in this connection. The inertia forces, particularly in drifting, at times reach figures that are even greater than the piston thrust. Practically all of this must be taken care of through the main crank pin and the necessary connections to the side rods at this point.

All are familiar with the large number of experiments which have been carried on to produce a steel that would give a higher elastic limit than the ordinary high-carbon open-hearth steel which was successfully used until engines reached their present proportions. The use of such steel for side rods, main rods and piston rods has been principally confined to heat-treated and quenched forgings, which permitted the use of sections which were considerably lighter than what could be used with the ordinary open-hearth annealed forgings. Steel has also been produced which gives a high elastic limit and which can be successfully used with ordinary annealing, permitting very considerable reductions in weight compared to the ordinary open-hearth steel formerly employed. The use of such a steel does away with quenched forgings and permits of rods being heated for closing in straps and similar work without destroying the quality of the material as is the case with quenched forgings.

Main and side rods have been produced and have been in successful operation for the past few years in which the piston thrust is carried directly from the main rods to the side rods back of the main wheel. This does not in any way reduce the piston thrust that must necessarily come on the main rods. At the same time, however, it does reduce very considerably the piston thrust that must be transferred through the main crank pin into the side rods, thereby alleviating to a very great extent the troubles that have been experienced with large side rod connections at the main pin. Such a design does not increase the total weight of the rods to an extent likely to cause any appreciable increased difficulties from a counterbalance standpoint.

The design of main and side rods as well as main crank pins will always be a vital question in the construction of locomotives. It has been necessary and always will be in designing the rods for locomotives to assume certain arbitrary limits of fiber stress based principally upon past experience. It is impossible to take into account all the stresses produced in rods when a locomotive is in operation, and for this reason the allowable fiber stresses in tension, compression and bending must be taken comparatively small in comparison to the elastic limit obtained in such forgings.

There has already been a great deal written and a number of experiments conducted regarding the proper design of rods to successfully stand up under severe usage and at the same time reduce to a minimum the ordinary difficulties presented from the standpoint of counterbalance. Hollow-bored piston rods, light designs of crosshead and piston, the use of high-tension steel for side and main rods as well as the use of hollow-bored crank pins are familiar to all. More careful attention should be paid to the quality and upkeep of rod bearings and every endeavor should be made to provide bearings of such quality and design that renewals will be reduced.

A main pin designed properly for heavy piston thrust must be so proportioned that the length will bear a certain relation to the diameter within very close limits. On account of the necessity for keeping cylinder centers as close together as possible because of road clearances, if a proper length of main pin is obtained, its proper size presents a difficult proposition. This is one of the great difficulties which the author is confident will be overcome in the near future by the proper application of a design previously mentioned, wherein a large part of the piston thrust is transmitted directly from the main rod into the side rod.

Before the advent of present day large locomotives with their tremendous piston thrust it was not a particularly difficult matter to design a suitable main crank pin. So long as the bearing pressure per square inch of projected area based upon maximum piston thrust was within a limit of 1,600 or 1,700 lb. the main pins would work satisfactorily. The ordinary design of smaller locomotives was such that the main side pin would also be sufficient. It has been found in comparatively recent years, however, that the old rule would no longer apply. In order for the main crank pin to be of sufficient size to withstand heavier piston thrust and still maintain the fiber stress within workable limits, it was necessary of course to increase the diameter proportionately. This brought up the question of rubbing speed. It is a well-known fact that if the rubbing speed is too high, bearings will heat and wear very rapidly regardless of the bearing pressure.

Counterbalance

It is a very difficult matter to separate the question of counterbalance from the design of connecting rods and reciprocating parts. There is a great diversity of opinion in regard to the proper amount of counterbalance which should be applied to locomotives. There are in operation heavy Santa Fe type locomotives which have between 35 and 40 per cent of the reciprocating weights counterbalanced and they are said by traveling engineers to ride easily. The author believes that with our present heavy engines with long wheelbase it is not necessary to balance as much as 50 or 55 per cent of the reciprocating weight. In fact, it is quite possible that we may be able to counterbalance a smaller percentage of reciprocating weight than has heretofore been attempted, especially for long, heavy engines, provided the revolving weights at the main pin can be properly taken care of. Every effort, however, should be made to balance all of the revolving weights on the main pin. If, for example, we lack 400 lb. of balancing the revolving weight on the main pin, the effect on the track is exactly the same as if we had 400 lb. of counterweight on any of the other wheels to balance reciprocating parts.

There is an added difficulty to this problem, because the action of the counterweight in wheels other than the main is exactly opposite to the force produced by the weight on the main pin which is not counterbalanced. This condition results in increased track stresses, as well as increased stresses in frames and other parts of the locomotive. There is also a tendency at high speeds when a condition like this exists for the main wheel to lift from the rail, while the wheels other than the main are exerting their maximum force on the rail. This reduction of weight on the main wheel at the time when the other wheels are exerting their maximum force on the rail provides a tendency for the main wheel to slip when it is impossible to slip the remaining wheels. No one, it is believed, can give any idea of the stresses which are produced in side rods, frames and other parts of a locomotive due to a condition of this kind. In fact, there have been instances where the rods were torn off and the crank pins loosened for this reason alone.

The author is of the opinion that no definite set rule can be established in this regard, but that each particular design is a study in itself, and wherever revolving weights at the main pin are encountered such that they cannot be properly counterbalanced, steps should be taken to provide the best means possible of reducing revolving weights at this point as well as providing reciprocating parts as light as possible consistent with strength. This of course has been accomplished in the past by hollow boring the main pins and piston rods and by using a light design of piston head, which indicates that a steel having a high elastic limit with the proper elongation and reduction of area should be employed. The use of such steel has already proved that it can be depended upon. One of the principal fundamentals in counterbalance is to keep the reciprocating weight as light as possible.

The Running Gear

On account of the large increase in the size of cylinders of present-day heavy locomotives over those used several years ago, the cylinder centers have been spread until they have reached practically the clearance limitations of the railroads, and the necessity for larger journals to carry properly the increased axle loads has caused the frame centers to be brought nearer together.

This condition increases very materially the distance from the center of the cylinder to the center of the frame, which of itself produces greater strain in the frame and at the same time increased pressure on the driving-box bearings as well as shoes and wedges. In addition to the above, piston thrusts have increased from approximately 65,000 lb. to approximately 150,000 lb., and means must be provided to properly take care of the increased piston thrust along with the increased overhang.

While discussing the subject of frames it is hardly possible to ignore the vital question of frame cross-bracing. Substantial and sufficient cross-braces should be applied between the frames and rigidly bolted thereto to form a rugged structure which will not rattle to pieces. Sufficient bearing for bolts and adequate bolting flanges are a very important feature. At the same time it must be borne in mind that there is a possibility of tying up the frame so rigidly that there will be a tendency for failures ahead of the front pedestal and just back of the cylinder fit at a point where it is practically impossible to obtain sufficient reinforcement.

It seems as though the design of driving boxes and driving-box brasses has not successfully kept pace with the rapid increase in piston thrust. We have in almost general use the same type of driving-box brass which has been standard on locomotives for years. The design is such that the brass extends about half-way down over the journal. Inasmuch as this brass must take up the piston thrust, it is very evident that we shall have trouble in taking care of driving-box brasses until a suitable design is produced—one in which the brass will cover much more of the front and back projected area of the journal than is now the case.

Guiding and Trailing Trucks in Connection with Long Wheelbase

With our present heavy Mikado and Santa Fe type locomotives the length of rigid wheelbase is almost if not quite double the rigid wheelbase in ordinary service 20 years ago. It is unnecessary to comment upon the fact that it is a difficult matter to operate such engines around curves of even comparatively small degree and at the same time prevent the rapid wear of hub liners and driving-box faces, thus increasing quickly the lateral play to a prohibitive point and necessitating work in the shop to overcome it.

Santa Fe type engines with 22-ft. rigid wheelbase are not uncommon. Engines of this type and of this size will weigh in the neighborhood of 400,000 to 420,000 lb. When we stop to think that to move this tremendous mass of material around a 16- or 18-deg. curve a force of many thousand pounds is required, is it any wonder that we obtain rapid flange wear and the necessity for re-turning tires before the proper amount of mileage has been obtained? In the majority of cases, it is believed, the force necessary to properly curve an engine of this kind has been applied at the front truck and the first driver. In most cases types of leading trucks have been used which produce a very small resistance on curves of small degree. In order to prevent rapid flange wear as well as to overcome the development of lateral play unnecessarily, designs have been produced which will give a high initial resistance of the front truck and provide a lateral motion for the front driver with adequate resistance so that some of the guiding force is transferred back to the second pair of drivers.

Since locomotives operate the greater part of the time on tangent tracks, it is necessary to have a high initial guiding resistance which will not be increased when curving. In other words, a flexible wheelbase is produced which has all the requisites of the ordinary rigid wheelbase, but at the same time will overcome many of the difficulties now encountered in an attempt to operate engines of this size and length. Many designs of trailing trucks have been produced with the idea in mind of helping to remedy the conditions which have been noted above. These of course have met in a way the conditions which it was necessary to overcome. There is much yet to be done in producing a trailing truck which will have the proper facilities for equalization of spring rigging and at the same time produce an initial guiding force which can be kept nearly constant, thus avoiding the high final lateral resistance which is found in a good many of the trailing trucks now in use.

In addition to the foregoing some work has been done in the way of producing a design by means of which the lateral play in locomotive driving wheels can be taken up without removing the wheels from under the engine or taking the boxes off from the axles. No doubt in the near future a practical device of this kind will be produced. This is another one of the many problems which can be worked out which will enable the railroads to keep their locomotives in service.

The advent some years ago of the power reverse gear overcame one of the great objections that engineers had to large locomotives. It is a fact that it is almost impossible for one man to reverse one of our large locomotives equipped with the ordinary hand reverse lever. Power reverse has come to be an essential part of engine equipment and has been found to be economical even though it may be used on a locomotive which could be comparatively easily reversed by hand.

Probably no one thing contributes more to the failure of side rods than the improper adjustment of shoes and wedges. If these are allowed to run loose, stresses in the side rods will amount to a very high figure and it is impossible to determine to what extent they may go. A satisfactory automatic wedge if properly applied and maintained will, no doubt, go a long way toward preventing side rod failures.

Means for Increasing Nominal Tractive Power

All railroads have points on certain divisions where there is a critical grade or the necessity of starting a heavy load under adverse conditions. At such places increased tractive power is required which is not needed elsewhere. We are therefore confronted with the problem of producing a device which can be set to work to increase the tractive power of a locomotive to such an extent that the critical grade or the necessity for increased tractive power to start a train under adverse conditions will be overcome, thus enabling the engine to take its full tonnage over the entire division. This device should be so made that it can be applied when necessary and thrown out when the additional tractive power is not required. Designs have already been produced wherein an additional tractive power of 8,000 or 10,000 lb. has been applied to the trailing trucks of large locomotives. There is also a possibility of applying such a device to the tender truck, thus availing ourselves of the adhesive weight of the tender to help boost the engine over the critical points in a division. There is always present a possible potential boiler capacity which can be brought out by the use of a variable exhaust or other device sufficient to obtain rapid combustion at slow speeds.

What has already been done along this line may be taken as a start in the right direction. A certain amount of development work must be done in order that these necessary improvements may be made to operate satisfactorily. These problems require the co-operation of the railroads to provide the necessary means for trying out such devices which, after having been carefully considered, show that they have possibilities for future use.

The Ash Pan

The question of ash pans is also one needing serious consideration. With the large increase in size of locomotives in many cases we have evidently lost sight of the importance of this necessity. There are in use a number of rules stating what the proper air opening in the ash pan should be, some saying that the ash pan air opening should be equal to the net gas area of the tubes and others that it should be a certain percentage of the opening through the grates. While many of these rules have in a way proven satisfactory, at the same time it would seem that to get at the question logically we should determine the amount of coal that can be burned economically per square foot of grate and then on this basis provide an ash pan air opening that will give the required amount of air to burn satisfactorily the maximum amount of coal which is expected to be consumed. The amount of air that will flow through a given opening in the ash pan, it is believed, can be very closely approximated from the vacuum produced in the smokebox. This, of course, is only a suggestion, and it may be that when the question is looked into more carefully a more desirable and accurate method of determining the required ash pan air opening for proper combustion may present itself.

Lubrication

Lubrication is a subject which has received much attention and a great number of combinations and experiments have been made to determine the most satisfactory method. With our present high superheat the proper introduction of oil into the cylinders and valves of a locomotive is worth serious consideration.

It is common practice in European countries to provide a forcefeed lubricator located very close to the cylinder. The ordinary method which they use in connecting up this lubricator is to provide a pipe to each end of the piston-valve steam chest. This oil supply opens directly over each end of the valve when it is in central position. In addition an oil pipe is supplied to the cylinder at its center. It is reported that by this method there is less carbonization of the oil than when it is fed into the steam pipes or into the center of the piston valve steam chest. Whether or not this is so the author has no means of proving, but it seems logical.

In order to increase the tonnage which a locomotive can haul it is just as vital to decrease the resistance as to increase the power. It is not an impossibility to provide roller bearings for passenger cars and there seems to be no reason why they cannot be used on freight cars. Of course, this would mean very radical changes in design and a gradual displacement of present equipment, but the reduction of rolling resistance and the better facilities for lubrication which would be provided would be sufficient in time to overcome the necessary expense. All this may seem rather far-fetched, but it is at least worthy of consideration.

Conclusion

In summing up the situation, it may be said that the use of the superheater alone has increased the capacity of locomotives when compared with saturated engines of the same design to such an extent that no one would think of building a large locomotive for up-to-date railroad service without the application of superheat. This is one of the greatest strides that has been made in the construction of locomotives in the past few years. We must not content ourselves, however, with what has been done with this one device. The large locomotive of today has become a necessity and is here to stay. What we need to do now is to avail ourselves of the opportunities offered in the application of many of the labor-saving and capacity-increasing devices which have already been worked out and are giving satisfactory service and at the same time look forward to the possibilities of applying other devices which are yet in their infancy, but which have proven beyond doubt that they are well worth our consideration and are of sufficient importance to warrant their adoption. There are many improvements yet to be made in locomotives and it behooves the operating officials of railroads as well as the leading minds in locomotive operation and design to get together and to continue to produce locomotives which in the next 20 years will be as far ahead of our present engines as our present locomotives are ahead of the locomotives that were built 20 years ago. Without the capacity-increasing devices which have been mentioned the large locomotive of today would be impossible—it could not be operated satisfactorily. Our large engines are an absolute justification of these improvements. Further developments are ready at hand and in their use lie the possibilities of still more powerful and economical transportation units built to operate within our present limitations of clearance and permissible rail loads.

The Functions of Management

Functional organization and management was the subject considered by the New York Section of the Taylor Society, on April 21, as reported in the Iron Age. The chief speaker was Henry W. Shelton, who had gained experience in his subject as assistant professor of organization and management at the Amos Tuck School of Administration and Finance, Dartmouth College; as head of the personnel section on the staff of the vice-president in charge of administration in the Emergency Fleet Corporation, and as consulting engineer in charge of the reorganization work at the Wilmer-Atkinson Company, Philadelphia.

Industry may be likened to an equilateral triangle, the speaker declared, one side being represented by thinking; the second, by feeling, and the third, by doing. In the past we have not known how to organize the feeling side of industry. In its first stage we had an unorganized, decentralized activity. We have now reached the second stage, where production is organized and centralized. And we are just getting into a third stage where particular functions are recognized and are being redistributed among individuals in a sensible way—in other words an organized, decentralized activity. Part of what he said is in substance as follows:

Authority must rest on knowledge of fitness—no longer on "dignity" of position. Don't keep hard and fast to any one group of standards. Keep re-analyzing and changing them as new personnel bring to the task greater or less powers. Open-mindedness to criticism is very essential. Every workman should be an inspector. Publicity is a great factor for promoting harmony.

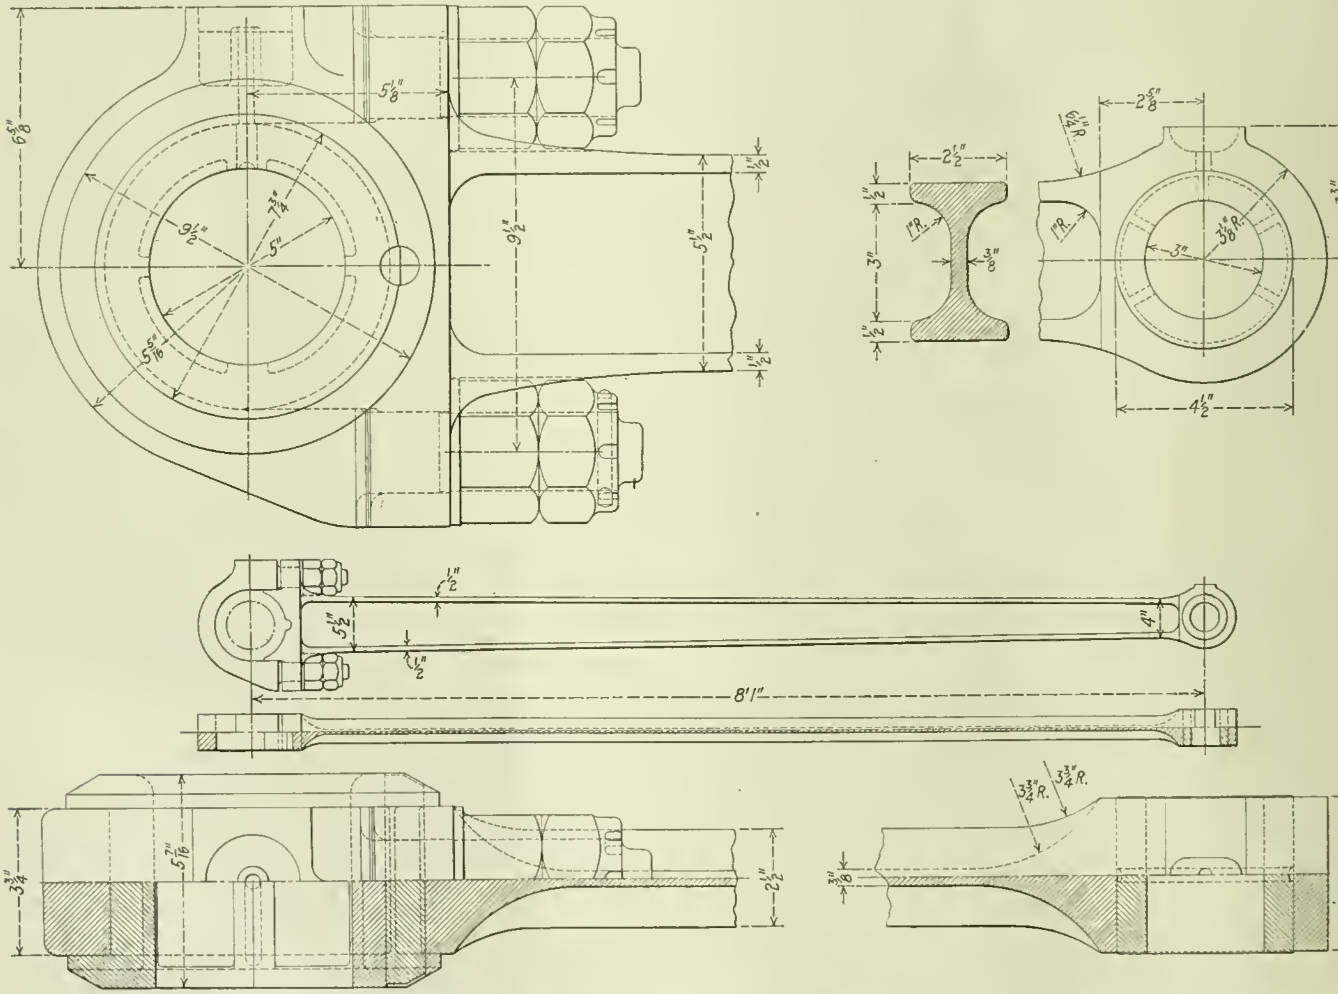
An Accomplishment in Light Reciprocating Locomotive Parts

While the possibilities of alloy steels as a means for reducing the weight of reciprocating parts of locomotives are well known in this country, it would seem that refinements actually accomplished abroad far surpass progress in this direction on American railroads. We are indebted to officers of the mechanical department of the Great Northern Railway of England for the accompanying drawing of the outside connecting rod designed for a new three-cylinder 2-6-0 type locomotive recently placed in service on that railroad.

The three cylinders used on the new locomotives are each 18½ in. in diameter with a 26-in. stroke as compared with two 20-in. by 26-in. cylinders on earlier 2-6-0 type locomotives. The rods for the old locomotives were of carbon steel and weighed 403 lb. each whereas the rods for the new locomotives are of nickel chrome steel and weigh only 295 lb. each. The dimensions and results of tests to which both rods were subjected are given in the following table together with the analysis of each.

	Carbon Steel Rod	Nickel-Chrome Steel Rod
Length	8 ft. 1 in.	8 ft. 1 in.
Weight	403 lb.	295 lb.
Yield limit (tons per sq. in.)	17.0	48.4
Breaking strength (tons per sq. in.)	33.6	58.0
Elongation	.84 in.	.40 in.
Diameter at point of fracture	.53 in.	.37 in.
Reduction of area	56 per cent	57.2 per cent
Ratio, yield limit to breaking limit	50.6 per cent	83.4 per cent
Analysis:		
Carbon	.28	.33
Silicon	.168	.21
Manganese	.686	.60
Sulphur	.033	.032
Phosphorus	.034	.039
Nickel	....	3.42
Chromium	....	.60

Particular attention was given in designing the rods to avoid sudden changes of section and especially sharp corners: the large radii used will be noticed. The strap ends were screwed with a round thread for the same reason. The rods were rough forged and then rough machined to within a quarter of an inch of the full size. They were then returned to the makers and heat treated and then machined to the finished size.



Light Weight Alloy Steel Main Rod Used on Three-Cylinder Locomotives of the Great Northern Railway of England

Principles to Govern Agreements Defined by Labor Board

Decision Terminating National Agreements on July 1 Instructs Officers and Employees to Draw Up New Rules

THE long controversy over the railway employees' demand for the perpetuation of national agreements was ended on April 14 by a decision handed down by the Railroad Labor Board which sustained some contentions of both the carriers and the employees. The award abrogated national agreements, remanded the negotiation of new agreements to the individual carriers and their own employees, and upheld the railroads' interpretation of the principle of collective bargaining and their contention that varying local conditions should govern the fixing of rules and working conditions. In these respects the decision was favorable to the railroads. The award also outlined sixteen principles with which the new agreements should be consistent. This constitutes one of the chief points for which the employees' representatives have been fighting. Accordingly both sides have expressed satisfaction with the terms of the decision.

The hearings prior to the decision, following the cross-examination of General Atterbury as described in the April issue, were uneventful. Voluminous exhibits were presented by W. Jett Lauck, consulting economist of the labor organization. The cross-examination of railroad executives was continued and Frank McManamy, formerly assistant director, mechanical department, division of operation of the Railroad Administration, was called to testify. Judge R. M. Barton, chairman of the board, was called to a conference at Washington with President Harding and Edgar E. Clark, chairman of the Interstate Commerce Commission.

Before the decision was announced, the Labor Board served notice that April 18 would be set as the date of hearing in the disputes between the railroads and the employees over wage scales.

S. Higgins W. L. McMenimen B. W. Hooper

Three New Members of the Labor Board

Text of the Board's Decision on National Agreements

After outlining the history of the controversy the decision said in part:

The evidence and arguments submitted in this case support the following conclusions:

The duty imposed by Section 301 on all carriers and their officers, employees and agents to consider and if possible to decide in conference all disputes between carriers and their employees has not been performed by the parties hereto either with regard to the wage or the working conditions portion of this dispute. The record shows that the representatives of the carriers were unwilling to assume the responsibility of agreeing to substantial wage increases. Hence, the conference of March 10 to April 1 on the side of the carriers was merely a perfunctory performance of the statute. Nor was the action of the organizations with regard to the individual carriers more than perfunctory. Naked presentation as irreducible demands of elaborate wage scales carrying substantial increases, or of voluminous forms of contract regulating working conditions, with instructions to sign on the dotted line, is not a performance of the obligation to decide disputes in conference if possible. The statute requires an honest effort by the parties to decide in conference. If they cannot decide all matters in dispute in conference, it is their duty to there decide all that is possible and refer only the portion impossible of decision to this Board.

Although Section 301 has not been complied with by the parties, the Board has jurisdiction of this dispute, as it is and has been one likely substantially to interrupt commerce.

The carriers parties hereto maintain that the direction of this Board in Decision No. 2, extending the national agreements, orders, etc., of the Railroad Administration as a *modus vivendi* should be terminated at once; and that the matter should be remanded to the individual carriers and their employees for negotiation and individual agreement.

The organizations maintain that the national agreements, orders, etc., with certain modifications desired by the employees should be held by this Board to constitute just and reasonable rules; and should be applied to all carriers parties to the dispute, except to the extent that any carrier may have entered into other agreements with its employees. They maintain that local conferences requiring necessarily the participation of thousands of railroad employees for several weeks would constitute an economic waste and would produce a multiplicity of controversies as well as irritation and disturbance. They also urge that to require local conferences would be to expose the local organizations on the several carriers to the entire power and weight of all the carriers acting through the Association of Railway Executives on the conferring carrier, that such a disparity of force would produce an inequitable result highly provocative of discontent and likely to result in traffic interruptions. They, accordingly, insist that the conference should be national.

The carriers maintain that rules negotiated by the employees and officers who must live under them are most satisfactory, that the participants in such negotiations know the intent of the rules agreed to and advise their fellow workmen and officers accordingly thereby avoiding a litigious attitude on both sides, that substantial differences exist as between the several carriers with relation to the demands of the service, necessary division of labor and other factors which differences should be reflected in the rules, that these local differences can be given proper consideration only by local conferences. The carriers refuse to confer nationally.

The Labor Board is of the opinion that there is merit in the contentions of each party and has endeavored to take action which will secure some of the advantages of both courses.

This Board is unable to find that all rules embodied in the national agreements, orders, etc., of the Railroad Administration constitute just and reasonable rules for all carriers parties to the dispute. It must, therefore, refuse the indefinite extension of the national agreements, orders, etc., on all such carriers as urged by the employees.

This Board also deems it inadvisable to terminate at once its direction of Decision No. 2 and to remand the dispute to the individual carriers and their employees. Such a course would leave many carriers and their employees without any rules regulating working conditions.

If the Labor Board should remand the dispute to the individual carriers and their employees and should keep the direction of Decision No. 2 in effect until agreements should be arrived at, it is possible that agreements might not be arrived at.

The Labor Board believes, nevertheless, that certain subject matters now regulated by rules of the national agreements, orders, etc., are local in nature and require consideration of local conditions. It also believes that other subject matters now so regulated are general in character and that substantial uniformity in rules regulating such subject matters is desirable.

The Board also believes that certain rules are unduly burdensome to the carriers and should in justice be modified. It may well be that other rules should be modified in the interest of employees.

To secure the performance of the obligation to confer on this dispute, imposed by law on officers and employees of carriers, to bring about the recognition in rules of difference between carriers where substantial, to preserve a degree of uniformity in rules regulating subject matters of a general nature, to prevent to some extent the operation in negotiations of a possible disparity of power as between the carriers and their employees, and to enable the representatives of employees of each carrier and the officers of that carrier to participate in the formulation of rules under which they must live, the Labor Board has determined upon the following action.

Decision

1. The direction of the Labor Board in Decision No. 2, extending the rules, working conditions and agreements in force under the authority of the United States Railroad Administration, will cease and terminate July 1, 1921.

2. The Labor Board calls upon the officers and system organizations of employees of each carrier parties hereto to designate and authorize representatives to confer and to decide so much of this dispute relating to rules and working conditions as it may be possible for them to decide. Such conferences shall begin at the earliest possible date. Such conferences will keep the Labor Board informed of final agreements and disagreements to the end that this Board may know prior to July 1, 1921, what portion of the dispute has been decided. The Labor Board reserves the right to terminate its direction of Decision No. 2 at an earlier date than July 1st with regard to any class of employees of any carrier if it shall have reason to believe that such class of employees is unduly delaying the progress of the negotiations. The Board also reserves the right to stay the termination of the said direction to a date beyond July 1, 1921, if it shall have reason to believe that any carrier is unduly delaying the progress of the negotiations. Rules agreed to by such conferences should be consistent with the principles set forth in Exhibit "B," hereto attached.

3. The Labor Board will promulgate such rules as it determines just and reasonable as soon after July 1, 1921, as is reasonably possible and will make them effective as of July 1, 1921, and applicable to those classes of employees of carriers parties hereto for whom rules have not been arrived at by agreement.

4. The hearings in this dispute will necessarily proceed in order that the Labor Board may be in position to decide with reasonable promptness rules which it may be necessary to promulgate under Section 3 above.

5. Agreements entered into since March 1, 1920, by any carrier and representatives of its employees shall not be affected by this decision.

Sixteen Principles to Govern in New Agreement

Exhibit "B," mentioned above, sets forth the principles believed by the Board to be just and reasonable in governing working conditions as follows:

1. An obligation rests upon management, upon each organization of employees and upon each employee to render honest, efficient and economical service to the carrier serving the public.

2. The spirit of co-operation between management and employees being essential to efficient operation, both parties will so conduct themselves as to promote this spirit.

3. Management having the responsibility for safe, efficient and economical operation, the rules will not be subversive of necessary discipline.

4. The right of railway employees to organize for lawful objects shall not be denied, interfered with or obstructed.

5. The right of such lawful organization to act toward lawful objects through representatives of its own choice, whether employees of a particular carrier or otherwise, shall be agreed to by management.

6. No discrimination shall be practiced by management as between members and non-members of organizations or as between members of different organizations, nor shall members of organizations discriminate against non-members or use other methods than lawful persuasion to secure their membership. Espionage by carriers on the legitimate activities of labor organizations or by labor organizations on the legitimate activities of carriers should not be practiced.

7. The right of employees to be consulted prior to a decision of management adversely affecting their wages or working conditions shall be agreed to by management. This right of participation shall be deemed adequately complied with, if and when, the representatives of a majority of the employees of each of the several classes directly affected shall have conferred with the management.

8. No employee should be disciplined without a fair hearing by a designated officer of the carrier. Suspension in proper cases pending a hearing, which shall be prompt, shall not be deemed a violation of this principle. At a reasonable time prior to the hearing he is entitled to be apprised of the precise charge against him. He shall have reasonable opportunity to secure the presence of necessary witnesses and shall have the right to be there represented by a counsel of his choosing. If the judgment shall be in his favor, he shall be compensated for the wage loss, if any, suffered by him.

9. Proper classification of employees and a reasonable definition of the work to be done by each class for which just and reasonable wages are to be paid is necessary, but shall not unduly impose uneconomical conditions upon the carriers.

10. Regularity of hours or days during which the employee is to serve or hold himself in readiness to serve is desirable.

11. The principle of seniority long applied to the railroad service is sound and should be adhered to. It should be so applied as not to cause undue impairment of the service.

12. The Board approves the principle of the eight hour day, but believes it should be limited to work requiring practically continuous application during eight hours. For eight hours' pay eight hours' work should be performed by all railroad employees except engine and train service employees, regulated by the Adamson Act who are paid generally on a mileage basis as well as on an hourly basis.

13. The health and safety of employees should be reasonably protected.

14. The carriers and the several crafts and classes of railroad employees have a substantial interest in the competency of apprentices or persons under training. Opportunity to learn any craft or occupation shall not be unduly restricted.

15. The majority of any craft or class of employees shall have the right to determine what organization shall represent members of such craft or class. Such organizations shall have the right to make an agreement which shall apply to all employees in such craft or class. No such agreement shall infringe, however, upon the right of employees not members of the organization representing the majority to present grievances either in person or by representatives of their own choice.

16. Employees called or required to report for work, and reporting but not used should be paid reasonable compensation therefor.

Following the announcement of the award, spokesmen for the labor organizations hailed it as a complete victory. At the same time E. T. Whiter, chairman of the committee representing the railroads before the Board, in commenting on the decision said in part:

> The decision reached has given opportunity for arrangements between individual railways and their employees which can be made much more reasonable than the rules and working conditions established by the national agreements, and which in a large measure can be adapted to the local conditions of each carrier. * * * The entire tenor of the Board's decision is

that the railways should be economically operated, that employees should render efficient labor for all the time for which they are paid, and that the artificial "pyramiding" of wages, which under the present rules has resulted in large waste, shall cease.

Wage Hearings Begin

In accordance with an order of the Board, the wage question was reopened on April 18 when hearings were started to determine what constitutes a just and reasonable wage under present conditions for various classes of employees. At the time the Board's announcement was made, disputes between 26 railroads and their employees had been certified. When the hearings began the Board had docketed 92 disputes. These were consolidated into one case although each carrier was granted the right to make a separate presentation.

The fact that the three new members of the Board were not present at the beginning of these hearings led to vigorous but ineffective protests against the opening of the case on the part of representatives of the employees. The Board did, however, grant a time concession in allowing the carriers and unions, instead of one day each for the presentation of their cases, as it had announced, five days each for this purpose. The Board also ruled that there would be a week's intermission between the carriers' presentation and that of the unions and that an additional week would be allowed for rebuttal.

The railroad's arguments for wage reductions were opened by J. G. Walber, speaking on behalf of the eastern carriers and taking up those arguments which are common to all of the roads in that territory.

Photo by International

From Left to Right: F. P. Walsh, B. M. Jewell and W. Jett Lauck

He presented a memorandum and statistical exhibits showing the reductions in wages in other industries and in the cost of living which have occurred since the present railway wage scales were fixed by the Board in July, 1920.

Mr. Walber showed by bulletins issued by the Bureau of Labor Statistics of the United States Department of Labor dealing with wage rates in a dozen important branches of industry, that very substantial reductions of pay were made in these industries in the period from January to March, 1921. The statistics cited, Mr. Walber pointed out, "indicate a general and widespread reduction in wages from 10 to 30 per cent—the majority of reductions are 15 per cent or over."

Mr. Walber also submitted statistics regarding the reductions in the cost of living, based upon compilations made by various commercial agencies and also by the Bureau of Labor Statistics and the National Industrial Conference Board.

"The latest figures available from the Department of Labor," he said, "are for the period ending December, 1920, while the National Industrial Conference Board has compiled its figures to March, 1921. By reference to the declines from the peak (July, 1920, when the present wages were fixed) to December, 1920, as shown by these tables, it will be observed that the Department of Labor Statistics indicate a decline in the cost of living of 7.4 per cent, and the figures of the National Industrial Conference Board a decline of 7.1 per cent. The decline to March, 1921, according to figures of the National Industrial Conference Board, is 17 per cent, and if the Department of Labor figures for March, 1921, were available it is reasonable to assume that the similarity in the results obtained by both organizations would have continued."

In substance, the exhibits filed by Mr. Walber showed that when the present railway wages were fixed in July, 1920, the cost of living was 104.50 per cent more than it was in 1914, while in March, 1921, it was only about 67 per cent more than in 1914, and is still declining. These exhibits also indicated that the average railway wage per annum is now about 133 per cent more than it was in 1914.

Individual Carriers Present Their Cases

Following the presentation of these two general statements, the individual carriers began the submission of volumes of statistical analysis, charts and data relating largely to decreases in the cost of living and the wages being paid by outside industries for both skilled and unskilled labor at various points and comparisons between this data and respectively the increases which have taken place in the wages of railway employees and the present scale of railroad wages.

One of the first large roads to present its case was the Pennsylvania whose statement and brief to the Board said in part:

We desire to call particular attention to the studies made of wages paid in outside industries marked Exhibit No. 8 which is the result of a study of 1,235 plants and covers over 155,000 employees, or approximately three times as many employees as in these trades on the Pennsylvania. This exhibit clearly shows that the preponderating rates paid in outside industries are generally below those proposed in the carriers' submission and, in addition, it is shown that there have been further reductions since the information was first obtained.

The exhibit referred to in the preceding paragraph shows that in comparison with the prevailing rate of 85 cents an hour now being paid by the Pennsylvania to shop employees and 62 cents an hour to helpers, the weighted average rates of pay in 1,235 outside industries for similar work are as follows:

Number of men	Occupation	Weighted average rate per hour
51,586	Machinists	64.7 cents
4,536	Blacksmiths	66.1 cents
10.271	Boilermakers	64.3 cents

New Members of the Labor Board

President Harding on April 16 sent to the Senate his nominations for three appointments on the Railroad Labor Board to succeed the three members whose terms expired on April 15. The new appointees are Ben W. Hooper, former governor of Tennessee, as a member of the public group succeeding Henry T. Hunt; Samuel Higgins, former general manager of the New York, New Haven & Hartford, and more recently vice-president of the Vapor Car Heating Company, to succeed W. L. Park of the railroad group, and W. L. McMenimen, deputy president of the Brotherhood of Railroad Trainmen, to succeed J. J. Forrester of the labor group.

A Freight Train moving before daylight! Just think of it! A press dispatch from Winnipeg reports Canadian wheat and flour, sold to American dealers, as being "rushed across the border" to avoid the heavy duty that would be imposed should the Fordney tariff bill become law. "A special Canadian National train crossed the line before daylight today, carrying scattered shipments."

The Advantages of the Exhaust Steam Injector

A Considerable Saving in Fuel Is Effected by This Device, Which Is Extensively Used in Foreign Countries

BY CLARENCE ROBERTS

THE exhaust steam injector is used for boiler feeding on a great many locomotives in England and the British colonies, and to some extent in France. In England and the British colonies there are about 4,000 in use, and it is claimed in England the device effects an average saving in fuel consumption of 10 per cent.

The writer has ridden on English and French locomotives running on railroads in France equipped with exhaust steam injectors, and it was observed they were operated with the same facility as the live steam injector, evidently giving no more trouble than the latter. The engine crews seemed to like and take an interest in them, operating them on all occasions practicable in preference to live steam injectors, a fact that argues well for it. Operating officials spoke favorably of this type of injector and said that their operation was quite as simple as the live steam injector and maintenance costs were little or no greater. A motive power official of the Northern Railway (France) said his road a few years ago built some very heavy 4-6-4 type suburban locomotives which were over-cylindered and consequently bad steamers. They were afterward equipped with exhaust steam injectors which so improved their steaming performance that they made too much steam even after enlarging the exhaust nozzle openings.

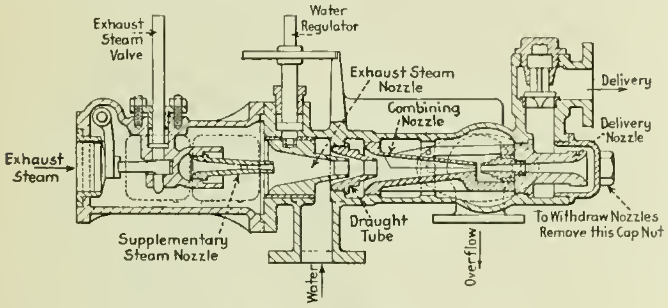

Fig. 1—Exhaust Injector and Valve

The exhaust steam injector was invented in England about the year 1876 and the early types when working with steam at atmospheric pressure were capable of feeding against boiler pressures up to 70 lb. per square inch. Since its invention it has been improved so that now it is as reliable as the modern live steam injector for locomotive boiler feeding. The latest types present several new and important features and represent a very great advance over all previous types. They restart automatically and when working with exhaust steam at atmospheric pressure are capable of delivering against a pressure of 120 lb. per square inch. With the addition of a small supplementary live steam jet the exhaust injector can feed against pressures up to 300 lb. per square inch. An auxiliary steam nozzle is provided for use when the locomotive is not using steam.

Principle of Operation

Few persons in this country have ever heard of the exhaust steam injector. To those who have read of it, it seems more or less of a mystery and contrary to all accepted principles that exhaust steam at atmospheric pressure should be able to force about ten times its own weight of water into a boiler under pressure. This seeming paradox, however, is easily explained when the action of the exhaust steam on the water is considered, for the same principles are involved as with the live steam injector, that is, a jet of steam moving at high velocity is condensed by a body of water moving at a low velocity; the momentum of the steam jet being transferred to the water, producing a combined jet moving with a resultant velocity sufficient to overcome the boiler pressure. While exhaust steam at atmospheric pressure has no velocity relative to the atmosphere, yet if it is allowed to issue into a vacuum, it has a very high velocity; the velocity of exhaust steam at atmospheric pressure flowing into a perfect vacuum is more than 2,000 ft. per second.

It is well known that when steam is condensed a vacuum is created, the degree of which is dependent upon the temperature of the water of condensation. In the exhaust steam injector a very high degree of vacuum is obtained by the condensation of the exhaust steam by the feed water in the combining nozzle of the injector. The highest vacuum is at the point of the steam nozzle where the steam and water meet. A vacuum of 24 to 26 in. of mercury is obtained, so that the exhaust steam flows in at an exceedingly high velocity. It there meets the feed water, and being condensed by it, gives up its momentum to the combined jet, which then flows along the combining nozzle where complete condensation takes place. The jet leaves the end of the combining nozzle at a velocity which is sufficiently high to carry it forward through the delivery nozzle and into the boiler. It will thus be seen the working of the injector is not dependent on steam being supplied under pressure as is so often supposed, the sole determining factor being the steam velocity.

A sectional view of the double jet type injector is shown in Fig. 1. This comprises a casing containing the various nozzles and also branches for the delivery, overflow and water pipes. The nozzles consist of the exhaust steam nozzle, draft tube, combining or flap nozzle and delivery nozzle, while in the exhaust valve casing is fixed the supplementary steam nozzle which projects into the exhaust steam nozzle. The exhaust steam entering the injector passes into the main central exhaust steam nozzle, at the mouth of which it meets the feed water. Condensation immediately takes place, a very high degree of vacuum being formed, and the combined jet flows forward at a high velocity through the draft tube into the combining nozzle. The region of high vacuum extends to the entrance of the combining nozzle, and at this point a second supply of exhaust steam is admitted, which, flowing

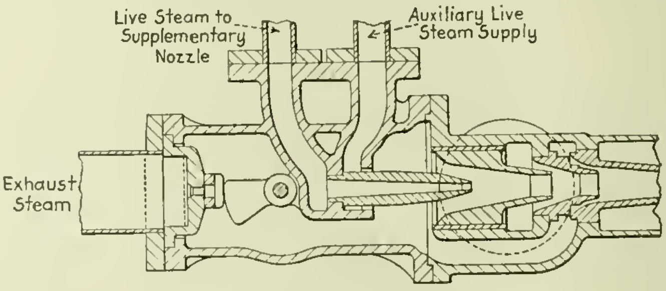

Fig. 2—Automatic Exhaust Valve

in at a very high velocity, impinges on and is condensed by the combined jet, imparting to it a further supply of energy, so increasing its velocity. After passing through the combining nozzle, the jet enters the delivery nozzle, where its velocity is reduced, the kinetic energy being changed into pressure energy, and leaving the injector, the water passes into the boiler. This type differs from the live steam injector in having a steam inlet nozzle of a much larger cross sectional area than that of a live steam injector of similar capacity, this being necessary to provide for the large volume of exhaust steam which must be passed.

An enlarged sectional view of the automatic exhaust valve is shown in Fig. 2. This governs the supply of exhaust steam to the injector, acts as a check valve when operating the injector with auxiliary steam when the engine is standing or running with steam shut off, and enables it to start automatically if the jet is in any way broken. As before stated, the exhaust steam alone develops a pressure of 120 lb. and for higher pressures a small jet of live steam is introduced through the supplementary nozzle. The steam supply for this nozzle is obtained through the passage of the exhaust valve casing shown in Fig. 2, from a pipe connected to a supplementary steam valve on the boiler. The small jet of steam introduced through this nozzle gives the additional pressure required to feed the boiler. Water regulation is effected by varying the area for the entrance of water into the nozzles, by moving the exhaust steam nozzle to and fro, so that the surrounding area between the end of the exhaust nozzle and the draft tube is varied, and consequently the quantity of water entering is regulated according to the amount required. When necessary to work the injector as a live steam injector (when the locomotive is not using steam), a supply of live steam is introduced into the automatic exhaust valve casing through the auxiliary steam branch, entering the injector at the annular nozzle surrounding the supplementary nozzle. This supply flows into the exhaust steam nozzles, replacing the exhaust steam, and the injector works exactly as when exhaust steam is used, being as reliable and simple an instrument as any live steam injector, and equally prompt in starting and certain in action.

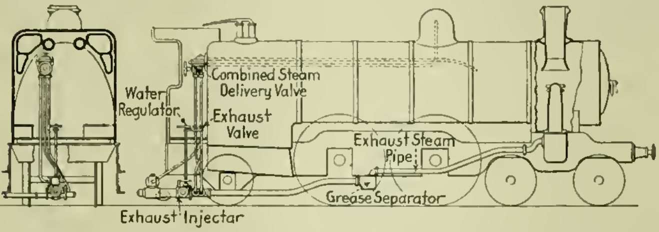

Fig. 3—Arrangement of the Exhaust Injector on the Locomotive

The exhaust steam injector is capable of delivering against pressures as shown on the following table:

Exhaust Steam Pressure Lb. per square inch	Delivery Pressure Lb. per square inch
1	120
5	150
10	180
15	210
Atmospheric pressure augmented by small jet of live steam from supplementary nozzle	300

In Fig. 3 is shown the method of applying this apparatus on a British type of locomotive. This is diagrammatic only and can be modified to meet the requirements of design of any type of locomotive. A grease trap is necessary in the exhaust pipe. The size of injector known as No. 13, having a 4½ in. exhaust pipe and 2¼ in. delivery pipe, has a capacity of 3,800 gallons of water per hour using exhaust steam in connection with the supplementary jet.

In their efforts to increase the operating capacity and efficiency of the steam locomotive in America railroad men seem to have overlooked or not realized the importance of the exhaust steam injector as a heat saving appliance, for it should not only prove decidedly more efficient than the live steam injector, but everything considered should be comparable with the feed water heater in point of economy.

For boiler feeding the injector has practically one hundred per cent thermal efficiency and its first cost and cost of maintenance is less than a boiler feed pump, though the live steam injector is not the most economical means for feeding a boiler if waste or exhaust steam is available and can be utilized for heating the feed water, but we must not lose sight of the fact that in feed water heating economy comes only from utilizing heat that is now going to waste for it cannot be considered a saving to utilize the exhaust steam from an appliance that replaces the injector for boiler feeding.

The advantages that should be derived from the use of the exhaust steam injector may be briefly stated as follows:

(a) Low first cost and low maintenance costs.
(b) Low rate of depreciation.
(c) Simplicity of design and ease of operation.
(d) The utilizing of exhaust steam for feed water heating which results in saving both water and steam and consequently fuel.
(e) Reduction in back pressure in the locomotive cylinders.

There should be a field for the exhaust steam injector in America. In England an average fuel saving of 10 per cent is claimed for the exhaust steam injector, and with our relatively higher back pressures we should obtain even a greater saving, so that the net saving in money probably would be as great or possibly greater than with feed waterheaters for which a 15 per cent saving is claimed.

The Rusting of Steel Containing Copper

It is generally believed that iron containing copper in amounts of small fractions of one per cent is less liable to rust than iron free from copper. To investigate this problem, comprehensive tests extending over six years were started in 1913 by Professor Bauer for German iron works. These works sent Thomas and Siemens and other steel in large sheets to be tested both with the scale on and after the scale had been removed. The steel contained about 0.1 per cent carbon, 0.5 per cent manganese and phosphorus and sulphur up to 0.09 per cent, nickel up to 0.2 per cent and chromium 0.04 per cent maximum. Copper was added in percentages up to 0.35. The weighed sheets were exposed to various atmospheres and liquids and the rust was removed and weighed.

The specimens were exposed for over four years in good country air, but the influence of the copper content on the rapidity of rusting was not noticeable. In the salt spray near the ocean, the rusting was more marked, but again the copper made no difference. In the impure air of an iron district, however, the effective influence of the copper was perceptible. In all cases the nickel in the steel also seemed to prevent rusting. Sheets were buried in slag sand and the corrosion of the steel indicated that the influence of the copper was to protect the Siemens steel and to hasten the corrosion of the other steel.

Summing up the tests, it would appear that in the presence of relatively high percentages of carbon dioxide and of sulphur dioxide, a slight percentage of copper and of nickel as well, seemed to retard the rusting of steel.

Electrolytic tests were conducted with a specimen suspended in dilute sulphuric acid and it was found the steel suffered less corrosion under these circumstances when a small percentage of copper was present than in the absence of copper. This was particularly marked in the case of steel relatively high in phosphorus. The copper seemed to counteract the evil effects of the phosphorus. Even in these tests the anti-corrosive effect of the copper on the steel was not strong, however.

The Cost of Boiler Scale

BY W. F. SCHAPHORST

No one disputes the statement that scale is a bad thing, that it has caused and is causing serious losses. The actual money loss due to a definite thickness of scale is a variable quantity, for much depends upon the kind of scale, whether carbonate or sulphate, hard or soft, etc.

The most commonly used rule for determining the money loss is that given in Sames' Mechanical Engineering Handbook as follows: "Scale of 1/16 in. thickness will reduce boiler efficiency ⅛; and the reduction of efficiency increases as the square of the thickness of scale."

The chart shown herewith is based upon the above rule.

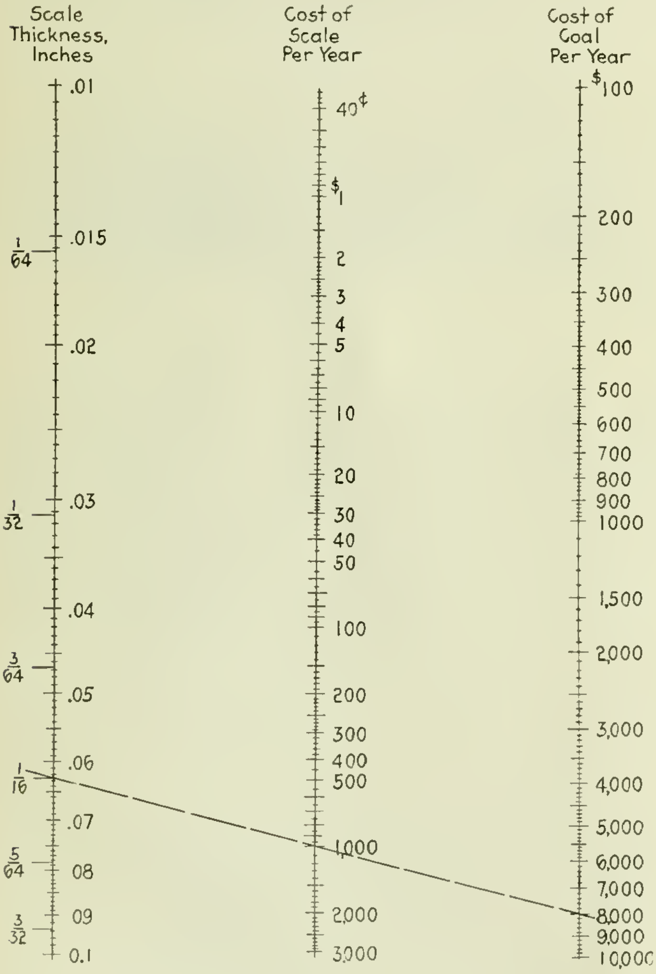

Chart for Determining Loss Due to Scale

It covers all scale thicknesses from .01 in. to 0.1 in. and for convenience shows thicknesses in fractions as well as in decimals of an inch. The dotted line indicates that where $8,000 is spent per year for coal, $1,000 per year is lost due to a scale 1/16 in. thick.

Whatever the thickness of scale and whatever the coal costs per year (up to $10,000), this chart shows the money loss in strict accordance with the given rule. It may help to indicate where the installation of a water treating device would save money or it may show how often boilers should be thoroughly cleaned.

Comparison of Steam and Electric Locomotives

At a meeting of the Franklin Institute held at Philadelphia on April 14 two papers were read on steam and electric motive power. The characteristics of the electric locomotives were discussed by N. W. Storer, general engineer of the Westinghouse Electric & Manufacturing Company, while the characteristics of the steam locomotive were treated by A. W. Gibbs, chief mechanical engineer of the Pennsylvania System.

Mr. Storer stated that he considered it probable that there would gradually be a radical evolution of operating methods in order to utilize the electric locomotive most effectively and discussed some of the factors to be considered in this connection. An important advantage would result from making the speed of passenger and freight trains more nearly uniform, as could be done advantageously with electric motive power. On account of its greater reliability the electric locomotive would not impose the same limitations on the length of operating division as the steam locomotive and greater mileage could be obtained from the individual units. Under certain conditions the use of aerial right over track was of great importance. Electrification opens up possibilities in the use of multiple level stations to increase station capacity and improves the operation of stub-end stations by decreasing the number of switching movements. In concluding, Mr. Storer discussed at some length the relative advantages of various types of motors and compared the speed-pull curves with those of typical steam locomotives.

Mr. Gibbs confined his remarks to the mechanical problem of transmitting power from the motors to the wheels and the behavior of locomotives as vehicles. He stated that while the transmission of power in electric locomotives seems simple it really is very difficult and while the electrical features of the motive power were often satisfactory, the mechanical features were troublesome. After discussing briefly the various types of transmission, Mr. Gibbs outlined some of the difficulties encountered in designing locomotives for high speed. In developing the design of Pennsylvania electric passenger locomotives, tests were conducted to determine the riding qualities of electric engines with various wheel arrangements. A section of track was prepared especially for measuring the stresses, a record being obtained by the impression of a steel ball on a steel plate inserted in special ties. The tests showed that a high center of gravity was advantageous and that symmetrical driving wheel arrangements were unstable. Some of the electric engines proved very destructive to the track and as a result of these tests, a design of locomotive with wheel arrangements corresponding to two eight-wheel engines facing in opposite directions and with motors above the wheels was adopted. In conclusion, Mr. Gibbs stated that there was still much to learn with regard to the behavior of electric locomotives as vehicles and further tests should be made to determine the most satisfactory types.

Production of soft coal in the week ended April 16 was marked by a slight but distinct recovery, says the weekly bulletin of the Geological survey. The output is estimated at 6,525,000 net tons, an increase of 416,000 tons over the week preceding and the largest since the second week of March. For several months the output of the mines has been very low.

Since the Period immediately preceding the war, the number of freight cars on the Italian railways increased from 90,000 to 120,000, while the number of locomotives in the same period fell from 4,400 to 4,200. This diminution accompanied an increase in the length of line operated amounting to 900 miles. Locomotives have not yet recovered from the hard usage undergone in meeting war demands. Proper repairs and the building of new locomotives were slighted during hostilities, and since the cessation of hostilities various dislocations and labor conditions have interfered with construction work in this line.—*Commerce Reports.*

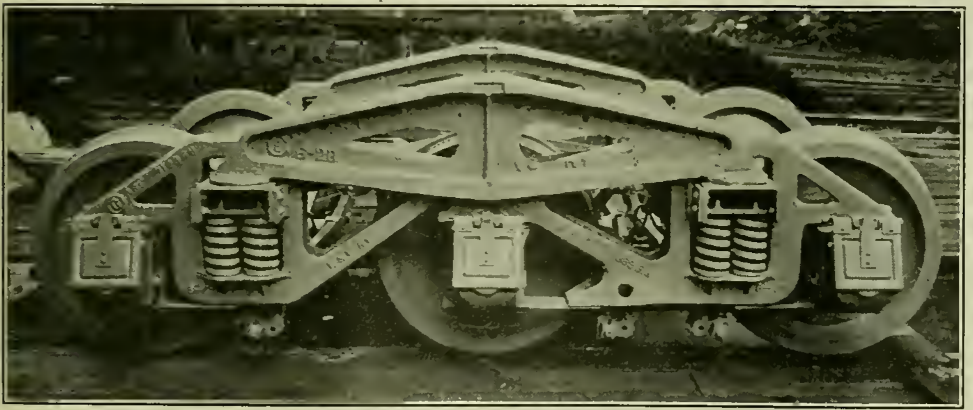
New Norfolk & Western 100-Ton Coal Cars

Body Supported on Side Bearings Instead of Center Plate—New Type Six-Wheel Truck

BY JOHN A. PILCHER

Mechanical Engineer, Norfolk & Western

THE lightest car for its load carrying capacity ever built for heavy train service is illustrated in the accompanying drawings and photographs. An order of 500 of these cars is now nearing completion at the Roanoke shops of the Norfolk & Western, under the supervision of A. Kearney, superintendent of motive power. The advantages of a car of such light weight can be judged from an estimate of the cost of operation prepared in connection with this design. It has been computed that if all these cars could be kept running at the same rate that the first one operated for the first three months, (about 90 miles per day), the additional earnings over those of the previous large capacity cars built by the Norfolk & Western, would pay for them in five years. This accomplishment is due in part to the light weight of the trucks and body and in part to the larger cubic capacity.



Side View of the New Type Truck, Which Carries the Load on the Side Bearings

The special feature of the design is the truck which carries the load on the side bearings instead of on the center plate. This arrangement not only gives perfect equalization of loads between the wheels at all times, but reduces the oscillation of the car to a minimum and contributes very materially to the lightness of both body and trucks. The average weight of car and lading is very near 253,500 lb.; the A.R.A. limit for a six-wheel car with 5½ in. by 10 in. journals. The general dimensions and weights of the car are shown in the tabulation. The equipment applied to this order includes wrought steel wheels, Miner friction draft gear, type A-18-S, with Farlow single key horizontal yoke draft attachments. Four hundred of the cars are equipped with Westinghouse K-2 triple valves and 100 with the Automatic Straight Air brake. The brake rigging has one brake beam per axle. The hand brake, arranged with a quick take-up, is geared to give braking power equivalent to the air brake.

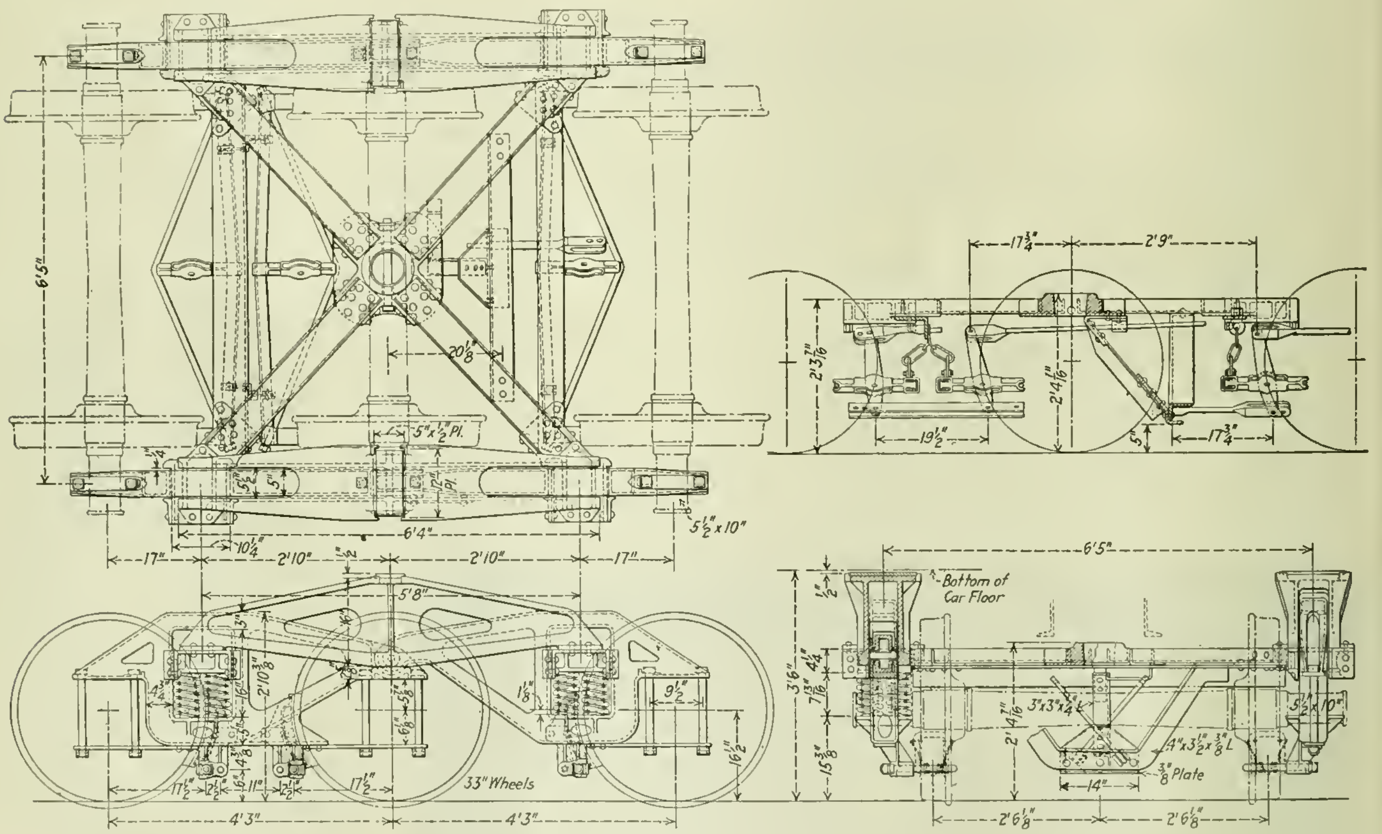
The truck is of the three-axle, articulated type, mainly of cast steel, with two side frames on each side, secured together over the center boxes. The boxes used are the regular A.R.A. standard, although the design lends itself readily to the use of the semi-pedestal type of box, now in very general use. It is the lightest six-wheel truck of this capacity ever built. The pair of trucks weighs 24,480 lb.

The springs are so located in the frames as to give equal load distribution on the wheels when equal loads are applied to each group of springs.

Beams made to straddle the frames reach from one group of springs to the other, on each side of the truck, and support the weight of the car at their centers. This gives an equal load on each group of springs. The beams rest upon, and are secured to spring caps tying them together lengthwise of the truck, and are themselves side members of a rectangular, cross-braced centering spider, which serves to hold the two sides of the truck together and in proper relationship. The truck is thus held square. The cross bracing holds the guide for the centering pin on the car body. The keepers, riveted to the outside of the spring caps, and the projecting lugs cast on them, coming inside the side frames, are the guides to hold the frames together and apart. The carrying beams, straddling the frames, are riveted to the top of the spring caps and serve in a like capacity.

Principal Dimensions and Weights of Norfolk & Western 100-Ton Coal Car

Length over striking plates	43 ft. 9 in.
Coupled length	46 ft. 2 in.
Truck centers	31 ft. 8 in.
Truck wheel base	8 ft. 6 in.
Height from rail to top of car side	11 ft. 0 in.
Height of center of gravity (loaded with 200,000 lb.)	81 in.
Inside length	42 ft. 7 in.
Inside width	9 ft. 6 in.
Outside width	10 ft. 1¼ in.
Cubical capacity—level full	3,122.5 cu. ft.
Cubical capacity—30 deg. heap	513.5 cu. ft.
Cubical capacity—including heap	3,636 cu. ft.
Revenue load	200,000 lb.
Weight of car body	29,020 lb.
Weight of two trucks	24,480 lb.
Weight of empty car	53,500 lb.
Total weight, loaded with 200,000 lb	253,500 lb.
Per cent revenue load of total weight	78.88 per cent.
Weight per foot coupled length	5,491 lb.
Weight of one truck	12,240 lb.
Rail load per pair of wheels	42,250 lb.
Density of load of 200,000 lb	55 lb. per cu. ft.



General Arrangement of the Six-Wheel Truck

The design, which is light in weight, readily gives the strength to resist forces in any horizontal direction. One of the cross-tie members is made of an angle to give it stiffness and permit the attachment of the dead end of one of the brake levers. A cable guard, to protect the brake beams from the cable used in hauling the cars up to the dumper, is attached to the under side of the diagonal braces, and is itself braced back to the center, so that it can serve as a fulcrum for the dead end of one of the brake levers.

The brake is arranged, one beam per axle, using No. 2 beams. The pull from the cylinder rods comes to two of the brake levers set on opposite sides of the truck, eliminating any turning movement on the truck. The separation of the brake lever system on the truck into two parts gives independent adjustment for brake shoe and wheel wear, and prevents accumulating lever angularity. All of the adjusting points are readily accessible. The truck is open and can be easily inspected from alongside the car. Since there is a possibility of low or soft spots in the track, the four points on the truck sides, upon which the four groups of springs rest, cannot always be kept in the same plane. The structure resting on the springs must, therefore, be either vertically strong enough to resist the differences in reaction at the four corners, produced by the differences in spring tension, in case any one of the spring seats leaves the normal plane, or it must be vertically flexible enough for any corner to follow the spring seat out of the normal plane, without having set up within it destructive stresses.

This rectangular cross-braced centering spider has been designed to meet these conditions. It was carefully proof tested in the following manner:

It was rigidly fastened to a stiff frame at the three corners, *A*, *B* and *C*, shown in the diagram of the spider, while the fourth corner, *D*, was attached to the plunger of a rail gaging machine having a stroke of 1½ in. This allowed the alternate lowering and raising of this corner below and above the normal plane. A counter on the machine recorded the number of movements up and down—each number on the counter representing a stroke up and a stroke down. A Berry Strain Gage, with points eight inches apart, was placed at the points on the diagram numbered 1, 2, 3, 4 and 5. Readings were recorded at corresponding points on the diagonals leading to the four corners at about the time the counter showed 2,212, and again when it showed 81,868. After this a change was made and the plunger of the gaging machine was attached to the corner marked *A*, the corners marked *B*, *C* and *D* being held rigidly in a plane. The counting was begun over. The readings of the Berry Strain Gage were taken on each diagonal when the counter registered about 6,155, and again when it indicated 99,138. It is to be noted from the table that differences in reading before and after the large number of movements is insignificant, showing no sign of deterioration. The highest unit strain in inches recorded is .00046, which, when using 27,000,000 as the modulus of elasticity, represents a fiber stress of 12,240 lb. per sq. in. Measurements were made to determine the forces applied at one corner to produce the movements ¾ in. above and ¾ in. below the plane of the other three corners of the centering spider. At the bottom of the table are given the results, which show that only a relatively small differential in loading at the corners will overcome the vertical stiffness of the centering spider.

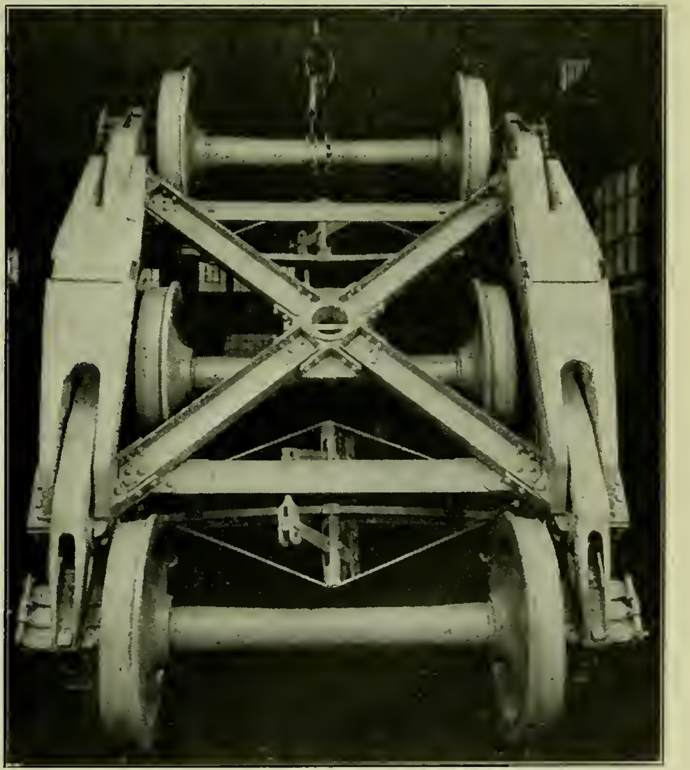
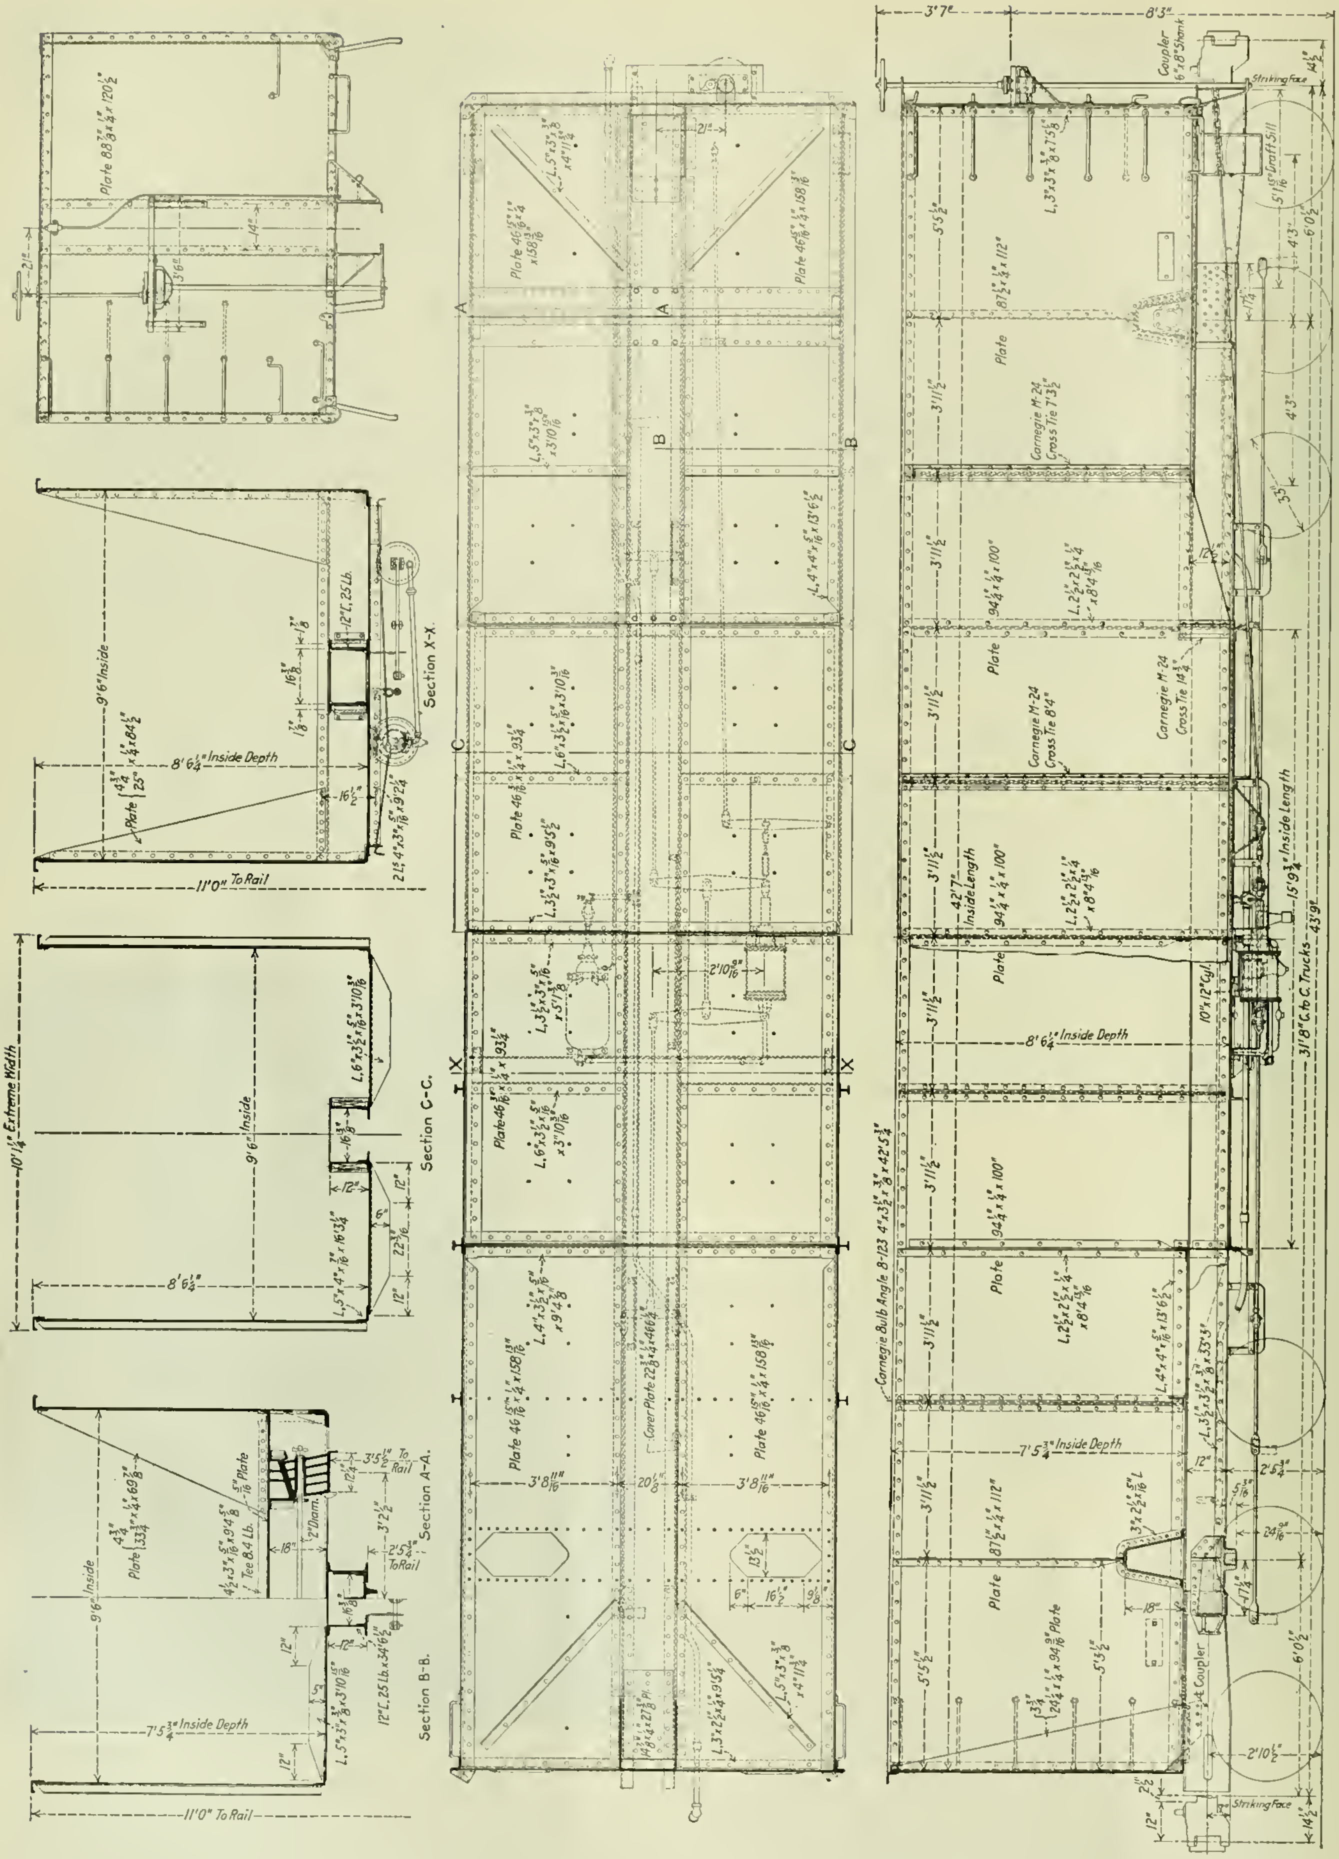
Diagram of Test of Flexibility of Truck Bolster

The Car Body

The use of the side bearings, placed over the center of the truck side frames for load carrying, obviates the necessity for the strong, heavy bolster members from side to side of truck, supporting the load at its center. This not only decreases

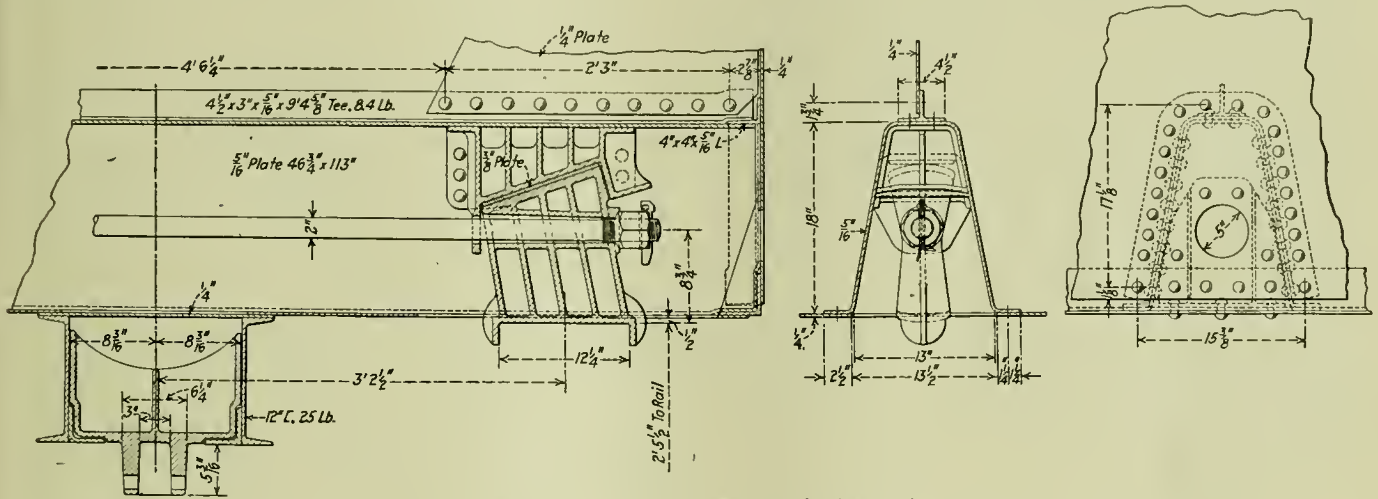


A View of the Truck from Above, Showing the Centering Spider and Beams Spanning the Side Frames



Plain, Side and End Elevations and Sections of the Car Body the weight of the truck, but also decreases the weight of the the body bolster show the location and details of the load-carry the load from the car side all the way to the center, but only for the very much shorter distance to the points over the truck side frames.

The general drawing of the car and the arrangement of the body bolster show the location and details of the load-carrying conical rollers. Only enough of the middle section of the conical roller is used to provide sufficient lateral movement at the roller for the car to negotiate a 35-degree curve. The bottom of the roller is limited in its lateral movement by the sides of the opening in the bottom of the car, through which the roller projects. The body bolster is made hollow to allow room for the roller. The bottom face of the roller is set in a horizontal plane, normal to lines of load forces, in order that there may be no horizontal components tending to displace the load-carrying side beams on the truck. The projections on the bottom side of the roller at each end serve as guides for proper placing. Normally, these projections should not come into action for holding the bottom of the roller in place on the truck side beam, as there are no normal forces tending to displace it. The upper sides of the conical rollers incline toward the center. The lateral component of reaction against the inclined surface on the roller seat is taken up by compression in the body bolster and tension in the rod tying the two opposite rollers together. In case anything should happen to this rod, these reactions will all be within the roller seat itself. The outside end of the roller seat is made of sufficient strength to take care of these forces if the occasion arises.



Arrangement of Body Bolster and Conical Roller

The tie rod passing through a slotted hole in the inside projecting lug on the seat serves to hold the rollers in place in case the car is jacked off the trucks. The roller is guided, on its top side, by the pocket in the seat. It is cast of high carbon steel, and bears against hardened-steel plates, top and bottom. It is made long and of large diameter, reducing to a minimum the probability of flattening the contact surfaces during any reasonable period of service.

The use of conical rollers of large size makes this approximately an anti-friction bearing, and reduces to a minimum the forces needed to rotate the truck under the car. Any slight flattening of the contact surfaces that might occur after a long period of service would only very slightly increase the forces needed for the turning. Even if after years of service the surfaces should flatten to an objectionable extent, the renewal of rollers and seats is a simple and comparatively inexpensive operation.

The roller seat at its top side conforms to the shape of the inside of the bolster plates and distributes the load over a large portion of the surface, requiring very little riveting to hold it. The holes in the sides of the car are used for entering and securing the tie rod connecting the rollers. They are reinforced on the inside of the side plates with bracket castings and furnish a place for a special hook provided with the wrecking outfits, for lifting the car body in any emergency. Some such arrangement is necessary since the use of ordinary hooks indiscriminately at any point on the loaded car would give such heavy concentration of loading as to tear and mutilate the car body.

A tee is used to increase the section of the top flange of the bolster girder, and its top extending web serves for the attachment of the bolster gusset plate. This gusset plate connection with the side of the car, together with the beaded angle at each end of the bolster, connecting the bolster web plates with the car side, transfers the load coming from the car side through the body bolster to the roller seat, without undue concentration at any point. The car body bolster is placed above the car floor line so as to give room under the car for the supporting beam on the truck over the center box and truck side frames. This allows reasonable depth and economy in the design of the beam.

On a hopper car the hollow bent plate bolster can be placed in the same relative position to the truck without being placed above the inclined floor of the car. The centering casting on the car body is integral with the draft gear back stop. The holes receiving the pin fastening together the body and truck center castings, are slotted in order to allow the necessary angular movement between truck and car. There is no normal vertical movement between these two parts.

The center portion of the car, between trucks, has the bottom placed on a line with the bottom of the center sills, thus gaining additional cubic capacity, and slightly lowering the center of gravity.

The cross diaphragms in the car framing become the ends of the depressed bottom. On the outside of the car, short pieces of tie section, the same as the side stakes, are placed so as to come opposite the cross diaphragms and bear against the car dumper blocking, supporting the car at a strong point of reaction. The side stakes and top coping angles serve the same purpose.

The vertical corner angles connecting the side plates of the car with the end plates have the flanges, attached to the end plates, turned out, so that the projecting edge of this flange, together with the edge of the plate riveted to it, will bear against the dumper blocking, thereby helping support the weight of the car and lading and protecting the grab irons from injury. Both the corner push-pole pocket and reinforcing bracket casting, under the center of the body bolsters, furnish placed for jacking and stooling the car.

The general details of construction can be understood from the drawings.

(This article will be concluded in the June issue.)

Annual Report of the Bureau of Explosives

Much interesting data on the handling of hazardous commodities is contained in the annual report of the chief inspector of the Bureau for the Safe Transportation of Explosives and Other Dangerous Articles for the year 1920, which has just been issued. To one unfamiliar with transportation conditions, it would naturally seem that the shipments that would cause the greatest damage would be those containing high explosives. It is interesting to note that the loss per ton for nitric acid and "strike anywhere" matches is considerably greater than for either high explosives or black powder. The greatest losses from any single commodity are those resulting from the transportation of gasoline, due principally to the large volume of the shipments.

The actual total loss for the year 1920 amounted to $1,090,806 for all kinds of dangerous articles. This is a decrease of over half a million dollars compared with the previous year. Nevertheless, the report states that the majority of the 1,977 accidents resulting in this loss should not have happened, as they were due to carelessness or ignorance.

Particular interest attaches to the statistics regarding transportation of gasoline, as the losses due to these shipments are greater than from any other single commodity. The total loss from this cause has been decreasing in recent years. In 1918 it was $900,106; in 1919, $691,635, and in 1920, $351,262. During the past year, special attention has been given to the bottom discharge valve in tank cars, as this has been a prolific source of loss. A summary of accidents chargeable to this part of the tank car shows little or no improvement in the last two years.

A comparison that has not been made in previous reports is shown in a summary of reported losses compared with the total production for several important commodities. The statistics for 1920, which are typical, show that the loss per ton was as follows:

Nitric acid	$1.71
Matches	.51 2/10
Black powder	.19 9/10
Charcoal	.08 7/10
Gasoline	.02
High explosives	.00

In discussing the importance of education, the chief inspector mentioned the good results secured by the organization plan prepared by the bureau for the purpose of interesting and educating railway employees in the regulation, which has been adopted quite generally by the railroads.

The glass carboys in which acids are shipped are not sturdy containers and many accidents are caused by breakage of these vessels. Recently an attempt has been made to prescribe suitable tests for carboys, and this work is outlined in the report.

The review of tank car matters points out that the casualties in gasoline tank car fires were reduced in 1920 to no deaths and 6 injuries, as compared with 2 deaths and 28 injuries in 1919. A review of the work being carried on by the bureau in connection with the A. R. A. tank car committee and the American Petroleum Institute is given. This pertains particularly to improvements in the bottom outlet valve, the dome closure and the safety valve. Special mention is made of experiments now being conducted for the purpose of developing a standard specification for tank cars for muriatic acid.

The concluding section of the report is devoted to a discussion of the detailed work of the bureau. Numerous statistical summaries are given and circulars issued during the year are collected and reprinted.

Saving Money in Car Repairs*

BY A. F. O'BRIEN

Little or no attention has been given to the revenue derived or lost in repairs to freight cars or to the study that is required of the men who have undertaken the task of keeping equipment in safe and serviceable condition. The average railroad man knows practically nothing as to how repairs to cars are handled or how the company is reimbursed for its expenditure in connection with the repairs to foreign equipment, the amount of which involves millions of dollars each year.

The American Railway Association rules must be thoroughly understood by those in charge of the work, and particularly so by the inspector of A. R. A. repair cards, whose duty it is to make up the repair cards in order that each operation may be described in such a way that there can be no question as to the operations performed.

After the repair cards are made up they are passed to the billing department for pricing. The duties of the bill clerk pricing these repair cards are nerve racking. He must read thousands of repair cards made up by hundreds of employees and know just what operation each one is trying to describe. A wrong interpretation of the repair card may mean considerable loss of money to the company. The bills rendered against the company by foreign lines is an item that must be properly checked. The bill clerk should be a practical car man, who knows the construction of equipment, the knowledge of which can only be gained in actual experience in the shop. Such a man is an asset to the company and his value cannot be over-estimated. He can tell at a glance whether the operation described on the foreign line repair card could be performed on a car in any certain series and eliminate such charges as are improper.

The amount of money saved in a year through the elimination of such improper charges may be represented in no less than five figures and this is no doubt also true where small items, such as pin chain clevises, nuts, air hose and numerous other parts are used to repair foreign cars in train yards and on line between stations and not reported. If train crews would realize that every air hose applied on the line between stations on account of being burst and not reported is worth $2.30, which amount should be charged to the car owner, and every knuckle $4.80, knuckle lock $1.95, brake shoe $0.56, etc., there would be an immediate increase in the number of reports of material applied on the road turned in.

Another item that takes its yearly toll in dollars and cents is the improper handling of equipment in yards by switch crews. This is an item that in the majority of cases a little forethought on the part of the men handling the equipment would prevent. A slight rake or the cornering of a car may not seem much to look at, but the cost to repair when figured up, with the present high cost of labor and material, would indeed surprise those responsible.

MAKING BOLTS FIT TIGHT.—Two novel and interesting methods of making a tight fit in bolts subjected to shearing stresses are described in the report of the Bureau of Standards, abstracted in the *Iron Age.* The bureau was requested to devise a method by which bolts could be secured with a tight fit over the entire length Two methods were tried, both of which gave satisfactory results. In the first case the bolts were finished a little larger than the holes in the plate. They were then immersed in liquid air until they contracted sufficiently to enter the holes quite easily. Upon warming up, the bolts expanded, gripping the plates tightly In the second method, each bolt was provided with a small hole along its axis and was finished to an easy fit in the plate. After insertion, a charge of powder was exploded in the small hole. This expanded the bolt causing it to grip the plate. Subsequent physical tests indicated that the strength of the joint secured by both methods was sufficiently high for the purpose.

Repair and Maintenance of Steel Freight Cars*

Necessity for Adequate Shop Facilities and Proper Organization Strongly Emphasized

BY SAMUEL LYNN
Master Car Builder, Pittsburgh & Lake Erie

HEAVIER motive power, with greatly increased train tonnage, has created a demand for cars of increased capacity. The limit of capacity apparently has not yet been reached, since one of the large car companies has, within the year, constructed cars of 120 tons capacity.

While no accurate figures are available, it is estimated that approximately 70 per cent of the two and one-half million freight cars in service in North America are either of all-steel, steel underframe or steel center construction. As this number of cars represents an investment of over three billions of dollars, the importance of keeping them in good repair and in service is self-evident.

Maintenance Badly Neglected

A casual inspection in almost any classification yard will reveal the fact that repairs to steel cars have been badly neglected during the past few years. Large numbers of cars may be seen with floor, hopper and side sheets badly corroded and in many cases rusted and worn entirely through. A close inspection will usually develop the fact that center sills are buckled either in front of, or between the body bolsters. This condition is due either to faulty construction, sills of insufficient area, abuse in service, or neglected maintenance. Conditions existing during the recent world war imposed many hardships upon the railroads generally, making it almost impossible for them to keep the maintenance of their freight equipment up to pre-war standards. Shortage of labor and materials, coupled with the pooling of equipment, had a tendency toward deferred maintenance, which resulted in merely patching up worn-out cars and keeping them in service long after they would have been shopped for rebuilding under a normal maintenance program. The large percentage of home cars on foreign roads resulted in neglect, since proper material for repairs of foreign cars was not generally carried in stock. This resulted in makeshift repairs, most roads doing only enough work on foreign equipment so that it would haul one more load, in the hope that it would carry that one load off the line and never return. The results of this practice are now most evident when cars are being returned to the home roads in large numbers and in almost universal bad order.

The speaker believes that the exterior of steel cars should be kept well painted, as by this process at least one side of the steel is protected against corrosion; in addition to this, well painted equipment is a good advertisement for any road. It is obviously impracticable to attempt painting the interior of open top steel cars, since the commodities usually carried in such cars consist of coal, coke, iron ore, limestone, furnace slag and mill products, which in the process of loading and unloading so badly damage the paint that it would serve no purpose as a protective coating. The interior of steel equipment is where corrosion is the most evident and is probably due to moisture laden with acids from the products of the mines and mills, or to electrolysis caused by impurities existing in the steel itself.

I would like to here state a few things that in my opinion are necessary to maintain steel car equipment properly and economically.

First: Shops should be provided at points where heavy repair steel car work is to be performed. They should be well lighted and ventilated, and in the colder sections of the country should be properly heated. Overhead crane service is desirable, and by proper arrangement eliminates the necessity for material tracks between the working tracks. Small wall or jib cranes should be installed for handling yoke riveters, etc. The money expended for shops will repay the investment many times over in a few years. While I would not say that a steel car cannot be repaired outside under adverse weather conditions, I believe that the work can be carried on more successfully where shops are provided.

Second: Shops should be well equipped with suitable machinery, properly located so that repair parts may be made economically without any lost motion or backward movement. It is a question whether or not it pays to attempt the manufacture of all steel car parts in the average railroad shop. Some of the larger railroads buy most of their car repair parts already punched and pressed into the proper shape ready for application. However, it is necessary to have sufficient machinery to make odd parts or to extend the supply when exhausted, as it is almost impossible to keep sufficient parts on hand to meet all conditions.

Punches, shears, hydraulic presses, heating furnaces, and a good supply of efficient pneumatic tools are indispensable in the modern shop and will soon repay the initial cost of installation. Sufficient compressor capacity with facilities for supplying dry air at all times is necessary for the economical use of pneumatic tools. Proper facilities should also be provided to take care of the scrap parts that will accumulate, and the shop and surroundings should be kept clean at all times. While this may not seem important to some, nevertheless it has a certain moral effect on the workman, which should not be underestimated.

Third: Other facilities must be provided, such as storehouses, storage yards, air brake shops, paint shops, oil houses, etc., depending on the size of the shops. The storehouse or material supply house should be located as near the shops as possible and electric tractor service or other means installed for convenient and economical transportation of materials. Fuel supplies and stores should be under direct supervision of the foremen in charge, or if the shop organization does not permit this, the storekeeper and car foreman should be very close together and work in perfect harmony.

The Importance of Supervision

Fourth: Another and probably one of the most important factors in repairs to steel cars is the quality and quantity of supervision. Sufficient intelligent supervision must be furnished or the work will lag and both the quality and quantity of the output will suffer. The gang foreman who comes into daily personal contact with every man under him is the keystone of any organization. He forms the contact point between the management and the men and when the contact is broken, the current ceases to flow. These men should be selected from the ranks, if possible, and should be men who have developed ability and initiative in their work and they should also have ability to handle the workmen. While a thorough knowledge of how to perform the work is necessary, this is not the first requisite, as ability

---

*Abstract of a paper read before a meeting of the Canadian Railway Club, March 8, 1921.

to handle men and personality stand above this qualification. Foremen should be intelligent and fairly well educated in order that they may read the rules, blueprints and instructions and apply them intelligently, and also that they may be eligible for promotion to higher positions as vacancies occur. Wages paid foremen should be sufficiently attractive to create an incentive for the men to fit themselves for such positions.

The successful supervisor, in addition to his knowledge of the work, should show loyalty toward his employer, have the courage to enforce discipline, insist on and obtain a fair day's work from every man in the service, and be absolutely impartial in handling his men in order to obtain and hold their co-operation and respect. He should also have the vision and ability necessary to discover trouble makers and weed them out before the remainder of the organization becomes contaminated. No man should be placed in the position of foreman unless the appointing officer feels that the man selected is capable of developing the necessary initiative and ability to accept any position up to the top of the shop organization, as those men selected for the bottom round of the ladder should be capable of advancing step by step until they reach the top. Most higher supervisory officers have not the time to mingle with the workmen and they must depend on their foremen to provide the little touches of personality and co-operation that are the life of any organization.

Fifth: Another important feature is the personnel of the shops. Wages paid and working conditions should be such that they will attract capable young men to seek employment in railroad shops. Unless this is done, there is a tendency for skilled mechanics to seek more remunerative employment in industrial work. This is particularly true in the large industrial centers. The tendency prior to federal control in some sections of the country, due to shortage of mechanics and inability to induce young men to enter the service, has been to hire foreigners from central and southern Europe, men who have never had any mechanical training, and to try to make mechanics out of them. These men come to us wholly unacquainted with our language, our customs, and our laws, and must be assimilated into our organizations. While at first a rather costly proposition, with proper and tactful handling they usually learn rapidly, and have become the mainstay of some of our car shop organizations. It is important that those charged with the handling of these men, should by careful and tactful treatment instill in them the principle of loyalty to their employers; with proper encouragement and fair dealing on the part of their foreman the majority of these men readily become acquainted with our methods of work. The nationalization of foreigners has become important and it is very generally conceded that they are more easily reached in the shops that in their homes. However, any tendency toward radicalism should be carefully watched and immediate steps taken to circumvent it.

The only commodity a railroad has to sell is transportation. Anything that tends to increase the quantity or speed of transportation is a distinct addition to the wealth and resources of the country. Good, efficient motive power may be essential, but without freight cars the railroads would have little use for locomotives. Estimating that four per cent of all the cars in the country are shopped, every day of unnecessary delay in returning them to service represents a per diem loss to the railroads of approximately $100,000. The importance of providing adequate shop facilities is self-evident.

Suggestion as to Repairs

In the actual work of repairs it is suggested that draft attachments and center construction be sufficiently strengthened so that the shocks incident to modern service will be absorbed and distributed throughout the car, without causing extensive damage to the superstructure. Center and draft sills should have sufficient area and should be protected against buckling by the use of cover plates. A common cause of failure is due to bodies of hopper cars not being securely fastened to center sills. A few rivets are driven in inside hopper sheets to hold the body to the sills, and the heads corrode and wear off, allowing the rivets to pull through the sheets. This results in the whole strain being thrown on the body bolsters, which are usually of a wide single plate type, with the result that they are unable to stand up under the strain. The sills start moving back and forth under the car and it soon gets in such condition that permanent repairs become a rather expensive proposition. Sides and ends of steel equipment should be properly re-enforced to prevent bulging out under load. Drop door equipment should be kept in proper working order to facilitate unloading. Care should be taken in repairing trucks to provide side bearing clearance and to see that brakes and all running gear are kept in good condition.

A well defined program of re-enforcement should be outlined and put into practice on all roads. The cost of such additions and betterments is usually insignificant when the future life and productive service of the car is considered. Money appropriated for such features is a good, sound investment when judiciously used, and should pay large dividends. Many roads make the mistake of repairing their older equipment in kind as they do not have exacting conditions on their lines. Such equipment should either be re-enforced or kept on their own lines and not offered in interchange, where there is a possibility of it getting out into the large industrial centers and in heavy tonnage trains, when it is almost an impossibility to keep it off the repair tracks.

This places an unnecessary burden of expense on both the owner and the handling line. As cars come into the shop for general repairs, a careful inspection should be made, and if the car has not deteriorated to the extent that it is felt advisable to scrap it, it should be repaired in accordance with a well defined re-enforcement program, as outlined. Otherwise, if this is not done, after considerable money has been spent on the car, due to inherent weakness, it will again be back on the shop track.

In conclusion, if the railroads were provided with the facilities and a maintenance program similar to that suggested in the paper was adopted by all roads, and an honest effort was made to maintain the cars in accordance with that program, the steel cars in the country would give the owners a better return for the money invested in the way of better service and in increased life of the cars.

Discussion

There were about 500 in attendance at the meeting; the discussion lasted two hours and had to be cut off because of the lateness of the hour. It was opened by Vice-President Grant Hall of the Canadian Pacific and Vice-President W. D. Robb of the Grand Trunk. A large number of visitors were present from the "States."

In general the discussion indicated that there were few roads owning steel cars which had adequate shops or facilities for taking care of them. The problem has been greatly complicated in the United States by the return of badly deteriorated cars to the home roads at the end of federal control. One road converted an old roundhouse and an old storehouse into steel car repair shops by equipping each of them with facilities and tools costing about $70,000. Five heavy repairs per day are now being turned out of each of these plants.

The metal used in steel cars was seriously criticised because of the rapid rate at which it deteriorates. It was suggested that a better steel be used, similar in composition to the iron used in the Baltimore & Ohio box cars which were built in 1862, the bodies of some of which are still in existence and have not suffered to any extent from rust and corrosion.

Heavier motive power and careless switching of cars has been responsible in part at least for the failure of some of the earlier designs of steel freight cars.

What is needed more than anything else is a systematic program for making heavy repairs to freight cars so that a certain percentage of the equipment will be given such repairs each year—this percentage to be based upon the number of years which a car can safely run between heavy repairs. Locomotives are shopped on a mileage basis. Why not establish a reasonable and scientific basis upon which to shop freight cars and then see that it is lived up to? This will keep the equipment in prime condition and at a minimum of expense after the program has been well established. It will be necessary to speed it up for some time, however, in order to catch up with the deferred maintenance.

Draft Gear Tests of the Railroad Administration

Results from Gears After Three Years' Service; Destructive Tests and Rivet Shearing Tests

The results of the tests with friction surfaces coated with foreign matter indicate that while new gears in laboratory tests may show acceptable capacities, depreciation may occur in service, not only from eventual wear, but from an immediate coating of the friction surfaces.

It has not been possible to investigate this as thoroughly as desired, but some little work of this character has been done in conjunction with the engineer of tests of the Norfolk & Western Railway. Experiments were made upon five different types of gears which had been in service for approximately three years each on N. & W. 100-ton coal cars. The gears were carefully removed from the cars so as not to disturb the deposit and glazing on the friction surfaces and were put in tight, individual boxes and carried immediately to the drop test machine.

The actual fall required to close the gears in their service condition was determined in as few blows as possible, after which a building up or restoration test was made by giving the gear additional blows until no further increase in capacity could be obtained. No attempt was made to clean the surfaces of these gears prior to the building up tests, as the test was intended to develop what recovery might be effected by simply working the gear. The gears were all in good condition as to wear, and would in every instance have been so declared upon surface inspection. The results of these tests are shown in Table IV.

Table IV—Drop Tests of Friction Gears Which Were Taken Out of Service, Norfolk & Western Railway

		Average results—9,000 lb. drop			
Make and type of gear 1	Number of gears tested 2	Drop test value of new gear total fall, in. 3	Total fall required to close gears when first removed, in. 4	Gear restored to—total fall, in 5	Number of blows necessary for restoration 6
Miner, A-18-A	10	19.9	16.4	17.5	18
Miner, A-59	2	27.0	18.0	20.5	32
Sessions, K	2	19.3	8.6	9.0	14
Sessions, Jumbo	2	28.1	15.0	16.5	21
National, H-1	10	31.2	19.4	26.9	32

In explanation, the Miner A-18-A gear is the same as the Miner A-18-S of the U.S.R.A. tests, except that the A-18-A has 3 in. travel and the A-18-S has 2½ in. travel. The Miner A-59 gear is an especially long gear, not usable in the standard pocket and hence not included in the U.S.R.A. tests. The Sessions K, the Sessions Jumbo, and the National H-1 are identical with the same types of draft gear in the U.S.R.A. tests.

Column 3 gives for ready reference the total average drop test value of the several types, when new and in good condition, as found in the U.S.R.A. tests. The Miner A-18-A is taken the same as the A-18-S. For the Miner A-59 a value is taken from previous tests of these gears.

Column 4 gives the average total fall, including the travel, required to just close the gears when first tested after removal from service. These figures therefore represent the value of the gear as in actual service, after a period of three years' use, as heretofore explained.

In this test the Sessions gears, which have the friction elements of unhardened cast iron working against unhardened forged steel, showed the greatest percentage of depreciation and the least restoration. The National gear, which has hardened steel friction elements working together, showed the next greatest percentage of depreciation and the greatest restoration. The Miner gears, which have hardened steel friction shoes working against a malleable iron barrel, showed the least percentage of depreciation and necessarily the least percentage of restoration. It does not thus appear that the character, and particularly the hardness of the friction surfaces, influenced this depreciation. On the other hand, the Miner gears were under a heavy initial compression in the cars and the Sessions and National were under practically none.

It is therefore probable that the tightness of the friction parts may have prevented the entry of the foreign material in the case of the Miner gears. In the case of these N. & W. gears, the friction shoes in the Miner gears were in every instance tight with the gears in position in the cars, while the friction members were loose in every one of the Sessions and National gears. As no measurable wear had occurred in the National gears the manufacturers offer in explanation of this loose condition of the friction members that an inferior lot of springs had been used, with consequent set and loosening of the friction parts in the car. In the case of the Sessions gears the designs provide for loose friction blocks in the car. Further investigation along the lines of gear depreciation, due to foreign material on the friction surfaces in service, should be made.

Destructive Tests

Immediately after the tests with coated friction surfaces, the same gears, one of each of the types included in the program, were tested to at least partial destruction under the 9,000 lb. drop, the gears being supported on a solid anvil. In each instance successive blows were given from heights beginning at 1 in. free fall of the weight and increasing by 1 in. increments, a record being made of the point at which each gear went solid and of the point at which destruction began, as evidenced by scaling, fracture, bending or shortening of some part of the gear. These tests are of the kind best suited to show the ability of a gear to receive over-solid blows and are designed to penalize weakness instead of putting a premium upon it, as set forth in a preceding chapter of this report. It will be noticed that some of the gears begin to show evidence of distress at a fall of just a few inches above the solid point.

Summary of Destructive Tests

The table No. V has been prepared to show the results of these tests and to grade the gears as to destructive value. It is quite possible that a repetition of lighter blows would in each instance have produced failure, but it is believed that no great error is made by this comparative grading.

Column 3 gives the total fall required to close the gears during this particular test. In some instances this varies slightly from the figure obtained in the original drop tests, due usually to the fact that some of the gears could not be fully restored in the immediately preceding tests with coated friction surfaces.

Table V—Performance of Gears in Destructive Tests

		9,000 lb. weight				
Make and Type of Gear 1	Test Gear No. 2	Total fall required to close gear in this test 3	Additional fall beyond closing point required to start failure 4	Development of failure 5	Average total fall 9,000 lb. weight required to close one commercial gear of this type Inches 6	Destructive value assigned to this type of gear. Inches fall 7
Westinghouse D-3	1	18.5	4	Rapid	19.8	23.8
Westinghouse NA-1	6	27.0	4	Rapid	26.0	30.0
Sessions K	10	15.2	2	Rapid	18.8	19.8
Sessions Jumbo	13	24.1	4	Slow	28.1	32.1
Cardwell G-25-A	16	20.8	2	Rapid	18.9	20.9
Cardwell G-18-A	19	20.3	3	Rapid	19.6	22.6
Miner A-18-S	22	16.5	7	Medium	19.9	26.9
Miner A-2-S	25	12.5	7	Medium	13.2	20.2
National H-1	28	33.5	17	Slow	31.2	48.2
National M-1	31	19.5	10	Slow	19.2	29.2
National M-4	34	19.5	6	Slow	21.5	27.5
Murray H-25	37	17.7	5	Medium	17.0	22.0
Gould 175	40	17.4	4	Medium	18.1	22.1
Bradford K	45	11.5	1	Rapid	10.8	11.8
Waugh Plate	48	12.2	2	Slow	13.9	15.9
Christy	51	14.3	8	Slow	19.6	27.6
Harvey 2-8 in. by 8 in. springs	54	7.9	5	Melium	9.5	14.5
Coil springs 2-8 in. by 8 in. Class G	57	5.8	2	Rapid	5.8	7.8

Column 4 gives the additional height from which the 9,000 lb. weight was dropped, reaching this by increments of 1 in. from the solid point, before visible distress of the gears began.

Column 5 has been inserted to denote whether the failure from this point on developed slowly or rapidly, under constantly increasing falls.

Column 6 gives for reference the figure accepted as the average total fall required to close a new commercial gear of this type, when in good condition, this column being the same as Column 10, Fig. 16.

Column 7 gives the comparative destructive values assigned the several types. This figure is obtained by adding to the average drop test value of the type of gear as given in Column 6, the over-solid values in Column 4. Thus in the case of the Westinghouse D-3, gear No. 1 of this type was subjected to this test. During the test gear No. 1 went solid at a total fall of 18½ in. and at a total fall of 22½ in., or 4 in. above the solid point, the barrel started to fail. Accordingly the destructive value of this gear has been set by adding 4 in. to the average total fall figure 19.8 in., giving a destructive value of 23.8 in. The same practice has been followed for all gears.

Rivet Shearing Tests

The draft gears for the U.S.R.A. cars were purchased on the requirement that they be of "150,000 lb. capacity" and the Mechanical Committee later defined a 150,000 lb. capacity draft gear in the following words:

"A 150,000 lb. draft gear should be defined as one that will sustain a drop of 16 in. (including travel of gear) of a 9,000 lb. weight, without shearing the rivets of one or both lugs, which are to be secured to suitable supporting members by nine ½ in. rivets of .15 carbon or under, driven in 9/16 in. holes."

A representative number of gears of each type used on U.S.R.A. cars were selected at random and subjected to the above test. The average of the results for each type was used to determine whether or not that type of gear met the terms of the specifications. In these tests the gears were supported upon a solid anvil and the weight was dropped from successive heights, increasing by 1 in. increments until the rivets sheared.

In testing the Sessions K gears, the highest capacity gears sheared the rivets at a lower drop than the lower capacity gears. In five instances the rivets sheared before the solid point of the gear was reached. In three instances the rivets sheared at the point of gear closure; and in but two instances did it require a blow from above the solid point to shear the rivets. In three instances the rivets were sheared at a point below the specification requirement when the successive blows by 1 in. increments were given the rivets. In each of the cases, however, when the gear was again set up and a single blow given from a height sufficient to produce a total fall of 16 in. the rivets did not shear. Thus, one of these gears, when given blows increasing by 1 in. increments, sheared the rivets at a total fall of 11 in., and when it was immediately thereafter given a single blow from a total fall of 16 in. the rivets were not sheared. The rivets in this re-test sheared at the next blow, or at a total fall of 17.2 in.

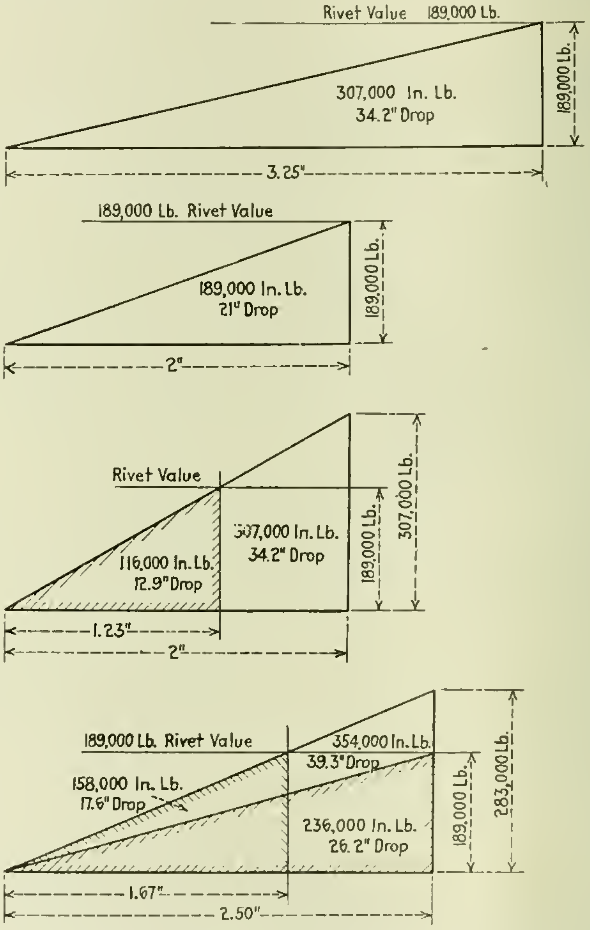

Fig. 3—Diagrams of Rivet Shearing Action of Draft Gears

For the Sessions gears it required on the average 2.7 in. less fall to shear the rivets than to close the gears. In the

Westinghouse D-3 gears the rivets usually sheared 1 in. above the solid point, although in a few instances it required an over-solid blow of 2 in. to produce shear. In the Cardwell G-25-A gears it required on the average an over-solid blow of 3.2 in. to shear the rivets. In one instance a 4 in. over-solid blow was necessary. In the Murray H-25 gears it required an average over-solid blow of 2.4 in. to shear the rivets.

Considering the Westinghouse, Cardwell and Murray gears, it will be noted that the number of over-solid blows required to shear the rivets is in inverse relation to the over-solid sturdiness or destructive value of the gears as given in Table V. The short travel of the Sessions K gear necessitates a higher ultimate resistance, so that the elastic limit of the ½ in. rivets is passed before the gear goes solid. In considering this test it should be remembered that the eighteen ½ in. rivets (9/16 in. when driven) have a shearing area of 4.47 sq. in., giving an ultimate shearing value of approximately 189,000 lb., with an elastic limit in shear of approximately 135,000 lb. In practice the rear draft lugs each have twelve ⅞ in. rivets in 15/16 in. diameter holes, or a shearing area of 16.57 sq. in., with an ultimate shearing value of 700,000 lb., or an elastic shearing limit of 500,000 lb.

Table VI has been prepared to show the results of these ½ in. rivet shearing tests made for the acceptance of gears for U.S.R.A. cars.

TABLE VI—RESULTS OF ½-IN. RIVET SHEARING TESTS. DRAFT GEARS FOR U. S. R. A. CARS 9,000-LB. DROP

9,000-*Lb. Drop*

Make and type of gear	Number of gears tested	Total fall to close gear, inches			Total fall to shear rivets, inches		
		Maximum	Minimum	Average	Maximum	Minimum	Average
1	2	3	4	5	6	7	8
Westinghouse D-3..	18	21.6	18.6	19.9	22.6	19.6	21.0
Sessions K	10	23.1	18.1	20.5	22.1	11.0	17.8
Cardwell G-25-A....	5	17.6	15.6	16.6	20.6	19.5	19.8
Murray H-25.......	7	17.8	16.8	17.6	20.8	17.8	20.0

In order to show for comparison how all of the gears perform in this test, and in order to study the specifications in the light of a full knowledge of each particular gear, one of each type of gear in the tests was subjected to the ½ in. rivet shearing test. This was done after the car-impact tests and was the final test given the gears.

The results are given in Table VII, the several columns of which are described as follows:

TABLE VII—PERFORMANCE OF GEARS IN ½-IN. RIVET SHEARING TESTS

Type and make of gear	Test gear number	Total fall required to close this gear solid anvil, Inches	Free fall required to shear rivets, Inches	Travel of gear when rivets sheared, Inches	Total fall required to shear rivets, Inches	One or both lugs sheared
1	2	3	4	5	6	7
Westinghouse D-3....................	2	19.50	17	2.47	19.5	one

Solid steel block...................	..	...	4	...	4.0	....

Column 3 gives the original total fall required to close each gear. During this test care was taken to see that all gears were up to this original capacity.

Column 4 gives the free fall required to shear the rivets of one or both lugs. This height of fall was reached through successive blows increasing by 1 in. increments.

Column 5 gives the actual amount of gear closure obtained in this test with the free fall of Column 4.

Column 6 gives the total fall required to shear the rivets, this being the sum of the quantities in Columns 4 and 5.

Column 7 denotes whether one or both lugs sheared, this, however, being of secondary interest.

In each of these tests the rivet samples were analyzed and the carbon content in no instance exceeded .15, the usual average ranging from .09 to .12.

Some of these results will, at first thought, appear inconsistent, but a more careful study will show that the results in general are approximately what should be expected when gears of different travels and capacities are tested upon undersized rivets. Thus the gears generally may be divided into two classes: those closing at four miles per hour or more in the car-impact tests and those closing at less than four miles per hour. Seven types as follows fall in the higher class:

National H-1.
National M-1.
National M-4.
Miner A-18-S.
Westinghouse NA-1.
Sessions Jumbo.
Sessions K.

It will be noted that in no case did a gear of this class require an over-solid blow to shear the ½ in. rivets. In six cases the rivets sheared before the gears went solid and in the remaining case the rivets sheared at the solid point. Furthermore, as might be expected, the gears of short travel usually sheared the rivets earlier than those of equal capacities and longer travel.

A more clear understanding of this action will be had from the diagrams of Fig. 3. At the top of this figure is shown a straight line diagram of a gear of 34.2 in. drop capacity and of 3¼ in. travel. The ultimate resistance of this gear is 189,000 lb. and the eighteen ½ in. rivets should shear at the same value, or just when the gear goes solid. Next there is shown a diagram of a 2 in. travel gear of the same ultimate resistance, 189,000 lb., and with this gear also the rivets should just shear at the solid point, but which in this case would be at 21 in. drop instead of 34.2 in. Next is shown the diagram of a gear of 2 in. travel but of the same capacity (34.2 in. drop) as the 3¼ in. travel gear at the top of the figure. The ultimate resistance of the gear would in this case be 307,000 lb. and the rivets, which have the value of 189,000 lb., should shear at 1.23 in. gear travel or at a drop of but 12.9 in. This gear, therefore, which is of the identical capacity as the 3¼ in. travel gear, will shear the rivets at 12.9 in. drop, whereas the 3¼ in. travel gear will require 34.2 in. drop. This increase in drop is due solely to the increased travel of the gear with consequent decrease in ultimate resistance. At the bottom of Fig. 41 are shown superimposed diagrams of two gears, each of 2½ in. travel, but the one of 26.2 in. drop capacity and the other 39.3 in. drop capacity, or just 50 per cent increase. In the case of the lighter capacity gear the rivets do not shear until the gear goes solid or at 26.2 in. fall. In the case of the larger capacity gear the rivets would shear at 17.6 in. drop. Here is shown how by simply increasing the capacity of the gear 50 per cent the ½ in. rivets are caused to shear 13.1 in. lower than with the lighter capacity gear. These conditions are for straight line gears and for shearing the rivets at a single blow. When a succession of blows is given from varying heights the difference becomes even more marked, as a heavier capacity gear begins to punish and permanently deform the light rivets early in the test.

The above principles are reflected in the test results. Thus the Sessions K gear and the Cardwell G-25-A were of practically equal drop test capacity but different travels, namely, 2 1/16 in. and 2¾ in. respectively. The Sessions K gear (2 1/16 in. travel) sheared the rivets at 12.5 in., while the Cardwell (2¾ in. travel) sheared them at 22.8 in. Again, the National H-1 gear sheared the rivets at 10 in. fall, while the National M-1 gear sheared them at 19.5 in. fall. Here the travels of the gears are the same, but one gear had a drop test capacity of 32.5 in., while the other had 18.5 in.

An effort was also made to test all the gears on full-sized rivets, a total of twenty-four ⅞ in. rivets (16.57 sq. in.) being used for the two lugs. The three gears tested in this way failed which showed the futility of attempting to use this method of testing. From this experience and from careful study, it is believed the present ½ in. rivet shearing test is not a fair method of grading gears. Car sills are designed for a load of 500,000 lb. and it therefore should not be expected to hold the draft gear to the limits required by this light test. It is believed possible, however, to develop a rivet shear test to grade gears of all capacities, and investigations have been outlined to develop a test of this character. In this work the following points will be established or disproved:

1. That rivet shearing tests should be designed to show smoothness of action and the ultimate dynamic resistance.
2. That such tests should not be carried beyond the solid point of the gear, because of the fact that all gears are not of equal rigidity when solid.
3. That the rivets should be of such area that a single blow may be given from a stated height, within the capacity of the gear, and the rivets not be sheared.
4. That the rivets should shear at a blow from not more than a stated height above the solid point; this in order to penalize over-solid weakness of construction.
5. That the tup should not be dropped through successive heights increasing by 1 in. increments because of passing the elastic shearing limit of the rivets before the gear is solid, but that the gear should be set up on lugs or the equivalent and a single blow given from a specified height for that particular gear and the rivets not be sheared. Using a new set of lugs, another single blow should be given from a second specified height at which the rivets should shear.
6. That the number of rivets used and the heights of drop should not be the same for all gears but should be set for each type in accordance with its capacity and travel.
7. That the rivet area and height of fall should be determined by the drop test capacity and travel of the gear.
8. That the test rivets should be of high carbon steel or other material having a high elastic shearing limit; this in order to avoid the uncertainty of the exact shearing point.
9. That when all gears are constructed of equal travel the question of rivet shearing tests will be greatly simplified.

Car Inspectors Propose Change in Interchange Rules

Suggestions Largely Intended to Remove Conflicts and to Effect Uniformity of Application

In the April issue of the *Railway Mechanical Engineer*, page 233, appeared the first installment of the transcript of the proceedings of an open meeting of the executive committee of the Chief Interchange Car Inspectors' and Car Foremen's Association of America, held at the Hotel Sherman, Chicago, on March 3 and 4, 1921, for the purpose of recommending changes in the Rules of Interchange. The following is a continuation of the discussion which took place at that meeting.

At the opening of the session on March 4, attention was called to the fact that Henry Boutet, one of the founders of the Association and chief interchange inspector at Cincinnati, Ohio, was unable to be present on account of serious illness, and the secretary was instructed to express to him in suitable manner the sympathy of the members present.

Proposed Change in Rule 4

M. E. Fitzgerald: I move the following change in Rule 4:

> Eliminate from the fourth paragraph of Rule 4, the words "with the exception of the cases provided for in Rules 56, 57 and 70."

Rule 56 pertains to cars intended to be equipped with metal brake beams and so stenciled if found with wooden brake beams. Rule 57 has to do with cars not equipped with A. R. A. standard 1⅜" air brake hose, and Rule 70 deals with steel wheels. . It is absurd to permit the owners of equipment to hold you responsible for wrong repairs to steel wheels, when they will not give owners who have cars equipped with more expensive devices similar protection. The case of the brake beams is fully taken care of and if an intermediate line repairs a car with wooden brake beams under it, they may bill the owner. If the car is stenciled the owner must use his repair cards as joint evidence. In the case of the wheels we have a recent arbitration decision. This is a defect that cannot be detected at night and the handling line, that did not make the repairs, is heavily penalized when it should not be.

Chairman Gainey: I do not agree that those defects cannot be detected at night. If a man cannot detect a cast iron wheel from a steel wheel, we might as well quit inspecting at night.

M. E. Fitzgerald: Cast steel wheels are overlooked because the stenciling is bad. In many cases owners are putting them in and permitting the cars to run and the handling lines are being heavily penalized. You have a car equipped with steel sills and you pull them out and put in wooden timbers. The only redress the owner has is joint evidence. There is as much money involved as in steel wheels; why shouldn't the man with the steel wheels do the same thing?

The motion was seconded and carried.

Mr. Pellien's motion was carried.

Change in Preface

F. H. Hanson: I would like to make recommendations for a change in preface of these rules. The first paragraph reads as follows:

> These rules make car owners responsible for, and therefore chargeable with, repairs to their cars, *except as otherwise provided.*

I move that the words "except as otherwise provided" be stricken from the rules for the reason that they are nothing but a loophole giving various roads a chance to deviate from the M. C. B. rules. If we are going to have rules, let us make them so they can be lived up to in one part of the country as well as in another part of the country. Recently we had an agreement under consideration and when I took it up with the other party as to why they wanted certain paragraphs in the agreement, when I thought all that was necessary was to say that the interchange would be handled in accordance with interchange rules, they called attention to the preface saying "except as otherwise provided" and said that they expected to take advantage of those words.

The motion was seconded.

F. W. Trapnell. "Except as otherwise provided" refers to Rules 32, 48 and 49.

C. M. Hitch: How can any interchange association or any other body make a local agreement?

F. W. Trapnell: I do not know of any local agreements running in the country today with any interchange associations except as to costs. There is a provision in the transfer rule whereby the A. R. A. says "unless otherwise provided." That is merely a matter of otherwise providing for the collecting of the cost of the transfer.

C. J. Wymer: Automatically this abrogates all of the penalty rules. I do not like to be quite so radical.

A. Herbster: Could that not be taken care of by making it read "Except as otherwise provided in these rules"?

F. H. Hanson: I did not mean to take out the responsibility contained in Rule 32. I would like to see the rules so worded as to still keep in effect Rule 32 as far as wrecks, derailments, etc., are concerned, without allowing any road to draw up any agreement that will conflict with the A. R. A. Rules.

The motion was lost.

Rule 9

M. E. Fitzgerald: I move that a reference be put in Rule 9, page 28, that repairing lines must state the type of triple valve when stenciled on the car, or not stenciled.

The motion was seconded and carried.

Rule 14

F. W. Trapnell: Under Rule 14, second paragraph, it says:

> Facing the B end of car, in their order on the right side of car, wheels, journal boxes and contained parts shall be known as R1, R2, R3 and R4, and similarly those on the left side of car shall be known as L1. L2, L3 and L4.

I move that the side of a car be from corner post to corner post on the right side, and from corner post to corner post on the left side in accordance with this rule.

The motion was seconded and carried.

Rule 17

F. H. Hanson: Referring to paragraph I, second paragraph, Rule 17, which reads:

> Cotter keys are not to be applied to knuckle pins of couplers on cars other than hopper and fixed-end gondolas.

I move that it be changed to read:

> Cotter keys to be applied to knuckle pins of couplers on all open top equipment except flat cars.

Practically all open top equipment is used in dumping machines.

The motion was seconded and carried.

M. E. Fitzgerald (C. & E. I.): I do not recall having heard any discussion on Rule 3. There is confliction between Rule 2 and Rule 3. For instance, Rule 3 says that cars will not be accepted in interchange unless equipped with all metal brake beams. What should you do with the car under load? Rule 2 says loaded cars must be accepted, and it specifies certain exceptions, which are not those in Rule 3. I move that it is the opinion of this Association that the reference in Rule 3 covers loaded or empty cars.

Secretary Elliott: What paragraph?

M. E. Fitzgerald: All of them. I merely called your attention to one. If the car is offered to you loaded and you accept it and run it and again load it, you never get to the point where the correction called for in Rule 3 is made. You should make the delivering line apply the metal brake beams before they offer the car, either loaded or empty. The rule merely says "Car."

The motion was seconded.

J. J. O'Brien: Do I understand Mr. Fitzgerald's motion to mean that he desires to stop the movement of traffic on loaded equipment simply because the car has wooden brake beams? I do not think we want to go on record as interfering with the loaded equipment. Rule 2 specifically states that loaded cars shall not be rejected. On empty cars it is different.

M. E. Fitzgerald: Rule 2 says that loaded cars must be accepted with certain exceptions. Rule 3 states plainly that cars will not be accepted in interchange unless equipped with all-metal brake beams, and several other items. What is the inspector going to do? I want the rule written so he is clear on it. The items I refer to are minor repairs,—brake beams and hooks on refrigerator cars to hold the doors open,—and when that rule was made it was the intention to enforce the application of those standards. If you permit the car to move and I accept it under load and run it with the wooden brake beams, I unload it, load it again and permit it to run with those brake beams and the other fellow has to take it. You will eliminate the necessity for the rule if you enforce it as the Association intended. Tie the car up and make the road with the car in its possession apply those standard features; that was the object of the rule.

C. J. Wymer (C. & E. I.): If this is intended to apply to empty or loaded cars, it ought to say so; it is in contradiction to Rule 2. If it only applies to empty cars, it should say so and remove that conflict.

The motion was carried.

F. H. Hanson (N. Y. C.): Rule 18, page 37, reads:

> When A. R. A. couplers of another make are applied to a car, the uncoupling arrangement shall be made operative at the expense of the company making the repairs.

I move that the following be added to that paragraph:

> except when applying Type D couplers in place of old style couplers.

In that event the expense for applying the uncoupling attachments should be borne by the car owner.

The motion was seconded and carried.

Mr. Jameson (Southern): The second paragraph of Rule 22 reads in part:

> Longitudinal sills (intermediate or side sills) may be spliced at both ends, on either side of body bolster.

A strict interpretation means that you cannot splice center sills except at one end of the car. Should it not read:

> Longitudinal sills may be spliced at both ends.

C. J. Wymer: The rule says "Longitudinal sills (intermediate or side sills)". That tells you what is meant by longitudinal sills. It confines the rule to intermediate and side sills, otherwise there would be no need for the parenthesis.

P. M. Kilroy (St. Louis-South Western): It seems to me that is put in to meet the point raised. It is enclosed in parenthesis to make it clear that you can do exactly what he says you cannot do.

M. E. Fitzgerald: As I read that rule, if you want to find out about splicing sills on either end you would read, "Longitudinal sills may be spliced at both ends," then, "intermediate or side sills on either side of the body bolster." Then find out what you can do with the center sills. The intermediate and side sills may be spliced on either side. The rule is clear and you can splice all longitudinal sills on both ends.

Mr. Jameson: I agree that is what the rule meant to convey, but it does not so state.

A. Herbster (N. Y. C.): Shouldn't the correction be in the second paragraph on page 40, which deals with the splicing of center sills?

Mr. Jameson: I move that we amend this by making it read:

> Longitudinal sills may be spliced at both ends. Intermediate or side sills on either side of body bolster.

The motion was seconded and carried.

C. M. Hitch (B. & O.): Referring to Rule 23. I understand there was quite a discussion not long since by a body of car men as to what portion of a cast steel truck side comprised what is termed the "tension member." I would like to ask the views of this body on that question.

W. K. Gonnerman (B. & O.): I have always considered the lower part the tension member and the upper part the compression member.

H. W. L. Porth (Swift & Co.): From an engineering viewpoint there are only two pieces of truck side frame that are tension members and those are the columns. The forces that take place in the so-called bottom cord are alternating; they may be either compression or tension. That has been demonstrated in tests at Purdue University and also in tests made at the University of Illinois.

P. M. Kilroy: It is true that from an engineering standpoint the columns are the true tension members, but there is also considerable tension between the oil box and the column in the bottom member, it may be alternating just as Mr. Porth says—but I think it would be perfectly clear to say that the top member was in compression and the bottom one in tension.

M. E. Fitzgerald: If that is a fact, the prints submitted by the A. R. A. are improperly marked.

H. W. L. Porth: That is the exact reason why the Committee on Welding marked the prints as they did,—from the tests that have been made at Purdue and Illinois. They found that these alternating stresses are in the members of the so-called bottom chord between oil boxes.

C. M. Hitch: That answers my question in a way, but I believe the bottom member of the cast steel truck side is termed the "tension member" and I believe that was the portion of the truck side it was intended should not be welded, for the reason that most of the trouble is in this member. I consider it a dangerous practice to attempt to weld it.

Inasmuch as it has been discussed by other bodies as well as here today, I move that this body ask the Arbitration Committee for an interpretation as to what portion of the cast steel truck side frame constitutes the tension member and what constitutes the compression member. *The motion was seconded.*

E. H. Mattingley (B. & O., C. T.): I would like to request Mr. Hitch to include in his motion that a foot-note be added stating that this refers to bottom members only. I do not believe, gentlemen, that there are any car men handling the repairing of cars today who do not consider the bottom member of the truck side frame as the tension member. You may talk about your engineering features, etc., but it practically replaces with a later modern device the arch bar, as the gentleman illustrated. The Arbitration Committee and the Welding Committee had in mind, as I understand it, that the bottom member of the side truck frame should not be welded.

Mr. Mattingley's suggestion was included in the motion.

M. E. Fitzgerald: If this goes into effect, hundreds of cars already welded will be refused in interchange as not complying with the rules. Some exceptions will have to be made as to dates of welding, excepting those previously welded on authority of the Association's prints.

C. M. Hitch: If this is submitted to the Arbitration Committee it will go to the proper place to be determined. It should be determined because car men are in doubt as to its meaning throughout the country.

The motion was carried.

Mr. Pellien (Ass't. C. I. I., Buffalo, N. Y.): Under Rule 32 I would like to insert a new paragraph. Call it paragraph (0):

Damage to any car if caused by clam shell or bucket in loading or unloading.

Many cars are being damaged in this manner at industrial plants, which damage cannot be termed other than unfair handling and is not protected by the present rules. We are having a number of those cases in the Buffalo district and we feel that Rule 32 is not explicit enough to place the responsibility with the delivering line.

I move that this change be recommended.

The motion was seconded and carried.

M. W. Halbert (Chief Inspector, St. Louis, Mo.): I move that the first paragraph of Rule 32 be changed to read as follows:

Dome covers, safety valves or outlet caps missing from tank cars.

It is felt that the importance of the outlet cap should be so generally recognized that the attention given it would make it next to impossible for it to be lost under fair usage.

The motion was seconded.

F. W. Trapnell (Kansas City, Mo.) Suppose this tank is shifted and the outlet boot is broken off and missing, we would have to card the cap but would have no place to put it on because the owner would be responsible for the outlet boot.

M. W. Halbert: That is only a technical point; we all know there are a great many of these outlet caps left dangling to the chain. They are not put in the proper place and they become lost.

Secretary Elliott: The case Mr. Trapnell mentioned is exceptional. From the experience we have had with tank cars, I think when the outlet cap is gone it is through carelessness, not through maintenance. They are so important that they should be maintained. That note will be a reminder to the car inspectors to particularly notice those things.

F. W. Trapnell: At large interchange points we find it to be a fact that with that outlet cap on, they fail to close their outlet valve. The minute the least thing goes wrong you have lost your tank of oil. The car goes to the man at the refinery or to the owner of the tank. He unloads it, leaves his outlet cap down, and if it hangs low enough to strike the rails, it is lost when the switching crew comes in to switch that car out, perhaps on the right of way of the refinery that owns the tank. Then the car is handled maybe fifty or sixty miles and delivered to somebody else. You want to penalize the railroads for the owner's carelessness. The roads do not have inspectors at all of those points by any means. I do not believe that they should be made the delivering line's responsibility.

Mr. Koeneke (Indiahoma Refining Company): It is absolutely obligatory to load the car with the cap off. The valve must be tight or the car cannot be loaded. Furthermore, if a car is shipped to an industry on a railroad and a cap is left off after unloading, it is the railroad inspector's duty to see that the cap is applied. It is against the regulations of the Bureau of Explosives to leave the cap off.

F. W. Trapnell: I was chairman of a committee that visited about seven refineries in our territory with a delegation of foremen appointed by the Superintendent's Association and no one knew of our mission. In one case we asked a foreman to take off several caps. Two of them were leaking a stream bigger than your two fingers. Those caps were never off when he started to load.

A. S. Sternberg (Belt Ry. of Chicago): We have had two cases lately with ice frozen in above the caps. When the cars were loaded the valve was screwed down and they thought it was closed because it was solid against this chunk of ice. It was one-fourth open. That indicates that the cap was not taken off. The thawing out or something else broke the cap and we lost the entire tank of oil.

M. E. Fitzgerald: This argument is to the effect that the caps are on the cars. Mr. Halbert merely wants to penalize you when they are not on the cars.

The motion was lost.

Mr. Owen (Peoria, Ill.): On Rule 32, paragraph (N), I move that failure to close hopper doors or drop bottom doors on coal cars be made the delivering line's responsibility and cardable in interchange. This is to insure that the doors are properly closed so the cars are suitable for loading. Many doors are coming down after they have been partly put up and the change in the rule is for the safety of the train men in handling.

The motion was seconded and on vote was lost.

Chairman Gainey: Referring to the part of Rule 32 that reads:

Damage to any car (including cars on ferries or floats) if caused by:
(a) Derailment.
(b) Cornering.
(c) Sideswiping.

If you are shoving a cut of cars down through the yard and a flat car breaks in two, the trucks run together and probably one or two pairs of the wheels go off the track. It is argued that was not caused by a derailment, that it was caused by the car breaking in two. I think that part of your rule ought to be changed and made more clear.

M. E. Fitzgerald: Isn't it a fact that we have interpretations to the effect that you may break a car in two? If you break it or the air hose bursts and the wheels do not leave the rails, such a condition would be owner's responsibility. If the car left the rails, even though you could prove that it was due to the air hose bursting, it would be a delivering line's responsibility because the car was derailed.

Chairman Gainey: Your rule says, "If caused by," and the cause was not the derailment of the car. It broke in two before it was derailed and the car breaking in two—which is owner's responsibility in fair usage—caused it to be derailed.

F. W. Trapnell: The Arbitration Committee gave us a ruling on that. There was a car up in the Cascade Mountains on the Great Northern. It was broken in two, fell off to one side and pulled the truck off with it. They ruled that the car was derailed and that it was the delivering line's responsibility.

C. M. Hitch: This is not the same case. The car was derailed and rolled off down the bank. Chairman Gainey refers to a car that remains above the rails on the trucks with some of the wheels on the ties. In some cases they claim that is the handling line's responsibility and in other cases they say it is the owner's responsibility. Let us have an interpretation.

Chairman Gainey: I think that the Arbitration Committee's ruling is right, but the rule should be worded differently. Why not change it to read:

Damage to any car (including cars on ferries or floats) if:
(a) Derailed.
(b) Cornered.
(c) Sideswiped.

A motion to recommend this change was made and seconded.

Mr. Owen: If you have a collision or impact that would cause damage to that car sufficiently to cause it to leave the rails, paragraph (D) would cover that, would it not? I understand that the transportation department considers approximately six miles an hour as a speed of safety in switching. If they are going twenty-five miles an hour, it seems to me it is unfair usage and rough handling. If there is an impact or collision sufficient to damage the equipment and knock it off the track, it would be a handling line's responsibility.

Chairman Gainey: That is not the point I am trying to get at. If I am shoving a cut of cars, ordinarily switching, and that cut of cars breaks in two and two trucks run together and the body fell over, it would be an owner's defect unless one pair of wheels dropped from the rail; then it is a handling line's defect, regardless of how it happened. That is why I say the wording is not right.

M. E. Fitzgerald: The motion will cover that particular case, but you have eliminated all of the other provisions of the rule. You have not followed it up with a provision covering the other paragraphs of Rule 32. The rule would then read that you are only responsible to the owner for a car derailed, cornered or sideswiped, not responsible for material stolen, etc., as incorporated in the rule.

F. C. Schultz (Chief Interchange Inspector, Chicago): I think this whole rule is wrong. The old system of combination is properly regulated. What is the difference whether one wheel or both got off?

M. E. Fitzgerald: I quite agree with Mr. Schultz that the rule is all wrong. We were arguing on a certain motion, however, and I think, taken in connection with Rule 43, you practically have the combination. There is no provision in Rule 32 protecting the owner or connecting line receiving a car so damaged, the car coming under Rule 43. I think this should be referred to a committee and settled here.

F. W. Trapnell: That is the way to handle it,—put in the combination.

Chairman Gainey: We can pass this over until tomorrow.

The motion was withdrawn.

M. E. Fitzgerald: Paragraph (E) reads:

Handling of cars with broken or missing couplers or couplers out of place.

Follow that by saying:

Except in cases provided for in Rule 33.

Make it owner's defect if you break a lift-bar on a man's car. It now can be billed against the owner under Rule 33 if you break his grabirons due to raking and do not bring about other damage. Under Rule 32, paragraph (E), it says that if you damage any part of the car due to coupling on to it another car, then it is a delivering line defect. They conflict. What are you going to do?

J. J. O'Brien (T. R. R. A. of St. Louis): As I interpret this rule, it was to obviate the general practice of the yard men in congregating bad order cars on a specified track with couplers out. The penalization was put there in order to make you handle your bad order cars carefully.

M. E. Fitzgerald: I quite agree with Mr. O'Brien, and we mark our bill "No bill," if you please, but still the rules conflict; one rule says it is the owner's defects and when it gets to the billing office they say that we are wrong in marking it "No bill." One of those rules should be corrected.

H. W. L. Porth: I believe the simplest way to clarify that is to change Rule 33.

M. E. Fitzgerald: In Rule 33, if you damage a car by cornering or sideswiping, you repair the defects and do not have a right to bill the owner because you have brought about other damage in connection with your safety appliance. I have produced a case where I did not bring any other damage about. I merely broke the two grabirons and a lift-bar.

H. W. L. Porth: In the damage to the side ladder, that would be in connection with the sideswiping, or other defects on the car that would denote sideswiping.

Secretary Elliott: I do not agree with you. We have lots of cases where there is no other damage to the car; ladders that extend out and are fastened on with half inch bolts in the casting, are torn off and do not touch the rest of the car.

H. W. L. Porth: I think that Rule 33 should be changed. We have a lot of cases where cars are sideswiped and there is no damage absolutely to the siding. Where grabirons and ladders are damaged we have no redress.

A. S. Sternberg: Paragraph (E) is all right in the sense cited by Mr. O'Brien but it is unfair where you break a coupler in the yard under fair usage and do not have some way to get at the repair track without being penalized. I would like to see that changed something like this: "Handling of cars with broken or missing couplers or couplers out of place unless handled immediately to repair trucks."

Secretary Elliott: There is no way to check that.

Rule 33

E. H. Mattingley: It seems to me that Rule 33 should be revised to read this way:

Owners will be responsible for the expense of repairs to safety appliances, while not involved with other delivering line defects, including items mentioned in Rule 32, except damage to running boards on tank cars when sideswiped or cornered.

A motion to recommend this change was made and seconded.

M. E. Fitzgerald: I move an amendment changing it to read:

Owners will be responsible for expense of repairs to safety appliances where not involved with other delivering line damages except as provided for in Rule 32, paragraph (e), and damage to running boards on tank cars when sideswiped or cornered.

Mr. Pellien: Why not ask some one acquainted with the billing end of the rules whether or not in cases cited by Mr.

Fitzgerald, billing could be taken care of without change in Rule 32 or Rule 33?

Mr. Martin (B. & O.): I would say as far as we are concerned, if the card comes in to us marked "No bill" we let it go and do not bill them. We have no right to change marks on a repair card.

A. Herbster: Suppose a card comes to your office marked "One side ladder broken, raked," and there is no notation on it? What would you do with that?

Mr. Martin: I would mark it "No bill."

Chairman Gainey: Every car foreman in this room, if a ladder is raked off, is charging the owner of the car for it if there are no other defects. Mr. Fitzgerald is talking about the end of the car where you couple another car on to it with a chain coupler, and damage your safety appliances. He wants the rule changed to say who is responsible in that case.

Secretary Elliott: Mr. Fitzgerald has a car with a coupler pulled out. That is owner's responsibility. In handling that to the repair truck he bends two grabirons. Rule 33 refers to safety appliances where not associated with other delivering line responsibility. He has no other delivering line responsibility.

C. M. Hitch: He has the handling line responsibility when he attempts to handle a car with a missing coupler, rams into another car and damages it. That makes him responsible.

A. Herbster: Prior to the insertion of "Except damage to running boards on tank cars when sideswiped or cornered," it was admitted that the damage to tank car in cornering was owner's defect. Tank car people recognized that fact and had this clause inserted to make it a handling line's defect so they would be reimbursed. They realized that if you sideswipe a car and tear off a grabiron, that was a minor defect and the owner should stand for it. We do not want to call it a handling line defect.

Mr. Martin: The question was asked what I would do if the car was marked "sideswiped." Go back a few years when we bent grabirons and when we did not have Rule 33. Some of you remember that it was almost an endless job to have those cases settled. I think it was the intent of Rule 33 to make safety appliances an owner's defect. But there is a conflict with Rule 32 and there is no question about it.

Mr. Fitzgerald: Take a car similar to the case I cited. I am going to mark my repair card, "Caused by coupling on to car number so and so, account draw-bar pulled out." I am going to send it to the billing office marked "No bill" and the billing department is going to check on me, which all good billing departments do. They are going to say, "Why did you mark that card 'No bill'?" I will say "Rule 32, paragraph (e)." But they will refer me to Rule 33. I had no other damage on that car. They have a technical right to take that exception, as it is clearly in the rules. I want that clarified.

Mr. Owen: If you were to include paragraph (e) as suggested, you would also have to include paragraph (g), "Shifting of loads from other cars."

The motion, as amended, was carried.

Rule 43

M. E. Fitzgerald: Referring to Rule 43, I move that the foot-note be changed to read as follows:

> In the case of damage to more than five longitudinal sills on wooden underframe cars, more than four longitudinal sills on composite wooden and steel underframe cars, more than three steel longitudinal sills on steel or steel underframe cars and both steel center members on tank *or other* cars constructed with two steel longitudinal sills only, the company on whose line such damage occurred must furnish owner statement showing the circumstances under which the damage occurred, if it is claimed that the damage was the result of ordinary handling. This statement in the case of cars reported under Rule 120 to accompany request for disposition of car, and in cases where it is not necessary to report car under Rule 120 to accompany the bill for repairs, *and to be furnished on request to receiving lines when cars are offered home in interchange where no Rule* 120 *request has been previously made.*

No company, tank car or otherwise, should receive any more consideration under the rules than any other car owner. Another reason is that cars are moving in interchange badly damaged, reaching the provisions of this rule, without any protection, and there is no provision in the rule to take care of a car so offered.

The motion was seconded and carried.

Rules 56 and 57

M. E. Fitzgerald: Referring to Rules 56 and 57, I make a motion that these both be eliminated.

The motion was seconded and carried.

Rule 58

M. E. Fitzgerald: With reference to Rule 58, I move that after the words "pressure-retaining valves" the words, "release valves and dust collectors where car is so stenciled," be included, for the reason that the rule is not clear and if a brake cylinder and reservoir is missing and offered in interchange, certainly the release valve is. We should protect all of the defects that could be associated with the other items mentioned in this rule.

The motion was seconded and carried.

Rule 60

F. H. Hanson (N. Y. C.): Referring to Rule 60, I move that a paragraph be added to Rule 60 placing an age limit for the removing of air hose for the reason that a great many roads already have an age limit. They remove the hose, say, when they become three years old. Other roads, possibly private line cars, allow their hose to remain on cars, and these are now being changed by roads that have an age limit. When you make out the bill you have to camouflage it and call it something else.

The motion was seconded and carried.

Rule 68

M. E. Fitzgerald: In connection with Rule 68, I move that it be changed to eliminate reference to delivering line's responsibility in connection with slid-flat wheels. I have no objection to advising inspectors what the limit is, but I want to make slid-flat wheels an owner's responsibility. The wording should be somewhat changed in order to do that, but I am not prepared to say how. There should be some instructions as to what a slid-flat wheel is.

The motion was seconded.

Secretary Elliott: Will you include in your motion that we eliminate reference in Rule 43 to Rule 68 also?

M. E. Fitzgerald: That is taken care of automatically.

The motion was carried.

Rule 70

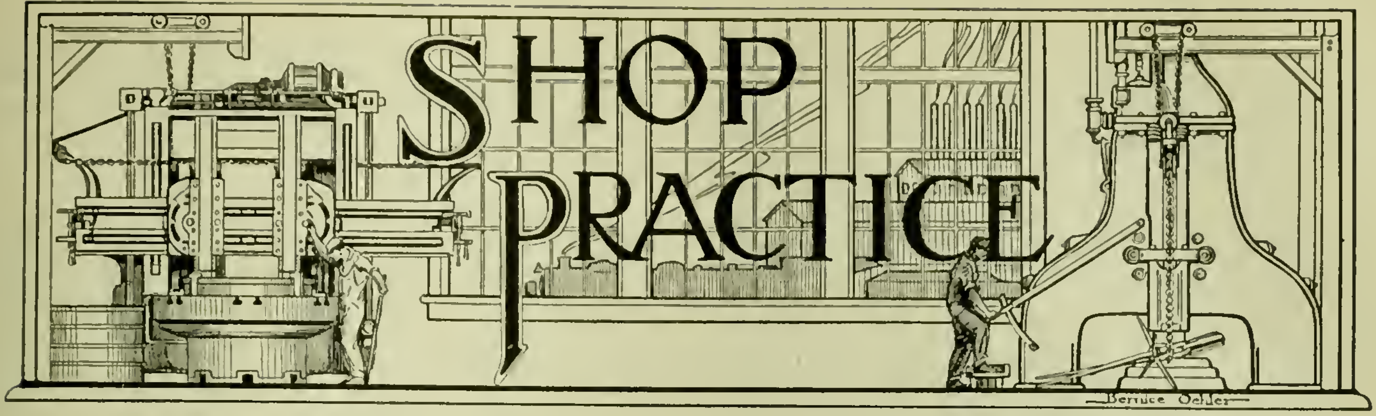
M. E. Fitzgerald: Referring to Rule 70, we have discussed the fact that defect carding for a cast wheel in place of a steel wheel is a joke. I move to eliminate Rule 70 so far as making the delivering line responsible. The owner is fully protected at the time the repair card is rendered. If you take out a pair of steel wheels and put in cast wheels, you owe the owner of the car some credit on the wheel. He has the right to get joint evidence and secure the same protection that he gets on other wrong repairs. He is not entitled to any other protection.

The motion was seconded.

F. C. Schultz: I used to feel that I could locate the man that put in the wrong wheels, but I cannot. They make changes without knowing they put them in. Inasmuch as the owner is protected, I think that this is entirely consistent.

A. Herbster: I think all of this change of wheels from rolled steel to cast iron took place during the railroad administration when no defect cards were applied. All of a sudden on a certain day the game was off and everybody commenced to slap on defect cards. That is the reason you could not locate the fellow that made the wrong repairs.

The motion was carried.



Uniform Heat Treatment of Steel*

BY H. C. LOUDENBECK

Engineer of Material, Union Switch & Signal Co., Swissvale, Pa.

To obtain uniform results in the heat treatment of steel is one of the most difficult of the heat treater's problems. Satisfactory results are dependent upon certain precautions which are often overlooked by the manufacturer. As a typical example, steel is purchased according to a specification that gives the desired physical properties when properly heat treated. The order is accepted by the steel mill and the steel manufactured and rolled accordingly. It is inspected by the purchaser's inspector who advises that it corresponds to the specification both chemically and physically and the shipment of the steel is then authorized. After it is received by the purchaser and perhaps retested, and he is satisfied that the proper heat has been shipped, it is unloaded in the stock yard either in a pile by itself or unloaded on a pile supposed to be of the same specification.

It is afterward discovered that through some error in marking the steel, it has been mixed with a heat having a different composition. The whole lot, however, has been delivered to the forge shop and made into forgings which were delivered to the heat treating plant, the results of which are obvious: irregularity, rejections, and endless trouble by the user. This is only one of the many irregularities which may be found after the steel has been received by the purchaser. For example, the steel may not be properly labeled or tagged or the tags may become lost and uncertainty exists as to the particular quality of steel stored in the yard. Again, parts of bars from the forge shop are returned to the yard, stored with steel of different composition, afterward made into forgings, the supposition being that the lot of forgings are identical in composition. From personal experience, the author is satisfied that great care should be used along these lines, especially as to the proper marking and storing of steel received in the forging yard.

What Is the Prime Requisite of a Foreman?

Must a foreman be a master craftsman in order to make good?

His job as a foreman is to inspire others and direct their efforts. He must be an executive, and, more than this, he must be a good business man, although this latter requisite is only just becoming evident in the railway operating world.

These requisites do not call for expert skill as a mechanic; they demand something very different and far more difficult.

What course should be followed in order to develop and select this kind of material for supervisory positions?

If possible, each heat should be piled separately in the yard and correctly labeled with the heat number and specification number. When this particular lot is used for the forgings intended, this heat number should follow on the forging itself. If this requirement is too great for practical forging operations, heats of similar physical and chemical properties may be segregated and given a suitable code number representing the quality of steel. For example, a steel requiring 0.40 to 0.50 per cent carbon may be divided into two grades, namely, 0.40 to 0.45 per cent carbon and 0.46 to 0.50 per cent carbon. This will enable the forger to make less changes in marking dies and will also require fewer changes in heat treating.

Another element which enters into the irregularity of heat treated forgings is the variation in the same heat of steel. For example, carbon and sulphur often vary considerably due to a segregated condition. Practically every heat varies more or less in this respect. Of course, this variation may be caused occasionally by mixed blooms of the mill but usually, it is due to segregation in the ingot which will cause a variation in the composition of the bars rolled from it. In other words, the blooms from the upper portion of the ingot will contain a higher percentage of carbon and sulphur than blooms from the lower portion of the ingot. It will be readily seen that bars rolled from these blooms will vary in proportion. A few examples on the variation of carbon in the same heat are illustrated as follows:

Size of ingot inches	Ingot No.	Heat No.	Carbon in per cent bottom of ingot	Carbon in per cent top of ingot
20 in. by 20 in.	4	4323	0.46	0.48
....	17	....	0.47	0.52
....	4	6933	0.49	0.50
....	12	....	0.46	0.50
....	5	4325	0.53	0.63
....	14	....	0.53	0.63
....	3	6934	0.45	0.53
....	1	....	0.45	0.51
....	5	4333	0.54	0.61
....	15	....	0.55	0.66
....	3	4335	0.47	0.50
....	10	....	0.44	0.51
....	4	7437	0.44	0.48
....	12	....	0.45	0.52

These are not exceptional heats. They were taken from the usual run of open-hearth practice. The ingots were cropped at the blooming mill until free of pipe as indicated by the shearing. This required from 20 to 35 per cent shear-

---

*Abstract of a paper presented by title at the Philadelphia convention of the American Society for Steel Treating.

ing. Samples were taken from the upper and lower bloom after the discard had been taken. It can be seen readily that bars rolled from the upper and lower blooms would have practically the same composition as given above. The sulphur in these particular heats was quite low, running not over 0.035 per cent, usually in the neighborhood of 0.025 per cent and no great segregation was shown in this respect. It would be interesting to observe the effect of high sulphur, say 0.06 per cent in the ladle analysis in regard to segregation since many contend that sulphur running 0.06 per cent or slightly over does not have a detrimental effect on the physical properties of the steel. While this may be true, it should be considered that most specifications specify that the drilling should be taken half way between the center and outside of the bar. When this is done it does not represent the sulphur which may be segregated in the center.

Our experience has been that segregation is more liable to take place when the sulphur runs over 0.05 per cent than otherwise. It has been found that where the sampling is done according to the accepted method, a variation from 0.06 per cent, half way between the center and outside, to 0.12 per cent, when taken from the center of the bar, this steel will not make a desirable forging and will cause considerable irregularity during the heat treating process.

Irregularity in physical properties of forging often is caused by variation in size and thickness of the forging at different portions, and in some cases this is very difficult to control in order to have a uniform hardness throughout the piece. For example, an axle having a pad considerably thinner than the main body of the axle will refine and harden much stronger than the main portion. While this is overcome, to a certain extent, in the drawing operation, the final results will show considerable variation in the parts. It is difficult to overcome this and it often is necessary to draw the axle so that it will show a minimum hardness in the body in order to bring the hardness on the pad to the maximum. In other words, a study must be made of the piece to be hardened before a definite program of hardening is accepted.

By abnormal heats is meant heats of steel having the proper chemical composition, but not having normal physical properties under regular heat treating. One particular heat which contained 0.36 per cent carbon and used for axle steel was difficult to refine with the ordinary process except in very small sections. Ordinarily no difficulty was found in hardening this steel to 250 Brinell by quenching in cold water from a temperature of 1,550 deg. F. However, in this particular case the maximum hardness obtained was 185 Brinell. The analysis showed it to be normal with the exception that it contained more than traces of aluminum. The steel manufacturer may draw his own conclusion as to the finding of aluminum in steel but we cannot but think it had something to do with the difficulty in refining the steel.

In our experience, cold water should be used for quenching wherever possible as it has better penetration and gives more uniform results.

The hardness of low carbon steels, however, can be considerably raised by quenching in a caustic soda solution. The strength of this solution should be 1 to 4. We have raised the hardness of a 0.20 per cent carbon steel from 185 to 300 Brinell by means of this quenching medium. This was obtained on a section about 3 in. by 4 in. It is necessary when using a solution of this sort to use a circulating system to keep the quenching medium cool.

Where oil is used it has been found that a grade of paraffine oil having a viscosity of 190 at 80 deg. F. gives good results. This is improved by the addition of a small amount of fatty oil. The addition of 20 per cent refined whale oil gives excellent results.

This article is intended to afford suggestions of a practical nature rather than a dissertation on the fine points of the art. Of course, it is understood that it is necessary to have the proper heat treating furnace, the proper temperature control, the proper time and manner of quenching, but unless the right grade of steel is provided for the purpose and steel of uniform quality, the results will be far from uniform.

Machining Driving Boxes

Various machines have been especially equipped for the rapid machining of locomotive driving boxes and generally some type of boring and turning machine has been used. In the case illustrated, an ingenious adaptation has been made of a machine intended for another purpose. A Sellers car wheel boring machine has been equipped with a two-jaw universal driving box chuck and proves very effective for the operation of boring the crown brass and facing the hub liner.

Sellers Car Wheel Borer Equipped for Machining Driving Boxes

The boring ram has been fitted with a head carrying a single boring tool and the facing operation is performed by the side facing head. The particular advantages of the machine are the ease and rapidity of centering the box by means of the universal chuck and the fact that no re-chucking is necessary for facing the hub liner. In addition, this arrangement eliminates danger of the hub liner being out of square with the bore of the box.

Cast Iron Cutting

The possibilities in cutting cast iron with oxy-acetylene have been demonstrated at a large Indiana manufacturing plant where, in remodeling some of the powdered coal furnaces in the power plant, it was found that the cast iron floor plates for the upper deck were several inches over size and would have to be cut off. The plates had been hoisted and bolted into position at one end before it was discovered that the other ends extended over instead of resting on the center of the supporting I-beam. The attempt to correct the fault by cutting off the excess lengths with drilling tools proved very slow work and, after two and one-half days of continuous drilling, during which time gangs of brick masons and machinists were forced to wait in idleness, only two of the four plates had been cut. The two remaining plates were cut in one hour and 45 minutes by oxy-acetylene operators, using standard Oxweld type C-6 torches, the work being done accurately so that the finished plates were found to line almost perfectly with the center of the beam. The plates were 1¼ in. thick and 60 in. long, the operation consuming 310 cu. ft. of oxygen and approximately 100 cu. ft. of acetylene. An interesting feature was the fact that the cutting was effected directly over and without injury to the beam.

Fuel Economy by Accurate Valve Setting

BY J. McALLISTER
General Foreman, West Albany Shops, New York Central

The possibilities of saving fuel by properly adjusting valves on locomotives equipped with outside valve gears are not fully understood. There are three methods of squaring valves on engines equipped with these gears: first, by equalizing valve travel; second, by equalizing lead, and third, by setting valves to correct, equal piston cut-offs. The first method is the cheapest and quickest as it does not require putting the engines on rolls. It is a simple matter to make a gage that will set the crank arm to an approximately correct position. Then all that is necessary is to scribe port marks on the valve stem, trail the engine and mark the valve travel, making what alterations are necessary to equalize the travel. In the second method it is necessary to place the engine on rolls in order to check the leads which are usually squared in the full gear.

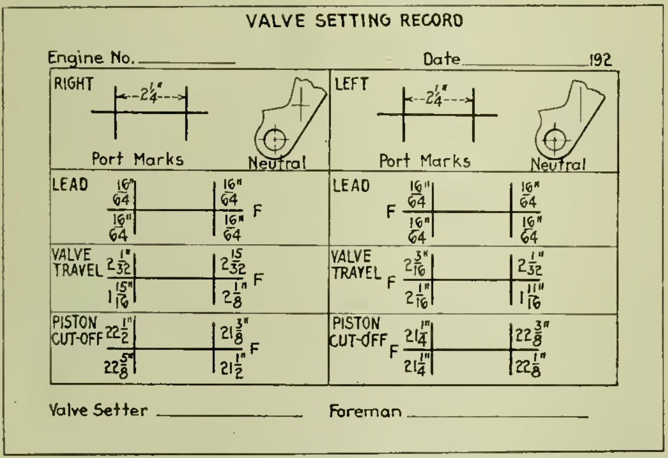


Fig. 1—Valve Events In Full Gear

The third method, although seldom used, is the only correct method of squaring valves. It is no more necessary that the ports open exactly the same distance than that they stay open the same length of time. In other words, the ports should stay open until the piston has traveled the same distance front and back, right and left.

In the third method the engine is placed on rolls with the main rods up and the lead squared in full gear as in second method, but the work is carried further: that is, the reverse lever is placed in the cut-off position (about 25 per cent), the engine run over and the piston travel measured at cut-off. Necessary alterations in the motion work will then make the piston travel the same at the points of cut-off.

It seems to be the prevailing opinion that if the valve travel or lead is equalized the other valve events will occur in regular order. Such, however, is not the case. On some locomotives, no matter how carefully the motion work is repaired and assembled, valve events do not follow in regular order.

The valve setting records shown illustrate this point clearly. These are not theoretical records, but copies of some filled out by the valve setter for an engine actually in service. Fig. 1 shows the lead, port opening and piston cut-off in full gear after alterations were made to square the lead. The lead was ¼ in. all around and attention is called to the fact that the piston travel at cut-off is one inch too great at the back end on both sides of the engine. The port openings are not at all in the same proportion.

Fig. 2 shows the events of the stroke with the reverse lever hooked up in the running cut-off position, no alterations being made. The piston travel is still about one inch too long on one side but has changed from back to front. The port openings are more equally divided.

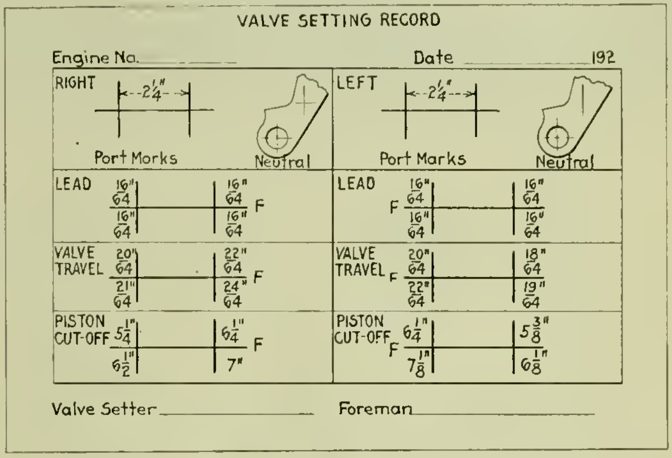

Fig. 2—Valve Events With Reverse Lever "Hooked Up"

The valve events after alterations were made to equalize the piston cut-off at 6 in. all around are shown in Fig. 3. Note the distortion of the lead, also that the port openings have crossed over, leaving the larger opening in back. This makes it evident that lead, port opening and piston cut-off do not follow in regular order.

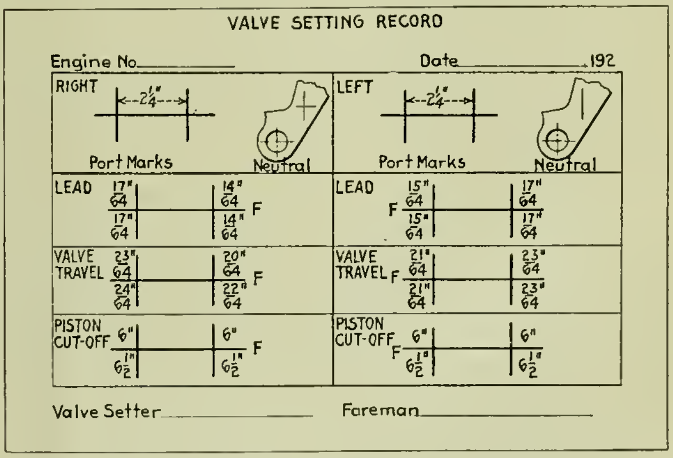

Fig. 3—Valve Events With Alterations to Equalize Cut-Offs

Unequal piston cut-offs have a serious effect on fuel economy. Assuming an engine is capable of making running time with a tonnage train at 6 in. cut-off, with valves squared as in Fig. 3, if the engine is held in shop and the leads are squared as shown in Fig. 2, the engineman cannot now make running time with the same train. The cut-offs will be at

5¼ in. and 6¼ in., and the reverse lever will have to be dropped. Assuming that the engine has either a screw reverse or a very fine tooth quadrant so it is possible to get a 6 in. and 7 in. cut-off, more steam than necessary will be admitted to each cylinder on each revolution. In other words, coal used to make that steam will be wasted and the total amount so lost in each trip will be considerable. The total amount wasted on all divisions will represent a serious economic loss to the country.

It is felt that the conditions found on this locomotive are by no means exceptional and resultant savings are large enough to warrant the most careful attention to squaring and equalizing the cut-offs in valve setting.

Some Facts Regarding Bearings

BY LOUIS A. SHEPARD

President, Hart Roller Bearing Company, Orange, N. J.

The use of ball and roller bearings which are correctly designed and accurately made in transmissions, machine tools and all machinery, subject to heavy, continuous operation is essential to reduce friction. Instances are known where the power saving over plain bearings in large factories so equipped has amounted to as much as 50 per cent, but this is exceptional. Ordinarily 15 to 25 per cent is more nearly correct. Undoubtedly there is a saving, which in medium sized factories even, is very appreciable in the course of a year and is a great help in reducing the overhead expense.

Not only is there a saving in power, but by using bearings particularly adapted to the machines, almost continuous operation is insured and the annoyance of shut downs to reline, adjust or replace plain bearings is avoided. This alone more than compensates for any increase in the first cost of application of the anti-friction bearings, for the loss of time and product is far in excess of any ball or roller bearing costs.

It is a well known fact that workmen usually do not give the proper attention to the cleaning and lubrication of plain bearings. In consequence great friction develops, the bearings burn and wear out quickly and generally require renewal at just the time when the shop is busy and machinery should operate continuously. In many cases repairs are made over the week end, but this is expensive and pay for overtime counts up rapidly. A properly designed ball or roller bearing, packed with the correct lubricant properly enclosed will operate at least fifty times longer than a plain bronze or babbitted bearing under the same conditions. This also makes a big saving in the amount of lubricating oil which must be used.

Often too little attention is given to the mounting and enclosing of the bearings, which can be so enclosed as to maintain the lubricant for long periods of time and prevent oil leaking or dripping on the floor or on material which is being manufactured. The load carrying capacity and speed of operation of ball and roller bearings exceeds that of the plain, bronze or babbitted bearings. Also ball or roller bearings having no adjustments are fool proof and will outlast other parts of the machine. In certain cases of adjustment being provided in machines the mechanism has been practically ruined by workmen tampering with such adjustments. As an additional advantage economies in space can be achieved by replacing the plain, bronze or babbitted bearings with ball or roller bearings.

In a sense the ball and roller bearing each has its particular field, yet a correctly designed roller bearing is generally superior to a ball bearing for load carrying purposes. Because of inherent features of design, a ball bearing is usually best suited to carry relatively light loads at high speeds of rotation. A roller bearing, on the other hand, is superior to the ball bearing for carrying large loads at moderate speeds and is admirably suited for installations where shock loads are encountered. A ball bearing cannot successfully absorb shock loads unless its rated capacity is far in excess of that which a roller bearing must have to carry successfully the loads occurring in the actual operation of the machine.

Given a ball of certain diameter and a roller of the same diameter with its length equal to the diameter, the roller will, for a given load, have a greater surface contact with its raceway than the ball. The direct compressive stress over this area of contact will therefore be smaller for the roller than the ball. Assuming a maximum safe working stress, the roller will safely carry a greater load than the ball at all speeds of rotation, since the drop in capacity at different speeds, due to fatigue stresses, is approximately the same for each. Size for size, made of the same material, and operating at the same speed, the roller bearing will, for a stated safe working stress, generally carry approximately 50 per cent greater load than the ball bearing. On the basis of dollars per pound capacity it is evident, therefore, that a roller bearing is a more economical installation than a ball bearing.

As the ball makes contact with its raceway under load, a certain area at the top of the ball and a certain area at the bottom of the ball, differing slightly in magnitude, will be in direct compression. The form of this surface contact area will be a warped ellipse. As a result, instead of having point contact at the top and bottom of the ball, surface contact occurs and a series of points on each side of the highest point of the ball will be touching the raceway. Since the ball should theoretically rotate about its own axis, and since the speed of rotation of a point on the periphery of the ball varies as the distance from an axis through the center of the ball, it follows that for any load applied to the bearing there will be a certain amount of slippage. This slipping tendency will further increase with an increase in load since the surface contact increases with increased load. The result is a sliding effect on the raceway which slowly but surely grinds it away. Slippage is not met with in correctly designed roller bearings. All points on the periphery of the roll necessarily have the same velocity at any stated speed of rotation of the bearing. Ball bearings are therefore limited in load carrying capacity by practical reasons in addition to the theoretical considerations already advanced.

A great many ball bearings are designed to carry both radial and thrust loads simultaneously, by employing angular contact between balls and races. Since it is a practical impossibility so to design the bearing that the velocity of each point of contact will be the same an additional spinning action is introduced.

This tendency, together with the slippage resulting inherently from any contact between balls and races, causes two different and distinct spinning effects on the raceway. For any appreciable radial and thrust load the wear and tear on the raceways is of serious import. A bearing should be designed for the performance of one function only. As one manufacturer of high grade ball bearings states in his catalogue, "radial and thrust loads cannot be carried ideally in one bearing simultaneously. Where combined radial and thrust loads must be carried, combination bearings (one radial and one thrust) assure maximum efficiency and durability."

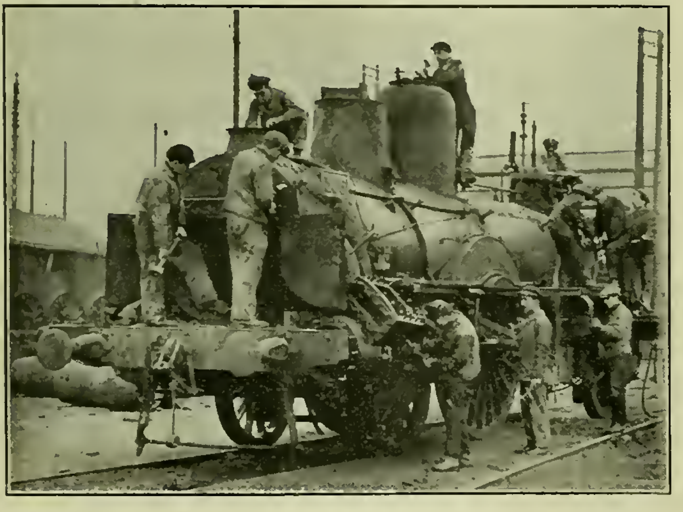
In any ball or roller bearing it is desired to obtain true rolling motion, revolution of balls or rollers around their axes in parallel planes, which means freedom from slippage and skewing and elimination of wear on parts. Load carrying capacity and speed also have to be considered. A properly designed and accurately manufactured roller bearing fulfils these requirements and becomes a money saving investment.

Paris-Orleans Apprentice Class Studying Mechanics

Paris-Orleans Apprentice Work Organized[*]

A Description of the Development of Courses for Apprentices of the Paris-Orleans During the War

THE Paris-Orleans during the war developed apprenticeship in its large repair shops and engine houses in 27 localities (37 apprentice schools). Schools at two large repair shops in Tours and Perigueux train apprentices for the various special work of repairing locomotives, cars, and trucks. Apprentices are trained at roundhouses with a view to doing repair work on locomotives and later, for recruiting as enginemen. In some exceptional cases they are also trained as boilermakers, machinists and blacksmiths at roundhouses. The total number of apprentices at these various points at the present time is about 1,200. The apprentices are given professional instruction of the widest possible range, and as wide a theoretical instruction as their intelligence and length of apprenticeship permits.



Locomotive Being Stripped by Second Year French Apprentices Before Being Taken Into Shop

The practical training is based on the following principle: "Apprentices should be watched and trained as carefully in their work as in their studies." Work which has no practical utility is reduced to a strict minimum and as soon as their professional knowledge allows the apprentices undertake practical work. The result of this method is to interest the apprentice who, knowing that he is doing useful work, puts more energy into it. He is paid from the start, being employed on useful work, and this helps lighten the burdens of his family.

The theoretical training consists of French classes, arithmetic, geometry, physics, mechanics, drawing and technology classes which occupy the apprentice about six hours a week.

Terms of Admission

The age of admission is between 14 and 17 years, according as the candidates are or are not holders of a certificate for primary studies. However, in the case of young men with a higher education (pupils of secondary schools) the age limit of 17 years may be raised. Apprentices answering to the above conditions and who have made a request for admittance, signed by their parents, either to the chief offices of the company or to the staff department in Paris are called to undergo a medical examination and a short entrance examination composed of: Dictation of 20 lines, with some grammatical difficulties; problems on the four rules and on one question of surface and volume; division of whole numbers, with proof by multiplication; reading.

After this examination, the candidates who have passed the medical examination are classed in order of merit and admitted according to the number of places vacant. Preference is given to sons or relatives of employees, to children of large families and to apprentices who already have some knowledge, that is, who have taken the pre-apprenticeship classes or supplementary classes.

Every boy binds himself to finish his apprenticeship in the establishment and the trade where he began and to remain in the company until his military service. An apprenticeship contract to this effect is signed jointly by the boy

---

[*] Translated and abstracted from an articles by M. Lacoin, chief assistant engineer, and M. Chassagne, mechanical engineer of the Paris-Orleans, in the August, 1920, issue of the Revue Generale des Chemins de Fer.

and his parents or guardians. The penalties for breaking this contract are: non-payment of the cash prizes mentioned below, which are normally paid at the end of the apprenticeship; proceedings against the parents or guardians for damages or injuries caused to the company by the apprentice leaving.

The number of apprentices in each establishment is regulated so that the total number of apprentices and workmen who are minors, does not exceed 25 per cent of the adult staff of workmen in any shop. Each apprentice remains on an average five years in the establishment before his military service. The number of apprentices admitted each year is therefore, on the average, five per cent of the strength of the adult staff of workmen in the establishment.

Instruction of Apprentices

The instruction given to apprentices consists of a professional manual education complemented by theoretical explanations, arithmetic, drawing and spelling, which last for about six hours per week. Wherever possible, apprentices are grouped in the workshop under the supervision of an instructor who is thus enabled to direct the instruction of 10 to 15 apprentices.

The employment of a single instructor has the advantage of allotting to this post the best qualified workman and gives to the new apprentices a single plan of work, which depend upon the instructor's qualifications. It also permits of more individual instruction, the apprentices being taught orderly habits of work and good conduct.

As far as possible, an instructor is chosen who is able to direct practical and theoretical instruction of the apprentices at the same time, thus maintaining a constant connection between the two branches. This object has been attained in some shops, but it is difficult to find teachers who unite practical and theoretical knowledge and in some large centers special teachers have been employed for the theoretical classes, keeping in as close touch as possible with the practical instructors.

Apprentices in Enginehouses

The program of practical instruction in the engine houses is slightly different from that in the repair shops because the former are only called upon to train engine fitters who can later become engine drivers and directors of repairs to locomotives.

The apprentice school program of the enginehouses is as follows: *First year.*—Half the day, the morning by preference, is devoted to methodical and progressive practice in fitting and to theoretical classes (18 hours fitting, and six hours of theoretical classes per week). The rest of the day is taken up by practical work in the repair of detail parts. The program of progressive exercises to be carried out by the apprentices is given in a book of machining notes and includes a course of work of about 10 months on the average. To complete the first year of practical instruction, apprentices who have performed their progressive exercises well are given supplementary exercises chosen from the following work: making or repairing face plates, V-ways, shifting-gages, various keys, screw and case dies, hammers, graving-tools, chisels, spanners, etc. Drilling machines, pneumatic hammers, parts of machine-tools in the workshop, etc., are overhauled and repaired.

Second year.—In the second year the apprentices cease to be systematically employed on the vise. The "mounting" apprentices are, wherever the number makes it possible, grouped in special gangs aided by one or two chosen workmen and a small number of laborers.

Thus organized, they carry out in its entirety the half-yearly and yearly repairs to simple locomotives or in some cases to compound locomotives, including the fittings, cocks and valves. This arrangement makes them learn all the work of mounting while preventing them from being employed as minor laborers, as is too often the case when apprentices are placed in a gang of workmen.

In localities where this arrangement cannot be carried out the "mounting" apprentices are either united with the third year apprentices or with the minor workmen to form a special gang under the conditions mentioned above, or grouped under the direction of an instructor to make part of a repair gang. They are not placed alone in the gangs even with a good workman. By isolating them in this way there is too much risk of making lesser hands of them, whose professional training would be mediocre.

The instructors see that they do not do work which is beyond their strength, and make each apprentice take the different places in the gang so that they do not specialize.

First Year Apprentices in Fitting Shop of Paris-Orleans

Third year.—In the third year the apprentices are still supervised and like those of the second year are grouped in special gangs under the direction of a chief mounter or chief of a group and carry out the half-yearly and annual repairs to locomotives, modern ones by preference, taking the place of the ordinary gangs entrusted with these repairs. In establishments where their number is small, they are united under the supervision of the chief of a group of men who have just finished their apprenticeship, thus forming a special gang. The best third year apprentices are made use of as monitors in the second year gangs.

In the course of the third year the apprentices also take in rotation a course of one month each in the forge, boiler and machine shops respectively. These courses, the program of which is drawn up in the beginning of the year, are described in a special notebook so that their proper execution can be checked by the inspectors. After completing the course, apprentices in roundhouses have a knowledge of locomotives which is a great aid in helping them to qualify as firemen and later enginemen.

Apprentice Work in Repair Shops

The program of practical instruction in the repair shops is as follows: apprentices (except those in wood-working, painting, upholstering and molding, who are few in numbers, and who begin immediately in their respective workshops) are placed in a school for iron-workers situated in the fitting shop. In this school they follow a program similar to that for apprentices in the enginehouse, and their time is divided between study and practical work. After six months they take a professional examination, the result of which is taken into account in deciding their definite distribution among the classes of mounters, fitters, machinists, boiler-makers and blacksmiths. In this distribution the physical aptitudes and tastes of the apprentices are also taken into account. The classification once made, the fitter and mounting apprentices remain in the iron-workers' school where they follow an identical program to that of the apprentices in the enginehouse. The boiler-maker apprentices and the blacksmith apprentices are placed in two special schools where they follow practical courses extending over a year.

The instruction given in the boiler-makers' school includes: a knowledge of descriptive geometry necessary for tracing the intersection of solid materials; tracing of sheet-irons in general; finally, the manual work of a boiler-maker.

The instruction given in the blacksmiths' school includes the theoretical rules for blacksmith modelers, the rules of soldering and the general work of a blacksmith.

After a year in the special school, that is to say about 18 months in the company, the boiler-maker and blacksmith apprentices are considered to have finished the special courses necessary to a knowledge of their trade and are placed in the boiler-makers' and blacksmiths' workshops where they do only practical work under the direction and with the advice of experienced workmen.

Theoretical Instruction

The theoretical instruction of shop apprentices covers three years. In the second year the apprentices revise the work already studied in the first year, and in the third year they take a special course of technology. Experience has shown that this procedure gives good results and has moreover the advantages of facilitating the organization of the classes.

Theoretical classes are held every year from October 1 to July 31. They last for six hours a week during the two first years at the rate of four sittings of about one and one-half hours, and only one and one-half hours per week in the third year.

The total number of instructors is 47 and the classes they teach are in addition to their normal work. They are distributed as follows: master mechanics, three; foremen, six; checkers, sub-inspectors, two; assistant foremen, ten; heads of gangs, nine; workmen, two; employees, 15, six being ladies.

First Year Apprentices in Forge Shop

Instruction is by means of specially written elementary courses drawn up by a central department and distributed to the instructors and to the apprentices. Abstract methods of explanation are avoided by referring to the various operations and apparatus used in the workshops and conducting demonstrations with the apparatus itself. The explanation of the lesson is aided by frequent questions to the pupils, followed by a short résumé.

The first and second year courses, which are the same, include 170 lessons in general technology, drawing and sketching, French, arithmetic, elementary physics and mechanics. The third year apprentices have at their disposal a course of study in technology including 40 lessons, one per week affording an elementary knowledge of the locomotive. This instruction is given in the form of appendices, the details of which are given below:

Appendix 1.	Boiler	6 lessons	30 lessons
Appendix 2.	Wheels, frames, suspension	4 lessons	
Appendix 3.	Parts, motors, arrangement of mechanism	15 lessons	
Appendix 4.	Various parts, special devices, tender, boiler, work and reading of graphs and diagrams	5 lessons	

These lessons are given by means of sketches, demonstrating apparatus and the parts of the machines themselves, either in the lecture room or in the workshop.

In the course of the three years the apprentices take oral and written examinations at the end of every half-year, in order to show the progress made. These also serve as a basis for proposals for increase of wages and bonuses, which are mentioned further on.

The apprentices' instruction is also at all times checked by means of questions put by foreman and higher agents of the central department on their rounds in the instruction centers. This checking of the apprentices' knowledge is also a check of the teaching given by the local instructors. Instructors should realize that technical instruction is only one part of the professional training, and that it is equally important to instil into the apprentices habits of discipline, order, method, self-respect, in a word, give them a moral training.

Competitions and Remuneration

Competitions are arranged at the end of the first year's apprenticeship after the half-yearly examinations, among the best students in the various shops and roundhouses of the company. At the end of these competitions there is a distribution of prizes, books and instruments, to the prize-winners. At these distributions, apprentices who have satisfactorily finished their apprenticeship receive a savings-bank book in which are inscribed the amounts of the various half-yearly bonuses accorded during the course of their apprenticeship, and an "end of apprenticeship" diploma.

The apprentices commence work at 25 cents, 30 cents or 35 cents per day, according to their value and their age, with successive increases based on the results obtained during the course of the apprenticeship. The apprentices may, therefore, attain at the end of their three years' apprenticeship, a daily wage equal or superior to that of the best junior workmen in the shop. They also draw special allotments on account of cost of living and residence, and those who have had more than 18 months' apprenticeship receive a premium of 10 cents per working day.

In order to interest parents in the children's work, the apprentices' progress is shown every month in an individual notebook in which is recorded professional skill, theoretical instruction, conduct, money advances allotted, and money drawn. This notebook is signed by the officer in charge of the apprentices who writes in it any observations he thinks it useful for the parents to see. The latter also sign this notebook after having noted each month the remarks made therein. The parents are also directly communicated with when their son does not give satisfaction in his work or his conduct, and are advised of all punishments he undergoes.

Second Grade Apprentices

Those young men who, in the course of their first year of apprenticeship, show that they are capable of attaining a higher degree of efficiency than the average, are allowed to follow extra classes called "second grade," which last three years. These young men have a special contract with the company signed by them or their parents or legal guardians.

A résumé of the second grade classes is given below:

Theoretical Second Grade Classes

First Year

1. Arithmetic.
   Algebra (functions of equation of the 2nd degree).
2. Geometry, plane and solid.
3. Mechanics (elements up to the determination of the centre of gravity).

Second Year

1. Mechanics (static and dynamic).
2. Physics.
   The Steam Engine.
3. Geometry, ordinary graphs.
   Descriptive Geometry (elements).
   French.

Third Year

1. Mechanics—rudiments of resistance of materials.
2. The Locomotive.
   Internal Combustion Motors.
3. Descriptive Geometry, drawing.
4. Electricity.
   Chemistry (rudiments).
5. Rudiments of political economy.
   French.

The second grade courses are carried on by means of correspondence. The pupils belonging to the different shops of the company receive the necessary directions for their studies from the chief agent and four assistants in charge of this course of instruction, who reside in Orleans. A summary of the lessons to be learned and instructions as to the works and pages to be consulted is sent to apprentices on Friday of each week. They have to make a résumé of the lessons learned in this way in a special exercise book, and this book is sent every two months to Orleans to be examined.

Second grade apprentices only study in common with their companions of the first grade, the technology and drawing classes. But so as to facilitate the study of the second grade program, three periods of study per week of 1½ hours each are given. These take place preferably during the time of the French classes, calculation, geometry and first grade physics, which they do not attend. It is necessary for them to complete these studies by private study outside of working hours.

An examination is held every six months, on the subject matter studied during the previous half-year. It includes written tests followed by oral tests. These oral examinations take place before a special commission which visits the principal centers where the pupils are grouped. They test by the questions put how the pupils are assimilating the knowledge which is being given to them by correspondence, and take advantage of this meeting to complete the knowledge required, explain and clear up the points which are obscure. At the end of the year, the best pupils receive prizes like the first grade apprentices. There are 32, 22 and 30 second grade apprentices in the first, second and third years respectively.

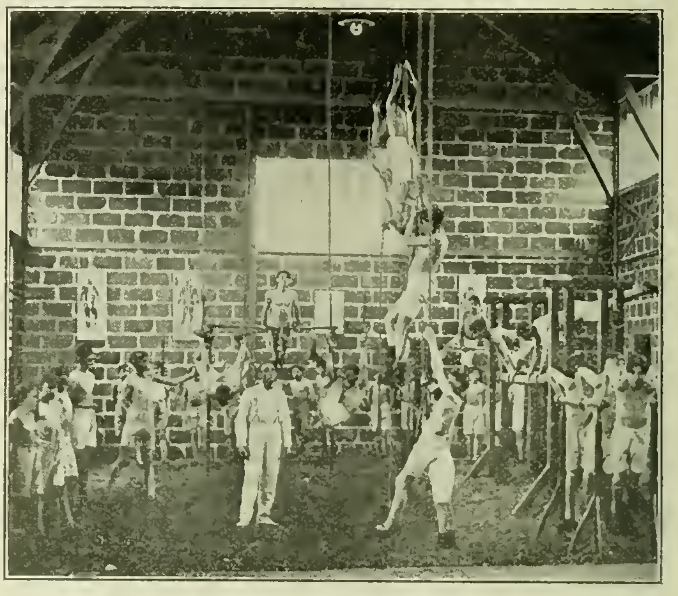
Physical Culture

With the object of improving the physical development of the young men, the company encourages an interest in sport among its staff, and especially among the apprentices. The heads of local departments take an interest in the work of physical development and to this moral aid is added pecuniary aid consisting in annual subscriptions to the sports associations formed by the employees of the company. At present there are nine associations of this kind. The company has, moreover, furnished a room in the repair shops at Tours and Perigueux, and organized classes for physical development for apprentices of less than 18.

Results Obtained

One of the greatest obstacles which is encountered in apprenticeship is the instability of the apprentices. They leave their employers as soon as the apprenticeship comes to an end, and even during the course of the apprenticeship. As a matter of fact, the wastage, which was fairly large before the reorganization of apprenticeship on the Paris-Orleans, has considerably diminished. The way in which apprenticeship is made to lead directly to the railway trade, and the various bonuses which are only paid at the end of the period of apprenticeship have a good effect. At the last promotion the wastage at the end of the third year did not exceed one per cent.

The apprentices who have followed the complete course after reorganization are sufficiently numerous to allow of estimating exactly the value of trained workmen. They have shown themselves clearly superior to the average of the workmen who were engaged before the war after military service. The output of the gangs of second and third year apprentices is excellent. As the total number of apprentices was 1,200, it may be hoped that the former apprentices will in future form the nucleus of the whole working staff, and that a very appreciable rise in professional and technical value will result.



Gymnasium for Apprentices on the Paris-Orleans

The second grade apprenticeship has shown each year about 30 young men who are of clearly superior capacity to the average and anxious to improve their knowledge. The second grade work, which is done outside the hours of manual labor, requires much energy and tenacity on the part of the apprentices. It may therefore be hoped that the old second grade apprentices will have the energy, and assure the basis of recruiting for head workmen, foremen, chief mechanics, and a part of the chief assistants in the shops, and that the result will be a still greater improvement of the average professional value among this class of employees.

It would be interesting to estimate the economic output of the organization apprentice which is, however, difficult to do with exactness on account of the complexity of the problem. The wages paid annually to the apprentices are about 3,500,000 francs. The general cost of the instruction is about 100,000 francs. The machinery which the apprentices repair is at a standstill a little longer than that which is repaired by regular gangs of workmen and this concludes the debit side of the apprenticeship account.

The credit side is more difficult to establish. The work done by the apprentices is in the first year very decidedly below the cost of the apprenticeship. In the last year the situation is reversed. On the whole, it seems that the value of the work produced corresponds very well to the cost of apprenticeship. We may therefore consider that the improvement of facilities for recruiting and developing valuable employees will be a clear profit.

Four Efficient Santa Fe Machine Shop Devices

Too Much Attention Can Hardly Be Given to Jigs and Fixtures Which Really Save Time or Labor

BY J. ROBERT PHELPS
Apprentice Instructor, Atchison, Topeka & Santa Fe, San Bernardino, Cal.

IT is often possible by the use of comparatively simple jigs or shop devices to extend either the range or kind of work performed on machine tools, the following devices having been developed and tried out with good success at the San Bernardino shops of the Atchison, Topeka & Santa Fe.

Turning Bevels on a Boring Mill

A device, used on a boring mill when cutting bevels or slants, as found on piston valve spiders, followers or bull rings, is illustrated in Fig. 1. A lathe may not always be available for this work and in a certain case a large number of spiders and followers had to be turned on a boring mill. As the mill feed forced the tool out, it was necessary for the machine operator to maintain the down feed by hand, just enough to give the piece being machined the desired taper. In order to tell when the down feed was correct, the device illustrated was developed.

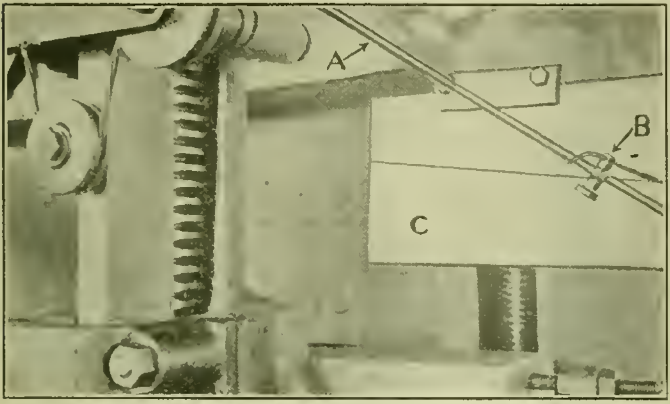


Fig. 1—Bevel Indicator Applied to Boring Mill

A 5/16 in. round steel rod *A* is electric welded to a rod key base plate approximately 5 in. by 2 in. by 5/8 in. To add stiffness, a shorter electric welded rod extends from the base plate to the initial rod at a point about 12 in. from the base. The base plate is fastened to the top of the boring mill tool bar by means of two 3/8 in. cap screws through suitable holes in the base plate, a standard surface gage scriber *B* being slipped on over the 5/16 in. rod. A piece of sheet iron *C*, chalked or white washed is secured to the frame of the boring mill as shown, and a line drawn on it at the required slant or angle which it is desired to cut. With this arrangement it is comparatively easy for the machine operator to feed the tool down by hand just fast enough to keep the point of the scriber on the line. The principle can also be readily applied in machining to an irregular line.

Removing Lathe Chucks

The method of swinging a lathe chuck out of the way to make room for a small job between the centers is illustrated in Fig. 2. On this particular lathe, it is often necessary to take off the chuck several times a day. With the arrangement shown a right angle arm *A*, arranged to swivel, is secured by means of brackets to the back of the lathe. Rod *B* with an adjusting nut on the top and a threaded lower end passes through a hole in arm *A*. The chuck is drilled and tapped to receive one end of rod *B* which has been previously threaded.

In operation, the chuck is loosened on the lathe spindle and the bolt *B* is turned into the chuck, the adjusting nut at the top being tightened until all slack is taken up. The lathe is then run back either by hand or power and the chuck comes off and can be readily swung back out of the way. After the job between centers has been done, the chuck can be swung forward and easily re-applied. This arrangement makes it possible for one man to handle a heavy chuck easily and in addition the chuck is kept off of the floor where it would be in the way and accumulate dirt.

Combination Square Attachment

An attachment to be used on a combination square in setting up driving boxes for boring is illustrated in Fig. 3. It is essential that the boxes be bored parallel with the shoe and wedge faces and at right angles to the hub faces. This device affords a convenient and effective means of checking the driving box set up.

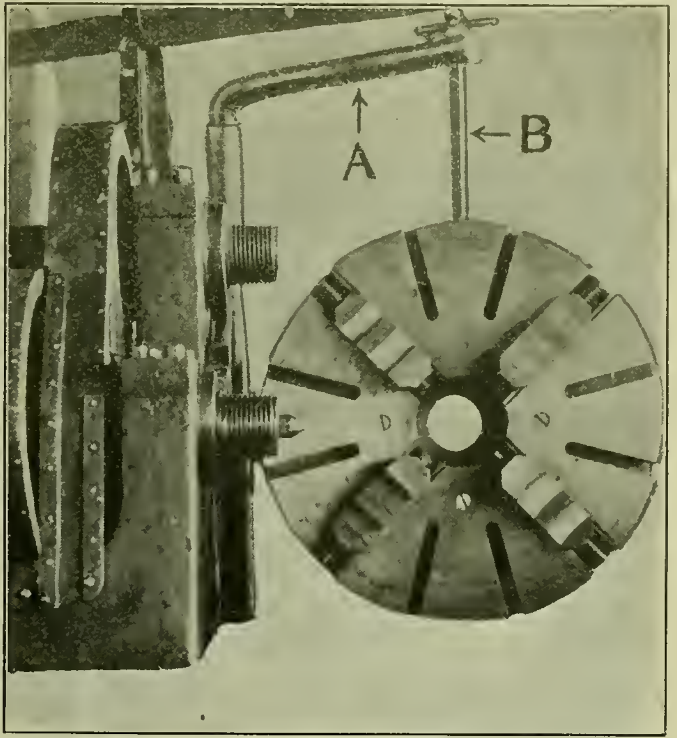

Fig. 2—Swinging Arm Facilitates Removal of Chuck from Lathe Spindle

As shown in the illustration, the device is simple and consists of a piece of sheet metal drilled with five holes to reduce weight and attached to a sliding head which may be held in any position on the scale by means of a thumb screw. The plate reaches over the driving box flange and makes it unnecessary for the operator to caliper from the scale over to the shoe and wedge way. He can tell at a glance whether the box is set up so that the bore will be parallel with the shoe and wedge. Approximately 180 boxes a month are being machined at this point and while this device saves only about three minutes on each box, the total saving in time is important. In addition the device makes possible more accurate work.

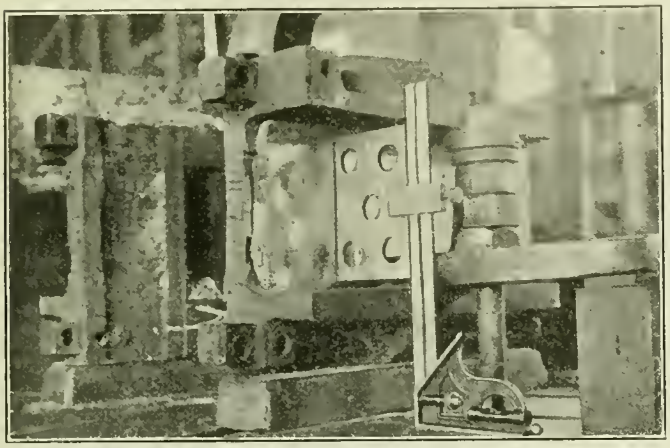

Fig. 3—Combination Square Attachment Aids in Setting Up Driving Boxes

Extension Table for Milling Machine

In cases where it is desired to perform a small milling machine operation on the end of a shaft or long machine part the extension table and V-blocks, illustrated in Fig. 4, can be used to good advantage, saving a considerable amount of time in setting up and assuring an accurate job. As shown, a slot is planed in this extension table or plate square with a rib on the under side so that in applying the plate all that is necessary is to tighten up two ⅝ in. by 2½ in. bolts to have the table square. Two V-blocks are arranged to slide back and forth in the groove as shown so that they will be square with the table in any position. This device opens up the machine to a much wider range of work, as for example the boring and facing of rocker arms on the boss ends and other similar machine operations.

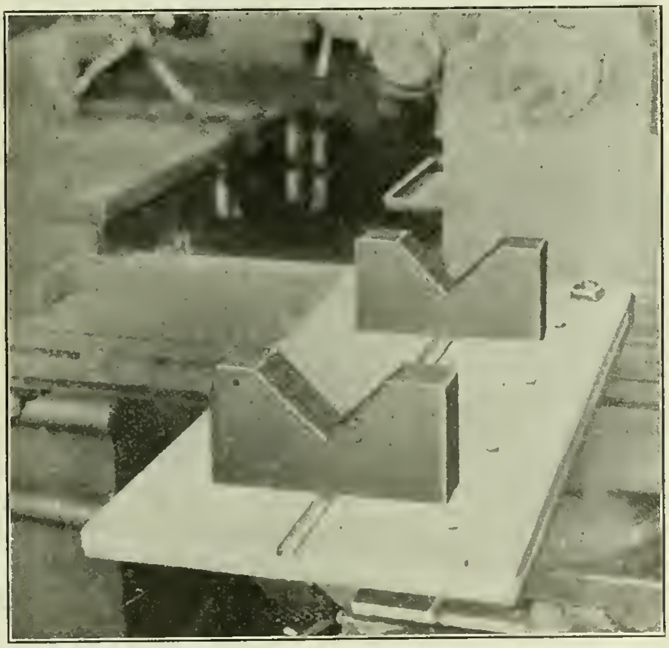

Fig. 4—Extension Table and V-Blocks for Milling Machine

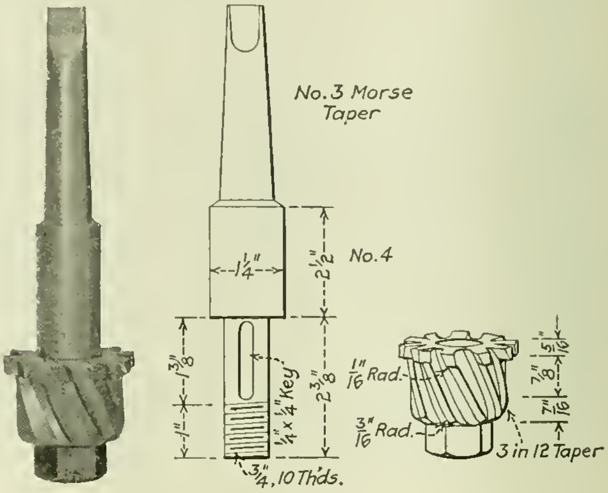
Reaming Tube Sheet Holes

BY GEORGE BREXTON
Tool Foreman, Grand Trunk Shops, Stratford, Ont.

For the rapid and smooth reaming of tube sheet holes, the tool illustrated has been found very satisfactory. Reamers formerly used for this work consisted of a roughing reamer of the shell type and a straight flute, finishing reamer for finishing. The roughing reamer had a taper of ⅜ in. in 12 in., but was found to be useless in the hands of a careless operator owing to the fact that there was no gage to indicate the size of the hole which, in many cases, was made larger than necessary. In addition, the long, spiral flutes caused a great deal of difficulty from sticking. The objection to the straight flute finishing reamer was the leaving of chatter marks and the necessity of changing from a square to a No. 3 Morse taper socket.

The new reamer, illustrated, is designed to perform both operations of roughing and finishing. It is made of Mushet high speed steel having a radius of ⅜ in. on the bottom cutting edge enabling it to remove rapidly any ragged edges or marks left by the ripping tool. A taper of 3 in. in 12 in. is provided on this reamer for a distance of 7/16 in. as indicated. This tapered section rounds out the tube hole and the ⅞ in. parallel cutting edges finish it to the correct size.



Reamer for Roughing Out and Finishing Tube Sheet Holes

A round filleted shoulder at the top removes the sharp edges on the tube sheet and prevents the copper ferrules from being cut in the process of beading or expanding. The reamer is detachable from its spindle as shown in the illustration, being held from revolving by a ¼-in. key. The spindle is machined to a No. 3 Morse taper. On account of the removable feature, the reamers can be changed easily from one size to another with the aid of a short ¾-in. spanner or wrench to tighten the holding nut.

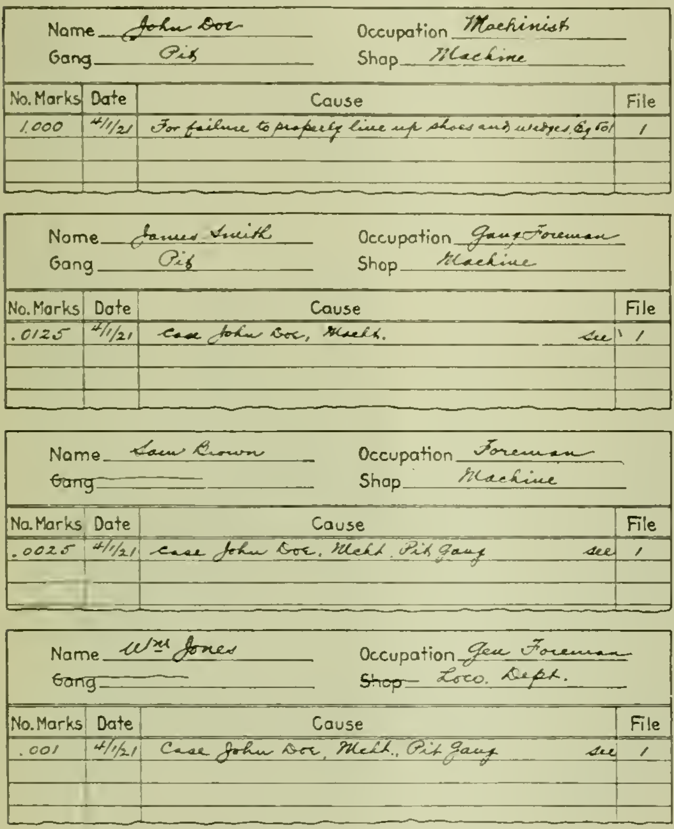
Protecting Metals at High Temperatures.—Calorizing as a means of protecting metals exposed to high temperatures is discussed in an article by Arthur V. Farr, recently published in the *Iron Age*. The treatment fuses aluminum into the exposed portion of the metal so as to form a homogeneous aluminum alloy for a certain depth, ranging from a few thousandths of an inch to the permeation of the entire mass. The formation of the oxide, alumina, prevents the penetration of oxidizing gases. The aluminum oxide surface must be preserved unbroken, and for this reason, machining is best done before the calorizing process. Calorized parts have been successfully used for carburizing and annealing boxes, pyrometer protection tubes, stoker parts, conveying apparatus, for furnace linings and baffle plates.

A System of Progressive Shop Discipline

Foremen and Men Are Held Accountable for Mistakes In Proportion to Their Individual Responsibility

BY GRANT GIBSON

An editorial published in a recent issue of the Railway Age contained the following statement: "The selection of men for prospective foremen should not be left to chance, as past experience has amply demonstrated the possibility of keeping personal efficiency records whereby the master mechanic or shop superintendent is enabled to tell at a glance which one of his employees will probably best fill a vacancy among the foremen."



Name John Doe Occupation Machinist

Fig. 1—Card Form for Individual Records

The above statement is true and there is no reason why efficiency records should not be maintained in railroad mechanical departments, as well as in transportation departments where the Brown discipline system is generally adopted. The latter system shows the merits and demerits of employees in the transportation department and the superintendents have little difficulty in selecting the right men to fill vacancies in the ranks of the supervisors.

In railroad shops in the past personal feelings, or the foreman's recollection of a man's past performance often decided who should be promoted. More recently the question was settled by seniority rules and irrespective of ability. Both of these methods are decidedly inefficient and it is, imperative that, to promote men intelligently, personal records must be maintained. The system proposed in this article will also result in checking up the ability of gang foremen, shop foremen, and general foremen. It is just as essential to maintain an efficiency record for the man who is now supervising as it is for the workman who will eventually be a supervisor. We want to know how efficient the gang foreman is in supervising his men because he may be needed as a shop foreman. Similarly, the shop foreman should assume a just proportion of the errors made by his gang foremen and the men working under them.

In other words, the supervisory force should be assessed for all mistakes, careless or otherwise, that occur under their jurisdiction as after all they too are responsible. Give them a black mark for these errors and it won't be long until those who are responsible for repeated demerit marks will show improvement or be released.

Numerals can be used to designate demerits, one demerit mark for a casual incident, two for one of a semi-serious nature and three for a serious one. It is necessary to designate a maximum number of marks in a given length of time to cause dismissal. For example, any employee who might get fifteen demerits in one year would automatically dismiss himself from the service. On the other hand, a clear record over a given period should eradicate a certain number of marks. The following is an outline of fundamental suggestions, the finer points of which could be easily worked out to fit local conditions.

In order that the system be equitable, a gang foreman must not be assessed one full mark for each mark given one of his men as ere long a gang foreman with a number of men would soon reach 15 marks and be out of service. Neither should a gang foreman handling forty men be assessed as heavily as one handling twenty men as in the first instance the foreman has a greater number of men to watch and, therefore, is up against a greater hazard.

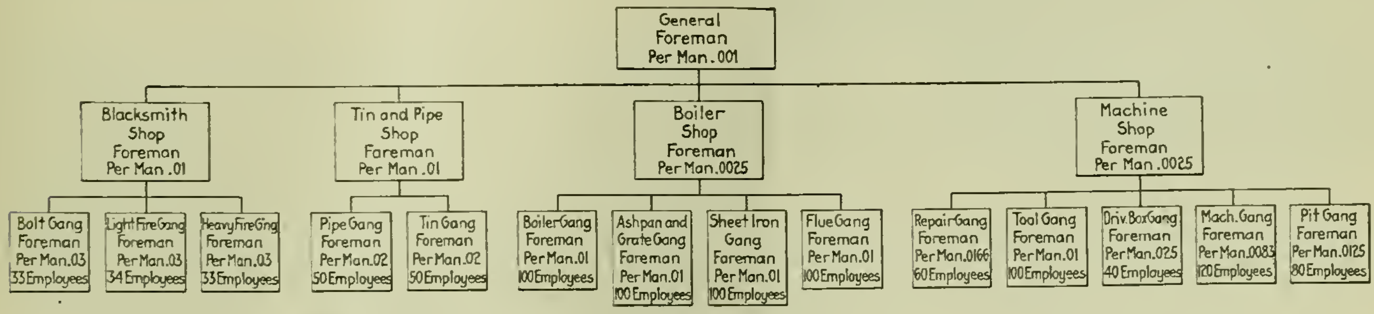

Chart 1—Percentage Demerits Charged Against Gang, Shop and General Foremen

The solution is to assess in percentages. The individual who makes the mistake is given one mark and his gang foreman is given a percentage of one mark based on the number of men in the gang. Chart 1 is an example of this percentage system and is based on a locomotive department employing 1,000 men. Note that the gang in the right block (pit gang foreman) consists of 80 men. Divide 1.000 by 80 and the result is .0125. The machine shop foreman has jurisdiction over 400 men. Divide 1.000 by 400 and the result is .0025. The general foreman is responsible for 1,000 men and should be charged with 1.000 divided by 1,000, or .001. Therefore, should one mechanic in the pit gang make an error, that calls for record discipline, he would be assessed 1.000 mark; his gang foreman .0125; the machine shop foreman .0025, and the general foreman .001.

It will, of course, be necessary to institute a card form for this individual record and Fig. 1 illustrates such a form and the entering of an error which affects the individual record of the four men as previously explained. These cards should be filed alphabetically in the general foreman's office. A file would have to be inaugurated to fit this system, arranging it numerically and giving the first case File No. 1, etc. Notification in writing of the individuals concerned is only fair so that their attention may be called to any black marks on their records. At the end of each month, the several cases of demerits should be summarized and bulletins posted covering them, leaving out the name of the individual concerned.

The principal virtue in this idea of progressive discipline is in the fact that the man higher up cannot overlook careless employees as his record suffers by reason of the mistakes of subordinates. If there are two or three marks on a foreman's record caused by the carelessness of one man, he is certainly going to keep his eye on this man and put the machinery in motion to educate him or else show cause to dismiss him.

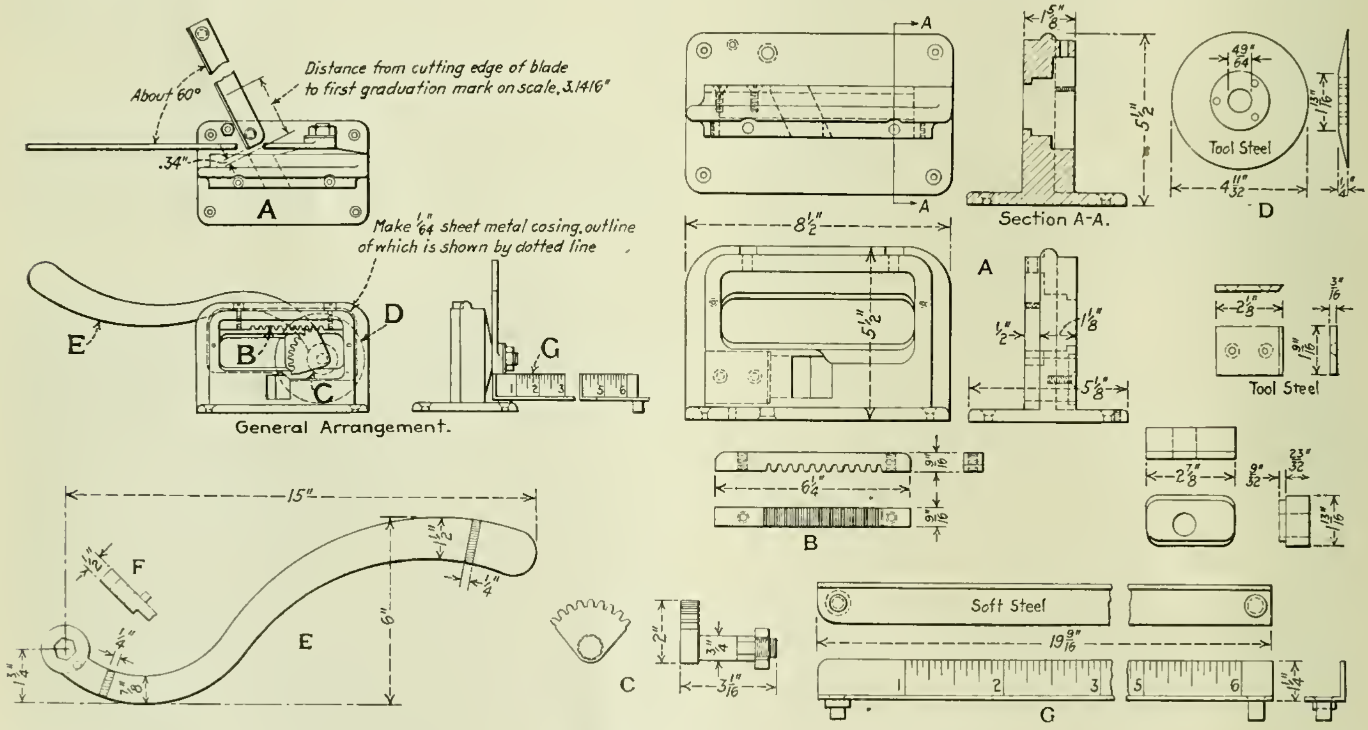
Second, a progressive discipline system as proposed would make it simple for a general foreman to make his recommendations to the master mechanic to fill a vacancy as a gang or shop foreman. If, for example, he needed a machine shop foreman an examination of the discipline cards of gang foremen would show the best man at a glance.

Another quotation from the Railway Age reads: "It is difficult to find an argument not already advanced for the more careful selection and training of railroad shop foremen." The proposed system of progressive shop discipline would do much to facilitate both the selection and training of shop foremen.

Soft Packing Cutter

BY NORMAN MACLEOD

Much waste in cutting fibrous packing for globe, angle, blow-off valves and miscellaneous valve stems can be eliminated by the use of a cutter which has been designed and proved satisfactory in one of the large shops of a prominent railroad. Details and the general arrangement of the cutter are shown in the illustration. The cutter consists of a frame *A* bolted or screwed to a work bench. Attached to the frame is a rack *B* in which is engaged a quadrant gear and shaft *C*. A circular hardened steel cutter *D*, operated by handle *E*, is slipped on shaft *C* and moves with the quadrant. Stop *F* regulates the throw of the quadrant.

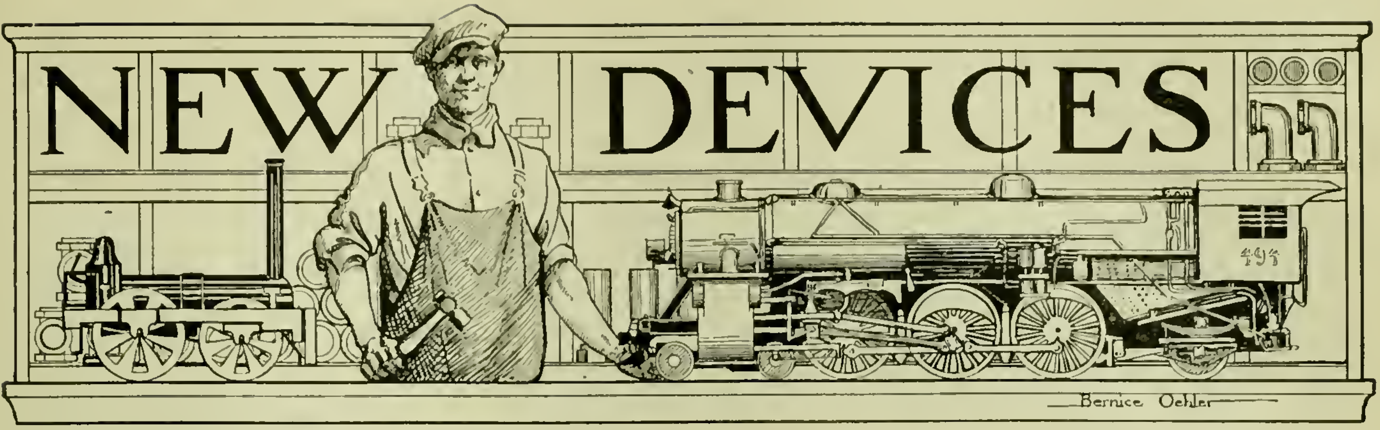


Details and General Arrangement of Soft Packing Cutter

Attached to the frame proper is a graduated gage *G*, the scale of which is marked for the various diameters of rods, in this case the graduations varying up to 6 in. in diameter. This gage is preferably made of an angular section to allow the packing to be held firmly and squarely while it is being cut.

Operation of the device consists in placing the packing through the opening in frame *A* provided for the purpose and cutting off one end, which will be at about 60 deg. according to the angle of the gage. The packing is then pushed on through until its extreme end coincides with the figure or graduation on the gage which represents the diameter of the rod for which the piece is intended. An overthrow movement of the handle gives the steel cutter a circular and also, with the rack and quadrant gear, a horizontal movement which carries the cutter through the packing.

The gage being set at an angle of about 60 or 65 deg. the ends of the packing are cut at such a bevel that when it surrounds the rod a tight joint is made.



Special Railroad Draw-Cut Shaper Attachments

THE special railroad draw-cut shaper, as finally developed by the Morton Manufacturing Company, Muskegon Heights, Michigan, is a heavy duty production tool capable of performing a large variety of machine operations in railroad shops. Owing to the fact that the cut is taken on the return stroke of the ram, deep cuts can be taken with coarse feeds and smooth, accurate work is assured.

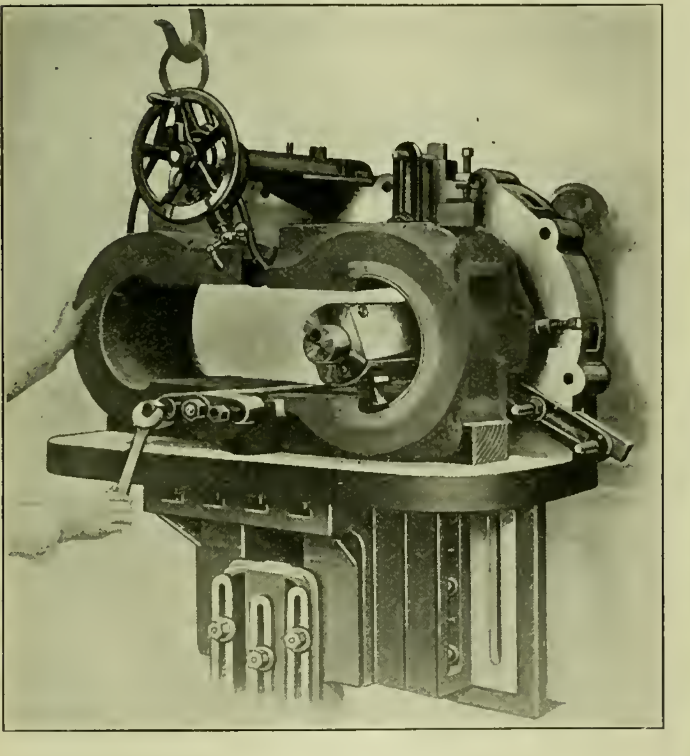


Fig. 1—Morton Double Chuck Driving Box Attachment

If the Morton draw-cut shaper was so highly specialized that it could be used only in machining driving boxes, its installation would be warranted only in those railroad shops having enough driving box work to keep the machine busy eight hours a day. The shaper can, however, be used on general machine work and special attachments have been designed for machining driving boxes all over and for finishing crown brasses, shoes and wedges, and main rod brasses. The addition of these attachments greatly increases the range of work for which the shaper is adapted and it can now be installed with profit in much smaller shops and roundhouses than heretofore. The flexibility of the machine and the ease of changing from one attachment to another make it a general utility tool which can be kept busy a large proportion of the time.

Double Driving Box Chuck

An improved double chuck for holding driving boxes is shown in Fig. 1. This chuck is made in the form of an angle plate which bolts securely to the knee of the machine and is alined at right angles to the ram. It is provided with a suitable opening for the ram and a special rotating head to pass through. Adjustable stops and binders secure the various sized driving boxes to the chuck.

A bracketed journal fastens to the top of the chuck and extends forward, bringing the operating hand wheel in a convenient position as shown. Power is transmitted through a universal shaft to the rotating arbor, which may be turned by hand in either direction. A limit stop screw is also provided in connection with the hand wheel so that the tool may be relieved on the return stroke when finishing the under-cut fit.

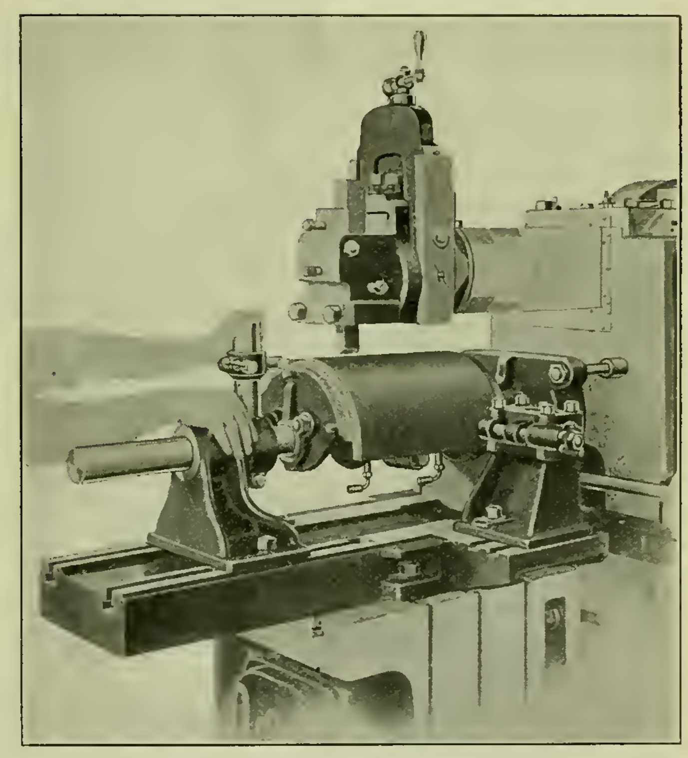

Fig. 2—Crown Brass Planing Attachment

In machining a driving box, the sides are first planed on the shaper without the use of the attachment. The attachment is then applied and one driving box centered by means of a scriber fitted to the micrometer projection of the rotating head. Micrometer setting of the tools is provided and the crown bearing can be machined accurately to size. The second box may be set up while planing the crown fit of the first box.

The under-cut fit is first roughed out while roughing the crown, a special forming tool being used for finishing. This tool can be set at a standard angle and rotated by hand feed so as to machine the box exactly to the line. The tool is relieved at each stroke and the stop advanced until the finish line is reached. After the brass is pressed in it may be planed to fit the journal if desired and a very true surface obtained by using a slightly crowned tool. For planing the shoe and wedge fit an extension bracket is bolted to the side of the knee and face of the saddle.

Planing the Crown Brass

For planing the outside of driving box crown brasses a special attachment is provided as shown in Fig. 2, a practical and efficient device for performing this machine operation. The base of the attachment is a rigid casting held in line with the ram by a tongue on the lower side. The arbor shown is rotated by a worm gear and turns freely in the head stock and tail stock bearings. The chuck for holding the brasses is keyed to the arbor and is held firmly against a shoulder by means of a clamp bolt. Set screws for lining and centering may be operated from the under side, and both front and rear heads are provided with set screws for holding brasses with rough ends. The two heads are drawn together by bolts so placed as to produce great pressure.

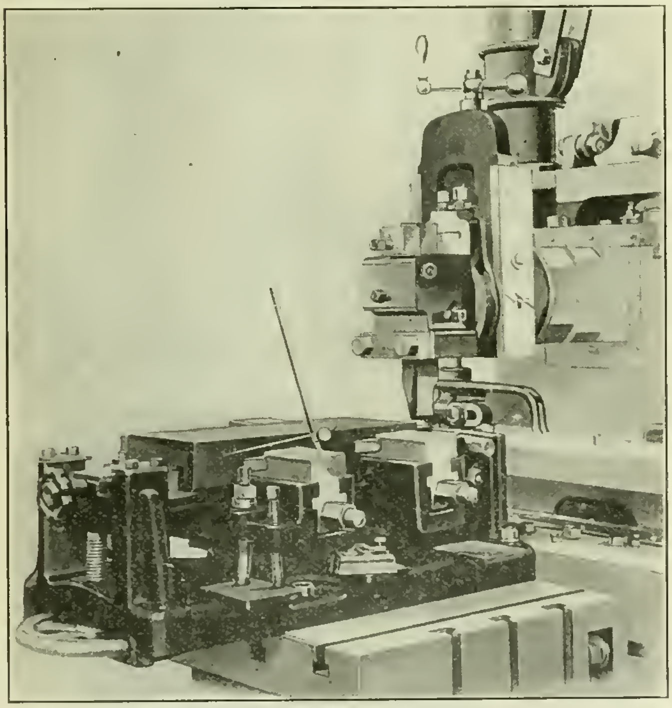

Fig. 3—Shoe and Wedge Planing Attachment

Chucks of different diameters are furnished for the various sized brasses and different lengths may be accommodated by means of the adjustable front head. The feed is obtained through a worm gear and shaft, connecting with the ordinary feed mechanism. Power feed in either direction is provided and the brass can be machined to the line scratched by the micrometer scriber. Adjustable transfer gages make it easy to caliper the driving box and determine the exact angle and position of the under cut. This angle is transferred to the crown brass by means of an outer gage.

Shoe and Wedge Attachment

An attachment for finishing the face bearings of shoes and wedges after they have been laid out and lined is illustrated in Fig. 3. Its construction is such as to make it readily adjustable to various angular requirements, all adjustments being made after the shoe or wedge is securely fastened in the attachment. One roughing and one finishing cut only is required. The principle of operation of the attachment will be evident from the illustration. The four adjustable jaws are expanded by a draw bar and a single screw. These jaws center the wedges of different size, bringing the inside (frame fit) parallel with the ram. Both sets of binders shown move freely in T-slots and are operated by single screws. The screw for elevating is operated by a hand wheel while the roll is obtained by means of two studs shown. When planing shoes the studs are loosened and the bar is elevated until it comes against a stop provided to hold the bar parallel with the shaper ram.

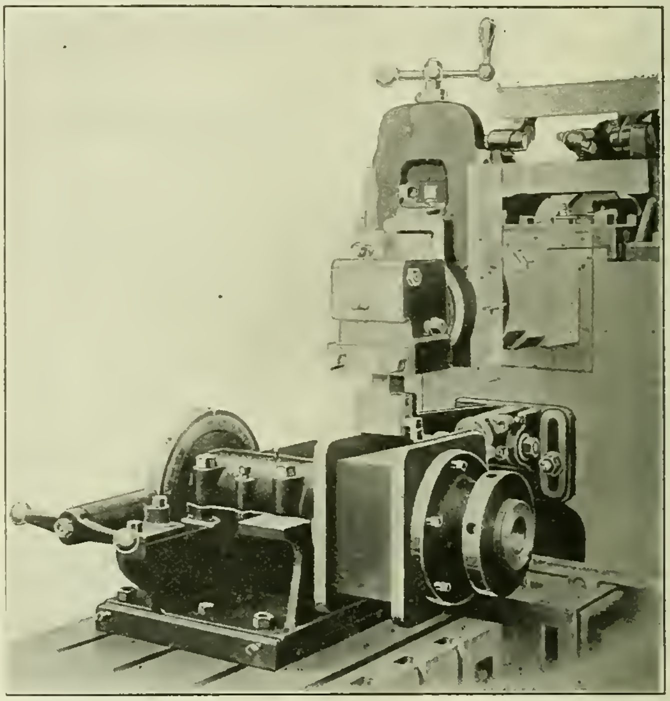

Fig. 4—Attachment for Machining Strap Fit in Rod Brasses

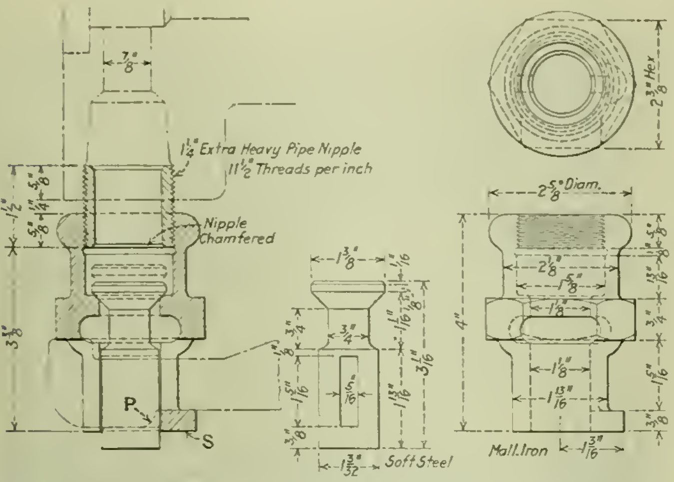
Machining Rod Brass Fits

Connecting rod brass fits in the straps can be accurately and quickly machined by means of the attachment shown in Fig. 4. The base plate of this device is provided with a tongue cast on the under side and fitted to a slot in the knee. The head is arranged to swivel on the base and is provided with set screws to secure perfect alinement, clamp bolts securely fastening the arbor in any desired position. Chucking is accomplished by fixed and sliding collars, pressure being applied to the sliding collar by a lever operated nut. Both collars are provided with cup pointed set screws which hold the brasses firmly and make it unnecessary to sweat the two halves together. An index plate is keyed to the rear end of the arbor and is provided with a plunger locking it securely at 90 deg. points. One side is graduated to 360 degrees so that any desired angle may be obtained.

The special tool holder furnished with this attachment is made of heavy machined steel slotted along two sides and one end to receive angular cutters. Two cutters are used at one time so constructed that they can be fastened in the holder independently of each other. With this form of tool holder, both sides of the strap fit may be machined at once to the exact size and parallel. An adjustable gage for setting the tool may be furnished consisting of a key-seated rod, one solid and one adjustable jaw. The gage is set by placing it directly on the strap and locking the adjustable jaw into position. The exact size is thus obtained for setting the tool.

Cylinder Cock Closes When Engine Drifts

A DEVICE for holding cylinder cock valves on their seats when an engine is drifting has been patented recently by L. P. Ligon, master mechanic, Norfolk & Western, Roanoke, Va., and found of great value in assisting lubrication and preventing dirt and other foreign matter from entering the cylinders with resultant unnecessary cutting and wearing. When cylinder cock bodies are of malleable iron and the valves of wrought iron, the seat cuts rapidly due to the valves being lifted by the vacuum in the cylinder when the engine is drifting. When brass or other soft metal is substituted for the wrought iron valve, the soft metal pounds out, necessitating frequent renewals.



View Showing Details and Cross Section of Closed Cylinder Cock

To prevent a cylinder cock valve from lifting when the engine is drifting a projection *P*, as shown in the illustration, has been made on the operating bar to engage the bottom of the slot in the valve when closed and hold it to seat. The projection enters for the full width of the valve when closed and passes out before the valve reaches the incline on the operating bar for opening it. A shelf *S* is made on the cylinder cock body to furnish additional support for the operating bar.

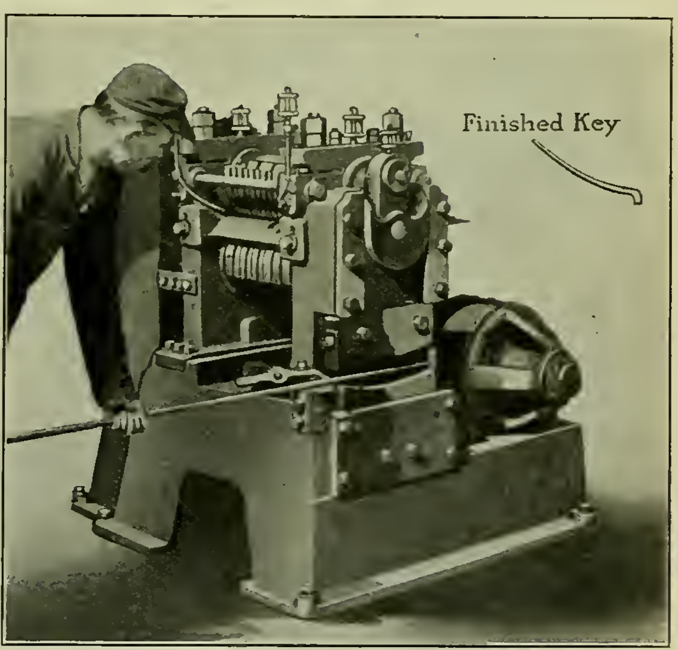
Engines equipped with cylinder cocks using this device have been in continuous service for more than a year without any renewals whatever being made, or any attention given to the cylinder cocks.

Brake Shoe Key Taper Rolling Machine

ALTHOUGH brake shoe keys have been produced by taper rolling for a number of years, many railroad men are not familiar with this process. Not only is the production of keys much greater but they are more uniform and of better quality than those obtained by drawing down under the hammer. The brake shoe key rolls, built by the Ajax Manufacturing Company, Cleveland, Ohio, have two horizontal roll-shafts to which are attached semi-cylindrical roll-dies, grooved to produce the taper of the key and operating between heavy housings. The upper roll-shaft is carried in slide housings and the pinions on the ends of the roll-shafts have exceptionally long teeth, so that the distance between roll-shaft centers can be varied. This adjustment regulates the thickness of the keys and also permits re-finishing the roll-dies, when they become worn, thus materially increasing their life. A side press operated from the upper roll-shaft shears off, bends and turns up the gib head on the brake shoe keys.

Either ½ in. by ⅞ in. rectangular or ¾ in. round stock of a convenient length to handle is used for making keys. Where cars are being wrecked, considerable scrap rod is available for this purpose. The stock is heated over a length of about two feet. The roll-shafts to which the dies are attached revolve continuously and during the half revolution when the roll-dies are not engaged, the operator ports the heated end between them against stock gages in the back. Front and rear guides hold the stock in position so that when the roll-dies engage, the stock enters into a groove and is rolled out toward the operator. He again ports it back into another groove making alternate flattening and edging passes.

Rectangular bars require only about four passes in the two flattening and one edging groove of the roll-dies; rounds require about six passes in the same three grooves, but the decrease in production because of the additional passes is more than compensated for when scrap rods are being thus reclaimed. The key is then sheared off the bar, bent and the gib head turned up in a single stroke of the side press. Two keys are completed at the same heat.



Ajax Brake Shoe Key Machine Performing the Final Operation in Making a Key

Because of the extreme simplicity of the operation, skilled or experienced operators are not required and production varies from 1,200 to 1,600 finished keys per eight-hour day, depending upon the activity of the operator and the kind of stock being used. Rolls of a similar type but larger size are used for tapering brake levers, crow bars, tong handles and other similar tapered forged pieces.

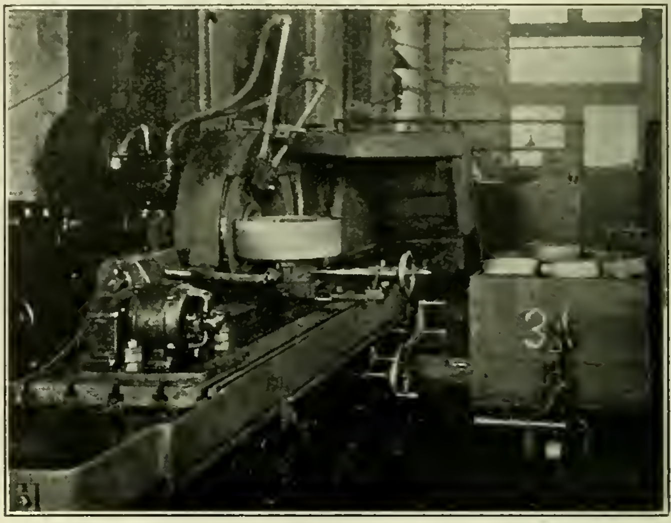
Improved Method of Crowning Pulleys

Crowning pulleys by grinding is not new but the method described in this article differs from others by employing a special fixture for use on a Diamond heavy duty face grinding machine. If a pulley is rotated about its axis inside a cylindrical wheel, a crown is obtained varying from zero to one equivalent to the segment of a circle the diameter of the inside of the wheel (28 in.). It is even possible to obtain a negative crowning or concavity by rotating the pulley against the outside of the cylinder wheel. Such concavities are not of importance as far as pulleys are concerned but might be of value in other classes of work. The pulleys are, of course, chucked and the edges finished before placing on the fixture. Production will vary somewhat depending upon the amount of stock to be removed and the regularity of the castings.

The peculiar shape of the wheel when trued for this work gives a very efficient shearing effect against the face of the wheel, resulting in high production. Working on 12 in. diameter pulleys, 4 in. wide face, the average production time of two to three minutes per pulley, floor to floor, is readily obtainable.

The pulley grinding fixture, illustrated, consists of two units, a plate with a vertical spindle and an electric motor with reduction gearing. The vertical spindle is of suitable diameter to fit the hole in the hub of the pulley and a pin, serving as a driving dog is inserted between the spokes. The pulley is rotated by power and the feed adjusted by hand. With a small change the fixture can readily be adapted to webbed pulleys.

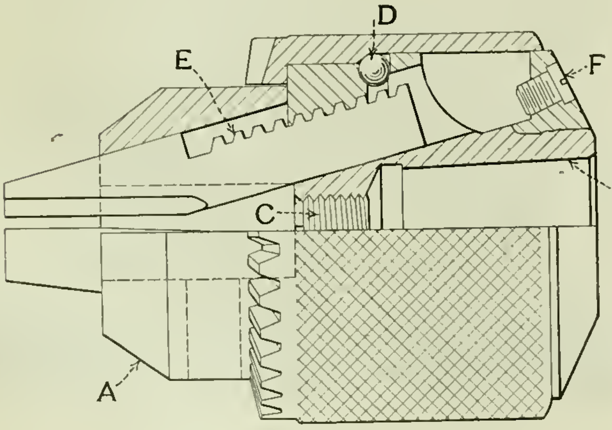
Pulley castings are usually very thin, often chilled, and frequently hard to machine. If machined on some types of lathes, low speeds and feeds are necessary and the percentage of breakage is high. Grinding offers the best solution of this as many other problems. The same principle can be successfully applied to the grinding of malleable iron brake shoes, rollers for conveyors, wheels for small trucks and similar work. This pulley grinding fixture is made by the Diamond Machine Company, Providence, R. I.



Diamond Pulley Grinding Attachment

Toothed Key and Sleeve Type Chuck

Accuracy, ease of operation and durability are features that have been kept in mind in the design of the new chuck made by the Jacobs Manufacturing Company, Hartford, Conn. This chuck is of the toothed key and sleeve type and is essentially the same as the chucks manufactured by this company for the past 18 years. The outward design has been changed slightly, however, to give better proportions as shown in the illustration.



Jacobs Toothed Key Type Chuck

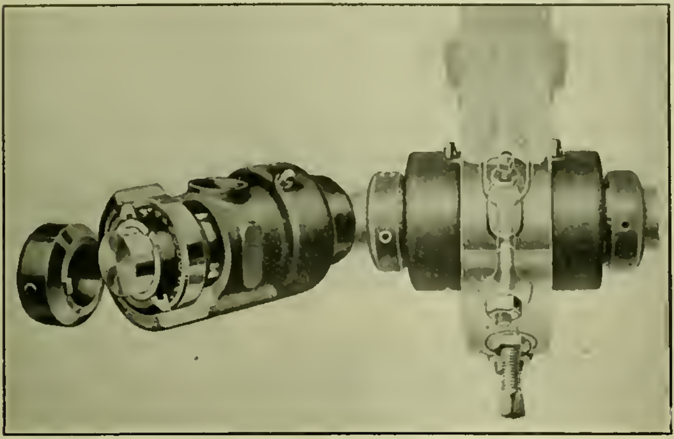
The body *A* is made of steel of a special analysis, deeply case hardened. Through a special process in this heat treating the taper hole *B* is left soft fitting it for use on a hardened and ground arbor. This taper hole is ground with great accuracy. A hole is drilled and tapped through the center of the body and fitted with a threaded plug *C* which may be easily removed with a screw driver if it is desired to insert rods or other material through the chuck. The taper hole on the chuck is of the same dimensions as those of previous designs. Each of the new chucks has been designed to meet the changed drilling methods of the last few years with relation to design, weight and capacity, all needless weight having been eliminated.

Ball bearings *D* inserted between the nut and the body reduce friction to a minimum making it possible to machine the thread *E* on the nut and the jaws with a coarser pitch than heretofore. Reduction of friction makes it possible to tighten the chuck with great ease, preventing undue wear on the keys, sleeves and other parts of the chuck at the same time giving greater gripping qualities.

An oil hole *F* inserted in the upper end of the chuck makes it possible to lubricate all of the working parts. One half the pressure on the key in tightening the chuck will produce the same results as in chucks of the previous design and the change in pitch of the thread on the jaws has resulted in reducing by one half the number of turns of the sleeve necessary to tighten or loosen the chuck.

Double Ball Bearing Hanger Boxes

Realizing the large amount of power lost in shops and factories where the shafting runs on plain bearings, the Fafnir Bearing Company, New Britain, Conn., has developed a double ball bearing hanger box designed to reduce friction and power loss to a minimum. Reference to the illustration shows that in this box the driving collar and wide inner ring, exclusive features of the Fafnir Bearing, make the usual adapter sleeves unnecessary and thus eliminate trouble in maintaining these parts.



Phantom and Assembled View of Fafnir Shaft Hanger Box

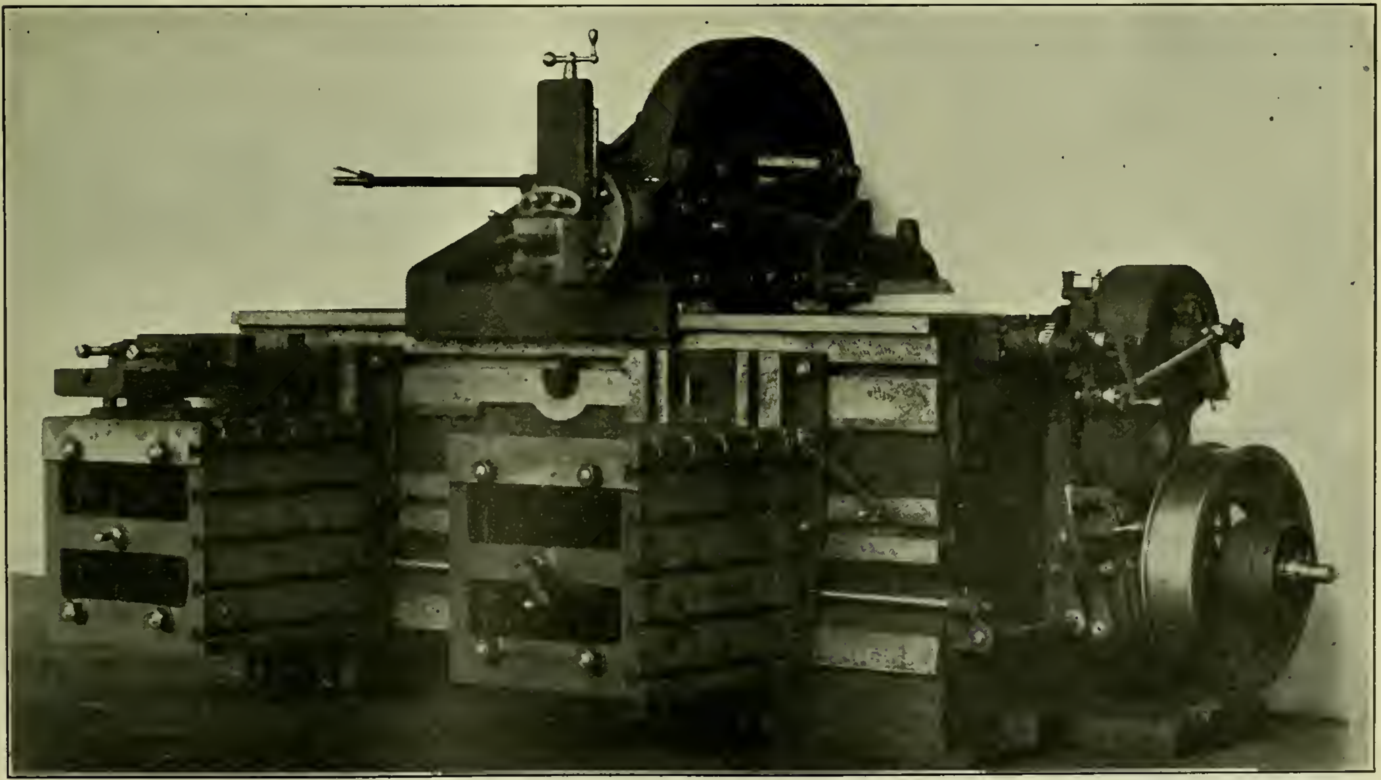
A collar is secured to the shaft at each end of the box by means of large set screws. The collar has lugs which mesh with corresponding slots cut in the inner ring of the ball bearing. Consequently the shaft, collar and inner ring revolve as a unit. Thus it will be appreciated that the collar drives the inner ring and transmits end thrust to the ball bearing. This construction makes it possible to ship each box completely assembled, and it can be put on the shaft as a unit, the driving collar being mounted on the shaft at each end of the box. There are no bolts or screws in the box to become loose and cause trouble; the wide inner rings of the ball bearings give the shaft ample support and provide a firm seat for the bearings; the box is supported in the middle and consequently any deflection of the shaft affects the box as a whole and does not interfere with the operation of the ball bearings.

Two ball bearings are installed in each box, being made of high-carbon, chrome alloy steel. The inner and outer rings and balls of these bearings are scientifically heat-treated and manufactured with extreme accuracy. Grease plugs are provided so that the bearings can be filled with grease when needed, which is not often. Felt packing rings prevent the lubricant from working out of the box. These double ball bearing boxes can be installed in any of the more common types of hangers.

Heavy Duty Traverse Head Shaper

The Putnam Machine Works of Manning, Maxwell & Moore, Inc., Fitchburg, Mass., has recently added to its line of modern machine tools, a 26 in. traverse head shaper. While this shaper is a general purpose machine, adaptable to use in any machine shop, it is essentially a railroad shop tool, and can be provided with the necessary equipment for efficiently machining the faces of driving boxes, shoes and wedges, and many other miscellaneous locomotive parts.

The principal features of this shaper, as shown in the illustration, are its generally heavy proportions, ability to transmit the power required for heavy cuts at high speeds



General View of the Putnam 26-In. Traverse Head Shaper

and to absorb the strains incident thereto. Every effort has been made to secure maximum convenience of control. The bed of the shaper is of rigid construction with all bearing surfaces hand scraped. The head has a liberal bearing surface on the bed and is gibbed. There are ample facilities for taking up wear and wipers keep the surfaces in contact free from dirt and grit. Power feed for the head along the bed is by means of a large screw carrying a ratchet on its extreme end for engaging, disengaging or reversing of feeds ranging from .01 in. to .17 in.

An open and shut nut in the head provides ready means for disengagement with the feed screw when it is desired to quickly traverse the head along the bed by means of a ratchet handle provided. The ram is of a strong box construction with ample bearing surfaces and is operated by the McCord quick return motion which produces a practically uniform cutting speed. Facilities are provided for quickly and conveniently setting the ram to any stroke or position desired. The tables are mounted on individual saddles and have vertical adjustment by means of screws mounted on ball bearings. Longitudinal adjustment along the bed is accomplished by ratchet handles which are attached to the saddles. The construction provides for the application of a circular attachment, if desired.

Drive by belt or constant speed motor is so arranged that speed changes are readily obtainable through a selective type gear box, all gears of which are made of chrome nickel steel, heat treated and hardened. They are lubricated by the splash system. A powerful friction clutch is used, operated from both ends of the machine by conveniently placed levers, and the act of disengaging the clutch applies a brake for quickly stopping the ram. Drive by variable speed motor is arranged with sufficient speed changes by gearing to give suitable speeds to the ram. Beds 14 ft. and longer are usually made into double machines, having the two heads independently driven by separate 7½ hp. motors.

Internal Micrometer of Unusual Design

A RADICAL departure from the usual construction of internal micrometers is embodied in a new instrument made by John Bath & Company, Inc., Worcester, Mass. In this measuring tool, four measuring jaws are provided having true cylindrical contact surfaces which make a broad line contact with the walls of the hole being measured. The measuring jaws are accurately lapped and nicely fitted without play in dovetailed slots. Perfect alinement and parallelism of the jaws is secured. The jaws are moved up the flat inclined supporting surfaces on the solid body of the micrometer by a micrometer screw of exceptional accuracy. The result is an internal micrometer which is as rigid as a solid plug. It is made in 32 sizes which will give continuous measurements by ten-thousandths from ⅞ in. to 3 in.

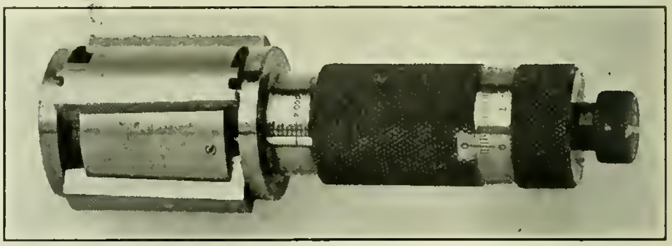
It is logical to measure cylindrical surfaces with a straight line contact, thus the use of the four parallel jaws with cylindrical contact surfaces, making a broad line contact with the internal cylindrical surface of a hole, gives uniformity in measuring machined, reamed or ground holes, and furthermore results in securing the limit of accuracy in measuring ring gages and the most accurate lapped holes. There is no indentation of the contacts in the surface being measured. The broad line contact secures at once a true measurement. When a measurement is taken and the jaws of the micrometer come in contact with the walls of the hole, they stop abruptly. Any number of persons will get the same result and the variations due to the sense of touch are, therefore, eliminated. A workman is enabled to ascertain quickly the exact size of the hole being machined. He knows the amount of metal removed per cut and all other conditions about the hole. This information gives him the assurance and ability to proceed rapidly in completing the work without risk of getting the hole over sized and adding to the spoilage loss.

A master reference ring gage, made by the John Bath Company, also departs from the usual form of construction. A deep wall section is provided with a series of concentric holes which have little effect in reducing the strength of the ring, but serve to reduce the weight materially and furthermore to provide for air circulation. This permits the ring to return more quickly to normal temperature after it has been heated or cooled. The construction of this master ring gage, therefore, results in securing maximum rigidity with minimum weight and the ability to expand and contract uniformly with changes of temperature.

Rules for Accurate Calipering

For accurate calipering, the surfaces of holes and of the micrometer should be washed with soap and water (preferably lukewarm water). This removes the grease, grit and all residue that may be left from gasoline, alcohol and other liquid and all sediment deposited from the atmosphere. After the contacting surfaces have been washed and thoroughly dried with a clean cloth or with new clean tissue paper, the micrometer is inserted in the hole and the jaws expanded until they are stopped by the walls of the hole, thus measuring the exact size of the lapped hole.

After having found the exact size of a hole, with the surfaces clean and dry, it is astonishing to note the changes which take place when oil or lubricant is present. Oil of any nature reduces the friction which caused the screeching and jerky movement, found when the micrometer was rotated in the ring, clean and dry. Oil makes the rotation of the micrometer smooth, and with oil present it is no longer possible to distinguish the large diameters from the small diameters; the high points from the low points. Furthermore, the micrometer can be expanded to be several ten-thousandths larger than the hole, and no appreciable difference in the force required to rotate the micrometer will be noticed. Oil entirely destroys "feel."



The 2-In. Bath Internal Micrometer

An excellent way to detect small irregularities such as depressions, high spots and slight conditions of bell mouth or taper in a lapped hole is to make use of a very thin film containing sediment or residue deposited from the air. If a lapped ring gage is first coated with castor oil, the excess oil being removed by vigorous rubbing with a clean cloth and the gage is allowed to stand for several hours, dust particles from the air will be deposited on the trace of oil left in the ring. A micrometer rotated in a ring treated in the foregoing manner develops a very thin brownish colored film by which it is possible to detect minute irregularities in holes. It is said that with the new Bath micrometer internal measurements can be made even more accurately and rapidly than external measurements with the usual form of micrometer.

Subscriptions, including the eight daily editions of the Railway Age, published in June, in connection with the annual convention of the American Railway Association, Mechanical Division, payable in advance and postage free: United States, Canada and Mexico, $4.00 a year; elsewhere $5.00, or £1 5s. 0d a year. Foreign subscriptions may be paid through our London office, 34 Victoria street, S. W. 1, in £ s. d. Single copy, 35 cents.

WE GUARANTEE, that of this issue 9,200 copies were printed; that of these 9,200 copies, 8,261 were mailed to regular paid subscribers, 8 were provided for counter and news company sales, 263 were mailed to advertisers, 32 were mailed to employees and correspondents and 628 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 49,400, an average of 9,880 copies a month.

The *Railway Mechanical Engineer* is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.)

Four locomotives were burned in a fire of undetermined origin which recently destroyed the roundhouse and machine shops of the Maine Central at Calais, Me.

W. O. Thompson, secretary of the Traveling Engineers' Association, has changed his headquarters from Buffalo, New York, to 1177 East Ninety-eighth street, Cleveland, Ohio.

The Transportation Club, Buffalo, N. Y., has appointed the following officers for the year 1921: Kendall B. Hassard, president; Judson M. Sells, first vice-president; Godfrey Morgan, second vice-president; Redmond J. Walsh, secretary and treasurer, and George C. Wilson, assistant secretary.

The United States Civil Service Commission has announced an open competitive examination for shop apprentices. Vacancies in the Bureau of Standards at $720 a year and positions requiring similar qualifications will be filled from this examination. Applications will be received by the commission at Washington, until August 1, 1921.

The Southern Pacific has recently completed a first aid station or emergency hospital at Bay Shore, South San Francisco shops, which makes the thirteenth emergency hospital unit on the company's Pacific system. The unit has an operating room, small ward, kitchen, waiting room and doctor's office, and the station is in charge of a trained nurse at all times.

Ninety miles in one hour and twenty minutes was the time made by a special train of two cars from Philadelphia to Jersey City on the afternoon of April 18, over the Philadelphia & Reading and the Central of New Jersey, a speed equal to 67.5 miles an hour. This train was run for J. L. Stokes, a banker, to enable him to connect with a train for Montreal, the Pennsylvania being blocked by a derailment and the Reading having no regular train for two hours. Mr. Stokes paid for the train $427.

Master Boiler Makers' Convention Deferred

The executive board of the Master Boiler Makers' Association has voted to defer the annual meeting which was scheduled to have been held at St. Louis, Mo., May 23 to 26.

Storekeepers' Annual Meeting

The Division of Purchases and Stores of the American Railway Association (Division VI) will hold a convention in Chicago, at the Hotel Blackstone, on Thursday, Friday and Saturday, June 9, 10 and 11.

General Secretary J. E. Fairbanks has issued a circular which says that the general committee of this Division, because of the financial stress and serious business conditions, has determined that it is necessary to defer the annual convention scheduled for Atlantic City. The Chicago meeting will be strictly for business. The sessions will convene at 10 a. m., city time. The general committee and standing committees will be in attendance. Members are requested to have such representatives of their supply departments attend as can conveniently do so. The meeting will consider Committee reports which are ready and will formulate a constructive plan for the future activities of the Division.

Machine Tool Builders Cancel Convention

The National Machine Tool Builders' Association announces that its spring convention, scheduled for May 19 and 20 at Atlantic City, N. J., is cancelled.

American Society for Testing Materials

The American Society for Testing Materials will hold its twenty-fourth annual meeting at the New Monterey Hotel, Asbury Park, N. J., on June 20 to 24, inclusive. Monday, June 20, will be devoted to committee meetings, and the first session of the annual meeting will be held on Tuesday morning, June 21.

Shop Construction

ATCHISON, TOPEKA & SANTA FE.—This road has awarded the contract for the construction of a blacksmith shop, 80 ft. by 307 ft., at San Bernardino, Cal., to Joseph E. Nelson & Sons, Chicago. The estimated cost is $150,000 and construction will commence at once.

Locomotives

The PEKIN-MUKDEN has ordered 19 locomotives from English builders.

The ATCHISON, TOPEKA & SANTA FE has ordered 10 Pacific, 15 Mikado, 15 Mountain and 10 Santa Fe type locomotives from the Baldwin Locomotive Works.

NATIONAL RAILWAYS OF MEXICO.—The General Equipment Company, New York, has sold to The Oliver American Trading Company, with New York City office at 61 Broadway, 65 rebuilt locomotives, including Mogul, 10-wheel and Consolidation type locomotives for use over the lines of the National Railways of Mexico in connection with the operation of the private freight trains of the Oliver company. This company, in addition to these 65 locomotives just purchased, also has leased 20 locomotives from American railroads, which, with the equipment they are now operating, gives it a total motive power of about 95 locomotives. This sale of the General Equipment Company has been made possible by virtue of certain arrangements between Senor Francisco Perez, Director-General of the National Railways of Mexico and

The Oliver American Trading Company, Inc., which plan provides a practical means of financing this equipment.

Freight Cars

The Delaware, Lackawanna & Western is having repairs made to 1,000 box cars at the Berwick shops of the American Car & Foundry Co. This is in addition to the 1,000 cars on which repairs were authorized to be made at the same plant last October.

The Atchison, Topeka & Santa Fe has ordered 1,000 50-ton gondolas from the American Car & Foundry Co.; and 300 50-ton gondola cars from Haskell & Barker Car Co., Inc.

The United Fruit Company, New York, has ordered 50 all steel ballast cars for the Pruxillo Railroad, Honduras, from the Magor Car Company.

The Beacon Oil Company, Boston, Mass., has ordered 20 tank cars, of 10,000 gal. capacity, from the General American Tank Car Corporation.

MEETINGS AND CONVENTIONS

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations and railroad clubs:

Air-Brake Association.—F. M. Nellis, Room 3014, 165 Broadway, New York City.

American Railway Association, Division V—Mechanical.—V. R. Hawthorne, 431 South Dearborn St., Chicago. Business meeting June 15 and 16, Hotel Drake, Chicago, Ill.

Division V—Equipment Painting Division.—V. R. Hawthorne, Chicago.

American Railway Association, Division VI—Purchases and Stores.—J. P. Murphy, N. Y. C., Collinwood, Ohio. Convention June 9, 10 and 11, Hotel Blackstone, Chicago, Ill.

American Railroad Master Tinners', Coppersmiths' and Pipefitters' Association.—C. Borcherdt, 202 North Hamlin Ave., Chicago. Convention September 12-14, Hotel Sherman, Chicago, Ill.

American Railway Tool Foremen's Association.—R. D. Fletcher, 1145 E. Marquette Road, Chicago. Convention August 9, 10 and 11, Hotel Sherman, Chicago, Ill.

American Society for Testing Materials.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa. Annual meeting June 20 to 24, inclusive, New Monterey Hotel, Asbury Park, N. J.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. Thirty-ninth St., New York. Spring meeting May 23 to 26, inclusive, Congress Hotel, Chicago, Ill.

American Society for Steel Treating.—W. H. Eiseman, 4600 Prospect Ave., Cleveland, Ohio. Annual convention September 19-24, Indianapolis, Ind.

Association of Railway Electrical Engineers.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago, Ill.

Canadian Railway Club.—W. A. Booth, 131 Charron St., Montreal, Que. Next meeting May 10. Annual meeting. Reports, smoker and entertainment.

Car Foremen's Association of Chicago.—Aaron Kline, 626 N. Pine Ave., Chicago, Ill. Meeting second Monday in month, except June, July and August, New Morrison Hotel, Chicago, Ill.

Car Foremen's Association of St. Louis.—Thomas B. Koeneke, 604 Federal Reserve Bank Building, St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis, Mo.

Central Railway Club.—H. D. Vought, 95 Liberty St., New York, N. Y. Next meeting May 12. Paper on the Manufacture of High Speed Steel will be presented by Felix Kremp, metallurgist, Atlas Crucible Steel Company, Dunkirk, N. Y.

Chief Interchange Car Inspectors' and Car Foremen's Association.—W. P. Elliott, T. R. R. A. of St. Louis, East St. Louis, Ill.

Cincinnati Railway Club.—W. C. Cooder, Union Central Building, Cincinnati, Ohio. Next meeting May 10. Paper on Experiences in Mexico will be presented by P. G. O'Hara, of the Galena Signal Oil Company. Entertainment by George J.. Breiel, Cincinnati Regalia Company.

Dixie Air Brake Club.—E. F. O'Connor, 10 West Grace St., Richmond, Va.

International Railroad Master Blacksmiths' Association.—W. J. Mayer, Michigan Central, 715 Clarke Ave., Detroit, Mich. Next meeting August 16, 17 and 18, 1921, Hotel Sherman, Chicago, Ill.

International Railway Fuel Association.—J. G. Crawford, 702 East Fifty-first St., Chicago, Ill. Next annual meeting, May 24-26, 1921, Hotel Sherman, Chicago, Ill.

International Railway General Foremen's Association.—William Hall, 1061 W. Wabasha Ave., Winona, Minn. Convention, September 12, 13, 14 and 15, 1921, Hotel Sherman, Chicago, Ill.

Master Boilermakers' Association.—Harry D. Vought, 95 Liberty St., New York, N. Y.

New England Railroad Club.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Next meeting May 10. Paper on New England, Its Rivers, Mountains and Seashore, will be presented by E. S. Jones, official photographer, Boston & Maine, and will be illustrated by lantern slides.

New York Railroad Club.—H. D. Vought, 95 Liberty St., New York, N. Y.

Niagara Frontier Car Men's Association.—George A. J. Hochgrebe, 623 Brisbane Building, Buffalo, N. Y.

Pacific Railway Club.—W. S. Wollner, 64 Pine St., San Francisco, Cal. Meeting second Thursday in month, alternately in San Francisco and Oakland, Cal.

Railway Club of Pittsburgh.—J. D. Conway, 515 Grandview Ave., Pittsburgh, Pa. Meetings fourth Thursday in month except June, July and August, Americus Club House, Pittsburgh, Pa.

St. Louis Railway Club.—B. W. Fraucnthal, Union Station, St. Louis, Mo. Next meeting May 6. Moving pictures and lecture on Thunder Bay to the Skeena River will be given by Capt. J. Milton State.

Traveling Engineers' Association.—W. O. Thompson, 1177 East Ninety-eighth St., Cleveland, Ohio.

Western Railway Club.—Bruce V. Crandall, 14 E. Jackson Boulevard, Chicago. Annual meeting May 16.

PERSONAL MENTION

GENERAL

M. B. McPartland has been appointed superintendent of motive power of the Denver & Salt Lake with headquarters at Denver, Colo., succeeding J. J. Connors, resigned on account of ill health.

O. P. Reese, superintendent of motive power of the Pennsylvania, Northwestern Region, with headquarters at Toledo, has been transferred to Chicago, succeeding O. C. Wright, assigned to other duties.

E. J. Summers, smoke inspector of the Chicago, Milwaukee & St. Paul, has been promoted to fuel supervisor, with jurisdiction over the system, and headquarters at Chicago.

John P. Kelly, for the past two years inspector of safety appliances in the Bureau of Safety, Interstate Commerce Commission, has been appointed senior railway mechanical engineer for that Bureau, with headquarters at Washington, D. C. Mr. Kelly was born in Great Barrington, Mass., on March 16, 1864, and received his early education in the public schools of that town; his engineering training was obtained in the engineering departments of the companies by whom he was employed. His first railroad service was on the Housatonic Railroad, now a part of the New Haven System, as water boy on passenger trains, in 1880. He was locomotive fireman in 1884, and locomotive engineman in 1887. He served as locomotive engineman on the New Haven and later on the New York Central; and in 1898 was appointed air brake instructor on the Central. In 1899 he was road foreman of engines on the Chicago & Alton; in 1901 he went to the New York Air Brake Company, where later he was appointed assistant mechanical engineer. In 1905 he resigned and went to the Westinghouse Air Brake Company but in 1910 resigned and devoted his time to the business of consulting air brake engineer, and to writing for the technical press. In 1912 he entered the employ of the New York Central Lines as consulting air brake engineer. Later he went into government employ as above stated.

J. P. Kelly

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

F. A. Gibbs has been appointed terminal road foreman of engines of the Atchison, Topeka & Santa Fe at Redondo Junction, Cal.

L. W. Gilbert has been appointed road foreman of engines of the Santa Fe at La Junta, Colo., succeeding C. A. Mays, assigned to other duties.

J. B. Merritt has been appointed road foreman of engines on the Second district of the New Mexico division of the Atchison, Topeka & Santa Fe, with headquarters at Raton, N. M., succeeding J. T. Stuvort, who has been transferred to the Third district.

Guy P. Mohler has been appointed terminal road foreman of engines of the Santa Fe at Needles, Cal., succeeding Earl Gilbert, transferred.

T. A. Roussin has been appointed master mechanic of the Missouri-Illinois which has been organized, with general headquarters at Bonne Terre, Mo., to take over the operation of the Illinois Southern. Mr. Roussin is located at Sparta, Ill.

CAR DEPARTMENT

Albert J. Krueger, whose appointment as master car builder of the New York, Chicago & St. Louis was announced in the March issue of the *Railway Mechanical Engineer*, was born on June 26, 1890, at Toledo, Ohio. He attended the Toledo High School and in 1908 entered the employ of the Lake Shore & Michigan Southern, later known as the New York Central. After serving successively as car repairer, car inspector, repair work inspector. piece work inspector, contract shop inspector, assistant general shop inspector and general shop inspector until December 1, 1916, Mr. Krueger entered the service of the Nickel Plate Road as general shop inspector and remained in this position until his recent appointment.

SHOP AND ENGINEHOUSE

Edward Bickerton has been appointed general foreman of the Canadian National Railways, with headquarters at Port Arthur, Ont.

Coincident with the consolidation of divisions on the Chicago, Rock Island & Pacific, appointments and transfers have been made as follows: G. M. Stone, master mechanic, with headquarters at Manley, Iowa, has been appointed general foreman, with the same headquarters. B. H. Smith, master mechanic, with headquarters at Fairbury, Neb., has been appointed general foreman, with the same headquarters. W. E. Danver, master mechanic, with headquarters at Amarillo, Tex., has been appointed road foreman of equipment, with the same headquarters. A. Hambleton, master mechanic, with headquarters at El Dorado, Ark., has been appointed general foreman, with headquarters at Shawnee, Okla.

H. M. Cooper has been appointed roundhouse foreman of the Santa Fe at Winslow, Ariz.

Charles Loud has been appointed assistant roundhouse foreman of the Atchison, Topeka & Santa Fe, at Las Vegas, N. M.

Minden McGee has been appointed foreman of the Santa Fe at Lamy, N. M., succeeding W. H. Sapp, transferred.

G. T. De Pue, mechanical superintendent of the Erie, with headquarters at Chicago, has been appointed shop superintendent at Galion, Ohio. The office of mechanical superintendent at Chicago has been abolished.

PURCHASING AND STOREKEEPING

J. F. Blasie has been appointed district storekeeper of the New York Central at Depew, N. Y., succeeding H. L. Grandy, transferred.

A. Herrera, formerly purchasing agent of the National Railways of Mexico, with headquarters at Mexico City, has been appointed to his former position. Mr. Herrera was born September 16, 1878, at Mexico City. He was educated at the Merchants' School of that city and entered railway service March 1, 1895, with the Mexican Central. After serving in several minor positions in the stores department he was appointed chief clerk of that department in 1901. In 1903 he was promoted to material accountant and served in that capacity until 1906 when he was appointed fuel agent. In 1909 when the Mexican Central was incorporated into the National Railways of Mexico, Mr. Herrera's duties were extended to include the maintenance of the fuel service of the entire system. In 1910 he was appointed purchasing agent. Mr. Herrera continued in this position until 1915 when, because of the revolution, he retired to private life. With the return of normal conditions he has again resumed the duties of his office.

A. Herrera

C. A. Dougherty, assistant district storekeeper of the New York Central at Elkhart, Ind., has been appointed storekeeper at Englewood, Ill., succeeding C. E. Shoup.

G. A. Goerner of the Chicago, Burlington & Quincy has been relieved of special duties assigned to him some time ago, and reappointed storekeeper at Clyde, Ill.

L. J. Green, formerly assistant general storekeeper of the New York Central at West Albany, N. Y., has been appointed storekeeper at Otis, N. Y., succeeding F. C. Vroman.

B. W. Griffeth, former assistant general storekeeper of the New York Central at Collinwood, Ohio, has been appointed district storekeeper, third district, with headquarters at Collinwood. Mr. Griffeth succeeds F. J. McMahon, who has been assigned other duties in the stores department at the same point.

R. S. Huffman, assistant general storekeeper of the New York Central at West Albany, N. Y., has been appointed district storekeeper, with headquarters at the same point, succeeding J. H. Seim, transferred.

W. H. King, Jr., assistant to the vice-president in charge of operation of the Seaboard Air Line, has been appointed general purchasing agent, and will succeed H. C. Pearce who has resigned.

A. L. Prentice has been appointed district storekeeper of the New York Central, with headquarters at Elkhart, Ind., succeeding C. F. Heidenrich, who has been transferred to Collinwood, Ohio, in the stores department.

J. B. Taylor has been appointed stores accountant of the Cleveland, Cincinnati, Chicago & St. Louis at Beech Grove, Ind., succeeding R. H. Kroger, assigned to other duties.

OBITUARY

F. V. McDonnell, master mechanic of the Northwestern Region of the Pennsylvania, with headquarters at Ft. Wayne, Ind., died on April 26.

Riley Laizure, formerly master mechanic of the New York, Chicago & St. Louis at Conneaut, Ohio, died February 24, 1921, at the age of 71 years, having been retired on a pension for one year. He is survived by a wife and three sons, one of whom, Lee R. Laizure, is now master mechanic for the Erie Railroad at Secaucus, N. J. Mr. Laizure was born in Steubenville, Ohio, and at the age of fifteen began work as a blacksmith apprentice at $9 per month, in a shop furnishing track tools for the Pennsylvania Railroad. After serving some time in the railroad shop at Denison, Ohio, he worked in the blacksmith shop of the Louisville & Nashville at Louisville, Ky., and left there during the panic of 1873 to enter the employ of a manufacturing company at Columbus, Ohio. Returning to railroad service, Mr. Laizure worked for the Pennsylvania Railroad and was one of the pioneers in the blacksmith shop department of the Erie Railroad. He worked for the Atlantic and Great Western at Galion, Ohio, when the gage was changed from broad to standard, and in later years served the Erie as blacksmith foreman at Susquehanna and Meadville. Returning to the industrial field in 1893, several years were spent directing blacksmith shop work for the American Locomotive Company at Richmond, Va., to be followed by 15 years as master blacksmith of the Nickel Plate at Conneaut, Ohio. Mr. Laizure was a mechanic of the old school, a well-known figure at the annual conventions of the International Railroad Master Blacksmiths' Association and highly esteemed by all those who knew him.

R. Laizure

SUPPLY TRADE NOTES

E. E. Goodwillie has been appointed sales agent in charge of the Cleveland office of the Bethlehem Steel Company, Bethlehem, Pa.

The G. M. Basford Company has removed its office from 30 Church street to the National City building, 17 East forty-second street, New York City.

The Rome Iron Mills, Inc., has removed its general offices from 30 Church street to the National City building, 17 East Forty-second street, New York City.

The Landis Tool Company, Waynesboro, Pa., has removed its New York sales office from 50 Church street to 51 Chambers street. M. G. Dunbar is the manager.

The Stone Franklin Company has removed its general offices from 30 Church street to the National City building, 17 East Forty-second street, New York City.

The Superheater Company removed its general offices on May 1 from 30 Church street to the National City building, 17 East Forty-second street, New York City.

The American Arch Company, Inc., has removed its general offices from 30 Church street to the National City building, 17 East Forty-second street, New York City.

The Franklin Railway Supply Company, Inc., has removed its general offices from 30 Church street to the National City building, 17 East Forty-second street, New York City.

Ralph T. Hatch has been appointed general manager of sales for the Reading Steel Castings Company, a subsidiary of the American Chain Company, with headquarters at Reading, Pa. Mr. Hatch entered railroad sales work with the B. F. Goodrich Rubber Company at Akron, Ohio, and was for several years railroad representative of this company. For the past 14 years he has been connected with the sales department of the National Malleable Castings Company, serving this company first as manager of Canadian sales with headquarters at Montreal, Can., and later going to the Chicago office of the company. At the time of his recent appointment he was serving as district manager of sales for the Northwestern territory, with headquarters at St. Paul, Minn., a position he had held for several years.

Ralph T. Hatch

The Universal Crane Company, Cleveland, Ohio, announces the removal of its plant from Cleveland, Ohio, to its new factory at Elyria, Ohio, which has recently been completed.

The Hutchins Car Roofing Company, Detroit, Mich., removed its New York City office on May 1 from 103 Park avenue to room 910 Canadian Pacific building, 342 Madison avenue.

The Lima Locomotive Works, Inc., has removed its executive and sales offices from 30 Church street to the National City building, 17 East Forty-second street, New York City.

The Railway Materials Company announces that on May 1 its general offices were moved from the Railway Exchange to suite 1900, Wrigley building, 400 North Michigan avenue, Chicago.

The Victor Tool Company, Inc., Waynesboro, Pa., has opened a branch office at 131 West Thirty-ninth street, New York, in charge of F. W. Curtis, manager, and Warren J. Boe, sales engineer.

The Gold Car Heating & Lighting Company on May 1 removed its offices from 17 Battery Place, New York City, and its warehouse to larger quarters at the Bush Terminal, 220 Thirty-sixth street, Brooklyn, N. Y.

The Standard Paint Company on April 1 changed its corporate title to the Rubberoid Company. There will be no change in the management or policy of the company, whose general offices will remain at 95 Madison avenue, New York.

Max Grant, whose appointment as manager of technical railway sales of the Glidden Company, Cleveland, Ohio, was announced in the March *Railway Mechanical Engineer*, was born in Berlin, Germany, in 1876. After serving for three years in the paint business in Germany he came to America in 1896, and went to the Devoe - Raynolds Company, serving first at Chicago and then at New York. About five years later he was appointed superintendent and later became manager of the Canton Paint & Varnish Company, Canton, Ohio. In 1910, he was appointed manager of the railroad paint department of the Wrinkle Paint Manufacturing Company, Columbus, Ohio, and since 1915, was manager of the railway paint department of the Tropical Paint & Oil Company, Cleveland, until his recent appointment as manager of technical railway sales of the Glidden Company with headquarters at Cleveland.

M. Grant

The W. T. Dunn Co., 10 High street, Boston, Mass., has been appointed New England sales agent for B. M. Jones & Co., Inc., 192 Chambers street, New York, importer of Mushet and Titantic tool steels, and Taylor's best Yorkshire iron.

Charles M. Chamberlin, secretary and director of A. M. Castle & Co., Chicago, for the past 20 years, retired from all active business associations on April 1. Fred C. Conners has been elected a director and secretary to succeed Mr. Chamberlin.

J. J. Connors, until recently superintendent of motive power of the Denver & Salt Lake, has formed a connection with the Lowe Brothers Company, Dayton, Ohio, as railway representative, with office at 1243 Monadnock building, Chicago, Ill.

The E. Horton & Son Company, Windsor Locks, Conn., has bought the chuck business of the American Company, Hartford, Conn. The American Company has specialized in the manufacture of a 3-jaw geared drill chuck known as the Ellison chuck.

The Modern Tool Company announces arrangements whereby the E. L. Essley Machinery Company, 551 Washington boulevard, Chicago, becomes exclusive selling agents in the Chicago territory for Modern plain and universal grinding machines.

The offices of the Pocket List of Railroad Officials and the official Railway Equipment Register, published by the Railway Equipment and Publication Company, have been removed from 75 Church street to larger quarters at 424 West Thirty-third street, New York.

Allan A. Ryan has resigned as a director of the Chicago Pneumatic Tool Company, New York, and also as a director of the Vanadium Corporation of America. Mr. Ryan has been succeeded on the board of the latter company by T. M. Schumacher, president of the El Paso & Southwestern System.

The Pressed Steel Car Company, Pittsburgh, Pa., removed its New York office on May 1, from 24 Broad street, to the Seaboard National Bank Building, corner of Broad and Beaver streets. The stockholders of this company at a recent meeting ratified an increase of capitalization from $25,000,000 to $50,000,000.

F. W. McIntyre has been appointed general sales manager of the Reed-Prentice Company and the Whitcomb-Blaisdell Machine Tool Company, Worcester, Mass., also the Becker Milling Machine Company, Hyde Park, Boston, succeeding J. P. Ilsley, who has resigned to go with the Taylor Steel Construction Company, New York.

R. A. Bole

Robert Alexander Bole, vice-president, director and district sales manager of Manning, Maxwell & Moore, Inc., New York, died on April 2, at the age of 62, in the Schenley Hotel, Pittsburgh, where he made his home. Mr. Bole was widely known in the iron, steel and railroad circles. He was born in Old Allegheny City, and received his education in the Pittsburgh schools. In early life he became identified with the Westinghouse Machine Company and rose from the ranks to secretary of that company. Following his long service with the Westinghouse interests, he became identified with the manufacturing company of Niles-Bement-Pond Company, New York, and resigned from that company to become associated with Manning, Maxwell & Moore, Inc. At the time of his death, he had been identified with the latter company for a period of 26 years.

Robert B. M. Wilson, sales engineer in the Indiana district for the Conveyors Corporation of America, Chicago, has been appointed sales engineer of the Chicago district, and E. W. Wolfe, who has been for several years with the company in a sales capacity, becomes an assistant to Mr. Wilson, with headquarters in the corporation's main office at 326 West Madison street.

Frank N. Grigg has been appointed southeastern sales manager of the Morton Manufacturing Company, with headquarters at 630 Louisiana avenue, Washington, D. C. Mr. Grigg will handle the sale of the entire "Acme Line" of railway appliances. C. H. Kadie, formerly master mechanic on the Southern Railway, is now in the sales department of this company and will assist Mr. Grigg.

William T. Lane, district manager of the Pacific Coast territory of the Franklin Railway Supply Company, Inc., New York, has been transferred from San Francisco to Cleveland, Ohio, as district manager of the Cleveland territory, and James McLaughlin, assistant to the vice-president at Chicago, has been transferred to San Francisco as district manager of the Pacific Coast territory to succeed Mr. Lane.

W. H. Noble has been appointed district manager at Chicago of the Texas Company, Houston, Texas, succeeding John J. Flynn, deceased. Offices have been opened at St. Louis, Mo., 1689 Arcade building, with F. E. Sheehan, representative in charge; Los Angeles, Cal., 1206 Merchants National Bank building, with J. B. Flynn, representative in charge, and at Oklahoma City, Okla., with L. R. Dallam, representative in charge.

The Cincinnati Grinder Company, Cincinnati, Ohio, has recently placed the sale of its line of grinding machines on an exclusive basis with the Marshall & Huschart Machinery Company in the Chicago district; Motch & Merryweather Machinery Company in the Cleveland, Cincinnati, Pittsburgh and Detroit district; Henry Prentiss & Co. in the New York and New England district, and will also maintain its own grinding specialists in the respective territories.

The W. R. Hickman Lumber Company has been organized in Cleveland, Ohio, with W. R. Hickman, for the past five and a half years sales manager for the Nicola Stone & Myers Company, as president. The company will specialize in railroad and industrial lumber, handling yellow pine, West Coast stock, ties and hardwood car material. The general offices of the company are at 1264 Hanna building, Cleveland, Ohio, with representatives in Hattiesburg, Miss., and Seattle, Wash.

The Lilly Varnish Company, Indianapolis, Ind., has been sold to an organization consisting of C. M. Malott, president; C. F. Brigham, vice-president and general manager; C. F. Hackathorn, vice-president in charge of manufacture and purchases, and W. I. Longsworth, secretary and sales manager. Mr. Malott is also president of the Indianapolis Paint & Color Company. William Lilly, who has managed the Lilly Varnish Company for a long time, will remain with the new organization as treasurer.

The Fosdick Machine Tool Company, Cincinnati, Ohio, have taken over all patents, drawings, patterns, jigs and fixtures covering the line of Pierle quick change high speed ball bearing sensitive drill presses, from the R. K. Le Blond Machine Tool Company. This acquisition by the Fosdick Machine Tool Company will give them a complete line of drilling machinery, consisting of heavy duty radial drills, heavy duty upright and gang drills, and high speed sensitive single and multiple spindle drills.

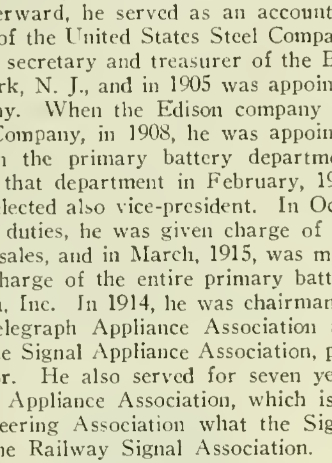
H. K. Porter

H. Kirke Porter, president of the H. K. Porter Company, Pittsburgh, Pa., died on April 10, at his home in Washington, D. C. He was born on November 24, 1840, at Concord, N. H., and studied at Newton Theological Institute and at Rochester Theological Seminary. He enlisted with the 45th Massachusetts Volunteers in 1862, and was mustered out of service in July, 1863. Mr. Porter served in the United States Christian Commission during the winter of 1864, and began his business life in 1866, as a member of the firm of Smith & Porter, manufacturing exclusively light locomotives. In 1871 the firm became Porter, Bell & Company. In 1879 it was changed to H. K. Porter & Co., and in 1899 was incorporated under the name of the H. K. Porter Company. During the past 20 years, the firm has been engaged in manufacturing heavy as well as light locomotives. This concern was the first to make compressed air locomotives for mine and general industrial use. Mr. Porter was a member of the 58th Congress from 1903 to 1905.

The Air Reduction Sales Company, Inc., manufacturers of Airco oxygen, acetylene and welding and cutting apparatus, moved its executive offices on May 1, from 120 Broadway to 342 Madison avenue, New York City. The New York district office at 160 Fifth avenue, New York, is now located at the Airco factory, 191 Pacific avenue, Jersey City, N. J. The company has secured control of the National Carbide Corporation of Virginia, with a new plant at Ivanhoe, Va., and will direct the policy and control the operation and sales of the Carbide Corporation.

The Elliott Company, Jeannette, Pa., announces the following changes in the company's sales organization: W. A. Darrow, who has been district sales manager of the Philadelphia office for the past ten or fifteen years, has been appointed special representative, with headquarters at Philadelphia. T. F. Crawford, St. Louis district sales manager, has been transferred to the Philadelphia office in the same capacity. C. L. Draper, of the Kansas City office, has been made district sales manager of the St. Louis office, and M. C. Sickels, of the Cleveland office, has been made Cleveland district sales manager, succeeding D. S. Tucker. All of the above will have charge of the sale of the products of the Lagonda Manufacturing Company, Springfield, Ohio, and the Liberty Manufacturing Company, Pittsburgh, in addition to those of the Elliott Company.

E. E. Hudson, vice-president and general manager of the Waterbury Battery Company, Waterbury, Conn., has been elected president of the company to succeed Charles B. Schoenmehl, deceased, and Francis T. Reeves has been elected treasurer. Mr. Hudson for the past 22 years, with the exception of a little over a year's time, has been in the sales and managerial departments of concerns manufacturing primary batteries and has been identified with the installation of the primary battery. In July, 1898, he served as chief clerk in the primary battery sales department of the Edison Manufacturing Company, remaining in that position until June, 1902. Shortly afterward, he served as an accountant in the controller's department of the United States Steel Company. In December, 1903, he became secretary and treasurer of the Battery Supplies Company, Newark, N. J., and in 1905 was appointed sales manager of that company. When the Edison company absorbed the Battery Supplies Company, in 1908, he was appointed assistant manager of sales in the primary battery department. He became sales manager of that department in February, 1909, and in September, 1913, was elected also vice-president. In October, 1914, in addition to these duties, he was given charge of the manufacturing, as well as the sales, and in March, 1915, was made division manager in general charge of the entire primary battery business of Thomas A. Edison, Inc. In 1914, he was chairman of the Railway Telephone & Telegraph Appliance Association and in 1916, he was chairman of the Signal Appliance Association, previously having been a director. He also served for seven years as a director of the National Appliance Association, which is to the American Railway Engineering Association what the Signal Appliance Association is to the Railway Signal Association. On January 1, 1917, he was elected vice-president and general manager of the Waterbury Battery Company and now becomes president of the same company.



R. G. Coburn

Ralph G. Coburn, president of the Stone Franklin Company, New York, has been elected also a vice-president of the Elvin Mechanical Stoker Company with headquarters at 50 Church street, New York, and E. W. Englebright, who became associated with the Elvin Mechanical Stoker Company in December, 1920, has also been elected a vice-president of that company. Mr. Coburn was born in Boston in 1882 and was graduated from Harvard in 1904. He then served, until 1909, with the American Glue Company in charge of its western territory, with headquarters at Des Moines, Iowa, and Chicago. On May 1, 1909, he opened the Chicago office of the Franklin Railway Supply Company as resident sales manager and in June, 1911, was appointed assistant to the vice-president in charge of eastern-southern territory, with headquarters at New York. In December, 1913, he was appointed eastern sales manager of the same company. In May, 1919, the Stone Franklin Company, New York, was organized to market the Stone Franklin car lighting system in the United States and Canada and Mr. Coburn was elected president of the new company, which position he retains in addition to his new duties as vice-president of the Elvin Mechanical Stoker Company.

TRADE PUBLICATIONS

Grinding and Polishing Machinery.—The Webster & Perks Co., Springfield, Ohio, has issued a catalogue made up of various bulletins which describe the different types of ball bearing and plain grinding and polishing machinery which they manufacture. An illustration of each machine and specifications are included.

Foundry Practice.—A very complete handbook on foundry practice has been issued recently by the Farrell-Cheek Steel Foundry Company, Sandusky, Ohio. The book, which is printed in four colors, not only describes, but illustrates profusely each operation required in the making of a casting, the same casting or pattern being used throughout.

Reamers at Work.—Under this title the Gisholt Machine Company, Madison, Wis., has issued an eight-page, illustrated booklet describing a solid adjustable Gisholt Reamer. This reamer is made in three body types: namely, shell reamer, straight shank machine reamer, and paper shank machine reamer. A size and price list is included in the catalogue.

Horizontal Return Tubular Boilers.—The Bigelow Company, New Haven, Conn., has reprinted in a separate book matter relating to their return tubular boilers and appearing in the company's regular catalogue. This includes a general description of this type of boiler, detailed instructions for setting, illustrations of boilers and furnaces and comprehensive tables of data.

Flange Oiler.—Catalogue No. 4 issued by the Hoofer Manufacturing Company, Chicago, contains 12, 5 in. by 8 in. pages devoted to a description of the Hoofer pneumatic flange oiler. A complete description of the construction and operation of this device is accompanied by suitable illustrations. A detailed illustration of the application of the lubricator, piping, control valve and oil distributors also is included.

Railroad Shop Grinding.—Under the title Grinding in Railroad Shops the Norton Company, Worcester, Mass., has recently issued a small 28-page booklet on this subject. The material is very interestingly arranged and accompanied by numerous illustrations. Among the subjects covered may be mentioned the grinding of piston rods, pins, car axles and wheels, valve parts, links, guide bars and miscellaneous shop tools.

Pointing, Thread-Cutting and Tapping Machinery.—The Webster & Perks Co., Springfield, Ohio, has issued a catalogue made up of various bulletins which describe and illustrate the different types of pointing, thread-cutting and special tapping machinery which they manufacture. The bulletins are grouped so that a separate section is devoted to a general description of each type of machine. Adjustable spring dies, and clamp die collars, optional holding devices, special holding devices and an improved geared rotary oil pump are also featured.

Advantages of Superheated Steam.—What Every Executive Should Know About Superheated Steam is the subject of Bulletin No. T-7 recently issued by the Superheater Company, New York. The bulletin discusses superheaters for stationary power plants and is designed to appeal to the executives and, therefore, has been made non-technical. After a brief explanation of superheated steam and the methods of producing it, the economies effected by its use are discussed, the concluding section dealing with the application of superheat to existing power plants.

Furnaces and Blowers.—A thorough discussion of various types of furnaces from the practical standpoint is one of the principal features of Catalogue No. 80 recently issued by the Chicago Flexible Shaft Company, Chicago. Particular attention is given to the requirements of furnaces for porcelain enameling, but much of the information is equally applicable to the types used in railroad shops. The general requirements of furnaces are taken up and muffle and semi-muffle types are discussed. This is followed by selections dealing with fuels and refractories. Several types of furnaces are illustrated and described together with the Stewart positive pressure blowers. The melting points of chemical elements and tables for the conversion of temperatures of the Fahrenheit and Centigrade scales are included.

The Present Situation in the Mechanical Department

THE railroad situation at the present time is a serious one for all concerned. Complaint is heard from the public that freight and passenger rates are too high. Yet despite these high rates the roads are not earning anywhere near the 6 per cent that was set up as a fair return by the Transportation Act. Normally, operating expenses are about 70 per cent of the gross revenue, but during the first three months of 1921 the larger roads on an average spent 92 cents out of every dollar for operating expenses. After paying taxes and rentals, less than two cents out of the dollar were left to pay interest on stocks and bonds. Such a condition could not be allowed to continue very long or a large share of the roads would have been bankrupt. The only alternative was to reduce expenses by stopping all but absolutely necessary work. Maintenance has been curtailed, many shops have been shut down entirely and other drastic economies have been put in force, but even so, many roads are still operating at a loss.

In times of business depression, like the present, it would be desirable for the roads to do more than the usual amount of work, instead of less. There is a great deal of equipment in need of repair and new locomotives and cars should be ordered in large numbers. But so long as the roads are unable to earn a fair return upon the capital invested in them, no one wants to lend them money and they cannot buy. So the first thing needed to get the railroads on their feet and to put railroad men back to work is an improvement in the earning power.

Some Prospect of Improvement

THERE is reason to believe that the roads will soon be in better condition to earn a fair rate of return. The freight traffic has increased slightly in recent weeks and any increase in revenue will permit an increase in the net earnings. However, a heavy traffic alone would not suffice, for during the last four months of 1920, with the new rates in effect, the roads handled the largest traffic ever known at that season of the year, yet their earnings were at the rate of only 3⅓ per cent annually.

It is doubtful whether the volume of business existing in 1920 will soon be restored. At any rate, it is evident that, regardless of the increase in traffic, there must be a considerable reduction in expenses wherever it can be effected. W. Jett Lauck has asserted that a billion dollars a year could be saved by more efficient management without any reduction in wages. This would be highly desirable if it were possible, but when the statement is analyzed, its absurdity becomes apparent. After the Labor Board had granted the wage increase last July and while the railroads were still handling a heavy traffic, their total operating expenses were at the rate of about $6,000,000,000 a year and of this amount almost $4,000,000,000 was paid out in wages. If a billion dollars was to be saved without reducing the payroll, all other expenses would need to be reduced almost 50 per cent. About four-fifths of this other $2,000,000,000 is spent for fuel and for materials and supplies. Railroads are universally known as being very close buyers, and there is no evidence that large sums can be saved in expenditures for material. There has been some reduction in prices during recent months and of course the roads will benefit by them, but not to a very great degree.

In the last analysis, some reduction in wages is inevitable. Fortunately, it is not only necessary; it is also justifiable. The report of the National Industrial Conference Board for May 1 showed that the cost of living was 65.7 per cent higher than in July, 1914, while the peak in 1920 was 104.5 per cent above the pre-war level. The Labor Board has recognized this situation and has announced that wages will be reduced. While such reductions are always unwelcome, the workers have little cause for complaint. There may be fewer dollars in the pay envelope, but they will buy as much in food, clothing and other items as did the higher wage six or eight months ago.

The labor unions in presenting their case before the Labor Board made sensational charges that have received wide publicity. The railroads' side of the case has not been as widely circulated and probably many of the employees have seen little of the evidence except that presented by their organizations and published in the unions' papers. It is important that railroad officers should know both sides and be able to counteract the propaganda of the labor organizations which may tend to cause dissatisfaction over the new wage scale. The rank and file of shop employees are intelligent, reasonable men and there is no reason to question that they will accept the decision of the board in the proper spirit if they are shown that it is necessary and also that it is fair.

Starting Over With a Clean Slate

THE abolition of the national agreements and the reduction of wages make the labor situation at this time particularly important. The first of July will open a new era in the relations between the railways and their employees. The rules drawn up and the precedents established in the next few months will probably determine the policies that must be followed for many years to come. Every railroad officer should be careful to get the right start under the new conditions. There has been too much hiding behind rules in the past; the time has come to see that every man gives a fair day's work for his day's pay. The foreman must deal with the men in a reasonable manner, but he must have the authority to enforce discipline which is necessary for efficient operation. Questions of minor importance must be settled locally and without losing the production of several men over every real or fancied grievance. Both sides should live up to a reasonable interpretation of the decisions made by the Labor Board. What is needed is absolute fairness and more regard for the spirit and less for the letter of the agreement.

More Repair Work Must Be Done

THE new working rules and new wage rates will probably bring about a gradual improvement in the railroad situation, although considerable optimism is required to foresee good times in the immediate future. The railroad situation is dependent on general business conditions and little improvement is expected before August. Eventually, of course, the traffic will increase to its normal volume and then the difficult problem will be to take care of it. Equipment has been going from bad to worse and the shops must soon resume operation on a big scale to prevent the equipment literally falling to pieces. Already the freight car situation is becoming very serious and a car shortage in the near future is not only probable, but inevitable if the present tendency continues.

Bad Order Cars, 14.2 Per Cent

A FEW weeks ago, on April 8, a new record for the number of freight cars standing idle was established when the car surplus amounted to 524,219. At the same time the number of bad order cars was about 250,000, so that actually there were 275,000 serviceable cars not in use. Since that time the idle cars have decreased and bad orders have increased. On May 1 the car surplus was 482,076 and the bad order cars 309,971, making the net surplus of serviceable cars 172,105. On May 15 the idle cars had decreased to 450,164 and the bad order cars had increased to 324,969, the difference being only 125,195, or 46,910 less than on May 1. A surplus of 450,000 idle cars may seem ample to take care of any increase in business, but when the actual surplus of serviceable cars is only 125,000 it is time the railroads took notice of the situation. If the demand for cars continues to increase as it did during the first half of May and if the bad orders also increase as fast, the small surplus of serviceable cars will be exhausted before July 1 and there will be an actual car shortage with over 350,000 idle cars, but all in bad order.
