The third Booke,

Intreating of all kind of excellent Antiquities, of buildings of
Houses, Temples, Amphitheaters, Palaces, Thermes, Obelisces, Bridges,
Arches triumphant, &c. set downe in Figures, with their grounds
and measures: as also the places where they stand, and who made them.

ROMA QVANTA FVIT I P S A R V I N A D O C E T

Although diuers Authors write many strange things touching Architecture, as the Egyptians, the people of Asia and Grecia, with diuers other nations, and haue left them for our example, (so that reading them, we may sufficiently satisfie our eares, and fill them with the greatnesse thereof, that is, touching the length, breadth and depth, that certaine places haue contained; yet we can not satisfie our eyes, nor the desire we haue to see such incredible works, vnlesse it had beene our hap to haue the contemplation thereof, for that the reliques of such works are almost, or for the most part vnterly defaced; or vnlesse we might haue seene them drawne in proportion vnto our eyes, as in this Booke we may not onely read, what the Romanes at the last, after other nations had built, but also the same Authors haue set downe vnto vs in Figure (as you may see them here) piece by piece, not only how many rods, ells, feet & palmes, but also the minutes thereof, and what compass they contained, all perfectly described. And although it was no part of my intent, to translate this Booke of Antiquities of Rome into our mother tongue, regarding the barrennesse of our language; or peradventure such a studie or fauour the same, are all too few to defray my charges therein: yet I haue not refrained to doe it, being thereunto compelled by the great works of the fortification of the City of Andwerp, and other great places; and for this cause specially, that euery man that wondreth at the greatnes thereof, which was made with most great cost & charges, may hereby see and consider, yea how much greater, & needles charges (to be compared vnto this) the Romanes (not speaking of other nation) haue in time past bestowed, in making of Obelises, Piramides, Thermes, Theaters, Amphitheaters, tryumphant Arches, and many more such like things, which serued only for pleasure & tryumph: whereby it is to be presumed, that they would haue made the fortifications of such Cities or Townes, made for the safety of the Land, far better then they now are. Now it is to be noted, that all, whatsoeuer the Romanes haue made, doth not wholly agree with Vitruuius rules, so that many which haue counterfeyted these, and such like peeces of worke, haue thereby beene abused and deceiued: for some would hardly beleue, that in those dayes (as well as at this time) all maner of workemen were one better then another, which many, vnawares and vnskillfully do many things, which good Antiquities would willingly not suffer, hereof they shall find good instructions in this Booke (and they may learne, if they will read it) how to discerne good from bad; wherunto the former printed fourth Booke is specially made: for in it the whole quantity of the measure is contained, as in the Epistle of the sayd Booke it is promised. So in this third Booke, you shall not onely find, first the Ichnographia, and then after the Orthographyes, with part of the Sciographies of the most famous Antiquities of Rome, Italy, and some of other places, but also of the most excellent buyldings in our dayes, specially those that are made by Bramant. So that the Reader being well instructed in the aforesayd fourth Booke, where all the Orders are well set foorth and declared, he may of himselfe iudge what is well or ill made, that at one time a man may, without any further labour, make a good and incorrigible peece of worke.

v. 1-5 in 1.

The first Booke of Architecture,

made by Sebastian Serly, entreating of Geometrie.

The first Chapter.

In needfull and necessary the most secret Art of Geometrie is for every Artificer and workeman, as those that for a long time have studied and wrought without the same can sufficiently witness, who since that time have attained vnto any knowledge of the said Arte, doe not ouely laugh and smile at their owne former simplicities, but in trueth may very well acknowledge that all whatsoeuer had bene formerly done by them, was not worth the looking on.

Seeing then the learning of Architecture comprehendeth in it many notable Artes, it is necessary that the Architector or workeman, should first, or at the least (if he can-
taine vnto any more) know so much thereof, as that hee may vnderstand the principles of Geometrie, that he may not be accompted amongst the number of stone-
masons, who beare the name of workmen, and scarce know how to make an answer
to a Point, Line, Plane, or Body is, and much lesse can tell what harmonie or
proportion meaneeth, but following after their owne minde, or other blinde con-
sents that haue vled to worke without rule or reason, they make bad worke, which
is the cause of much vncut or vnreuen workmanship which is found in many places.
Therefore seeing that Geometrie is the first degree of all good Art, to the end I may
teach the Architector so much thereof, as that he may thereby be able with good skill,
to haue some reason of his worke. Touching the speculations of Euclides and other
mathematicians, that haue written of Geometrie, I will leaue them, and onely take some
things out of their Garden, that therewith by the shortest way that I can, I may
bring at of diuers cutting through of Lines, with some demonstrations, meaning so-
ly and openly to set downe and declare the same, both in writing and in figures,
that every man may both conceiue and vnderstand them, aduertizing the Reader
not to proceed to know the second figure, before he hath well vnderstood
and found out the first, and so still proceeding, hee shall at
last attaine vnto his desire.

{ * * }

Of Geometrie

A Poynt.

A Line.

Parable.

Superficies.

Perpendicular.

FIRST, you must vnderstand that a poynt is a picke made with a Pen or Compasse, which can not bee divided into any because it containeth neither length nor bredth in it.

A Line is a right consecutiue imagination in length, beginning at a poynt, and endeth also at a poynt, but it hath no bredth.

When two Lines are set or placed of a little by denesse or the other, those two lines, according to the Latine phrase, are Parable, and by some men they are named Equidistances.

When those two Equidistances also are at each end closed together by another Line, it is then called a Superficies: and in all spaces in what manner soeuer they are closed, and shut up, led Superficies or plainnes.

When there is a straight vpright Line placed in the middle of a crose straight line, then it is called a Perpendicular or Cather, and the ends of the crose or straight Line on both sides of the perpendicular, are called Straight corners.

When a leaning or straight Line is placed vpon a straight without Compasse or equalitie, as much as the same Line be much shall the corner of the straight Line be narrower below other so much broader then a right or euen corner: and the corner in Latine is called Acutus, which signifieth sharpe, and the other corner Obtusus, which signifieth dull.

A corner or point called Piramidal, and also Acutus in Latine when two euen long straight lines meet or ioyne together at an end, as the figure right against this declareth.

And when such a figure is closed together at the foote the same by a long straight line, it is then called a Triangle, because it hath three sharpe corners.

When a Triangle with two euen straight lines, is closed with a longer line then these two are, it shall haue such a corner as you see.

But a Triangle which is made of three unlike lines, it shall also have three unlike corners.

When two long and two direct do one right lines are ioyned together at the foure corners, it is called Quadzangle with euen sides or corners, but when the foure lines are all of unlike or contrary lengths, then it is a Quadzangle of vneuen sides, as this figure sheweth.

You must note that although all foure cornerd figures may be called Quadrangles: nevertheless, for that the direct foure cornerd figures are called Quadratus: for difference from them, I will name all figures which are like vnto a table, (that is longer then broad) Quadrangles.

When foure euen long straight lines are ioyned together at the corners, they are called Quadratus, which are foure cornerd: when you make the two corners thereof sharpe, and the other two corners somewhat blunter, then it is called a Rhombus.

Although you may turne and make all the figures aforesaid right foure square: Yet the workeman may finde other figures with other corners. The which (as I will hereafter shew) hee may make foure square.

Superficie of a crooked Line.

When a man with his Compasse draweth a bowe, and after that draweth an other bow right against it, that is called a Superficie of crooked Lines, with two like corners: and then draweth a straight Line from the one corner to the other, and from one point or center where the Compasse stood to the other, another straight Line. Thereby you shall finde the right foure parts thereof.

But if a man drawe a whole round Line with his Compasse, that is called a full Circle, or round Superficie, and the point in the middle is called the Centre. The vtmost line is called Circumferentie: and if you draw a straight line through the Center, it is called a Diameter: because it deuidenth the Circle in two euen parts.

Of Geometric

The halfe Circle.

When the halfe Circumference is cut through the Center of the Diameter, then it is called halfe a Circle; and if you make a straight line by right in the halfe Circle, then that line maketh two even quarters of a Circle, and divideth the Diameter also into two halfe Diameters.

Vhen a man draweth foure even long lines, and joyneth them together, they make a perfect cornered Quadzatus; then if you draw a straight line from the one corner to the other, it is called Diagonus: because it divideth the foure corners into two even parts.

Now when a workeman hath seene a forme of some of the most necessary Superficies, hee must proceed further, and learne to augment or diminish the same, and to turne them into other formes: but yet in such sort, that they may have even parts in them.

And first, if out of the length of the Diagonus aforesayd, by the adding of three other even long lines, hee maketh another foure square: that foure square shall be once as great againe as the first, which is to be understood in this sort: That if some square of A. B. C. D. by the Diagonus is divideth into two Triangles, and the greater foure square A. D. F. E. containeth foure such Triangles: but for that the two first foure squares hang one within the other, therefore for the better shewing thereof, they are here once againe set downe severally: whereby you may see that the Quadzate G. (as I said before) containeth two Triangles, and the Quadzate H. containeth foure such Triangles, so that the proove thereof is clearely to be seene.

If within a foure square you make a Circle which toucheth the foure sides of the said foure square, and within the said foure square an other Circle which toucheth the corners marked A. B. C. D. Then the outmost Circle must be once as great againe as the innermost: and then if about the greatest Circle you make another foure square as C. D. E. F. then the two foure squares must in like sort be once as great againe as the other. The proove wherof standeth hereby marked with the letters K. L. so; clearer understanding of the same.

By this also, the proiecture of the soote of the Bases of the Tuscan Columns or Pillars, and also the breadth of the fundation of them underneath by Vitruvius declared, is set forth.

The workman must yet proceed farther, and learne to know how to change a Triangle into a Quadzangle, and also at last bring it to a right Quadzate, to the which I will set downe diuers formes. First, take a Triangle with euen corners, as A. B. C. and diuide the Base (which is the name of all lower lines) B. C. in two euen parts, and there place the letter E. Then from the point E. to A. drawe a line, which will diuide the Triangle into two euen parts. Then if you take that part which is marked A. E. C. and ioyne it to the other part, marked A. E. B. it will make a Quadzangle, as A. D. B. E. made of a Triangle.

You may also change this Triangle in other manner, diuiding the lines A. B. and A. C. each in two like parts as F. and G. Then drawe a line through D. E. as long as the Base B. C. Then shut up the two Equidistances, corner wise: and then the Quadzangle B. C. D. E. containeth so much in it as the Triangle A. B. C. and the prooffe thereof is, that the two Triangles B. C. F. and G. E. C. containe so much in them, as the two other Triangles A. F. H. and A. I. G.

A Triangle with euen points, may be diuided thrice into two equall parts, diuiding each side in two parts, as in the figure P. Q. R. it is seene through the three lines, which on either side make two great Triangles.

The same Triangle P. Q. R. may thus be changed into a Quadzangle: divide the side P. Q. and the side P. R. each in two equal parts, then draw a line S. T. as long as Q. and R. and then draw a line direct downward from T. R. to close it up: and then that Quadzangle contains as much space within it as the Triangle aforesayd, because that the Triangle which is cut off P. S. V. is of the like greatnesse with the other Triangle marked V. R. T.

And although there is a Triangle of unequal sides, yet a man may make it a Quadzangle, in such sort as I sayd before of the right Triangle: for although the two Triangles that are cut off, and those two that are added unto it, are not of one greatnesse, yet the Triangles A. F. I. and B. D. F. are one as great as the other, and againe, the Triangles A. G. K. & G. C. E. are also of one greatnes: so that those that are cut off, and those that are added thereunto, are of one quantitie. By these alterations aforesayd, a man may easily measure how many fete, elles or rodes foursquare, are contained in a three cornerd Superficies.

But if falleth out, that a Triangle (which is three cornerd) Superficie or plaine, must be parted crosswise in two equal parts: then out of one of the sides that you will cut through, you must make a right foure square, as from the side A. B. and draw therein two Diagonals from corner to corner, which will shew you the Center C. and draw one Circle through that three cornerd part which you will divide, and so you shall find the two points, where you shall drawe your deviding line. He that desireth any proove hereof, may take each piece and alter it into a Quadzangle, and alter into a Quadzate, as hereafter shall be shewed, and he shall find it true.

An Architect or must also undergoe other burthens, for that hee must know how to divide a piece of ground, that no man may be hindred thereby. As for example, if there were a piece of ground that lay three cornerd wisse, with unequal parts, having on the one side thereof a Well, but not in the middle: and this ground, or three cornerd piece of Land is to be divided into two equal parts, in such sort, that each of them may have the use of the Well: it must be done in this manner. I make a Triangle marked A. B. C. and the Well is marked with G. Now divide the line B. C. with a darke line in the two equal parts as the letter D. sheweth, and then drawing a line from D. to A. then the Triangle is divided into two equal parts: but both of them can not yet come to the Well: then drawe another line from the Well G. to A. and from the point D. you must set an Equidistance against G. A. marked with E. & drawing from G. which is the Well: the blacke line to the letter E. it will divide the ground in two even severall parts, and each of them shall have the Well at the end of his ground, so that part A. B. G. E. containeth in it inke as many fete or rodes, as that part which is marked G. E. C.

Shewed before, how a man should make a four square Superficie once as great again as it is, but it may fall out, that a man is to make it but halfe as great again, or more or lesse, as he thinketh good, or as occasion serueth, which the Architector is also to learne of necessity. Which to shew, I set downe a right fouresquare thing marked A. B. C. D. which I will haue thre quarters greater: the same thre quarters I set by the side thereof, so that the same with the Quadrate together make a Quadzangle A. E. C. G. To bring this Quadzangle into a right Quadzate, you must lengthen the line A. E. yet a quarter longer, or from the side of the Quadzangle E. G. and place F. there: then upon the line A. F. make halfe a Circle: which line will shew you the one side of the Quadzate which you seeke for: which Quadzate being made, will containe as much in it, as the Quadzangle already made. And in this manner you may change all Quadzangles which are long four cornered pieces of worke, into a iust and true Quadzate.

Now to proue that, which I sayd before, you must soyne the Quadzangle with the Quadzate together, in one foure square Superficie as Q. R. S. T. and from the corner R. to the corner S. draw a Diagonus, and it is certaine that that Diagonus will make two euen parts. Now Euclides saith, that when a man taketh any euen parts from euen parts, the rest of the parts also remaine alike: then take the Triangle K. L. and the Triangle M. N. which are both alike: the right foure cornered Superficie P. is of the same greatnesse, that the longer Superficie O is.

Alse, you may easily change a Quadzate into a Quadzangle, as long or as narrow as you desire to haue it, doing thus: Make your Quadzate A. B. C. D. and lengthen your line A. B. and the line B. C. which done, then set the length of the Quadzangle, which you desire to haue upon the line A. G. Then from the point G, draw a line along by the corner of the Quadzate D. to the line C. F. and there you find the shortest line of the Quadzangle: and so to the contrary you shall by the least side of the Quadzangle finde the longest also, as you may also proue by the fore-sayd Figure: for when you take away the Triangles M, N, and O. P. which are both alike, then the two parts which are K. L. are also alike.

Of Geometric

Architector may by chance have a piece of woꝝke of divers unequal sides come to his hands, which he is to put into a Quadꝛanguler or Quadꝛate forme, to know what it containeth, and specially when it belongeth to moꝛe then one man, whether it bee Land or any other thing. For although the Architector or Surveyor of Land could not skill of Arithmaticke or CIPHERING: yet this rule cannot faile him, noꝛ any other man that desireth to find out the deceite of a Taylor. Thus, I say then, let it bee what forme soever it will, I set downe this hereafter following. First then, seeke the greatest Quadꝛate or Quadꝛangle, that you can take out of it: that done, seeke yet another Quadꝛate or Quadꝛangle, as big as you can take out of it, out of the rest of the said woꝝke: and if you can after that make moꝛe Quadꝛates or Quadꝛangles out of it, I meane all with right corners, take them out also: but if you can find no moꝛe in it, then make Triangles also as big as you can, of which Triangles (as you are taught befoꝛe) you may make Quadꝛangles, and let every piece severally be marked with Characters, as in the figure following may be seene.

Let by example your many cornered figures first be marked with the great Quadꝛangle with these letters A. B. C. D. and then with a lesse Quadꝛangle, as E. F. G. H. the rest are all Triangles. Now set the greatest Quadꝛangle L. in a place by it selfe, and then the other marked with M. which set vpon it, that the two corners or sides may be alike: which done, lengthen the line E. F. and the line E. G. and where they stay or touch vnder the great Quadꝛangle L. there set an I. from this I. a Diagonall line, being drawn thꝛough the corners B. H. the same line shall be drawn to the point: that, by the shutting of the Characters B. M. L. D. will shew you another Quadꝛangle, of the like quantitie that the Quadꝛangle M. is: so that the whole Quadꝛangle D. C. L. M. containeth the two aforesayd Quadꝛangles. Touching the Triangles, when you have changed the same (according to your former instruction) into Quadꝛangles, as you may see by the Triangle N. so may you put that Quadꝛangle also in the greatest Quadꝛangle (for lesse trouble.) The great Quadꝛangle A. L. M. C. is once againe placed aboue with the small Quadꝛangle O. P. Q. R. set vpon it, and the Diagonall line is placed behind the greater (which is L. M. T. S. both marked with N. so that the Quadꝛangle A. C. S. T. containeth thꝛee Quadꝛangles L. M. N. and as many moꝛe as there are: you may in this sort bying them all in one Quadꝛangle: if there falleth out any crꝛeked lines, the skillfull Architector or woꝝke-man may almost bying them into a square, and those Quadꝛangles, if need be, may also be reduced into perfect foursquares, as aforesayd.

The Architectoz must haue a well proportioned Cornice, which if he would make greater, keeping the same proportion, hee may doe it as he is formerly taught, as in this Figure following is shewed by the short line marked A. B. and the longer line marked A. C.

Architectoz or workman, must likewise learne to augment & make greater a hollowed colūne, which hee may also doe by the two lines aforesayde, and although the Colūne should be a Dorica (yet it is to bee understood of all kinds of Colūnes. This rule wil also serue (not on-ly for the three figures set downe) but also for as many, as if I should shewe them, it would containe a whole booke of them alone, and therefore this shall suffice at this time for the workeman.

The further that any materiall thing standeth from our sight, so much it seemeth to lessen, and diminish by meanes of the ayre, which consumeth our sight: therefore when a man will make or place one thing above another, against any place or wall, & would have the same thing to shew above in the middle, and beneath, as great in one part as in the other, it is convenient for him to follow this rule, which is, for that our sight runneth in circumference: therefore a man must first chuse the place, from whence he will see the same: there placing a Center, and then draw a quarter of a Circle from your eye bywards. Which deviding in even parts, you shall, by the lines that goe out of the Center through the Circle against the wall, find the Unequall parts: the which although bywards against the wal, they shal seeme greater: yet in your sight they will shew al of one greatnesse. By this rule you may also measure heights, syding your selfe with the numbers.

Of Geometrie

When a man hath a line or other things of unequal parts, and there is also another longer line, or some other thing, which a man would also divide into unequal parts, according to the proportion of the shorter line, then let the shortest line be A. B. and the greatest line A. C. now it is necessary that from the uppermost point A. you should make a corner as A. B. and A. A. Then take your longer line, and set it with the end C. upon B. and let the other end rest at the hanging line A. A. then from every point of the uppermost line A. B. let a hanging line fall upon the line A. C. so that they may be equidistant with the line A. A. & where y^e said lines cut through each other, there is the right division proportioned, according to the smaller. This rule shall not only serve the Architect for many things, as I will partly shew; but will also serve many Artificers to reduce their small works into greater.

For example of the figure aforesaid, I suppose, Houses or pieces of Land to be of divers wideness, which should be narrower before then behind. Which Houses, by fire or warre are so decayed, that in the forepart between C. D. there were but some signs of division to be seen of the houses, and behind the houses betwixt A. and B. no signs at all to be seen. Now as the misfortune was past, and that every man desired to have his part of his inheritance, then the Architect, as an Empire, according to the rule aforesaid, should divide the longest line according to the proportion of the shortest, to give every man his share: as you may see by this Figure following.

Many men are of opinion, that straight lines, in what maner soeuer they are closed, containe as many spaces one way as another, (that is to say) if a man had a cord of forty foote long, and should lay it diuersly in a round, long, thre coznerd, foure square, or five coznerd forme: but the superficies are not of one selfe same space, which may be seene by these foure square figures following; for the first line holdeth on either side ten, which is forty: and the space containes ten times ten, which is an hundred. The other line vpon the two longest sides containes fiftene spaces, and on the shortest sides five, making forty also: but five times fiftene make but seuentie and five.

If the Quadrate stretch further out, so that the two longer sides were eghtene a peece, then the shortest sides must each haue thre to haue forty vpon the line, but the space should containe but sixe and thirtie. And hereby you see what a perfect forme may doe agaynst an vnperfect. And this rule the workeman shall vse, that he may not be deceiued when he will change one forme into another.

Of Geometric

If a man should make three points (which should not stand upon a right line) and desiring to have a circumference made, the compasse must passe along vpo each of these poyns. To doe it from the poynnt one, to the poynnt two, hee must draw a line, and from the poynnt two, to the poynnt three another: which two lines shall each of them be divided into two equal parts, and setting the Squiers halfe way in them, as you see it in the figure, by that crosse it will shew you the Center, wherein you must set one foot of the Compasse, and with the other draw the Circle through all the sayd three poyns.

Y^e may find the Center of three poyns another way, without your Compasse, making a two cornerd superficie from the one poynnt to the other, through the which Corners two straight lines being drawne long enough downwards where they crosse one over the other, they will shew you the Center of the three poyns.

But for if a workman holds this to be a superfluous speache, and a thing of no moment, it may be that a workman may have a pece of a round worke to doe, which he is to perfitt and make full round, by this rule hee may finde the Center, Circumference, and Diameter thereof, as the figure sheweth.

WE find in Antiquities, and also in moderne works, many Pillars or Columnes, which beneath in the topnts at the Bases are broken asunder, which is, because their Bases were not well made according to their corners: or else, because they are not rightly placed: so that they haue more weights vpon them on the one side, then on the other, whereby the Cantons breake, which the workeman by knowledge of the lines, and helpe of Geometry, may present in this maner: That is. Hee must make the Pillar round vnderneath, and his Base hollow inward: so that when you place the Pillar by the Lead, it may presently settle it selfe without any hurt. To finde this roundnes, you must set the one poynt of the Compasse vpon the highest part of the Pillar that is vnder the A. and the other poynt thereof vpon B. and then drawe, or winde it about to C. and that shall bes the roundnesse, making the hollowing of the Base, according to the same measure: you may dos the like with the Capitall, as you see in the Pillar by it.

Of Geometrie

If a workeman will make a Bridge, Bowe, or any other round Arched piece of worke, which is wyder then a halfe Circle, although Masons practise this with their lines, whereby they make such kinds of workes, which shew well to mens sight, yet if the workeman will follow the right Theozicke and reason thereof, hee must obserue the order heretofore shewed. When he hath the wydenesse of the height, then he must make halfe a Circle out of the middle: after that, vpon the same Centre, hee must make another lesser Circle, which must be no greater then he will make the height of the Bow or Arche: then he must deuide the greatest Circle in equal parts, which must al be drawen with lines to the Centre: then you must hang out other Perpendiculars vpon your Lead: and where the lines that go to the Centre cut thzough the lesser Circle, from thence you must draw the crosse lines toward the Perpendicular, and where they close together, there the Bowe or Archo which is made, shall be closed: as by the points or prickes hereafter is shewed.

But if you desire to make the Bow or Arche lower, then you must follow the rule aforesayd, and make the innermost Circle so much lesse, which is to be understood, that the more parts that you make of the greater Circle, so much the easlier you shall drawe the crooked lines which you would haue: from this rule there are many others obserued, as hereafter you shall see.

Calling the former rule to minde, I devised the manner how to forme and fashion divers kindes of vessels by the same, and I thinke it not amisse to set downe some of them: This onely is to bee marked, that as wide as you will make the vessels within, so great you must make the innermost Circle. The rest, the skillfull workeman may make by the figures, that is, how the lines are drawne to the Center, and the Paraboles, and out of the small Circle. The Perpendiculars hanging, the vessels are formed: the foote and the necks may be made as the workeman will.

BUT if you will make the body of the vessel thicker, then you must make the halfe Circle so much the greater, and make the belly hanging downe under it, to touch the great Circle, by the falling of the Perpendiculars vpo the crosse line, as by these Figures 3. 4. 5. it is shewed: whereby a man by this meanes may make divers vessels, differing from mine. The necks and covers of these vessels are within the small Circles: the other members and Ornamentals are alwayes to bee made, according to the wil of the ingenious workman.

Of Geometric

It is an excellent thing for a man to study or practise to do any thing with the Compass, whereby in time men may find out that which they never imagined: as this night it happened unto me, for that seeking to find a nearer rule, to make the forme of an Egge, then Albertus Durens hath set downe: I found this way to make an Anticke vessell, placing the foote beneath at the foot of an Egge, and the necke with the handles about upon the thickest part of the Egge. But first, you must frame the Egge in this manner: Make a straight crosse of two lines, and divide your crosse line in ten equal parts: that is, on each side five. Then, set the Compass upon the Center A. and with the other foote thereof, draw in two parts, that is, to C. making halfe a Circle upwards. That done, set one foote of the Compass upon the point marked B. and with the other draw in the uttermost point C. drawing a piece of a Circle downwards toward the Perpendicular, and doing the like on the other side, you must make a point below. Then take the halfe of the halfe Circle above that two parts, and place it at the uttermost point of the Perpendicular upwards about O. where the Centre to close the Egge, shall stand: the rest under shall be for the foote: the necke, without doubt, may be made two parts high, and the rest according to the workemans pleasure, or according to the figure hereunder set downe.

You may also make another forme of a Cup or vessell, after the rule aforesayd. But from the point A. (which doeth shew the breadth of the foote, and the widenesse of the mouth) you must make your Circle upwards, from C. unto the two Perpendiculars, where the body shall be closed by. The necke standing above it, shall be two parts high: but the rest of the workmanship shall be made according to the will and desire of the workeman.

By this meanes you may make the other different kindes of Cups or beffels: but these that follow, you must make in this sort: you must divide your crosse line in twelue parts through the point A. making two Perpendiculars to the foote and the necke: then setting one foote of the Compass upon B. and the other foote upon I. drawing a piece of a Circle downe-wards, towards the Perpendicular: and the like being done on the other side to the Figure of 2. then place your Compass upon the point C. and touching the sides 3. and 4. then the bottom of the beffell will be closed up: then place the Compass upon the point betwene I. and A. and it will bee the roundnesse of the beffell above: the other foure parts serue for the necke of the beffell, with the rest of the worke.

Again may make a beffell onely by a Circular forme, making therein a Circular crosse, and dividing every line in to six parts: the halfe circle shall be the belly of the beffell, and a first part upward for a Frese, that there may bee moze place to beautifie it: an other part shall be the height of the necke, and another part the cover: and for the foote, although it be but a halfe part high, it may well goe a first part without the round: and although I haue set downe but six manner of cups or beffels, yet according to the rule aforesayd, a man may make an infinite number of beffels, and a man may alter them by their Ornamentals, whereof I say nothing, that you may see the line the better.

Of Geometrie

A Man may make Duale formes in diuers fashions, but I will onely set downe foure. To make this first figure, you must set two perfect Triangles one about the other, like a Rhombus, and at the ioynting of them together, you must draw the lines through to 1. 2. 3. 4. and the corners A. B. C. D. shall be the foure Centers, then set one foot of the Compasse vpon B. and the other vpon I. and draw a line from thence to the figure 2. After that, from the point A. and 3. to 4. you must also draw a line: which being done, set the one ende of the Compasse in the point C. and then draw a piece of a Circle from 1. to 3. and againe, the Compasse being in the Center D. draw a piece of a Circle from 2. to 4. and then the forme is made. You must also vnderstand, that the nearer that the figures come to their Centers, so much the longer they are: and to the contrary, the further that they are from their Centers, the rounder they are: yet they are no perfect Circles, because they haue more then one Center.

For the making of the second Duale, you must first make these Circles, as you see here drawing, where 4 foure straight lines stand: the foure Centers shall be I. K. L. M. Then placing one point of the Compasse in K. you must draw a line with the other point from the figure of 1. to 2. Againe, without altering the Compasse, you shall set the one foot of the Compasse in I. and so draw a piece of a Circle from the figure 3. to the figure 4. and that maketh the Compasse, of the Circle. This figure is very like the forme of an Egge.

The third forme is made by two foure cornerd squares, drawing Diagonen lines in them, which shall shew the two Centers E. H. and the other two the corners F. G. Then draw a piece of a Circle from F. to the figure 1. and so to 2. Do the like from E. to 3. and 4. which done, from the points G. and H. make the two sides from 1. to 3. and from 2. to 4. and so shut by the Duale.

If you will make this fourth Duale, then make two Circles that may cut through each others Center, & the other two Centers for the closing of the Circle be N.O. after that, whether you draw the right lines or not from the points O.N. you shall shut up the sides from 1. and 2. and from 3. to 4.

And although our Authour sayth, there are foure formes of Duales: yet this last figure is of the same forme as the first, onely this is easier to make.

Touching the Circles, there are many figures which are round, and yet some have 5. 6. 7. 8. 9. and 10. corners, &c. But at this time, I will speake onely of these three principally: because they are most common.

This Octogonus, or eight points, is drawn out of a right foure cornered square, drawing the Diagonus which will shewe you the Center: then set one foote of your Compass upon the corners of the Quadrate, and leading the other foote through the Center, directing your Circle toward the side of the Quadrate, there your right points shall stand to make it eight cornered: and although a man might only doe it by the Circle, making a crosse therein, and deviding each quarter in two, yet it will not be so well, and therefore this is a surer and more perfect way.

The Hexagonus, that is, the six cornered Circle, is easiest made in a Circle: for when the Circle is made, you may divide the Circumference in six parts equally, without stirring the Compass, and drawing the line from one point to another, the six corners are made.

Of Geometrie

BUT the Pentagons that is five cornerd, is not so easly to be made as the others are, because it is of an uneven number of corners, notwithstanding you may make it in this manner: When the Circle is made, then make a straight crosse therein: then divide the one halfe of the crosse line in two parts, which is marked with the figure 3. then place the one foote of the Compasse upon 3. and with the other, placing it under the crosse, drawe downeward to the crosse line marked 2. from thence also from under the crosse, you shall finde the length of every side of the Pentagonus. In this figure also you shall finde the Decagonus, that is, ten corners: for, from the Center to the figure 2. that shall be one side thereof, you may also make a sixtē cornerd figure out of this widenesse 1. 2. and place a Particular line upon the point 3. And Albertus Durens saith, that the same also will serue to make a seven cornerd figure.

This figure will serue such men as are to part a Circumference into unequal parts, how many soever they be: but not to bring the Reader into confusidnesse, with making of many formes, I will onely set downe this divided into nine corners, which shall serue for an example of all the rest, which is thus: Take the quarter of the Circle, and divide it into nine parts, and foure of these parts will bee the ninth part of the whole Circumference: you must also vnderstand the same so, if you divide a Quadrate into eleuen, twelue, or thirtē parts, &c. for that alwayes foure of these parts bee the iust widenesse of your parts required.

There are many Quadrate proportion, but I will here set down but seven of the principallest of them, which shall best serue for the use of the workeman.

First, this forme is called a right four cornerd Quadrate.

The second forme or figure in Latine, is called Serquiquarta, that is, which is made of a foure cornerd Quadrate, and an eght part thereof ioyned vnto it.

The third figure in Latine, is called a Serquitertia, that is, made of a foure squared Quadrate, and a third part thereof ioyned vnto it.

The fourth, is called Diagona, of the line Diagonus: which line deuideth the foure square Quadrate crosse through the middle, which Diagonall line being toucht from vnder to the end thereof upwards with the Compasse, and so drawen, will shew you the length of the Diagonall Quadrate: but from this proportion there can bee no rule in number well set downe. The

The first figure is called a Serquialtera, that is, a foure square, and halfe of one of the foure squares added on to it.

The first is called Superbittentercias, that is, a foure square, and two third parts of one of the foure squares added thereunto.

The seventh and last figure, is called Dupla, that is, double: for it is made of two foure square formes ioyned together: and we finde not in any Antiquities, any forme that passeth the two foure squares, vnlesse it bee in Galleries, Entries and other to walke in: and some gates, doores, and windowes haue stood in their heights: but such as are wise will not passe such lengths in Chambers or Halls.

Many accidents like vnto this, may fall into a workmans hand, which is, that a man should lay a ceiling of a house in a place which is fiftaine foote long, and as many foote broad, & the rafters should be but fourtene foote long, and no more wood to be had: then in such case, the binding thereof must be made in such sort as you see it here set downe, that the rafters may serue, and this will also be strong enough.

Of Geometrie

It may also fall out, that a man should finde a Table of ten foote long, and threë foote broad: with this Table a man would make a dooze of seven foote high, and foure foote wyde. Now to doe it, a man would saw the Table long wyse in two parts, and setting them one vnder another, and so they would be but six foote high, and it should be seven: and againe, if they would cut it threë foote shorter, and so make it foure foote broad, then the one side shall be too much peeced. Therefore he must doe it in this sort: Take the Table of ten foote long, and threë foot broad, & marke it with A. B. C. D. then sawe it Diagonall wyse, that is, from the corner C. to B. with two equall parts, then draw the one peece thereof threë foote backwards towards the corner B. then the line A. F. shall be foure foote broad, and so shall the line E. D. also hold foure foote broad: by this meanes you shall have your dooze A. E. F. D. seven foote long, and foure foote broad, and you shall yet have the threë cornerd peeces marked E. B. G. and C. F. and C. left for some other vse.

It happeneth many times, that a workman hath an eye or round window to make in a Church, as in ancient times they used to make them, and he doubted of the greatnesse thereof, which if he will make after the rules of Geometry, hee must first measure the breadth of the place where he will set it, and therein he must make a halfe Circle: which halfe Circle being inclosed in a Quadrangle, then he shall finde the Center by two Diagonall lines: then he must draw two lines more, which shall reach from the two lowermost corners about the Center, and touch the last halfe of the Circle about: and where the sayd lines cut through the Diagonall lines, there you must make two Perpendicular lines, which Perpendicular lines shall shew the widenesse of the desired window: the last about it, may bee made the first part of the Diameter, being round in breadth.

If a workeman will make a Gate or a Doore in a Temple or a Church, which is to be proportioned according to the place, then he must take the widenesse within the Church, or else the bredth of the wall without: if the Church be small, and have Pilasters or Pillars within it: then he may take the widenesse betwene them, & set the same bredth in a foure square, that is, as high as broad, in which foure square, the Diagonall lines, and the other two crosse cutting lines will not onely shew you the widenes of the doore, but also the places and poynts of the ornaments of the same Doore, as you see here in this Figure. And although it should fall out, that you haue thre doores to make in a Church, and to that ende cut thre holes, yet you may obserue this proportion for the smallest of them. And although (gentle Reader) the crosse cutting thowow or deuiding is innumerable, yet for this time, lest I should be too tedious, I here end my Geometry.

Here endeth the first Booke of Architecture, treating of Geometry, translated out of Italian into Dutch: And now out of Dutch, into English, for the benefit of our English Nation, at the charges of Robert Peake. 1611.

The Old Boston The Old City Hall

The Old Boston City Hall, designed by the architect John Russell, was a landmark building in the city. It was a three-story structure with a prominent pediment and a central entrance. The building was constructed of brick and was one of the finest examples of Federal-style architecture in Boston. It was located on the corner of State and City Streets. The building was destroyed by fire in 1822 and was replaced by the current City Hall building. The drawing shows the exterior of the building, highlighting its classical features and the intricate details of its facade.

ANNO DOM. 1611.

The second Booke.

A Treatise of Perspective, touching the Superficies.

The second Chapter.

Although the subrill and ingenious Arte of Perspective is very difficult and troublesome to set downe in writing, and specially the body, or modell of things, which are drawn out of the ground: for it is an Arte which cannot be so well expressed by figures or writings, as by an vnderstanding, which is done severally: Notwithstanding, seeing that in my first Booke I have spoken of Geometry, without the which Perspective Arte is nothing: I will labour in the briefest manner that I can in this my second Booke, to shewe the workeman so much thereof, that hee shall be able to aide and helpe himselfe therewith.

In this worke I will not trouble my selfe to dispute Philosophically what Perspective is, or from whence it hath the originall: for learned *Euclides* writeth darkely of the speculation thereof.

But to proceede to the matter, touching that the workeman shall have cause to vse, you must vnderstand, that Perspective is that, which *Vitruuius* calleth *Scenographic*, that is, the vpright part and sides of any building or of any Superficies or bodies.

This Perspective then, consisteth principally in three lines: The first line is the Base below, from whence all things haue their beginning. The second line is that, which goeth or reacheth to the point, which some call sight, others, the horison: But the horison is the right name thereof, for the horison is in euery place where soeuer sight endeth. The third line, is the line of the distances, which ought alwayes to stand so high as the horison is farre or neere, according to the situation, as when time serueth, I will declare.

This Horison is to be vnderstood to stand at the corners of our sight, as if the workeman would shew a piece of worke against a flat wall, taking his beginning from the ground, where the feete of the beholders should stand. In such case it is requisite, that the Horison should be as high as our eye, and the distance to see or behold that worke, shall be set or placed in the fittest place thereabouts, as if it were in a Hall, or a Chamber, then the distance shall be taken at the entry thereof: but if it be within, or at the end of a Gallery or Court, then the distance shall be set at the entry of the same place, and if it be in a Streete against a wall or an house, then you must set your distance on the other side, right ouer against it. But if in such a case the streete is very narrow, then it were good to imagine a broad distance, lest the shortening fall out to be ouertedious or vnpleasant vnto you: for the longer or the wyder the distance is, the worke will shew so much the better and pleasanter.

But if you will begin a piece of worke of fise or sixe foote high from the ground whereon you stand, then it is requisite that the Horison should stand even with your eyes (as I sayd before) but if a man should see no ground of the worke, whereon the vppermost part doeth stand (and a man would worke very high) it would not be correspondent with the eyes: In such a case a man must take vpon him to place the Horison somewhat higher, by the aduice of some skillfull workman, which maketh histories or other things vpon Houses, thirtie or fortie foote high aboue a mans sight, which is vnfittingly. But cunning workmen fall into no such errors; for where they haue made any thing aboue our sight, there you could see no ground of the same worke, for that the notable Perspective Art hath bridled them: and therefore (as I sayd before) Perspective Art is very necessary for a workeman: And no Perspective workeman can make any worke without Architecture, nor the Architecture without Perspective.

To proue this, it appeareth by the Architectures in our dayes, wherein good Architecture hath begun to appeare and shew it selfe: For, was not *Bramant* an excellent Architector, and was he not first a Painter, and had great skill in Perspective Art, before he applyed himselfe to the Art of Architecture? and *Raphael Durbin*, was not he a most cunning Paynter, and an excellent Perspective Artist, before he became an Architector? And *Balthazar Perruzze* of *Sienna*, was also a Paynter, and so well seene in Perspective Art, that he seeking to place certayne Pillars and other Antike works perspectively, tooke such a pleasure in the proportions and measures thereof, that he also became an Architector: wherein he so much excelled, that his like was almost not to be found. Was not learned *Ieronimus Genga* also an excellent Paynter, and most cunning in

Perspective Arte, as the faire works, which he made for the pleasure of his Lord *Francisco Maria*,

Duke of *Vrbis*, can testifie, vnder whom he became a most excellent Architector? *Iulius*

Romanus, a scholler of *Raphael Durbin*; who, by Perspective Arte and Paynting, be-

came an excellent Architector, witnesseth the same. Then to come to my

purpose; I say, that a man must be diligent and vigilant in this Arte,

wherein I will begin with small things, and then proceed to

greater; vntill I haue shewed you the full Arte and man-

ner thereof, as I desire.

The ende that men by small matters may attaine to greater, therefore I will begin to shew how to shorten a foure cornered thing, from whence all the rest shall bee deriued. Then the Base of this foure square thing, shall be A. G. and the height of the Horizon (as I sayd befoze) shall bee imagined according to the sight, and that shall be P. whereunto all the lines doe runne, as the lines of the sides A. P. and G. P. then at the one ende of the Quadrante you must set a Perpendicular line, which is G. H. which done, then drawe the Base A. G. K. long inough, and then out of the Horizon drawe a Paralell or an Equidistant line from the Base, as far as you will that the eye or sight shall stand from that which you will looke on; for how much the more you will haue the foure square thing to seeme shorter, so much farther you must goe with your sight I. from H. to behold the foure square thing. And then, taking H. I. for the distance from the point I. to the corner A. draw a line, and where the line cutteth through the Perpendicular line H. G. that is on B. there the termination of the shortening of the foure square thing shall bee; as you may see in the figure following. But if you will make more foure squares one above the other, vpon the same Horizon or point: then you must draw another line from the shortening point of the foure square or Quadrant, to the letter I. and where it cutteth through the Perpendicular line aforesaid, that is at C. there the second Quadrant shall be cut off, and in like sort you must draw another line to the point of the distance: and where it toucheth the Lead, or Perpendicular line that is on D. you shall make the third Quadrant, the same may be done with E. and so you must goe, vntill you come vnder the Horizon.

The rule aforesaid is the perfectest, and you may pprove it by the line G. H. which is called the line of the Quadrante: but because it is cumbered with a greater number of lines, and so more tedious: therefore the rule ensuing shall be shorter, and easilier to be done then the other: for when the Base A. G. is drawne, and the two sidelines make a Triangle A. P. G. then you must draw the Paralels of the Base & of the Horizon long inough; and as farre as you will stand from the worke to see it, so farre you must set the Perpendiculars I. K. from the point G. the termination of the first shortened Quadrant: and if you will place more Quadrants upwards from that Quadrant, you must doe as I sayd befoze: and although there are other wayes to shorten a Quadrant, yet will I follow this order, as being the shortest and easiest to be set downe in writing.

Of Perspective

A Man must also be himselfe into diuers distances and grounds, and therefore you must make the ground following, which is of three Quadrantes high, in this manner. First, you must draw the line A. B. as long as the bredth of the worke shall be: which line of Base, must be deuided into so many equall parts as are needfull, which being all drawne to the Horizon or point, then you must place the distances as farre as you desire, according to the rule aforesayd; for here is no place to set it in, although it is a length and a halfe from the Base, as you see it marked with 1. Which Base, because it is of foure parts, therefore the first Quadrant containeth fyeteene small Quadrantes, which are found by the line B. D. for where that line cutteth throughe the foure lines, which goe to the point; there you must drawe the Paralel ouer, that thereby the sixtē Quadrantes may be formed: But if you will set other Quadrantes vpon it; then (as aforesayd) you must draw another line to the distance D. and where that cutteth throughe the other lines that reach to the point, that shall bee the termination of the second Quadrant, containing in it also foure times foure Quadrantes: The like must bee vnderstood of the third Quadrant, (and more besides if need bee.) But you must also vnderstand, that the lines marked D. runne all the distances, as it is taught before.

If you will make a pavement with great Quadrantes to be cut or Compassed with fascien, fallen or lifts, as you will terme them, then upon A. B. you must deuide the fallen or Quadrantes, and draw them all to the Horizon; then you must imagine the distances as you are taught before: and the line D. B. being drawn: from the point B. to the point F. fallen, or Borders. To draw the Paralels, then if you will make the like Quadrantes somewhat higher, then you must draw another line to the distances: and where it toucheth the Horizontall or Radfall lines, there also you must draw the Paralels through; so you must also doe with the third, and the point of the distances of these figures stand as farre from A. as the line or Base A. B. is long: If you will make diuers formes in these Quadrants, as Crokes, Crosses, five points, or eight points, I will shew the manner of them particularly, because I will bee as bryefe heere in as I may.

[Faint, illegible text, likely bleed-through from the reverse side of the page.]

[Faint, illegible text, likely bleed-through from the reverse side of the page.]

[Faint, illegible text, likely bleed-through from the reverse side of the page.]

Of Perspective

This figure is a Quadrant, containing in it a Kite or an other Quadrant, which with the points thereof toucheth the sides of the uttermost Quadrant; whereby it is but halfe so great as the uttermost Quadrant, as I have taught you in the first Booke of Geometrie, and the maner to make this, is thus. First, you must make a Quadrant (as you are taught before) with his distances; and in this Quadrant you must draw six Diagonall lines, and also the right crosse lines, whereby you may easily finde the Kite, as you see it in the figure directly against this. In this sort you may make the Kites in the other Quadrantes before set downe, that is, to draw Diagonall and crosse lines in them without taking other distances.

In this figure there is a crosse shewed (to make it) you must divide the lowest line or Base of the Quadrant in five parts; of the which five parts, one parte is the breadth of the crosse: which breadth being drawn to the points, the Diagonall lines will shew you the Parallel lines of the crosse, to be where made is.

The eight pointed figure you may see in Perspective booke in divers formes, which formes are all difficult inough: but that I may seeke the easiest way to make as I can in this my writing: Therefore I have set downe the manner thereof hereunto annexed, which is very easily; and that is thus. The Quadrant being made in shortening, you must divide the Base into ten equall parts, and on either side you shall leave three parts, and in the middle four parts, then the two lines being drawn to the Horizon, you shall find the terminations of the Parallel lines, by the Diagonall lines, which hereby you may close by the eight corners, as you may see it in the Figure.

The shortest way to place this five cornered Quadrant, in Perspective workes, is thus; When the Quadrant according to the rule aforesaid, is placed in shortening, then you must make foure equal parts of the Bases, whereof two shall be in the middle, and on each side you must leave one, and then draw the lines upwards to the Vertex or points: then you must draw the Diagonall lines, and in the middle where they meet together, you must draw a Parallel line cleane through, by the which you shall finde all the points to make this five cornered Figure.

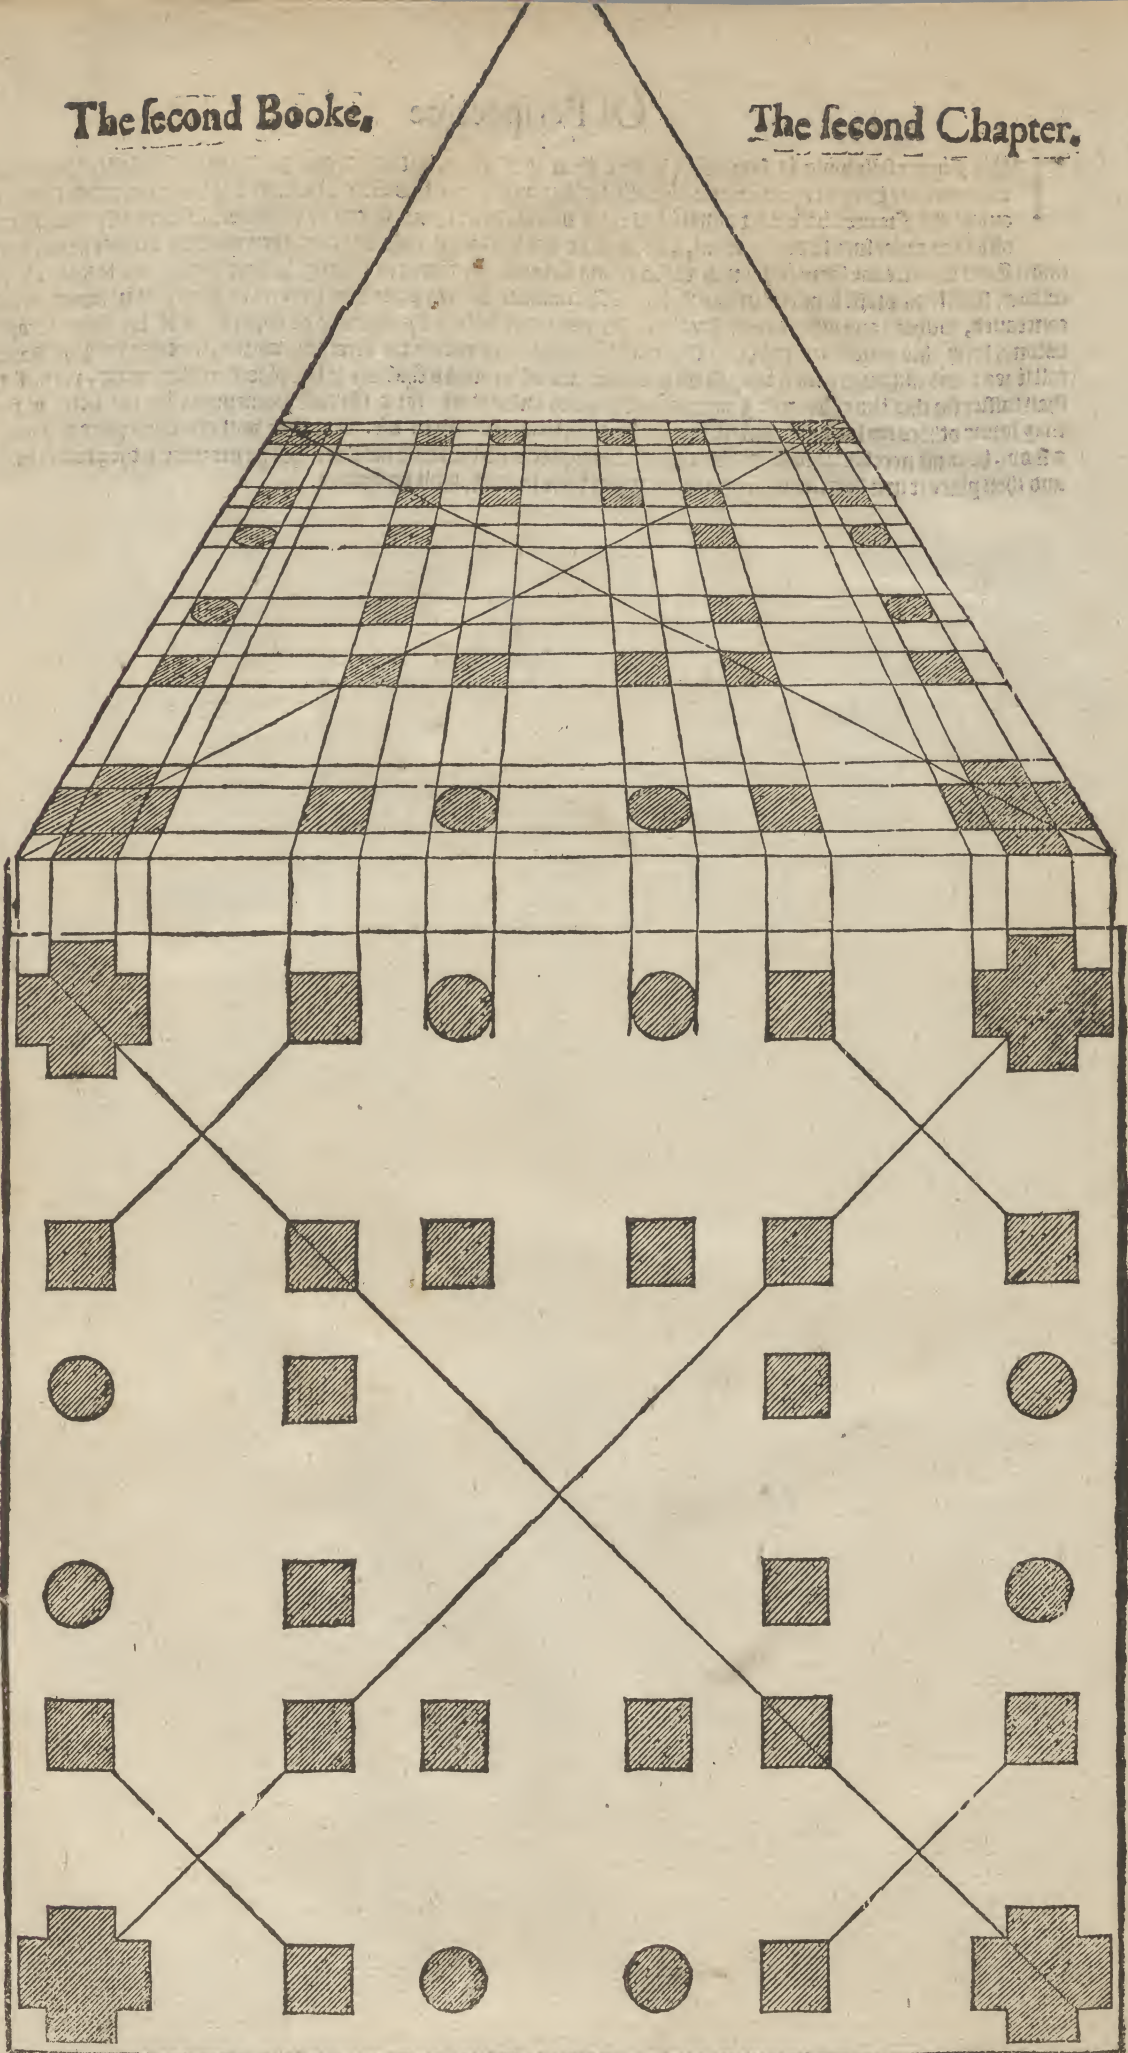

Now I haue shewed how you shall make simple or plaine Perspective workes of foure corners, of five corners, and eght square corners: Now I will shew, how you shall make them double, that is, that every simple figure shall haue his band. When you haue made a plaine Superficies of five points, according to the rule aforesaid; then as much as you will haue the band or safe to be in breadth, that you must draw upon the Base, and draw that also up to the Vertex: and where the Diagonall lines cut through it, there you must draw Parallel lines both vnder and above: and then draw two Diagonall lines more, out of the foure innermost points or corners of the five cornered Superficies; and so you shall finde your terminations to shut or close up your smallest five points or cornered Superficies. Which second Diagonal, Parallel, and Horizontall lines are all drawn with pickes, for a difference from the first lines; that you may know them one from another.

The like must be done with the eght cornered Superficies or Perspective work, for when the same is made within a fouresquare, making the Compass of what breadth you will, according to the rule aforesaid: then out of every point or corner of the eght square, a small line being drawn to the Center, you shall finde the termination to shut by the innermost eght square; and then, when from point to point the lines are drawn, then one square or Compass is full made. This eght square forme may be changed into a round, four way the middle on either side, or else without, once the points or corners; a good workeman may easily draw a Circular shortening round line with his hand.

Although I haue said befoze that a man may make a round Circle about an eyght square, yet for moze securitie you may by this way attaine to a moze perfection therein; for that the moze points or sides the Circular forme hath, the round Compasse or Circle will be the fuller. But to make this Figure, it is necessary to make halfe a Circle vnder the Bases; and to deuide the Circumference into as many parts as you will, so that they be euen; in this forme the halfe Circle is deuided into eyght parts, so that the whole Circle must bee sixteene parts; which being done, you must set Perpendicular lines in all the parts of the Circumference, as farre as to the Bases of the shortned Quadrant, these parts being euuated to the Horizon, and two Diagonall lines drawn in the Quadrante, they by cutting through the Horizontall or Radiall lines, will shew you the Paralell lines. Then if you will draw a little vnto the other bytwards going ouer the points: then the formes will be closed, as you see them heere; whereby it will be easie for you to draw a round forme with your hand, for it is impossible to bee done with the Compasse to make it short n well. This figure you must be expert in, and you must also vnderstand it well, and so you must those that I haue befoze set downe, befoze you proceed farther: for they will serue you for many pieces of worke hereafter ensuing, as you shall both see and find to be true.

This Figure following is somewhat harder then that before, but when you goe from the smallest to the greatest, you conceive things the easier, and specially he that will learne this Arte; he must not leave nor refuse to exercise any of the Figures before set downe, but must vse all the diligence he can to be perfect in them all, and hee must also take a pleasure to doe them all, otherwise he that will omit now one, and then another, because he can hardly understand or conceive them (although I labour and strue at all times in setting downe these rules to shew all difficulties) shall little profit himselfe in this Arte. The manner how to place this ground in Perspective forme, is easily conceived, without any other demonstration: for you must follow the manner or operation of the figure before set downe, with his advertisement; that the two Diagonal lines evermore direct the worke, together with the Horizontall lines: and although a man may shew many formes of grounds that are to bee placed in shortening, yet these two shall suffice for this time, because I have other things to entreat off: for a skilfull workeman, by the helpe of these, may forme others for his purpose, and such as he shall have occasion to vse. And if he will erect any peece of worke for a show, he must necessarily first measure the Orthographic with the same measure that he measureth the ground withal, and then place it in a shortening manner, as when time serveth, shall be shewed.

Of Perspective workes, touching Bodies or Masse things.

The third Chapter.

Touching the grounds and other Superficies of diuers formes, I thinke I haue sufficiently spoken. Now I will speake of Bodies which are drawne by out of the ground: and first, you know that I haue taught before, how you should frame an eght square forme plainly in it selfe; and then, I haue shewed how you should compasse this Figure about, with a border or edge: but if a workeman will shew an eght square Figure in Perspective

wise, as a Well, then he must first make the ground, as he is taught before, as high as hee will, that the sayd Well shall stand elevated aboue the ground or soke thereof: there hee must make the same forme once againe, drawing it to the same Position; then from all the uppermost corners or points to the lowest; you must drawe Perpendicular lines as well from the innermost figures, as from the uttermost, whereby the through cutting eght square bodies will be formed, as you may see in the Figure hereunto annexed.

I haue spoken before of the open frame of a Well with eght points or corners, which is necessary to be learned, how to make it, before you make the solide body thereof, as this figure sheweth, which is the same that is before shewed, both forme and measure, but all the lines which cannot outwardly be seene, are hidden; and there is as much difference betwene an open body and a solide, as there is betwene the modell of a mans body, that is nothing but bones without flesh and skinne: and a living body of a man covered ouer with flesh (although it is hidden vnder it.)

And as those Paynters are much perfecter that haue seene, and perfectly beheld right Anatomies, then others that onely content themselves with the outward bare shew of the Superficies, so it is with Perspective workes; for they that wel vnderstand and perfectly beare in minde the hidden lines, they shall better vnderstand the Arte then others, that content themselves only with the shew of outward Superficies. It is very true that when a man hath sufficiently experimented, practised and beareth in his mind these inward hidden lines, then helping himselfe with the principall, hee may make many perfect things without vsing all this labour.

For these three figures following, every one is drawne out of the square, in such manner as I have taught before; and they goe all three to one Position or point as they should do, or as need requireth; by the which figures any man may helpe himselfe in many things, as I have further declared: and he that is perfect in these, may make all kinde of round formes, and without knowing of these, hee can doe little in round formes. For out of these figures you may draw a round Solide or Pyramidall Building with Pillars, or without Pillars; and also a round winding paire of Staires: for this Figure will shew you how to make the Staires round, with other things more, and yet not without your owne industry: for the things that by these may be made are wonderfull and infinite, so that you ware not weary, and spare no paynes till you are perfect in them, because that the bowing or Arches of gates and other things will seeme hard unto you, as I will hereafter shew you; notwithstanding that they take their beginning altogether from these.

But if any man that desireth to learne this Arte, will at the first understand these figures, as some blantly will take upon him to doe it. I beleue certainly, he will bee put to an non plus, and deceave himselfe; but if by learning all the former things, he proceedeth unto these as well in Geometrie as in Perspective Arte: Then, I say, he is of a very grosse understanding, if he cannot understand or conceave these figures, or the figures that hereafter follow.

These three figures, to speake truth, are but Superficies; nevertheless, if you draw Perpendicular lines from all the terminations, as well within as without: then you shall have a through cutting or open body, and the innermost lines covered, then they will be a Masse body: And wonder not, gentle Reader, nor let it be strange unto you, though I doe sometimes make a long discourse of some things, for (as I sayd before) they are not only learned by many words and great paynes, but it is also necessary that they were shewed unto some men playnely by drawing them before them, that they may the better conceave them.

Of Perspective

The most part of great Rivers of water-falles that fall downe from high Hills or Mountains, by meanes of tempests with great force and power, when they enter into a Valley, then sometimes they run out of their Channel, and so much ground as they then blurpe vpon on the one side, so much they lose againe on the other side; and so doeth Perspective worke in cornered things, for that as much as a man loseth of the point or corner whereon he looketh, so much greater the other point or corner sheweth that standeth out, which is shewed in the Figures hereunto annexed.

The Reader must then marke that the square in the middle signifieth the thickenesse of a square Colonne or Pillar, and the border that is without and goeth about it, signifieth the thickenesse or bearing out of the Bases and the Capital. The Figure vnder this platfome is the Base, and the vppermost Figure is the Capitall; the manner how to shorten them I will shew you: You must make the Pillar flat before without thiknes, and vpon it you shall forme the Bases and Capital, making the Proiecture or bearing out thereof on either side alike, but you must draw them lightly as the prickes here. A set forme doe shew you: then draw the side of the Pillar which you will haue seen towards the Horizon; and having found how thicke the decreasing or shortening side must be, by the rules that are shewed in the first part of Perspective worke, so you shall haue the shortening ground of the Pillar, wherein you must lightly drawe the two Diagonal lines long enough through, and from the Bases below, which is same in the shortening; you must draw a line towards the Horizon, which you shall also let goe downe or sincke so farre, till it reacheth beneath the Diagonal lines, and there shall be the terminations of the shortening Bases: and thus you see that the Perspective taketh somewhat off from them, that is, the space betwene the points and the full blacke line; then from the terminations to the other vtermost point of the Bases, you must drawe a Paralel line vnder the ground of the Pillars, so long that it may touch the Diagonal lines, and there you shall finde that which is taken of from the Bases on the one side, and given to them on the other side, and the Proiecture of the Bases sheweth, that the one point is drawne inwards, and the other cometh further out, then the vppermost line of the Bases being also to the Horizon: then vpon the shortening side by a line you finde the third parte of the Bases below, and that which is here spoken of the Bases, you must vnderstand the same also of the Capitalls.

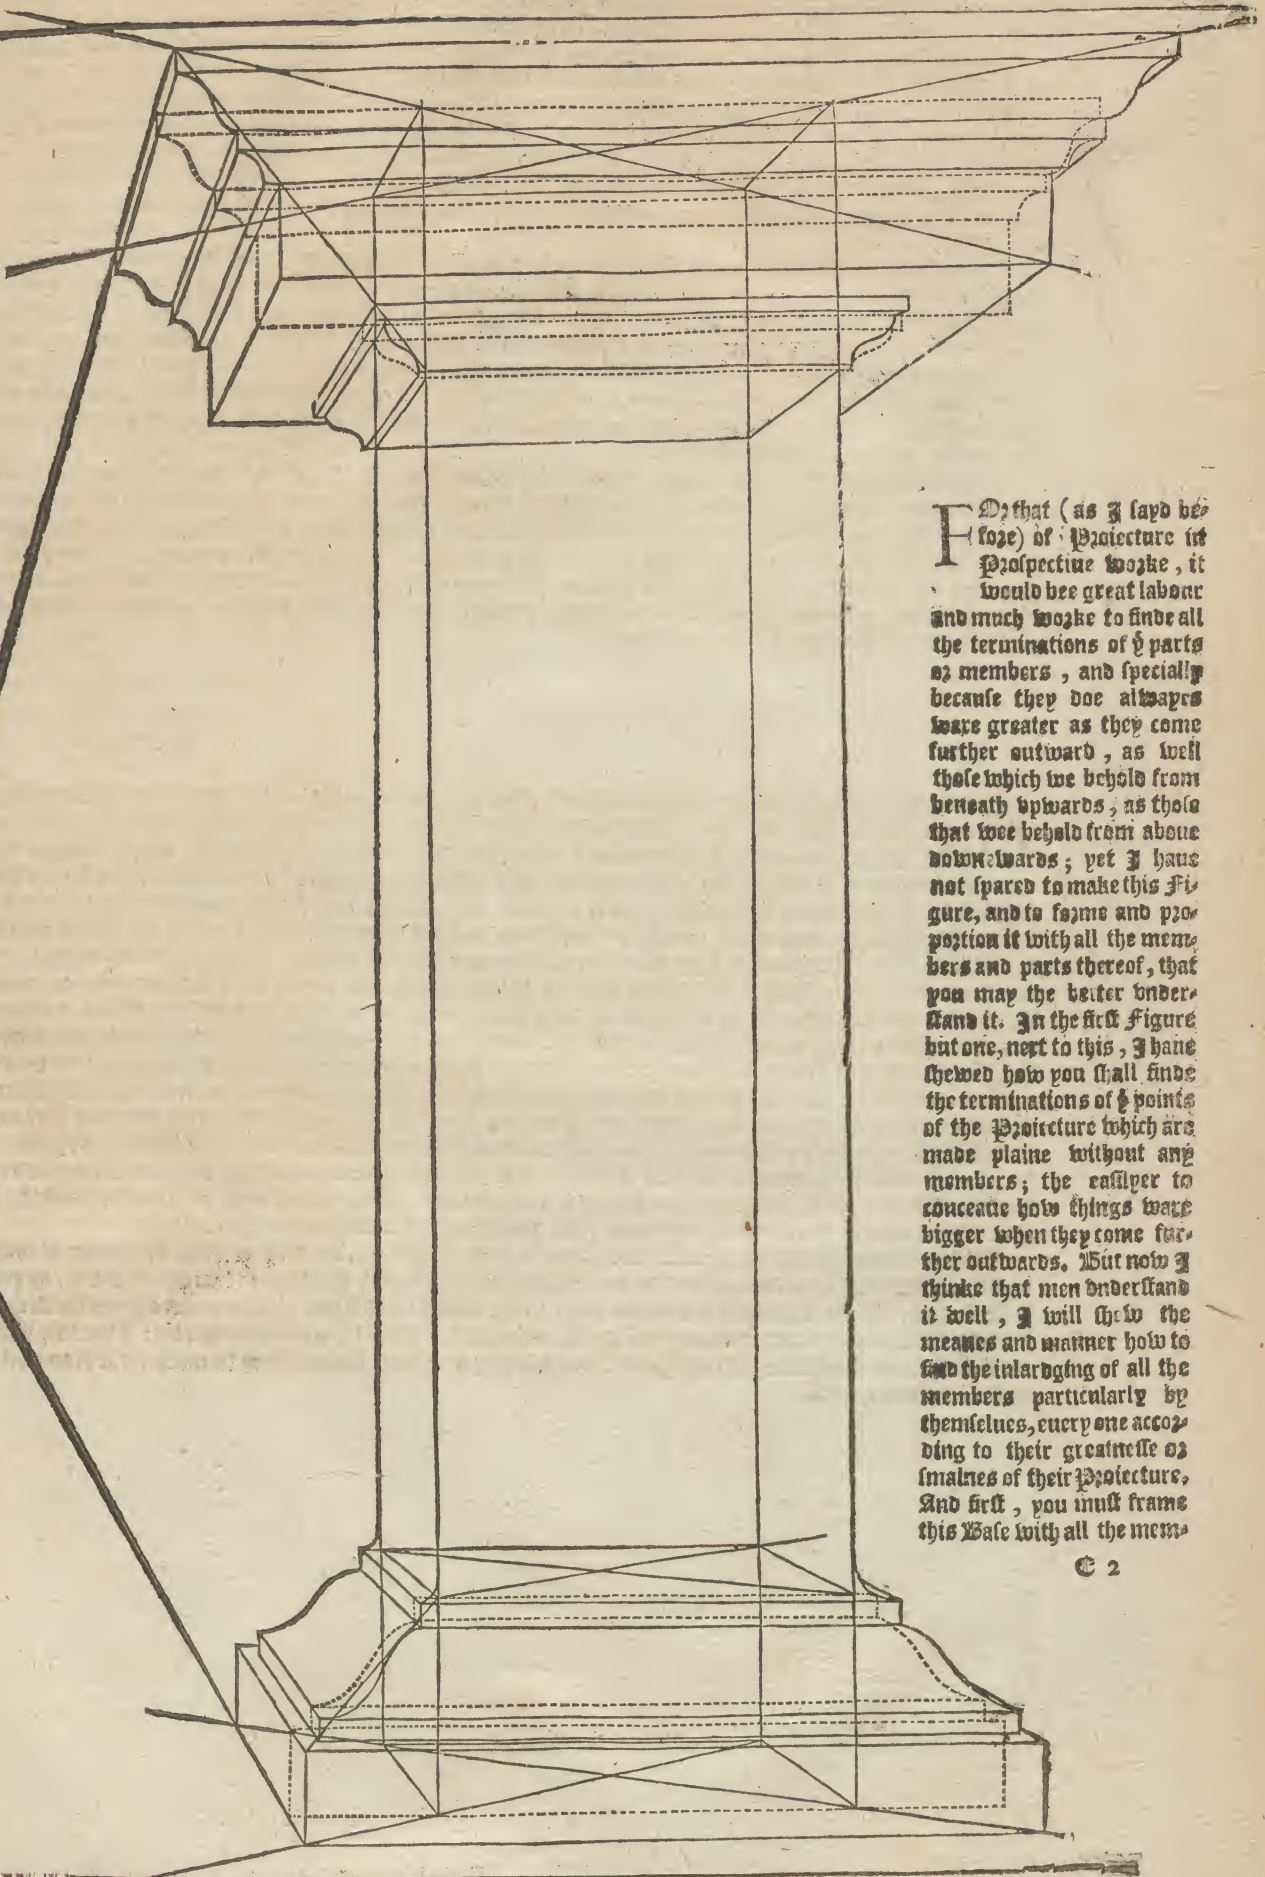

Of Perspective

THE other three Figures are the same which are shewed before; the first were hollow, but these are perfect and solide with all their members, and although that in the Figures before I have not shewed how you should forme and frame these members, which in trueth would be a very confused and troublesome thing to set downe in writing; therefore I have only shewed the first terminations, that a man may keepe them well in his memozy, and in these present Figures I have shewed how they shew in a mans sight, that you may see the effect that they worke: but from henceforward because (as I said before) it is a troublesome thing, I will make another forme of them with all their members by darke lines: and then (according to my abilitie) I will set downe the manner how to finde the terminations of the members one after another, for all of them grow a little one over, or more then the other.

But you must consider that these Bases and Capitals on the one side grow inward, and on the other side beareth out, which you must well remember, that you may first bee well instructed herein touching that which you will make. For it is true that the Theoziche consisteth in the understanding; but experience is gotten by practise and right use or handling: Therefore the most notable Painter Leonardus Vinci, was never pleased nor satisfied with any thing that he made, bying but little worke to perfection, saying, the cause thereof was that his hand could not effect the understanding of his mind: And for my part, if I should do as he did, I should not, neither would I suffer any of my works to come forth: for (to say the truth) whatsoever I make or wyte, it pleaseeth me not: but (as I sayd in the beginning of my worke) that I had rather exercise in worke that small talent, which it hath pleased God to bestow vpon me, then suffer it to lye and rot under the earth without any fruit; and although I shall not please thereby such as are curious, to set downe the ground and perfection of all things, yet at least I shall helpe yong beginners that know little or nothing thereof, which hath alwayes bene my intent.

For that (as I sayd be-
 fore) of Perspective in
 Prospective worke, it
 would bee great labour
 and much worke to finde all
 the terminations of y^e parts
 or members, and specially
 because they doe alwayes
 waxe greater as they come
 further outward, as well
 those which we behold from
 beneath upwards, as those
 that wee behold from above
 downwards; yet I haue
 not spared to make this Fi-
 gure, and to sayme and pro-
 portion it with all the mem-
 bers and parts thereof, that
 you may the better under-
 stand it. In the first figure
 but one, next to this, I haue
 shewed how you shall finde
 the terminations of y^e points
 of the Perspective which are
 made plaine without any
 members; the easlier to
 conceaue how things waxe
 bigger when they come fur-
 ther outwards. But now I
 thinke that men understand
 it well, I will shew the
 meanes and manner how to
 find the inlarging of all the
 members particularly by
 themselves, every one accor-
 ding to their greatnesse or
 smalnes of their Perspective.
 And first, you must frame
 this Base with all the mem-

bers, and with the right Perspective thereof, to bee without any shortening before, yet you must draw it lightly with a piece of Lead, or some other thing, as it is shewed unto you here with pickes; then in the ground or foot of the Pillar you must draw the two Diagonall lines long inough out, and thereby (as I sayd before) you shall find the diminishing and the increasing of the particular parts of the crests of the said Bale, whereas the undermost line or foote of the crests of the Bale, beare much more broader and longer then those that are marked with the pickes; then at each corner of the Crest of the Bale you must draw an upright line almost as high as the first crest of the Bale (although I have done it) but upon the uttermost point not to comber the worke within: then you must draw the uppermost corners of the first Crest with pickes also, toward the Horizon, which downwards will touch against the two upright lines; and there shall be the terminations to close or shut up the second great Crest with a full blacke line: then draw another blacke line from the innermost point of the Crest upwards to the Horizon, and there the shortening Crest shall be closed.

And as this Crest or Plinth is closed and drawn on all sides with blacke lines, so you must doe with all the other lines of the Bale, so when from the uppermost corner of the first marked Bale you draw a helving line to the innermost corner of the greatest Crest with the blacke lines, by it you shall lightly find the terminations of all the parts or members, drawing the corners of the first Bale towards the Horizon. And when you have formed all the innermost corners of the Bales, by the Horizontall line you may easily doe the second, and by the Paralel lines the uttermost of all; although by the lines of the distances, you may bring the said corners somewhat nearer as you may see by the Diagonall lines. But at this time I will not speake of that difficult or hard worke, for he that hath any understanding herein, may here with helpe himselfe.

That which is here sayd of the Bales, you must also understand of the Cornices, onely that every thing is contrary; and where you set Perpendicular lines below, which cut through the Horizontall or Radiall lines, so you must also fall about the Lead lines or Cathetes upon the Horizontall lines, as you may better see it and learne it in the Figure, then it can be exprest by words: and you must not be afraid or abashed, although at first you cannot conceave it, for that by practising you shall in time finde it, for it is not sayd that a man shall or can learne all things at once in one day: by this Cornice you may make all Cornices, be they higher or lower, harder or easier, alwayes drawing every member and part towards the Horizon as it should be done.

Although there are divers manners & wayes to place Columnes one behind the other, standing upon one ground in Perspective wise, thereby to make Portales, Galleries and other things, yet this hereunto annexed is the easiest. First, you must make a Pavement with a quantitie of foure cornered Quadrants, as it is also shewed in the beginning of this Booke; which may be of such breadth, as you will: Say that these foure square stones are two foote broad, which shall be the thickness of a Pillar: betwixt the two first Pillars beneath in the breadth, there shall be eight square stones, and the height of the Pillars made of what quantitie you will; and they being raised toward the Horizon, then you must draw two severall lines over both the Pillars, and then out of the middle of the first line you must make two halfe Circles about upon the flat side before, and divide them in as many parts as you will; which parts shall be drawne to the Center of the halfe Circle, standing in the uppermost line: then out of the middle of the two severall lines you must draw the lesse halfe Circle, and all terminations of the flat Arch being drawne to the Horizon, then the first Arch or Gate is made: the other two Pillars upwards drawne to the Horizon, then the first Arch or Gate is made: the other two Pillars upwards shall also stand eight Quadrants distant from the first Pillars, which will make a foure cornered place on all sides: containing 64. square stones: and you must doe with this gate as you did with the first, onely (when they are all of one wydenesse as these are) you need not divide the Arches againe, for the Horizontall lines of the stones of the first Arch will shew you the terminations of all the other Arches, and also how long the Gallery must be, and how many Arches it must containe. I have placed no Arches here in the sides, because I would not comber you too much at this time; but I will speake thereof hereafter particularly.

The two Dories on each side are both partly covered with the Pillars, but the wydenesse of them is of foure Quadrants, besides that from the corner of the dories to the Pillars on each side there is two Quadrants, as you see the halfe thereof; and the other halfe you must suppose to be behind the Pillars. The beames above the Arches which beare up the Chamber above, you may well guesse, although I write not particularly thereof: I have not like wise set the Bases nor the Capitals upon these Pillars, because they should not darken them too much; but in another place I will also entreat thereof.

Of Perspective

These two Bowes or Arches are onely made to know how to ioyne their Bases and Capitals to them, wherof in the seuerall places I haue spoken befoze, and shewed how they rise on the one side, and fall or decrease in sight on the other side; that a man may the better learne how to doe them: for in truely, if a man could shew it vnto you in effect, you would the easier vnderstand it; but to set it downe in writing or Figures as I doe, that men hereafter might know and learne them: it is requisite to entreat of them moze at large, and that you may the better discern and perceiue the poyns of the thin lines from the other poyns or corners of the blacke lines; therefore here I haue placed the poyns of the distances and the Horizon downward; and haue placed the Pillars in other manner vpon this ground without Quadrant stones: In this manner set the bredth of the two first Pillars vpon the Base of such thickenesse as you will, and draw them inwards, towards the Horizon, then you must imagine the distances, as I haue already taught you: and these distances are set on both sides, and on epyther point of the distances you must draw a line both toward the right and left poyns or corner of each Pillar.

These Diagonall lines will not enely shew you the thickenesse of the first or foremost Pillars when they thorten, but also the thickenesse of the two other Pillars which stand inward, which are all marked with prickes (and as I haue likewise said befoze) that which is here sayd of the Bases of the Pillars, the same also must be vnderstood vptward of the Capitals: touching the thickenesse of the bowes or Arches vnderneath, I haue shewed in the Figure befoze. how you must place the Center in the middle of the foure crosse point lines, to draw the halfe Circumference: The foure square or Quadrant above, is as great as that below on the ground; I need not shew how you shall make it, for you see it plaine enough in the Figure.

This Figure is like the former, onely that the members of the Bases and Capitals are added thereunto; thereby to make it more perfect unto you, and to shew you how a thing will stand when it is full made and finished, although I haue shewed it before; neuertheless, when a man is perfect herein, then he may by practise helpe himselfe well enough without all this labour, using discretion and bearing in remembrance that, which he hath impinted in his mind: For in trueth, by this meanes (I meane the ground) a man may by practise make many things; which if they be made with discretion, and by a workeman, will alwayes beautifie the worke, as these bowes or Arches do, which vnder are deuised with Quadrantes, as you may see them. There are, as you know, first two Centers to forme the Arche vnderneath; now a wise workeman must not alwayes seeke for the perfection of the edge of these Quadrants; but for example, say that the Arche vnderneath is deuised into eght parts, where of sixe shall be for the Quadrant, and two parts for the edge or border that runneth about it; now you must deuise the space betwene the one Center and the other, also in eght parts, but they must shorten or lessen a little, that is, the neather part against the vpper; & then the compasse being set somewhat lower, and made narrower: then you must draw the vppermost border, and then the compasse being set a little below the neathermost Center; you must in like sort drawe the other edge or border: after, you must square or deuise the Quadrants, leauing the space betwene both, once so broad againe as the other, which must be drawn by towards the Horizon; and as much as you will make the Quadrant sinke: you must also draw out of the last Center with the Compasse. And in this manner a man may make diuers formes and compartments (but as I haue said) you must make them all with iudgement, and therefore it is very conuenient that a man should be well instructed therein; for that being onely the principall terminations, you must make the rest by practise: But I am of opinion, that some rigorous Perspective men will take hold of these my words, (to whom I answer) that if they meane I haue failed or done amisse, let them proue what difference there is betwene saying and doing.

Of Perspective

The manner how to make a crosse roffe of a Gallery or House in Perspective worke, is alwayes very trouble-
some to shew it unto any man; and therefore also, it is much more troublesome to declare it in writing for men
hereafter to understand it. Nevertheless, because it is very necessary to be knowne, I will doe the best I can
to shew it.

First, you must chuse the bredth and height of the greatest Arch or Bow that you desire to make, and then by the di-
stances you must make a perfect shortening Quadzant, and also a lesse Bow or Arch. The greatest Arch before shalbe
devided into epght equal parts, and those parts must be drawne towards the Horizon to the smale Arch, which being
done, then you must let those parts of the greatest Arche below upon the Base; and with the helpe of the Horizontall
and Diagonall lines, you may make a shortening Circle within the Quadzant, as in the other places before you have
bene taught. The terminations hereof shall be 1. 2. 3. 4. 5. which shall be set upwards beside the great Arche, as you
see it there also marked with 1. 2. 3. 4. 5. Without this round below I have drawne the Paralels with prickes to the
wall, and where they end, there you must set all your Perpendicular lines upright, which are come out of the Parallel
lines of this Circle.

Then you must draw the terminations aforesayd, which are placed above, along by the Perpendicular lines with
lines to the Horizon; and where the sayd Horizontall lines cut through the Perpendicular lines, which are drawne up
from below; there you must make halfe a shortening Circle: and that which is marked on this side with Ciphers, must
also be understood to stand on the other, as you see it in the Figure.

These two halfe shortening Circles being made, then you must draw a right blacke line above out of each of the
middles, which are marked 5. and where that cutteth through the middlemost line, which goeth from the greatest
Arch to the Horizon, there shalbe the terminations: also the middle of the crosse worke; and then out of all the termina-
tions of the two halfe Circles, you must draw crosse lines on the sides, and where every one of them following an Hori-
zontall, toucheth the Arch marked with 2. 3. 4. there the terminations shal stand to forme the halfe Circles in the crosse,
through the which a man with a stedfast hand from termination to termination shall make a shortening halfe rounde
crosse with prickes, as both on the right and left hand you may plainly see in the Figure. In this manner the worke
should goe, although it stood somewhat out at the sides; but it is better first to print it well in your memozy, before you
seeke an other forme where the Horizon standeth on the one side, that then you may the easlyer make that which is
scene on that side.

Of Perspective

Having shewed in crosseworke on both sides, how you should place the Arches on the sides in shortening manner and drawne them up out of the ground, although that they be single: now will I shew you a hollow Arche, and the manner how to shorten it: But before I proceed thereunto (for it is very combersome and difficult) first I will shew you the Pillasters that should carrie the sayd Arches: which Pillasters stand so plainly in the Figure that I shall not need to take much paines to write of them. In this Figure I have not made the first Arch, that I might not darken the sight of the Arches on the sides, which Arches on the sides, I have also but marked how they shall stand, and are alwayes drawne out of the fouresquare Quadrant, as you see by the order of the foure square Quadrant, but the hindermost Arch which standeth not in the way, I have drawne fully, and placed it also in his foure square.

Above in the top or roose, I have made the round foyme, whereof you may make a Kettle or Tribunal; and you may also make it thus, when it is somewhat loncke. Touching the foure Pillasters, they (as I have taught before) are bound by the Diagonall lines comming from the poyn't of the distances, and also that each Pillaster is thre cornerd: standing like a thre cornerd hooke, and on each end (the Arch resteth whereof there shall be foure) two Arches before, and two on the sides, so that the roose will be right foure square, wherein you may make crosse worke or other manner of Roose worke. And if you will make other kindes of works by the same; you must alwayes follow this rule: Item, where you can not well vnderstand my writing, you must helpe your selfe with the figures, which figure also standeth open, so that with a little labour; a man may easily conceave it altogether, although there were nothing spoken of it.

Now you see, what way you must follow to place Arches on the sides in shortening manner. And first, you must thinke upon the third former manner Superficies, wherein I have sufficiently shewed you the manner how to frame a round body; but in this Figure I will shew it more perfectly. Wherefore a man must imagine that the round Body lying below in his square is made, and shall serve for the two Bowes on the sides. This Body then being made (as I have shewed before) and as you see it better now, you must first set it, where the Arches begin above the Horizon. And the same Perpendicular lines which stand corner wise from the middle of the four cornerd body, must be set like Parallel lines on the right & left sides upwards from the two Arches, there (as it is aforesaid) to direct the Horizontall lines, as you may see it plainly in the Figure. But you must understand, that the two crosses below in this Body, are the two Centers to draw the Stones of the Arches both above and below, they also signify the Centers of the Bowes upon the Horizontall lines within the Arches.

You must also understand, that the blacke lines doe forme the Circumference without, and the pickes or thin lines betoken the forme within, which is covered in the Arches: so that the Arches do shew through to be made of pieces, of the which pieces a man may learne to make divers Compartments underneath in the Arch. Now when a man can make this Arch well, then hee shall not neede still to take all this labour, but by two principall lines helping himselfe with pickes, he may frame the Arch; and specially, because that the Arch which should come before, couereth or hideth a great part of the Arches on both sides: which Arch I have not made here, that I might not darken or shadow the other shortening Arch. Neither need I write any thing of the Circumferences above in the top or Roofe, (nor the eight corners within) so that in the next Figure you shall see them; neither will I speake any thing of the Circumferences in the ground, for they are made (as I have taught you heretofore of all others) and of the round body below (of the which there hath beene more sayd) a man may make many other things which are not here to be spoken of.

The place Pillars with their Arches open grounds or platfomes, I thinke there is sufficient spoken before; and what soever I haue spoken of foure square Pillars, is also to bee vnderstood of round Colunnes, for that a man must take all round things, out of foure square things as well the Spira of the Base, as the round of the Capital. He that can make all the Figures aforesayd perfectly, and particularly this last body, shall helpe himselfe well, and not onely to doe the like things, but also to do many moze. If I should in this small Treatise shew all that I coulde set downe, it would make a most great Colunne; and peraduenture I should want time to set forth the rest of my Booke, which I haue already promised: for there are many things that belong to Building, which need not to bee set downe in Perspective worke.

Let vs now begin to rayse the Building here set downe out of the ground, which before, and at the one side is seene, as I promised before to shew you.

The shortest and surest way is, to make a ground with many Quadrants; and imagine that it is mese with the Foot, with the Elle, or other measure: But let vs now take euery Quadrant for two foot, and as before there are foure Quadrants from one Pillar to the other; and the Pillar also containeth a Quadrant, there shall also be foure Quadrants backward in the length from one Pillar to the other, as you may see it altogether in the Figure.

The Pillars then being set of such height as you desire, then the Arches vpon them must be made; and the manner how to make them, you may expressly see in the Figure. And although you cannot see the Arches that are behind them, yet I haue made them here that you may see their terminations: they are in some places drawne with full blacke lines, and in some places with prickes.

About the Arches you must make the Architraue, Frise and Coznice; the Proiecture whereof, you must make as I haue sayd and taught heretofore, that is, how they make their corners against the two Diagonall lines, and by the like rule you shall also make the vppermost Coznice, as you may see in the vppermost part, where the small Quadrant with the Diagonall lines stand. The doozes that stand vnder in the Gallery, are each of them two Quadrants broad, and foure Quadrants high; below in the ground there are certaine tokens which shew like Dayles, which signifie the wydenesse of the windowes about the Coznice: which windowes if they stood whole there, then they would be twice as high as they are broad. The other Dayles vpwards betwene the shortening Pillars, are also the breadth of the shortening Pillars, which (as I sayd before) are all foure Quadrants high, but they are partly covered with the Cozniccs. The part of the Arch which standeth at the ende, is separated from this Gallery, as the ground also sheweth it.

I haue here made no Bases nor Capitals, that the other things might not bee confounded: but you must vnderstand that they must be placed in the worke, as is sufficiently before shewed. And by this rule you may draw diuers Buildings out of the ground, as in the Figure following shall be shewed in diuers formes. The Centers of the Arches you see them marked, standing all vpon one Horizontall line.

Of Perspective

Now I have shewed the manner how to make a Gallery with Arches and Pillars, with other things thereunto belonging; now by an easier way I will shew some forme of Houses that are to be built out of the ground. You must make a ground of foote worke with Quadrants reaching long enough upwards, which Quadrants must each of them be reckoned at two foote square.

And first, at the entry of the House there shall be a dooze of five foote broad, for that it containeth two Quadrants and a halfe in the shortening: and the height thereof shall be of ten foote, because it is five Quadrants high: Her Pillars or Antipagmentum shall be a foote broad, because they containe a halfe shortening Quadrant; the Frise shall also containe as much: and the Cornice shall containe so much lesse, as the under part thereof bearing over containeth, and shall be made according to the rule aforesayd. Touching the part letting over the dooze, the Hogdillions or Pivittles, shall stand right above the Pillars or Antipagmentum of the dooze. And that litle dooze upon the letting, shall stand right in the middle above the lowest dooze, and shall be two foote broad. In the other cozner of this first House, there shall be another dooze, the widenesse thereof shall be sixe foote; you may make it round or square above as you wil. But why doe I spend my time to set downe all these measures, which you may so plainly see in the Figure; onely it is necessary to warne such as are studious herein, that what worke soever a man rayseth out of the ground, consisteth in three principall things, that is, in length, bredth and height. The length is of certaine Houses or Rottes, containing a certaine number of feet. The bredth consisteth of Windows, Doozes, Gates, Shoppes, and such like things. The height consisteth of Portes, Windows, Lettings, Cornices, Columnnes, Rookes, and such like things. But there is yet another, that is of the thickenesse of the Wallles, Pillars, Columnnes and Pillars: The length is taken from the shortening Quadrants, and from thence also you take the bredth. But the height is taken out of the bredth in the Quadrants, which bredth must be taken from the Quadrant or halfe Quadrant, which toucheth it on the hithermost side as it standeth: as also from the hithermost dooze, which is ten foote high, there you must take the measure from the Quadrants, which come to the Paralels on the nethermost corner or paynt of the dooze; for if there you take five Quadrants in bredth, it shall be height within the Antipagmentum. And that which I have sayd of these doozes, you must also understand of all the other things: The thickenesse of the Wall is two foote, for you see it containeth a Quadrant. The bearing over of the second House is of five foote, measured upon the ground: the like also the bearing over or letting of the first House containeth. To conclude all things, as I have said, rising out of the ground on all sides, I have set no Cornices, nor any other ornaments in this Figure, that you may the easier understand it; but a man of ripe iudgement and understanding knowing the terminations, can by his owne invention helpe himselfe to make faire Buildings. And for that I may not spend too much time herein, I will make others to giue you more light therein.

Of Perspective

The Stayes, degrees or goings by, are very necessary in Buildings, and therefore I will shew divers kinds thereof, and first I will begin with the easiest. According to common custome a Staye or step is about halfe a foote high, and about a foote broad upon the step; then let the square stones of this ground be a foote square, therewith we will make a paire of staires of five foote high, and threë foote broad: at the foote of the ground we will take the measure of the breadth, which both on the right and left sides shall be set in Perpendicular lines on the Corners of the Stayes, which shall be divided into ten, as the lines A. B. shew you. When all the parts of A. B. shall be raised to the Horizon, and then you shall take nine Quadrantes upwards in length: and where as two lines are set by cutting through the Horizontal lines of A. B. there the corners D. C. of the uppermost steps shall be, containing a square of threë Quadrants on each side. From the hithermost points of the same upper steps, you shall draw two holding lines to the lowest steps; against the which the Horizontal and the Perpendicular lines of the Quadrant shall come together and shut by the Stayes.

These Stayes are slozened on the one side, and the other is plaine or profil, and containeth a step lesse in the height, which maketh foure foote and a halfe; it is also threë foote broad, as it is marked under it on the ground. By this rule you may make Stayes or degrees as high as you will, and make some resting places in the way: alwayes taking the measure from the foote of the ground, as well of the slozening, as of those that are upright.

The going up being plaine or profil maketh a great show, and yet are very easie to set in all places, I meane in the turning, and may serue for many things, specially in Buildings, where a man going up softly and with ease, giueth the beholders a kind of pleasure to view them, principally in common places, for that there is a going up on eyther side, so that vpon the one side men may goe up, and on the other side they may goe downe; and although there are only but two goings up, yet by this a man by his own inclination may deuise others. Now these Stayzes are made, and with what reason, you may by the Figure perceauie them, although I should say nothing thereof: for as it is sayd before, the Quadrants are of a foote broad, and the steps halfe a foot high, and so the bredth of the step is one foot. The bredth of the Stayzes is five foote, both the first and second: The resting gate containeth in widenesse three foote, and is six foote high; which although it seemeth to be shut, and a small dooze opening in it: yet it may be made whole open and otherwise closed. The two sides about the three steps are five foote broad, although here it is but one foote, because of the narrownesse of the Paper. The Perpendicular lines on the sides, signifie leaning places; and they should serue well also to the steps, but lest they should comber the worke, I haue left them out.

Of Perspective

Amongst other things which show well in Perspective worke, I finde that goings vp or steps are very comely, and the oftner that they turne, the better they shew; therefore I have made these two goings vp turning, which stand in profil, yet you see the ground and the steps. This first going vp is five foote high and three foote broad, as you may see it marked in the ground with prickes: the resting place betwene the first and second going vp, is two foure squares long, which is necessary, because of the turning. At the end thereof you finde a Portale, the doze thereof is two foote wyde, the Antipagmentum is halfe a foote on epyther side, so that the place is three foote full. The Perpendicular lines on the right side of the plaine, signifie certaine leanings, which may bee made of Iron, Wood, or Stone; the like may be made along the Stayres both vpward and downeward, setting a Baluster vpon every Stayre: The height of this raile or leaning, shall be two foote and an halfe; soz so it is easie to lay a mans hand vpon. Note these Stayres are made vpwards out of the ground, although it may well be seene by the Figure without declaring it: yet I will say some thing thereof, to ease them that are thozt of memozy. The resting gate or round doze vnder the plainesse betwene the second and the third going vp, is no deeper then to the wall: Above the same doze there standeth another going vp, of foure steps, which to make, I have sufficiently shewed; other wise a man should continue the ground at the resting doze, to draw them vp from it.

Touching the severall kinds of Stayzes, I am assured that they may partly be understood without describing them in wrytings, and specially the middlemost which goeth vp on both sides; and so shall the uppermost also, because it is rayed vp from the ground as well as the other, and is sixe foot broad, as you may see and tell it on the ground vpon the plaine stones. The two Arches vnder the two goings vp are each a foot in thickenesse, whereby a going downe is foure foote within, and is also drawen out of the ground as the rest are. The other goings vp, which you see through the Arches; you may sufficiently perceiue by them how they are made: and so it is with the two paire of Stayzes on the left hand, for from the first steps at the resting dooze, you may easily see how they are rayed vpon of the ground, and above at the end of them they have a piece of plaine ground to come to the other Stayzes, which also is drawne vp out of the pauement as the rest are, that is, each step halfe a foote high, and a foote broad. But it is hard to measure in so small things, but it sufficeth that hereby you may see the manner thereof: and when you make them great you shall find that they will come well enough to passe. Under the Stayzes last named, there standeth also a round dooze which is sixe foot wyde: vpon this ground, and on these Stayzes a cunning Painter might place diuers Figures in severall formes, eyther standing or sitting vpon the Stayzes; and lying vpon the ground in shortening manner, and that in this wise: You may place the Figures where you will with feete, and then take sixe feete or squares whereon they stand, and that shall be their height, for that it is the height of a common or ordinary man: this you must obserue both before and behind, and in every place. If the figure be vpon a step, then take the measure of that step whereon it standeth, and make it twelue steps high, which shall be sixe foote: And is the Figure lying, doe the like; but if it lieth in shortening manner vpon the ground, then you must take the length by the shortening Quadzant.

Of Perspective

I have shewed many kinds of goings up, but there are other kinds, and he that is not well instructed in the former will hardly vnderstand these two which I haue here set downe. The first shall be winding Stayres in foure square, and he that can make these foure square Stayres, may well make the round Stayres, for it is all one thing, specially if he beth the rule before set downe of the round bodies.

The Figure P. is the ground of this winding Stayre, but it is much lesse then the uppermost to get ground. This foure square ground in shortening you must make halfe a foote high, which shall be for the first step. Then before at either end, you must make a Perpendicular line by right, and in it make as many halfe feete as you desire to make the Stayres high; you must also place the like Perpendicular lines betwene the middle, & the corners: then you must draw the terminations both on the right and the left sides upwards to the Horizon, which must cut through the Perpendicular lines, which are drawne out of the terminations of the steps; and of the same height that the two cornerd Perpendicular lines are: and of the same measure you must make the other two Perpendicular lines betwene the corners and the middle. Then in the middlemost termination of the ground you must place an other Perpendicular line, and deuide it also in halfe feete, as the other Perpendicular line on the side is: So out of this Perpendicular line of the Centers against the nearest Perpendicular line beneath on the left hand, you must frame the first step with two lines: The second step you shall also frame and shut up out of the Perpendicular line of the Centers in the corner following. Then from that point or corner you must draw a line to the Horizon, which against the second Perpendicular line will make the termination of the third step, which shall also be shut above, according to the aforesaid rule: from that point or corner of the step you must also make an Horizontal line, which will touch the termination of the fourth step; which being closed, then you must raise that corner also to the Horizon, and that will shew you the termination of the fifth step. And when that step is also closed with lines: then you must draw the point towards the Horizon, which line will shew you the terminations of the sixth step against the hindermost Perpendicular line: and that being also closed up with lines, then out of the same corner you must draw a Parallel line to the termination of the seventh step, and not towards the Horizon, because it is another side of the foure square. Thus you must worke round about from step to step, allwayes following this rule by the which you cannot faile.

Of Perspective

That I may not forget to set down all kinds of Stayes, and specially such as often times fall out to be made, therefore I have made these Stayes, whereon a man may goe by on all sides, whereof the ground standeth about on the right hand, but yet very small. These Stayes must thus be made. First, you must make a four square shortening body of halfe a foot high, upon this you must draw two Diagonall lines, and from the corner inwards there shall be a foote broad left on epyther side, and the terminations thereof drawne to the Horizon, and so from the Diagonall lines you shall see the corners of the second step. Now I need not set downe unto you how you shall finde the lessening corner of the second step, the which is round about shut by with Paralel and Horizontall lines: then upon the second plaine you must draw two Diagonall lines, which doing (as I sayd before) will shew you the third step, which also being closed by with lines, you shall also find the fourth and fifth, with the like rules: This Pyramides is fantastically framed upon them to fill by the place. Also I need not set down to what uses these Stayes may serue, for that the halfe of them is commonly found in diuers pieces of worke, as the gates of Pallaces, Churches, and other dwelling Houses, and the ascending by to Altars: By this way also you may make round Stayes, and also Stayes of five or eyght corners, as by their formes I have shewed.

I have promised the studious Reader by this my labour to shew as much touching Perspective worke, as I can; that hee might shew his conceit touching Houses or Buildings in Perspective wise, meaning to set downe some simple manners thereof, as if he should forme a single or double ground, thereupon to raise a body, and therewith meane to make an end. But falling from one worke to another, I am entred into a Labozinith; which peradventure is too farre above my reach: which cometh to passe by meanes of some men that haue entreated me therunto. And therefore, as I thought at this time to make an end of my second Booke, I begin to handle a harder matter, which rule is onely called an outward foure square: neuer thelesse, it is as well drawne by the Horizon as by the distances, as you may see in the Figure following; which sheweth a right shortening foure square, containing in it another foure square, the which also may be formed by the distances without Horizon: some men place the sides of the foure square vpon the Base, once so wyde againe as before. And as you see two like sides of the foure square ouer the corners, so are the distances alike marked D. And as much more as you will haue this foure square to shorten, so much you must draw the distances from the Horizon; and as much as you will that the edges of the foure square shall be broad, so many breadths must you draw vpon the Base, betwene A. C. twice drawne. All the terminations of this foure square standing above the corners goe all to the distances, and none to the Horizon, but onely the foure square that is set therein.

Now I haue shewed, how you should shorten a Superficies, ouerpoint or outward foure square: here I will shew how to in-bosse or beare out the body thereof with the same Horizon and distances also, which body within is hollow, and you may heare it by as high as you: but I haue purposely left it somewhat low, that you might see the ground thereof. And by this Figure you may conceaue to how many things this may serue; and also how you may increase or diminish it, according to skil and iudgement. This shall suffice for these fouresquare models or hollow things: but I will shew how you shall make them to Cresses or Cornices.

Of Perspective

This Figure is also formed by the aforesayd Horizon, and the like distances as the other before, onely that they stand a little nearer: Now to create this body both above & beneath, you must imagine the greatnes of the creast, and draw the same greatnes both above and beneath the body; then giue the Crests above their due Projection, and from those points you must let Perpendicular lines fall to the points of corners below, whereby you shall have the Projectiones of the Base and top thereof, which must be drawne towards the Distances, and not towards the Horizon. Now you see how the Cornices stand without the soursquare body: but this is onely for Cornices that are made without members, not to comber you with the shadowing of them, so I will speake of them hereafter particularly.

I spake before of Cornices without members, which might serue this hollow Quadran, and how you shall make the terminations thereof. Now in this Figure I show you the sayd Cornices with their members, which you may also make in other maner as it pleaseth the workman, that is, to make them bigger or lesser, as I haue spoken of other Cornices, alwayes vsing good discretion and iudgement to chuse and make such members therein, as may show well in mens sight. There are some Cornices which reach so farre ouer, that men can not see the members thereof vnder them; therefore in that case the members are so to be made, that they may be seemely and pleasant in mens sight.

The foure Figures aforesayd haue their distances equally broad from the Horizon, that is, as much on the one side as the other; but the Figure following is of an other manner: so that the Horizontal lines serue both for distances. To vnderstand it, begin thus: First, the Base A. B. is made and is placed in foure equal parts, as C. D. E. the lines C. D. are drawne on the right hand towards the Horizon, and the lines A. C. are drawne towards the Horizon on the left side, which forme a perfect shortening foure square; which foure square you see more on the one side, then on the other. The foure points or corners of these foure square things, are F. G. H. C. If you diuide these foure square things in two parts, then you must diuide the Base D. E. in two parts, and the terminations thereof being drawne to the right side, there you shall finde the halfe of your foure square marked with two Stars. But if you will lengthen it an other halfe foure square, then draw a termination E. to the right Horizon, the lines at I. K. the other halfe foure square, so that these Superficies shall be of two perfect foure corners: And this will serue the ingenious workeman for many things, which I will not here set downe for breuitie sake.

This body hereafter following is rayed by out of the former Figure before set downe, and is made with the same Horizon; which body containeth two Quadrants in length, & one Quadrant in height, for the line C. D. is set in perpendicular manner vpon the nether most corner, wheron the other Superficies are set: thus then this body is of two foure squares, I meane two foure squares in length, and one foure square broad and high. And this body (as I said before) shall serue for many things: But if you will haue more cubits in the length, then lengthen the Base in so many parts more, and you shall alwayes finde the truth hereof. And if you will make a border or crease about this body, then you must follow this rule aforesayd.

Of Perspective

But till you make diuers things vpon one ground, then it is conuenient that first you make a pavement, as you see it here set downe, and thereupon frame what you thinke good vpon the Quadzans, and the lesse the Quadzans are, and the more in number, you may the easier frame things vpon them. The crosse made vpon this ground is onely to show you the way and entry thereunto, but for such a forme, you may make a forme of a Chyistian Church as they are now built. The other forme by it, sheweth a piece of a foundation of a House, but all these things you may make in a greater forme, and set them forth as you will, sometime placing the Horizontall lines in such manner that you may see more of the out sides, but yet the Horizontons must stand all of one height.

Of this Superficiall Figure aforesayd, I haue rayled these bodies, to shew how the Horizontons of them doe stand in the worke as well aboue as below, as you shall finde by experience, and in trueth these workes which you see ouer the poyns or corners, containe a Booke alone by themselves: but (as I sayd before) my meaning was to show but thre or foure Figures of them, yet I will show ten of them; intending to leaue the student some worke, whereof I am well assured: For that he hath more eyes, and more patience then my selfe, hee shall finde many things which I write not of, nor yet set downe.

Vpon this Paucement (as I sayd) you may soyme or frame what you will, but in this Paucement here ensuing, you see a colunne lying, being eight square, which is three Quadrans in thickenesse, and foureteene in length. This eight square colunne may be made out of a colunne of foure square, as befoze in an other place is shewed: which foure square you may see drawne herein with pickes, and the terminations of the eight square with blacke lines. But because that this eight square colunne is so much scene on the sides, the readier to make it out of the foure square: I have therefore made an other picce by it, the which, because it draweth nêrre to this Horizon, is scene moze befoze, then the other, although not so long; for it is but halfe so long as the other, as you may see & tell it in the ground or flat thereof. And if it were so that this eight square Figure reacht nêrre to the Horizon, it would then be better scene, yet it would not be wholly scene befoze, because it standeth without the foure square and corner.

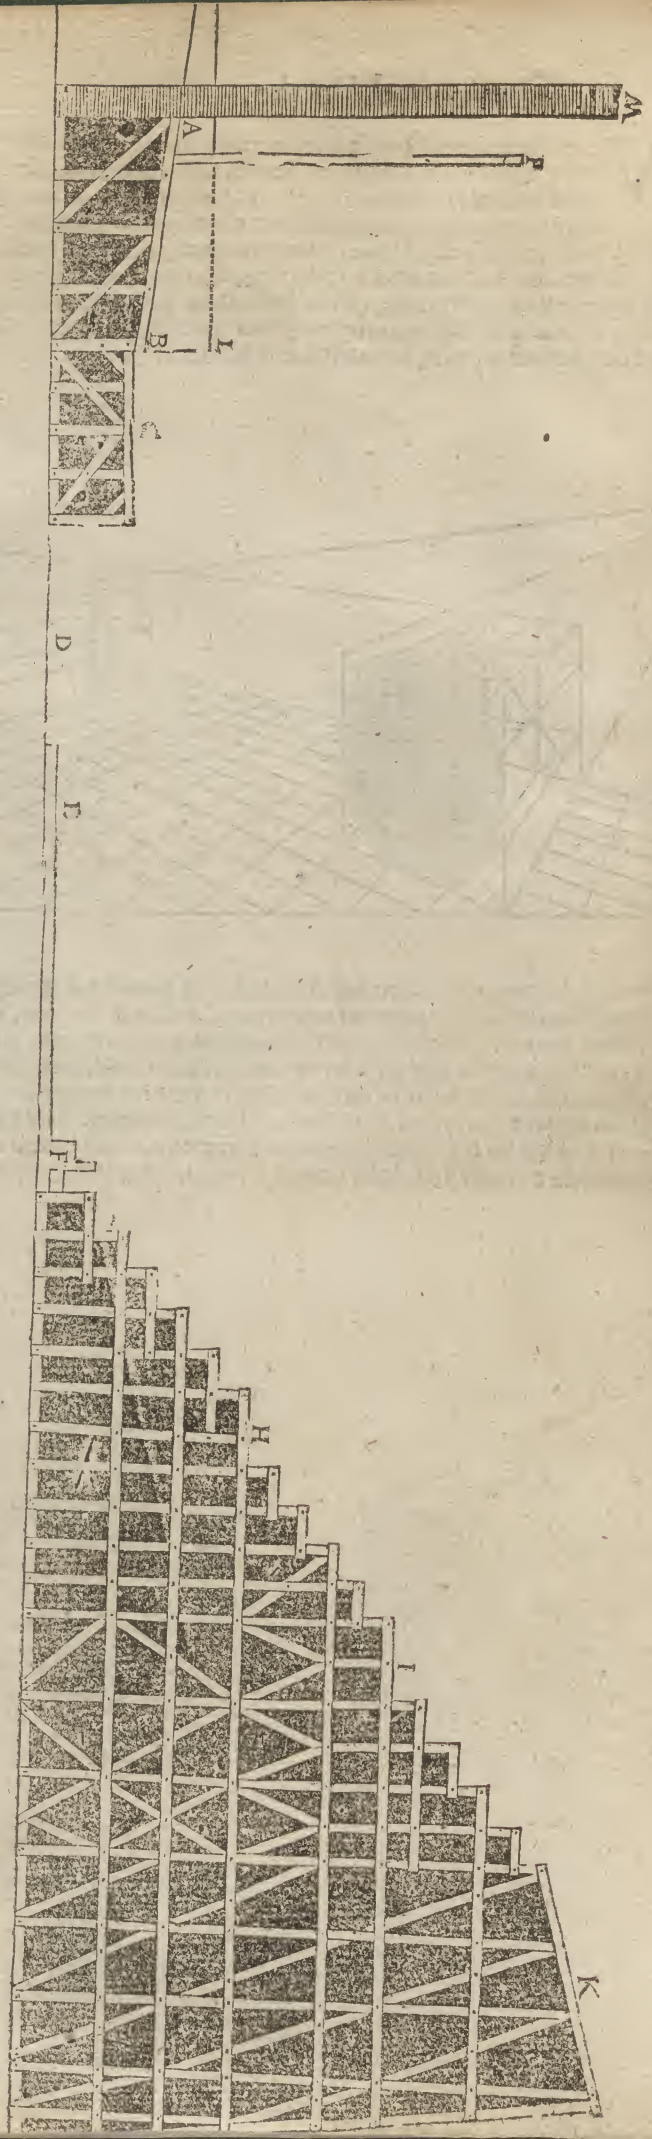

These Colunnes are the same which are befoze set downe, but the other well hollow, and these make, whereby an expert workeman may finde out many things exercising this way, although there are other meanes to be used, as Albert Duier hath shewed, to looke through holes with a thread: There is also another way, which is drawne out of flat formes which is the surest way, but very troublesome and hard to describe in writing; wherefoze I have chosen this as the easiest way to be shewed. And if I had not undertaken to show other things of moze importance, I would have drawne divers bodie and houses after this manner. But for that I meane to entreat of Scenes, and the preparing of places for to show Comedies and Tragedies, which is now used in this age, and specially in Italy, therefore I will make an end of these foure cornerd things, leaving it to another (as I sayd befoze) to set forth moze thereof.

Of Perspective

Because I meane hereafter to entreat of Theaters, and Scenes belonging unto them, as we use them in these dayes. In the which Scenes it will be very hard for a man to shew how, & where a man should place the Horizon herein, because it is an other thing then the rule before declared: Therfore I thought it good first to make this profil, that the ground by the profil may both together be the better understood; yet it were convenient first to studie the ground, and if it so falleth out that a man cannot attaine to all within the ground, then hee must procede to the profil to see the better instructed therein. First therefore, I will begin with the Scaffold before, which as the eyes shall stand elevated from the earth, and shall be flat, made by the water compasse, marked with C. And the Scaffold from B. to A. shall stand heaved up under the same A. a ninth part of the length thereof, and that standing by behind the seate marked with an M. above it, is the wall of the Hall or other place, against which, or where this Scene shall be made. That which standeth a little distant from the Wall Perpendicular wise, is marked P. That be the backe or upholding behind of the Scene, that a man may go betweene it and the other wall. The termination O. is the Horizon. The lines with pyckes comming crosse upon the water compasse from L. to O. where it toucheth the backe P. there you shall placethe Horizon onely to serue for the sayd backe. And comming forwards to L. this line shall alwayes be the Horizon, for all the Diagraphie of the Houses which shall stand forwards or outwards: But the Seenographies or shortening sides of the Houses, they must haue their Horizons standing further to O. And it is reason, which in effect haue two sides (as they must be built that men may see out of them on both sides) should happen two Horizon lines, this is touching the profil of the Scene. But the place which is called Proscenium is that which is marked with P. and the part marked with E. is called Orchestra, which is rayled halfe a foote from the earth, where you see F. marked, are the places for Noblemen and Knights to sit on. And the first seate or step, marked G. are for the Noblewomen and Ladies to sit on: and going up higher, there must the meaner sort of Nobles sit. The broader place, marked H. is a way, and so is the place marked E. Betwene H. and E. must sit Gentlemen of quality. And from L. upwards meaner Gentlemen shall sit. But the great space, marked K. shall be for common Officers and other people: which place may be greater or lesse, according to the length of the Hall, or any other place. And the Theater, with the Scene or Scaffold, which I made in Vincente, was almost in this sort: and from the one corner of the Theater to the other, was eyght and twenty foote; for it was made in a place where I had room enough, but the Scene or Scaffold was not so broad, because it was placed in a lodge. The frame of the seates was all made in one, as you may see in this Figure. And because the Theater stood in an open place which had no wall, whereunto it might be made fast, therefore in the circumference I haue made it sticking out, for the more strength and fastness thereof,

A Treatise of Scenes, or places to play in.

Among all the things that may bee made by mens hands, thereby to yeeld admiration, pleasure to sight, and to content the fantasies of men; I thinke it is placing of a Scene, as it is shewed to your sight, where a man in a small place may see built by Carpenters or Masons, skillfull in Perspective worke, great Palaces, large Temples, and diuers Houses, both neere and farre off; broad places filled with Houses, long Streets cross with other wayes: tryumphant Arches, high Pillars or Columnes, Pyramides, Obeliscens, and a thousand saye things and buildingz, adozned with innumerable lights, great, middle sort, and small, as you may see it placed in the Figure, which are so cunningly set out, that they shew forth and represent a number of the brightest stones; as Diamonds, Rubins, Saphirs, Smaragdes, Jacinthes, and such like. Where you may see the bright shining Moone ascending only with her hoznes, and already risen by, befoze the spectators are ware of, or once saw it ascend. In some other Scenes you may see the rising of the Sonne with his course about the world: and at the ending of the Comedie, you may see it goe downe most artificially, where at many beholders haue bene abasht. And when occasion serueth, you shall by Arte see a God descending downe from Heauen; you also see some Comets and Stars shot in the skyes: then you see diuers personages come vpon the Stage, richly adozned with diuers strange fozmes and manners of Apparell both to daunce Porticoes and play Musicke. Sometimes you see strange beasts, wherein are men and children, leaping, running, & Tumbling, as those kind of beasts vse to doe, not without admiration of the beholders: which things, as occasion serueth, are so pleasant to mens eyes, that a man could not see fairer made with mens hands. But soz that we are entred into another manner of Perspective worke, therefoze I will speake moze at large thereof. This Perspective worke wherof I will speake, although it be contrary to those rules which are shewed befoze, because these aforesayd are imagined to be vpon a flat wall: and this other rule because it is materiall and imbolded or rayed outward, therefoze it is reason we obserue another rule therein, according to common custome. First, you must make a Scaffold, which must bee as high as a mans eye will reach, looking directly sozward; soz the first part thereof which is marked C. But the other part behind it, whereon the Houses stand, you must rayse by behind against the wall at least a ninth part thereof, that is, you must denide the playne Stage or Scaffold in nine parts; and then you must make the Scaffold higher by a ninth part behind: then befoze at B. which must be very euen & strong, because of the Pozisco dancers. This hanging downward of the Scaffold, I haue found by experience to be very pleasing, soz in Vincence which is as sumptuous and rich a Towne as any in all Italy; there I made a Theater and a Stage of wood, then the which, I thinke, there was neuer a greater made in our time, in regard of the wonderfull sights that there were seene, as of Wagons, Elephants and other Poziscos. There I ordained, that befoze the hanging Scene there should be a Scaffold made by water compasse, which Scaffold was 12. foot broad, and 60. foot long, according to the place wher it stood, which I found to be very pleasing and fit soz shew. This first Scaffold, because it was right, therefoze the pavement thereof must not obey the Horizon, but the Quadrants, wherof on every side were foure square, from whence at the beginning of the rising Scaffold B. all the Quadrants went to the outermost Horizon O. which with their due distancces do shorten very well. And soz that some men haue placed the Horizon of this Octograhie against the wall right about the Scaffold, whereby it seemeth the Houses ranne all in one; therefoze I determined to place the Horizon befoze the dore, which pleased me so well, that I used the same kind of order in all these kind of works: and so I counsell those that take pleasure in such Arts, to vse and esteeme this way soz the best, as I will shew in this Figure following, and haue also declared in the proffil of the Theater and Scene.

And because the preparation soz Comedies are done in thre sorts, that is, Comicall, Tragicall and Satirical; I will first entreat of the Comicall, whereof the Houses must be made as if they were soz common or ordinarie people, which soz the most part must be made vnder roofes in a Hall, which at the end thereof hath a chamber soz the pleasure or ease of the personages: and there it is that the ground of the Scaffold is made (as I said and shewed befoze) in the proffil. Therefoze C. is the first part being the flat Scaffold; and suppose that each Quadrant containeth two foote on eyther side, so that they vpon the hanging Scaffold befoze on the Base be also two foet broad, which is marked B. And (as I sayd befoze) my meaning is not to place the Horizon hereof against the backe behind in the Scaffold, but as farre as it is from the beginning of the pavement B. to the wall, so farre I would also that men shall passe behinde through the wall, and so shall all the houses and other things show better in the shortening: and when by convenient distancces you haue dyaloned all the Quadrants towards the Horizon, & shortened them, then you must shorten the houses right with the foure square lines; which houses are the great lines marked vpon the ground, aswell soz those that stand by right, as those that shorten. All such houses I alwayes made of spars, or raffer or laths, couered with linnen cloth; making dozes and windowes, both befoze and in the shortening, as occasion fell out. I haue also made some things of halfe planks of wood, which were great helpe to the Daynters to set out things at life. All the spaces fro the backe to the wall marked A. shall be soz the personages, to the which end the hinder most backe in the middle shall stand at the least two foote from the wall, that the personages may goe from the one side to the other, and not be seene. Then you must rayse a termination at the beginning of the pavement B. which shall be the poynt L. and from thence to the Horizon there shall be a line dyaloned, as it is marked in the proffil with prickes, which shall be of like height; and where that toucheth the hinder most backe of the Scene or Scaffold, there the Horizon of that backe shall stand: and that Horizon shall serue onely soz that backe. But if you stretch a corde or any other thing to the termination L. then you may fasten a threed to it, to thrust backward or forward, to vse it out of the fixed Horizon, & all the Octograhie of the houses befoze. But the Horizon which goeth through the wall, shall serue soz all the shortening sides of the houses: and soz that men should breake the wall, if they would vse all this Horizon in grosse, which may not bee done, therefoze I haue alwayes made a small modell of wood and Paper inke of the sameignes, and by the same modell set it downe in grosse, from piece to piece. But this way will fall out hard soz some men to vnderstand, neuertheless, it will be necessary to worke by models and experiments, and by studie a man shall find the way: and soz that a man can hardly finde any Halls how great soeuer, wherein he can place a Theater without imperfection and impediment; therefoze to follow Antiquities, according to my power and abilitie, and by studie a man shall find the way: and soz that a man can hardly finde any Halls how great soeuer, wherein he can place a Theater without imperfection and impediment; therefoze to follow Antiquities, according to my power and abilitie, and by studie a man shall find the way: and soz that a man can hardly

the places soz the noblest personages to sit, marked F. The first steps marked G. soz the noblest women to sit vpon. The place H. is a way, so is the part marked I. In the middle betwene these degrees are steps the easier to goe vp. The places marked K. must bee made so great backward as the Hall will affoord, which is made somewhat slooping, that the people may see one ouer the others head.

Of Perspective

Touching the disposition of Theaters and other Scenes, concerning the grounds thereof, I haue spoken sufficiently; now I will speake of the Scene in Perspective worke: and so; that Scenes are made of three sorts, that is, Comical, to play Comedies on, Tragicall, for Tragedies, and Satiricall for Satires. This first shall be Comical, whereas the houses must be slight for Citizens, but specially there must not want a bawdyhouse or balwy house, and a great Inne, and a Church; such things are of necessity to be therein. How to raise these houses from the ground is sufficiently expressed, and how you shall place the Horizon: neuertheless, that you may be the better instructed (touching the former of these houses) I haue here set downe a Figure, for satisfaction of those that take pleasure therein; but because this Figure is so small, therein I could not obserue all the measures, but refer them to invention, that thereby you may chuse or make houses which shew well, as an open Gallery, or lodge through the which you may see an other house. The hangings ouer or showing out, shold well in shortening worke, and some Cornices cut out at the ends; accompanied with some others that are painted, shold well in worke: so doe the heeles which haue great bearing out, like lodgings or Chambers for men, and especially about all things, you must set the smallest houses before, that you may see other houses ouer or about them, as you see it here about the balwy house: for if you place the greatest before, and the rest behind still less, then the place of the Scene would not be so well filled, and although these things vpon the one side be made all vpon one floore: neuertheless, for that you place great part of the lights in the middle, hanging ouer the Scene or Scaffold, therefore it would stand better if the floore in the midst were taken away, and all the roundels and Quadrons which you see in the Buildings, they are artificiall lights cutting through, of diuers colors; which to make, I will shew the manner in the last of this Booke. The windows which stand before, were good to be made of Glasse or Paper, with light behind them. But if I should here write all that I know to serue for this worke, it would be ouerlong to rehearse; therefore I referre that to the wit and discretion of those that exercise and practise themselves herein.

Of Perspective

Houses for Tragedies, must be made for great personages, for that actions of loue, strange adventures, and cruell murders, (as you reade in ancient and moderne Tragedies) happen alwayes in the houses of great Lords, Dukes, Princes, and Kings. Therefore in such cases you must make none but stately houses, as you see it here in this Figure; wherein (for that it is so small) I could make no Princely Pallaces: but it is sufficient for the workeman: to see the manner thereof, whereby he may helpe himselfe as time and place serueth: and (as I sayde in the Comicall) hee must alwayes study to please the eyes of the beholders, and forget not himselfe so much as to set a small building in stead of a great, for the reasons aforesayd. And for that I haue made all my Scenes of laths, covered with linnen, yet sometime it is necessary to make some things rising or bolting out; which are to be made of wood, like the houses on the left side, whereof the Pillars, although they shorten, stand all vpon one Base, with some Stayes, all covered ouer with cloth, the Cornices bearing out, which you must obserue to the middle part: But to giue place to the Galleries, you must let the other shortening Cloth somewhat backwards, and make a cornice about it, as you see: and that which I speake of these Buildings, you must vnderstand of all the rest, but in the Buildings which stand far backward the Painting worke, must supplie the place by shadowes without any bearing out: touching the artificiall lights, I haue spoken thereof in the Comicall worke. All that you make aboue the Wooke sticking out, as Chimneyes, Towers, Pyramides, Oblisces, and other such like things or Images; you must make them all of thin boards, cut out round, and well coloured: But if you make any flat Buildings, they must stand somewhat farre inward, that you may not see them on the sides. In these Scenes, although some haue painted personages therein like supporters, as in a Gallery, or doore, as a Dog, Cat, or any other beasts: I am not of that opinion, for that standeth too long without stirring or moouing; but if you make such a thing to lie sleeping, that I hold withall. You may also make Images, Histories, or Fables of Marble, or other matter against a wall; but to represent the life, they ought to stirre. In the latter end of this Booke I will shew you how to make them.

The Satiricall Scenes are to represent Satires, wherein you must place all those things that bee rude and rusticall, as in ancient Satires they were made plaine without any respect, whereby men might vnderstand, that such things were referred to Rusticall people, which set all things out rudely and plainly: for which cause Viruuius speaking of Scenes, saith, they should be made with Trees, Knotes, Herbs, Hills and Flowres, and with some countrey houses, as you see them here set downe. And for that in our dayes these things were made in Winter, when there were but fewe greene Trees, Herbs and Flowres to be found; then you must make these things of Silke, which will be more commendable then the naturall things themselves: and as in other Scenes for Comedies or Tragedies, the houses or other artificiall things are painted, so you must make Trees, Herbs, and other things in these; & the more such things cost, the more they are esteemed, for they are things which stately and great persons doe, which are enemies to nigardlinesse. This haue I sene in some Scenes made by Ieronimo Genga, for the pleasure and delight of his lord and patron Francisco Maria, Duke of Vrbia: wherein I saw so great liberalitie vsed by the Prince, and so good a conceit in the workeman, and so good Art and proportion in things therein represented, as euer I saw in all my life before. Oh good Lord, what magnificence was there to be sene, for the great number of Trees and Fruits, with sundry Herbes and Flowres, all made of fine Silke of diuers colours. The water courses being adozned with Frogs, Saules, Toxuses, Loads, Adders, Snakes, and other beastes: Knotes of Coralle, mother of Pearle, and other things layd and thrust throught betweene the stones, with so many seuerall and faire things, that if I should declare them all, I should not haue time enough. I speake not of Satires, Pimpes, Per-maids, diuers monsters, and other strange beastes, made so cunningly, that they seeme in shew as if they weat and stirred, according to their manner. And if I were not desirous to be briefe, I would speake of the costly apparel of some Shepheards made of cloth of gold, and of Silke, cunningly mingled with Ambrotherp: I would also speake of some Fishermen, which were no lesse richly apparelled then the others, hauing Nets and Angling-rods, all gilt: I should speake of some Countrey mayds and Pimpes carelesly apparelled without pride, but I leaue all these things to the discretion and consideration of the iudicious workeman, which shall make all such things as their patrons sern them, which they must worke after their owne deuises, and neuer take care what it shall cost.

Of Perspective

Of Artificial lights of the Scenes.

LPromised in the Treatise of Scenes to set doone the manner how to make these lights shining through, of tiuers colours, & first I will speake of a sure colour which is like to a Zaphir, and yet somewhat sayzer. Take a piece of Salamoniacke, and put it into a Barbers Basen, or such like thing, and put water into it: then bruse and crust the Salamoniacke softly therein, till it be all molten, alwayes putting moze water vnto it, as you desire to haue it light or sad colour; which done, if you will haue it sayze and cleare, then straine it thzough a fine cloth into an other bessel, and then it will be a cleare Celestiall blew, whereof you may make diuers kinds of blew with water. Will you make an Emerauld colour, then put some Saffron as you will haue it pale or high coloured, for heere it is not necessary to prescribe you any weight or measure, for that experience will teach you how to doe it. If you will make a Rubbie colour, if you bee in a place where you may haue red Wine, then you need not vse any other thing; but to make it pall with water, as need requireth; but if you can get no wine, then take Brazill beaten to powder, & put it into a Kettell of water with Allum, let it scethe, and skum it well; then straine it, and vse it with water and Cinneger. If you will counterfeit a Gallayes, you must make it of red and white Wine mingled together; but white Wine alone will shoue like a Topas or a Crisolite: The Conduit or common water being strayned, will be like a Diamond, and to doe this well, you must vpon a glassie ground frame certaine points or tablets, and fill them with water. The manner to set these shining colours in their places, is thus, Behind the painted house wherein these painted colours shall stand, you must set a thin board, cut out in the same manner that these lights shall be placed, whether it be round or square, cornerd or ovaile, like an Egge; and behind the same board there shall be another stronger board layd flat behind them, for the bottels and other manner of glasses with these waters to stand in, must be placed against the holes, as it shall necessarily fall out, but they must be set fast, lest they fall with leaping and dancing of the Dyriscoes. And behind the glasses you must set great Lampes, that the light may also be stedfast: and if the bottels or other vessels of glasse on the side where the light stands were flat, or rather hollow, it would shoue the clearer, and the colours most excellent and sayze; the like must be done with the holes on the shortening side: But if you need a great light to shoue moze then the rest, then set a tozch behind, and behind the tozch a bright Basor; the brightnes whereof will shoue like the beames of the Sunne. You may also make glasse of all colours and formes, some soure square, some with crosses, & any other forme with their light behind them. Now all the lights seruing for the colours, shall not be y same which must light the Scene, for you must haue a great number of tozches before the Scene. You may also place certaine candlestickes about the Scene with great candles therein, and about the candlestickes you may place some vessels with water, wherein you may put a piece of Camphir, which burning, will shoue a very good light, and smell well. Sometime it may chauce that you must make some thing or other which should seme to burne, which you must wot thzoughly with excellent good Aquauite; and setting it on fire with a candle it will burne all ouer: and although I could speake moze of these fires, yet this shall suffice for this time; & I will speake of some things that are pleasing to the beholders. The while that the Scene is emptie of personages, then the workman must haue certaine Figures or formes ready of such greatness as the place where they must stand, will afford them to be, which must be made of passe board, cut out round and paynted, signifying such things as you will, which Figures must leane against a rule or lath of wood, crose ouer the Scene where any gate, doze, or way is made, and there some one or other behind the doze must make the Figures passe along, sometime in forme of Postions with instruments, and some like fingers; and behind the Scene some must play on, vpon certaine instruments and sing also: sometime you must make a number of foote men and horsemen going about with Trumpets, Phifes and Drummes, at which time you must play with Drummes, Trumpets and Phifes, &c. very softly behind, which will keepe the peoples eyes occupied, and content them well. If it be requisite to make a Planet or any other thing to passe along in the Ayze, it must bee framed and cut out of passe board; then in the hindermost and backe part of the houses of the Scene, there must be a piece of wire drauue aboue in the rofe of the house and made fast with certain rings behind to the passe-board painted with a Planet or any other thing that shall be drauue softly by a man with a blacke thzad from one end to the other, but it must be farre from mens sight, that neither of the thzads may bee saine. Sometime you shall haue occasion to shoue thunder and lightning as the play requireth; then you must make thunder in this manner: commonly all Scenes are made at the end of a great Hall, whereas usually there is a Chamber about it, wherein you must roule a great Bullet of a Cannon or of some other great Ordinance, and then counterfeit Thunder. Lightning must be made in this maner, there must be a man placed behind the Scene or Scaffold in a high place with a boze in his hand, the couer whereof must be full with holes, and in the middle of that place there shall be a burning candle placed, the boze must be filled with powder of bernis or sulphire, and casting his hand with the boze vpwards the powder flying in the candle, will shoue as if it were lightning. Wnt touching the beames of the lightning, you must draue a piece of wyze over the Scene, which must hang downewards, whereon you must put a squib cone, red ouer with pure gold or shining lattin which you will: and while the Bullet is rouling, you must shoote of some piece of Ordinance, and with the same giuing fire to the squibs, it will woake the effect which is desired. It would be ouerlong if I should speake of all things which are to be vsed in these affaires; therefore I will leane speaking of Perspective things.

FINIS.

Here endeth the second Booke of Architecture, entreating of Perspective Arte; translated out of Italian into Dutch, and out of Dutch into English, at the charges of Robert Peake, for the benefit of the English Nation; and are to be sold at his house nere Holbozne Conduit, vnder the Sunne Tauerne. 1611.

The third Booke of Antiquitie.

The fourth Chapter.

Mong all the ancient building to bee seene in Rome, I am of opinion, that the Pantheon (for one piece of worke alone) is the sayrest, wholest, and best to be vnderstood; and is so much the more wonderfull then the rest, because it hath so many members, which are all so correspondent one to the other, that whosoever beholdeth it, taketh great pleasure therein, which proceedeth from this, that the excellent workeman, which inuented it, chose the perfitest forme, that is, the round forme, whereby it is vsually called, Our Lady of the Round: for within, it is as high as it is broad. And it may be, that the sayd workeman, considering, that all things proceeding orderly, haue a principall and onely head, whereon the nether parts depend, was of opinion, that this

piece of worke should haue onely but one light, and that, in the highest part thereof, that it might spread abroad in all places alike, as in effect you see it doth: for besides other things which haue their perfect light, there are sixe Chappels, which (for that they stand within the thickest of the wall) should be darke, yet they haue their due light, by the meanes of some drawing windowes, about in the top of the sayd Chappels, which giue them second light, taken from the vppermost hole, so that there is not any small thing in them, but it receiueth a part of the light, (and this is not made without great iudgement:) for this Temple, in old time, being dedicated to all the gods, by which meanes there stood many Images in it, (which the diuers Tabernacles, Seates, and small windowes shew) it was necessary that every one had his due light. Wherefore such as take pleasure to make Images, and other imbossed or grauen worke, must consider, that such a Cabinet should haue his light from aboue, that every one, standing in his place, neede not looke for light to see, but that they may bee seene altogether at one time. But to come to my first speach: For that the Pantheon seemeth vnto me to be the perfectest peece of worke that euer I saw, therefore I thought it good to set it first in the beginning of this Booke, and for a principall head of all other peeces of worke. The founder of this Temple (as *Plinie* writeth in more then one place) was *Marcus Agrippa*, to accomplish *Augustus Caesars* last will, who being intercepted by death, could not finish it: and so it was built about foureteene yeeres after the byrth of our Lord, which is about 5203. yeeres from the beginning of the world.

In this Temple (as *Plinie* writeth) the Capitals were of Copper; and hee writeth also, that *Diogenes*, the Image-maker of Athens, made the excellent Characters in the Pillars, and that the Images placed about the Frontespicium were much commended, although by the highnesse of the place they could not be so well discerned. This Temple was consumed with lightening, and burnt, about the 12. yeere of the raigne of the Emperour *Traian*, which was about 113. yeeres after the byrth of Christ, and in the 5311. yeere of the creation of the world: and *Lucius Septimus Seuerus*, and *Marcus Aurelius Antonius*, repayed it agayne, with all the Ornaments thereto belonging, as it appeareth in the Architraue of the sayd frame: which Ornaments, you must presume, were all new made, otherwise the Characters of *Diogenes* would still haue bene seene there. But in truth, the workman that made it, was very iudicious and constant; for that he proportioned the members thereof very iudiciously to the body, and would not suppress the worke with many cuttings: but as I will shew, when time serueth, how to place and deuide them excellent well. Also, in all the worke, hee hath obserued the worke of Corinth, and would mixe no other with it: and withall, the measures of all the members are as well obserued as euer I saw or measured in any other peece of worke, whereby we may call this Temple an example of workmanship. But leauing this matter (for that it giueth the workeman little, or no instruction to the purpose) I will proceede to the particular measures: and that I may goe forward orderly in these Antiquities, the first Figure shall be the Ichnography. The second, the Orthography. The third, the Sciography.

Of Antiquitie

This Figure following is the Ichnography, that is, the ground of the Temple aforesayd, which is measured by the ancient, or old Romish Palmes placed along by the side hereof. And first, speaking of the Portall, whereof the Columnes are 6. Palmes & 29. minutes thicke. The Intercolumnes (which are the spaces from one Columne to another) are 8. Palmes and 9. minutes: the breadth of the Portall is 40. Palmes: the breadth of the flat Pillars of the Portall, is like the Diameter of the Columnes: the breadth of the Seates betweene the Pillars, is 10. Palmes: and the Pilasters on the sides are 2. Palmes: the wideness of the Gates is 26. Palmes and a halfe: the wideness of the whole Temple (that is, of the Floore within, from one wall to another) is 194. Palmes: and iust so much is the height from the Floore to the vndermost stone of the window aboue. The sayd round hole is 36. Palmes and a halfe broad: each of the sixe Chappels that are made within the thickenesse of the wall, are 26. Palmes, and 30. minutes; and goe halfe as deepe into the wall as the thickenesse of the foure square Pillars on each side. But the principall Chappell is thirtie Palmes broad, and also is an halfe Circle, besides the Pillars aforesayd. The thickenesse of the Columnes, containyng as much. The Columnes of the Tabernacle betweene the Chappels are two Palmes thicke: the thickenesse of the wall that goeth round about the whole body of the Temple, is 31. Palmes. And although that the Chappels make the walles hollow, yet betweene them there are hollow places made within the walles, which some say, were left for places to receiue wind, because of earthquakes. But I am of opinion, that they were left so vnfilled, to spare stufte, because they are made circlewise, and are strong inough. The going vp, which you see here on the left side, was also on the right side, to go vp the Portall: men also went from thence round about the Temple, ouer the Chappels, through a secret way, which is yet there: through the which also, they went without on the steps, to clime vp into the highest parts of the buildings, with many goings vp which are round about it. It is thought, that this foundation was all one masse or lumpe, and without, many places hollow, so that some neighbours marking it, and seeking to build, haue found such a foundation when they digged.

This is the old Romish Palme, which is deuided into twelue fingers, and each finger is deuided into foure parts, which are called Minutes, by the which measure this present Figure, with all the parts following, was measured.

Of Antiquitie

The forme of the Pantheon without.

The Figure hereunder, sheweth the whole forme of the Pantheon right before, and although at this time men go downe into it by certaine steps; yet as it was made at the first it was seven steps above the ground. It is no wonder that such and so old a piece of worke is yet whole and standing still, for that the foundation was not sparingly made; for it is thought that it was once as broad againe vnder as it is above, as it had bene found by the neighbour workemen: but let vs proceed to the particular measure thereof from the earth vpwards. I sayd before, that the Diameter of the Columnes of the Portal is five Palmes & nine and twenty minutes, but the height is foure and fiftie Palmes and nine and twentie minutes, without the Bases and Capitals: the Bases are three Palmes and ninetye minutes high, and the Capitals seven Palmes and seven and thirtie minutes high; the height of the Architrave is five Palmes, the Frise is five Palmes and thirtie minutes high; the Cornice is foure Palmes and nine minutes high, above from the top of Scina of the Cornice, to the point of the Ceuell, are foure and thirtie Palmes, and nine and thirtie minutes. The Tympanum, that is, the flat part of the Ceuell, is thought to haue bene adorned with siluer images, although it is not set downe in writing; but considering the great power of such Emperors, I am perswaded that it was so, for if the Gothes, Vandals, or other nations (which spoiled Rome more then once) had bene desirous or couetous of Copper, they might haue taken it from the Architraves and other Ornaments in Portals in great abundance: but let it be as it will, there are Figures and tokens same, which shew that there were Figures and tokens of Apettall standing thereon.

The ground of the Pantheon called Rotonde.

The inner part of the Temple or Pantheon.

This Figure following sheweth the Pantheon within, which forme (as I said) is taken from Sphera, because it is so wide from one wall unto the other, as it is high from the Pavement to the open place upon the top thereof; which width and height are both a hundred nineteene and foure Palmes upwards, from the Pavement to the highest; and from the Cornice to the highest part of the roofe is also the same measure. that is, each the halfe of one hundred nineteene and foure Palmes. The Quadrants in the roofe are all like that in the middle; and it is thought that they were also beautified over with Silver plate by certaine remnants thereof yet remainyng to be seene: for if they had bene of Copper, they would yet be seene there, or else those over the Portals would also have bene taken away.

Let no man wonder that in these things (requiring Perspective Arte) that there is no Pavement or other shortening seene, but I make it onely out of the ground to shew the measure of the height thereof, that you might not misse it by shortening: But in the Booke of Perspective Arte these things are shewed in their right shortening manner (and that in diuers wayes) that is to say, in Superficies, and many bodies, and diuers sorts of houses, serving therunto: I will not now set downe the measure of Cornices downwards, for hereafter I will shew the Figures piece by piece, and thereof set downe a generall measure.

The Chappell in the middle, although here it sheweth well with the other worke, yet many men are of opinion that it is not ancient, because the Arch thereof wanteth the five pillars, which is a thing neuer used by good Antiquities; but it is thought that it was made greater in the Christians time, as the Christians Temples alwayes have one principall Altar which is greater then the rest.

Of Antiquitie

This Ornament is yet standing above the Doricall of the Pantheon, which is made in this manner, all of Copper plates, the halfe Circle is not there; but (here was a crooked Superficies finely made of Copper: and many men are of opinion that the beautifying thereof was of Silver, for the reasons aforesaid: but whereof it was, it is not well knowne; but it is true, it was excellent faire worke, considering that which is yet to be seen.

This Figure here under set downe, sheweth the manner of the Portall within, the which both on the sides and bozom is well set out with Marble, and also without, although by continuance of time is much defaced. The foure Pillars are caneled with such a number of Canels, as you see it here under set downe; and because this round Columne is thinner about then the Diameter, where the edge or bozom of the Architrave is as thicke as the Columne: If a man would make the Architrave equall with the foure cornered Pillars, which lessen not about, then the edge would haue had no Perpendicular, for it would haue wanted as much as the lessening of the round Columnes. Thus the skillfull workeman hath placed the Architrave so much right about the the foure Pillars, because such things show well. Touching the doores, they are twenty Palmes, and two minutes wide, and fortye Palmes and foure minutes high. Of the other severall measures I will hereafter speake at large.

This Base is one of those which standeth fast to the flat Pillars, in the second order, which for that they stand farre from mens sight, haue one Astragalus for two, not to show ten the work.

The proportion of this Dore is already set down touching breadth and height, but the Pillasters thereof is the eighth part of the breadth of the widenesse of the light: and although Vitruvius maketh the Pillaster of Dorica and Ionica about the five part, yet this is not vnseemely, because it is Corinthie; for the Corinthian Columns are more lightly then others, yet it seemeth to be so much thicker then the sides are of a good depernesse, so that a mans sight beholding them all at one time, it seemeth not to be so small as in effect it is; the Pillasters on the sides and the Superficies of Architraue upon them is said to be all of one piece, and I for my part haue some no diuision of parting therein: the particular measures stand here on the sides.

The Cornice, Frieze, and Architraue stands about the Dore of the Pantheon, touching the measure thereof, the Architraue or Superficies is the eighth part of the light; the Frieze, because it is breuit, is a third part lesse then the Superficies, the Cornice is as high as the Superficies; the other members are proportioned according to the greatnesse, whereby a man may finde the rest with the Compass.

Of Antiquitie

These all the parts of this most excellent and beautifull piece of worke it is convenient to turne it on every side, and therefore having shewed the outside thereof maiestically as it standeth, with all the things which you see before: now will I shew the lodge, the Postall and the entring into the Temple, side wayes as it standeth. Touching the measure, the thickest, and the height of the Columnes and the Pillars, it is before set downe, and therefore needlesse to be rehearsed, it sufficeth onely to see the disposition of the things within, which, although they be small, they are drawne and proportioned in their measure according to the greatnesse. The small Pillars at the going into the Temple are soursquare, in manner of Pillasters, the measure thereof I will hereafter set downe, for they are also at the Corners of the Chappels within round about the Temple, and as much as the space of these three inter Columnes holds, so farre reacheth the Copper rofe, whereof I spake before.

I will not take upon me to write of euery severall cutting or hollowing of the Columnes whereof there are many in the Pantheon, but onely of the Columnes befoze the great Chappell, because they are very fayze and excellent worke, I will shew something, to the which end the Figures marked with A. and B. shew the outward worke of the grauing of the Columnes of the great Chappell, that is, in the flat and in the byrightnesse and standing by: touching the forme and the fashion it is sufficiently shewed in these two Figures; and thus will I shew you the measures thereof. The Canals are foure and twenty in number, euery Canall being nine minutes and a halfe broad, the Thozus with the two Quadzats or lists are both together foure minutes and a halfe, for the Thozus is thre minutes, and then there resteth a minute and a halfe, which deuised into two parts, enery Quadzate on epyther side is thre quarters of a minute. This hollowing pleaseeth the beholders passing well, and such worke is vpon the Basilica de foro transtoro, for the beautifying of a Gate, as it is shewed in the fourth Booke. The Base marked with C. is the Base of the sayd Columnes of the great Chappell in the Pantheon, whereof the height is two Palmes and eleven minutes and a halfe, which is in this manner diuided, The Plinthus vnder is ninetene minutes high, the vndermost Thozus is seuentene minutes, and the Quadzate aboue it is thre minutes and a halfe: The first Scotie or Trochile is eight minutes and a third part, the Quadzate vnder the Astragal is halfe a minute, so is the other aboue the Astragal, the two Astragals are six minutes and a halfe, and so each Astragal is thre minutes and a quarter. The second Scotie or Trochile aboue the Astragals is six minutes, the Supercilie (so named by Vitruuius) or the Quadzate vnder the second Thozus is one minute: That Thozus is seven minutes and two third parts high, the Cinete, that is the band of the Columne about the Thozus, although the Base be not one, is thre minutes; the Proiecture of this Base is thre and twenty minutes proportioned in manner as it is here vnder shewed.

Of Antiquitie

This Figure following representeth a part of the Pantheon within, that is, from the Pavement till you come by to the second Cornice, which beareth by the Tribune or the round rooffe; and also above the Cornice you see the beginning of the foure square hollowing of the said Tribune: This Figure also in the nether part sheweth the wideness of one of the five Chappels, whereof two are in forme of the halfe Circles, and the other foure in forme of a Quadrangle; yet in show they seeme all to be of one forme: each of these Chappels have two round Columnes, and the corners have their foure square Pillars, as you may see in the ground of the Pantheon aforesaid, and in this Figure following. And although it be not set in Perspective manner, whereby a man might see whether it were a rounde or foure square Chappell, that is omitted because of the measure thereof, notwithstanding this is made for a foure square, which you may see by the forme of the blind windowes which are within the Chappell, for the other should runne more about. The thicknesse of these Columnes is five Palmes thre minutes lesse, the height of the Bases is two Palmes and one and twenty minutes, the height of the Columnes without the Capitals is fourtie Palmes, the height of the Capitals is five Palmes and thirtie minutes; and so the whole Columne with the Bases and Capitals: is fourtie and eight Palmes high. The height of the Architrave, Fræse and Cornice, are altogether thirteene Palmes and a halfe, and this height in all is divided into ten parts, whereof thre parts are for the Architrave; the other thre are for the Sopper or the Fræse, and the other foure parts are for the Cornice: Touching the rest of the other members, I set downe no measures, because this is proportionably declared touching the principallest of them that stand on the side thereof marked with P. And in truth, a man in this Cornice may perceine the iudicious skill of the workeman, who therein touching the mutiles, would not cut any dentiles therein, thereby not to fall into that common error, wherein so many ancient workemen have fallen, and at this day more moderne workemen. The error I meane is this, that all the corners wherein mutiles stand, and vnder have dentiles cut in them are vicious, and by Vitruuius are reiected in the second Chapter in his fourth Booke: and although that in this Cornice the forme of dentiles are, notwithstanding, because it is vncut, it is not to be condemned in this respect. Above this Cornice there is a Podium, or a manner of bearing out, whereof the height is seuen palmes and five minutes, which commeth not farre out, for the Pillars stand not farre out from the Wall: the height whereof, together with the Architrave, Fræse and Cornice, is fourtie Palmes and five and thirtie minutes, which height being divided into five parts, the one part shall be for the Architrave, Fræse and Cornice, the which Architrave, Fræse and Cornice proportioned according to the greatnesse, stands marked with the letter M. In this Cornice, and also in the Architrave, the members are so well divided, part cut, and part vncut, that it darkeneth not the forme thereof, but rather the more, because vncut members are mixed with the cut members, and so you see a wonderfull grace in them: the window above the Chappell is to giue light to the same Chappell, which light, although it be not principall, neuerthelesse, because it is radially drawne by from the bypermost open place, it giueth the Chappell the diuine light: betwene the Pillars, and also above the windowes, there are many fine stones intermixed, and the Fræse of the first Cornice is fine pzeall Stone.

Of Antiquitie

This Figure sheweth one of the Tabernacles which stand betwene the Chappels, and the Pillars on the sides represent the soure square coyned Pillars of the Chapples, here againe you may see the notable iudgement of this workeman, who seeking to ioyne the Architrave, Fræse and Coznice close to the wall, and marking that the soure square Pillars standing on the sides, were not so farre distant from the Wall, that a man might make the whole Proiecture of the Coznice therein: therefore hee made the Scine theron, and the rest of the other members hee turned into a Falcie, whereby the work was more seemely and accompanied with order. The two blinde windows are thought to haue bene placed for idols. The soote of the Tabernacle is 9. Palmes and 11. minutes high, the thicknes of the Columnes are two Palmes, the height sixtæne Palmes without Bases or Capitalls, the Bases are one Palme high, the height of the Capitalls are two Palmes & a halfe; the Architrave is a Palme, & Fræse also is as much, which is also of fine profil, but the height of the Coznice is a Palme & a halfe, the frontispice is 5. Palmes high, & Architrave above & two greatest Pillars, is a Palme and thre quarters, the other measures shal hereafter be shewed; & of these Tabernacles there are thre with sharpe genels, and thre with round genels, that is the fourth part of a Circle.

These foure Figures hereunto annexed, are members of the Tabernacles in great; as the letters A. B. C. D. shew them. Touching their measures in height, it is thewed before, and for the rest it is sufficient for the workeman that all things from member to member are set out in great, and proportionably with great diligence brought into this forme, although it may bee that such as study Vitruuius will: thinke this Cornice to bee too high for the proportion of the Architraue and Fræse; and I for my part would not make it so high, but to see the same in a place that hath great distances, and which standeth not very high, it sheweth to bee in good proportion. The Capitall is farre from Vitruuius order of writing, for it is higher without the Abacus, then Vitruuius maketh it with the Abacus: notwithstanding, according to common opinion, they are the sayest Capitalls that are in Rome. (and not onely the Capitalls of the Tabernacles) but they also of the Chappels are of the like forme, and those of the Pozzall also in such sort, that I iudge (as I sayd at the beginning) that I haue not found a building of greater obseruation of order then this: but if I should write all that are in it, both within and without, I should peradventure be ouer tedious, therefore I will make an end of this wonderful Building, and speake of other Antiquities.

Of Antiquitie

This Temple of Bacchus is very ancient, and also whole inough, and also so; worke, sayzenesse of Stones, Plaster, both in the Pavement and in walles, also in the Tribunes or round rofes in the middle, and in the roofe of the round walke, made altogether after the order of Composita: the whole Diameter within from Wall to Wall, is 100. Palmes long, whereof the middlemost body set about with Pillars, containeth 50. Palmes: in the intercolumnes I find great difference to licken y one to the other, because that the middlemost intercolumnes or spaces betwene the Columnes where you come in, and out of the Portall are 9. Palmes and 30. minutes; and the other right euer against them are but 9. Palmes and 9. minutes: those that are over against the greatest Chappell are 8. Palmes and 31. minutes, and the other foure Columnes resting hold 7. Palmes 8. minutes, and some 7. Palmes 12. minutes. The widenesse of the entry within and of the foure cornerd Chappell over against it, follow the intercolumnes, and so doeth the widenesse of the two great places or round Chappells their intercolumnes. The other places or Chappells are 7. Palmes and 5. minutes broad. The measure of the Portall before, may be taken by the measure of the Temple, which Portall is round Roofed: without before the Portall, there was a walking place made in forme of an Egg, which was 58. Palmes long, and in the middle it was 140. Palmes broad; and as it appeareth by the decayed monuments, it was full of Pillars, as it may be sene in the Figure.

Here before I shewed the ground of the Temple with the measure thereof, now in this Figure I will shew the
 Dytagraphic thereof within, for without it is wholly defaced; the height from the Pavement to the uppermost
 part of the roofe is 86. Palmes, the thickeffe of the Columnies is two Palmes and 14. minutes; the height of
 them is 22. Palmes and 11. minutes. The height of the Base is one Palme and 7. minutes. The height of
 the Capitall is 2. Palmes and a quarter. The height of the Architraue is one Palme and a quarter, so much also the
 Fræse holdeth. But the height of the Cornices are two Palmes and a halfe. The particular members, as of the Bases,
 Cornices and Capitalls, you see here vnder proportioned, according to their greatnesse, and marked in their severall
 places. This Temple standeth without Rome, and is dedicated to S. Anne.

Of Antiquitie

The Achgraphie hereunder placed is the aforesayd walking place before the Temple of Bacchus, with a ledge round about it, as you may perceiue by some very ruineous places thereof, and all about bristane each intercolunne there was a place or seat beautified with small Pillars, where it is thought a certaine 3dall stood, (and as it is sayd) this walking place was made Duale wise, yet being long as of 583. Palmes and 140. Palmes broad.

The Temple of Bacchus (as I sayd) is full of many Ornaments, and of diuers Compartements, whereof I haue shew-
ed some part, but not all. The thre inuentions hereunder placed are in the same Temple, some of faire stone and the
other of Pillaster.

This Temple of peace the Emperoz Vespasian caused to bee made by the Parhet in Rome, which Temple is commended of Plinie, for it was much beautified with grauen worke and Dilaiter of Stucco; and besides these Ornamentals of the said Temple, after the death of Nero, Vespasian caused all the Images both of Copper and Marble to be placed therein, which King Nero had gathered together out of diuers places, which were no small number. Vespasian also placed in it both his owne and his childrens Images made of a new kind of Marble brought out of Echiopia, called Bassalto, being of an Iron colour, a kind of Masse much commended in those times. In the said Temple and the principall Chappell thereof, there stood an Image of white Marble very great, made of many pieces; of which reliques there are many pieces yet to bee seene in Campidoglio; and among other pieces there is a foote, whereof the maple of the great Toe is so great that I late

easily by it, wherby a man may guesse the greatnesse of the Image, and it was made by an excellent workman.

This Temple is measured with Elles, and the Elle is divided into 12. parts, called ounces, the measure which standeth in the middle of the ground of the Temple is halfe an Elle: First, the length of the lodges about is 122. Elles, the breadth is 15. Elles, the widenesse of the places before in the lodges containe 10. Elles, the thickenesse of the Pillars at the entrie is five Elles, and betwene the one Pillar and the other is 10. Elles, the goings in on both sides, both of the Portall and of the Temple are 16. Elles wide, the length of the whole Temple is about 170. Elles, the breadth containeth 125. Elles, the principall place in the middle of the Temple is 35. Elles. The sides of the Pillars against the which the round Columnnes stand are 9. Elles and a halfe, and the thickenesse of these Columnnes are 4. Elles, 4. ounces and a halfe, and they are canelert, every one having 24. Canells: the cane or hollowing of each Canell is 5. ounces broad, and the list there of one ounce and a halfe, the breadth of the principall Chappell is about 37. Elles, and is halfe a Circle. Those on the sides marked A. B. are 37. Elles broad, and goe 16. Elles into the Wall, which is lesse then halfe a Circle: the thickenesse of the Wall round about the Temple is 12. Elles, although in many places, because of the Poves, it is much thinner. The Circumferences of the Chappels are 6. Elles thicke, betwene the one Pillar and the other, it is 45. Elles; you may conceave the quantitie of the measure of many places and windows with other particular things, by the measures aforesayd, for the Figure is proportioned. Touching the Orthographic, which is the Figure hereafter following, because the ground is all covered over with the ruines therof, I could not measure it from the ground to the top, but as much as I conceived by that part of the ground, and also of the ruines which are there to be seene, I make this piece standing upright. I am not certaine whether the Columnnes have this pedestall under them or not, because that men cannot see the foot of the Columnnes. And although that Phai much commendeth this Building, yet there are many unhandsome things in it, specially the Cornices above the Columnnes, which are net accompanied with any thing, but stand bare and naked alone.

This Building is called Templum pietatis, it is made altogether of a kind of rough stone, which is there called Tiburium, after the River of Tiber; but for that the stone is spongie and full of holes, it was covered all over with a kind of Plaster called Stucco, it is very ruinous, for therein you see no proportion of; windows: neuertheless, I have placed them in the ground where I thought them fittest to stand. This Building is measured with an other Elle, which is divided into 60. minutes; & the line through the middle of the ground of the Temple is the third part of the said Elle: First, the Columns are an Elle & 18. minutes thicke; the intercolumnes 3. Elles and 14. minutes, the breadth of the gates is 4. Elles and 14. minutes and a half, the thickness of the wall is one Elle and 20. minutes, the length of the Temple is 18. Elles and 20. minutes, the breadth of the Temple is 8. Elles and 30. minutes: the Gallery round about the Temple was flat roofed with foure square pearches: but howe the broad place before the Temple was roofed I cannot conceaue, because it is so ruinous. The columnes of this Temple haue no Bases nor any Cinthie, or Proiecture, but stand bare vpon their ground, & well made of Tiburium, and covered ouer with Stucco. This Temple had the fronspice both behind and before.

Of Antiquitie

The height of the Columnes with the Capitall is 3. minutes lesse then 10. Elles, the thickeſſe below (as I ſayd before) is 1. Elle and 18. minutes; and the thickeſſe above is 1. Elle and 15. minutes. The height of the Capitall is 47. minutes, but the bozel & the cinctie of the Columnes are alſo reckoned with it; the height of the Architrave is 36. minutes, the height of the Fræſes is 1. Elle & 65. minutes. The Cornice is 1. Elle & 8. minutes high, & from thence upwards, the Simpanum is two Elles and two minutes high. The other particular members marked with y characters are in greater ſozme, and accordingly proportioned.

At Tinoue this Temple standeth upon a Kiner, & is called the Temple of Vesta, the most part thereof is ruinated; it was well wrought after y^e Corinthia manner: befoze it is raised ty from the earth as the Base thereof standeth, but behind is moze then 7. Elles of Wall under the Base.

Of Antiquitie

This last Temple is measured with the last Elle of 60. minutes, and first, the Columns are one Elle and 17. minutes thicke, the intercolumnes 2. Elles and 34. minutes; betwene the Columns and the Wall is 2. Elles and a halfe, the thickenesse of the Wall is an Elle and 13. minutes, the Pavement of the Temple within is 12. Elles and a halfe: the Pedestall marked A. with the Columns and their ornaments serve for the whole order of the Temple. The height of the Base of the Pedestall is 45. minutes, and the felde of the Pedestall is 2. Elles and 48. minutes. The Cornice is 37. minutes and a halfe high, the height of the Base of the Columns is 38. minutes and a halfe; the Trenke of the Columns is 10. Elles high: the Capitall is an Elle and 24. minutes high. The Architrave, Fræse and Cornice all together are about two Elles and a halfe high. The Dooze marked with S. Y. is 9. Elles in height, the bredth of the light under is 4. Elles 4. minutes, but the widenes above is 3. Elles 54. minutes, the which is lessened above, according to Vitruvius doctrine. The Antepagmentum is 52. minutes and a halfe broad, but the Supercillie (because of the lessening) is but 51. minutes; the Fræse is 30. minutes high, and the Cornice 24. The Window marked with T. X. is one Elle 46. minutes and a halfe broad, the height containeth 5. Elles 3. minutes, and is lessened above, as the Dooze is. The Antepagmentum is 31. minutes and a halfe broad, and the Cornices containeth as much, but the other particular members, are in greater forme marked with the same letters set by them, and well proportioned: This Window is wrought both within and without.

This is the third part of the common Elles of 60. minutes, wherewith the Temple aforesayd, and this also is measured.

Without Rome this ruinous Temple standeth, and for the most part is made of Brick; you see none of these ornaments therein which I haue here placed in Figure; but as it may be conceiued by the ground thereof, and also considering the proportioned height, it was made of that fashion as the pieces marked A. B. standing by the ground doe shew. Thus we haue the measure of the Ichnographie of the ground of the Temple, by the which measure a man may conceiue the worke of the Ichnographie: This Ichnographie or platforme, is measured by the olde Romane Palme: and first, the dooze of the Temple is 24. Palmes wide, the Diameter of this Temple is 69. Palmes and a halfe: the two places on the sides are as wide as the Dooze; the Dooze of the lesser Temple is also of the same breadth, so are the foure Chappels also where men goe in, of the same wideness, but backward they are wider, because the walles of the side runne to the Center of the Temple, and those foure Chappels (as it may be conceiued) receiue their lights from the sides: the Diameter of the small Temple is 63. Palmes long, the little Chappels, both they that are hollowed out, and those that are eleuated, are 15. Palmes broad: but of those two eleuated or raysed Chappels, I cannot tell how they ended aboue, for there standeth not so much by sight as a man may conceiue any thing thereof certainly, but onely a beginning aboue the earth; and (as I haue said) although a man cannot see in what maner this Building stood aboue the ground, yet according to my conceipt, I haue made this Ichnographie. And therefore on the one side marked B. representeth a piece of the great Temple, and the other marked with A. sheweth a part of the lesser Temple.

The old Roman Palme of 12. fingers, and 48. minuts,

Of Antiquitie

This Temple placed vnder this is without Rome, and is very much ruinated, and for the most part is made of Bricke, it is not very great, it cannot also be discerned, that it had any light in it but at the doozes, and from the windowes about the Coynices. And all the rest of the holes were placed for Idols or such like things; the measure of this Temple was lost by the way, but yet I remember well that the Temple was a full Quadrant and a halfe, as well on the ground as aboue, therefore I set downe no other measure, but a skilfull workeman may helpe himselfe therewith by inuention.

This small Tempel is of no great compas, and all made of Bricke; it is measured by the olde Romane Palme, the length of the lodge or Gallery is 40. Palmes, the breadth therof is 16. Palmes, the Door is 10. Palmes, the places in the walles within, are all of one widnes, that is, 14. Palmes; the space between them is 6. Palmes, the rest may bee guessed by sight; so; I guess the height from the Pavement to the Architrave to be 40. Palmes, and the Architrave, Frise and Cornice to be 9. Palmes; and touching the rest, I made account that if I allowed a Palme by sight for the round rose, then the whole Tempel should be about 70. Palmes.

The ancient Roman Temple.

Of Antiquitie

This Temple is without Rome, made part of Marble, and the rest of Brick, it is much decayed, it is thought that it was a Sepulchre, and on all sides it is right foure square; frō the one Wall to the other is 30. Palmes broad, the thickeſſe of the walles is 2. Palmes and a halfe, the wideſſe of the Chappel is ten Palmes, the Dore is five Palmes broad, the height of the Pillars with Baſes and Capitals is 22. Palmes and a halfe; the thickeſſe of the Pillars is not much above two Palmes: The Architrave, Fræſe & Cornice are 4. Palmes high, from the Cornice to the height of the rooſe is 11. Palmes: the height of the Voltes of the Chappel is 20. Palmes.

This Temple hereunder set downe is A Tioli by the River, much decayed, which had the frontispice befoze and behind the Columnes, on the sides are more then halfe without the wall; the widenesse of the Temple from the one wall to the other, is 17. Elles measure by the same measure that Templum pietatis is measured withall, the length of the Temple is 8. Elles, the thickenesse of the wall is one Elle and 11. minutes, the thicknes of the Columnes of the Portall is an Elle and a third part, the height of them with Bases and Capitals is about 12. Elles, the height of the Architrave, Fræse and Cornice is three Elles, the Frontispice from above the Cornice to the height is 3. Elles, the height of the basement is 3. Elles and a halfe. In the Fascie befoze, there is no show of a Dooze, nor of any places in the Walles, by reason of the ruinousnesse thereof, but I have drawn it out thus, to make the more show, because I iudge it had bene so; neither can you see any windowes in the walls nor sides, nor yet behind, although I have placed them here in the ground, where I thought best. The measure of the members both of the Basement and the Cornices above, I will not name particularly, for they are proportioned according to Antiquitie, whereof you may see some parts.

The third part of the Ell aforesayd.

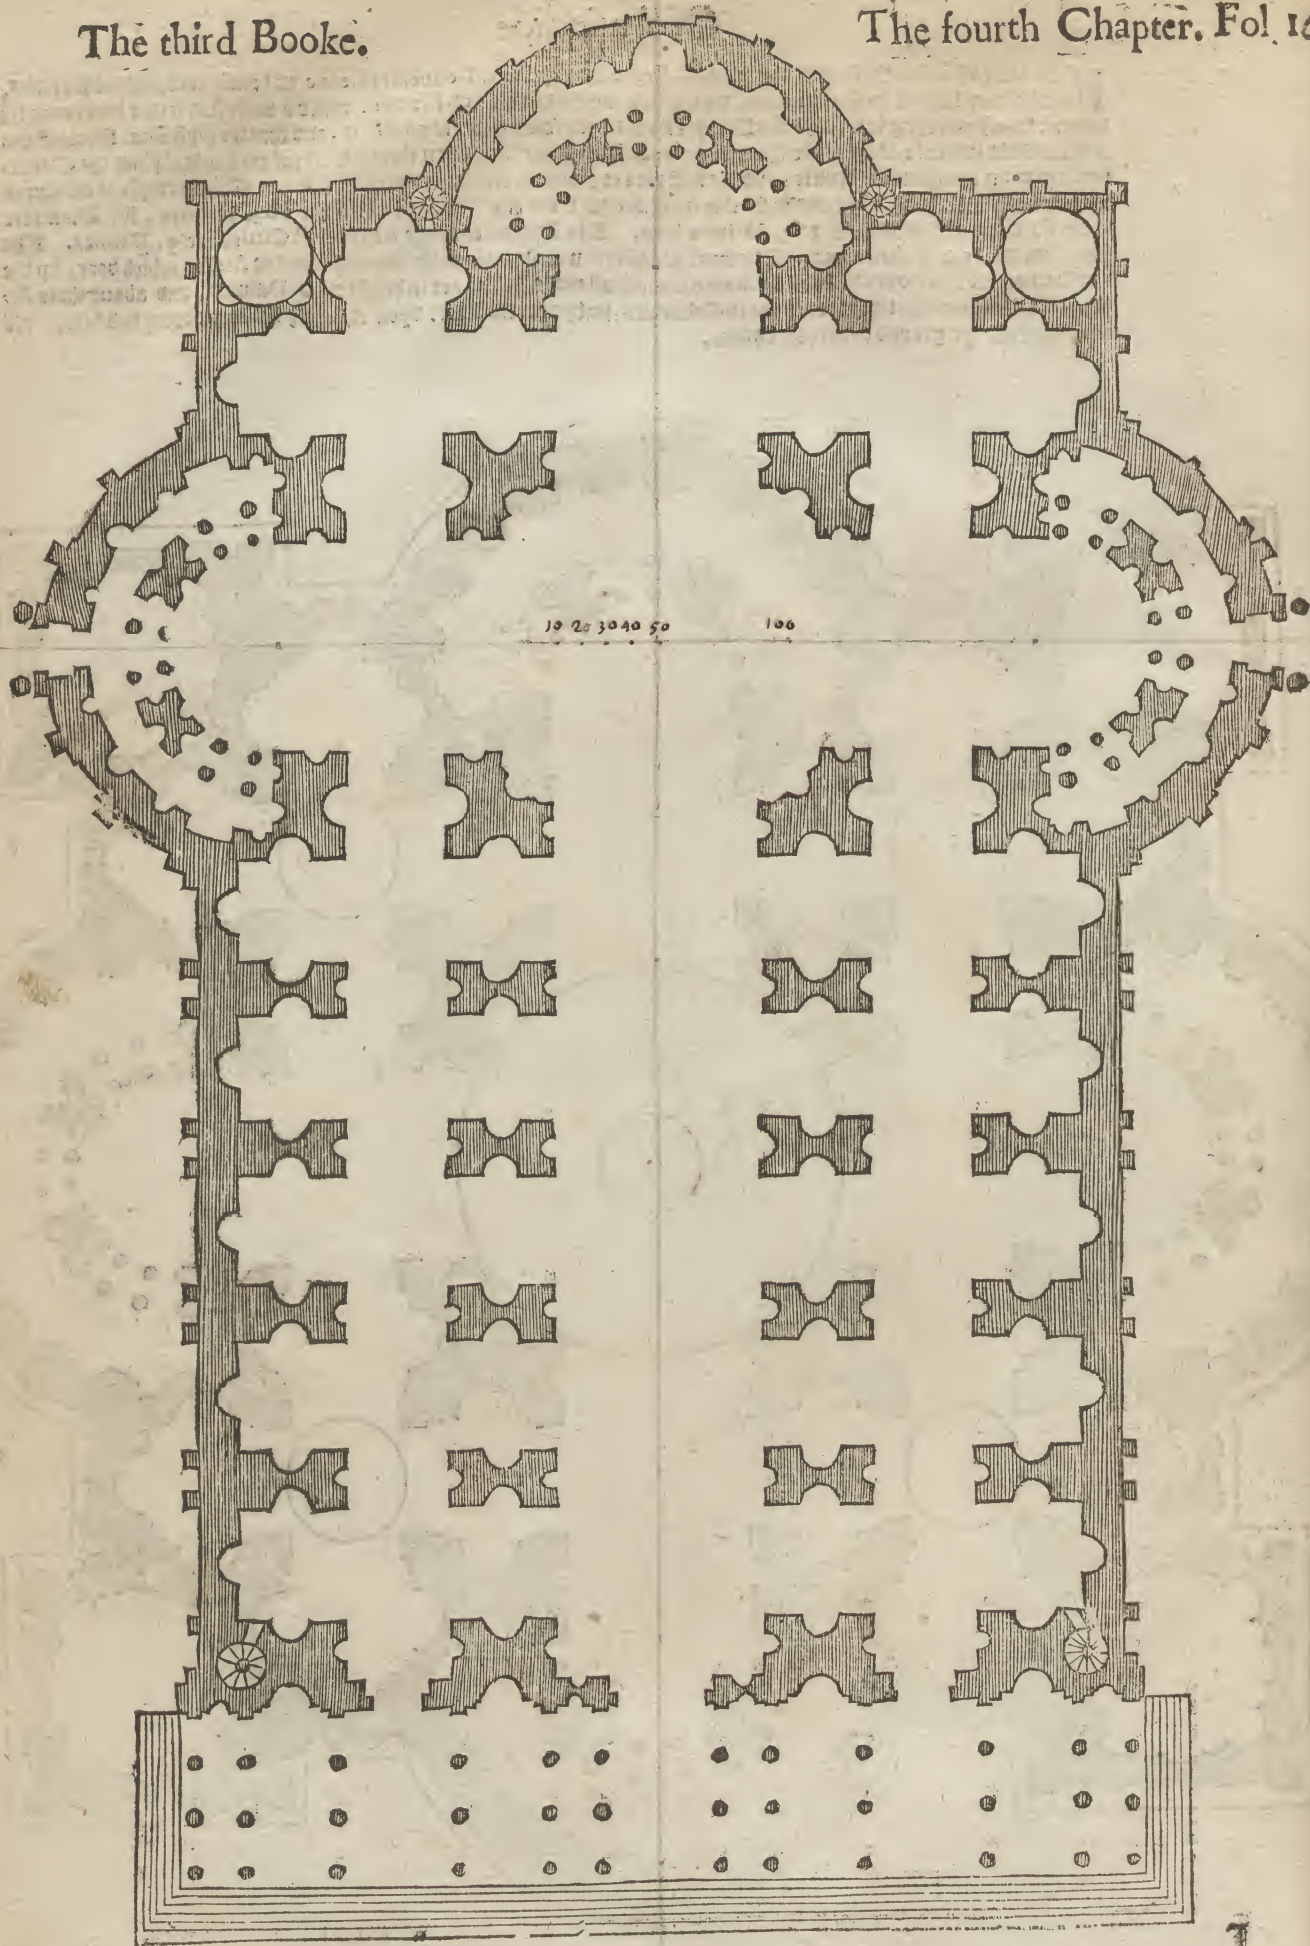

Although at the beginning of this Booke, I said I would speake chiefly of Antiquities, yet I will not omit to treat of some moderne things made in our time, and specially, because our age hath flourished with so many good wits for invention of Architecture. There was in the time of Pope Iulio the second, a workeman called Bramante of Cassel durante in the Dukedome of Vrbino, who was a man of so great understanding in Architecture, that it might be sayd (by meanes of the ayde and performances which the Pope gave him) that hee raysed up good Architecture againe, which from ancient time till then had bene hidde and kept secret: which Bramante in his time layd the foundation or beginning of the wonderfull worke of S. Peters Temple in Rome, but being prevented by death, did not onely leaue it unfinished, but the modell thereof also was left imperfect, wherein diuers ingenious workemen sought to busie themselves both to perfect and finish it; and amongst many others Raphael Durbin, Painter, a man also very skillfull in Architecture, following Bramantes Steps, made perfect this draught, the which in my opinion is one of the fayrest draughts that are to be found, out of the which the ingenious workeman may helpe himselfe in many things. I will not set downe all the measures of this Temple (because that it is well proportioned) and a man may by part of the measure find out the rest. This Temple is measured with the old Romane Palme, and the broadest walke therein is 92. Palmes broad, those of the sides are but halfe as much: by these two measures you may guesse the rest.

Of Antiquitie

In the time of Iulius the second, there was in Rome one Balthazar Petrucio of Sienna, not onely an excellent Painter, but also very skillfull in Architecture, who following the doctrine of Bramante, made a modell in forme hereunder set downe: whose meaning was, that the Temple should haue foure gates to go into it, and that the high Altar should stand in the middle thereof: at the foure Corners he made foure Sacrifices, vpon the top whereof men might place the Clocke-towers for an ornament therunto; and the first part of Facie thereof looked into the Citty. This Temple is measured with the olde Romane Palme, and first, it is in the middle from one Pilaster to another 204. Palmes, the Diameter of the Circle in the middle is 184. Palmes long. The Diameter of the foure small Circles is 65. Palmes. The Sacrifices are 100. Palmes wide. The foure Pilasters in the middle make foure Bowes or Arches which beare by the Lanthorne, and these foure Bowes or Arches are all full made, which are in height 220. Palmes, and about these Arches a Tribune excellently set forth with Columnnes, with a round Roofe vpon it, which Bramante ordained before hee died, whereof the ground is here set downe.

19 20 30 40 50

100

The scale is 40' in an inch

The Figure hereunder set down, is the ground of the Tribune that should haue gone about ouer the foure Bowes or Arches (as I sayd before) whereby a man may perceiue, that Bramant in such case was bold to draw a piece of worke, then circumspect therein; because so great and masse a piece of worke should haue an excellent foundation to stand very fast, and not to be made vpon foure Bowes or Arches of such an height. And for confirmation of my speach, the foure Pillars, and also the Arches without any other waight vpon them, are already settled and suncke, yea, and rent in some places: neuertheless, because the inuention is sayre and costly, and a thing to giue good instruction to a workman: I thought it good to place it here in a modell: but not to be tedious in setting downe the measures, I will shew some of the principallest; the rest you may finde with the small Palme which standeth here within the ground, which length containeth 50. Palmes: the thickenesse of the first Colonne without, is 5. Palmes, the thickenesse of the second Colonne within, is 4. Palmes, and the thickenesse of the third Colonne is 3. Palmes and three quarters. The wideness of the Tribune within, is 188. Palmes, the Diameter of the small Lanthorne within the middle, is 36. Palmes; the rest you may guesse by the small Palme.

Of Antiquitie

This is the Orthographic both within and without, drawn out of the Trigonographic also set downe, whereby you may conceaue the great masse & waight which should haue stood vpon the foure Arches; which waight may giue any wise workeman matter to consider, that it had bene fitter to set it vpon the ground, and not in the ayre vpon such a height; and therefore I counsell all workemen rather to be doubtfull then too rash: for if hee bee doubtfull, he will make his worke surer, and not despise another mans counsell;

which doing, hee shall selde faile: but if hee be rash and stout, hee will not take any other mens aduise, but will trust onely to his owne inuention, whereby oftentimes his worke doeth him more shame then honor: therefore I conclude, that stoutnes proceedeth from presumption, and presumption from small vnderstanding; and I say, that doubtfullnesse or bashfullnesse is a vertue, making a man to thinke hee knoweth little, although his vnderstanding be great: the measure of this worke is to be found by the aforesayd small Palme.

This ground set under this, is also an invention of Bramant, though it was not yet made, which agreed with the old worke: that part which is marked with B. is S. Peters Church to Montorio without Rome, and that part marked with A. is an old Cloyster, but that part in the middle, Bramant ordayned, thereby to helpe himselfe with the old worke: the place marked C. signifieth a Gallery with foure Chappels in the corners. The place B. standeth under the ayre: the part marked E. is a little Temple, which the said Bramant made: the measures whereof shall be shewed in much greater forme in the lease ensuing. I have said nothing touchyng the measure of the ground, but I have set this here onely for the invention.

Of Antiquitie

In the last side I promised to shew Bramans Temple in greater forme, which is not very great, but was onely made in remembrance of S. Peter the Apostle, for it is said that hee was crucified in that place: the said Temple is to bee measured by the old Romane foote, which foote is fyve fingers; and every finger is foure minutes: wherof also you shall finde the measure by the Romane Palme, augmenting the said foure fingers. The Diameter of this Temple is of five and twenty foote, and two and twenty minutes. The widenesse of the walks round about the Temple is seven foote, the thickenesse of the Columns are one foote and 25. minutes. The widenesse of the Door is three foote and a halfe: The Quadrants with the roundels within, which goe round about the Temple, shew the Locutory of the Temple about the Columns: the thickenesse of the wall is five foote; the rest of the other measures you may conceave by the fact.

The halfe of the Romane foote.

This is the said Temple standing by, which sheweth the one halfe without, and the other halfe within, and is made altogether after the Dozica, as you see by the Figure. I will not speake of the particular measures: for by the

ground you may conceive this which stands by it, for that this (though it be small) is set downe by the measures thereof, and from the great reduced into the small.

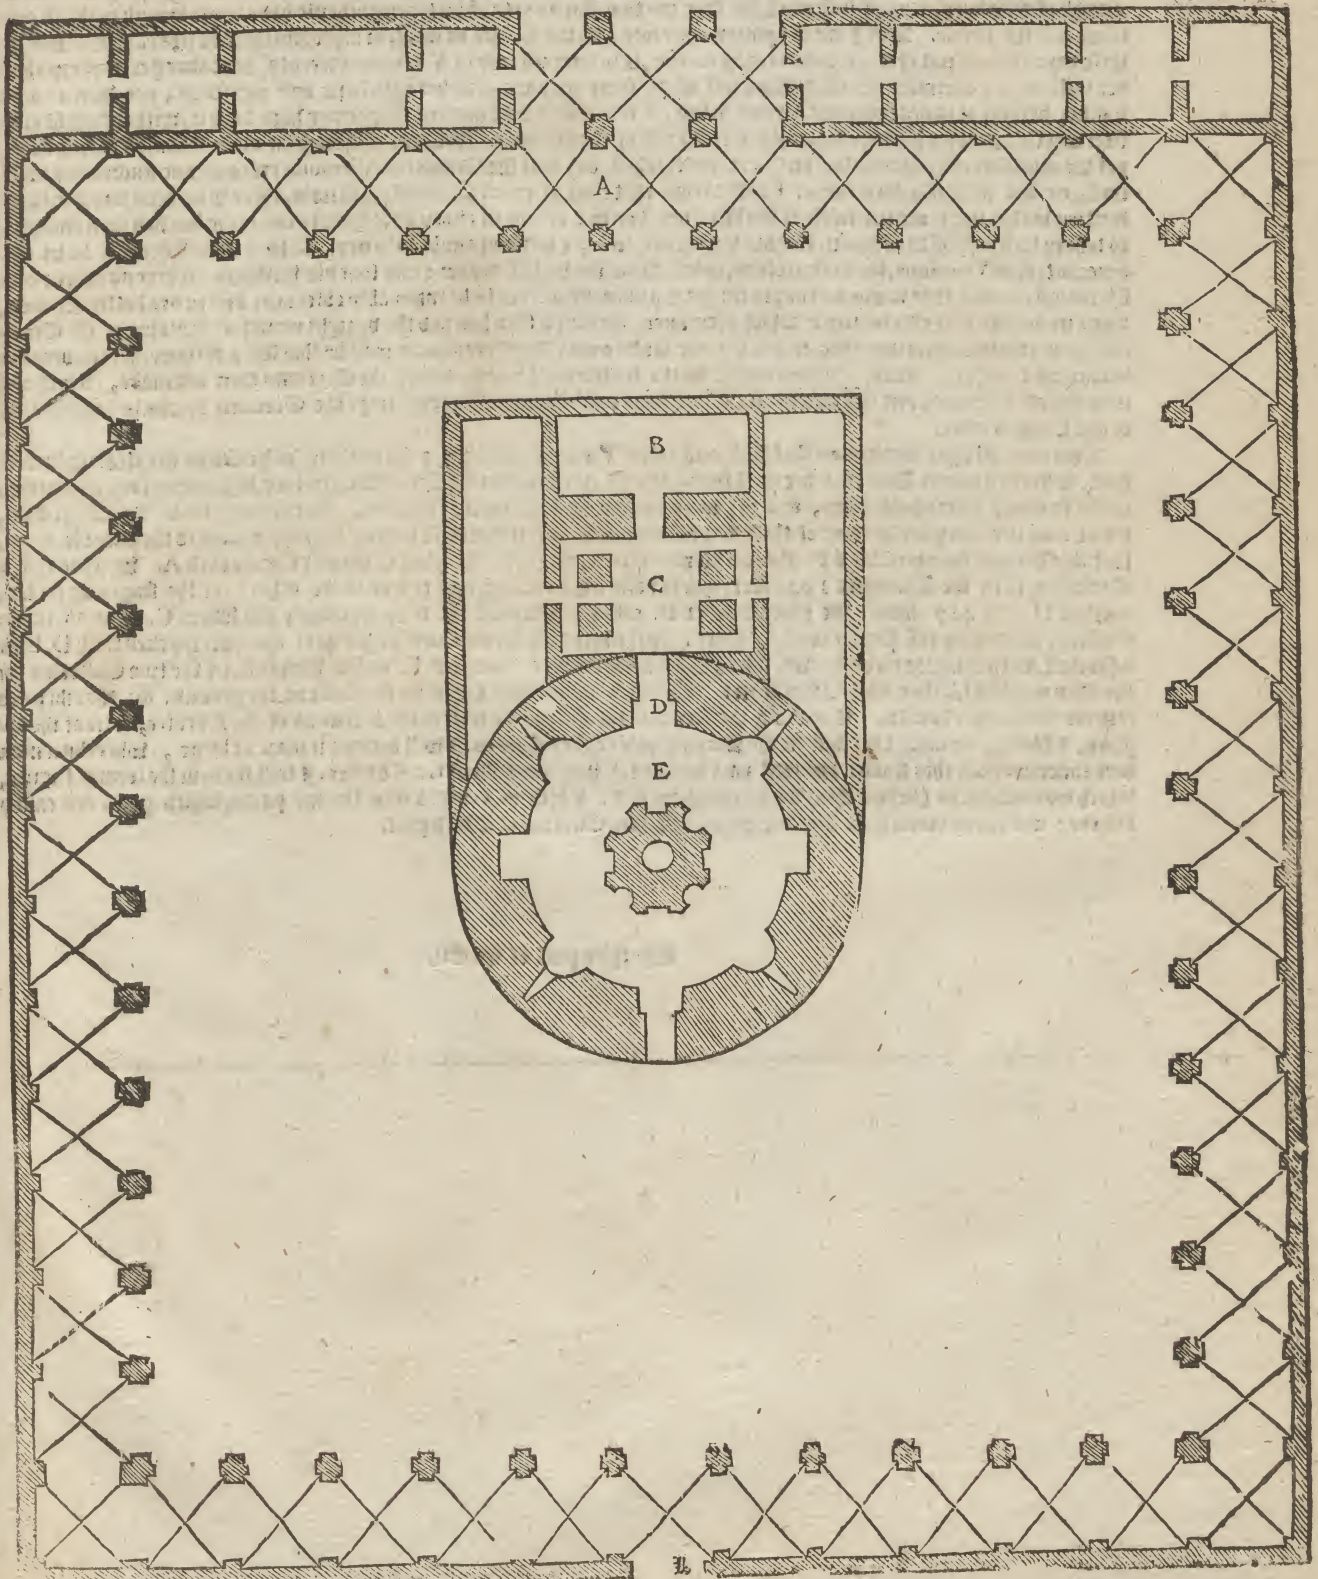

Of Antiquitie

Now I haue shewed the outside of S. Peters Temple, to this I will shew the innermost part, which is made with such proportion, that the workmen by the widenesse of the ground, may finde all the measures: and although that this Temple sheweth too high for the breadth, for that it is thought and shewed to be as high as it is broad: notwithstanding, by the opennesse of the windowes, and the Niches or Chappels that are in it, the height thereof is not amisse, and especially by meanes of the double Cornices, which goe round about, and cover much of the height together with the Projecture, the Temple sheweth much more as it is,

This Building is without Rome. at S. Sebastian, and is all fall in downe to the ground, especially the walke about, but the Building in the middle (because it is very rare worke) is yet whole, and is made of Brick: you see no ornaments in it at all, & it is dark, because it hath no light but at the Dore; and about the foure hollow places in the wall, some small Windows. The ground of this worke is measured with the old Romish Palme, and the lengths with the breadths are measured with roodes, and every roode is ten Palmes. First, the walke or Gallery marked A. is 49. roodes and 3. Palmes, the other two longer, are 56. roodes and 3. Palmes: the breadth of the walke is 32. Palmes: the thickenesse of the corner Pillars, with all their members, is 12. Palmes: by the which measures you may conceive the rest. Touching the Building in the middle, the place B. is uncovered, and is in length 7. roodes and 6. Palmes: the breadth is 3. roodes and 4. Palmes: the part marked C. is covered, and containeth 4. roodes in foure square. The foure Pillars are ten Palmes thicke: the thickenesse of the wall round about the round Building, is 24. Palmes: the place marked E. is roof: and that part in the middle is a masse, which beareth the roofe; in the middle whereof, there is an opening: and this masse is beautified with many hollow seats in it, which stand right, and accompany those that stand in the wall: touching the heights (because of the brokennesse) I measured it not; and especially, because there was no beautifullnesse of Building.

Of Antiquitie

This Theater Augustus made in the name of Marcellus his Nephew, and therefore it was called Marcellus Theater, it standeth within Rome, you may at this day see part of it standing upright, that is part of the Galleries without: it is onely of two rules, that is, Dorica and Ionica, a worke, in truth, that is much commended, although the Doricall Columnes have no Bases, nor any Circles or Proiecture under them, but stand playnely without any thing under, upon the flat ground of the Gallery. Touching the ground of this Theater, men could not well conceaue it: but not long since, the great Patrician of Rome, going to make a house, the situation whereof was to be set vpon part of the Theater (his house was made by one Balkhalar of Sienna, an excellent workman) and as he caused the foundation to be digged, there were found many reliques of diuers Cornices of this Theater, and a great part of the same Theater was discouered, whereby Balkhalar conceyted the whole forme thereof, and measured it with great circumspection, placing it in the forme following: my selfe being at that time in Rome, saw many of the Cornices, and found friendship to measure them, and in truth, there I found as excellent formes as euer I saw in any old Ruines, and most in the Capitalls of Dorica, and also in the impostes of the Arches, which, me thinks, agree well with the doctrine of Vitruuius. Likewise the Fræse, Triglyphen, and Pethopen, agree well inough: but the Dorica Cornice, although it be very full of members, and well wrought, yet I found it to differ much from Vitruuius instructions: for being licentious inough of members, was of such a height, that the two third parts of such height should haue bene inough to the Architrave and the Fræse. But I am of opinion therfore, (by the licence of these, or other Antiquities) that a workman in these dayes should not erre, (which error, I meane, is to doe contrary to Vitruuius precepts) nor to bee peremptory that hee will make a Cornice, or other thing iust of the same proportion as hee hath saide and measured, and then let it in worke, because it is not sufficient for him to say, I may doe it: for ancient workemen haue done it, without consideration whether it be proportioned according to the rest of the building. Besides, although an old workman was so bold, yet we must therfore not bee so, (but as reason teacheth vs) wee should obserue Vitruuius rules as our guide, and most certayne and infallible directions: for that from that time of great Antiquity, till now, there is no man found to haue written better, nor more learnedly of Architecture then he: and as in euery Arte there is one more learned then another, to whom such authority is giuen, that his words are fully, & without doubt belieued. Who then will deny (if he be not ignorant) that Vitruuius, for Architecture, is worthy of the highest degree: and that his writings (where no other notable reason or cause is to moue vs) ought for the vtility thereof to be inuolably obserued, and to bee better credited, then any worke of the Romanes: which Romanes, although they learned the upright manner of building of the Grecians, neuertheless, afterward when they became Rulers over the Grecians, it may be that some of them thereby became licentious: but certaynely, if a man might see the wonderfull worke which the Grecians then did make, (which are now almost all spoiled and cast downe in time of warre) hee would assuredly iudge the Grecians worke to surpasse that of the Latines farre.

Therefore all these workemen that shall condemne Vitruuius writing, & specially in such cases as are clearly vnderstood, as in the order of Dorica, whereof I spake, should erre much in the Art of Architecture, to gaine say such an Authour, as for so many yeeres hath bene, and yet is approved by wise men, learned. Now hauing made this digression, which was necessary for the good of those that would not haue considered so much, turning againe to the purpose, I say, that this ground was measured by the old Romanes foote, and first, the place in the middle, marked A. which is called Orchestra, is in the Diameter 194. foote, and is halfe a Circle from one corner to the other: of the Stages or Seates, marked H. it is 417. foote: the place marked B. called Proscenium, is very spacious; and where C. standeth, is the Gallery, which they call Porticus of the Scene, in the middle whereof stood the Pulpit: that part marked with D. was a Portall, with Stayres on both sides, which went vp to the places marked E. called Hospitalia: the two Galleries on the sides marked G. they used to walke in: Of which things men can see no more about the ground, for that they are covered with other houses. Touching the severall measures, as well of the Scene as of the Theater, and of the degrees, I will say no more: for that in the Amphitheatre called Coliseo, I will declare it more at large, whereby a man may conceaue how this stood: but that part without, which went about the Theater, I will shew in the second Figure, which was measured (before this) with a common Ell, which is diuided into twelue parts, which parts are called ounces: and euery ounce hath five minutes; of which Ell, this is a third part.

The third part of the Ell.

Of Antiquitie

This Figure following representeth that part without, of the foresayd Theater, and is measured with the Ell aforesayd: and first, the thicknesse of the Columnnes beneath in the nether part of the first order, is an Ell and 43. minutes in Diameter: and the thicknesse of the Diameter above vnder the Capitall, is an Ell and 16. minutes: the height of the Capitall, is halfe the thicknesse of the Columnnes beneath, the which Capitall is more perfecter marked in the fourth Booke, in the order of Dorica, in Folio E. 3. And the same Capitall is marked with B. Likewise also the impost, whereon the Arch resteth, is as high also as the Capitall, and standeth also in the same lease E. 3. The Pilasters, beside the Columnnes, are 19. minutes: the widenesse of one Arch, is 7. Elles and 9. minutes: and the height is eleuen Elles and sixtēne minutes; the height of the Architrave, is 49. minutes: the height of the Fræse is one Ell and epght minutes. The height of the whole Coznice, is an Ell, and fourtie minutes: the widenesse of the second Arch of the second order, is as wide as that below; but the height is ten Elles and fourtie and epght minutes: the height of the Pedestall vnder the Columnnes of this second order, is an Ell and fourtie and epght minutes: the thicknesse of the Columnnes, is an Ell and twenty & foure minutes: the height of the said Columnnes without Bases or Capitalls, is 11. Elles, 27. minutes: the height of the Bases is 44. minutes: the height of the Capitall, that is within the Volutes, from the list of the Columnnes, to above the Capital, is 36. minutes: but the Volute hangs over the Astragal or Bazzell 20. minutes and a halfe, which in all, from beneath the Volutes, to above the Abacus, is 47. minutes and a halfe: the bzeadth of the Abacus of the sayd Capitall is one Ell and a halfe: but the bzeadth of the Volutes is two elles: the height of the Architrave is 59. minutes: the height of the Fræse is 58. minutes: the height of the Coznice is an Ell, & 48. minutes: which Coznice, in truth, is halfe so much more as it should be (if we will credit Vitruuius pzecepts.) But I pray you, gentle Reader, esteeme me not presumptuous, neither yet account me for a corrector of the works of Antiquitie, from whence men learne so much: for my meaning is onely, willingly to let you vnderstand and know that which is well made from that which is ill made: and that I will not doe after my owne conceite, as if you were taught by me, but by the authoritie of Vitruuius: and also of good Antiquities, which are those which best agræ with the doctrine of that Authoꝝ. The Base of this second order, and the Pedestall vnder it, the Impost of the Arches, and withall, the Architrave, Fræse and Coznice, you shall altogether find in the fourth Booke of the order of Ionica in Folio K. the second, and are all marked with T. Likewise you shall find the Capitall in the same fourth booke, behind in the lease I. the 4. marked with M.

The third part of the foresayd Ell, of 60. minutes.

Of Antiquitie

In Dalmatia there is an ancient towne called Pola, lying by the Sea side, wherein you may see a great part of a Theatre, in the making whereof, the expert workeman did helpe himselfe with the hill whereon it standeth, being the hill for part of the degrees or steps to goe up, and in the playne below, he made the Orchestra, Scene, and other buildings belonging to such a piece of worke. And in trueth, the ruines and the pieces which are yet at this day found, doe shew that it was a most beautifull and sumptuous piece of worke of stone and workmanship, besides this, there you may see a great number of Columnnes, some standing alone, others with Pillasters, and some Corners with foure square Pillars, and some halfe round, all bound together, and well wrought, after the Corinthia manner. This Building was measured with a moderne or vsuall foote: which foote is divided into twelue parts, named ounces, whereof the one halfe hereafter followeth. The Figure hereafter following, sheweth the Ichnographic, and also the Prosall of the Theatre, whereof this is the measure: the widenesse of the Orchestra which is halfe a Circle, is in Diameter about 130. foote; the degrees or steps round about, with the two wayes or strates, are of 70. foote: the way marked T. comes even with the plaine of the Pulpit of the Scene to the foureteenth step. The widenesse of the Porticus round about the Theatre, is 15. foote, and the sides of the Pillars inward, is of 17. foote & a halfe, but the fore-ranke of the Pillars round about the Gallery, together with the Columnnes, holdeth about five foot in bredth, and from the one Pillaster to the other, it is about 10. foot wide: and this is touching the ground of this Theater. The two greatest Quadzans marked O. are the Hospitalia, from the which places men went into the entrie or passing through, marked T. which comes by to the street, halfe way to the steps, as you may perceiue by the Prosall marked T. and vnder the going through, is part of the going in. The Hospitalia is five and fourtie foote, the bredth of the Scene, is 21. foote, the bredth of the Porticus or Gallery before, is 27 foote, and the length is like the house; the Building which standeth about the grounds of the Theatre, signifieth the Prosall, which is cut through the sides of the Theatre. The Arch marked with A. signifieth the going in, the second Arch C. and B. are vnder the steps, the Cornice besides marked with D. is the impost of the Arches: there is no going up to this Theatre, for the hill above, sayd eased the workeman therein, and men might also goe by to the Theatre from the Scene, because it was toyred to the sayd Theatre: but the Theatre of Marcellus is seperated from the Scene, and therfore the goings by were necessary.

This is the halfe foote of measure, whereby this Theatre was measured with all the ornaments.

Of Antiquitie

This Theater (as I haue sayd) was very rich of ornaments, all of Stone, and made of Corinthia worke, very well and richly wrought, and by as much as is seene by the ruines which lie scattering about the Scene, was very beautifull of Columnnes vpon Columnnes, both double and single, and also in the innermost and outtermost parts, with diuers ornaments of Doores and Windows. The innermost part of the Building is much ruinated: and touching the measures, I can say little; but of the outtermost parts, I will say somewhat of their measures. The first, a rusticall or clownish order, wherein there is no Columnnes, is eleuated from the earth, together with the whole Coznice, marked E. about 16. foote: the height of the first Pedestall, is five foote, the height of the Columnnes with the Bases and Capitals, is 22. foote; the thickenesse of the Pillars, with the Columnnes, is 5. foote: the thickenesse of the Columnnes alone, is two foote and a halfe: the widenesse of the Arches, is about ten foote: and their height twenty foote: the height of the Architraue, Frase and Coznice, is about five foote; the second Pedestall marked X. is of foure foote and a halfe: the height of those Columnnes are about sixtene foot, the Architraue, Frase and Coznice, is foure foot high. I set not downe the measures of the particular members, but in the Figure you may conceaue them; for they are iust of the same proportion: I set not downe the measure of the Scene, nor of the other parts within: onely I haue here set forth a part of the Porticus of the Scene, which is marked P. And also the Coznice, Frase and Architraue marked F. was in the highest thereof: the Capitals marked S. stode within, with some halfe round Columnnes, rayed out of some Pillars, things that were very well wrought: all which things (as I sayd before) are so sumptuous, both for Stone and workmanship, as they may well be compared with those of Rome: the Coznice, Frase and Architraue, marked A. was in the highest part of the Theatre: the Coznice marked B. is the impost of the second Arch: the Architraue, Frase and Coznice, marked C. is the Coznice about the first Arch, the Coznice marked D. is the impost of the Arch: the Coznice marked with E. goeth about the rusticall basement round about the Building: this line hereunder is halfe a foote, of the whole foote wherewith this Building was measured. And wonder not, gentles Reader, that I set not downe all the measures more precisely; for these things of Pola, were measured by one that had more vnderstanding in casting, then in measuring.

The halfe foote, whereby this is measured.

Of Antiquitie

A Ferentia, an old Towne lying by Verulan, there is yet to be seene the forme of a Theatre, much decayed, being of no great workmanship, and lesse ornaments, for any thing a man may perceave by the same; for there are no pieces to be seene whereby a man may conceit any matter of importance. But you may yet see in the Porticus going from the Theatre, there were foure square Pillars, also the Stayes thereof were very simple and playne: and because it is so much decayed, you can hardly discern how they stood. The Scene of this Theatre is much different from others, as you may see in the ground thereof: neither is there so much standing above ground, that a man may perceave how the Scene and the Pulpit thereof stood. This ground was measured by the ancient foote, and first, speaking of the Orchestra A. which is halfe a Circle, the Diameter thereof is 141. foot and a halfe long. The body of the Theatre, that is, from the Orchestra, to the outtermost of the Corner Pillars of the Porticus, is 35. foot: the Pillars of the corner on eyther side, is 5. foote broad: the entry of the Porticus on the side of the Scene, is 8. foote: the vault under the Stayes, is 22. foote: the thickenesse of the Wall about the Orchestra, is 3. foote and a halfe: the Hospitalia, marked X. is in length 40. foot and a halfe; and in breadth 30. foote: the widenesse of the Porticus about the Theatre, is 17. foote: the Pillars are thicke and broad, 3. foote and 3. quarters: the widenesse of the Arch, is 9. foote: the iust breadth of the Orchestra marked B. is 20. foote: the place of the Pulpit C. is in length 40. foote and a halfe; but the breadth is 12. foote: the going through, is 9. foote. The place marked D. should be the Porticus behind the Scene: yet there is no shew of any Columnes; but it sheweth that there was a wall standing by the water side. The breadth of this place, is 19. foot and a halfe. Without this Theatre there standeth the foundation of two Buildings, but they are so much decayed, that you can find no end of them: neuertheless, the Building marked F. for as much as you see of it, sheweth that it was ioyned to other things. The widenesse wherein the F. standeth, is 31. foote. The 2. small places or Sanctes holding by the one side, are eyght foot and a halfe; and on the other side, ten foot and a halfe. The Arches where the foure Columnes stand (which I take be made in that manner) are in length 27. foot and a halfe, and in breadth ten foot and a halfe. The breadth of the Building marked E. is twenty foot: the hollow places in the sides, are 17. foote: the length of all together, is 60. foote, and is distant from the Theatre one hundred and one and fortie foot; and from the other Building, seuentie foote and a halfe.

The halfe of the olde foote.

Of Antiquitie

The Figure vnder this, marked A. I thinke to haue bene the Scene of a Theatre, it standeth betwaine Fondi and Terracina; but there is so little to be seene of the Theatre, that I measured it not: neither did I measure this part of the Scene, which is moze decayed then it sheweth here: but as I sate on horse back, I made a slight draught thereof. The Doze marked B. standeth at Spolera, and is very old, made after the Dozica maner, which likewise I did not measure, but made onely the inuention and forme thereof. The Gate marked C. is betweene Foligus and Rome, out in the Stræt: and although it seeme a licentious and vnseemly thing, that the Arch should breake the passage of the Architrave, Fræse and Cornice; yet neuertheless, the inuention disliked mee not. I measured onely the bredth and the length, the which I found to bee eighteene foote, and one and twenty foote and a halfe. I thinke it had bene a small Temple, or a Sepulchre; but be what it will, it sheweth well to a mans sight.

B

C

It is sayd, that this building was call'd, Poeticus, of Pompeo: others say, that it was the house of Mario: but it is called by the Common people, Carac'hario: which building, as farre as I can learne, was onely made for men to ease themselves in: for there is no dwelling in it at all: and although this building at this day is almost decayed, yet it was very great, and contained many places, as you see by many houses of this building which are found in the earth. Where the Line standeth, is now the way to goe from Campo Flozo, to the Jewes place: and where the Crosse is now, the houses of Sancta Crose stand: where G. stands, is the Jewes place: where the M. standeth, bee the Parcellarii: where the C. standeth, is the Churchyard of S. Saluatoric: and where the E. is cut through, is the Forefront of the houses of Celis: so that thereby you may see the great compas thereof. The three round things were Stayes to goe by to the two empty Roundles. And for that there is no shew of Stayes to be seene in those two, it is to bee conceaued, that they were open places to make water in, (for such things are necessary.) The ground of this worke is measured by the same Ell that the Theater of Marcellus was measured withall: which measure you you shall finde here, after the Dobiliscen, and (halfe an Ell shall be thirty minutes.) And first, the thicknesse of the Pillasters is three Elles and a halfe: the thicknesse of the Columnnes is two Elles: the Intercolumnnes, are on all sides, nine Elles and a halfe: the Pillasters of the foure Corners, are so much more then the outermost Corners stand ouer them: which Corners were made with good iudgement, for they vphold the Corner by strength, and with beauty of worke. Hereby workemen may learne how to make Corners with Columnnes, and with Pillasters bound together, that the Corner may also be foure square, as the Columnne is, which giueth the Corner more fastnesse, then if the same Corner were ordeane along the Pillaster: and for the Corners which are ordeane in, if you see them ouer the side in Diagonall maner, where the two round Columnnes couer the Corner, then they will seeme vpperfit Corners, and specially, because they are seene on all sides.

Of Antiquitie

Touching the Technographie, I haue sayd inough; now I must speake something of the forme about the ground, although there is not much thereof to be seene: neuer thelesse, there is yet so much standing vpright (although it be hidden) that thereby the backe part thereof without, is to be conceaued, which, in trueth, is an ingenious inuention, for a fast worke, and especially in the first order, which you call Dorica, although it hath neyther Architraue, Triglyph, nor Cornice: But yet there is the forme, and that very subtilly made, with great strength and sayze Building (as well of hard stone as of Bricks) as you may see in the Figure following. The thickenesse and bredth are thewrd before: the height of the Columnes with Bases and Capitals, seuentaine Elles: and the height of the Arches, fiftene Elles. The height of the Cines, that is, the shutting stone about the Arch, is 2. Elles: the height of the binding, which is in stead of an Architraue, is 2. Elles, and so much is the Facie about it. The second order seemeth vnsupportable, for that there is a waight of Pillasters standing about an open hole: a thing which in trueth is false & erroneous to speake in reason. Neuer thelesse, for that the first Order is so fast and strong, by meanes of the shutting stone about in the Arch; as also with the crosse stone vpon it, with the fast Facie vpon that, and by reason of the good shouldres of the Arch, which altogether shew to be such a strength (as in effect it is) that the Pillasters that rest vpon it, seime not to oppresse the worke, as they would, if it were a simple Arch, with an Architraue, Fræse and Cornice: for which cause I blame not this inuention therein. The wideness of this Arch is 4. Elles: the height is nine Elles: the bredth of the Pillasters, is two Elles and an halfe: the thickenesse of the Columnes, is an Ell and a fift part in Diameter: the height of the Columnes is eleuen Elles and an eyght part with Bases and Capitals, and are made after the Corinthia manner. The height of the Architraue, Fræse and Cornice, is two Elles and thre quarters. Although I can giue no particular measures of this Cornice, Fræse and Architraue, because such things are not to be seene, yet there is onely so much wall, that thereby a man may conceaue the Freeles, Cornices and Architraue.

The third part of the Ell, wherewith this is measured.

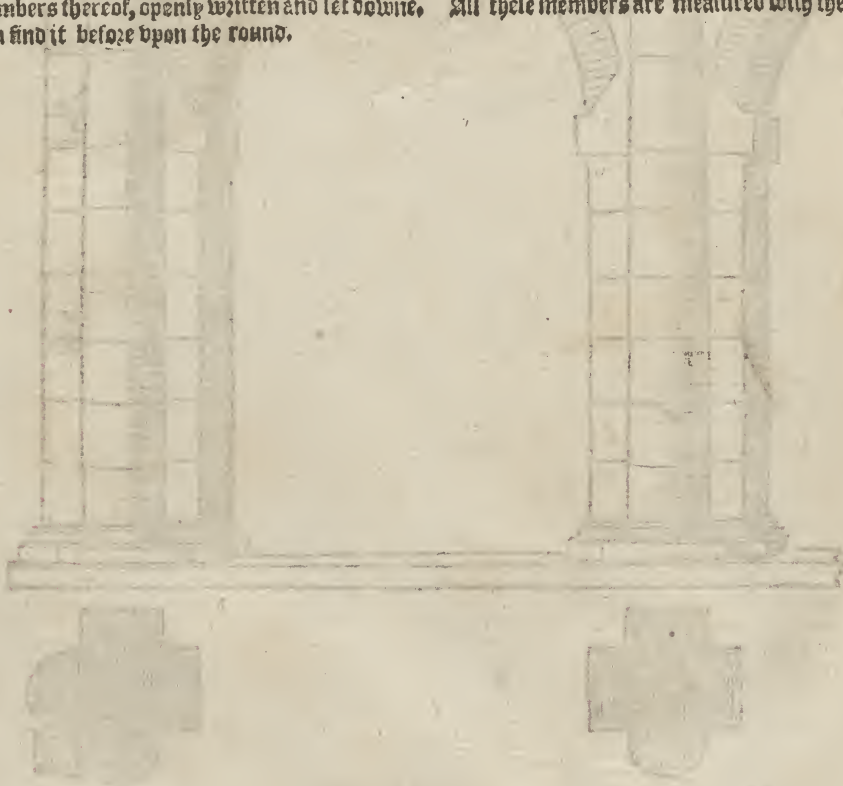

Of Antiquitie

Among other faire Antiquities in Rome, there are two Columnes of Marble, all cut full of Discozies, very good in booke worke. The one is called Antonianus Columne, the other Traians Columne: and for that Traians Columne is the wholest, I will speake somewhat thereof. This Columne, as men say, the Emperour Traian caused to be made, which is all of Marble, and made of many pierces; but so closely ioyned together, that they seeme to bee all one picce: and to giue the particular measure thereof, I will begin at the fuste of the Basement thereof: And first, the degre or step in the first rest, is thre Palmes high, the Plinthus of the Base, is a Palme and eyght minutes high; the carued or grauen Base is as much: the flat of the Basement is 12. Palmes and sixe minutes high: the grauen Cornice is a Palme and an halfe high. The place where the Felson hangeth in, is two Palmes and ten minutes high: the whole Base of the Columne, is sixe Palmes and 28. minutes, and is deuided in this manner: the Plinthus where the Eagle standeth vpon one corner (but you must imagine that there is one at every corner) is thre Palmes and ten minutes high: the Chorus above it, is thre Palmes and eyght minutes high: the Cinete is ten minutes high. The height of the Columne, that is, the body, is 18. Palmes and 9. minutes: the Astragall with the Quadrants or lists vnder the Echine, is 10. minutes. The height of the Echine, is 2. Palmes and 2. minutes: the height of the Abacus, is 2. Palmes & 11. minutes: above vpon this Columne, there is a Pedestall of a round forme, through the which men crept fro the winding Stayres, and may goe easily round about, because the plaine ground thereof, is 2. Palmes and a halfe broad: the height of this Pedestall is 11. Palmes; but the Base is two Palmes, and the Cornice above, is a Palme high. The Crowne above the Pedestall, is thre Palmes and a halfe high: the thickenesse of this Pedestall, is 12. Palmes and ten minutes: the thickenesse of the Columne above, is 14. Palmes, and the thickenesse below, is 16. Palmes: the roundnesse marked A. in flat forme, sheweth the thickenesse above: and the Circle marked B. is the thickenesse below. The widenesse of the winding Stayres, is 3. Palmes, and the Spill foure Palmes. The bredth of the Basement, is 24. Palmes and 6. minutes; in the which space are cut two Compartements, where in is contained an Epitaph, vnder which many Trophees are cut: and in the Epitaph are these letters hereunder witten.

S. P. Q. R.
 IMP. CAESARI DIVI NERVAE. F. NERVAE,
 TRAIANO AVG. GERMANIC. DACICO
 PONT. MAX. TRIB. POT. XVII. COS. VI. PP.
 AD DECLARANDVM QVANTAE ALTI TV-
 DINIS MONS ET LOCVS SIT EGESTVS.

This Columne is historiographed with excellent good cut worke, and orname along with Herries; it is also stoned in Dozicall manner: in the flintings the Figures are made in such sort, that rising vp or bearing out of the Figure, the forme of the Columnes and flinting, is nothing disparaged; betwene which Figures there stand some Windows, which giue light to the winding Stayres: and although the said Windows are placed orderly, yet they hinder not the Discozie at all, and yet they are 44. in number, and I will shew the whole Columne in the Figure following: but these are the members thereof, openly witten and set downe. All these members are measured with the olde Romane Palme, as you find it before vpon the round.

SENATVS

P

Of Antiquitie

I have before sufficiently spoken of the breadth of Traians Colunne, and of the particular maner thereof, now I will shew the whole Colunne proportioned as it is: So then, the Colunne marked with T. representeth Traians Colunne: but from whence the Obelisces spring or proceede, and how they were brought to Rome, and to what end they serue, I will not speake of, so that Pliny declareth it at large: onely I will set the measure here, and shew the forme of some things which I have seene and measured within Rome: And first, the Obelisce, marked O. is without the Capena, and is all grauen and cut with Egyptian letters: the thickenesse thereof in the soote, is ten Palmes and a halfe: the height is 80. Palmes: and this onely was measured with the ancient Palme: but the other thre by it were measured by a moderne or vsuall Ell of 60. minutes, whereof the line that is betwene the Obelisces, is the halfe, and is deuided into 30. parts. The Obelisce marked P. standeth in Vaticano (that is) at S. Peters, and is of Egyptian stone: in the top whereof (they say) the Ashes of the Emperour Gaius Caesar stand: the thickenesse thereof below, is 4. Elles and 42. minutes: the height is 42. Elles and a halfe: the part aboue, is thre Elles and foure minutes thicke: and vnder at the soote standeth these letters.

DIVI CAESARI. DIVI IULII. F. AVGVSTO. TI.
CAESARI DIVI AVGVSTI. F. AVGVSTO SACRVM.

The Obelisce marked Q. lyeth at S. Rochus, broken in the middle of the street in thre pieces, and men say likewise, there lyeth buried in the earth a Ladie called A la Augusta: the thickenesse beneath of the said Obelisce on each facie, is two Elles and 24. minutes: the height is 26. Elles and 24. minutes: the thickenesse aboue, holdeth an Ell and 35. minutes: the Basement was all of one piece, and the Obelisce marked R. is in circo Antonino Caracalla, and is broken, as you see in the forme. The thickenesse of the Obelisce, is two Elles and 25. minutes below, and aboue one Ell and 33. minutes: the height is 28. Elles, and 16. minutes: and all the Pedestals are proportioned thereafter. And although (peradventure) there are moze of them in Rome, which I haue not seene, yet these which I haue seene, are here set downe to your sight, as being best knowne.

This Amphitheater of Rome, called Colifera, Vespasianus the Emperor caused to be made in the middle of the City, as Augustus had appointed it before: the Technographe are divided into 4. parts (as the building is of 4. Orders) that you may understand it the better because of the great artificialnesse thereof. This Amphitheater is measured by the ancient measure: and first, beginning at the outermost parts: The Pilasters before the Amphitheater are 10. Palmes and 6. minutes broad: the thickness of the Colonne is foure Palmes; but the Pilaster on either side is three Palmes and 2. minutes: the distance betweene the Pilasters is 12. Palmes; but the 4. principall goings through hold 22. Palmes: the thickness of the Pilasters in the sides is 12. Palmes. The widthnesse of the Amphitheater inwards, is 20. Palmes and, both of them rofed. The other Pilasters towards the Center, because they lessen themselves, I will not set downe, but by these outward you may perceive it, because they are all proportioned according to the same: the innermost part of the 2. Technographe like the 1. but the Galleries are a little broader: for the Pilasters are

The third Ground.

not so thicke on the sides as the innermost: the inwardest Gallery is crose rofed. And in this Porticus there are some small Tribunes marked X. in the middle whereof, there stand foure square holes, and I thinke also they are made to give light to those places. The 3. ground without is also like the 2. but the walking places are so much wider, as the Pilasters are thinner: and the outermost walking place is crose rofed; and the innermost round. All the doors marked V. came to the Stayes, that thereby every one might goe into his place, according to his degree. The 4. ground is like

The second Ground.

The Degrees layned thus.

This Space, from the one Shaft
to the other, were Degrés
where the people sat easily.

without, but there are
Arches, & Colúnes are
betwéne both, there
you shall see in y^e D^y
& last ground, ma
ether the whole space
walking places was co
for y^e it is so much de
no signes of w^{at}
in the outward part
beginnings of Arch's
toyned to the wall,
toeth; & men did clime
were fall to y^e wall, as
to, to the outtermoſt

Windows, as you may better conceiue of
it in y^e Profil, on y^e side of y^e Stages in y^e fi
gure following. The spaces, as well as y^e
2. shafts, contayne y^e Steps or Degrés for
men to sit on; & every degré was so broad
y^e a man (sitting easily) might go vpon the
same without troubling another: within
these degrés there were lesse Steps, for
ease, y^e every man might go into his place,
as in y^e figure G. & H. is shewed: in which
Degrés, there are some hollow Chaire's,
from the top to y^e bottom, to auoid the wa
ter downward; as also for mens water,
as you may see in the figure H. These de
grés to sit on, hung downward a good fin
ger, that no water should stay vpon them:
which degrés were excellently well ioy
ned together, as in the figure I. sheweth.

The first Ground.

Steps betwéne
the Degrés.

I haue shewed the Ichmographie of the Romish Colisco, in foure sorts, euen like as the building is of foure sorts or orders: now I must shew the Pzofill thereof, by the which a man may conceaue a great part of the inward things: therefore the Figure following sheweth the whole building aboue y^e earth, as if it were cut through in the middle. In which Figure, first you see all the degrees whereon the Spectatozs sate: there also you may perceiue how many wayes the goings by were, which (in truth) were very easie to go by & downe, so that in short time the Amphitheater was filled with a great number of men, without hindzance one of another. You may also see in the outward part, how the thicknes of the Pillasters, and the walles vpwards lessened, which on the inside are draine in, and being so draine in, giueth the building great strength: and to shew it to be true, you may see there, at this day, some part of the Facies without, yet whole, from the top to the bottome, and yet the inward parts are decayed, and that hath the draineing inward of the Centre done, which made the wozke lighter, taking, as it were, a forme of a Piramides. But this is not obserued in the common building in Venice, but rather the contrary, because the walles without are in Perpendicular maner, and lessen inwards: and this they doe (for want of ground) to get the moze space vpwards, but that which helpeth such buildings, is, that there are no Arches in it, nor Rofes, of any maner, that force the walles to giue out, but the number of Beames which are layd and fastned in the walles, bind the walles and the rones of the house together, and so such buildings stand fast so long as the Beames indure, which men from time to time reue: neuertheless, these kinds of buildings last not so long as the ancient buildings did, made in such order as you see in the Colisco, whercof I will speake agayne. And withall, (as I sayd) the innermost part being so ruinous, that men see no part of the innermost wozke, which is cut off by the line that hath Shaffs or Arrowheads at the ends: and for that you see no parts thereof at all, whether that the vppermost parts of the highest steps, vpwards to the top, were all covered with double Galleries, or that the Pozticus was alone, and the other left open: therefore I haue made it in two maner of wayes: the one is (as you see in the same Pzofill) ioyned with all the wozke: and the other maner is, which standeth without the degrees or steps, which order also agreeth with the other, if you let it so, that the two Walks in the Pedestals mate each with the other: but for that you see some remainders of the crossed Rofes, which yet hang within on the walles, as the fourth ground sheweth, the which, I iudge, was onely a Pozticus, and that the other part was vncovered to receiue the people, and being so, must receiue them better then if the Galleries had bene double: Now to turne to the beginning of the degrees or steps, that I leaue nothing vntouched, as nere as I can, I say, by meanes of the ruines, and filling vp with matter fallen, the playne, or the place in the middle is so filled vp, that a man cannot marke how high the first degrees of the playne were eleuated: but by the instructions of those that haue scene the end, the first degree was so high, that the wild and vntamed Beasts could not hurt the beholders: and there was also a Workwring, and other strates, of a reasonable bredth to go round about, as it is shewed where it is marked with C. The two open places, the least and the greatest Arch, were to bring in light. The places standing vp about the degrees or steps which are covered and marked A, are Doores, wherby men went without, by the Stages to the Theater.

The Profile of the Amphitheater of Rome.

Of Antiquitie

The outward part, that is, the Orthographie of the Romish Coliseo, is made of foure Stoies: and the first Stoie next about the Ground, is made after the manner of Dorica: and although there are in the Freese neither Triglyphes nor Metopes, nor yet guts in the Epistolie or Architraue; neither Fulmines and guts vnder the crowne, yet it may be called Dorica. The second Order, is after the manner of Ionica: and although the Columnnes be not fluted, yet in effect they may be called Ionica. The third Stoie, is after the manner of Corinthia, but firme worke without cutting, vnesse it be the Capitalls, the which with their height are not exquisitely made. The fourth Stoie, is Composita; other call it Latina, because it was invented by the Romanes: some others call it Italica. But it may well be called Composita, were it but for the mutiles which stand in the Fræse, for that no other Stoie haue their mutiles in the Fræse, but that. Many men aske why the Romanes made this Building of foure Orders, and made it not all of one forme or order as many others are, as that of Verona, which is all of rusticall worke, and that of Pola also. A man may answer thereunto, that the old Romanes, as rulers ouer al, & especially of those people, from whence the three former Orders had their beginning, would let those 3. generations one about another: & about all those orders, the Composita, as found by themselves; thereby signifying, that they as triumphers ouer those people, would also triumph with their workes, placing and mingling them at their pleasures. But omitting these reasons, we will proceed to the measures of the outermost parts and Orthographie. This Building was eleuated from the earth two degrees: the second degree was five Palmes broad, and the first two Palmes; the height was little lesse then a Palme: the Base of the Columnne was two Palmes, no more is the Dorica: the Columnne is foure Palmes thicke and six minutes: the height is 38. Palmes and 5. minutes, with Base and Capitall: the height of the Capitall is about two Palmes: the Pilasters on euer side of the Columnnes, are three Palmes and three minutes: the widenesse of the Arch is twenty Palmes, and the height is 33. Palmes: from vnder the Arch, to the Architraue, is five Palmes and six minutes: the height of the Architraue is two Palmes and eght minutes: the height of the Fræse is three Palmes and two minutes: the Coznice as much. The Pedestall of the second Order, is eght Palmes and ten minutes high: the height of the Columnnes, with Bases and Capitalls, is five and thirty Palmes, the thicknesse is foure Palmes: the Pilasters and Arches are like those beneath: but the height of the Arch is thirty Palmes: from vnder the Arch, to vnder the Architraue, is five Palmes and six minutes: the height of the Architraue is three Palmes: the height of the Fræse, is two Palmes and nine minutes: the height of the Coznice, is three Palmes and nine minutes. The Pedestall of the fourth Order, called, Composita, (here our Author hath forgotten the third Order, but howsoeuer, it differeth not much from the Ionica) the Pedestall of the Composita, is twelue Palmes high: the vnder-Base thereof, is foure Palmes: the height of the Pillars, with Bases and Capitalls, is thirty eght Palmes and six minutes: the height of the Architraue, Fræse, and Coznice, is about ten Palmes, diuided in three, one part for the Coznice, the second for the Fræse, wherein the Mutiles stand, and the third for the Architraue. But for what cause, or reason, the workeman set the Mutiles in the Fræse, (things, which peraduenture, before that time were neuer made) I haue deliuered my opinion thereof, in my fourth Booke, in the beginning of the Order of Composita. The Pillars of the fourth Order are flat, and rise but a little: all the rest are round Columnnes, (that is to say) three fourth parts, rising out of the Pilasters: the Mutiles above the windows upheld some beames, the which are boazed through with holes for men to draw cords to cover the hole Amphitheater, as well against the Sunne as the rayne: for what cause the Columnnes are all of one thicknesse, and lessen not one more then the other (as it seemeth they should; and as Vitruuius would) as the second Order are lessened a fourth part, I haue also declared my opinion in the fourth Booke, and the ninth Chapter. In the treatise of making Columnnes, longer or shorter; and that the particular members may also be noted, I haue marked them also by the Orthographie of the Coliseo, which are proportioned according to the principall, together with their Characters wherunto they are likened.

Of Antiquitie

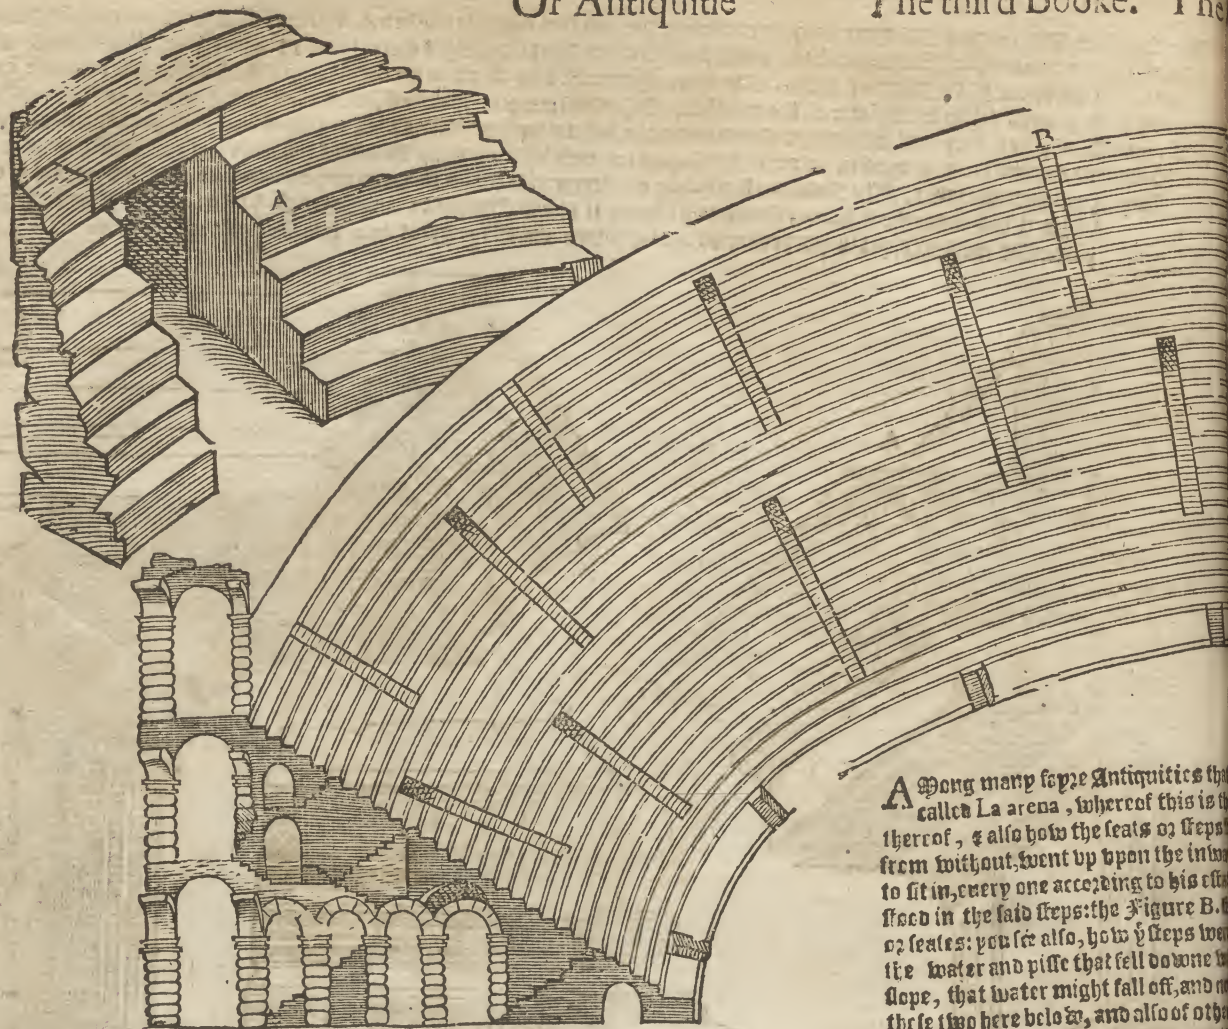

In **Vispello**, a very old Towne in Italy, there is a very
loide Port or Gate, the worke whereof is **Doricke**, al-
 though it hath neither **Triglyphes**, **Metopes** nor **Guts**:
 the two **Towers** on the sides thereof may bee called **Por-
 dernes** worke, in regard of the **Dynaments** above:
 which **Towers** are both of one fashion, although I have
 left one of them out. The **Architographie** is underneath
 the **Figure**, and was measured with the ancient foote: and
 from one **Tower** to the other, are **60.** and **10.** foote: the
 middle **Gate** is **20.** foote wide: each **Porterne Gate** is **10.**
 foote wide: the **Pilasters** betweene the 2. **Ports or Gates**,
 are **10.** foote broad: the height I set not downe, but onely
 the invention, because it pleased me well. The **Stayes**
 under the **Towers**, with the ground, **E.** are by our **Author**
 made on both sides: but according to his ground, the
Stayes must come as they stand above the ground **C.** or
 else not, then the ground must bee made like **D.** This,
 and other things moze (although there consisteth no great
 matter therein) I thought god to note, that you may know
 that I have set the towne peece by peece as I found them.

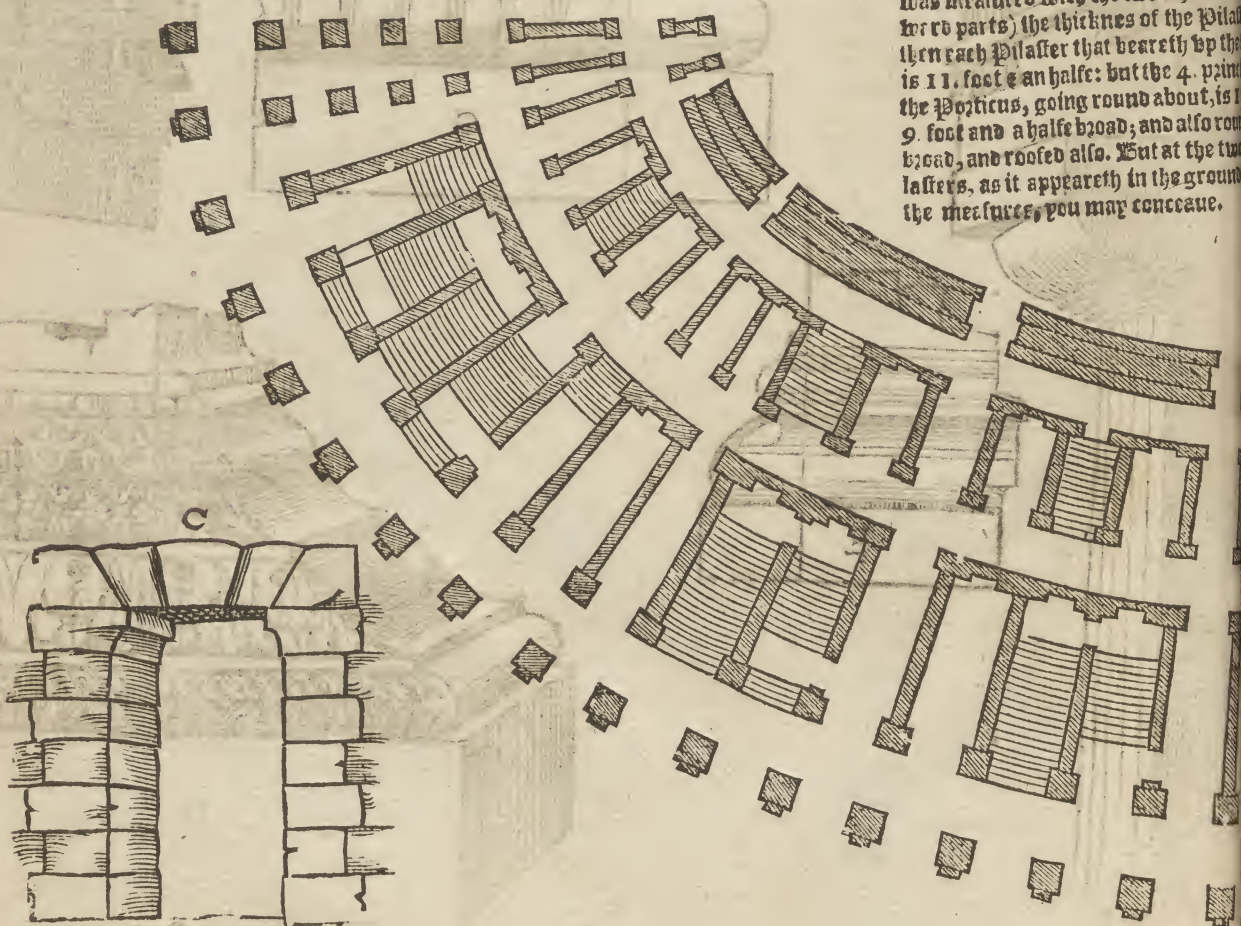

These Cornices, Basements & Bases, are reliques of Antiquitie: and that which is marked A. a piece of the Columns with Architraves, Friezes & Cornices; and also with the Basement above, which was all of one stone: the height thereof was 11. ancient foot, proportioned in that manner, as was found without Rome by the River of Tiber. The order marked B. was found in the foundation of S. Peters, and Bramante caused it to be carried againe in the ground, in the same place: all the members also were of one piece; it was 6. ancient foot high, & proportioned thereafter. The Base marked C. is at S. Markes, very well wrought, of Corinthia worke, but not very great, it is a foot & an halfe high, and proportioned accordingly. The Basement marked D. was found in a place called Capranica, very well wrought: the height of the Base, without Plinthus, is 2. Palmes, and also proportioned thereafter. The Base marked E. was not very great: it was found among certaine ruines, and by reason of the Afragala: which it had above the Thozus, therefore I esteeme it to bee Composita: and although I set downe no other proportion of all these particular measures, yet they are collected and set downe out of the great, into the small measure orderly.

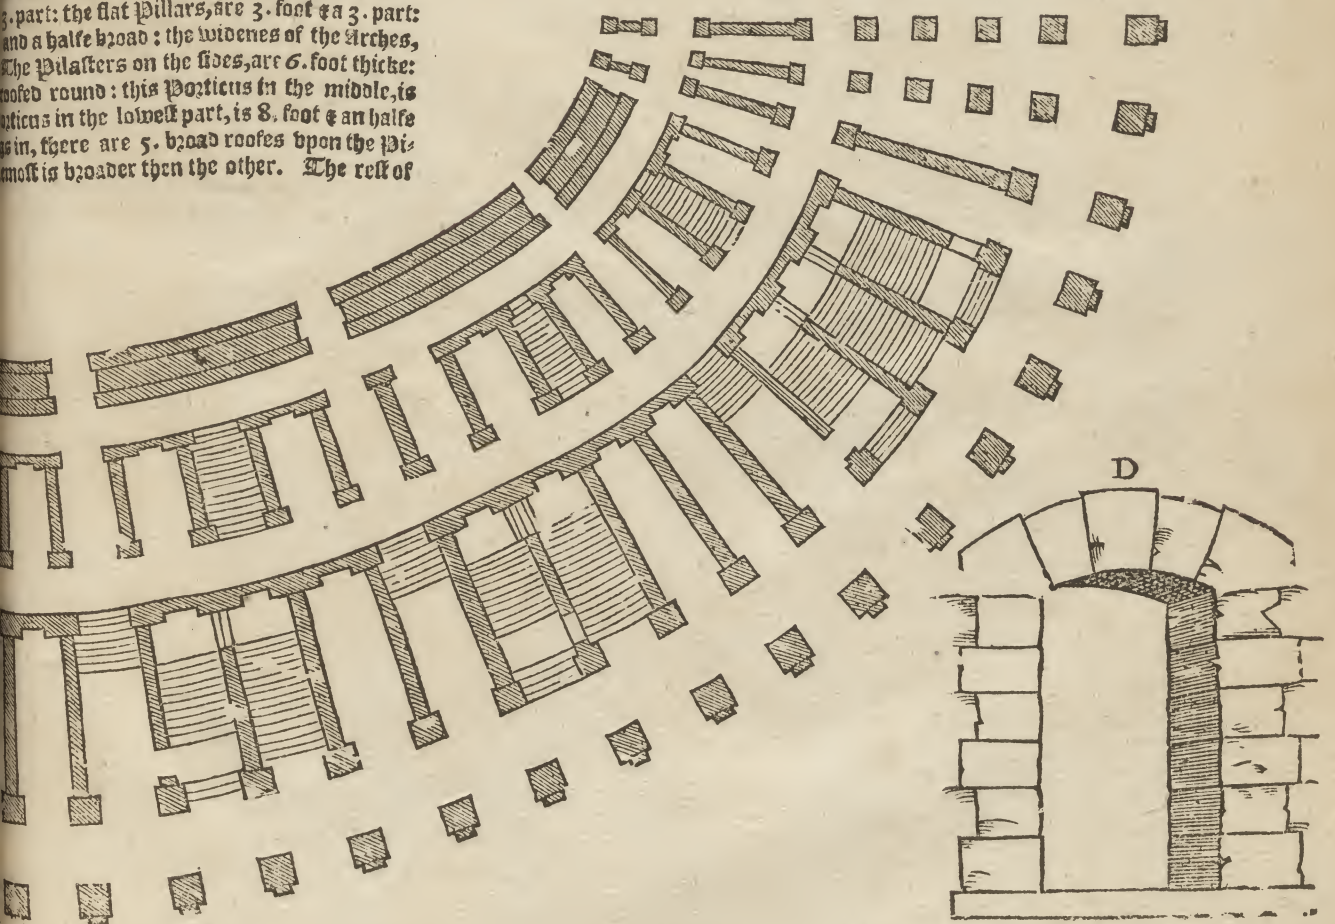

Among many saye Antiquities there
 called La arena, whereof this is the
 thereof, & also how the seats or steps
 from without, went by upon the in
 to sit in, every one according to his cla
 fied in the said steps: the Figure B. sh
 of seats: you see also, how the steps were
 the water and pisse that fell downe to
 slope, that water might fall off, and not
 these (two here below, and also of other
 was measured with the foot whereunto
 for 20 parts) the thicknes of the Pillar
 then each Pillar that beareth up the
 is 11. foot & an halfe: but the 4. part
 the Opticus, going round about, is 11
 9. foot and a halfe broad; and also round
 broad, and roofed also. But at the top
 ladders, as it appeareth in the ground
 the measure, you may conceaue.

there is an Amphitheater of rustical worke. It hath also a part standing upright in the side upon the steps were little doores, whereby men went, and from thence went to the places for men. The figure marked A. It hath also in the doores of the steps downe 7 steps were made, in the degrees of the sides of 7 steps were to ascend any man: the steps also were made somewhat in. In the inner part are many little doores, like the rude worke. The greatestes of this Building is measured: and first, (speaking of the outside) the flat Pillars, are 3. foot & a 3. part: and a halfe broad: the widenes of the Arches, the Pillasters on the sides, are 6. foot thicke: the round: this Porticus in the middle, is in the lowest part, is 8. foot & an halfe broad: there are 5. broad roofes upon the sides: the most is broader then the other. The rest of

Of Antiquitie

Touching the Ichonographie of the sayd Amphitheater, I haue set downe the principall measures, and partly spoken of that part which standeth upright: now I will speake of the outward part, which worke can no other wise be called, then rude and rustycall, and haue likewise spoken of the thickeesse and breadth, therefore I will rehearse it no more: onely of the height I will say some thing: And first, the height of the first Arch is 23. fote: the height of the Pillars 27 fote: the Foorme of the Architrave, Frise and Cornice, is 6. fote high: the Place best high above the Cornice, is 2. fote and a halfe high: the height of the second Arch is 24. fote, and his wideneesse 12. fote: the height of the Pillars is 24. fote and a halfe: the height of the Cornice, Frise and Foorme of the Architrave, is 5. fote and a halfe: the widenesse of the Arch is 9. fote and 3. quarters: the height of the Arch is 17. fote and a halfe: the height of the broad Pillars is 20. fote and a halfe: against these Pillars, as farre as a man may perceiue, there were Images, of god bignesse, set: the third and last Cornice is 5. fote high. But I will not set downe the particular measures of the Cornices, for that I haue set them downe with great diligence, according to the greatnesse in this small Foorme, which shall be the first Figures in the side following, and there below, the Profil or cutting of the outermost part of the Amphitheater shall stand. And thirdly, there followeth the Ichonographie of a pece of the sayd Amphitheater without, which is all wrought after the rustycall manner, with stones of Verona, being very hard: but the Cornices are somewhat better made: which Cornices haue diuers and severall Foormes of the Romanes, and are very like unto the Cornices of the Amphitheater of Pola. Touching the playnesse of this Amphitheater, which by the Common people is called, La arena, (taken from arena) which is sand, which was therein strowed for certayne Playes or sports, which were there presented or Acted: and therefore I could not see the ground thereof: but as it was told me by some old men of Verona, when the Playes were there made upon the sand, then presently there came water, in the sight of all the beholders, which past through some Conduits, and in short space filled all the place full, so that there they might make battalles, and thrust one at another with Scutes and Boates, in the water, and the place dyed by agayne, as at the first. This, and many other things, men may believe, if we consider the great magnificence of the Romanes, in the Antiquities of Verona. There are yet upon the great River of Adige two sayze ancient Bridges, betwene the which two Bridges, there was a most sayze and notable Spectacle, whereon there might stand a great number of people, to behold the Playes and sports there made in Boates, upon the water: which Spectacle was made along by the water side, against a hill: and higher upwards, about this Spectacle, there was a Theater, the Scene whereof, and the Spectacle joined together: (and for that, as I sayd before, the Theater was made very artificially in the hill, so is it above the Theater in the height of the hill) there was a great building, which surpassed all the other: but the ruines of these buildings are so many, and so cast downe in processe of time, that it would be great charges and losse of time to find them out: but for that in many places of the hill I haue seene some parts thereof, therefore it makes me wonder thereat. It was also, with good reason, that the Romanes made such things at Verona (for that, in my opinion, it is the best situated place of all Italy) as well for playnes as hills, and also for waters, and specially, the men of that Towne are very familiar and friendly people.

Of Antiquitie

Great things, and in diuers formes, were made by the famous Romanes; but by the ruines thereof men can not iudge whereunto they serued, & principally this Building which was named *Leserze Zone di Severo*: of which Building you see a corner of the House yet standing, which is of 3 rofes, all *Cozinthia* worke. But it may be saene, that from the rofe it was made of another manner of Buildings, because some Pillars were hollowed and crested, and some smoth; besides, the Capitals and other formes are not all of one worke. I haue not measured the height of this Building, but onely the ground and thicknesse of things: and so; as much as I can conceane, the roofes aboue lessen one more than another, the fourth part, as *Vicruuius* writes in his description of *Theaters*. This Figure hereunder, sheweth the ground of the Building, & also the skie or rofe of the *Lacunary* aboue the *Columnnes*: it was measured with the foote that measured the *Theater of Pola*. First, the thicknesse of the Wall, is 3. foet and an halfe: betwene the one Wall & the other, it is 4. foet and an halfe: betwene the Wall and the *Columnne*, is 5. foet and 3. quarters: and so is the space betwene the *Columnnes*: the thicknesse of a *Columnne* is 2. foet and 4. quarters. In this Building you see no *Chambers* at all, no; any shew or signes of *Stayzes*, or goings up into the lodgings: but men may conceane, that it was much greater, and that in other places both *Stayzes* and *Chambers* might haue stood; and to speake truth, this Building, when it was whole, was a notable piece of worke, in regard of the great number of *Columnnes* and *Pillars* that were in it, together with the costly worke thereof.

The ground of the Amphitheater in Pola.

At Pola, a town in Dalmacia, this Amphitheater is in the middle of the Town, & yet very whole: which building hath nothing but 5 first wings without, with the 4. counterforts, eche made of 3. Pillasters; which, I beleue, were made for 5 strengthening thereof, because this wall stand thus alone: so that nothing at all was made of the Building within, but the outermost wall, with the Arches marked A. But by the shew of some holes which are within the wall, men may iudge, that there they made 5 Axes and seats of wood, when they made their sports, and held their feasts: neuertheless, for a beautifool of the Figures, I haue set down the part within, as in my opinion, it should bee made. This Amphitheater was measured with a moderne fote, which is shewed here vnder the ground: the widenes of the Arches, is 9. fote, & 2. ounces, but the 4. principall Arches are 15. fote wide, 5 forefront of the Pillasters is 4. fote & 2. ounces: the first Pillar, is 2. fote and 2. ounces broad: so the Pillasters on each side, are one fote broad: the Pillasters in the sides, are 5. fote and 3. ounces: betwene the Pillasters of the counterforts, and the other Pillasters, it is 3. fote and 4. ounces.

Of Antiquitie

Touching the Orthographie, or the ground of the Amphitheater of Pola, I have sufficiently spoken: but now I must shew the Orthographie of the part standing up, beginning at the nether part: as touching the Basement, it hath no terminations of measures, (the cause why, is,) so that the Hill is not even: so that the Hill the Pedestall is not onely lost, but also the whole first order of the Arches, with all their Cornices upon them, and the Hill is the height of the plaine of the second story; therefore I will set downe no height of the measure of the Basements: but will begin from thence upwards. The height of the Pedestall vnder the Pillar, is 2. foot and an halfe: the height of the Pillar, or flat Columne with the Capitall, is about 16. foot: the height of the Arch, is 17 foot and an halfe: the height of the Architrave is a foot and 9. ounces high: the height of the Frase, is 9. ounces: the height the Cornice, is one foot & 10. ounces: the height of the bozle-wering or place breast-high (if there bee any other) above the Cornice, is as high as the Cornice: the height of the Pillar is 21. foot & 9. ounces, with the Capitall: the height of the Arch, is 18. foot and one ounce: the thickness of the Arch, is 1. foot and 9. ounces: the Architrave, Frase and Cornice, are of the same height that the vndermost is: the Basement marked X. is 4. foot and 4. ounces. From the Basement to vnder the Cornice, is 19. foot: the height of the Cornice is one foot and an halfe. And this is touching the Orthographie of the Amphitheater, the which Orthographie is on the next side, marked P. and so that (as in the Treatise of the Orthographie I have sayd) the Amphitheater hath some Pilasters on foure sides, which were made for strengthening & counterfozting of the walls: the which wall stood within, without any thing else; and therefore I meane to shew how it stood: the Figure marked Q. sheweth the sides of this counterfozt: & that part marked H. representeth a Pilaster: that part marked I. sheweth the Profill of the wall of the Amphitheater: betwene the Pilaster H. and the wall of Pilaster marked I. is a going through of three foot and an halfe wide: so that two men may goe through together. These counterfozts haue their ground in euery order of story, whereon the people might stand; but there are no steps nor signes of steps, but were made of wood, as may be seene by some holes for the windows. And that the Cornices of this present Building may be the better vnderstood, therefore I haue set them there besides in greater forme, that a man may know their members, by their Characters or Lettres which they are marked withal. The manner of this Cornicement is much different from the Romish, as men may see: and I, for my part, would not make such Cornices in my worke; but with the Theater of this Towne, I would serue my turne, because they are of a better manner of worke. I am of opinion, that this was an other workeman, different from the other, and it may be that this workeman was a high Almaine, because the Cornices are made much after the Dutch manner.

The halfe common foot, wherewith the Amphitheater is measured.

Of Antiquitie

AT Mount Caballa within Rome, where now the stone horses *Paritiles* and *Phidia* stand, is the ruines of a most costly Pallace, whereof one part stood upon the hill, but the part of the goings up was made right against the descending of the hill, as you may see in the *Profill* hereunder. The *Ichographie* of this building was measured with a common *Ell*, the third part whereof standeth hereunder. And first in the *Niches* or hollow places, marked *T.* and *N.* were found the figures of *Tiberius* and *Nikus*, which are now set in *Waldeneric*: the place marked *A.* is a *strate* or way of 10. *Elles* broad: the part marked *B.* is 12. *Elles* square: the part marked *C.* is 36. *Elles* in length, and 18. *Elles* broad: the place *D.* is 36. *Elles* square: the walks round about are 4. *Elles* broad: the place over against *C.* *B.* is of the like measure. The wideneſſe of the four *payze* of *Stayzes* is 4. *Elles* each of them: the places *E.* are *Courts*, whereof each of them are 114. *Elles* long, and in breadth 62. *Elles* and a halfe. The *Galleries* *F.* are 13. *Elles* broad: the greatest *Stayzes*, to goe up to the playne of the Pallace, are 11. *Elles* wide: that part by the *Cozners* marked *K.* is 12. *Elles* and a halfe broad, and long 16. *Elles* and a halfe: the parts *H.* are *Counterfozts* to hold up the *Stayzes*. The place *G.* is a *Court*, which gave light to the place within: the two goings in marked *I.* were to goe up the *Stayzes*, and the building began where the *Stayzes* stand. The great stately *Frontispice* in the middle of the building, was of such breadth, as the middlemost part held without the *Courts* or *Galleries*. The two figures, *K.* and *+*, which stand without the building, the one sheweth the *Cozner* *K.* in greater and perfect forme, and the other is a *Cozner* of the *Court* *D.*

These 3. Figures are members of the aforesaid Palace: the part underneath in small forme, is precisely the Profile of the first part of the Palace, that is, the Arches whereby men went by to the plaine of the Building, because it was upon the hill: and they were magnificent and stately. That part upon the hill, where the Colonne F. is marked, is the side of the said building. This great Pillar marked F. is the corner Pillar of the frontispice, which is 4. square; but all the rest are round, for that round Pillars are not fit for corners: this Pillar is three Elles broad in the lowest part, and above, it is 2. Elles and 2. third parts: the height, with Base and Capital, is 39. Elles, and is suited from the top to the bottom. The height of the Architrave, is two Elles and an halfe: as also the Frieze, which is finely cut, and the height of the Cornice is three Elles and an eyght part, and all proportioned according to the greatnesse. The Frieze on the sides was an hundred Elles long: the Cornicement with the Frontispice, as much as three Quilles containeth, is of one piece of Marble; and the Frontispice rose up in the middle one first part.

Of Antiquitie

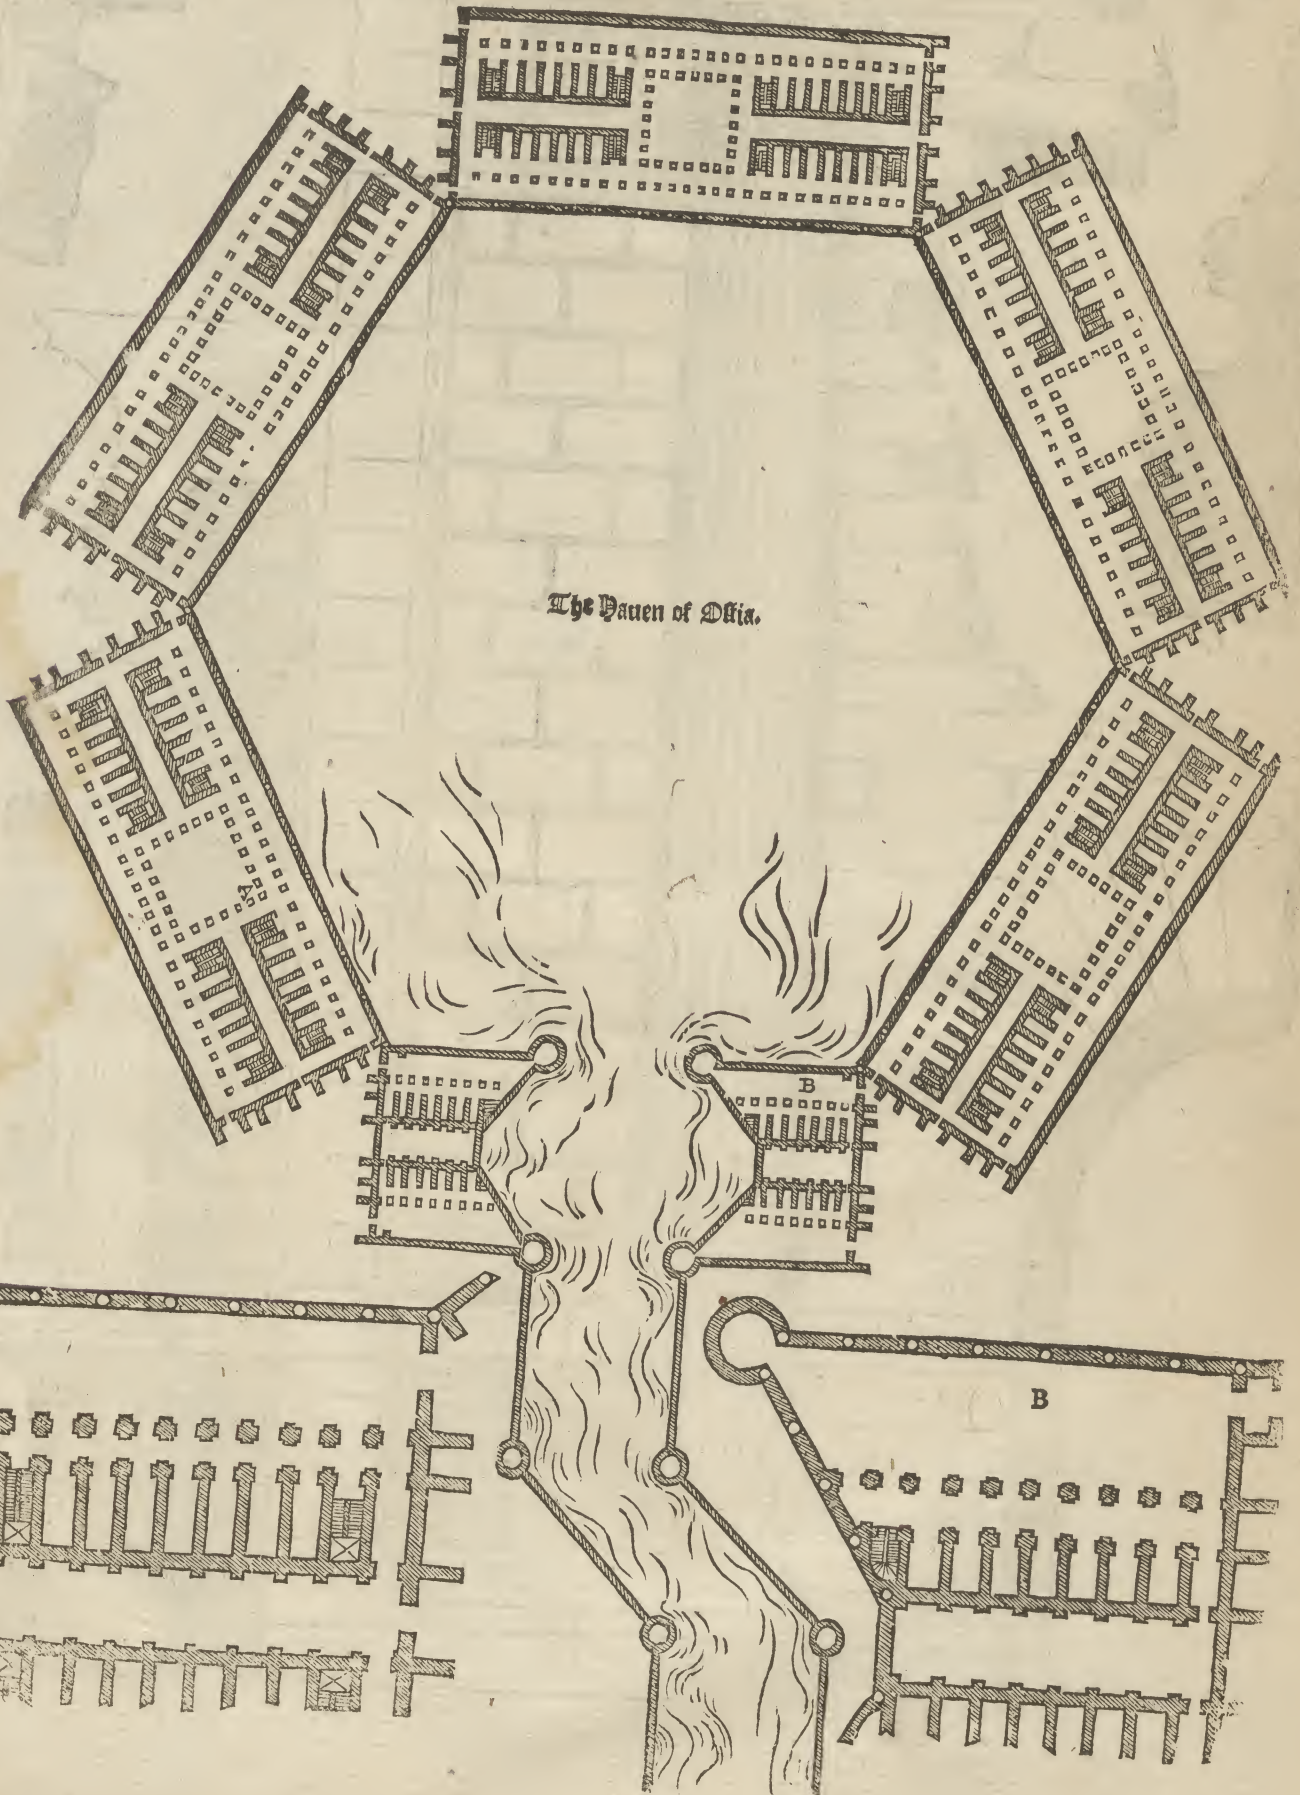

Among the ruines of Rome, there are many things found out, the which a man cannot marke nor imagine what they haue bene: a man also seeth there many ruines, which are now cast downe and ouerthrowne; whereby a man may conceaue the high mindes of the Ancient Romances: amongst which Antiquities, this hereafter following, is one, as you may perceaue by that which yet standeth. This Building is called the Basilica del foro traianico: and a man may imagine the greatnesse thereof by the height of this Pillar, although you see not the ending thereof upwards; for the vppermost Cornice is not there in the worke, neither is there any pieces thereof among the ruines to be found, whereby a man should conceaue what stood aboute such a Building. This ruine was measured with a common or moderne Ell, which is diuided into 60. minutes: the halfe whereof standeth betwene the Obelisks: this Colonne stood 7. degrees elevated from the earth, of indifferent height: the thicknesse of the Colonne marked C. is 3. Elles in Diameter: beneath at the Base and in the vppermost part, vnder the Capitall, the Diameter is 2. Elles and 40. minutes: the height of the tronke or bare Colonne, without Base or Capitall, is 24. Elles and 55. minutes: the height of the Base below, is one Ell and an halfe: the height of the Capitall, is 3. Elles and 26. minutes: the height of the Architrave, is two Elles, and 23. minutes: the Cornice betwene the Colonne and the counter-pillar, which Cornice is marked D. is 1. Ell and 48. minutes: the Cornice aboue (as I haue sayd) is not found there: the counter-colonne is flat, and is of the same proportion like the round Colonne, and lesseneth also aboue, as the round doeth. The Capitall is formed like the Capitalls of the Pantheon of the Rotund: the Base marked C. is placed there besides in better forme, and is proportioned in measure like the greater: likewise, there also you see the Cornice D. in greater forme. I haue set downe the measure of the greatest Colonne C. now will I speake of the lesser, marked B. which Colonne vnder it, hath a very sayze Base: the height whereof, is 6. Elles: the thicknesse of the sayd Colonne in Diameter beneath, is one Ell and a third part; and it is lessened aboue accordingly, as the greatest is: the height thereof with the Base & Capitall is 13. Elles and 2. third parts: the height of the Base, is halfe the thicknes of the Colonne beneath, and is fashioned like the greater: the height of the Capitall is one Ell & an halfe: which Capitall is very well made, and the forme thereof in great, is seen in my other 4. Booke, in the beginning of *h* Composita. This Colonne is fluted, as the Figure thereof sheweth, and hath also a flat Colonne of the same forme: the Architrave, Frieze and Cornice aboue this Colonne, are about 4. Elles: which Cornice hath the *Opus* without Dentiles, and is very like the worke of the Pantheon; and by as much as I could perceaue, this lesse Colonne serued for an ornament of a Gate or *Porte* of the sayd Basilica.

The third part of the common Ell, wherewith this is measured.

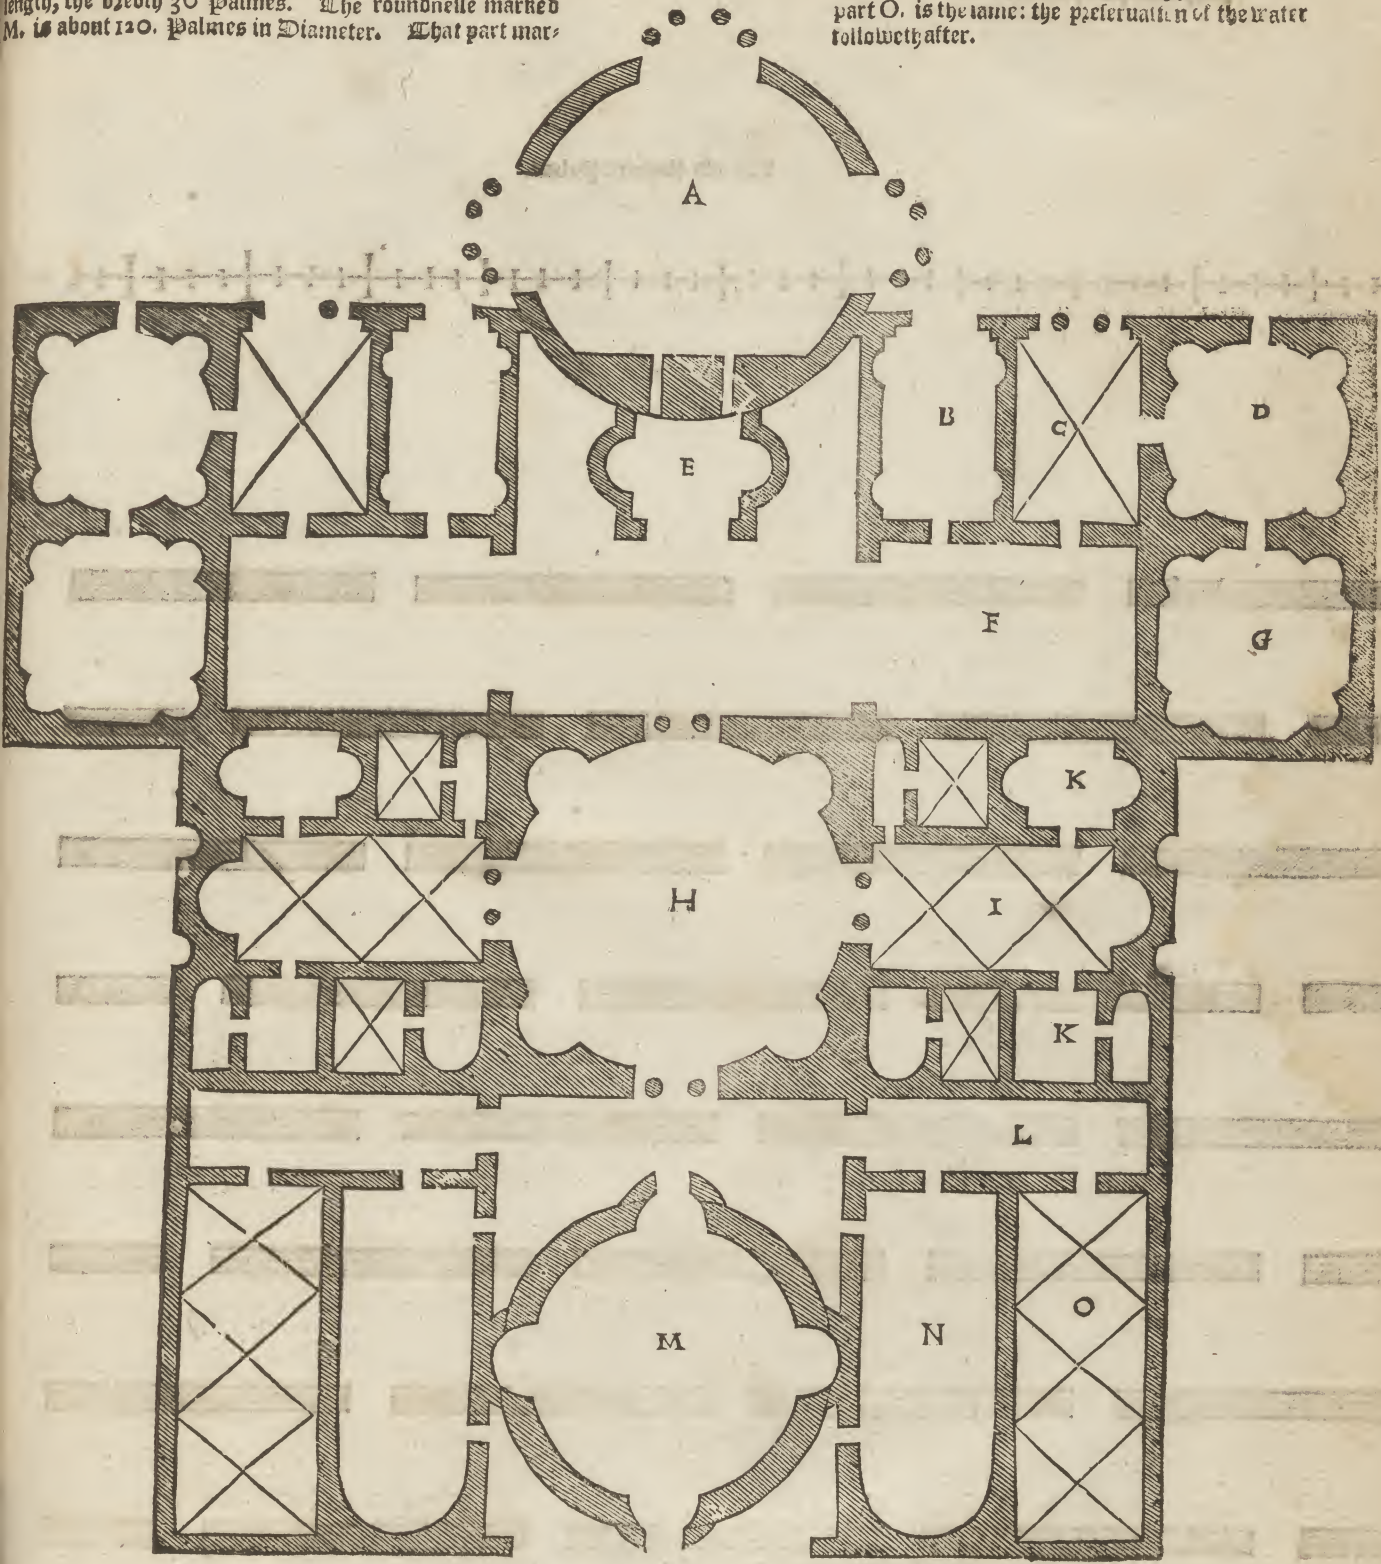

Of Antiquitie

The Romanes (because of their great proud mindes) alwayes sought to build things of great maiestie, which might shew their great power both by Water and Land: and to that end they made the wonderfull Haven of Ostia, for the ease of the Citie of Rome: which, in truth, (in regard of the commoditie and greatnesse of the Building thereof, and specially, the great strength thereof) may well bee called wonderfull. It is of forme Hexagonick, that is, 6. cornered: and each Facie is 116. roodes long, and each roode is 10. Palmes: by these principall measures, you may vnderstand the greatnesse therof; every Facie had a large walking place, with Galleries round about, & 4. Appertiments also, compassed with Galleries, and a walking place in the middle. Along the Water side there were trunckes of Columnes orderly plac'd, wherunto the ships were fastened; and at the mouth of the Haven, there were towers to defend it from the enemy in time of need. And for that you can hardly perceave the Appertiments in so small a forme, therefore I have placed them beneath in greater forme, and marked them with A. and B.

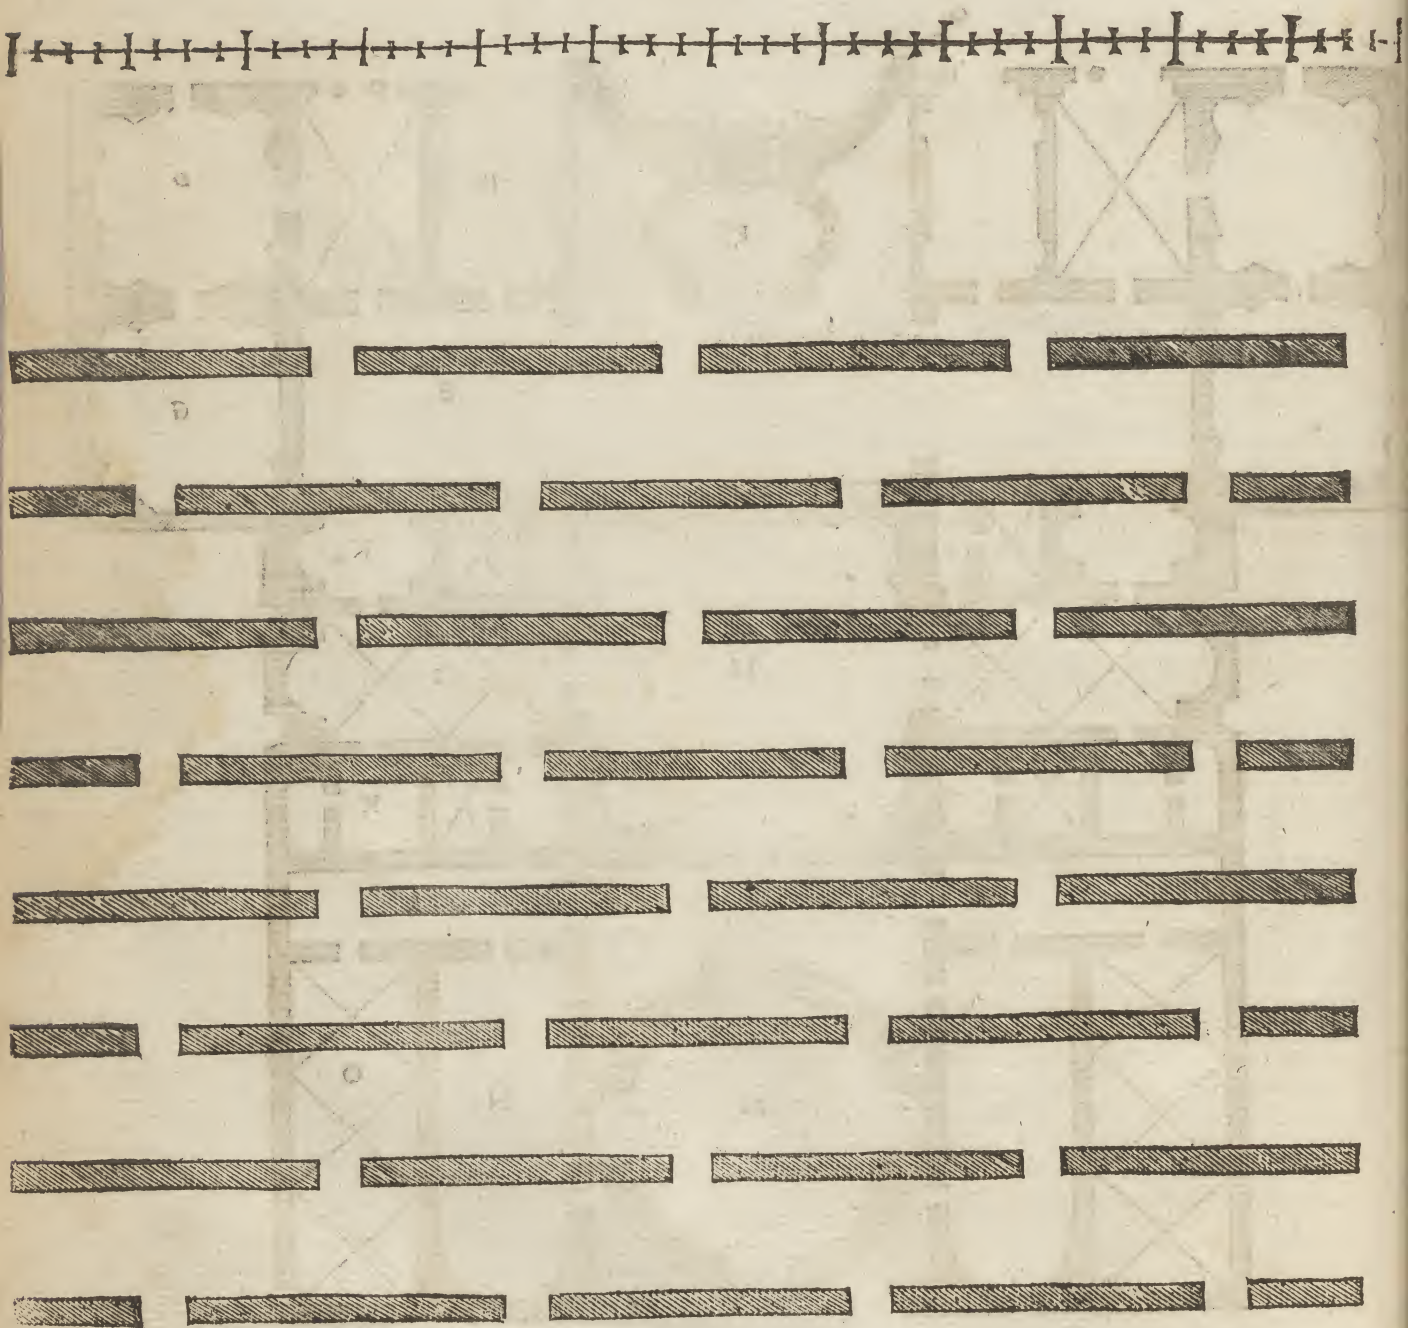

The Thermes of Ticus are lesse then the other, and therefore by the people they were called Therma minori: nevertheless, (after my opinion) they are well made: the Pchnographie of these Thermes is measured with the ancient Palme. First, the Diameter of the round sozme marked A. is about 150. Palmes: the part B. is in length 80 Palmes, and in breadth 51. Palmes: the part C. is 80. Palmes: the part E. is 120. Palmes long, and 70. broad: the sozme D. is about 100. Palmes in Diameter: and the Hoztall E. is 50. Palmes in length, and in breadth 60 Palmes. The sozme D. is about 100. Palmes in Diameter: and the Hoztall E. is 50. Palmes in length, and in breadth 60 Palmes. The part F. is 120. Palmes long, and 70. broad: the egypt ranked part marked G. is about 100. Palmes: the round part H. is 150. Palmes in Diameter. The part I. is 100. Palmes, and is almost two four squares: the two parts, each marked with K. is 30. Palmes on eyther side. The part L. is 125. Palmes, in length, the breadth 30 Palmes. The roundnesse marked M. is about 120. Palmes in Diameter. That part marked N. is 148. Palmes long, and 57. broad. The part O. is the same: the preferuati on of the water followeth after.

Of Antiquitie

The preserving, or the place where the water of the Thermes of Titus, the sonne of Vespasianus was kept, is wonderfully made, and very Artificiall, and that is, for that the Arches of these preservations are placed in such good order, that a man, standing in the going through of the one, seeth them all onerthwarts: and this is the place which the people commonly call, The seven Valles, and it was so; this cause, because the spaces are seven in number: and in them you see onerthwarts, backwards and forwards, alwayes 7. in number: the thicknesse of the walls, is foure foot and an halfe: the widenesse of the Arches is five foot: from one Arch to the other, are 27. foot: the widenesse from one wall to the other, is 15. foote, and they are round roosed, of an indifferent height. The walles and roofes are plastered with most hard plaister.

The old Romane Palace.

This Temple hereunder set downe is A Tiouli by the Riuer, much decayed, which had the frontispice before and behind the Columnes, on the sides are moze then halfe without the wall; the widenesse of the Temple from the one wall to the other, is 11. Elles measure by the same measure that Templum piccatu is measured withall. the length of the Temple is 8. Elles, the thickenesse of the wall is one Elle and 11. minutes. the thicknes of the Columnes of the Portall is an Elle and a third part, the height of them with Bases and Capitals is about 12. Elles, the height of the Architrave, Fræse and Cornice is th:æ Elles, the Frontispice from above the Cornice to the height is 3. Elles, the height of the basement is 3. Elles and a halfe. In the Fascie before, there is no spot of a Doore, no: of any places in the Wall, by reason of the rottnousnesse thereof, but I have drauone it out thus, to make the moze show, because I iudge it had bene so; neither can you see any windowes in the wales no: sides, no: yet behind, although I haue placed them here in the ground, where I thought best. The measure of the members both of the Basement and the Cornices above, I will not name particularly, for they are proportioned according to Antiquitie, wherof you may see some parts.

The third part of the Ell aforesayd.

Although at the beginning of this Booke, I said I would speake chiefly of Antiquities, yet I will not omit to treat of some moderne things made in our time, and specially, because our age hath flourished with so many good wits for invention of Architecture. There was in the time of Pope Iulio the second, a workman called Bramante of Cassel duringe in the Dukedome of Vrbino, who was a man of so great understanding in Architecture, that it might be sayd (by meanes of the ayde and performances which the Pope gave him) that hee repared by good Architecture againe, which from ancient time till then had bene hidden and kept secret: which Bramante in his time layd the foundation or beginning of the wonderfull worke of S. Peters Temple in Rome, but being prevented by death, did not onely leave it unfinished, but the modell thereof also was left imperfect, wherein diuers ingenious workmen sought to busie themselves both to perfect and finish it; and amongst many others Raphael Durbin, Painter, a man also very skilfull in Architecture, following Bramantes steps, made perfect this draught, the which in my opinion is one of the fairest draughts that are to be found, out of the which the ingenious workman may helpe himselfe in many things. I will not set downe all the measures of this Temple (because that it is well proportioned) and a man may by part of the measure find out the rest. This Temple is measured with the old Romane Palme, and the broadest walke therein is 92. Palmes broad, those of the sides are but halfe as much: by these two measures you may guesse the rest.

This small Temple is of no great compass, and all made of Brick; it is measured by the olde Romane Palme, the length of the lodge or Gallery is 40. Palms, the breadth thereof is 16. Palms, the Doore is 10. Palms, the places in the walles within, are all of one widenes, that is, 14. Palms; the space between them is 6. Palms, the rest may bee guessed by sight; for I guess the height from the Pavement to the Architrave to be 40. Palms, and the Architrave, Frise and Cornice to be 9. Palms; and touching the rest, I made account that if I allowed a Palme by right for the round rose, then the whole Temple should be about 70. Palms.

The ancient Roman Palme.

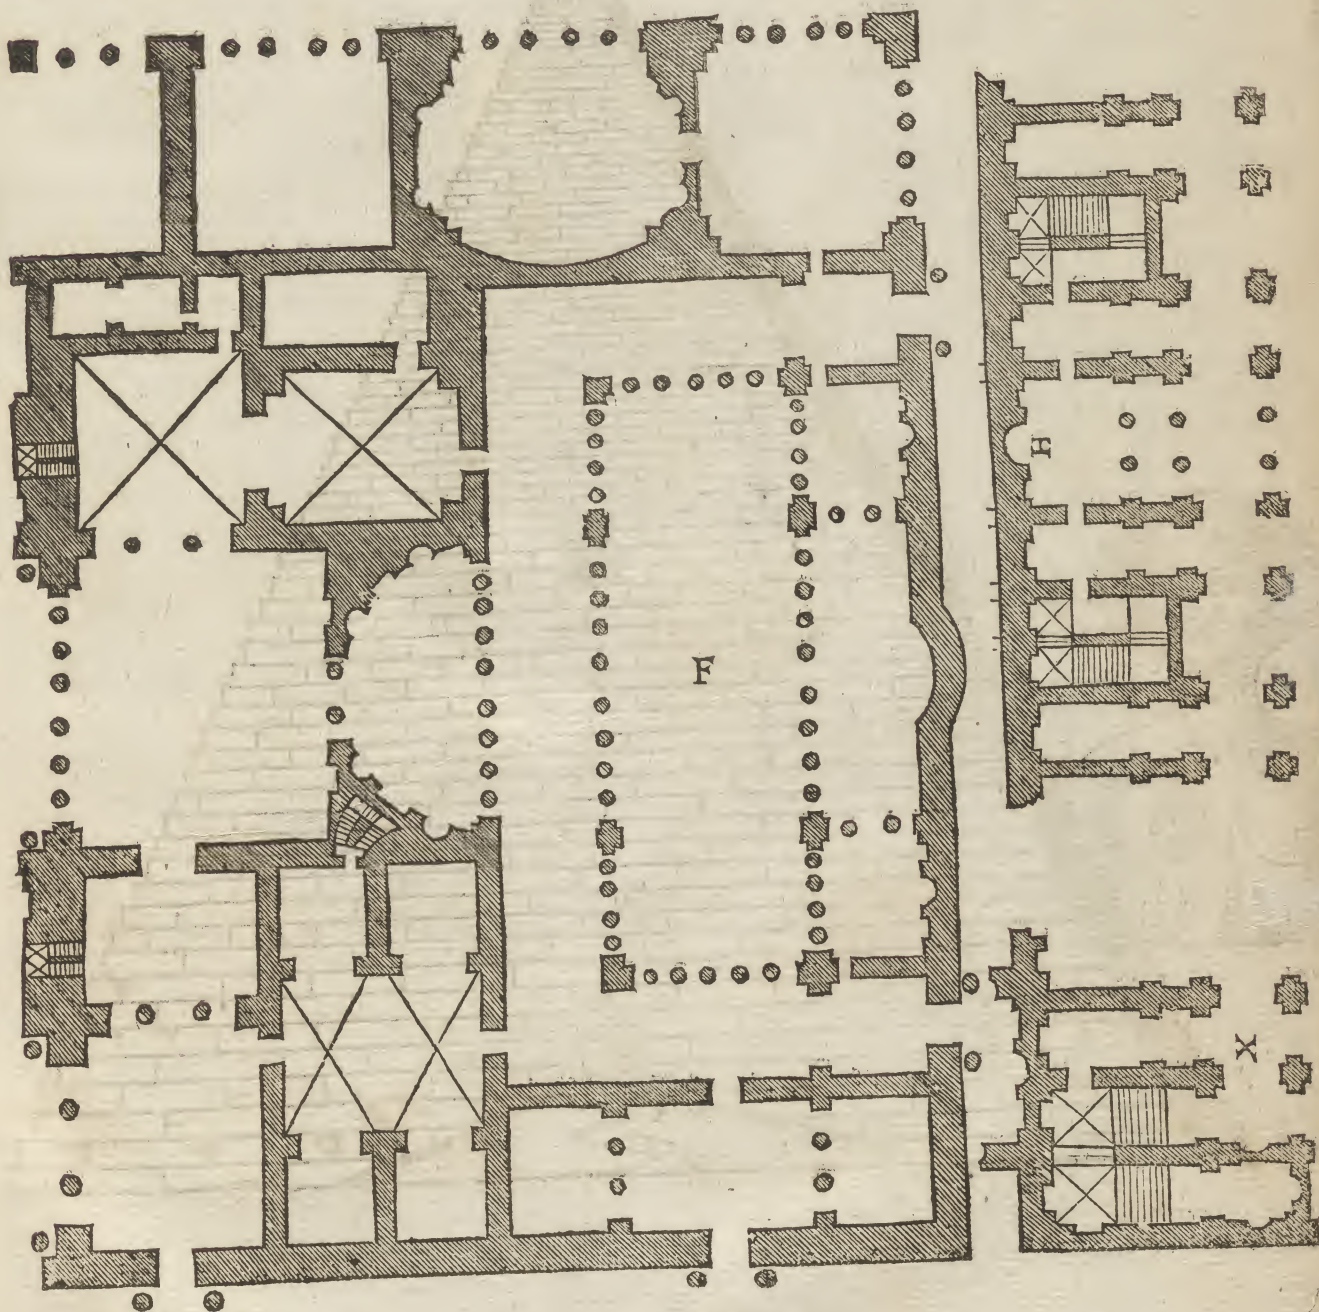

This Temple is without Rome, made part of Marble, and the rest of Brick, it is much decayed, it is thought that it was a Sepulchre, and on all sides it is right foure square; frō the one Wall to the other is 30. Palmes broad, the thickness of the walles is 2. Palmes and a halfe, the wideness of the Chappel is ten Palmes, the Dore is five Palmes broad, the height of the Pillars with Bases and Capitals is 22. Palmes and a halfe; the thickness of the Pillars is not much above two Palmes: The Archtraue, Frise & Cornice are 4. Palmes high, from the Cornice to the height of the rooffe is 11. Palmes: the height of the Volves of the Chappel is 20. Palmes.

Although these Figures stand thus without order, and in many pieces, yet the wise workeman shall know, that they are members of the Thermes afoze shew'd, beholding the letters which stand in them (which comparing with the others) he shall find what parts they are. Also, he must know, that the parts H. and X. belong not to the part F. so; the Figures hereunder are three severall parts; although, for necessitie sake, they are set one by another. I have also not set downe the particular measures: for the workeman shall better helpe himselfe with the invention, then with the measure.

Of Antiquitie

A Bout seven miles from Alcaire there is a Piramides, whereof I will shew the forme, and also set downe the measure, as I had it from a Gentleman of Venice, who measured the same himselfe, and was both vpon it, and within it. This Piramides was measured by Paces, and euery Pace is more then thre ancient Palmes: the Base, on euery side, is 270. Paces, and is right foure square: it is all of hard stone, and you may cline vpon it without, (but not easily) but set his foot vpon them: the number of the Paces or steps, from the Base to the top, or the highest part, is 210. and they are all of one height; so that the height of the whole Piramides is as much as the Base. Many belæue that this Piramides was a Sepulchre: for that within it, there is a place in the middle, whereon lyeth a great stone: thereupon men presume, that some great person hath there bene buried: but going in, vpon the left hand, you find a going by of stone, which turnes about the Piramides within, through the which you goe by the Station, in the top within. About the middle of this Piramides there is another going in, but it is fast shut: on the top of this Piramides, there is a faire flat or playne, about 8. Paces broad on euery side, whereby workemen know, that it was the same playne that was made at the finishing of the Piramides. Not farre from thence, there is a head of hard stone, with part of the breast all of one stone; the face whereof is 10. Paces long: and in this Figure there are some Egyptian letters: of this Piramides and head, Peter Martir writeth, and hath also saine and measured them, which differ not much.

The Therme made by Dioclesian, was used for diuers common and open sports, and specially to bathe in; where-
 into it becometh to haue great quantitie of water, which was brought by Pipes a great way off; and it was kept in
 certaine Cisternes, which stood in the Thermes of Dioclesian, in this manner as is hereunder set downe: it was
 made with Pillars, and aboue it was crosse rofed, with walles about them, of very good stufte; which was so
 firme, that at this day it is yet to be seene: the thickenesse of the Pillars is of each side foure foote: betwene each two
 Pillars is 12. foote of the old Romane foot, although the sayd Therme is measured with Palmes: and this line hereun-
 der is halfe an olde foote.

The halfe ancient foot.

Of Antiquitie

In Rome there are many ancient Triumphall Arches, among the which, this Building, by the greatest number, is accounted for a Triumphall Arch: yet by the knowledge that men have of it, it is thought to be a Porticus, or a Gallery, like unto a Warre or Exchange for Marchants: it may be it was made by some one nation alone; as yet to this day in great Townes and Cities, every nation hath a severall place, although they are not by that means divided. This Porticus or Gallery stood in Nel foro Boario, and in ancient time was called, The Temple of Janus: which is measured with the ancient Palme. This Building hath foure gates, as the ground hereunder dooth shew: betwaine the one and the other Pillasse, there are 22. Palmes: round about this Porticus, there are 48. niches or hollow places: but there are no more then 16. to set Images therein; all the rest are but for shewes, as being not deepe enough cut into the wall: which places were beautified with small Pillars somewhat bearing out from the wall, as you see them, and were Corinthia worke, but now it is spoiled of all such ornaments.

The ground of the figure following.

The height of the Arch is 44. Palmes : the height of the Bales beneath, marked E. is 1. Palme and an halfe. The Facie D. within the corners, is turned into a Cornice, and is the like height. The iudgement of the workman pleased me well in y^e piece, which is, that he made no Cornice in the innermost part, that might frowble the people that should be therein : the height of the other Cornices are not measured, but the formes of them diligently counterfozted, followe hereafter.

Of Antiquitie

The five pieces of Cornices hereunder set downe, are the ornaments of the Porticus aforesayd. The Base E. and the Facie D. were measured, and in this forme, the great measure set downe; but the other were counterfeited by sight, with their heights where they stand: and there is little difference betwene the one and the other, for parts, and also in height. The Figure C. is the Facie vnder the first Piche or hollow place.

The Arch Triumpht, next following, is called Titus Arch Triumpht; whereof this Figure hereunder, is the ground, and is measured with the ancient foote. The wideness of the Arch is 18. foote and 17. minutes. The thickness of the Colonne, is a foote and 26. minutes and an halfe. The foote wherewith this is measured, is of 64. minutes, whereof the halfe is here set downe.

I have spoken of the widenesse and thicknesse, now I will set downe the height: And first, the height of the Bow or Arch is as much againe as the breadth. The Base of the Pedestall is 2. foote 4. minutes lesse in height. The Cornice of the Pedestall is 3 5. minutes high. The height of the Bases of the Columnes is about one foote: all these parts, and also the Capitall of the Colunne, well proportioned in measure, stand in the beginning of the Composita Order, in my fourth Booke. The flat of the Pedestall is foure foote and a halfe high. The height of the Colunne without Base and Capitall 17. foote and 13 minutes. The height of the Capitall is 1. foote and 27. minutes. The height of the Archtraue is one foote and 19. minutes. The Fræse is one foote and 17. minutes. The Cornice is 2. foote and 6. minutes high. The Basement of the Epitaph is of the same with the Fræse. The height of the Epitaph is 9. foote and 12. minutes: the breadth is 23. foote: which members shall hereafter be set downe, and figured more at large.

Of Antiquitie

It would be troublesome both to the writer and to the Reader, if I should set downe all the parts of these Ornaments, from member to member, as they are diligently measured; & that not onely with foote, but also with parts of minutes; but I have taken the paynes onely to set the same downe out of the great into the small forme, in such sort, that he that is discrete, may with his Compasse find the proportion thereof. It is true, that the Ornaments of the most part of the Triumphant Arches in Rome are much contrary to Virruvius writing; and this, I thinke, is the cause, that the sayd Arches are, so; the most part, made by the Roofes of other buildings, (that is, of as many sorts of peeces as they could get:) and it may be, that the workemen in those dayes were selfe willed, and stood not much vpon obseruation, because they were things seruing for Triumphs, and it may bee (as it hapneth oftentimes) made in haste. That part here on the side set downe, marked A. is the Base of the Epitaph. B. is the highest Coznice, fræse, and Architraue: which Coznice, in my opinion, is very licentious for diuers reasons: The first, it is proportioned too high: from the nother Architraue, and aboue it, there are too many members, and especially Dentiles and Dentiles, which standing alike in one Coznice, are disliked by Virruvius, notwithstanding it is very well wrought, and specially the Scima aboue: but had I such a Coznice to make (observing the right order) I would make the Scima lesse, and the Coznice moze: I would leaue the Dentiles as they be, and I would not cut the Denticales, but the Cimæd. The Architraue her: of pleaseth mee well inough. The two members marked C. shew the Facie and the Profil of the Dentils, which is the closing stone of the Arch. The members marked with E. are, in truth, rich for worke, but yet so rich, that the one darkeneth the other: but if the parts were so denided, that the one were grauen, and the other plain, I would commend it moze. And herein the workeman that made the Pantheon, was very iudicious, for that you see no such confusion in his Ornaments. The worke vnder this Arch is very well made and denided; it is also a fayre Compartment, and rich of worke. But it may be, that such as are too much conceited to commend Antiquities of Rome, will (peradventure) thinke that I am too bold to censure vpon that which hath bene made by such skilfull ancient Romans; but in this respect I would haue them take my speeches in good part, for that all my intent is, to shew it them that know it not, and such as will subiect themselves to heare my opinion: for it is not sufficient to make ancient things as they stand, but it is another thing with Virruvius aduice to chuse out the best and fayrest, and to reiect the worst. It is true, that the chiefest part of an Architector is, that hee mistake th: not himselfe in giuing his censure, as many doe, who being obstinate in their opinions, make all things as they haue sene them, and hereby couer their unskilfulness, without giuing any other reasons of things: and there are some that say, Virruvius was but a man, and that they also are men sufficient, to make and inuent new things, without regarding, that Virruvius confesse th: to haue learned it from so many skilfull men, partly in his owne time, as also by meanes of the writing of other work men.

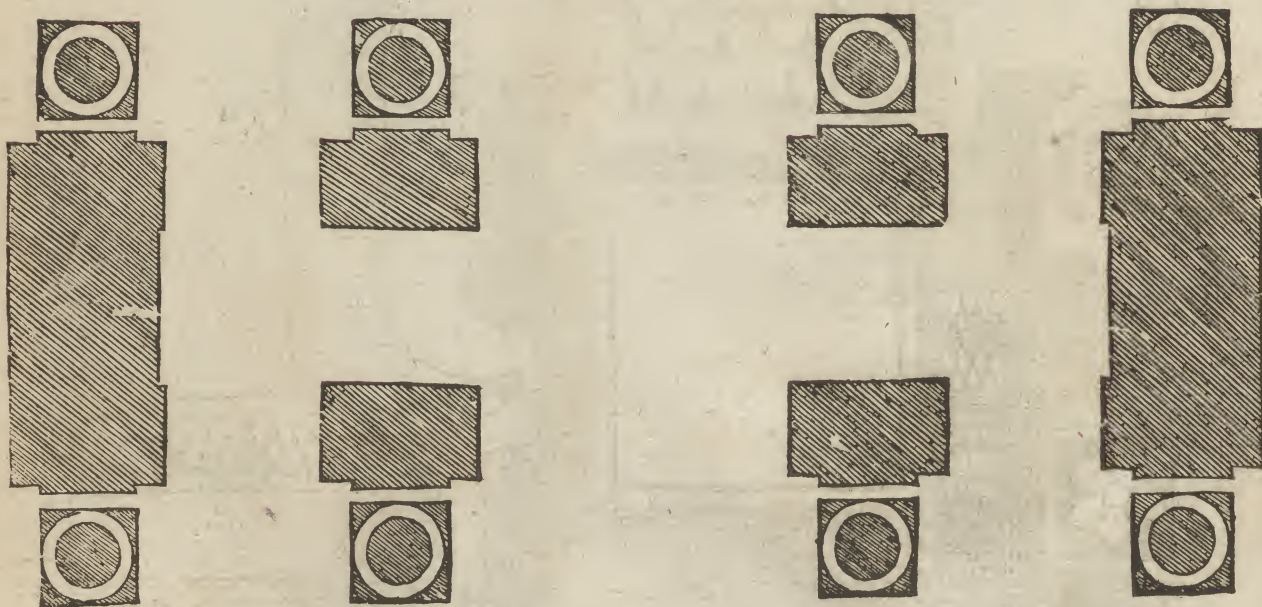

Of Antiquitie

Beneath the Campidoglio there is a Tryumphant Arch, which by the inscription may be conceiued to be made in the time of Lucius Seprimus Seuerus, and vnder his name, and by that which men marke and sufficiently find, it is made with Ropes of other buildings: it is also well adozned with good cutting and graving: it is richly wrought both on the sides, and also befoze and behind: it was measured by the old Romane Palme of 12. fingers, every finger of 4. minutes, which in totall maketh 48. minutes. The wideneſſe of the Arch in the middle is 22. Palmes, 15. minutes and a halfe. The widenes of the Arches on the sides is 9. Palmes, 30. minutes. The thickeſſe of the Arch in the sides is 23. Palmes, 25. minutes. The little Gates within the Arches are 7. Palmes and 30. minutes wide. The breadth of the Pilasters with the Columnes is 8. Palmes and 7. minutes. The thickeſſe of the Columnes is 2. Palmes, 30. minutes. The thickeſſe of the flat Columnes is 28. minutes. This Arch is now vnder the earth as farre as about the Pedestall, (so: so high the earth is there rapted with the ruines) but there was a part left vncovered to measure it, but they could not come to the Base to take the measure thereof, because it was troublesome to remove the ruines.

The ground of the Arch Tryumphant of Lucius Seprimus.

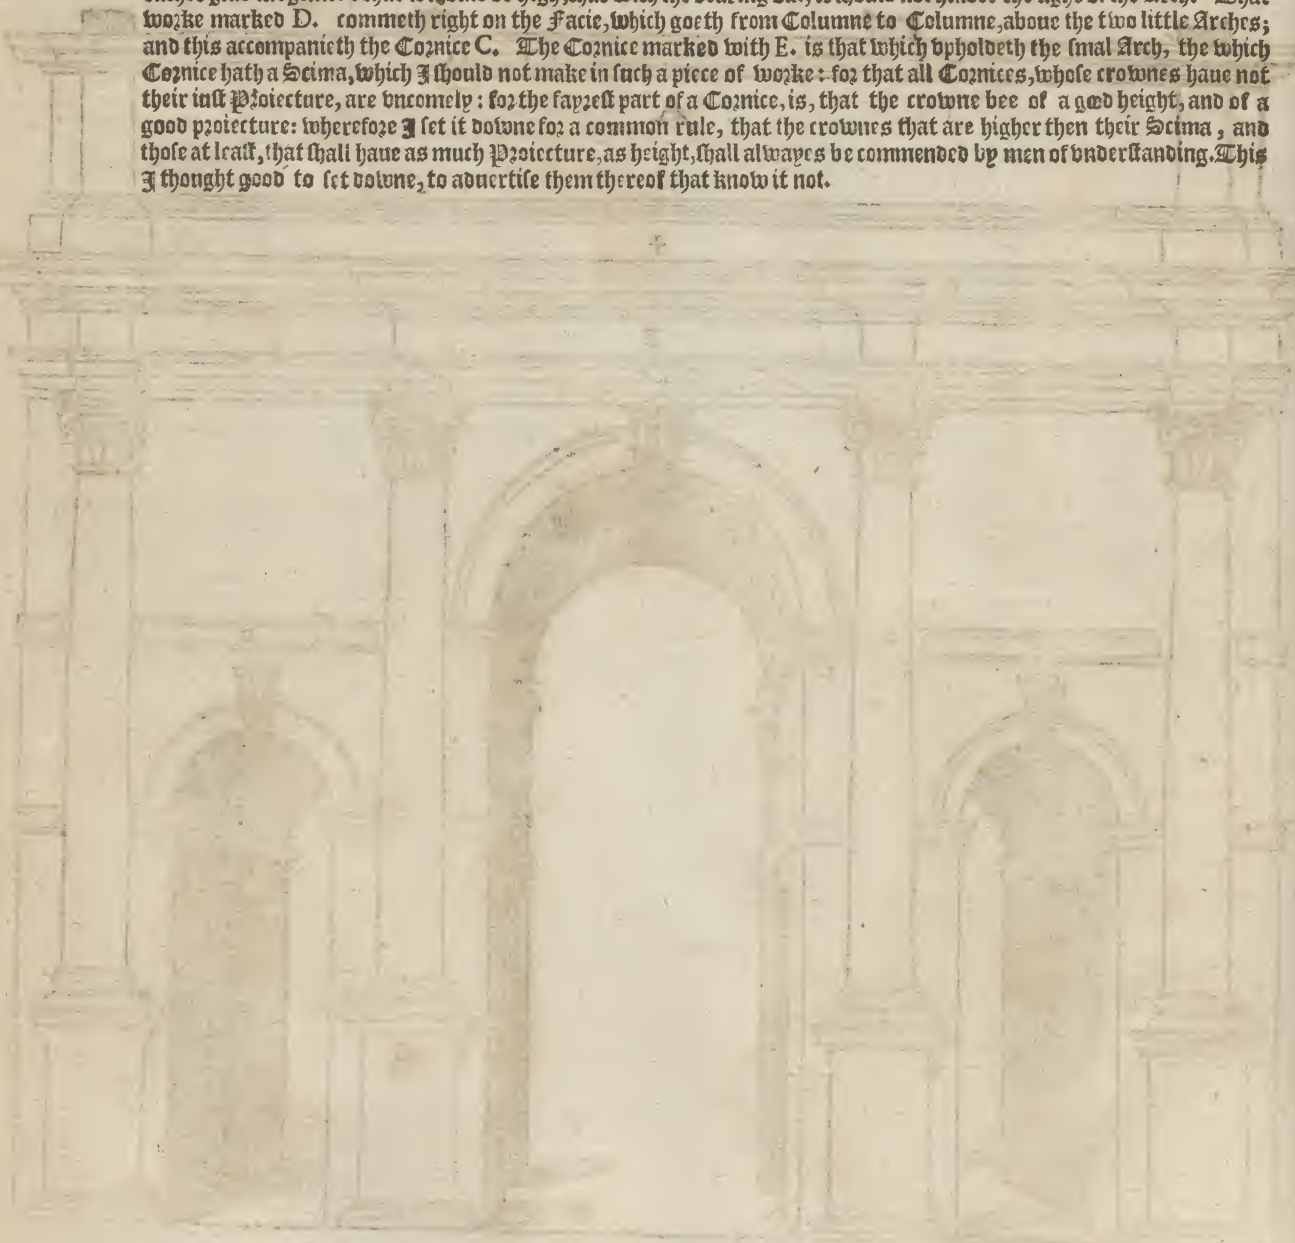

Before, I have set downe all the measures of this Arch, touching the Ichnographie, that is, the thickness and breadth, now I will speake of the height. The height of the middlemost Arch, is 45. Palmes and 3. minutes. The height of the Arches besides, are 25. Palmes. The height of the Pedestall, is about 10. Palmes: The thickness of the Columns is 2. Palmes and 30. minutes in Diameter beneath: but above vnder the Capitall, they are 2. Palmes and 16. minutes. The height of them, is 23. Palmes and 25. minutes. The height of the Architrave, is one Palme and 30. minutes. The height of the Fræse, is one Palme, and 3. minutes. The height of the Cornice, is two Palmes and 14. minutes. The height of the Plinthus, above the Cornice, marked **F**. is 23. minutes. The Base about the Plinthus, is halfea Palme. The vppermost Cornice, is one Palme and 2. minutes, and proportioned in a greater sorte.

 PONTIF. MAX. TRIBVNIC. POTEST. XI. IMP. XI. COS. 3. PRO.
 COS. ET. IMP. CAES. M. AVRELIO. L. FIL. ANTONINO. AVG.
 PIO FELICI TRIBVNIC. POTEST. VI. COS. PROCOS. P. P.
 OPTIMIS, FORTISSIMISQVE PRINCIPIBVS
 OB REMPVBLICAM RESTITVTAM IMPERIQ. POPVLI ROMANI PRO.
 PAGATVM INSIGNIBVS VIRTVTIBVS EORVM DOMI FORISQ. S. P. Q. R.

In the side before, I haue set downe all the heights and breadths of the Arch Triumphant, of Lucius Septimus Severus: now I will shew the particular, and leuerall parts thereof, as I said before. There is no measure of the Base of the Pedestals, but it may be thought, that they containe as much at the least, as the Coznice of the Pedestals: which Coznice is a Palme, and so much the Base may hold: of which part, the forme standeth heere in the middle, marked G. The Base of the Colunne standeth thereby marked F. the which Base hath a stone or counter-Base vnder the Plinthis: and this may peradventure be done, because the Colunnes could not reach to such a height as they should. The Capital is here not set downe, because you shall see the like in the beginning of the Order, called Composita, in my fourth Booke, for this is Composita worke. The height of the Architrave, is one Palme and 30. minutes: the Frase is 9. Palmes and 3. minutes: which Frase, for that it is full of graving, theweth of a small height where it standeth: and by Vitruuius writing, it ought to stand the fourth part higher then the Architrave; and this is lesse. The height of the Coznice, is two Palmes and 14. minutes: which in truth is much too high, according to the proportions of the other members; and it theweth so much the greater, because it hath more proiecture of height: and this makes me specially believe, that this Arch is made of diuers pieces of other buildings, because of the shrinking of the members. The forme of the Architrave, Frase and Coznice, is marked with B. The height of the Base, above the said Coznice, is halfe a Palme: the height of the last Coznice, is a Palme and two minutes, and hath such a great proiecture, and hanging over, as you see in the Figure: and in such place, I blame not the Coznice; but affirme that it was made with great iudgement: for that the great proiecture makes the Coznice thew greater, because it is seene from vnder upwards, and for that there is like matter, it is not in vaine for the building. This Coznice here is marked with A. The Coznice which beareth by the greatest Arch, is marked with C. whereof the Proiecture is much too great: and for my part, in such a subiect, I would rather giue iudgement that it should be high, that with the bearing out, it should not hinder the sight of the Arch. That worke marked D. commeth right on the Facie, which goeth from Colunne to Colunne, about the two little Arches; and this accompanieth the Coznice C. The Coznice marked with E. is that which vpholdeth the smal Arch, the which Coznice hath a Scima, which I should not make in such a piece of worke: for that all Cozniccs, whose crownes haue not their iust Proiecture, are vncomely: for the fayrest part of a Coznice, is, that the crowne bee of a good height, and of a good proiecture: wherefoze I set it downe for a common rule, that the crownes that are higher then their Scima, and those at least, that shall haue as much Proiecture, as height, shall alwayes be commended by men of vnderstanding. This I thought good to set downe, to aduertise them thereof that know it not.

Of Antiquitie

In the kingdome of Naples, viz. betwaine Rome and Naples there are many Antiquities, for that the Romanes had great pleasure in those places: among the which, this Triumphant Arch is sene, being yet all whole and sayre to sight: and therefore I thought it good to set it among the number of the rest of the Arches (which were made by the Romanes.) This Arch is at Beneuente, on this side of Naples, and was measured with a moderne Ell, whereof the third part is hereunder set downe. The Figure here below, is the zchnographie of the same Arch; and to the w by whom this Arch was made, is needlesse, because it may be vnderstood by the writing that standeth thereon. The wideness of the Arch, is eight Elles: the thickeesse of the Columnes is an Ell: the Pilaster vnder the Arch, is also as broad: the inter-columne holds thre Elles: the height of the Arch, is almost as much againe as the breadth: the height of the Base of the Pedestall, with the vnder-Base, is one Ell, ten ounces and sixe minutes: the flat of the Pedestall, is two Elles, ten ounces and five minutes: the height of his Cornice, is nine ounces: the height of the Bases of the Columnes, is seuen ounces: the height of the Columnes, without Bases or Capitals, is nine Elles and foure ounces. The thickeesse of the Columnes beneath, is an Ell in Diameter, and aboue is lessened a sixt part: the height of the Capitall, is an Ell, five ounces and an halfe: the height of the Architraue, is 15. ounces: the Frise is seuentene ounces high: the height of the Cornice, is one Ell, thre ounces and an halfe: the Plinthus, which standeth as counter-Base about the Cornice, is 19. ounces and a quarter high: the Base standing vpon it, is 11. ounces high: the height of the Epitaph, is foure Elles and two ounces: the height of the outtermost Cornice, is one Ell and thre minutes: the height of the impost of the Arch, is halfe an Ell.

This Ell wherewith the Arch is measured, is deuised into 12. ounces, and each ounce into 5. minutes, which comes from 12. ounces to 60. minutes: and this is the third part of the sayd Ell.

Of Antiquitie

The Ornaments of the Arch of Beneuaten, which I haue shewne in the lease before, are here, according to the measure set downe, with the Originall. The Base of the Pedestall, and the Cornice thereof, marked F. are, in truth, two peeces of good proportion, and saye peeces for Cornicements. The Base of the Pedestall, together with the Counterbase vnder it, is one Ell, 10. Dunces and 6. minutes high: the Cornice of the sayd Pedestall is 9. Dunces high: the Base of the Colonne is 7. Dunces high, and is of Corinthia worke, very well proportioned according to the Colonne, and standeth here marked with E. I haue not set the Capital here: for that men (as I sayd before) shall find such a one in the beginning of the Composita, in my fourth Booke, because this Arch is Composita worke. The Arch, Frase, and Cornice, which stand about this Colonne, are here marked with C. which peeces are also well proportioned on the remnant of this building: and although that the Cornice is somewhat higher then Vitruuius would haue it, neuertheless it is well proportioned of members, and the same flat is not in it that is found in other Cornices, which haue the Putiles and the Dentiles standing together: but this workeman, being circumspect therein, would not cut the tatch in the Dentiles, although he hath set the soyme thereof in the Cornice, to runne such a slaunder. The same consideration the workeman that made the Pantheon had, in the first Cornice about the Chappels, round about the Temple within: and therefore I counsell a workeman, to auoyde such a scandall, and not to repose himselfe vpon the doing of licencious and wilfull workemen, and excuse themselves, saying, Ancient workemen made it, and therefore I may make it as well as they. And although some will argue and say, Why, so many workemen, and in so many places of the world, (not onely in Italy) but also in diuers other places, haue made Cornices, with Putiles, and ingrauen Dentiles, and that such a custome is now turned into a Law, yet I would not obserue the same in my worke, nor counsell others therevnto. The Counterbase, vnder the Epitaph, about the Cornice, marked B. is 19. Dunces and a halfe high: the height of the Base thereupon is 11. Dunces: the height of the Epitaph is 4. Elles 4. Dunces: the height of the Cornice is one Ell and 3. Dunces. I much commend the Base of this Epitaph. I commend the Base of this Epitaph, with so little proiecture, for the seeing by vnder it, but the Cornice whereof I will speake, is much too high, according to the proportion of the Epitaph: but were it of lesse height, and the Crowne more, and of more proiecture, I iudge, it would stand better, and I would commend it more: also, if there were not so much caruing or grauing in it: for the members ought so to be deuised, that the one were playne, and the other grauen. But there are many workemen, and most at this day, that, to make men take pleasure in their bad workmanship, make so many cuttings in it, that thereby they confound workmanship, and take away the beauty of soyme from it: and if euer, in times past, that tall and single things, breut, were by skilfull workemen commended, at this time they are not so. This Figure, marked D. is the Impost of the Arch, and is well knowne for such a member; the same Cornice changeth it selfe in a Facie, which goeth round, as you see, and is halfe an Ell high: and although this Impost of the Arch sheweth no Sculpture, yet is it grauen where it standeth; but I forgot to draw it so.

Of Antiquitie

By the Amphitheater of Rome, which by the people is called Coliseo, there standeth a very faire Triumphant Arch, which is wonderfull rich of Ornaments, Images, and diuers Histories, it was dedicated to Constantine, and is vsually called, Larco de Trafill. This sayre Arch, although it is now buried a great part within the earth, by meanes of the ruines, and rising of the earth, is neuerthelesse of great height, and the Gates and passages through it, are yet higher then two squire squares. This Arch (as is befoze sayd) is passing sayre to the eye, and wonderfull rich of Ornaments & graving. It is very true, that the Cornices are not of the best maner, although they be exceeding richly graven, whereof I will speake hereafter. This ground hereunder, sheweth the Technography of the sayd Arch Triumphant, and was measured with the old Romish Palme: the breadth of the greatest Arch is 22. Palmes and 24. minutes: the widenesse of the lesser Arches on the sides is 11. Palmes, 11. minutes and a halfe. The thicknesse of the Pilasters are 9. Palmes and 4. minutes: the thicknesse of the Arches in the sides, is 21. Palmes and a halfe: thus the place within the Arch is almost squire square: the thicknesse of the Pedestals is 3. Palmes and 29. minutes: the thicknesse of the Columns is 2. Palmes and 26. minutes; which Columns are Aricked or hollowed, by some called chanelled, and are whole round with their Pillars behind them.

The ground of the Arch Triumphant of the Emperour Constantius.

The wideneſſe and thickneſſe of this Arch, is ſufficiently ſet downe; now I will ſpeake of the height thereof: and firſt, the Baſe of the Pedekfall, with the Plinto, is one Palme and 30. minutes high. The height of the ſat, is 7. Palms and 5. minutes: the height of the Cornices of the Pedekfalls, is 42. minutes: the height of the counter-Baſe, vnder the Baſe, or the Plintus of the Colonne, is fiftie and two minutes: the height of the Baſe is 60. minutes: the height of the body of the Colonne, without Baſe or Capitall, is 26. Palms and 25. minutes: the height of the Capitall, is 2. Palms and 35. minutes, and is Compoſite. The height of the Architraue, is one Palme and 11. minutes. but the Fraeſe is much leſſe, and yet grauen; which, as I haue ſayd, at other times is contrary to the doctrine of Vitruuius. The height of the Cornice is a Palme and 21. minutes. The height of the counter-baſe, vnder the ſecond ſtoop, is 3. Palms and 9. minutes: from thence to the higheſt part of the Cornices, is 21. Palms: but the height of that Cornice is 33. minutes. The Pedekfalls about the ſame Cornices were not meaſured, and thereon ſtood Images, and about the Cornices marked B. were Images placed againſt the 4. Pillasters, which repreſented the priſoners with whom hee went in triumph. The letters which ſtand here, are about the Arch, in the place marked A. beſides many others, which ſtand in diuers places of the Arch.

IMP. CAES. FL. CONSTANTINO MAX. P. F. AVGVSTO. S. P. Q. R.
 QVOD INSTINCTV DIVINITATIS MENTIS MAGNITVDINE, CVM EXERCITV SVO TAM DE TYRANNO, QVAM DE OMNI EIVS FACTIONE, VNO TEMPORE IVSTIS REMPUBLICAM VLTVS EST ARMIS, ARCV M TRIUMPHIS INSIGNEM DICA VIT.

Of Antiquitie

I have spoken of the proportion of the measures of the Triumpht Arch of the Emperour Constantine: now I will speake of the severall parts and Cornicements, and set their measures downe. And first, the Base marked F. is of the Pedestall of the said Arch: the height whereof, is a Palme and 30. minutes. The height of the Plinthus vnder the Base is 28. minutes: the rest of the parts are measurably divided, and proportioned accordingly. The height of the Cornices of the Pedestall, which stand marked vnder the Base E. is 42. minutes, and is also proportioned according to the principall. The counter-Base, vnder the Base of the Columnes (which I thinke were placed there accidentally) to heighten the Columnes, is 32. minutes high: the whole height of this Base of the Columnes, is 53. minutes: touching the height of the Columnes, I spake before, and also of the Capitals, of which Capitals, the forme standeth not here, for that the like doth stand in my fourth Booke, of the Order of Composita: the height of the Architraues, Frazes and Cornices, is also spoken of before: and this Cornice is very seemely, for that there is no licentiousnesse in it, which is in some other Bases of this Arch; as it is in the impost of the middlemost Arch, marked C. the which impost is greater and of more members and parts, then the great and principall Cornice, and is altogether confosed in members, and that which is most intolerable, the Dentiles and Mutiles are one about the other: and although the Dentiles were not there, yet there needed not such a Cornice to beare by an Arch. Herein the workeman of the Theater of Marcellus was more circumspect then this: for the imposts of the Arches of the said Theater, are the sayest and best of shew for imposts that ever I saw, and such, as from the which a man may learne to make the like. The impost of the lesser Arches marked D. is one Palme and 23. minutes and an halfe high: the which impost would stand much better, if the two flats betwene the Astragal above, and the Echine vnder, were turned into plainnesse only; which then would serue for an Abacus, or also for a crowne, having the due Proiecture. The Base vnder the second story marked A. is 16. minutes high: the height of the vppermost Cornice, is 43. minutes, which height should bee too little in so great a distance, if it were not that the great Proiecture or Gallery, or ouerhanging holpe it not; because they are seeing upwards, from vnderneath, which sheweth it to be much greater then it is: therefore I much commend this Cornice in this respect. And truly, all the Cornices, whereof the crowne hath more proiecture then height, answere alwayes better, and may be made thinner of stone, so that the members of the building endure lesse weight: neuertheless, you must not make them of too many licentious proiectures: but you shall read hereof in Vitruuius, where he entreateth of the Order of crownes, after the maner of Ionica and Dorica: for he doeth there teach you clearely inough.

This Figure should stand in Folio 52. and the figure in Folio 52. should stand in this place.

Of Antiquitie

Without Ancouen upon the haire, there is an head which reacheth it selfe a good way into the Sea, which was not made without great cost and charges: it was to defend the ships from the Levant sea. Upon the end of the height thereof, standeth an Arch triumphant, all of Marble and Corinthia wooke; and there is nothing in it but the Capitalls, which are done in very good wooke: and in truth, this building is so handsome, and of so good correspondencie, the members also agreeing with the whole body, that a man, although he vnderstand no Art, would neverthelesse take pleasure in the beautie thereof. And those that vnderstand somewhat, seeing such congruities, are not onely well contented, but also thanke the good workeman, that hath given vs somewhat in these dayes to learne out of this faire and well made building: in the ornaments whereof, there is the order of Corinthia as well obserued and kept, as in any other Arch that is to be found, and by reason of the strength thereof, it is all whole; onely it is vnfurnished of many ornaments. This faire Arch, as it is conceyued, Nerua Traianus caused to be builded: whereupon, in the highest part of the Arch (as it is sayd) his Image was erected, sitting on horse backe, seeming to threaten the clouds and people, ouer whom he looked and gouerned, lest they should rebell againe: which Image was of Copper excellently well made. There were also betwaine the Columnes, about the Cornices, certayne Images of Copper, as the letters in those places written, doe shew: there are also tokens of holes, which shewes that there were Kings of Copper, or other such like things hanging in them, which might bee taken from the Cottes, Vandals, or other enemies. This building was measured by the ancient foote, the ground is hereof standeth hereunder. The widenesse of the Arch is ten foote: the thickenesse inwards is nine foote and two minutes: the thickenesse of the Columnes is two foote, 11. minutes: the Intercolumnnes, or spaces betwaine the Columnes, is 7. foote, 5. minutes: the Columnes stand without the wall, 1. foote and 11. minutes: the height of the Arch is 25. foot and 1. third part: and this height; although it holdeth moze then two square, is not therefore misshapen, when you behold the whole masse together: the height of the Pedestals with all their Cornices, is 5. foote: the breadth is three foote, 15. minutes and a halfe: the height of the Bases of the Columnes, together with the Underbases, are 1. foote and 36. minutes: the height of the Columnes to the Capitalls, is 19. foote, 22. minutes and a halfe: the thickenesse vnder the Capitall, is one foote and 56. minutes: the height of the Capitall is 2. foote, 24. minutes, with the Abacus; and the Abacus is 10. minutes: the sayd Capitall you shall find in my fourth Booke, in the beginning of the order of Corinthia: the height of the Architrane is one foote and 12. minutes: the height of the Frieze is one foote and 18. minutes: the height of the Cornice is 1. foote and 22. minutes: the height of the Plinthis above the Cornice, is one foote, 6. minutes and a halfe: the height of the Base above the sayd Plinthis, is 30. minutes: the height of the Epitaph vnder the Cornice, is 6. foote and 22. minutes; but the Cornice above it was not measured.

The halfe of the old Romish foote.

Of Antiquitie

In my opinion, I haue sayd enough of the measure of the Arch of Ancona, yet that the parts of the Cornices may be the better vnderstood, I will shew them here greater: and first, I will set downe the lowest parts, as they stand above the ground of the worke. The height of the Pedestall, marked G. is sayd to be of 5. foot, with all the Cornices thereof: but the height of the Plinthus of the Base, is 18. minutes: the Base about the Plinthus, is 19. minutes, and a third part high: the Cornice of the Pedestall, is 20. minutes, and a third part high; so much doeth the stone also hold, standing thereby, marked F. which, by my aduice, is placed there, to heighten the Columnes, and sheweth not badly, but moze, because it is set forth with a list round about it; whereby the Base differeth from the Plinthus: and so, in my opinion, standeth well. The Base, which is Corinthia, together with the Cincte of the Colonne, is 43. minutes high: and the Proiecture, is 16. minutes and an halfe in breadth: the thickest of the Pedestall, is 3. foote, 15. minutes and an halfe: the thickest of the Colonne, is 2. foote, 11. minutes: and there stand 13. hollowings, or chanelles, without the Pilaster: the wideresse of one chanel, is 7. minutes and a halfe: and the List which parteth them, is 2. minutes and a halfe. The height of the Capitals are the thickest of the Columnes below, without the Abacus: which Capitall hath a very sayze forme, whereby we may be perswaded and belceue, that Virruuius doctrine is false, and that Virruuius vnderstood the height of the Capitall without Abacus: (and soz this cause) soz that the most part of the Capitals that I haue seene and measured, are most of such height, and higher, and specially the Capitals that stand in the Rotund: whereof, in the beginning of this Booke you may see one. The height of the Architraue above the Colonne, is one foote and twelue minutes. The height of the Fræse, is one foote and eyghtene minutes. The height of the Cornice, is one foote and two and twenty minutes. These thre are marked together with an A. The Plinthus about the Cornice is one foote, six minutes and an halfe high: The Base vpon it, is thirte minutes: the space wherein the letters are wrytten, is six foote and two and twenty minutes, and is marked with X. The Impost of the Arch is marked D. the height whereof is 1. foote and sixtene minutes: but the vppermost Cornice, as I haue sayd, was not measured. The height of the Mensole in place of the closing stone, marked B. about the Arch, is thre foot and 30. minutes: and hath a foote and 14. minutes without the wall, in the vppermost part; and in the parts below, it comes out a foot. The foure tables with the Cornices vpon them, which stand betwene the Columnes, are thought to be placed there, soz holding vp of halfe Images: the forme whereof, standeth here marked E. and is there also by the Profill on the side, where by a man may see how they are wrought: soz they are full of worke, euen to the Center. The height of the Cornices, standing about them, is 32. minutes: and although I haue not shewed all the Proiectures & heights from part to part, yet I haue with great diligence reduced them from the great, into a small forme, and were (as I sayd befoze of the rest) measured with the old Romane foot.

Of Antiquitie

The Colone of Pola in Dalmatia, is adorned with many Antiquities: besides the Theater & Amphitheater, whereof I spake before, there are other Buildings, whereof now I will speake. There is an Arch Triumphant, of Corinthia worke, rich of ornaments, for Figures, works, and Strange devices; so that from the Pedestall upwards, there is no worke nor space left engraven, not onely before, but also on the sides, and within, and under the Arch, wherein are many and diuers works, so that it would require long time to declare them particularly: therefore I will shew such parts thereof as are necessary for a workeman, for inuention and Arte. The ground of the Arch following standeth hereunder, measured with a Moderne or common foote, whereof the halfe is here set downe. The Arch is 12. foot and a halfe wide: the height is about 21. foot. The Pilasters in the sides inward are 4. foot thicke. The thickness of a Colonne is one foote, 9. ounces and a halfe. The Intercolonne is 2. foot, 3. ounces and a halfe. The Pilaster of the Arch is one foot, 2. ounces broad. The height of the Plinthus under the Base of the Pedestall, is one foote. The Base is 4. ounces high. The flat of the Pedestall is 3. foot: the Cornice 4. ounces. The Plinthus marked D. vnder the Colonne is 4. ounces. The height of the Base with the Plinthus is 10. ounces and one quarter. The height of the Colonne is 16. foote, one ounce and 3. quarters. The height of the Capitall is 2. foot and one ounce. The height of the Architrave is one foote and one ounce. The height of the Frase is one foote and 3. ounces. The height of the Cornice is one foote and 10. ounces. The height of the Plinthus above the Cornice is one foote and 2. ounces. The height of the Base of the Pedestall, and also of the Plinthus vpon it, is one foote and 2. ounces: but the height of the Base alone is 10. ounces. The height of the flat of the Pedestall is 2. foote and one ounce. The Cornice is 6. ounces. The Cauec above the Cornice, (which Vitruuius, as I thinke, calleth Corona lisa) is 5. ounces: and this is the measure of the ground following.

The halfe common foote.

This is the ground of the Arch triumphant of Pola:

The measure of this present Arch is set downe befoze: in this side following, the particular parts shall bee shewed.

These great letters hereunder, stand in the Frise, marked Y.

Of Antiquitie

In the side before, I have spoken of the vniuersall measure of the Arch triumphant of Pola, and have also shewed the Figure thereof, and partly set downe some of the richest and fairest ornaments of the same: Now I will set downe the particular measures of the parts thereof: and first, I will begin with the nether parts, as that was placed first above the ground. The height of the Plinthus vnder the Base of the Pedestall, is one foot; although that vnder it there lieth another of much more height, but it is vnder the earth: the height of the Cimatic turned about about it, with the Afragalus, is 4. ounces: the flat of the Pedestall, is 3. foot high: the Cimatic about it, is 4. ounces, & so much also is the vnder-Base, about the Cimatic: the height of the Base of the Columnnes, is 10. ounces, and is very well cut and grauen: and although the forme is Dorica, yet the delicate works thereof shew that it is Corinthia: the Columnnes are fluted or chanelled from the top to the bottom; and there are also many hollowings without the Pilaster, as the Figure hereafter doeth shew. The height of the Cap tall with the Abacus, is two foote and one ounce: the which Capitall is higher then the thickness of the Columnne beneath. Neuertheless, it is very well, and sheweth pleasing to sight; it is also richly wrought, as it is here shewed in the Figure thereof: and alwayes, as the Capitall of Corinthia is in such proportion against the Columnne, I would thinke it better to the view of workemen; then if with the Abacus it had but the height of the Diameter of the Columnne: and although Virruuius writeth thus (as is before sayd) yet may his text be falsified. The height of the Architrave, is one foot and one ounce: the height of the Frieze, is one foote and two ounces: the height of the Cornice, is a foote and ten ounces: which Cornice is very licentious, although it be rich of worke, because such richness of worke confoundeth it: but that which is most unseemely in it, is the Echine with the Duale about the Scima, a thing, in truth, much vsightly: and that, which is more worthy laughter, is, that the said Echine in the upper part, is cut through, without being covered with any list, that it might not bee consumed with the water. But there hath alwayes bene licentious workemen, as there are yet in our dayes, who, to please the people, make much grauing in their workes, without respecting the qualities of the orders, and will also in Dorica worke, which should bee fast and strong, vse much grauing and cutting, as in Corinthia worke, which, by their folly, asketh many ornaments. But wise and iudicious workemen will alwayes obserue Decorum: and if they make worke after Dorica maner, they will follow good Antiquities: which, for the most part, agree with Virruuius precepts. If they make any worke after the Corinthia maner, then they cover them with Ornaments, as that kind of worke requireth. This I haue set downe, to aduertise those thereof that know it not; for they that know it, neede not my aduice. Now to come to the purpose agayne: Above this Cornice there is a Basement, which maketh out the Pedestalls; the Plinthus vnder the Basement, which is there set against the proiecture of the Cornices. (for otherwise, in looking by, it would darken the Base) is a foot high; above it standeth the Base, whereof the height is 10. ounces: the flat of the Basement, is 2. foot & 1. ounce high: the Cornice about it, is halfe a foote high; which Cornice is very seemely, and the parts thereof deuide themselves very well from each other, for that betwixt the two carued members there standeth one playne about: the Cornice is that member of part, called Corona lisis, as I vnderstand Virruuius, whereof the height is 5. ounces. Above these there are some stones that shew to no end at all, but it may be thought, that some things stode vpon them: the height of these stones is 10. ounces: the height of the Impost of this Arch is 10. ounces; the which Impost is very licentious made: and although those 3. members one above the other, are diuers, yet they are like each other in proiecture: and therefore in the worke they stand to no good effect: the other parts you shall know by the Characters in the great Arch.

Of Antiquitie

In Verona, there are many triumphant Arches; among the rest, there is one Gate, called Castel Vecchio: the which, I truly, is of good proportion: this Arch, as men conceane, was wrought both before and behind, and also on the sides: it had two goings in, as you may perceave by the ground which is yet seene, although I shewed but one side onely. This building was measured by the same foot, wherewith the Arch of Pola aforesayd was measured. The wideness of this Arch is ten foote and an halfe: the thicknesse of the Columns, is two foot and two ounces: the intercolumnnes, are 4. foot and 3. ounces: the Pilaster or Pillar of the Arch, is 2. foote and 2. ounces broad. The thicknesse of the Arch in the sides inward, is 4. foot and an halfe: the wideness of the Tabernacle betwene the Columns, is two foot and ten ounces: and thus much for the wideness and thicknesse: but coming to the height, the Base of the Pedestall of the Columns, together with the Plinthus, is one foote and three ounces high: the flat of the Pedestall, is foure foot, three ounces and an halfe: the Coznice is ten ounces and an halfe: the height of the Base of the Columns, is one foot: the height of the body of the Colunne, without Base or Capitall, is 17. foote and three ounces: the height of the Capitall, is two foot, foure ounces and an halfe. The height of the Architrave, is one foot and an halfe: the height of the Frise is one foote, 7. ounces and an halfe: the height of the Coznice, is one foot and ten ounces: and although that in this Figure there is the Frontispice, yet you see it not in the Arch; for from the first Coznice upwards, there is nothing at all: neuertheless, although the wall is this yere consumed, yet you may see there some signes, wher by a man may conceane that the Frontispice hath bene there. The vppermost Coznice is not there, and therefore I set no measures, according to all Antiquities: but I haue made one, with such measure and formes, as my selfe would haue made it, having for a common rule, that the vppermost things stand the fourth part lesse, then the nethermost: this Coznice therefore, shall be the fourth part lesse then that which standeth vnder it, and is thus deuised, that the whole height should be set in foure parts and an halfe: the halfe part shall be for the Astragal with the list, and the fourth part shall be for the Scima. The Proiecture must be like the height, & so shall this vppermost Coznice be made in maner aforesaid. Betwene the Columns stand Tabernacles, wherein there were Images, wherof the wideness is two foot and ten ounces: the height is seven foote, and the depth thereof in the wal, is one foote and ten ounces: the height of their Balcement, is 4. foot, with the Base and Scima: the little Pillars on epyther side, are halfe a foot thicke: the Architrave is 7. ounces and an halfe: the Frise is 6. ounces high: the height of the Coznice without the Scima, is 4. ounces: the height of the Tympanum of the Frontispice, is 8. ounces. Above these Tabernacles are small tabiets, with other Coznices: the which tabiets are two foot broad, and hold one foot in height: the height of each Coznice is 11. ounces: the height of the opennesse of the Arch, although it be somewhat digged below, is yet twice higher then broad: for the wideness thereof, is 10. foote and a quarter: and the height is 23. foote and an halfe. The Capitall vnder the Arch, is as high as broad: the worke of this Arch is Composita, and vnclely set out with Images of Marble and Copper, as you may perceave in the voyd places.

This is the ground of the Arch following.

This forme of the Arch Triumphant of Castel Vecchio in Verona, is made as it is here set before: and although from the Frames by wards, there are no signes of ornaments; neuertheless, it do stand so. And for that the parts hereof are so small that you can hardly vnderstand them, in the next side they shall bee set downe in a greater and playner forme. This Arch triumphant (by that which is found written within the inner parts thereof) by some is sayd, that Vitruuius caused it to be made: but I beleue it not, and that for two reasons or causes. First, that I see not in the Inscription, that it saith, Vitruuius Polio: but it is possible that it was another Vitruuius, that caused it to be made. The second reason is this, that Vitruuius Polio, in his writing of Architecture, doeth bitterly condemne and reiect Pillars and Dentiles, standing together in one Cornice, and such a Cornice is found in this Arch. And therefore I conclude, that Vitruuius, the great and learned Architect, made it not: but bee it as it will, this Arch hath a good forme and proportion.

These letters are vnder the Tabernacle in the Pedestall.

Of Antiquitie

Because I have not fully written the particular measures of the members of the aforesayd Arch, neither haue I shewed it in such forme that a man may conceaue the particular measures: therefore you may see them here set out in greater forme, and in such sort as they are: and first, the height of the Plinthus, vnder the Base of the Pedestall, marked G. is a foote and thre ounces. The height of the Base aboue vpon it, is 6. ounces. The flat of the Pedestall, marked F. is 4. foot, 3. ounces and an halfe high. The Cornice vpon it, is 10. ounces and an halfe high. The Base of the Colunne, is one foote high. The Plinthus of this Base turneth into a Corona liss; which me thinkes, is very pleasant: for that I haue seene some Greeke Pedestalls so. The Colunne is scypped, chanelled or hollowed, from the top to the bottom. The height of the Capitall of this Colunne, is one foot, 4. ounces and an halfe: but the forme is not here, because it is shewed in the beginning of the Order of Composita: which Capitall, in effect, is Composita, although the Arch may be wholly accepted to bee Corinthia: and this Capitall standeth in that place, marked C. Also, in the same place you see the Capitall of the impost of the Arch, which is marked with D. But the little Capitall of the Tabernacle betwene the Colunnes is here marked H. And the Cornice also, with the Base, marked E. is that which is vnder the Tabernacle. The Figure C. is the table aboue the sayd Tabernacles, and the Figure marked D. is the Architrane, Fræse and Cornice, of the Frontispicium of the Tabernacle. The Figure marked with B. is the trozke which goeth about the Arch: the Cornice marked A. is the principall Cornice aboue the Arch; the which, in effect, is very comely, and well wrought: yet it is vicious, as I haue often sayd; that is, the Mutiles and the Dentiles therein are by Virruuius relected, with many strong reasons. But in this, many men affirme, that sithence Virruuius time, many wozkemen haue made Mutiles with Dentiles, in most places of Italy, and there round about, so that now there is no question made thereof; but every man hath libertie to make that in his wozke which he findeth and seeth in Antiquities: whereunto I answer, that disprouing the same, they haue proued their cause to be good. But if they will acknowledge Virruuius for a learned Architector, as most wozkemen affirme, then (reading Virruuius with god indgement) they must confesse and acknowledge, that they haue done amisse therein.

The halfe of the foot, wherewith the Ichnographic, and the Orthographic, together with the ornaments of this Building, are measured.

Of Antiquitie

In Verona, at the Gate Dei Leoni, there is a Tryumphant Arch, with two like goings throught, which I neuer saw in any other place besides, but many with 3. Arches: which building, although it hath the figure of 8. windows, yet go they not throught, neyther yet very deepe in the wall: whereby you may iudge, that some round Images stode in them. Above the first Cornice this building is hollow, in maner of a spich or seate, but not very deepe in the wall, but yet with helpe of the proiecture, or striking out of the Cornice, men might stand there to doe some thing or other, while the Tryumph lasted: but for that this concerneth the workeman very little, I will speake of the measures. And first, the opening of the 1. Arch is 11. foote wide, and 18. foote high: the Blocke under the Pedestall, is one foote high: the Base of the Pedestall is 3. Dunces: the flat of the Pedestall is 2. foote and one Dunce high: and the Cornice is 3. Dunces: the height of the Bases of the Columnes is 8. Dunces and a halfe: the height of the Columnes, without Bases or Capitalls is 12. foote and 1. third part: their thicknes is 1. foot, 4. Dunces: the height of the Capitall is 1. foote, 8. Dunces: the height of the Architrave is one foote, 5. Dunces: the height of the Fræse is one foote, 8. Dunces; and so much is the height of the Cornices: from the Cornices to the second Roote is 3. foote and a halfe, whereon there are certayne Figures, whereupon Images had stode, made fast to the 7. Pilasters, betwæne which, little windows, beautified with small pillars, stand, but not much bearing out: the widenes of a window is 2. foote, 2. Dunces: their height is 4. foot, 3. Dunces: the height of the greatest Columnes is 5. foote, 4. Dunces, with Bases and Capitalls which are flat, not not much rayfed vp. The height of the second Architrave is 6. Dunces and a halfe: the height of the Fræse is one foot and a halfe: the height of the Cornice is 10. Dunces and a halfe: the Corona lies above the same Cornice, is 10. Dunces high. The Base of the second Pedestall is one foote; the flat of it selfe is 3. foote, 7. Dunces and a halfe high: the Base of the second Columne is 8. Dunces: the height of the Columnes is 8. foote, 3. Dunces and a halfe. The thicknesse of the sayd Columnes is 10. Dunces and a halfe: the height of the Capitall is one foote, one Dunc and a halfe: the height of the Architrave is one foote and one Dunc: the height of the Fræse is 1. foote, 2. dunces: the height of the Cornice is one foote, whereon there standeth some part of the wall, but a man cannot perceiue what it might be. This Arch is not very thicke, neyther beautified on the sides, for that behind this Arch there is another, standing so nere together, that a man can hardly goe betwæne them both, as I will shew hereafter when I speake of the other figure: the windows stand not in any good order, but somewhat vnseemly: for the 2. windowes are not right in Perpendicular vpon the sharpe poynt of the Frontispice, but some part aside, which sheweth not well: and for that I could not endure such disorder, I haue placed them orderly. The Capitalls of these Arches are part Composita, and part Corinthia, as hereafter I will set do bene in Figure.

Louing Reader, Coroneus, a Paynter in Verona, hath counterfeited this Arch: the Cornice under the Timpanum is not there: for he placeth there certayne order of figures resting vpon the Architrave: the which Architrave, you must vnderstand, is betwæne the 2. Columnes ouer each Arch, and is somewhat flat, because of the writing following.

Ouer this Arch, on the right hand, these letters following stand.

T. FLAVIVS P. F. NORICVS, IIII. VIR. ID. V. F. BAVIA. Q. L.
PRIMA SIBI, ET POLICLITO, SIVE SERVO, SIVE LIBERTO MEO,
ET L. CALPVRNIO VEGETO.

Of Antiquitie

Here befoze, I spake of the vniuersall measure of the sayd Arch, and thereunto let doone the forme, according to the proportion of the same, but cannot giue perfectly the particular parts in so small a forme. Of which members, for that there are diuers ornaments in them, I will in this lease declare them: touching the height and thicke-
I will speake no moze, for I haue done it already: but I will shew which they are. The Figure marked G. is the first Pedestal, with the Bases, and the beginning of the Columns, the which is hollowed: all the members are proportioned according to their greatnesse. The Capitall marked E. hauing the Architrane upon it, followeth upon the first Colonne, as the hollowing sheweth. The Figure marked D. is the Architrane, Frieze and Cornice together, which stand about the first Colonne: which Cornice, by the authoritie and example, which is by me in many places alledged, the iudicious Reader may know, whether they be erroneous or good. The Capitall marked F. is that, which upholdeth the Arch upon the fouresquare Pillars; these two Capitalls are called, Latine woork, and very sayre. I will not, as I haue said, speake of the measures, for that this Figure is proportioned after the principall, and with great diligence transported from the great into the small.

The halfe of the common soke, wherewith the aforesayd double Arch, with the following ornaments, is measured.

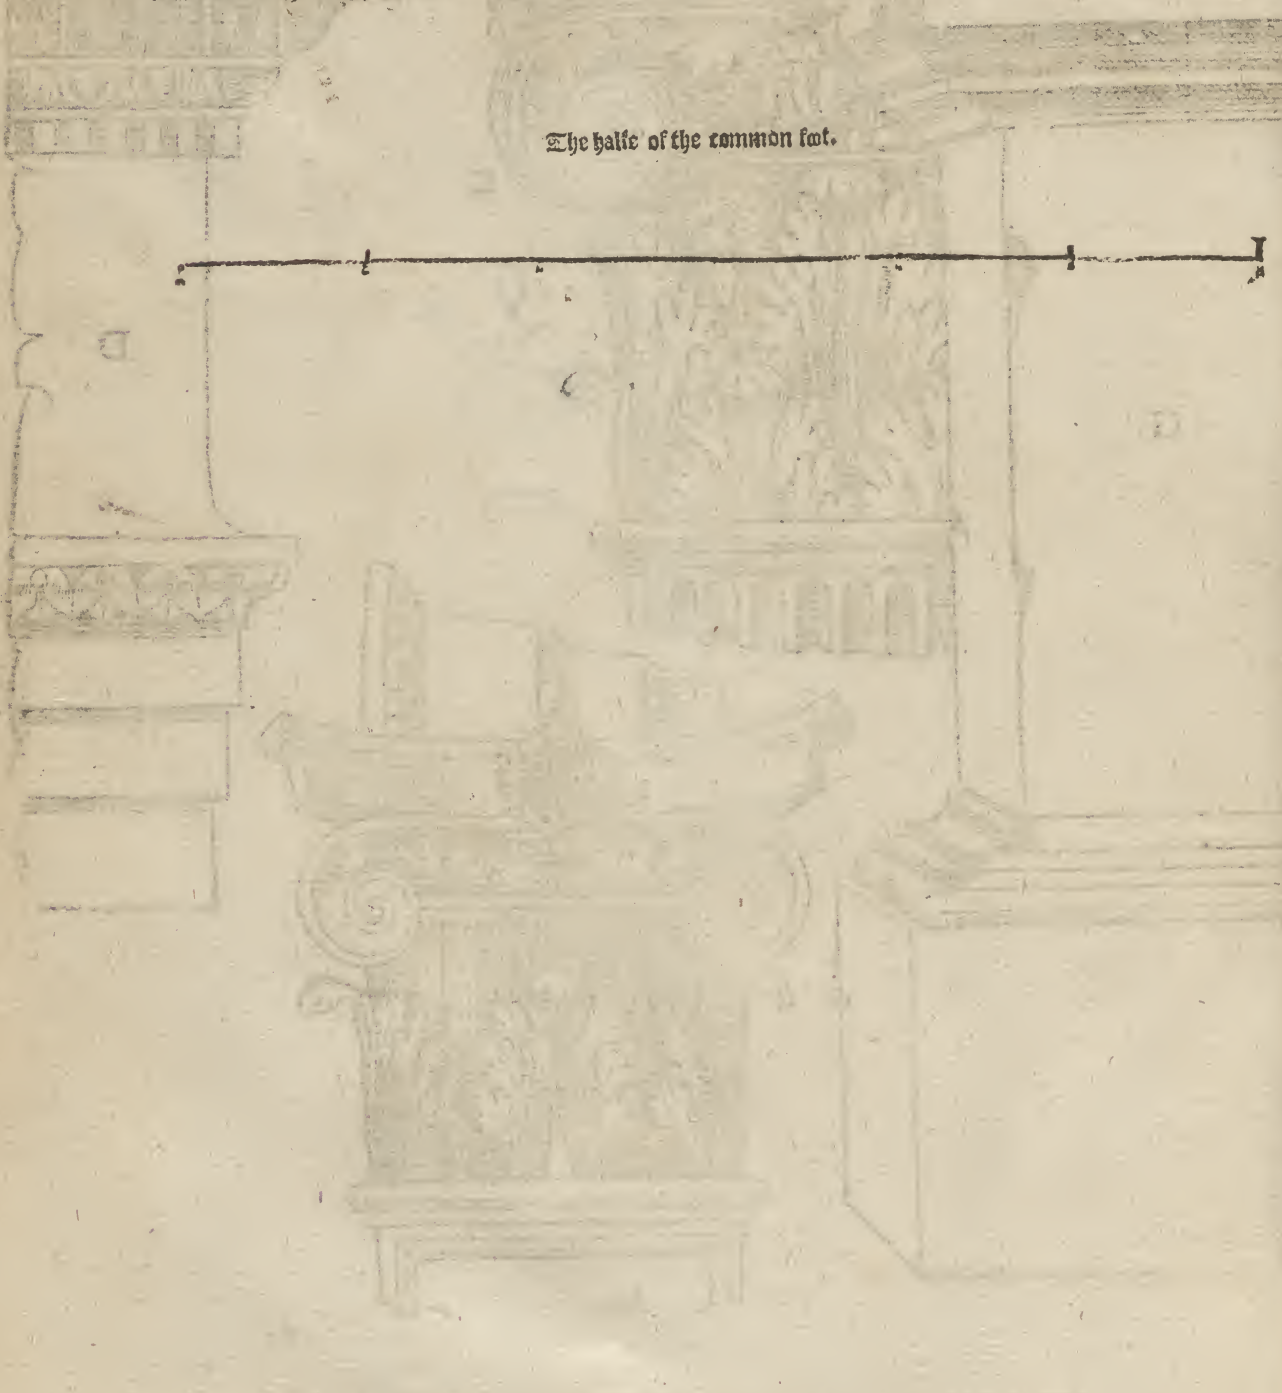

Of Antiquitie

As I sayd before, the Arch is very rich of ornaments, and among them, some very sayre and perfect; some also very vicious & ill made: and in truth, I finde nothing that moze misliketh me, then the Cornice marked D. in the other lease, for the reasons befozesheved: but all the rest befoze set tobove are of good propoition, as well the woikes as the Cornices. And as the parts of the first stozy are, so are these following of the second stozy. The Dentiles marked H. are in the beginning of the second stozy above the Frontispicie: upon which Images (as I have declared) there were Images fastened against the flat Pilasters. The window marked I. is the forme of one of the Windows with the Cornice upon it, and therefore iust of his measure. That Capitall and the Base marked K. is of the same windowes, shewed in greatest forme, that the members may be the better understood. That Base and Capitall marked L. is the little Pillar betwæne the Pilasters and the window: and in truth, in these two Bases, that is, that of the greatest of the small Pillars ioyned with the lesser, the woikeman was very sudicious to accord or agré the one with the other, that the greatest Pillar should have his due Base, and the lesser should also have a lesse Base, according to propoition, which I commend much. The Architrave, Fræse and Cornice, marked C. sheweth that of the second stozy, above the small Pillars: this Cornice is very sãmely, and not confused with cutting. The Pedestall marked B. sheweth that of the last stozy, whereof the Base marked M. doth rest: also the Capitall which standeth above, is his companion, and is truly Corinthia, the which is confirmed to the pzinipall, for woike and fashion, and in my opinion, very sãmely. That Architrave, Fræse, and Cornice, marked A. sheweth the last Cornice: the Architrave is not vicious, because it hath onely two Facies; for if it had threë, it would, by the farre distance, stand cumbered: the Cornice with the Dentiles, liketh me well, because it hath no Dentiles; and is also well divided with members: neither is it confused with much graving, but hath a sãmely Proiecture, which beaueith by the height thereof a little.

The halfe of the common foot.

Of Antiquitie

This Arch triumphat was made before the Arch aforesayd, which the table sheweth, wherein there standeth P. VALERIVS. Q. CECILIVS. Q. SERVILIVS: P. CORNELIVS. it is thought it was set up in the time of Hanibal. This is measured with the same measure that the other is: the widenes of each Arch is 11. foote: the height is 17. foote: the Pilasters of the Arch are one foote, 8. ounces broad: betwene the 2. Pilasters are 5. foote, 4. ounces: the sides, eche holdeth 3. foote. The Cimatie under the C. in place of an Architrave, is 6. ounces and an halfe: the height of the Frise, is one foote, 7. ounces and an halfe: the list about the Frise is 2. ounces: the Cimatie under the Dentiles, is 4. ounces and a quarter: and the Cimatie above it, is one ounce and an halfe. That Astragall is one ounce. The Cimatie under the crostone, is one ounce and a third part: the crostone is 3. ounces and an halfe high: the list is 2. ounces: the Proiecture of all, is an ounce and a quarter. The Scime is 3. ounces and an halfe high: but the list is 2. ounces: the Proiecture of all, is as much as the height. The Basement above this Cornice, is one foote, one ounce and an halfe in height: the thiknesse of the hollowed Columns, is 1. foote, 3. ounces: the height without Capitals, is 7. foote, one ounce and an halfe. The Capitall is 10. ounces high. This Colunne hath no Base nor Cinthe. Carettus, who also counterfeited this Arch, seth but foure places where Histories are grauen, and 5. Colunnes in this third story: in the second story but 4. windowes, and 5. Pilasters: and above them, 5. Colunnes: the third Cornice you cannot come into.

This figure
 B. is the
 Architrave,
 Frieze & Coz-
 nice above the
 windows, and
 the height of
 the first Frieze
 is 8. ounces, &
 a 3. part. The
 second Frieze,
 is 9. ounces &
 an halfe. The
 Dentils are three
 ounces. The
 Frieze is 1. foot
 and 4. ounces
 high: the breadth
 of the triglyphs
 is one foot: the
 list therabout
 is a 3. part of
 an ounce. The
 other about
 that, is 1. ounce
 and a 4. part.
 The Cimatie
 vnder the Den-
 tils, is 2. ounces
 and a 4. part.
 The height of
 the Dentile is
 4. ounces and
 a 3. part. The
 Cavet above
 it, is 1. ounce.
 The Astragals
 are 3. quarters
 of an ounce: the
 Cimatie above
 it, is 1. ounce
 and a quarter:
 the height of the
 Corona is 4.
 ounces: the Ci-
 matie is 2. ounce-
 s: the height
 of the Dentile is
 4. ounces: the
 list is 2. ounces
 & an halfe: the
 Protector of
 all, is like the
 height of whole
 height may be
 called Dorica,
 only the great
 Astragal: but
 it was a toy of
 the work-
 mans hand.
 Many other
 things are in
 Verona, where
 of I will not
 speak, because
 they are very
 licentious; &
 specially the Arch triumphants, called Dei Barfari, because it is barbarous work.

B

H

C

Of Antiquitie

Having spoken of many Antiquities, and placed them in Figure; it is requisite that I also shew some of those that were made in these dayes, and specially, of Bramants worke, although I have not altogether omitted it, having shewed the wonderfull worke of S. Peters Church, and other things belonging to holy Temples. And in truth, a man may well say, that he restored good and perfect Architecture, as yet, by the meanes of Iulio P. M. many sayze pieces of worke were made by him in Rome, do witness; of the which, this set here, is one: this is a Gallery made in Beluedere, in the Popes Court, wherein are two sayze things to be seene: the one is, the strength thereof; the which, for that the Pillasters are of so great bredth and thickenesse, will last, while the world endureth: the other, for that there are so many accompagments so well set out, with good inuention, and excellent propoztion: this worke is measured with the ancient Palme. The bredth of the Arches, is 18. Palmes: and so much are the Pillasters: the bredth of the Pillasters is deuided into 11. parts: one part on eyther side of the Pillaster, which beareth the Arch shall haue, which is two parts: other two parts shall be giuen vnto one Columne, that is 4. parts: 2. parts shall be giuen to the little Pillasters of the Niches, or hollow seats, and 3. parts to the Niches themselues: so are the 11. parts distributed. The height of the Pedestals shall be halfe the wideness of the Pillasters. The height of the Base of the Pedestals, shall haue one part of the before sayd 11 parts. The Cornice is the 9. part lesse then the Base. The height of the Columnnes, with Bases and Capitalls, are of 9. Diameters, and thereunto also the seventh part. The Base is halfe the thickenesse of the Columnnes. The Capitall is of the same thickenesse: and the seventh part for the Abacus. The height of the Architraue, Frise and Cornice, is as much as the Pedestall without his Base. And this height is deuided into 11. parts, foure for the Architraue, 3. for the Frise, because it is engrauen, and 4. for the Cornice, as the halfe Circle of the Arch is drawne; then the heights of the lights will be double: after that, the impostes being drawne in their places, the which are of halfe a Columne thicke, and so the Niches or seats, and the Quadzans aboue them, haue their certaine propoztion.

Because I could not (by reason of the smallness of the Figure) perfectly shew the parts of the Gallery aforesayd; therefore I have shewd them hereunder in greater sozine: the part C. is the Pedestall of this Gallery, and vpon it the Base of the Colunne standeth, proportioned according to the great: the part B. sheweth the impost of the Arch, with a part thereof. The Figure marked A. sheweth the Architrave, Frise & Cornice above the Colunnes. The generall measures, touching the height, are already shewne, therefore not to be mentioned againe: for they are proportioned after the great. In this Cornice the workeman was very iudicious, that he suffered the Corona to go through vnbroken; and suffered the other parts of the Corona to beare outwards, which is very seemely, and the croone the stronger, and keepeth the whole worke from water: with which intention, the workeman may helpe himselfe in diuers accidents; for the reaching out of Cornices stand not alwayes well, but in some places well, and in some places ill; and the bearings out vntolerable, where the Colunnes on the sides haue no Plasters: of these bearings out, I will say more in the fourth Booke, in the handling of foure maner of Symetrie of Colunnes.

In the leafe befoze, I shewed a piece of worke of Bramants making: and now I will shew another of his workes, from whence a wise workeman may helpe himselfe much, by meanes of the diuers and sundry ornaments that are in it. In this Gallery, the workeman would shew thre stoies or orders one aboue another, viz. Dorica, Ionica, and Corinthia: and in truth, the orders were faire, well set out, and placed: notwithstanding, that the Pillasters of the first stoye or order being Dorica, were somewhat too weake, and the Arches too wide, to the proportion of the Pillasters; and therewith the weight of the wall of the Ionica order standing vpon it, was an occasion that it was broken, ruinated and decayed in short time. But Balchazar of Science, a skilfull workeman, repayed the decayed ruines, making counter Pillasters, with vnder-Arches: therefore I haue said, wise workemen may learne of this building, not onely to imitate saye and well made things, but also to beware of errors, and alwayes to consider what weight the nethermost stoye is to sustaine: therefore I counsell a workeman rather to be timorous, then over-bold; for if he be timorous, he will alwayes chuse the surest way, and make his worke with consideration, and will vse counsell, yea of such as are lesse skilfull then himselfe, of whom sometime men often learne: but if he be high-minded, and trusteth too much to his own skill and knowledge, then he will scoyme another mans counsell, whereby oftentimes he deceyueth and ouer-shooteth himselfe; so that oftentimes his worke falleth out badly. Now I will turne to speake of this Gallery, and set downe some notes of the proportion thereof. The widenesse of the Arch shall bee deuised into eyght parts, whereof thre parts shall be for the breadth of the Pillasters, and the height of the Arch shall containe 16. of such parts. The forepart of the Pillasters shall be deuised into foure parts, whereof two parts shall be for the Pillasters of the Arches, and the other two shall be for the thicknesse of the Columnnes: the height of the Pedestals shall containe halfe the widenesse of the lights: the height of the Columnnes shall bee eyght parts of their thicknesse, with the Bases and Capitals. The height of the Architrave, Frise and Coznice, is a fourth part of the length of the Columnne. The second stoye shall bee lesse then the first by a fourth part, viz. That from the Pauenment of the Dorica stoye, to the highest of the Coznice, shall be deuised into 4. parts, and 3. of them shall be for the whole stoye of the Ionica worke, and so shall all the parts particularly bee lessened in themselves a fourth part. The like also shall be done with the third stoye, which is Corinthia, in regard of the second order, although it standeth not here, because the Figure is drawne too great: but not to put the Reader in a maze or doubt at the Columnnes which stand here in the middle, as desirous to know how they end at the top; you must vnderstand, that you shall finde such inuention in the fourth Booke, in the Order of Dorica in the side H 2. that although that those Columnnes are Ionica in the sayd Booke, notwithstanding, you may make them Corinthia. And that the workeman might the better vnderstand the members and Coznicements of this worke, I haue shewed them in greater forme, and proportioned them according to the principall: I speake of the members of the first stoye: for a man could not easily come to measure the other.

Of Antiquitie

A Beluedere, at the entry of the Popes Court, through the Gallery, which I have set downe before, for the places alwayes goe upwards, there is a going vp which is very sayze: at the head wherof, you come to a plaine, which hath the forme of a Theater; the ground whereof is shewed vnder this: and thereto I haue set the Prosill, that you may vnderstand it. Here I haue kept no account of the measures, desiring onely to shew the inuention of the sayze, and the halfe Circle as it standeth. This halfe Circle is very much eleuated from the Court of the Popes house to the Palace-ward: and behind the halfe Circle, you find a great playne with sayze appertements; at which place, you goe through the two Gates, which you see in the sides of this halfe Circle, in which places there are many faire Images, and among the rest Laocoon, Apollo, Tyber, Venus, Cleopatra, and Hercules.

Of Antiquitie

Without Rome, at Monte Mario, there is a very fayre place, with all things belonging to a place of pleasure, of which particular parts I will rather reffrayne to speake, then not shew them sufficiently, onely I will speake of a Gallery, with the Facies thereof, made by an excellent workman Raphael Durbin, who hath made diuers appertements and beginnings to other workes, as the Courtill, although that it is square, yet he had fashioned it round, as the foundation partly sheweth. That Vestibulum marked A. and the two places, B. and C. stand not in such forme, but I haue placed them there to fill by the ground: for the part C. endeth in an hill, as also the part E. but in the other side of the Gallery marked F. there is no halfe Circle, and that was left out, not to pinch some of the appertements; but to accompany other members by it. The order of this Gallery is very fayre: the roffe whereof is concordickly altered: for that the middle part is with a round tribune; and those two on the sides are crosse-wise. In which roffe, and also in the walles, Ian van Vdenen hath made wonderfull great pieces of paynted worke: so that regarding the fayre and excellent workmanship of Architecture, with the beautifying of paynting, together with diuers ancient Images, this Gallery may well be called, one of the fayrest that euer was made. And whereas it is spoken of an halfe Circle which doth not answer the rest, neither the workman not willing to leave it vnderdecked or vnfurnished, his Disciple Iulio Romano, in the facie thereof, paynted the great Gyant Poliphemus, with many Satyres round about: which worke, Cardinall de Medicis, that after was Pope, by the name of Clement, caused to be made. The measure of this Gallery I will not set downe, but the inuention shall suffice the workman, for that all things are proportioned according to the great, and hereafter you shall see it made by sight, together with the Facie of the Gallery, but the Pitches or hollow teates on the sides are not there.

By this part following, marked B. A. you may conceiue the roffe of the aforesayd Gallery, the fayrenesse whereof sheweth well in the heaving vp of the tribune in the middle, going alwayes binding with the duplication of Pillars, to each Facie of the Pillasters: which Pillars (in regard the Coronas remaine whole) make not the Pillaster shew bare, but rather such breaking of Pillasters into two Pillars, maketh a large ceiling vpwards, and stands (neuerthelesse) in manner and place of a firme Pillar: for the Base of the sayd Pillasters follow also. And so that in the Figure following in the Pillasters within the Gallery is to be deuided into three, of the which a man may make two flat Pillars, and at the corners one Intercolonne: so that (as it is sayd) although there are two flat Pillars with one Intercolonne, yet, altogether, it is but one Pillaster.

This is the Orthography of the ground shewed Folio 69. and as I haue sayd, I will not speake of the measure thereof, but onely of the inuention: and although that here on eyther side, onely one Pilaster, with his Columnnes, is shewed, yet is it not vnlike some Galleries, whereof I haue spoken before, and that appeareth by the double Columnnes, together with the piches or hollow seats, with the Quadrans about them. In Belvedere there are many other things, which I haue showne, & among other things, there are wonderfull winding Stayres, in the ground whereof, there standeth a Fountayne, flowing exceedingly with water, the which going by is all full of Columnnes in the innermost part: which Columnnes are of foure Orders: viz. Dorica, Ionica, Corinthia, and Composita: but that which is most wonderfull and ingenious, is that betwene one and the other Order, there is no difference or distance, but men goe from the Dorica to the Ionica, and from the Ionica to the Corinthia, and from the Corinthia to the Composita, with such cunning, that a man cannot perceine where one Order endeth and goeth into the other: so that I am of opinion, that Bramane neuer made a fairer nor costlier piece of worke then this.

Of Antiquitie

Among other Cities of Italy, Naples is called, La Gemile, and that not onely in respect of the great Barons, Lords, Carles, Dukes, and great numbers of Gentlemen therein, but also, because it is so well furnished with stately Houses and Palaces, as any other parts of Italy. And among other pleasant places that are without the Citie, there is a place called Poggio Reale, which King Alphonsus caused to be made for his pleasure, in that time (then most fortunate) when Italy was in peace, and now unfortunate, by reason of the discords therein. This Palace hath a very faire situation, and is well divided for Roomes, so that in each corner thereof might bee lodged a strong company of men: in the middle there are five great Chambers, besides the Roomes under the ground, together with some secret Chambers. The forme of this faire building in the ground, as also, the building that standeth byright, is here set downe in the next leafe: the measure thereof I set not downe unto you, onely, because I will shew you the invention: for a workman may imagine of what greatnesse he will haue a Chamber, being all of one greatnesse; and then from those Chambers he may imagine all the measures of the rest of the building: which building the Noble King vsed for his pleasure, because men accustomed to dwell in the Countrey in the Summer time. The Court of this Palace is compassed with double Galleries: and in the middlemost place, marked E. men go downe a payre of Staires into a fayre eating place, in which place, the King and his Lords vsed to banquet and eate at pleasure; in which place he caused certayne secret places to bee opened, whereby in the twinkling of an eye, the place was full of water, so that they sate all in water: likewise at this Kings pleasure, all y^e water boyded out of the roome againe, but there wanted no shifts of clothes to put on, nor yet rich and costly beds for them to lye in, that would rest themselves. O voluptuous Italians, how are you impouerished by your discords! I will not speake of the most beautifull Gardens, filled with all kind of flowres, with diuers compartements of the Orchards and Trees of all kind of Fruits, with great abundance of Fish-ponds and Fishes, of places and cages of diuers Birds both great and small, of fayre Stables, filled with all sorts of Horses; and of many other fayre things, which I will not speake of, for that Marcus Anconius Michaell, a Gentleman of that Towne, very learned in Architecture, hath skene it, and hath written of it at large in a Latine Epistle, which he sent to a friend of his. But to turne againe to the parts of the said Palace, which is right soure square, it is within, Galleried round about, one aboue the other: in the soure Corners, within the thickenesse of the walls, stand the winding Staires to goe by into the building. The soure Galleries without, marked B. are not there, but for the commoditie and beautifying of the house, they would stand well there.

In this Figure hereunder, I have shewed the Orthographie both within and without: the part marked A. sheweth the part without: the part marked B. representeth the Galleries within: the part C. sheweth the ruines within. I have not set downe the covering or raise of this house: for according to my opinion, I would have playstered such a building, that it might onely be used for a walking place, to behold the countrey about.

The ground of the Poggio Real of Naples.

Of Antiquitie

Considering the fayre Building of Poggio Real, I haue thought good to set downe such an other here in this place, but to other forme for appertements, and peradventure with moze ease, for that the places are all of one greatnes, which is not so good a forme: but it is necessary that the first should be greater then the second. In this place I make you no place for lights within, for that it is a place in the countrey, being not cumbr'd on the sides; it hath light enough on all the foure corners: but some men may say, that the Hall with the foure Chambers, because they haue no light but through the galleries, are darke, for it is no perfect couer: to which I answer, that the house being made to be used in the time of great heat, hauing no place in the middle, the Hall and the Chambers will alwayes be cold, by reason the Sunne cannot come vnto them. These places will be very pleasant at nonetime, for that the said places haue not so great lights as the other dwellings; yet haue they so much light as they need: such like may be seene in Bologna, which are made in this manner with Galleries, and daily inhabited. This Building is so disposed, that the corner places being of great thickenesse, the rest shall be strong enough, yea, although the walls had no great thickenesse, in regard they are all counterfoits one to the other, yet shall they be of sufficient strength. I will not speake of the measures, for that this being proportioned, the skilful workman may imagine (according to his pleasure that caused it to be built) first the greatnes of the ronne, then deuide it into so many feet or other measures, thereby to measure all the rest of the building, as the situation of the place may beare it. When this building, about all things, shall be placed, that the Sunne may rise vpon one of the corners, and so shine vpon all the sides thereof: for if it stands with one side to the East, and the other to the West, then it will follow, that the South side shall neuer enjoy the Sunne-shine vpon it, which were rumaticke and vnholefome.

Men may build in diuers and sundry sorts vpon the ground aforesayd: but so; that this is a place of pleasure, I thought good, for the brauenesse thereof, to make it after the Corinthia maner. I will not trouble my selfe to speake of the measure nor height; for in my fourth Booke, in the Order of Corinthia, O 2. you shall find a Tree: the, which, together with the iudgement of y^e wise workman, will serue to set down this measure. And, for that in this Facis there is no shortening at all, whereby you may know the Galleries, the flat and closed places eche from other; therefore I will set downe the two highest sides at eche end: you must conceaue it to haue flat Pillars from beneath upwards; that part betwene both, which is lower, you must suppose hath two Galleries, one aboue the other, the Cornices whereof would be round: the same is to be vnderstood to be both behind, and on both sides. Pen may also make aboue the Galleries a Terrace or Pavement, to defend the raine, the Gallery being made with a Leane-to, or Raile, out betw of y^e second story, would haue more light. For 2. causes I haue made the small windows aboue the great, in the first story. The 1. is, if you will make the windowes so low, that a man sitting, may easly see out of them, then (if you should make the windowes no higher then the doze) there would bee too much space betwene the windowes and the rose of the house, which would greatly darken the house: and otherwyle the windowes bying much moze light into the Hall. The 2. is, that the Chambers by the Hall need not bee of such height, but you may make hanging Chambers therein, whereto those windowes will serue. I might speake of many other things, which I referre to the iudgement of the workman.

A first, I was not minded to set this ground, no; yet the building of the 100. Columns, placed in M. 1. in this
 Rocks; so; that they are things which the Autho; hath made by reports and heare-say, which I esteeme not wo;:
 thy to be set by things that are counterfeited and measured: yet that it should not be sayd, that I have published
 this Booke lame and vnperfect, and not full as the Autho; made it, which might haue giuen slanderous and enu-
 ous persons occasion to scozne and scandalize this Booke; therefore I haue not scretly set this here, but also added this o-
 ther Figure following by him set downe in the leafe R. 3. And now to turne to this ground, our Autho; sayth, that in
 Ierusalem (as it was told him) on a hill, there is a building cut out of a reasonable greatnesse, in manner hereunder set
 downe: and so; that by meanes of the wideness of the middlemost part, the rooffe should not fall in, therefore the two
 Pillars were left in the middle, and withall, two of a middle sort by them, with two lesse also befoze, vnderholding
 the rooffe, which altogether were cut out of the rocke with instruments. In the first entry are foure little Chappels.
 In the middle there are 18. and behind there 8. and a doze locked, which sheweth, that men went further: the great-
 est Chappel is wide the length of a man, whereby you may iudge the greatnesse of the building. This place hath no
 light, no; can be perceined that it had any light. The Chappels are taken out, as the Figures A. and B,

For that our Authoz before, speaketh of an Arch triumphant in Verona, called Dei Borfari, which he termeth to be barbarous and confused of parts and members, as (according to the writing of Vitruvius of good Antiquities) in effect it is: p̄suert̄helesse, for that Iohannes Carocetus (which our Authoz alledgeth) hath set it downe for an ornament of Verona, in his booke of Antiquities, much better, and with more deliberation then all ȳ rest of the Figures by him made (for in trueth, ȳ rest are very grosse: Wherefore I thought if god to helpe it here to the curious Reader that he may see and also note (by Vitruvius rule aforesaid) what is good or ill in it, which may peradventure please some of this countrey better then another, because they be to seeke for much worke in their Architects. And for ȳ this Figure was too great in forme, therefore I have here set downe but the halfe; and you must conceaue the other side, that is, an Arch with windowes and other ornaments, like these: the foot of Verona, wherewith this building is measured, standeth here on the sides in halfe proportion: of which foot, one small standeth in the Pedestal, vnder ȳ great Columnes; whereby the measure is to be concepted: for the sayd Carocetus giues no other warrant of all his Figures (but onely of the Figure of the wonderfull spectacle, as hee termeth it) with the Theater above it: but above all, with the goings vp to the hill; where a Temple of Ianus standeth, as our Authoz sheweth afterward in Folio l. 3. in this present Booke. Of this building, Carocetus saith more then of all the rest: and for that I may satisfie the Reader at full, of all that is sayd in this Booke, therefore I haue caused this figure to be printed alone, because it was too great, and (in my opinion) too grosse, to set herby.

Vale.

The halfe face of Verona, wherewith this building is measured.

The end of the third Booke.

Translated out of Italian into Dutch, and
out of Dutch into English, at the charges
of *Robert Peakes* and are to be sold at
his house neere Holborne Con-
duit, next to the Sunne
Tauerne. 1611.

The fourth Booke.

Rules for Mafontry, or Building
with Stone or Bricke, made after the five maners
or orders of Building, viz. Thufcana, Dorica,
Ionica, Corinthia and Compoſita: and
thereunto are added examples of Antiqui-
ties; which, for the moſt part, agree
with the inſtructions of *Vitruuius*: with
ſome Figures more, added vnto them,
which were not in the firſt, and ſome
deuiſes of the Author, which are
corrected, and heſcunto
annexed.

*Translated out of Italian into
Dutch, and out of Dutch
into Engliſh.*

Holborne conduit, next to the
Sunne Tauerne.

ANNO DOM. 1611.

To the wel-willers of Architecture.

Vitruuius sayth, that such as haue built without learning or instruction (although workemen) could neuer make any famous or commendable pieces of worke: no more can others, being no workemen, such as haue followed the letter or writing onely, and made no prooffe: of which, some haue presumed to fater their doings vpon Vitruuius: yet in diuers places of their writings, which are found, they could not close vp their rules orderly, but haue left many things doubtfull, and (more) haue esteemed that to be good and commendable, which in worke is not to bee endured. The cause of this error, is, that the last Booke of the sayd Vitruuius, wherein the Figures are, was lost: whereby men might haue knowne and found out his meanings: so that hereby it appeareth, that some Antiquities haue beene very bare in their workes, and especially, in their Orders of Dorica, because Vitruuius nameth no Dorica Bases: but in stead thereof, speaketh of an Attica. Now it may be, regarding that he there speaketh not of any Order of Attica, therefore they durst not make any Dorica Bases or Columnnes: on the contrary, others possibly contemning the darknesse of the writer, (or for want of knowledge) haue so far exceeded their Author in many things, that they haue not onely forsaken and left the examples and reasons of good Antiquities, but also (more then that) haue made their workes vnseemely, and ridiculous to mens eyes, as may be seene in diuers ancient workes: whereby, gentle Reader, many workmen, well seene in both, haue beene cumbred therein, and especially in this our time, Bramant of Castle Durant, Balthazar of Sciencie, and many others, for that (not onely by meanes of Iulius the 2. Pope, but) also by others, good Architecture was bettered in their times: who, after long disputation and searching of many, as well Authors and Commentaries, together with the examples of good Antiquities, haue with authority (to make an end of all doubts) not only added this Spira Attica, of the Dorica, but also as many orders as now are used, beginning at the Tuscan, as the grossest and slenderest of all the rest; and haue reduced the same into a certaine and common forme, together with their ornaments and measures: which rules Seballian Serlius, a workeman and scholer of the sayd Balthazar, hath written, and set out in figures; so that, leauing the obscurities of Vitruuius, we may make an incorrigible worke. And for that all those that loue workmanship, vnderstand not the Italians, therefore (in my opinion) I haue translated the most certayne and best rules out of Italian into Dutch, and out of Dutch into English; onely the names of all Procelles, Bases, Capitals, Cornices, &c. which are not named in Dutch nor English, for that Bastian, by Vitruuius termes, vseth the common and moderne Italian words, which by some should be as hardly vnderstood as the Latine. But I would commend him, that seeing we take vpon vs to follow Vitruuius writings, that we giue him the name of Vitruuius, that the learned might bee vnderstood of the workeman, and the workeman also vnderstood of the learned. And for that the workeman might the better read it, I haue printed it in our ordinary Dutch letter. And although this fourth Booke of seuen was first set out, because it is the best, yet the other also are no lesse fit and conuenient to further Architecture or Art of Building, as in the ensuing Epistle you shall see.

Sebastian Serlius to the Reader.

Loving and friendly Reader, after I had collected certaine rules of Architecure, thinking that not only those of deepe conceyt would vnderstand them, but that also each indifferent man of wit might conceaue them, as he is more or lesse addicted to such an Art; which rules are deuided into seuen Books, as hereunder shall be set downe: but for that this Art requireth it, therefore I thought it requisite to begin with this fourth Booke, and to set it out, first, which is more to the purpose, and more necessary then the rest, for the knowledge of many sorts of Building and ornaments thereof, to the end that euery one may haue some knowledge of this Art, the which is no lesse pleasing to the mind of those workmen that thinke vpon things that are to make, then also to mens eyes when they are made. Which Art, by the wisdome of the famous and excellent spirits that are now in the world, doth flourish in these dayes, as the Latine tongue did in the time of *Iulius Casar*, and *Cicero*. Then with glad and ioyfull heart receyue at least my good will, (though the effect ensueth not) which, in trueth, I haue (to pleasure and satisfie your minds) in this respect.

In the first Booke, I will entreat of the beginning of Geometry, and of diuers cuttings through of lines, in such sort, that the workman may yeeld reason for that he worketh.

In the second Booke, I will shew in Figure, and by reason, as much of Perspective Art, that if the workman will, he may declare his conceyt or purpose, by reasons and figure.

In the third Booke, workmen shall see the Ichnographie, that is, the ground: the Orthographie, that is, the raising vp of a Building before. The Scenographie or Sciographie, that is, the insight, by shortening of the most part of the Buildings that are in Rome, Italie, &c. diligently measured, and set by them in writing, with the places where they are, and their names.

In the fourth, which is this, I will speake of five maner of Buildings, and of their ornaments, as *Thuscan*, *Dorica*, *Ionica*, *Corinthia* and *Composita*, that is to say, mingled. And by these, the whole Arte is learned.

In the fift, I will speake of diuers kinds of Temples, set downe in diuers formes, that is, round, four-square, six-cornerd, eyght-cornerd, Ouall-wife, and crosse-wife, with their ground, heights and shortenings, diligently measured.

In the sixt, I will speake of all dwellings, which, at this day, may bee vsed, beginning at the meanest house or cottage, and so from degree to degree, proceeding to the most rich, fayre and princely Palaces, as well in Countrie villages, as in great Cities or Townes.

In the seuenth and last, shall be set downe many accidents, which may happen to workemen in diuers places, strange maner of situation, repaying of decayed houses, and how we should helpe our selues with pieces of other buildings, with such things as are to be vsed, and at other times haue stood in worke.

Now then, to proceed readily herein, I will begin with the greatest and rusticke order of Building, that is, the *Thuscan*, being the playnest, rudest, and strongest, and of least grace and seemclineffe.

The Author to the Reader.

The ancient workemen in times past (as Vitruvius affirmeth) dedicated their workes and Buildings to the gods, according to their natures, strength or weakenesse; so is the forme called Dorica ascribed to the gods, Iupiter, Mars, and valiant Hercules, taking such formes from strong men. The forme called Ionica, is ascribed to the goddesse Diana, Apollo and Bacchus, as of the nature of Matrons, that is, of wise & sensible women, which are both tender and strong: for Diana, by her feminine nature is tender, but by vsing to hunt, she is strong: Apollo, by reason of his beauty, is tender; but being a man, he is strong: the like of Bacchus. But the Corinthia is taken of mayds, and they ascribe all to the goddesse Vesta, and her chaste mayds: yet at this time I thinke it good to proceed in another sort, nothing differing from the ancients aforesayd. My meaning is, to followe the maner and customes of the Christians, that I (as far as I may) will ascribe holy Buildings to God and to his Saints: and profane buildings, as well publicke as private, I will ascribe to men according to their professions. So say I then, that the Tuscan maner (after my opinion) is fit for strengths, for Gates of Cities, Townes and Castles, places for treasure, munition and Artillery to keepe them in; for prisons, hauens of the Sea, and such like things, seruing for the warres. It is true, that rusticke and playne worke, that is, such Buildings as are made of rough Stones, and others that are made somewhat smother, according to the pleasure which the Stone-cutters take therein, are sometimes mixed with Dorica, and sometimes with Dorica and Corinthia. Neuertheles, for that the Tuscan order is the roughest set forth, farre more then the other are, I am of opinion, that the Country Building is moze like vnto the Tuscan, then any of the rest: which you may playnely see to haue bene obserued by the Tuscans, as wel in their chiefe Cities and Townes of Florence, as without in their Country Villages, in so many rich and fayze Buildings, made after the rustickall maner, as may be seene in all Christendome, mixed with such a slight manner of worke, as the workeman thought good. Therefore I conclude, that such Buildings are moze agreeable to Tuscan order, then any other. Therefore, altering somewhat from Antiquities, and some others of ours, I will in diuers sorts shewe of such workes, viz. how to make Gates of Cities, Townes, or Forts; as also, in publicke and private places, Houses, Galleries, Windows, Pitches or seats, hollowed in worke, Bridges, Water-courses, and such like severall Ornaments, as may happen into a workemans hands to doe. Men may also (not differing from the ancient rules) mixe this rustickall maner with the Dorica, and also with Ionica; and sometimes with Corinthia, at the pleasure of those that seeke to please their owne fantasies, which a man may affirme to bee moze for pleasure then profit: therefore the workeman ought to proceede with good aduice, especially in publicke buildings, wherein comeliness is commendable.

In the beginning of this Booke, I obserued the Comedians order, who (when they intend to play any Comedy) first send out a Prologue, who in few wordes giueth the audience to vnderstand what they intend to entreat of, in their Comedie. So I, meaning in this Booke to entreat of fine maner of Buildings, viz. Tuscan, Dorica, Ionica, Corinthia and Composita, haue thought good, that in the beginning thereof, men should see the Figures of all the severall kinds whereof I purpose to entreat of. And although that in the Columns and their ornaments, all the measures and proportions are not set downe, but onely the principall, by generall rules; yet will I not sayle, as occasion shall serue, to set them downe in particularities: but this is done, as I sayde, to shew in generall rules for an Introduction onely, the better to be vnderstood of every workeman, and in the beginning will obserue Vitruvius order and termes, marked on the sides with A. B. C. that every workeman may name them according to his country speech. And first, the Stilobato, or Tuscan Pedestall, I meane the flat, without Crowne or Base, shall bee a perfect fouresquare. The perfect Dorica shall be as much moze as the drawing of a line from corner to corner, of the perfect fouresquare, placing it by right. The Pedestall Ionica, shall be of one fouresquare, and an halfe: the Pedestall Corinthia, shall be a fouresquare and two third parts thereof. The Pedestall Composita shall bee of two perfect fouresquares. Also, wonder not, that the Chapter next ensuing is the fifth, which others would esteem the first; for that the first Booke doeth containe a Chapter of Geometry: the second of Perspective, shall be of two Chapters: the third of Antiquities, shall be of one Chapter, which maketh foure Chapters: so that, this considered, the next shall be the fifth.

Of the order and maner of Thuscan workes, and the Ornaments thereof.

The fift Chapter.

IN Vitruuius fourth Booke and seventh Chapter, we find, that a man should make a Thuscan Colunne of seven parts high, with Capitall and Base, which measure should be taken from the thickeesse of the Colunne below. The height of the Bases or Basement, should be the halfe of the thickeesse of the Colunne, which shall bee divided into two equal parts, whereof one shall be the Plinthus, the other divided in three, two parts thereof shall bee the Thorus, the third the Cintha. The Proiecture you shall make in this maner: First, make a Circle as great as the Colunne is thicke below, placing it in a fouresquare: without the fouresquare draw another Circle, close about the corners of the fouresquare, which shall bee the Proiecture. And although all other Bases haue their Plinthus fouresquare, yet this of Thuscan must be round, as Vitruuius teacheth. The height of the Capitall must bee like the Base: that divide into three parts: one part shall be the Abacus: the other shall be divided in foure parts, three for the Echino, the fourth for the Annulo or Cintho, which may be called, a Girdle, Band, or List in English. The third part resting, shall bee for the Hypotrachelium, or Freefe. The Astragali with the Cintha, is halfe the Freefe, but that divided in three, two shall be for the Round, the third his List, the bearing out must bee as the height: and although this List is here named with the Capitall, yet it is a part of the Colunne, which Colunne ought to be made thinner aboue a fourth part; also the Capitall in the uppermost part shall not be greater then the Colunne below. The maner to lessen the Colunne is thus: Let the body of the Colunne be divided in three parts: the third part below shall hang at the leade, and the other two third parts you shall divide into as many equal parts as you will: then at the third part of the Colunne draw halfe a Circle, and from the lines that hang there, from the outermost corners of the Capitall inwards, measure the eyght part, which in all shall be a fourth part: from vnder the corner (where the Colunne is thinnest) you shall draw two lines by a leade, to the halfe circle, and those parts of the circle outwards, you shall set below, in as many euen parts as the two third parts of the Colunne holdeth: which being done on both sides, then there shall be as many Paralels or crosse lines, drawn from the one poynt of the halfe circle to the other, each line being marked with number, from the top downewards, and the like vpon the lynes that divide the Colunnes; which numbers being orderly placed, then it is certayne, that the first line shall agree with the thinnest part of the Colunne aboue: after, take the second line of the halfe circle, and set it vpon the second line of the Colunne, then the third vpon the third, and the fourth vpon the fourth: when that is done, there must be a lyne drawne from the Base of the halfe circle, to the lyne 4. and from the lyne 4. to the lyne 3. and from the line 3. to the lyne 2. and from the line 2. to the lyne 1. also a lyne: and so from the second side of the Colunne: and although that the lynes in themselves are right, yet they make a crooked lyne, which the iudicious workeman knoweth how to regaire and moderate at his will on all sides in the gathering of the lynes. And although this rule is made for the Thuscan Colunne, which is lessned aboue a fourth part, yet it may serue for all sorts of Colunnes, and the more the dividing of the Colunnes and the halfe Circle are in number, so much the lessening will dimynish.

- A. Abacus or tailloer.
- B. Echinus.
- C. Annulus or Cineta.
- D. Dipotrachelium or Frase.
- E. Afragalas.
- F. Annulus or Cineta.
- G. The thickenesse of the Colunnes above.

- H. The thickenesse of the Colunne below.
- I. Cineta.
- K. Cozus.
- L. Plinthus.

- M. Proiecture or bearing out of the Base.
- N. The thickenesse of the Colunnes below.
- O. The thickenesse of the Colunnes above.

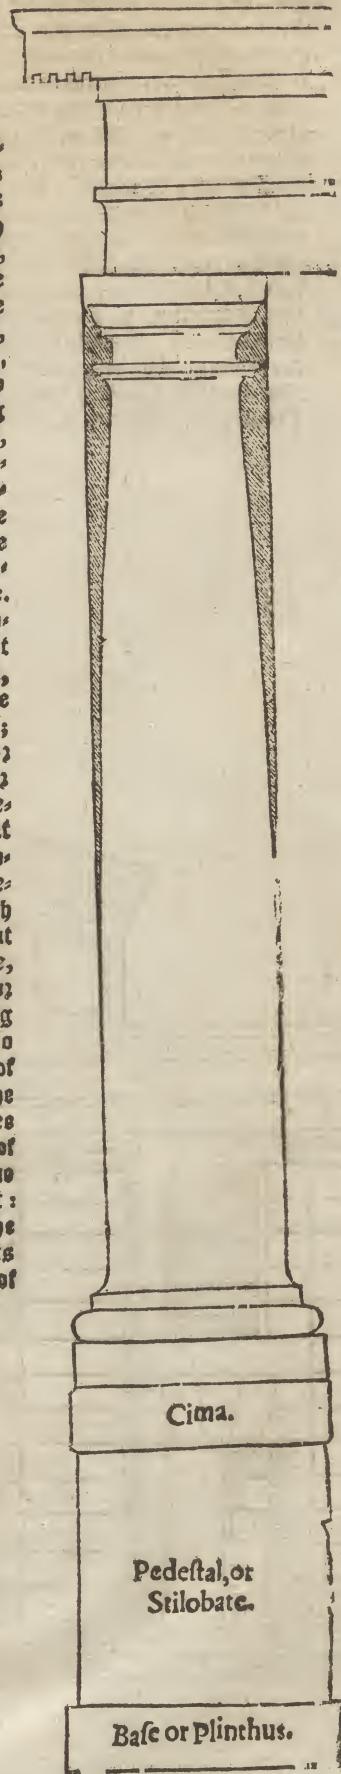

Of the Tuscana

The Colonne being finished with the Capitall and Base, then the Architrave, Frise and Cornice are to be set thereon. That Epistolum or Architrave must be as high as the Capitals, and the Venia or Lisk, the first part thereof. That Sophorus or Frise of the same height. The Cornice also, with her members, must be the like: and the same being divided in foure parts, one part shall be for the Cimatic, two parts for the Corona, and the last for the Facie under the same. The Projecture or bearing out of them all, must be at least so much as their height: And under in the Corona you may cut channels or hollowings, great or small, as the worke is, at the pleasure of the workman. But, for that this worke is grosse, and plaine of members, a man (in my opinion) may take upon him to adde some parts vnto it, which may seme to belong vnto the same; which must be done when men desire to make the worke shew better, as you see in this here vnder set downe. I commend also those crownes that haue most Projecture or bearing out, without their fouresquares; especially, when the Stones are fit to beare it: Which Projectures are both commodious, and beautifull the worke: commodious in this, that the walking place vpon them will be broader, and it will also keepe the worke from water: beautifull in this, that when men behold the worke with convenient distance from it, it will shew the greater; and where the Stones bee scant, by reason of their smallnesse, the Projecture will supply that want, by shewing greater.

Although I said before, that the Tuscan Colonne (according to Vitruvius rule) ought to be of seven Diameters high, with Bases and Capitals, which proportion is approved good; nevertheless, for that the first Colunnes (as you have heard in my small Booke) were made in five parts, taking the measure from mens feet, which is the first part of the same: And also, for that the Colunnes called Dorica, are now of seven parts, the ancient workmen having another part unto them, to heighten them, therefore, in my opinion, by the same authority, for that the Tuscan Colonne is stronger then the other, I judge, it might be made lower then the Dorica; and, by my advice, be made but of five parts, with Bases and Capitals, this you may hold for a common rule. And, for that neither Vitruvius, nor any other workman that I have seen, have set downe no rule for the Stilobato or Pedestal, and in Antiquities, as far as I can see, were by workmen made, as necessitie required; whether it were for raising of Colunnes, or to a going by with staves, to Galleries, or by any other occasions: Therefore, not being compelled thereunto, I am of opinion, that every workman should to each kind of Colonne set a convenient and seemely Pedestal, as reason requireth, and as hee seeth cause. It is certaine and well knowne, that the Pedestal at least must be square, that is, the body thereof, without Base or Cime, therefore the Tuscan Colonne being the best of all, the Pedestal thereof ought to be a perfect square: the top part thereof ought to be as broad as the Plinthus of the Base of the Colonne: the height should be divided into four parts, one part wherof shall be set vnder, for the Plinthus, and one for the Cime, which members shall be vncut: so then, if the Colonne be of five parts, the Stilobato or Pedestal shall be of five parts also in it selfe, according to the proportion of the Colonne.

Of the Tuscana

I have promised in this Booke, onely to intreat of the ornaments and different maner of Buildings: therefore I will not, at this time, shew how men should place the Gates of Townes and Forts, with their sides, places to lay out Cannons, with other circumstances of defence, leaving such care to the workemen belonging to warres, according to the situation and accidents of time and place. But I will shew you, that when the Gates of the Citie, Towne or Fortresse are placed, how men, in my opinion, should set them forth, setting down some Figures thereof. You must understand, that each Gate or Post is to bee after the Italian maner, and ought, of necessity, to have a Posterne Gate, which are called Porten van Secourse, which are the small Ports on the sides. But to observe the Symetry, that is, a due measure, it is thought to be made in this manner. The measure of the Gate is thus, as much as the breadth of the light shall be for the breadth of the Pillars on epyther side of the Gate: the flat of the Pillars thereof shall be as broad as the third part of the light, and the height, with Capitals and Bases. The height of the Bases shall be a third part of the breadth of the Pillars, and so much also the Capitals, observing the rule set downe in the first Columne. That Cypselum, Zophorus, and Corona shall be altogether of such height, as the breadth of the Pillars, by the rule aforesayd. Betwene the one Pillar and the other, the Posternes or small Gates shall bee, and the widenesse shall bee as broad as the flat Pillars. The height shall be twice as much as the breadth: the Pillars shall be the third part of the sayd Posterne. The elevation or raising up above the gate, shall bee as the workemans will. But the proportion of the Fastigies or Frontispicie (which is called with vs, the spanning, cover, or rofe) I will shew in two sorts in the order of Dozica.

Ad so; that the workeman ought to be capious of inventions, to please himselfe and others, the Gate of the City, Towne, or Fortresse, may be set out in this maner, obseruing this rule: that so broad as the going through of the Gate is, the height shall be as much, and halfe as much agayne, that is, 2. parts in bredth, and 3. parts in height. The Pillars shall be the 8. part of the widenesse of the Gate: and the Columnes stand for the round Columnes and flat Pillars, being the fourth part of the Gate. But so; that the Colonne is a thirde part set into the wall, and is bound fast with other stones, moze for shew then bearing, it is to be made 7. parts high, and also of 8. at the workemans will, which will set forth the Gate with moze shew. The widenesse of the Porterne shall be the halfe of the middle Gate, shall be the Supercilie, or Architraue thereof, as we call it: and if you find not a stone all of one pece fit for it, then you shall make the Cunei or Pennants as you see them heere in the Figure. And thus the proportion of the Porterne shall be, that is, 3. parts in bredth, and 5. of the like parts in height. The Cunei or Pennants of the Arch, shall be 15. In the Bases, Capitals, Architraue, Fræse, and Cornice, you must obserue the rule aforesayd; and the eleuation in the middle shall be at the workemans will, as I sayd of the other: and all such workes, the groser they be made, and bo& out, the stronger they are so; fortification.

Of the Thuscana

A man may make Gates of Townes and Forts in another maner, both playner and stronger, following the order hereunder set downe: and the proportion of the widenesse of the Gate shall be as much as the height is under the Facie, which beareth up the rooffe: and from the Facie upwards, as much higher as the halfe Circle; yet alwayes at the workemans will to be increased or diminished, and especially, as he is by accident restrayned. The two Portes are to be made, as I have before shewed: Their widenesse must be the halfe of the middle Gate, and so much of the wall shall be left betwene the great Gate and the two small: which height shall be doubled with the bredth, and the Facie, which upholdeth the Arch, shall also hold up the Cornice of the small Gates. Yet must wee take such order, that the Facie showing through, should bee the Supercilio, which, as I sayd, may bee altered at the will of the workeman; without altering them from the Figure.

Divers kinds of ornaments, many times, put the workeman in mind of things which he peradventure would not have thought of: Therefore the figure ensuing will serve the workeman to good end in building, as occasions shall serve: as in the wall of a fortresse, where the wall being of a good thickness, this worke within it would first serve for a place to stand vpon in, making the walking place above broader; and easily for defence in time of warre: and for more securitie, it might within be filled up with earth. It might also be the workemans chance, to build about an Hill: and to free himselfe thereof from the waters, that alwayes with the rayne fall from it, & make the earth to sinke, it is therefore necessary for the workeman to set the like buildings against such an Hill, whereby he shall be assured from such suspicion, and it will also be a great strengthening to the worke. The like invention Raphael Durbin used at Monte Mario, a little above Rome, in the Vineyard of Clement the seventh, by him begun in the time of the Cardinal Ieronimi Gonga: and without Pisera, for the defence of water against a Hill, was made the like.

Of the Thuscana

Ancient workemen, in this kind of rusticall worke, haue vsed many and severall kinds of Buildings, as you may see hereunder, wherewith a workeman may helpe himselfe in many things, as necessitie requireth: the measure shall be, that the light shall be a perfect foursquare, and the wall betwene both, shall be a fourth part lesse. That Supercilie or Architraue, shall haue the fourth part of the light, and shall be made of Pennants which run vpon the Center in vnequall numbers: and about the Supercilie shall be layd an halfe Circle, deuised in nine equal parts, the lines being also drawne vpon the Center. The Cunei or Arch-stone being formed, and the three pieces layd betwene it, with the Facie aboue it, will in this sort be an everlasting worke. But so that the Cunei of the Architraue must lye fast, it shall be needfull to fill the halfe Circle with Bricks. And for the moze beautifying, you may vse Kotes, as the ancients vsed to doe, as you may, at this day, see in Rome at S. Cosmians and Damian; which, although the Stones be old, yet it is very strong.

As in the beginning I said, the workman may use this Gate in diuers places, but not for Fortresses, for the passage through serues not for Artillerie, or other great preparation for wars; neuertheless, this part may well serue for the outtermost Port or Gate: The proportion shall be, that the light or opening shall be twice so high as the breadth. The Archstones of the halfe Circle shall be nine, drawing vpon the Center of the Circles. The Facie vnder the Arch shall be the seventh part of the Gates; from the Facie downewards to the Pavement, shall be denided into seuen parts and an halfe, and shall be six stones broad: three whereof, shall be each a part and an halfe, the other three of one part; and thus the seuen parts and an halfe are denided. The height of the middlemost Archstone, or the closing Stone, which you will, shall be halfe as broad as the Gate. The Facie about the Archstone, must be as broad as a foot, that is, the thinnest part of the sayd Stone: but the middlemost Archstone, and also the soote vnder, shall be a fourth part broad.

Of the Thuscana

The proportion of this Gate, viz. the opening is twice as high as broad: the Pillar and the Arch are a fifth part of the breadth of the light: the great Pillar shall be once so broad againe, and the height of five breadths. The height of the Base shall be a fourth part, and the Capitall a third part, and so great the Capitall or impost under the Arch shall be. The Frieze in the place of the Architrave shall be as high as the Capitals: the Frieze also as much, and also the Cornice, following the rule aforesayd: the rest may be found with the Compass.

Although the Gate hereunder set downe is much different from the fashion of the rest, yet, for that it is Thulcan worke, and ancient, I thought good to set it here, the which, in former time, was in Rome, En Capo de la militia Traiana, although by the decayes thereof, now not to bee seene; the two piches or seats that stand by it on the sides, are out of their places, with which the ingenious workeman may serue his turne withall, if he place them where they should stand. The proportion of them (by the rule also layd, may easily be found: touching the gate it selfe, I will set downe no measure, for it is very easie to be found.

Of the Thuscana

This maner of Gate is covered by the first part of the Circle, and is very strong worke, yet the Pennants will not agree with other Buildings of Stone: therefore if a man will make such worke, it would stand well in a wall of Bricke. Touching the proportion, I will not speake, for that it is easie with a COMPASSE to find the measure thereof. But the Pitches or seats, placed by it to fill up the place, the workeman may, at his pleasure, set where he thinketh best, and they may not onely serve for Pitches, but also for windowes: if they should be used for Pitches to place Images therein, it is necessary, that the height should exceed the double proportion of the breadth or somewhat more, that they may be more fit and correspondent for Images to stand in, which is alwayes referred to the workeman.

Of the Tuscana

In times past, the Romanes used to mingle Dorica, Ionica, and sometime Corinthia, among their rustical buildings; but it is no errour, if a man mixe one of them in a piece of rude worke, shewing in the same, nature and Arte, so; that the Columnes mixed with rough Stones, as also the Architrave and Fræse, being corrupted by the Pennants, shew the worke of nature: but the Capitalls, and part of the Columnes, as also the Cornice, with the Frontispicis or Gueuell, shew worke of Art. Which mixture, in my conceit, is a good sight, and in it selfe sheweth good strength, therefore fitter for a Fortresse then for any other Building: neuertheless, in what place soeuer the rusticall worke is placed, it will not bee amisse. In such mixtures Iulius Romanus tooke more delight, then any other man, as Rome witnesseth the same in sundry places, as also Mancua, and without Rome, the sayre Palace called vulgariter El. Te. Which, in truth, is an example in these dayes, both of good Architecture and paynting. The proportion of this Gate is to bee made thus: the widenesse must be of double proportion; that is, twice so broad as high, iust vnder the Arch. The Pilaster shall be the seventh part of the widenesse, and the Columnes twice as thicke as the Pilasters: the height with the Capitall shall be eyght parts. The Capitall, Fræse, Architrave and Cornice, shall bee made as is sayd before: also, the Fastigium, Frontispicium or the Gueuell shall also bee shewed in Dorica order. The halfe Circle of the Arch, shall be divided in eleuen parts, so; the stones of the Arch; but the closing-stone shall bee greater: the which stone the workeman may at his will, hang somewhat out. The Facte which do; uphold the Arch, shall bee halfe the thickenesse of the Columnes: from thence downwards, you shall divide it into nine parts, whereof two parts shall bee for the nether part of the Columnes: the other seven divided into equall parts, shall be the stones which bind the Columnes, drawing crosse ouer them. And the ruderer this worke is boxed out (yet artificially) it would, in that case, shew more workemanlike, especially the Stones that bind the Columnes and also the Pennants.

It is not sufficient that the worke should be strong, but it must also be made artificially, to please mens sight. Wherefore this building of Stone is not onely very strong, but also ingenious and pleasing: with which invention, the workman may serue his turne in many things. The proportion shall be, that the opennesse in the bredth, shall be once, and halfe as much as in height: the halfe Circle is deuided into 9. parts and an halfe, because the middlemost stone is one fourth part broader then the rest. The height of the closing Stone, is halfe the opennesse of the light. The flat Facie holding the Arch, is the first part of the light: from the Facie downewards are 7. parts made: the Facie about the Pennants, shall be as broad as the closing Stone vnder it, which may be made hanging out vnderneath the eyght part of his bredth. Touching the binding of the other Stones with the Pennants, you see it playnely in the Figure.

Of the Thuscana

For that pleasure is sometimes turned into beautifying, and sometimes to ornaments surpassing necessitie, to the Art, according to the wealth of the builder: This inention is made for pleasure, strength and beautie: for pleasure, in regard of the opennesse thereof: strength, for that betwixt both, there is good use of wall, well bound together: and for beautie, because it is rich of ornaments; with which inention a workeman may helpe himselfe much, in diuers things, as I haue sayd. The proportion thereof shall bee, that the closed or masse worke shall bee as broad as the opening: which opening shall be of twice so much height. The Pillasters shall be the eighth part of the widenesse, and the Columnes the fourth part. The inter-Columnes, that is, the widenesse betwixt the two Columnes, shall be the thicknesse of one Columne. The height of the Columnes, with Bases and Capitalls, shall be of eight parts. In the Architrave, Frise, Cornice, Bale and Capitall, the rule aforesayd shall be obserued. The Pennants and other bindings are seen in the Figure: and although the Columnes surpass the rule two parts, yet, because they stand nere together, and are made fast in the worke, more for beautie then strength, it may passe well inough, by the authoritie of ancient workemen.

Is an excellent thing in a workeman to be full of inuention, in regard of the diuersitie of accidents which belong vnto building: so sometimes a man shall find some of Columnes, but so low or short, that they serue not for that purpose, for which men would vse them vnto, vntill the workeman deuise some meanes to helpe them. Therefore, if the Colonne be not so high as it will reach to the Facie, that lyeth like y^e roofe of this Gallery, then with these maner of Pennants a man may rayse it higher, if on both sides it hath good strong shoulders: touching the wayght aboue, it will be very chargeable, therefore to make it without binding of iron barres, it would not be sure: but it is lesse to be feared, if the Gallery were not so broad, but that it might be covered with stones that were all of one piece, or else to make strong beames therein. The propoztion hereof shall be, that the widenesse of the Arches shall be the thicknesse of 4. Columnes, and the height twise as much. The least space betwene the Columnes, shall be of the thicknesse of 3. Columnes, and the height, of the thicknesse of 6. Columnes, and each widenesse shall be once agayne as high as broad. The Columnes, if they be ouer-burdened with wayght, should be of the measure before set do wne; the rest are clearely to be seene in the Figure: but touching Bases and Capitals, I haue sayd sufficient at the first, in the treaty of the first Colonne.

Of the Thuscana

As this Arch is very strong, considering the concordance of the binding, so also it is ingenious and pleasing to view. Which invention shall not onely serue for Galleries of such worke, but for Bridges over Rivers; Conduits to carry water from one Hill by to another, and so to a Conduit. The proportion is, that the widenesse from one Pillar to another, and also the height, shall be to the Facie that beareth the Arch. The Facie shall be the seventh part of that widenesse; height: from the Facie do downwards is devided into six parts: the halfe Circle into nine parts and a quarter; so the closing stone is the fourth part more then the other: the rest may be found with the Compasse.

It may sometimes fall out, that a workeman should need many holes in great walles, for the building of his House, whereunto this worke belongeth, to carry the wayght for strengthening thereof: and were there not so much need of light, some of them might be filled up with Brick. The proportion shall bee this, that the space of the lights and the massie wall, shall be both of like bredth, and twice so high as broad, although all such things are to bee increased and diminished at the workeman's pleasure. The like worke is yet to be seene in Rome, being not very old made, but such as are in these dayes made, and stronger. The example whereof is at S. Colmas and Damianus.

Of the Thuscana

It is said, that sight preserues memozy, where by oftentimes that is made, which woorkemen would not haue made, if it had not beene made befoze in some other place, and so, at some times, you shall see in a Court or elsewhere a side of a Wall, that shall haue neyther Doze nor Windows in it, and yet it is well set out in this rude maner and bozish kind of woрке: by which inuentton, a woorkeman may helpe himselfe: In which places a woorkeman may set Images, or other reliques of Antiquitie. Touching the measures and propoztion thereof, I will not set it downe, for I leaue it to the woorkeman so; to heighten or make broad, as occasion serueth.

For that the most part of the Supercilies or Architraves, as we call them, that are set over Gates or other things, by reason of the widenes (if the stones be not of a good bignesse) may yeeld to the waight, whereby in time, they breake and decay, as you may see in many places: Therefore you shall, although it bee in great distance (so that the Hoilders on the sides be strong) make such worke of peeces, as hereunder are in diuers wayes set downe: which, without doubt, will be very strong: and the heavier the waight is above, the longer it will last.

Of the Thuscana

Although that in Virruvius writings there is no mention made in what maner men in ancient times made places in Palaces and common houles to make fire in, yet men find in olde buildings some shew of Chimneyes, to give a way to boyd smoke, neyther can I find by any woorkeman the truth of any such matters: neuerthelesse, for that men many yeres since haue vsed, not onely to make fires in Halls and Chambers, for their ease, but are also wont to make diuers ornaments in, and ouer such places; and for that I intend in this Booke to speake of all the Ornaments that a woorkeman may haue cause to vse in building, therefore I will shew some formes of Chimneyes or fire places, after the Thuscana maner, as shalbe needfull in such buildings: the one delicately made without the wall, the other rusticall woork, made within the wall.

The first rufficall workes were made in this manner, that is, peces of stone roughly hewen out; but the ioyning together were proportionably made.

After, they divided the stones in more proportion and shew, with flat lists, and for more beautie, and for ornaments sake made these crosses in them.

Other workemen brought in wrought Diamonds, and made them decently in this manner.

And in proesse of time, things altered: workemen, for flat Diamonds, set flat tables, and rayfed them somewhat higher, as in this figure is to be seene.

Some other workemen used more differences and samelyer worke, neuertheless, all such workes haue their originall from rufficall worke, which is yet commonly called, Workes with poynts of Diamonds.

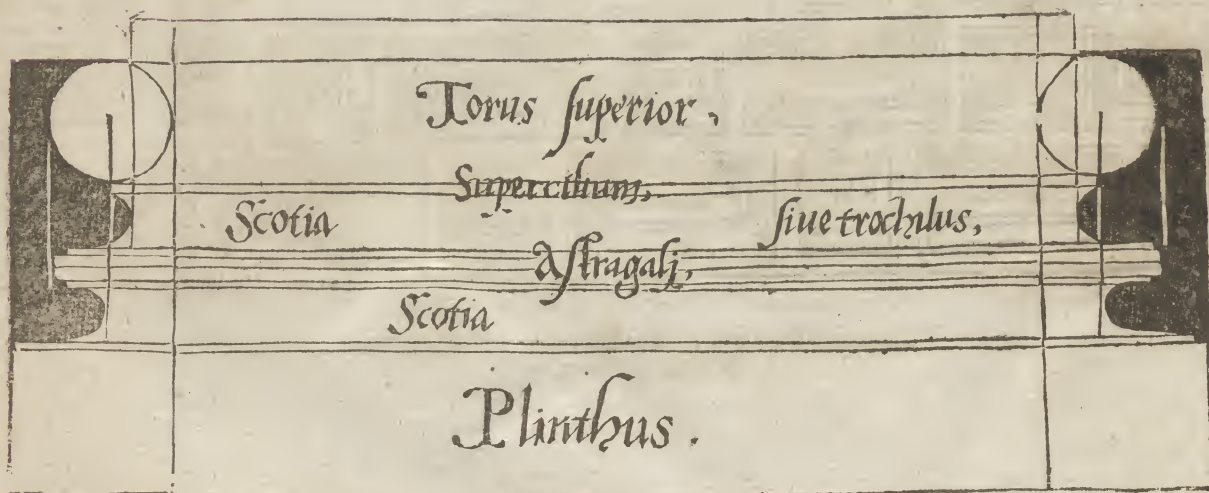

Here endeth the maner of Chuscan worke, and now followeth the order of Dozica.

The maner of Dorica, and the Ornaments thereof.

The sixt Chapter.

THE Ancients (as we haue heard) considering the state of their gods, ordained Dorica worke, and dedicated the same to *Iupiter*, *Mars*, and *Hercules*; but we build Temples, and dedicate them to *Christ*, *Paul*, *Gregory*, and such holy personages, that were not onely professed Souldiers, but also valiantly and boldly lost their liues, and shed their blood for the faith of CHRIST. All such belong to Dorica, and not to their gods onely, but to men of armes, and strong personages, being of qualitie more or lesse: for whom, if a workeman make or build houses or palaces, they must be Dorica: and the nobler the man is for whom such worke is done, the stronger and statelier they ought to be; and the more effeminate that they are, the more slenderer and pleasanter the building shall be, as I will shew when time serueth. But now we will come to the maner of the worke. *Vitruuius* speaketh of this Dorica worke, in his fourth Booke and third Chapter: but touching Bases of Columnes, hee speaketh thereof in his third Booke; although some are of opinion, that he speaketh & meaneth of the Bases of Corinthia, for that they haue bene much vsed on the Corinthia Columnes, and Ionica. And some also thinke, that Dorica Columnes had no Bases, hauing respect to many ancient buildings; as the Theater of *Marcellus*, one of the fayrest workes in *Italy*, being the middle downewards Dorica: which Columnes had no Bases, the body of the Columnes resting vpon a step, without any other support. There is at *Carcer Tulliano* the signes of a Doricall Temple, the Columnes whereof are without Bases. You may also see in *Verona* an Arch tryumphant, of Dorica worke, where the Columnes are without Bases. Neuerthelesse, for that workemen haue in former times made the Corinthia Bases in another maner, as I will shew hereafter: Therefore I affirme, that the Bases Atticurga, which *Vitruuius*, in his third Booke, so nameth, are the Dorica Bases: and this wee see, *Bramant* hath obserued in his Buildings which he made in *Rome*: which *Bramant*, being the light and Inuentor of good and true Architecture, which from Antiquitie to his time (being vnder Pope *Iulius* the second) had bene hidden, we ought to beleue. Then this Base of Dorica shall be the height of halfe the thicknesse of a Columne: the Plinthus the third part of his height: of the rest there shalbe foure parts made; one shall be for the Thorus aboue: the other three shall be set in 3. euen parts: the one for the Thorus aboue, the second for the Trochile or Scotia: but the same being deuided in seuen parts, one part shall be the vppermost list, and another the vndermost. The Proiecture or bearing out of the Base, shall be of halfe the height, and so shall the Plinthus of each Facie hold a thicknesse and a halfe of the Columne. And if the Base standeth below our sight, the corner vnder the vppermost Thorus, (being of it selfe darkened) ought to be somewhat lower then the other. But if the Base standeth aboue our sight, the corner aboue the nethermost Thorus (also of it selfe darkened) shall be greater then the other. Thereto also the Scotia, darkened by the Thorus, in such case shalbe made more then the measure appoynted. And in such cases the workeman must be iudicious and wary, as *Vitruuius* would haue him to bee learned in the Mathematicall science, that doth study his Booke.

Add so; that Virruvius hath deuised this order of Dorica by models, making the Colunne of two models in thicknesse, and the height with Capitalls and Bases of 14. Modelles; so then, the height of the Base is a Modell: the bodie of the Colunne is 12. models: and the Capitall one modell, which is 14. models in all: The height of the Capitall shall be deuised in 3. parts, whereof one shall be for the Plinthus, or Abacus, wherein also the Cimatie is to be understood: the second, the Echino with the Annulo: the third, the Hypotrachilo or Fræse, which Hypotrachilo shall bee in thicknesse the first part lesse then the Colunne below. The bredth of the Capitall in the uppermost part shall be in each Facie 2. Modelles and a sixt part: and this is according to Virruvius writing. Although I am of opinion, that this place is falsified touching the Proiecture, which, in effect, is very lame, in respect of that we see in Antiquities; therefore, after this Capitall, I will make another after my fantasie, with the particular measures thereof, better described, so; that Virruvius doeth it too briefly.

The Capitall being deuised into 3. parts, as I sayd befoze, I say also, that the Plinthus or Abacus should also be deuised in 3. parts, one part for the Cimatie with her Rule, List, or Fillet: but the same thicknesse deuised in 3. shall bee the List, and the other two the Cimatie. The Echinus shall also be deuised in 3. parts, and 2. third parts being for the Echinus, and the rest for the Annulo, which shall also be deuised in 3. parts, giuing each of them one. The Fræse shall bee as the others. The Proiecture of each part shall be like the height: and so doing, it shall bee made by moze certaine rules, better, and moze easily so; shew.

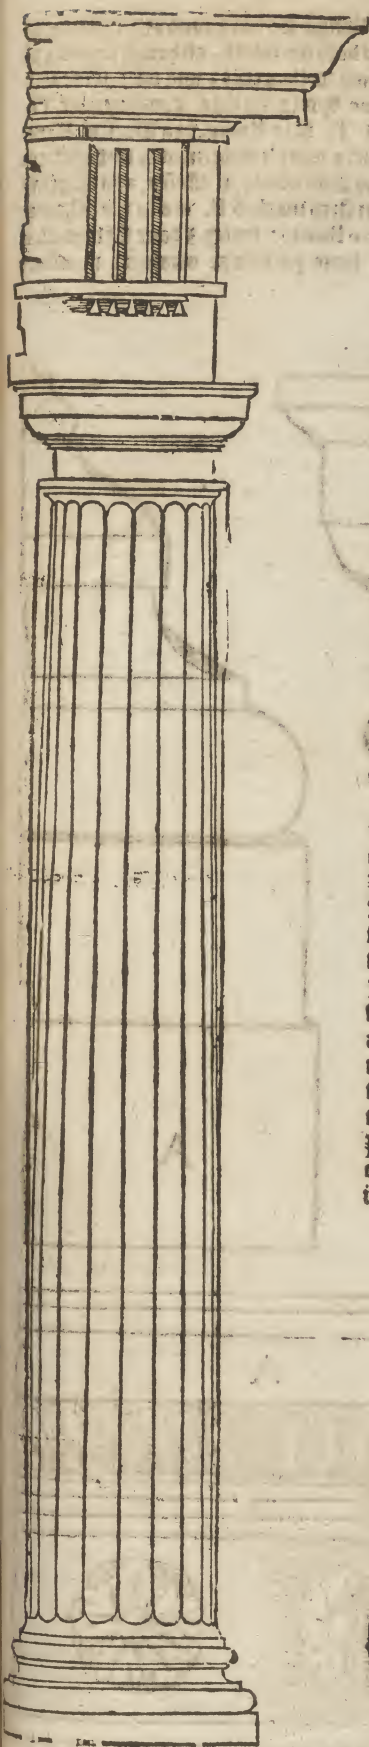

Of the Dorica

Vpon the Capitall you place the Epistila or Architrave, the height whereof shall be one Modell, and divided in 7. parts, one shall be the Tenia or Lisk: the Guttas or small Lisks under the Tenia (which Vitruvius nameth Sub tenia) are in all, the first part of a modell: which height being divided into 4. parts, the 3. parts shall be the Guttas, and the other the Lisk. The Guttas shall be six in number, hanging under the Triglyphes. The height of the Triglyphes or Triglyffe shall be one Modell and an halfe, and the breadth one Modell: which breadth divided in 12. on either side there shall be one left for the halfe Channels or hollowings, and of the 10. parts resting, 6. shall be for the flat of the Triglyphes, and 4. for the Channels or hollowings in the middle. And from the one Triglyph to the other, there shall be the space of a Modell and a halfe: which space shall be right 4. square (by Vitruvius named, Pethopha.) In which spaces, as you please, you may set, cut, or graue, Dye heads, with Dishes; and that, not without secret signification. For in ancient time, when the unbeleuing folke sacrificed Oxen, they also used Dishes, & Platters thereunto, placing such things round about their Temples for ornaments. Upō the Triglyphs, you must place their Capitalls: the height whereof shall be one first part of a Modell. Above the Triglyphs or their Capitalls, the Cozona must be placed with 2. Cimatices, the one above, the other below: and they both together divided into 5. parts, 3. for the Cozona, and two for the Cimatices. But the height of them all, shall be of halfe a Modell: upon the Cozona, you must place the Scima: the height whereof is halfe a Modell, and to it you must adde one eyght part for the Lisk thereof above. The Proiecture of the Cozona shall be of 3. parts: two be in one Modell: in the ground of the Cozona, right above the Triglyphes, the Guttas were orderly set, as you see them in the Figure hanging beside. Also, betwāne the Triglyphes are cut Fulmines, that is, winged lightning: or you may traue the spaces bare. The Proiecture or bearing out of the Scima must be like the height thereof: euen so, each part of the bearing out of the Cozona shall haue their Proiecture like their height. But the more Proiecture the Cozona hath, if the Stone may beare it, the more statelyer it sheweth. This, we see, that the ancient Romanes did obserue, as shall be shewed when time serueth, both in Figure and measure.

If you will strike or channell the Col-
 umnes, you must make 20. in num-
 ber, in maner hollowed, and from the
 one side to the other: in the spaces of the
 st. kes there must a straight line be
 drawne, which shall be the side of one
 4. square: which 4. square being made,
 placing the one foote of the Compas in
 the Center, and with the other touching
 both the one and the other end of the line,
 drawing it about, it will make the right
 hollowing, which shall be the fourth part
 of a Circle, as it is her under shewed.
 And if, for the raping by of Colunnes, or
 for other occasions, it were necessary to
 have the Stilobatum or Pedestall being
 not high enough, to be made higher, then
 the flat of the Stilobatum shall be like
 the Plintho of the Base of the Colunne:
 and the height, that is, the euen or flat
 shall be thus: of the breadth shall be made a
 perfect 4. square; and from the one corner
 to the other, a line drawne for Diagonus,
 and the length of the Diagonus shall be
 the height of the flat, as you may see it
 here beneath, which being divided into
 5. parts, there shall be one part set above
 for the Cimatie, with that belongeth ther-
 unto, and one other part shall be given to
 the Base, and so this Pedestall shall be of
 7. parts, as the Colunne is. And al-
 though this Proiecture of the Capital is
 contrary to Virruvius rule, because it is
 Perpendicular with the Plintho of the
 Base: yet for that I have seen the like in
 some Antiquities, and have also placed
 some of the like sort in pieces of worke,
 I thought it not amisse to set this here,
 for the use of those, that will make it like,
 although some of Virruvius schollers,
 not having seen the like in any Antiqui-
 ties, will contradict it: but if they marke
 the Abacus of the Corinthia, whose
 Proiecture also hangeth on the Plinthus
 of the Base, they will not so hastily re-
 iect this Proiecture.

Of the Dorica

For that I find great difference betwene the writings of Vitruvius, and the things of Rome, and other places of Italy; therefore I have here set downe some, which are yet extant in worke to be seene: which, although they bee of small forme, without numbers or measures, yet they are proportioned according to the great, and with great diligence reduced into small forme. The Capitall R. was found without Rome vpon a Bridge, standing ouer Tigber. That Capitall V. is in Verona, in an Arch triumphant. That Capitall T. is in Rome, in a Dorical Temple, called Al career Tulliano. That Capitall P. was found in Pesaro, with diuers other commendable Antiquities: the bearing out whereof, although it be great, yet it sheweth well to the eye. The Bases, or Bases, and Capitall A. are at Rome, in Al foro Boario. The Cornice, Capital, and Impossa of an Arch marked B. are in the Theater of Marcellus. The Cornice, Frase, and Architrave, are also in Rome, in Al foro Boario: which I haue shewed, that workemen may chuse that, which liketh them best. Hereafter I will set downe some particular measures necessary for the workeman.

The parts of the Triglyphes and Metopes being in this order vnprepared, and yet very necessary, I will take paynes to declare so well as I can. First, although Vitruuius affirmeth, that the Models of the worke Perastilos, viz. of five Columnes, may be distributed and deuided into 35. parts: yet I find not, that the parts may stand so, for this cause, that giuing the middlemost inter-Columne 4. Metopes, and the other spaces 3. the sayd number will not make the whole: but, as I conceaue, if you set 42. as you may see and reckon in this Figure following, as also in the worke Thetruskilos, that is, of 4. Columnes: the Worke saith, that the Forefront of the whole worke should be deuided into 23. parts, which, I assure you, cannot stand so, if you will giue the middle space 4. Metopes, and the other two eche of them 3. But, by my aduice, there should be 27. as you may see in the Figure following. When, if the principall of the Temples be deuided into 27. parts, the Columnes shall bee 2. Models thicke, the middlemost inter-Columnes shall be of 8. Models, that is, the thickest of 4. Columnes, and the inter-Columnes besides, shall be each of 5. Models and an halfe, that is, two and a quarter, and a quarter and halfe: and so shall the 27. bee distributed. And aboue each Columne his Triglyph being set, & the Triglyphes deuided with Metopes, according to the rule aforesayd: then the middlemost space shall haue 4. Metopes, and those on the sides shall haue 3. The height of the Columne, Capitall and Architraue, &c. shall be also made according to the rule: but the height of the Fastigium or Ceuell shall bee the ninth part of the length of the Cimatie, that is about the Cozona, setting the measures vnder the A. backwards to the vndermost Cimatie of the Cozona B. The Acroteria or Pedestall marked A. vpon the Fastigium shall be halfe the height of the Fastigium or Ceuell, that is, of the euen or flat, which Vitruuius calleth Timpanum, and they shall be as broad as the Columne is aboue, and the middlemost must be an 8. part higher then the other. And for that this Dooze or Gate is of Dorica, and is hard to be vnderstood, therefore I will shew in the best sort I can, both in writing and Figure. Vitruuius saith, that from the Pauement to the Lacnary, that is, from the ground of the Gallery, to the roofe of the same vnder A. must be deuided into thre parts and an halfe, and two parts shall be for the height of the lights: so sayth my Autho, in my opinion. But for that a man cannot so well in a small Figure explaine the particular measures, I will make it more greater and perfecter in the next leafe.

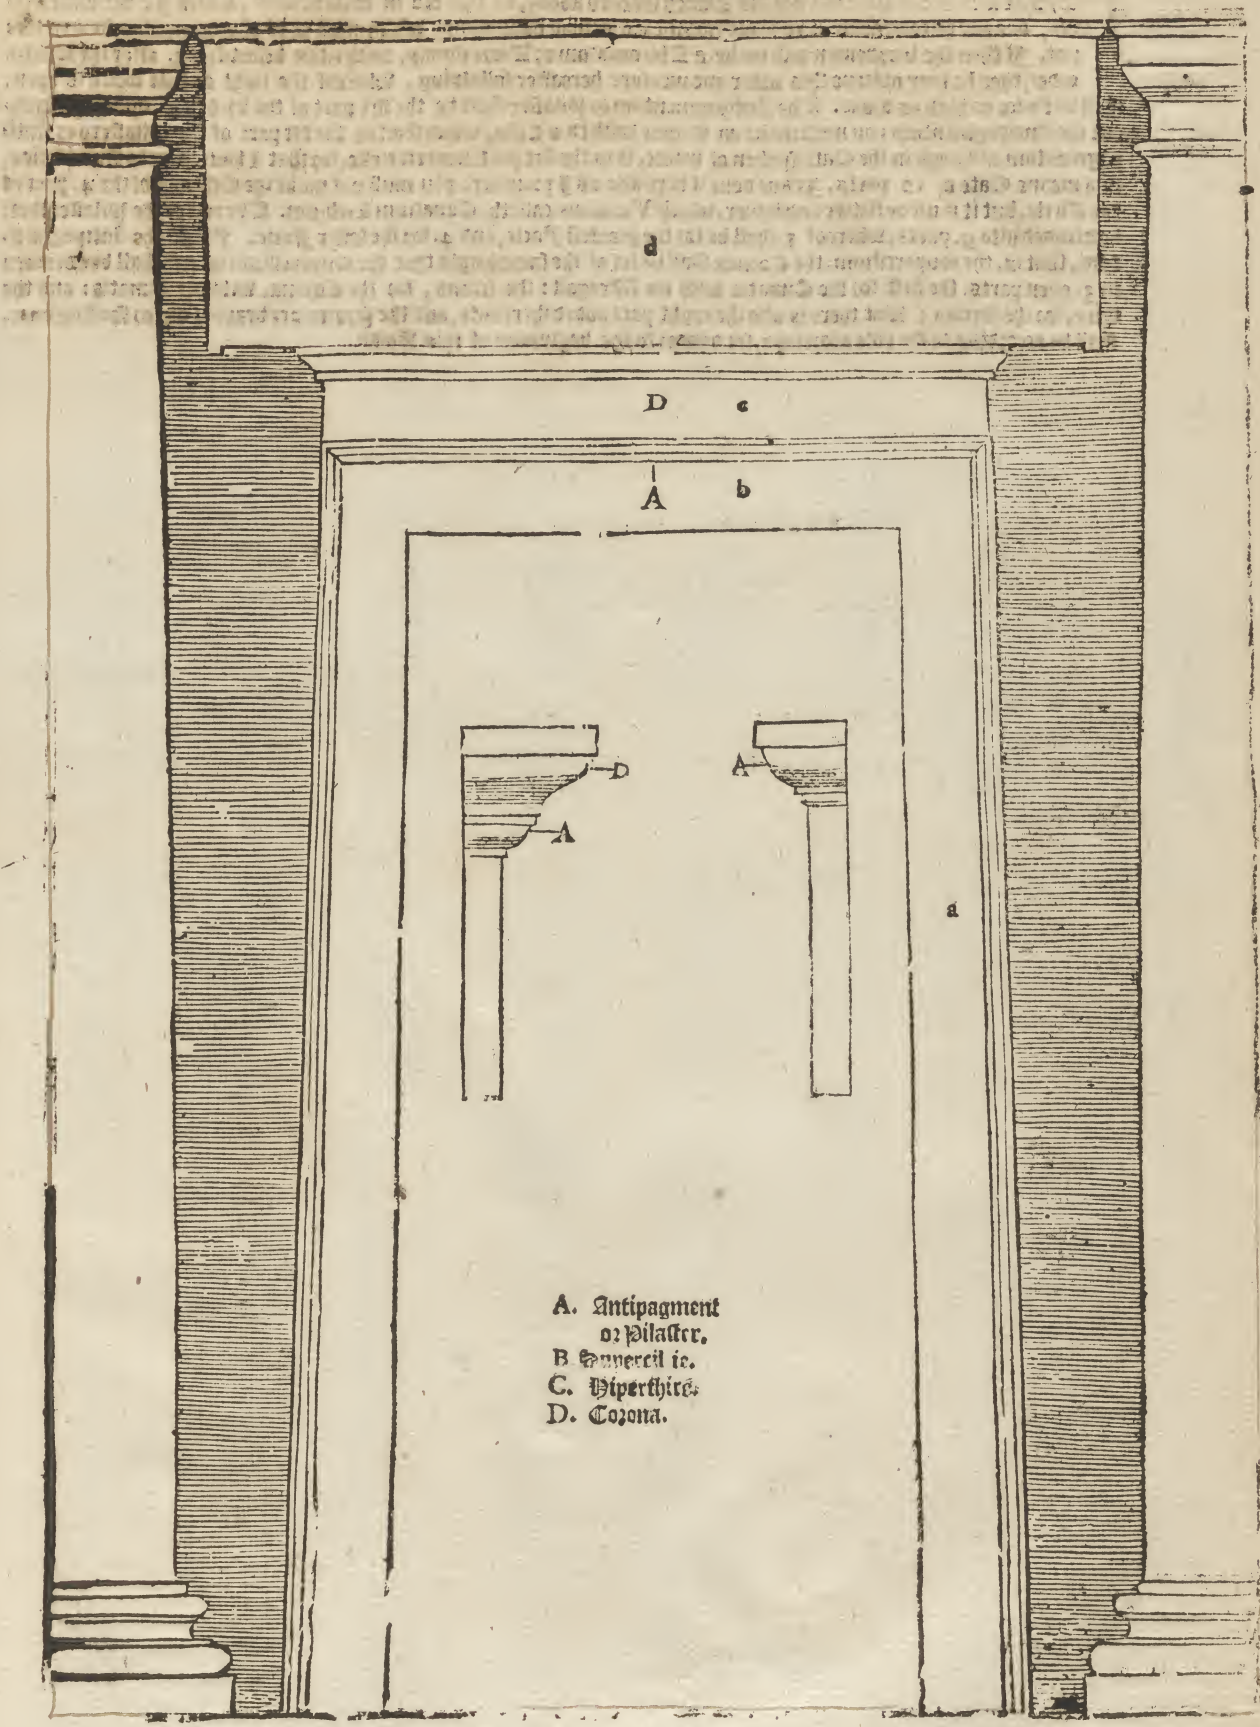

Having made (as is before said) three parts and an halfe from below upwards, 2. parts shall bee for the height of the light, which height being divided in 12. one part shall be the breadth of the Antipagmentum or Pilaster, and the light shall be 5. parts and an halfe broad: but if the light vnder be of 16. feet, the Pilaster shall be lessened a 3. part in the uppermost part: and the same Pilaster shall also be made thinner a 14. part above. That Supercilie or Architrave shall be of the same height, in the which the Cimatum Lesbium with the Astragal is to be made: which Cimatie shall be the 16. part of the Supercilie, I meane the Astralogus Lesbium, as it is shewed in the Figure A. It seemeth, that the Authoz meaneth onely the Cimatie about the Supercilium: but as it is seene in some Antiquities, therefore it is so made, in regard of the Antipagmentum. Upon the Supercilium, in stead of a Fræse, you shall set the Hypertygium as high; in the which, the text sayth, men cut the Cimatum Dozicum, and that Astragalum Lesbium in the Scima Sculptura, which is confused. But here I let my selfe to vnderstand, that the meaning of the Authoz is broken, where he sayth, Scima Sculptura: he would haue sayd, Sine Sculptura, that is, without cutting or grauing; and that is, Cimatum Dozicum, together, with the Astragalum Lesbium: the proportion whereof standeth in the Figure marked A. D. Now, for that the text saith, that the Cimatie of the Corona shall be of like height of the uppermost of the Capitals, which being so, then the Corona will be very great: to which (according to the Authozs meaning) I haue giuen as much Proiecture as the height of the Supercilie is. Although such Crownes will neuer be handsome or seemely in worke, neuertheless, to intricat of the Dynaments, I thought good to set downe my opinion herein, and to shew it in Figure.

Corrections of the aforesayd text, by S. Serlie.

I haue perused Vitruuius writing nearer, and with more deliberation, where hee speaketh of the Cimatie Dozica, and the Astragalo Lesbium, in the Scima Sculptura: and I find, that Scima Sculptura is meant of flat cutting, rising very little: now, for that I haue found many such like in Antiquities, viz. where the Astragals, Leaues, and Egges, &c. haue but small or little Proiecture or rising vp, therefore I let this for instruction of Translatozs, to be corrected touching Dozes.

And for that our Authoz hath set this correction of the Cimatie and Astragal here, wherein, in my opinion, there consisteth no great matter, I thinke it not amisse to helpe him a little in this matter touching doozes, wherein consisteth much. For where Vitruuius saith, that you must divide the part from the Pauement to the Lacunary in 3. parts and an halfe, it must be vnderstood, above towards the Timpanum marked B. and then the dooze would be well, and the Corona would be like the Plinthus of the Capitall. Now, for that the text is so different in other plaees, as in the middle of the Pedels, whereof Casarianus sayth, that he hath found 3. or 4. sorts; so it is to be feared, that this also is not well vnderstood. Thus much I haue (with your licence) thought good to set downe here, that the building should not be left imperfect, as our Authoz doeth. For although he sets downe the Figures of more dozes, yet hee sheweth not how they shall stand in the Building aforesayd.

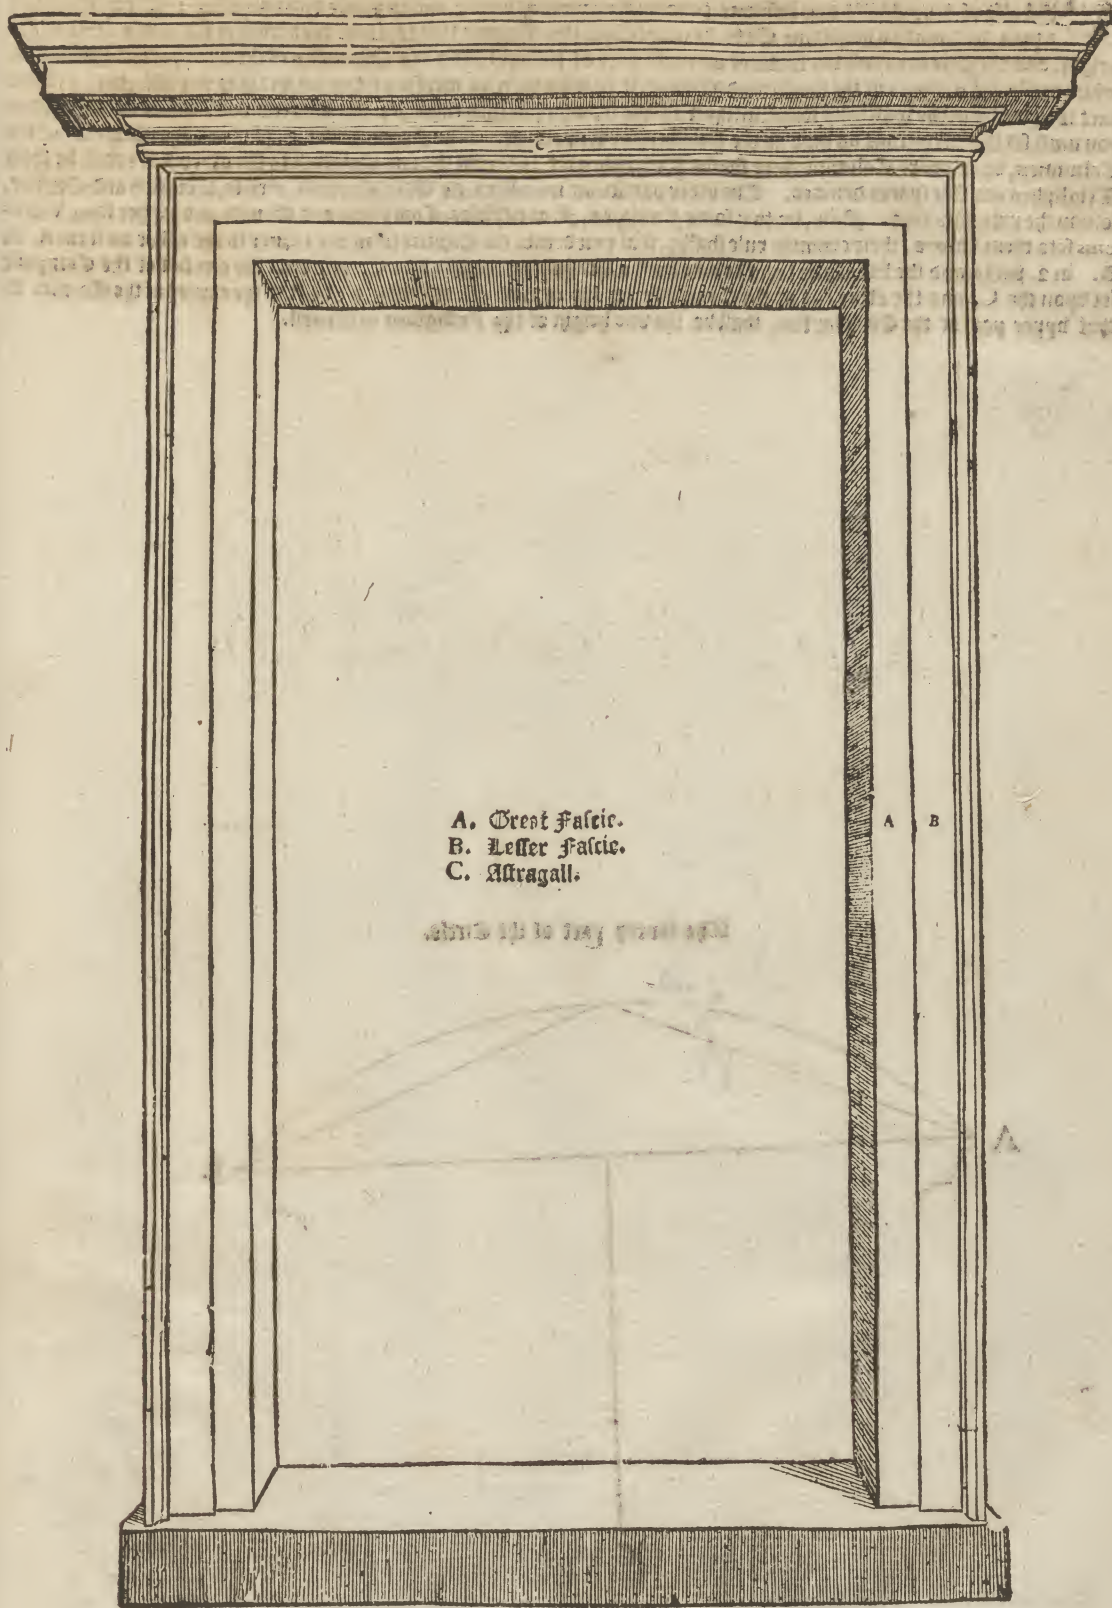

- A. Antipagment
or Pilaster.
- B. Emercil ie.
- C. Hyperthire.
- D. Corona.

Of the Dorica

For that men in our time doe not vse Dorica lessened above, as they did in ancient time; which I, for some reason, doe not discommend, yet some skillfull workeman have many, which most part of common workemen like not. If then the workeman will make a *Chromatum* of Dorica simply, with litle beautifying, after the Dorica order, then he may observe this order and measure hereafter following, whereof the light or that which is open, shall be twice as high as broad. The *Antipagmentum* of Pilaster shall be the first part of the breadth of the light: without the *Antipagmentum* you must make an *Echine* with two *Liffs*, which shall be the first part of the Pilasters or *Antipagmentum*, although in the Gate, spoken of before, it is the first part: nevertheless, for that I have seen in Antiquities, in a meane Gate of 12. parts, I have done it here also, as I promised: you must not make the *Echine* of the 4. part of the Circle, but it must be flatter and lower, which *Vitruvius* calleth, *Cimatum Lesbium*. The rest of the Pilaster shall be divided into 9. parts, whereof 5. shall be for the greatest *Facie*, and 4. for the lesser *Facie*. Above the *Antipagmentum*, that is, the *Supercilium*, the *Cornice* shall be set of the same height that the *Supercilium* is, and shall be divided in 3. even parts: the first, for the *Cimatis* with the *Astragal*: the second, for the *Corona*, with her *Cimatis*: and the third, for the *Scima*: But there is also the eighth part added therunto, and the *Prolectura* bearing out or *Quoting* over, shall be according to the rule aforesayd, set downe in the beginning of this Booke.

- A. Great Fascie.
- B. Lesser Fascie.
- C. Astragall.

A B

Of the Dorica

Although that in the Order of Dorica Vitruuius maketh mention of one Doric Gate onely, and darkly inough (in my opinion) as I shewed before, I thinke it requisite, that men shall not onely vse one sort of Doric Gates, but also of diuers sorts and fashions, to beautifie a piece of worke, and to please diuers minds : Therefore, when a man will make a handsome Gate, he may follow this Figure: that is, to set the breadth of the Doric twice in the height: and the Pillaster must bee made of an eyght part of the light, and the Columnes of the thirde part of the breadth; which shall be set 9. times in the height: and although it be moze then the measure set down, yet it is not false, because some part is made vp in the wall: also some Antiquities vse it, which in such cases are not ouercurious. Upon the Columnes you must set the Architrane as high as the Pillasters or Supercille. The Fræse shall be 3. parts of the thiknesse of the Columnes, vpon every Columne there shall be Triglyphes set, and from the one Triglyph to the other, there shall be three Triglyphes and five spaces deuided. The other particular members, as Base, Capitall, Fræse, Triglyph and Coznice, follow the rule aforesayd. Now, for that some Fastigies, Frontispicies, Coverings and Genels, are higher then Vitruuius sets them downe, their common rule shall be, that you deuide the Coznice from one corner to the other, as from A. to B. in 2. parts, and the halfe shall hang downeward, straght by the Lead to C. and then the one foot of the Compasse set vpon the C. and the other foot of the Compasse on the corner of the Coznice B. that vpper part of the Circular line, shall be the due height of the Fastigium or Genell.

The fourth part of the Circle.

A. Supercilie.
B. Epistilie or
Architrave.
C. Zophorus or
frons.

Of the Dorica

A Iteration oftentimes is better and more esteemed, then perfect simple forme in her owne nature: therefore it is the more pleasing, when a piece of worke is made of diuers members and parts, although of like nature, as you may perceyue in the Figure following, wherein there are Triglyphs and Gutiles, all in one order: which, in effect, I neuer saw in any Antiquities or writings. But Balchazar of Sienne, one that read and sought out all Antiquities, may, peradventure, haue seene some, or at least himselfe was the Inuentor thereof, placing Triglyphes about the Dooze, where they beare least streesse, and the Gutiles about the firme part of the Pilasters, which beare all the wayght of the Fastigium, and in my concept, samely, and was much commended by Clement the seventh, who, assuredly, was a man excellently seene in all Artes. This part shall haue the height double proportioned; but the Pilaster shall be the 7. part of the height, and the Supercilles the halfe thereof. The bredth of the Triglyphes and Gutiles, is the halfe of the Supercilles, and the height a double bredth, making 2. Gutiles ouer one Pilaster, and 4. Triglyphes ouer the Dooze: the spaces shall be all 4. square. About the Gutiles and Triglyphes, you must set the Capitall or Abacus: the height or thicknesse whereof, shall be a 4. part lesse then the bredth of the Triglyph, and the Cimatie the 3. part of the Abacus: The height of the Corona with her Cimatie, shall be as broad as the Triglyph is, and the Scima also as much: the bearing of the Corona before, shall be as much as the space from one Abacus to another, that in the ground there may be perfect foure squares: But the Projecture or ouer-bearing both on the right hand and on the left, shall be halfe so great as before. The Projecture of the Scima and the Cimatie, shall be each according to their height. That Fastigium in the highest part, shall be a fift part of the widenesse, from the one corner of the Scima in the right line, to the other.

Mutiles.

Although a man may make diuers kinds of Gates in Dorica worke, yet for that at this day men couet after nouel-
ties, especially, when they are made by rule and reason, although the Columne, Fræse and other members are
mixed with rusticall Building, yet herein you may see forme and fashion: and whereas I haue sayd, that a man
should vse rustical and woorsly woorks in Forts and Fortresses; now this may serue for a change, but not without,
so, receiuing of shot in them, &c. The light thereof is also double in height: the Colunnes two times so broad as the Pl-
lasters, being 14. Models high, with Capitals, Triglyphes, Felligium, &c. Let the Reader doe his pleasure further
herein, for me thinkes there consisteth little herein, and there is inough sayd as before.

Meaning was, in the beginning of this Booke, to speake onely of the ornaments of the five Orders of Buildings, as of Columnnes, Pedestals, Epistiliums, Zophorus, Cornices, Gates, Windows, Niches, & such like things. But, after that I determined to augment and enrich this Volume, in shewing diuers Facies or face parts of Edificies, Temples, Palaces and Houses, &c. And for that, when as the Colunne standeth vpon the ground, they are commendable; yet oftentimes it falleth out, that men haue not their Colunnes thicke enough, nor long enough, as they desire, so that it is necessary to place Pedestals vnder them: therefore I haue made this order following, the proportion whereof shall be as followeth: that the widenesse shall be double in the height: the Pilaster with the Arch, shall be a 12. part of the widenesse: the Colunne as thicke againe: the inter-Colunne halfe the widenesse of the light or Dore: the widenesse of the Niches, 2. Colunnes thicke, and 4. in height: the Pedestals, 4. Colunnes thicke in height: his breadth, and the rest, as is before sayd. The Colunne, with the Base and Capitall, shall be 9. parts high: the Epistilium is halfe a Colunne thicke: the Triglyph of the same breadth, and twice so high with the Capitall. The Triglyphes placed as you see them, the Corona and the rest of the members shall be made as is before shewne. The height of these Seuels somewhat exceed Virruuius writings; but I haue seen such an other, somewhat higher, in Antiquities, being made of the first part of the Corona in length. The Acroteria shall be of height and breadth like the Colunne above, without Cornice: and the middlemost a sixt part higher, as also the Colunne a 9. part, being made fast in the wall.

Of the Dorica

This Figure following, may be used by the learned workman for diuers things, and may be altered according to the accidents that shall happen: it will also serue for a Painter to beautify an Altar withall, as men at this day doe in Italy: it may also serue for an Arch triumphant, if you take away the Basement in the middle. Likewise, you may beautifie a Gate withal, leaning out the wings on the sides: sometimes, for setting forth a Window, a niche, a Tabernacle, or such like things: which proportion shall be made thus, The opennesse or widenesse shall be deuided in 5. parts, and one of them shall be the thicknesse of the Columnnes: the Facies or List round about shall be halfe a Colonne thicke. The height of the light shall be the thicknesse of 7. Colonne, and the Base and Capitall together, of the thicknesse of a Colonne, and in all, shall be eyght parts high. That Pedestall shall be 3. Colonne thicke in height, the breadth or forepart like the Plinthus vnder the Colonne. The inter-Columnnes on the sides shall be one Colonne thicke, and in the Corners shall stand the fourth part of a Colonne: the wings on the sides, wherein the Niches are, shall be of the thicknesse of a Colonne and a halfe, but the Niches a Colonne broad, and 3. in height. The Architrave shall haue the halfe thicknesse, and the Trigliph also as broad, but the height without the Capitall shall be a 4. square, and two 3. parts; whereby, placing the Trigliphes on the right side, and on the left, right aboue the Columnnes, and betwene both 3. Trigliphes, and 5. Pethophes more: the deuisions shall rightly come to be 4. square in the spaces. The Corona and the Frontispicie, and all the other parts, as well below as aboue, shall be made as is taught in the beginning. And for that the Trigliphes on the sides differ from Verrius doctrine; yet, notwithstanding, I haue sene them in Antiquities stand vpon the corners, the workemen may, at their good pleasures, make them in tozke, or beare them out, as occasion shall serue. Further, I had no meaning to set any grounds or platformes in this fourth Booke, for that it is intended to be intreated of elsewhere; yet such foresights as are hard to be vnderstood, I wil set the Ichnotypie or ground, for more light to the Reader.

Of the Dorica

Although in Antiquities, as farre as is found, taken from Grecians had placed the Epistolia upon the round Colonne, they set nothing else but the Festigium upon that, being the same order in Churches and Temples, and not in any other buildings: Nevertheless, I will not omit to set downe some manner of Houses without Arches: for if you will make Arches with their fouresquare Pillars and round Colunnies before them for beautifying of the worke, seeking to make much light in your Gallerie, the Pillars with the Arches will hinder a great deale of light: When if you will set the Arches onely upon the round Colunnies, that were altogether false, for that the foure corners of the Arch would surpass the roundnesse or body of the Colunnies: therefore I intend, to make some Houses and other Buildings without Arches, both of this order, and also of the other. This shall therefore be made in this manner, that the greatest inter-Colonne shall be the thickness of foure Colunnies, and the smallest of one and an halfe. The height of the Colunnies shall be of nine parts, with Bases and Capitalls: the Architrave, Frise, and Cornice, &c. shall be made according to the former rule: the widthnesse of the windowes are of two Colunnies thickness: the height a fouresquare and two third parts: and their Pilasters one sixt part of the light, having the Cornice above, like the Capitall. The doores shall be of the breadth of three Colunnies, and seven in height: and so shall the lights of the windowes, and of the doores, be all one height. The Triglyphes and Metopie shall be divided, as you may perceiue, as you may perceiue. The second story shall be lesse or shorter by a fourth part, according as Vitruvius giueth counsell: so also, shall the Architrave, Frise, and Cornice be a fourth part lessened: the windowes thereof, with the Pilasters, should be as broad as the lowest. The ornaments in the Niches shall stand in Perpendicular, with the Colunnies: and the height of the Niches, shall be as broad as the inter-Colunnies: their heights shall be of two fouresquares and an halfe: the third story shall be shorter a fourth part then the second: The Architrave, Frise and Cornice accordingly: but being together divided in three parts, one shall be for the Architrave, the second, for the Frise and Dentils or Modillions, and the third, for the Cornice: You shall find the particular measures hereof after the Composita: the windowes shall also be as broad as the lowest, but the Niches shall be a fourth part less: the rest you shall lightly find.

Although in the Tuscan Order, in the Facie 13. I have shewed the like invention, this, notwithstanding, differeth: for that this Gallery would be round roled, and where the Arches are, the crossings would be made as you see in the ground. And for that the Columns cannot uphold the stones, alwayes giuing out, therefore about the Columns, you shall lay or fasten Iron bindings, in the sides, as you see it in the platforme, but they will last longer, if they be made of brasse. The proportion of this Facie shall be made thus: The greatest Intercolunnes shall be 4. Columnnes thicke, and the least two. The height of the Columnnes, with Bases and Capitals, shall hold 7. times their thickenesse. The Epistilium shall be threë soure parts of a Columnne thicke: about the which, there shall be a halfe Circle made, the breadth thereof shall be halfe a Columnnes thickenesse: vpon the Arch you shall set the Cornice of the height of the Epistilium. Betwene both the Arches there shall be the manner of a window made, the wideness thereof shall be like the Intercolunnes vnder it: and the List or edge, as broad as the Arch. That Canet or Trochile, and the Echine about the windows, and part of the Cornices, shall, neuertheless, beare out somewhat about the windows, for to beautifie the same. The wideness of the Doores shall be two Columnnes, and one fourth part. The Pilaster or Antipagmentum, shall be a first part of the light: the height of the light shall reach to the Supercilie, iust vnder the Capitall of the Columnne: which forme of Capitals shall follow about the doores and windows. The light of the windows shall be in breadth two Columnnes in thickenesse: but these thickenesses aforesayd, in these cases, are to be vnderstood as the Columnnes fall out. The length of the light shall be a soure square and a halfe: The Piches shall also be of the same height. The Rose about, or the second Stage, as you will terme it, shall be lesse or shorter a fourth part, deuided in this sort: The Podium or part best high, of one Columnne and a halfe in thickenesse. The rest shall be deuided in five, one of them shall be Architrave, Frise and Cornice. The Piches with the Ornamentals shall stand in Perpendicular about the windows, betwene the Arches; but shall be in breadth five parts: two parts shall be the Columnnes, the rest the Piches with the Pilasters. The Cornice about the Piches shall be the breadth of one of these Columnnes: and the Bases, the halfe breadth thereof. The windows betwene the Piches, shall in the light containe one fourth part lesse then the doore, and of double height: but of the rest of the Ornamentals (so that this worke is somewhat mixed) you shall find further satisfaction in the Ionica and Corinthia. The Triglyphes in this composition, be thwirt the one and the other, will not make their Apertures right soure square, because I haue set threë Triglyphes about each window, and as many ouer euery of the Piches, as you may see in the figure: wherein, if there be any thing wanting in the measure, or else what, I alwayes referre my selfe to the rule set downe in the beginning.

For that sometimes, some men will haue altogether Arches and Galleries, and soz that it is confused worke, to place Arches vpon round Columnes, yet a man may make square Pillars vnder them with Bases and Capitals, like the other. And although this house is whole, which is but little soz a man that hath a great living, yet you may set it forth in 5. Arches, also in 7. Arches. The Dimension whereof may be, that each Intercolonne may be of the thickness of foure Columnes. The height of the Columnes with Bases and Capitals of six parts: and about them the Arches to be set of the breadth before, of halfe a Colonne: the opennesse shall bee of double proportion. About the Arches you must place the Architrave, Fræse, and Cornice: the height of them all shall be of 2. Columnes thickness: and being deuided in 3. parts and a halfe, one part shall be the Architrave, halfe a part soz the Fræse, and one part soz the Cornice: soz the other part, you shall follow the rule aforesayd. The doze shall be two Columnes outward: the Pilaster, the first part of the light: but the Cornices of the doze, and the windowes, shall haue the height of the Capitals. The windowes shall be a Colonne and a halfe bearing out: and their length or height, shall be taken in Diagonall manner. The corner Columnes shall be as broad as the other: but they shall be of 8. parts and a halfe high. The second story about this, shall be a fourth part lesse: the corner Columnes, with Architrave, Fræse and Cornice, lessened accordingly: The windowes about the Arches, with the Pilasters, shall be as wide as those below: but the height of the 2. squares, and the Fræse about them, shall be as broad as the Supercilium: the Cornice also as much: The small windowes about them, are made soz two purposes: The first, the rooms being high, as they shew outwardly, will make the chambers and other rooms much lighter. Secondly, soz necessity a man may make hanging chambers in them, and then those lights will serue to good purpose. The third story shall be lesse then the second a fourth part: and the same being deuided in 3. parts, one part shall be soz the Architrave, Fræse and Cornice: and that part deuided in 3. one part shall be soz the Architrave and Fræse, and the third soz the Cornice: and in the Fræse, the Guttiles and Modillions shall be deuided, as you see them. The lights of the windowes shall be as the other, but they shall be a twelfth part higher, because they are further from the light: the Pilasters, Fræse and Cornice, shall be like the other. The Frontispice and Arches shall be made, as I haue sayd, in the dozes and gates of the Order of the Dorica: soz beautifying, or to place another row of Arches in it, you may set Acroteries or Pilasters vpon them, which will passe well in the making of their fire places, or chimneys soz a noyding of smoke. The spaces betwene the windowes, that remaine white, are left to be paynted, as the workeman will, or at the pleasure of the owner of the house. But soz more security of this building, it shall be necessary to place these Iron bands in it, or at least, ouer the Gallery, as is taught before.

Pilasters.

Of the Dorica

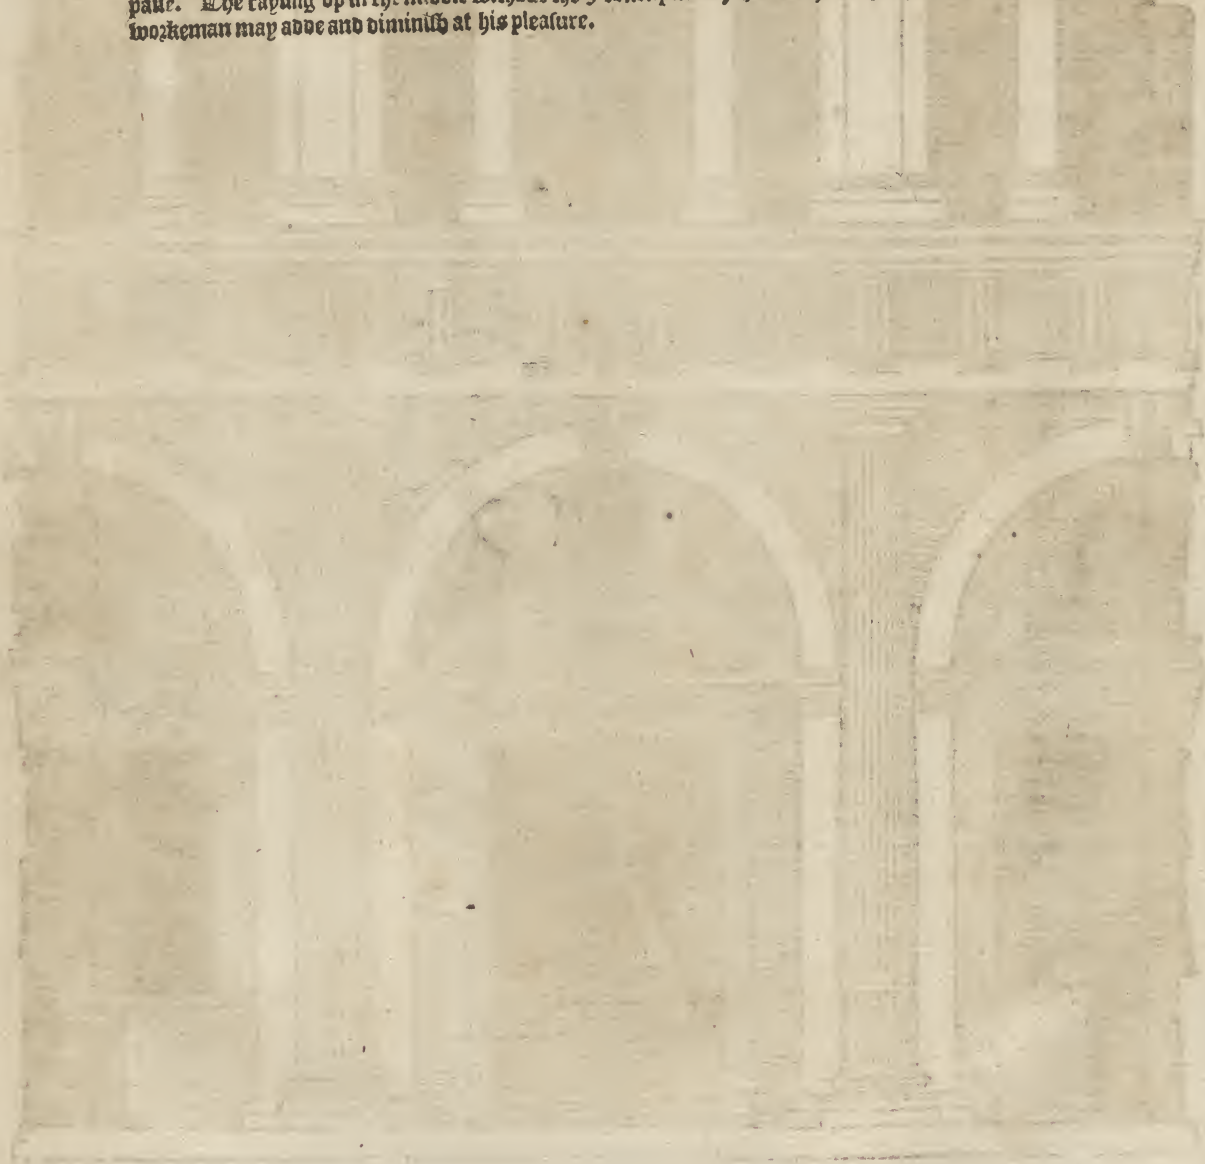

In the famous Towne of Venice, because houses stand nere together, they are forced to make their lights as they may, so that their Building differeth much from that Building of Italy: notwithstanding, the workeman may give them light enough, observing Antiquities, which shall be thus made and devised: You shall divide the widenesse of an Arch in 2. parts and an halfe: whereof one shall be for the bredth of the whole Pillar: the thicknesse whereof shall be the halfe, the round Columnes also as much: the height of the Arch shall be of one 4. square, and two 3. parts: you may also make them of two 4. squares, heightning the rest accordingly. The Fynish or Capitall under the Arch, shall have the halfe thicknesse of the Colonne, according to that which is shewed before, of the Theater of Marcellus. The Dooze shall be of thre Colomnes thicke in widenesse, the height of a foure square and two 3. parts: the Pillar or Antipagmentum shall be of the 8. part of the light: the Corona shall be like the Capitall: but the scima being set vpon it, you shall make the Fastigium as is before sayd, and above it give more or lesse light, as the house requireth. If the building stand in a field or an open place, you make stops, which shall well fall out with the building: above the Colomnes, the Epistilium must be set of halfe a Colonne thicknesse: the bredth of the Triglyphes also as much: the height shall be made more or lesse, at the workemans will, that the spaces may be 4. square; whereupon you must set the Cornice of a 6. part higher then the Epistilium: the particular parts and measures, you shall make according to the rule before set downe. The Roofe above shall be a 4. part lesse, making a Plinthus under the Colonne, of such a height, as the Proiecture of the Cornice beareth: the rest must be divided in 5. parts, one part shall be the Architraue, Frase, and Cornice, (which, as before is taught) shall also be divided in thre parts. The Colomnes which vphold the Architraue, shall be nine parts high, the lesser Colomnes which vphold the Arch, are thinner then the rest a third part: the spaces in the middle, under the Arches shall be twice so wide as the sides: so then, the Cornices being placed vpon the Colomnes which beare the Arch, and the halfe Circle made vp to the Architraue, also, the eyes or holes besides the Arch, then it will be exceeding light: and where there wanteth a Chamber, you may shut the middlemost lights, and the sides shall serue for windowes. Neuerthelesse, this order being observed both without and within, it will not stand much amisse; for the place that by, shall be for a Fire place or Chimney, which ought alwayes to be made betwene two windowes, like to a mans face, where the windowes are the eyes, and the Chimney the nose, which alwayes drawes the smoke.

Of the Dorica

To divide this present Facie, sayth the Authoꝝ (foꝝ otherwise he maketh no pꝛeface) you shall divide the bꝛedth in 14. parts, and one of these parts shall be foꝝ a Colonne: the middlemost inter Colonne shall be of 6. parts, and the other each of 3. parts: the windowes shall be of a Colonne and an halfe: the height of them, two 4. squares and an halfe. The Pilasters shall be of the first part of this light: the windowes in the first stoꝝy are of the same bꝛedth: the nethermost, shall be a perfect 4. square, and the other of a 4. square and an halfe. The port oꝝ Gate shall be 5. Colunnnes wide, that the Colunnnes may have a fast foundation: the height of this Gate is a 4. square, and of two 3. parts: the Arch-stones, and the rest, you shall see sufficiently in the Figure: from below vnder the Arch, vntill you be above the Facie, shall be 2. Colunnnes thicke. And although that all other stoꝝies oꝝ buildings, being one stoꝝy above another, would alwayes bee shortened a fourth part: yet in this case, (by my aduice) foꝝ that the compartition of the Colunnnes, being above this rusticke worke, and that the rough worke should not take too much place when it is of sufficient strength, it is requisite that it should bee of the same height. Above the first order, as you shall make a Podium of a Colonne & an halfe high, whercon you must set the Colunnnes in order (as it is taught) the height without the Podium shall be divided in 5. parts, whercof 4. shall bee foꝝ the Colunnnes, the other foꝝ their ornaments, whercof the Triglyphes shall be divided, as you see, observing the rule also sayd. The middlemost shall be dealt thus, that the small Colunnnes shall be the halfe of the greater, and the middlemost inter Colonne shall be as broad againe as those that stand on the sides, which shall be like eyes of the windowes. Above the windowes, to make more light, you shall make the eyes, and above the smallest spaces in the middle, you shall make that you see here in the Figure, foꝝ to accompany the same eyes. And although there rest particular parts, you shall alwayes seeke them foꝝward, where you shall be assured to find them. The third order oꝝ stoꝝy, and that which belongeth thereunto, shall also be made lesse a 4. part, but the windowes as broad as the lowest, as also their heights, and all other things, you may easily find with the Compendium. The raising vp in the middle without the Frontispicium, shall bee halfe the third order in height: foꝝ the rest, a workeman may adde and diminish at his pleasure.

Before, I haue shewed in two figures, how to make the Facies or forefronts of Houses after the Venetians maner: but so; that in such works men would willingly haue some places bearing out, which are, for the most part, made ouer the water, for fresh ayre of the water, whereon the most part of buildings haue their sayest forefronts or Facies; as also, to see the triumphes oftentimes made there in Boates and Shyps: to which purpose, the sayd bearings or inttyngs out serue well, and yet neuertheless, are vnseemly things, and haue no other supporters but the Podillions: Now, such things as haue not their foundation strongly layd and made, hurt the walles of the house or building, whereof ancient workemen were very carefull, and made no such bearing out, but onely Cornices: therefore I say, if a man will make any such things in any building with good aduice, it is necessary that the first wall should be so thicke, that it may stand so farre out as the flat of the bearing out requireth, as may bee percepued in the round: and so; that the middlemost wall standeth out more then the sides, if you will not make it so thicke, then you may make a strong Arch within, to vphold the middlemost, although it be hollow and of small weyght. This bearing out, is to bee vnderstood aboue the Facies of the rusticall worke: which being made, then the compartement of the Facies shall bee aboue this, so that the middlemost part shall be of thre portions, and the sides of thre and an halfe, I meane within the walles, as the ground sheweth. The height of this second order or story, shall be like the vndermost, according to the rules aforesayd: and first, you shall make the Podium of an indifferent height, to keane vpon: then that which resteth shall be deuided in five parts, one of those shall bee the Epitilium, with the rest of his parts. The widenesse of the middlemost part, must be thus: the opennesse with the Arch must be as great againe as the sides, and the height doubled; so the Architraves being set vpon the Colammes, for the vpholding of the Arch, all the Windows shall bee vpon a roome: likewise also, for more commoditie of light and ornament, the eyes of the Windows shall bee made. These ornaments, together with many other things, if a man, in regard of cost, will not make them of Marble, or of other stones, they may be set forth with painting. The thiro order or story shall also bee a fourth part lesse then the second: and so every other part thereof accordingly, following the rule aforesayd: and although the Ionica be set before the Dorica, which ancient workemen sometime haue done, you shall find the proportion thereof hereafter in his place.

Although the workeman hath seen so many inventions in this Dorica worke, yet they will not further him wth ornaments of Chimneyes: but I will set two sorts thereof here in Figure, one indifferent whole, & in the thickness of the wall, for a small round Chamber or House: the other, for a greater place without the wall, or at one with Projections: for if a small Chamber should be cumbered with a Chimney, it is requisite to make it wholly within the thickness of the wall, and the height of the opening being made, according to the situation of the place, shall be divided into foure parts and an halfe, and shall be the breadth of the Pilaster, but the Architrave shall containe the halfe: the Tenia or List, going round about, shall bee a seventh part, and all his other Lists of the same breadth: the Triglyphes and Projections, shall be halfe the breadth of the Architrave, but their height you shall take in this manner, that the Putiles stand above the Pilasters, and the Triglyphes divided betwene both, the Gethopes may have their square of the breadth of the Architrave, but yet the Gethopes or spaces betwixt the Projections, shall not bee square. The Capitals of the Putiles and Triglyphes, shall bee so high as halfe the breadth of the Triglyphes. The Corona, with the Scimatie and Scima, shall bee as high as the Architrave; and being divided in two parts, one part shall be for the Corona; of the other you must make three parts, one for the Cimatie with the List, the other shall be for the Scima with his List. The bearing out of the Corona shall be so great or little, that the spaces betwene the Capitals of the Triglyphes in the ground of the Corona, may be square, so that, if men will sit round about it, they may have their place of light. The Projection of the Scima with the Cimatie, shall be made like that height which standeth above, at the discretion of the workeman. But if the Chimney be very small for a little room or Chamber, then a man shall make the Pilaster of the seventh part of the height of the opening.

Of the Dorica

This other Chimney without the wall, shall be made thus, when the height and wideneſſe of the place, according to the ſituation, is appointed, the ſame height, from the ground up to the Architrave, ſhall be divided in 4. parts, one part for the Architrave, Frieſe, & Cornice, their parts being made according to the rule aforesayd: and whereas they ſhew greater, that is, becauſe men ſit them vnderneath, the bredth of the Modillions ſhall be the 7. part of their height: the Capitals the halfe of that bredth, and ſhalbe divided as it is ſaid of the Doricall Capitals: ſome leſſen the bredths of theſe Modillions vnderneath the fourth part, that the ſoote of them may giue out a fourth part, ſo that the Plinthus vnder the ſoote, is as broad as the uppermoſt part. But if you will make ſuch Modillions all of one bredth, I would commend it in a great worke, for that the vndermoſt drawing to the wall, & going from our ſight, leſſen themſelues: for that the part which receaueth the ſmoke, is Piramides-wiſe, which wil not ſtand well in a great height. You may ſet it vpon the firſt Cornice higher or lower, as you will, or according to the ſituation of the place. This building of Chimneys may be made in great forme: but if you will make them ſmall, then you ſhall divide the height from the Pavement to the Architrave in 5. parts, whereof one ſhall be for the Cornice: the bredth of the Modillions ſhall be the ninth part of that height, the Capitall of halfe the bredth: and thus it will bee more ſeemely in an indifferent meane forme. This I ſpeake by experience, for that I haue obſerued this greateſt meature in ſmall formes in making of Chimneys, but they prove to great.

The end of the Dorica order: and here followeth the Ionica.

Capitals.

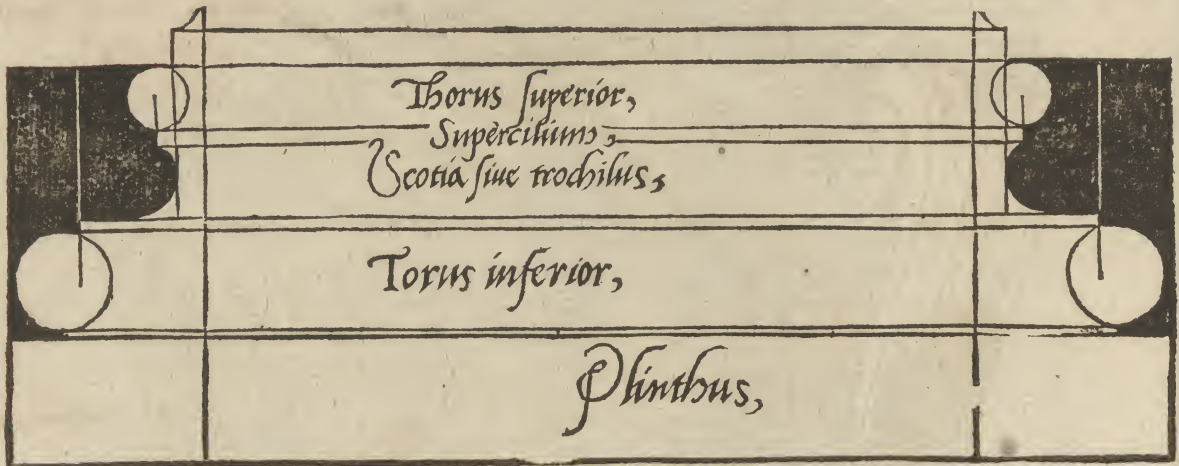

Corbitions.

Of the order of Ionica, and the Ornaments thereof.

The seventh Chapter.

Vitruvius speaketh of Ionica, in his fourth Booke and 1. Chapter: and as I also said, the ancient Pagans tooke this kind of worke from women, and ascribed it to *Diana, Apollo, & Bacchus*, &c. But we that are Christians, hauing a Temple to make of this worke, we will dedicate it to such Saints as are of nature, eyther weake or strong: so likewise, common workes are fit for peaceable people, men, neyther great workemen, nor all too simple in workmanship: and such workemen are fittest for such worke. Now let vs come to the measures: the Ionica Columnne, by a common rule, must be of 8. parts, with Capitall and Base: although that *Vitruvius* sayth, it must be of 8. parts and an halfe; so may men sometimes make it of 9. parts and more, as some indifferent workemen haue affirmed. But this, I say, shall be made of 8. parts, which must hold his thickenesse below, and so shall their Bases be of halfe the same thickenesse, which *Vitruvius* setteth downe diligently, in the 3. Booke, and in the third Chapter of the same Booke, in this maner, that the Base aforesayd, must be of halfe the Columnnes thickenesse, but the Plinthus must be of the third part thereof: which Plinthus taken of, you shall make seuen parts of the rest; whereof three shall be for the Thorus, and foure shall bee for the two Scoties or Trochiles, with their Astragals and Lists, so that each Trochile must haue his Astragall. The Astragall shall be the eyght part of the Trochile, the Lists halfe the Astragals. Although each Scotie with the Appendances are all of one height, yet the vndermost shall be greater; for it shall shoot out vnderneath, to the outermost part of the Plinthus. The Proiecture on eyther side, shall be one eyght part, and one sixt part: so that the Plinthus on eyther side shall be one fourth part, and one eyght part more then the thickenesse of the Columnnes. Now, for that the Cinthe or List is suppressed by the greatnes of the Thorus, I am perswaded that it ought to be made the halfe greater then the other. Obserue in all the members and parts with discretion, as should be vsed in the Dorica.

WH that the Base of the Ionica Pillar, written of by *Vitruvius*, contenteth not the greatest workemen, because the Thorus is very great, and the Astragall small, vnder so great a member, according to the iudgement of expert workmen, that haue oftentimes disputed the same, with reuerence, and much respect of such an Authoz; I will frame one here according to my opinion. The Plinthus being made, as I sayd before, the rest shall be deuicid in three parts, whereof one part shall be for the Thorus: the other vnder that Thorus deuicid in sixe parts; one of them for an Astragall, the Cinthe the halfe thereof. The Cinthe or Supercilium vnder the

Chorus, must be as broad as the Astragal. The rest is for the Scotic or Trochile: the other three parts that rest, shall also be divided into six parts: one for the Astragal, one halfe for the Cinthe, and the undermost also the like: the rest is for the Scotic comming at underneath, as is before alleaged.

The Jonica Capitall shall bee made in this manner: the height shall be the third part of a Colunne, and the former part of the Abacus the bredth of a Colunne in thicknes: to it also must be added the 18. part; which in the whole, shall be nineteen parts, but inwards a part and a halfe: at eyther end the line Catheta must be drawne, which shall containe 9. parts and an halfe, which is the halfe bredth of the Capitall: one part and a halfe shall be for the Abacus, which Corners you must make like the right or left side, for both are ancient: the 8. parts that are hanging under the Abacus, shall be for the Volutes. And for that it would be trouble: me in this small Figure, especially to set downe before your eyes the numbers, therefore in the Lease following, I will shew it better in great, and therewithall the manner how to make the Strickes in the Colunnes, with the Figure of the side of the Volutes, and of the Capitalls. But if the Colunne be of 15. foote downwards, then it shall be lessened a sixt part above, as it is written of the Thulcan order: but if it be of 15. foote upwards, then I referre you to Vitruuius, touching the same, in his third Booke and second Chapter.

WHICH the Capitall of this Ionica is made, you must make the Volutes, which shall be made by the line, called Catheta, which wee heere call, The right Lead: and when you leaue the Abacus vnderneath foure parts, then the first part shall be for the eye, and so there yet resteth thre parts from the eye downewards; and so in all, they make eyght, as is befoze sayd: the eye shall be deuided in six parts, and the numbers set therein, as it is here set downe; then place one foote of the Compas upon the poynt 1. and the other foot vnder the Abacus, drawing netherward, by to the Catheta, to the eyght part; then letting the same foote of the Compasse stand, bying the other foot of the Compasse to 2. and drawing it bywards againe to the Catheta. Then hold the foot of the Compasse there, bying the other foote to 3. drawing it then downewards againe to the Catheta: keeping that foote there also, bying the other vpon the poynt 4. then drawing it againe to the Catheta, holding the Compasse there, the foot will come vpon 5. so drawing about, doe likewise to 6. and then it comes to shut with the eye; there you may make a rooffe, if you please. The rest of the particular members you shall easily find with the Compasse. The Strikes of the Columnes, which wee call Channels or hollowings, shall be 24. in number, and one of them shall be 5. parts: whereof 4. shall be for the Gattes or Channels, and the 5. for the List, by Vitruuius called Strix: and so from one side of the flat of the List to the other, you shall draw a straight line, the middle whereof shall be the Center of the hollowing out. But if the workeman please sometimes to make a thinne Columne to shew thicke, then there must be 28. strikes: the Abacus of this Capitall is as broad on the sides, as befoze: which sides are proportioned according to that, which is sayd befoze. Friendly Reader, I haue layd this Volute, according to my simple vnderstanding, because Vitruuius writing is hard to vnderstand, and which is moze, promised the same Figure in the last Booke, together, with diuers other ornaments, which Booke is not to be found.

S. Serlii vpon the speach aforesayd.

Loving Reader, there are many things which cannot fully, from poynt to poynt, be shewed in Figure, vnlesse the workeman must helpe himselfe by practise, like as the Cincke or band of these Volutes: which (if the Capitall be very great) will stand well: if the breadth containeth the fourth part of the eye, and if the Capitall be of indifferent greatnesse, then it must be made of a third part of the eye: but if the Capitall be small, then it must be the halfe of the eye, alwayes at the workemans discretion: for I haue seene it so in Antiquities, although they differ. The thicknesse being marked aboue, vnder the Abacus, then you must place the Compasse a little below the figure 1. from aboue the Catheta downewards: then agayne, you must place the Compasse a little aboue the figure 2. drawing your line from beneath vppwards to the Catheta.

Now, whereas I haue sayd, that the last Booke promised by Vitruuius, is not found, by meanes whereof, diuers opinions are spred abroad touching the same, some affirming, that in Vitruuius time, there were many vnskillfull workemen (as there are now also) hauing better fortune, then good vnderstanding: (others) that presumption, suffer to vnskillfulnesse, beareth such sway among common workemen, that vnderstand not themselues, it is thought, that Vitruuius refused, or at least, would not publish it, in regard of the vnthankfulnesse of such as neglect good learning. Some also affirme, that it was too hard a matter for him to place them in figures; which I can hardly iudge to be the mind of such an Authoꝝ. But whereas some affirme, that this last Booke was so pleasing and acceptable, in regard of the figures there at large set out, and he being ouer-rarefull in looking vnto it, was robbed thereof, among other riches and treasures, by vnskillfull persons: this I beleeue best, is as warre, which is enemy to all good Artes, which yet, at this day, is especially to be lamented, for that men by the figures, might haue made diuersities of worke in the right maner.

Of the Ionica,

I have declared hereafter, according to Vitruvius writing, how to make Ionica worke, as farre as my learning shall serue. Now, I will shew how some Antiquities in Rome, of that worke, are made, yet standing. The Capitall M. standeth yet in the Theater of Marcellus, wherof I will set downe some general measures: the forehead of this Abacus is like vnto the Columne below. The Volutes giue out a first part of the Abacus, and so farre out as the halfe of the Abacus: the height of the Capitall is a third part of the Columne below; but for that some workemen thought that Capitall to be but barely set forth, they haue added the Frase which you see in the Capitall, vnto it, making the height of the Capitall of 2. third parts, of the Columnes thickeneſſe below, which Capitall is at this day to be seen in Rome, with others of the like.

As for that it may sometimes happen to the workeman, to make a square shutting with Ionica Capitals, so that some workemen haue erred in placing of the Volutes; to helpe or ease you of that error, it shalbe needfull to make the corner Capitals, as you see them in this ground: of such Capitals, there was the like found in Rome, which caused many to stude, where it was made, in such maner, for it was called, The confused Capitall: but at last, after long disputation, it was concluded, that it had stood in an open corner, shutting by the order of the Columnes marked A. But if the workeman haue flat Columnes to place against the wall, in this corner, that the Volutes may come alike on both sides, the workeman may place them, as in the ground B. is set downe.

The Epistilium or Architraue is made thus: If the Colonne be of 12. to 15. foote high, the Architraue shalbe the halfe of the Colonne beneath: if it be of 15. to 20. foote high, then it shalbe deuiced in 13. parts: one shalbe the height of the Architraue; and from 20. to 25. foote, the Colonne shall be deuiced in 12. parts and a halfe: one part shalbe giuen to the Architraue: If the Colonne be of 25. to 30. foote high, then the Epistilium shall be the twelfth part of that height: If the Colonne be higher, you must increase the Architraue more: so: the further it goeth from a mans sight, so much more it loseth of the greatnesse. The Architraue being made of his due light, and deuiced in 7. one shalbe the Cimatic: the Proiecture thereof, also as great. That which is ouer, is deuiced in 12. thre shalbe giuen to the first Facies, foure to the second, and five to the third. The thicknesse of the Architraue vnder, shalbe like the Colonne aboue, in the thinnest part: but the thicknesse of the Architraue aboue, shalbe like the thicknesse of the Colonne below. The Zophorus or Fræse shall haue the measure according to the length of the worke: but if there be somewhat to cut or graue in it, then it must be made a fourth part higher then the Architraue: but if it be made playne, without cutting or grauing, then it must be a fourth part lesse. The Cimatic must be set vpon the Fræse, which must be the seuenth part of the same Fræse: and the proiecture also as much. Aboue the Cimatic must the Denticules be placed, in height, like the middlemost Facie: and the Proiecture like the height. The bredth of their teath must be double in height. The intercutting or hollowing betwene the teath, shalbe a third part lesse. The Cimatic is the first part of the Dentile. The Cozona, with the Cimatic thereof, is the greatnesse of the middlemost Facie: The Proiecture of the Cozona, with the Denticules, is as much as the height of the Fræse, with the Cimatic. The Scima is an eyght part higher then the Cozona. The rule or list thereof shall be a first part, and the proiecture like the height: Also our Author affirmeth, that all Cephozes or cozners will stand well, when their Proiecture is like the height.

Of the Ionica

For that the works of Rome differ from the writing of Vitruvius, I will frame another Colunne, whereof the Architraue, Fræse and Coznice, shall be the fourth part of the height of the Colunne: which 4. part deuided in 10. parts, thre shall be for the Architraue, deuided after the rule aforesayd: 3. for the Fræse, and 4. for the Coznices: which 4. shall bee deuided in 6. whereof one shall be giuen to the Denticules, one to the Cimatic which vpholdeth the Putiles, and two to the Putiles and the Cozona; the rest to the Scima. The Proiecture of all, shall be at least as much as the height: vpon such a Coznice was found written, A Sante Sabina, at Rome, in a building of the order of Ionica.

And if sometimes it be necessary to rayle vpon Colunnes, being not compelled or pinched by any thing thereabout, then the propozition of the Pedestal shall be thus; it shall be as broad before as the Plinthus of the Colunne: but the height of the flat of the Pedestal shall be a fouresquare, and a fourth part: which deuided in six parts, one shall be for the Base, and one for the Coznice, which in all is eyght parts: so shall the Pedestal be of eyght parts like the Colunne. This must alwayes be vnderstood in common, that it is left at the discretion of the workeman.

By reason of the great difference, which I finde in things of Rome, from those which Vitruuius writeth of; therefore I haue here shewed some of them, that are best knowne at this day, extant in Rome to be seene in worke. The Coznice, Fræse, and Architraue marked T. is in the Theater of Marcellus, in the Ionica order, about the Dozica; the Pilaster with the Base thereupon, also marked T. is in the same order, vnder the Ionica Columne. The Coznice for the impost of an Arch, also marked T. is of the same order, and vpholdeth the Arch. The Coznice with the Mutiles marked A. was found at S. Adrians, and S. Laurence, in Rome. That Architraue marked F. was found in Nel Friulle: which Architraue, for that it had thre Facies without Astragals, I iudge to be Ionica. Here is nothing said of the measures hereof, for I haue diligently reduced them from the great into the small: which measures are easie to be found with the Compass.

Of the Ionica

Although that the *Chromatum Jonicum*, that is, the dooze by *Virruuius* described, in my opinion, not proportioned to answer the building (as it ought to do:) therefore I will speake thereof, according to my knowledges: I say then, that *Virruuius* writing is not right, touching the height of the light of *Chromatum Doozicū*, viz. from the Pavement to the Lacunary, there were 3. parts and an halfe made, and two parts thereof were for the height of the light, whereby the Corona was very high, as also of the Doozica. But there followeth yet another errour, viz. making the Gate or dooze 5. parts high, setting three parts thereof below, as *Virruuius* saith, also lessened in the upper part, like the Doozica: then I finde, that the widenesse thereof cometh to be broader then the inter-Columne in the middle, making a Temple of 4. Columnnes, with the measure which *Virruuius* hath set downe in his 3. Booke, as I haue set it downe here in Figure, that workemen may see the correspondencie of this Gate or Dooze, with the Temple thereof; which, in my opinion, is not ill, for this cause, for, if the dooze of the Doozica, which order of Columnnes is lower then that of Ionica, hath the height of 2. soursquares, and a little more, I say, the Ionica doozes, whose Columnnes are higher, ought to be higher also for light, then the Doozica. But it is not so much, according to *Virruuius* Booke, which saith, 5. parts in height, and 3. parts in breadth: but let all this be spoken with reuerence of so great an Authoꝝ. Peruerthelesse, taking the parts in *Virruuius* Booke, which may be to some purpose, I will make another Figure thereof, without lessening it about: but he that for his pleasure will lessen it about, obserueth the Doozica order.

The Translator.

What *Virruuius* saith, touching the height of the light of the Dooze or Gate of this Doozica building, there is sufficiently spoken: but touching the widenes of this Gate or Dooze, where he saith, that the height or opennesse thereof should be deuicid into two parts and a halfe, and the widenesse thereof, to haue one part and a halfe: It may be (as it is in other places) that the place is falsified; and it may also be, that it is a quarter too much: for if it be made of 10. in height, and 5. in breadth, the light then being of 2. soursquares, would be reasonable, so the Intercolumnnes were as wide as from the Doozica: for it is of soure Diameters, and this but of three Columnnes wide, and the *Antipagmentum* would not be darkened, so that leaning out but a quarter, this building would thereby be made perfect.

I say, that the light of this dore ought at least to be of 2. soursquares high, the Antipagmentū oꝝ Pilaster shall be the 12. part of that height, made in such maner as is said of the Epistilium Foricum, & thereto the Astragals shall be added, as it is shewed in the Figure E. If a workeman will cut any thing in the Fræse about the Supercilium, then it must be a 4. part higher then the Supercilium: but if you leaue it plaine, it must be a fourth part lesse. The Cozona, with the other members, shall be as high as the Supercilium, deuided as you see it in the Figure F. The Ancones oꝝ Prothirides, shall be broad above, like the Pilaster, but in the nether part, like the height of the hanging light, shall be lessened a fourth part; from the which the leanes hang, as you see in the Figure F. That part of the Circle, in stead of the Fastigium, shall haue his height made in this maner; with a Compasse you must reach the two corners of the Scuna in the vppermost part, and one foot of the Compasse sinking to the point of the crosse, with the other foot, the part of the Circle being drawne, shall be the height, which will be the third part of a Circle: which maner of making oꝝ not making of a Fastigium, shall be alwayes referred to the pleasure of the workeman; it may also serue for windowes.

Antons,
oꝝ Prothi-
rides.

Of the Ionica

The light of the Gate following, is more then of double proportion, viz. of two four squares and a quarter: the flat of the Pillars shall be the 8. part of the breadth of the light, and the Columnes shall be twice as thicke: the same Columne shall be lessened above a sixth part: the height shall be of 9. parts, with Bases and Capitals, according to the measure aforesaid. And although these Columnes hold a part more then the rule aforesaid, yet it is not therefore true, for that the 2. third parts stand onely without the wall, bearing no other waight then the Frontispicium: further, if by any accident these Columnes should exceed 9. parts, yet were it not to be blamed: for they are onely set for an ornament, being made fast in the wall. The height of the Architraue shall be like the Supercilies ouer the doze: the Fræse shall be cut, and shall be made higher, as is before: if it be not cut, you may lessen it so much lower: the Cornice shall be higher, like the Epistilium or Architraue: with the other parts you must handle, as it is said in the beginning of this order. The Frontispicie shall be referred to the will of the workeman, eyther to make it higher or lower, by any of the aforesaid rules. By this intention, a workeman may helpe himselfe in many things, making the light high or low, as need shall require; as sometimes of a four square, or of two thrd parts: but if the workeman be not otherwise compelled, I should best commend the double proportion, that is, of two four squares.

Of the Ionica

Although I haue set this rusticall Gate in the order of Tuscana, and not onely in many places applyed it to the Tuscana, but also mixed it with the Dorica, yet I haue placed it here with the Ionica: although it is not therefore to be set in all buildings that are made after the Dorica, neuertheless, to good intent and purpose, as without in the countrey, in such a case also, it is not to bee discommended in a Citie or Towne, for a Merchants or Lawyers house; in which places it is tolerable. But in what place soeuer a man will make it in a maner of bearing ouer, then the proportion of this worke shall be thus: the light vnder the Arch shall be two square squares. and the Pilaster the 8. part of the breadth of the light: the Colonne shall hold the fourth part thereof, but the height shall be 9. parts with Bases and Capitals. The Arch of the halfe shall be deuised in 13. parts and a quarter, because the middle mass stone shall hold a quarter more then the rest. The Architrave, Frieze and Cornice. are together the fifth part of the Colonne: of which three pieces, the workman shall make 11. parts: 4. for the Architrave, 3. for the Frieze, and 4. for the Cornice. The height of the Podium shall be the breadth of the light. The Cornice and the Base, may be taken out of the aforesayd Stilobato: but the other Base, Capitall, Architrave, and Cornice, shall be made as it is sayd in the beginning. The Archstones and the other that bind the Colannes, you may see in the Figure.

Of the Ionica

Although the height of this Arch is not of double proportion, as the most part of those which I have shewed, yet it is not false, but is made by good discretion, for that it may sometime fall out, that in the compartition of a Facies, upon occasion of any necessary height, and to make the Arches unequal, which should be so to place the principall gate in the middle, which in such case should not attayne to such height: but if we be not constrained by any necessity, I more commend the double height, then any other proportion. The wideness then betwene one Pilaster and the other shalbe 3. parts, and the height 5. but afterwards the wideness being divided in 5. then the whole Pillars which stand before the 2. Pilasters, have 2. parts, and the thickness of the Columnnes shalbe of one part: the Pilasters shall each of them be of halfe a Columnne in thickness: likewise the Arch, and the Impost which upholdeth the Arch, are of the same height made, as it is shewed in the Theater of Marcellus marked T. The Columnnes shalbe 9. parts high, with Bases and Capitals, made according to the rule, in the beginning of this Chapter set downe: the doors in the middle shalbe halfe the wideness betwene the Pilasters: the height shalbe found in this maner: The Pilaster being made of the first part of the height, the Cornice like the eyes of the Impost, placed above it, and the Scima upon that, making afterward the Frase the fourth part lesse then the Antipagmentum, then the height will find it selfe, which will be little lesse then two squares. The Frontispice shalbe made according to a rule set downe in the Dorica: the Architrave, Frase and Cornice shalbe made in height, of the fourth part of the heights of the Columnnes, by the rule aforesayd. The Stoory above shalbe lower by one fourth part: so shall the Architrave, Frase and Cornice bee of the fifth part of that height, which shalbe the fourth part of the height of the Columnnes: but touching the division of the particular members, you shall find them in full measure in the Order of Composita. The windowes being made with Arches, shalbe in bredth like the door: likewise the Pilasters and the Arches, but their height shalbe two squares and a halfe, which is to give more light in the chambers. The Columnnes shalbe flat, and one fourth part shorter then the lower. The bredth of the Piches betwene the Columnnes and the windowes, is one Columnne and a halfe, the height of foure Columnnes thickness. Thus of any parts or members that bee resting, you shall find meanes to make them by the prescription of the aforesayd rules of that order: for of this Corinthia, you shall find the measure in the beginning of that order. Above this Stoory, he that will, may make a walking place, well defended from water: and that the height of this Podium were of reasonable height to leane upon, or to rest upon with a mans armes, these Facies would bee a great beautifying to the building, and much ease to the inhabitants.

Of the Ionica

Sometimes, as is sayd, a workeman shall find a great number of Columnes, but so low, that they will not reach high enough for his worke, if he cannot helpe himselfe therewith, and apply such members, to serue the building which he hath in hand: therefore if the height of the Gallery riseth higher then the Columnes, then in the middle of the Facie you may make an Arch, being vpholden by the Architraue, which shall be aboute the Columnes, which Architraue shall bee the Impost or vpholding of a round roafe. But where the Arch shall be, there shall be a Crociere, as the workeman may see in this ground: and for strengthening thereof, let there be Iron or mettall barres layd ouer, as it is taught in the Dorica Order. But the deuiding of this Facie shall be such, that the middlemost Intercolunne shall be of 6. Columnes thickeesse: and the height of the Colunne, with Bases and Capitals shall be of 8. parts: the Architraue holdeth as much as the Colunne is in thickeesse above: likewise the Arch: above the which the workeman shall make a Cornice, which height shall hold a fourth part more then the Architraue, without the Thozus vnder, with the List: which Cornice shall also serue for a Capitall vpon the Pillars, above the Colunnes, and shall be of the same bredth that the Colunne is above. The Intercolunnes on the sides shall be of 3. Colunnes in thickeesse: the height of the doze shall be so, that the Architraue vnder the Arch shall serue for the Cornice above the doze, changing partly her members, as it is figured. Vnder the Cornice there shall be a Fræse set, which shall be a fourth part lesse then the Architraue, the Supercilies with the Plaster of the same height. But as much as shall be vnder the Supercilies, to the stayres, of that halfe, the bredth of the light shall be made; and so the light shall be of two fouresquares. The windowes shall stand as the eyes of the doze stand, and their wisenesse shall be of two Colunnes thickeesse, but the height shall be taken in Diagonall maner: the second Order or Stozy shall be a fourth part lesse then the first; the Podium being taken of a reasonable height, that which resteth shall be deuided in 5. parts, foure whereof shall be for the height of the Colunnes, the other for the Architraue, Fræse and Cornice, obseruing the given measures of such a Stozy. The bredth of the window in the middle, is with the Antipagmentum as wide as the light of the doze, but the light shall be double in height: in the Ornamentals above, workeman may follow and obserue the rule set doune. The windowes on the sides shall be like those that stand below, and their height like the greater: the rayling vp in the middle above the second Stozy, shall also be a fourth part lesse then the other, and euery part thereof lessened accordingly: for the light thereof, the order of the lowest Stozy is obserued: but the making of this third Stozy, or the not making thereof, is at the pleasure of the workeman.

Of the Ionica

As it is said in the beginning of this Booke, the maner and order of the Ionica being made after the Feminine kind, it is so likewise a materiall thing, that hauing a Chimney to make of that order, wee must, as nere as we can, make some shew of that sexe therein: the proportion whereof shalbe thus, that the height of the opennesse, being placed, it shalbe from the ground of the Chamber or Hall, to the Architraue, eyght parts high, and that shall be according to the placing of the Columnnes, which shall be such like, monsters or strange formes (as we call them) made in this maner, which shal serue for Spogillions. The Architraue, Frase and Cornice, shall be the fourth part of the height, as it is befoze sayd. The table vpon the Capitals, which couereth the Architraue and the Frase, I iudge, that ancient workemen haue vsed to finde more space to write in, and also, for that they were desirous of nouelties: which table, whether it be made or not made, is referred to the will of the workeman. The second order, with the Dolphins, is made for two causes, the one is, to make the mouth of the Chimney, which doeth receyue the smoke wider: the other is, to make a Piramicall forme, making the necke of the Chimney in a Chamber, but it is still at the will of the workeman, to make them more or lesse, or not at all.

Of the Ionica

This other maner of Chimney is very easie for small rooms, and they are used to be made lower then a mans sight, that the fire, which is enemy to mens eyes, may warme the rest of a mans body. The widenesse of this Chimney is a full soursquare: the Pilaster shall have a first part of the widenesse: the Cimatie the seventh part of the Pilaster. Of the rest you may make 12. parts, 3. shall be given to the first Frieze, 4. the second, and 5. the third Frieze: and for more beautifying, a man may also make the Astragals, as you see them here in the sides. The height of the Colates shall be like the 3. Friezes without the Cimatie, and of them must be made 3. equal parts, one part for the Frieze, with the chanelature or hollowing, and the other for the Echine, with the Astragal and List, the third shall be given to the Volutes, which shall hang on the sides like the Cimatie, but the leanes shall hang downe as low as the Architrave. The height of the Cozona, with the two Cimaties, and the Scima, are like the second and third Frieze, together with the Cimatie: but the Projecture of Cozona, Cimatie, and Scima, each of them hold as much as the height. This like forme I have made in worke, very well liked of: but, as is sayd of the other. if by occasion of worke it taketh overmuch place, then you may make the Pilasters of the 8. part of the widenesse, so will they be much more seemely of themselves. That part made over for an Ornament, is also at the workemans will, for this Chimney is to stand in the thickeesse of a wall, so that this Ornament, of this Order, would serve for a window or doore.

Here endeth the Ionica Order of building: and there followeth the Corinthia.

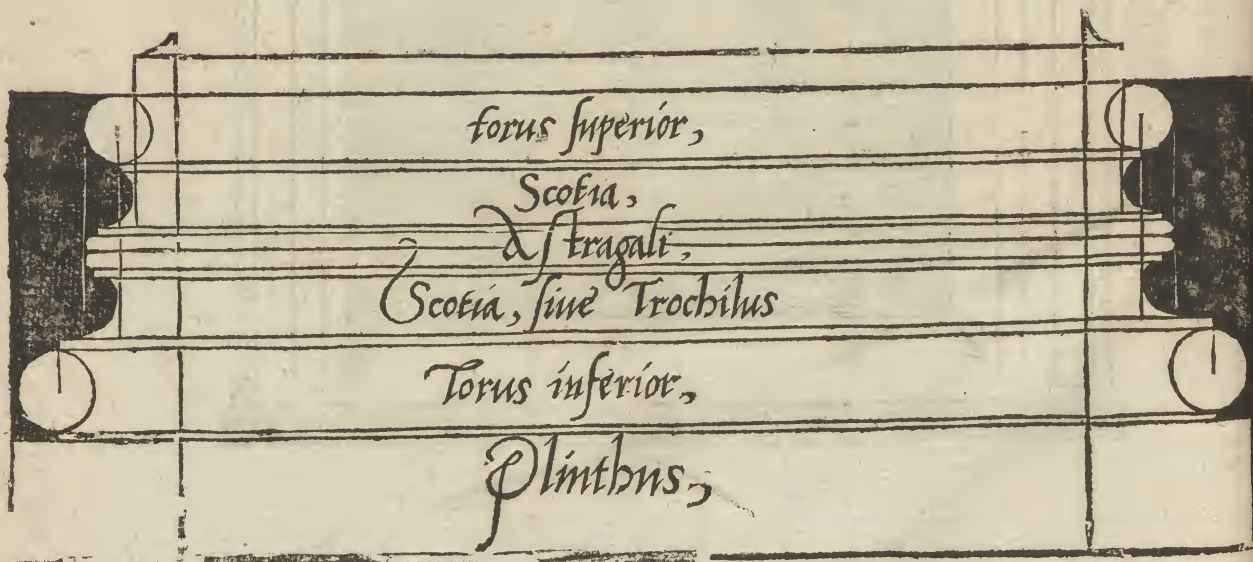

Of the order of Corinthia worke, and the
Ornaments thereof.

The eyght Chapter.

Of Corinthia worke, *Vitruvius* speaketh onely in his fourth Booke, and the first Chapter, in a manner as if he would say, that the same, which is sayd of the Ionica Columne, is in Corinthia worke: and in his second Chapter hee speaketh of Mogdilions among the Coronas, therefore not giuing any other rules or measures of the other parts: but the ancient Romanes vsing this order of Corinthia much, (as also the rest) made the Bases of these Columnes, with a great number of members or parts full of worke: of which Bases to set downe some rules, I will speake of one of the fayrest buildings in Rome, that is, the Pantheon, called by the name of, Our Lady de Roronde, setting downe all the measures thereof. The Columne of Corinthia worke is made by a common rule, consisting of 9. parts in height, with Capitals and Bases: the Capitall whereof, shall be as high as the Columne is thicke below, but the Base shall be of halfe the thickenesse of the Columne. Of this halfe, or height of the Base, there shall be foure euen parts made, whereof the one is for the Plinthus, the other three shall be deuided in five equall parts, whereof one part shall bee for the Thorus aboue, but the Thorus vnder shall be a fourth part thicker: so that which resteth shall be deuided into 2. euen parts, whereof one part is for the Scotie below, with the Astragall, and two Lists or borders: that Astragall shall be the sixt part, and each list or border the halfe thereof: but the list or border vnder the nethermost Thorus, shall bee a third part more then the other. The Proiecture of the Plinthus shall stand aboue in another order of Columnes, making them like the Ionica order; but if the place be beneath vpon the ground, then the Proiecture shall be like the Dorica order. Also, according to the place where the Bases shalbe placed, so the workeman must adde or diminish, as is before sayd: for as these Bases stand beneath the sight, it will stand well; but if it bee placed aboue the sight, then all the places that are vsed by the other members, with their seueral distances, shall be made greater, then by this rule is prescribed. And the higher they be set, so much the lesse and fayrer seeme the members: herein the workeman of the Roronde was well aduised, for that hee made the Bases aboue the first story within, with two Scoties, but yet with one Astragall alone, in stead of two.

The derivation of the Capitall Corinthia, was from a Bay of Corinthia: but so that Vitruvius in his fourth Booke and first Chapter describeth his petraea, whereof I will not trouble my selfe to speake of, thus much I will say: If a workman had a Temple to make for the Virgin Mary, or any other Saints that were Virgins, or Houses or Sepulchers for persons of honest life and conversation, then a man might use this manner of worke. The height of this Capitall shall be like the thickness of the Colonne below: the Abacus the seventh part of that height. Of the rest there shall be thre parts made: one for the leaves below; the other for the leaves in the middle; and the last for the Volutes, as we may call them. But betwene the Volutes and the middlemost leaves, there is a space left to the lesser leaves, from the which the Volutes grew. The Capitall marked B. shall be underneath like the Colonne above: vnder the Abacus, there is a Cintha made, the height whereof shall be halfe the Abacus: of which Abacus, thre parts being made, one shall be for the Cimatic with the Lists, and the rest for the Plinthis. Under the foure corners of the Abacus, the greatest Volutes are made; and in the middle of the Abacus, there is a flower as great as the Abacus is thicke, vnder the which the least Volutes shall be made; vnder the greatest, and also vnder the smallest Volutes, the middle leaves shall be set, betwene the which the least leaves shall grow out, and out of them the Volutes spring. The middlemost, and also the vndermost leaves, shall each be 8. in number, standing betwene each other, as the figure C. sheweth. The thickness of the Abacus, from point to point, shall be two Diameters of the Colonne below: which Diameter shall be placed in a square, & a Circle drawne without the square, which shall touch the foure corners: then, without this great Circle, another square being made, and divided in Diagonall, that is, crosswise, those lines will shew to be two Diameters in length (as Vitruvius teacheth). But from the line B. C. you shall make a perfect Triangle: and vpon the corner X. shall be to make hollow the Abacus: from the spaces, betwene the great Circle and the small, there shall be foure parts made, one part shall rest above A. and thre shall be thus taken away: the one foot of the Compass being set vpon X, the other vpon A. drawing about from B. to C. where the crooked line shall reach on the two sides of the Triangle, there shall be the termination of the corners of the Capitalls. The example is in the figure D. in this manner. The Abacus shall come in perpendicular, with the Plinthis of the Base.

T Duching the Architraue, Fræse and Coznice of the Corinthia, as I haue sayd in the beginning of this Chapter, Virruuius setteth dozne no measure thereof, although he setteth dozne the originall of the Putiles, which may bee made in all manner of Coznices, as wee see in Antiquities: but to proceed orderly, and not to leave Virruuius writing to much, I will set the ornaments of Ionica in this Chapter, adding thereto the Astragall in the Architraue, and an Echinus vnder the Crostone, as some Arch-Architects in Rome haue done. So I say, when the Architraue is made as it standeth by the Ionica, vnder the middlemost Facie, there shall be an Astragall made of the epyght part of the same Facie, and vnder the uppermost Facie also, one of the epyght parts of the sayd Facie wrought with Lead, as you see: after that, when the Fræse is set with the Cimatie, and thereto the Denticles with the Cimatie, then you must place the Echine above it, of such height as the first Facie is, the which with the Projectures and cuttings, shall shew more then the middlemost Facie: above the Echine, you must set the Corona, Cimatie, and Sima, as it is sayd in the Ionica Order.

Some Romish workemen, proceeding with more boldnesse, haue not onely placed Echines above the Denticles, but also made Putiles and Dentiles together, in one Coznice, which is much condemned by Virruuius in his fourth Booke, and second Chapter: for that the Dentiles represent certaine teeth, by Virruuius called *Aleri*, and the Projections are for the supporting of other ends of wood, by the sayd Author called *Cantery*: which two kind of beames may not stand together in one place; and I, for my part, could neuer endure Dentiles and Putiles in one Coznice, although Rome aboundeth therein, and diuers places of Italy also: but proceeding orderly in this worke, I find a generall rule, that is, that the height of the Colammes with Bases and Capitals, shall be divided in 4. parts, whereof one is giuen to the Architraue, Fræse and Coznice, and such a height agreeth with the Dozica: the fourth part shall be divided in 10. parts: 3. shall be for the Architraue, as also sayd, 3. for the Fræse, and 4. for the Coznice. But of those 4. there are 9. parts made, one shall bee for the Cimatie above the Fræse, 2. for the Echine with the Liff, 2. for the Putiles with their Cimatie, 2. for the Corona, and the 2. last parts for the Sima, with her Cimatie, which shall be the fourth part of the Sima. The Project of all shall be as also sayd: you may also make this Architraue, Fræse and Coznice, of the first part of the height of the Colamme, as Virruuius sayth in his fifth Booke, and seventh Chapter of the Theater.

The lessening of the Corinthia Colunne shall be made, as it is sayd of the other: and also thereafter as the height is, but of 16. foote downward: it shall be lessened above the first part, by the rule aforesaid: and if it bee striked or chaneled, then you shall make it like the Ionica; but from the third part netherwards the carving or hollowing shall be full, as you see it in the Figure on the sides. The Corona is without Spaties, whereof the Architrave is halfe the Colunnes thickenesse: the Frase, for that it is cut, is the fourth part more then the Architrave: and the Cornice without the Cimate of the Frieze, is as high as the Architrave: the height of all together is somewhat lesse then the fifth part of the Colunne: neuertheless, if the Proiecture of the Corona bee well made, then it will shew to bee higher then it is, and shall bee lesse wayght upon the building: wherefore, that the skilful workman may chuse out those parts, that best serue his turne, that he may not exceed Vitruuius doctrine, and the good Antiquities, which men, by his writing, acknowledge, if by any accident this Colunne had need of a proportioned Pedestal, being not let by any occasion, then the proportion thereof shall be thus: the breadth shall be divided in 3. parts, whereof 2. parts shall bee for the height, that is, one fourth parts, and 2. third parts, (I mean the flat) which height shall be divided in 7. parts: one for the Bases, one for the Cornice above, which shall in all be 9. parts, proportioned according to the Colunne: but of the particular members of the Bases and Cornices, I will hereafter shew more, with some Antiquities, whereof men may take such measure as shall best serue their turnes.

Of the Corinthia

Among other Antiquities of the Corinthia, which are sene in Italy, I thinke the Pantheon of Rome, and the Arch triumphant, at the Haven of Ancona, are the sayest and best to be sene: of which Arch, the Capitall hereunder marked A. is with great care proportioned after the great: which height is contrary to the writing of Vitruvius: neuertheless, it had good correspondencie; & it may be, that Vitruvius meant, that the height of the Capitall should be one Columnes thickenesse without the Abacus: but the text herein is falsified, for that I haue not onely found this Capitall, but others more of such proportion. The Columnes hereof are chaneled, as it is shewed here: the Pedestall with the Base vpon it, is a member of the same Arch, also proportioned in the small: the Cornice hereunto added, was found at Al foro transitorio in Rome: that marked with A. is very handsome, for a Corinthian Cornice without Modifications: that marked with B. is a little sayer, but that with C. is the vnhandsomest, because of the double parts, which haue no good grace from the Corona downewards: and also, for that the Corona, vpon so much Cornice, hath so small Prolecture. The Base of the Pedestall marked D. in my opinion, is very saye, and also the Basement with E. I thinke hath bene a thing that hath continued in some building: which things, altogether, men may applie to the order of Corinthia; and in the Janica I haue sene the like. The Architrave V. is in Verona, in an Arch triumphant, which Facies standeth contrary to Vitruvius writing: yet I haue set them here to shew such difference.

Of the Corinthia

Of the doozes of Corinthia worke, Vitruvius speaketh nothing at all; but I will speake of the Antiquities which are yet to be seene. The Gate or dooze marked S. Y. is at Truoh, upon the Riuer of Auiene, in a round Temple, made after the Corinthia maner, which dooze is lessened aboue the epghteenth part. The height is aboue, 2. 4. squares: the rest of the members are proportioned after the great. The window T. and X. is in the same Temple, and lessened abone like the dooze: the Pilasters or Antipagmentum are all proportioned, which a man may find with the Compasse. The dooze following, marked P. Z. is that of the Pantheon in Rome, also Corinthia worke; which is 20. ancient Palmes broad: the height 40. And it is sayd, that the Antipagmentum is all of one piece, and I also haue seene no other. The Antipagmentum of this dooze is the byedth of the 8. parts of the light thereof, and in the sides it is of a good thickenes. But for that you cannot see the fiest, without seeing a part of the soes, therefore it seemeth to such as looke on it, to be broader then in effect it is. And this dooze, because it is so high, comes in Perpendicular, and is not lessened as the other aforesayd: all the other members are proportioned according to the greatnesse. The Base aboue the Gate, is like that of flat Columnes aboue the first order, which I haue set downe by the Corinthia.

Of the Corinthia

The dooze hereunder set downe, is at Palestina, and is Corinthia: the widenesse is 2. four squares: the Antepagmentom or the Pilaster is broad the first part of the widenes, divided in maner aforesaid. The Sophore or Frise is the fourth part more then the Supercilie. The Cozona and the rest, are like the Supercilie, divided as you see in the Figure. The Brothyrides or Ancenes, with that which is upon them, hang so slightly or loosely, as you see. The Frontispicie is made, as in the order of Dorica, in the second Facie, is sayd.

Al though this Dore differeth from all the other, that euer I saw in any Antiquitie, neuer thelesse, it is very pleasing to the sight, and the weth well: which Dore is without Spoleta, about halfe a mile without the way, in an ancient Temple, made of the Corinthia maner; of the proportion and particular members, I will say nothing; for hee that seeketh nere, may find it with a Compass.

Of Corinthia

Of this Order of Corinthia, which is pleasing unto all men, I will make more sorts of buildings, setting downe some generall rules, to satisfie those that take pleasure to read this worke: and so; that ancient workemen, in times past, that desired to make their things strong and everlasting, made Pillars (wherein the Pilasters are closed) which beare up the Arches of a great thicknesse; for that cause, the Forefront or Facie ensuing hath the Pillar (that is, the whole body) as broad before as the widenesse of the Arch is; but the thicknesse is 1. fourth part lesse. The thicknesse of the Columnnes shall bee a first part of the Pillar. The Pitches betwaine the Columnnes are 2. Columnnes thicknesse in bredth: their height is somewhat lesse then 2. fouresquares. The height of the Pedestals of 3. Columnnes thicknesse. The height of the Arch shall be made of 2. fouresquares. The height of the Columnnes with Bases and Capitals, shall be 9. parts and a halfe. The bredth of the Arch with the Pilasters, shall be of halfe a Colonne. The Impost which beareth the Arch, shall be of the same height, made, in maner, like that of the Theater of Marcellus, in the Order of Ionica: which Impost shall serue for a Cornice above the doore: but the height of the doore shall be made thus: Under the sayd Cornice, the Supercilie shall be also made of the like height; and from thence downewards there shall be 2. equall parts made to the Stayres; whereof, one shall be the bredth of the light, and likewise the Cornice of the windowes. The light of the windowes shall be taken Diagonall wise: and the Antepagmentum a first part of the light. The particular members of the Pedestall, Base and Capitals, shall be made, as in the first part of this Order it is layd. Above the Columnnes, the Architrave, Frieze and Cornice shall be set, divided in such maner as is shewed in the beginning. The height of the second Storey shall be a fourth part lesse then the first, and all the members lessened accordingly, as you may see and measure, it in the figure: the elevation above this I esteeme not for a whole Storey, but much lower: the height thereof is as much as the widenesse of the Arch below, and the Cornice which serueth for Architrave, and Frieze, shall be the first part of the height of that Storey; which measures you may take from the Capitall Dorica: and for more Ornament, a man may set a Fattigies above: but setting it in the middle, it would hardly agree with the two small above the Pitches, vnlesse it ran round, whereby the worke should be changed, and shew better to the sight.

Of the Corinthia

When a workeman will build a Temple, the higher the ground or Pavement is elevated, so much statelier the building will shew, so; so right ancient workemen haue done, although they used other formes of Temples, much different from this here set downe: so; they made a body alone, but wee, that are Christians, make our Temples in three parts, setting one part in the middle, and 2. parts on the sides: and sometimes the Chappels are made without the sides, as you see in the ground. The widenesse of this Facie shall be of 32. parts: one whereof shall be the thieknes of a Colunne: the middlemost inter-Colunnes shall containe 7. parts: the greatest inter-Colunnes on the sides shall bee 4. parts and an halfe. The inter-Colunnes with the Niche shall be 2. parts: and so the 32. parts shall be distributed. The Arches with the Pilasters shall be halfe a Colunne broad: the widenesse of the Dore shall be of 3. parts and an halfe: the height of 7. parts: the Impost vnder the Arch is as broad as the Arch. The height of the Pedestall is 3. parts: the height of the Colunne, with Capitall and Sales, is 9. parts and a halfe. The Architrave, Frise and Cornice shall be the fourth part of the height of the Colunnes: and so so; the particular members and parts resting, the first rule shall be obserued. The windowes, Niches and other ornaments, a man may conceaue in the figure and measure. The second storie shall be a fourth part shorter then the first, and all the members lessened accordingly: but the Architrave, Frise & Cornice, shall be placed in 3. equall parts, as I sayd of the other. The Fastigies shall be made, as Vitruuius hath shewed in the order of Dorica. The 2. sides that stand for beautifing and vpholding, shall bee the fourth part of a Circle, whereof A. and B. is the Center: and aboue each Arch that parteth the Chappels, a man may set such things, which will be a great vpholding to the middlemost worke, and also along vpon them, the water may fall from the vppermost roofo to the nethermost.

Faint, illegible text at the top of the page, likely bleed-through from the reverse side.

Of the Corinthia

The deniding of this worke ensuing shalbe thus, that the Pillar shalbe the third part of the widenesse of the Arch, but the thickenesse of the first part: the thickenesse of the Colunne also as much. The height with Base and Capital of ten parts and an halfe: the Arch, Pilaster, and impost of the halfe Colunne: the measure of the Impost a man may take from the Dorica Chapter, altering the members: the same shall also serue for a Cornice about the doore, and for supporting of the windowes about the shops: the height of the Arch (so sometimes upon occasion, a man shall be forced to haue it so low as you see) shall be of 3. parts in the bredth, and 5. in height: and the doore also shall haue the same proportion. The Antepagmentum shall be the first part of the light, and if the workeman will make the height of the Arch of double proportion, the doore also will be of such proportion: but the Colunnes should need a great stone vnder the Bases, with which things ancient workemen holpe themselves. The height of the Architrave, Frieze, and Cornice are of 2. Colunnes thickenesse, as it is said in the first part of the rules, or in manner of some Antiquities aforeshelved. And so; that the space vnder the Arch to the soiler, which is euen with the flat of the Cornice, should be too great to make crossewise, in such case my aduise should be, to make an Arch right behind the Colunne, and to make each space bettewise, as you see in the ground. The height of the second story shalbe one 4. part lesse then the first, decided in this manner: the Podium shall bee as high as the thickenesse of two of the lowest Colunnes, and from thence vnto the top shall be made 5. parts, one for the Architrave, Frieze and Chynice, and 4. for the Colunnes: the Arches with the Pilasters shall be of halfe a Colunne; and for the rest, you shall obserue the generall rule: and if the Facie standeth in any place or market, as it is shewed by the winkels or shops, it will be easie and comely to make a leaning about the vppermost Cornice: but for salety from rayne, snow, and frost, aboue all other things, it shall bee requisite to make a rooffe or pauerment well closed and leaning forward, because of the water: but it will be surer, if it be covered with lead. And although good workemen condemne and shun the setting of a Colunne in an empty place, which I also commend not, neuertheless, so; that I haue sene the like matter vpon the Porticus of Pompey in Rome, but made after the Dorica manner, therefore I haue presumed to set the like, if it may serue any mans turne.

Of the Corinthia

For that the Venecians, in their buildings, use much Corinthia worke, and also many windowes and Podiums, therefore I have made one here, which is full of windowes & Podiums, & have also made Storey upon Storey, which is more commodious then hearings out and leanings over are, and the building will have a better shew; for that all the things which a man may see within, will be seemely. The Comperition of this Facie shall be thus: The breadth shall be divided in 30. parts, and one of those parts shall be the thickeesse of a Colunne: the middlemost Intercolunnes shall be of 4. but all the rest of 3. and so the 30. parts shall be distributed. The height of the Colunnes shall be of 10. parts & a halfe, with Bases and Capitals. The Architraue, Fræse and Coznice shall, together, be the fift part of the height of the Colunnes. The members shall be deuyded, as aforesayd. The light of the Windowes are a Colunne and a halfe wide, all in Perpendicular from the top to the bottome: but the height of the first windowes are of 3. parts broad, and 4. high: and those that shall stand vpon them, haue their height in Diagonall maner. The widenesse of the Doze shall be of 2. Colunnes: and the height 4. The Antepagmentum, with the Supercilie, Fræse, and Coznice, shall be deuided, as it is sayd of the other before: and so shall the Coznice also of the Doze be, as the windowes below are. The second Storey shall be lower then the first the fourth part: but the leanings with the Balusters being made, as high as a window is broad, the rest of the height shall be deuided in 5. parts: one for the Architraue, Fræse and Coznice, and the other 4. for the Colunnes, with Bases and Capitals. The height of the windowes shall be of 2. fouresquares: with the rest of the Ornamentals, you must doe as I haue sayd of the like: and also the Doze of the Gallery shall be like that below. The third Storey shall be lessened more then the second one fourth part, and euery member proportionably; onely, the height of the windowes, they shall be of 2. fouresquares, and rather higher then lower, because the height of it selfe lesseneth: The eleuation also in the middle, shall be the fourth part lessened, as it is sayd of the other. The Architraue, Fræse and Coznice are the fourth part of that height. The Fastigium shall be made, as it is sayd of the Dozica Temple: and if there remayneth other measures, you must alwayes turne to the first rule. Hereunder I will set no flat ground: for the Perspectives of the Galleries shew all clearly.

Of the Corinthia

AS I haue at other times sayd, that the workeman shall haue Columnes inoto, but yet so short, that sometimes they will not serue his turne, vntilse the indullrie and cunning of the workeman bee such, that he can helpe himselfe therewith. The composition of this Facie shall bee thus, that the wardenesse of an Arch shall be of double height in bredth: the Pillar shall be halfe the same wardenesse before: but that Pillar being made in thre parts and an halfe, one part thereof shall be the thickenesse of one Colunne: The inter-Colunne of a halfe Colunne: and so much also the Pilasters and the Arch hold. The height of the Pedestals, without the Plinthus vnder them, shall be as much as the whole bredth of the Pilaster, the members being deuided, as I haue sayd of the Pedestals of Cozinthia. The height of the Colunne, with Bases and Capitals shall be of 11. parts, and that shall not therfore be false, for it is set fast on a stone, moze for ornament, then for vpholding of any waight. The height of the Architrane, Fræse, and Coznice shall be made of the fourth part of the Colunnes, and in Perpendicular the Colunnes shall beare out all the members without the Cozona or Cima, which will goe right through without crookening; for good Antiquities vied to doe so: and *Bramant* also, the light of Architecture in our age, made such a house in Rome, called *Beluedere*. The wardenesse of the dooze, shall be of foure Colunnes thickenesse, and twice as high. The Antepagmentum, Supercilie, and Fræse, shall be made so, that the Coznice, which vphold the Colunnes, shall serue also aboue the dooze, and also ouer the windowes. The wardenesse whereof shall be of thre Colunnes thickenesse, and the height of five. The second story shall be lesse then the first, the fourth part: but the whole height being deuided in 6. one shall be for the Podium, foure for the spaces of the windowes, and the other for the Architrane, Fræse and Coznice, deuided in such maner, as you shall see it in the order of *Composita*. The wardenesse of the windowes are in Perpendicular to the nethermost; and the bredth twice in the height: the rest of the ornaments, as windowes and Piches, shall be done as in this *Ionica Gate* is shewed, which being wrought with moze liuelynesse and flourishing, will be a *Corinthian worke*. The bredth of the Piches with the Pilasters, shall be in Perpendicular aboue the Colunnes, but the wardenesse thereof, being deuided in 7. fives shall be for one Piche, and 2. for the Pilasters. The height shall be of 3. bredths, because they stand farre from sight, whereby they shew shorter. The Pillars aboue the Coznice are made for ornament, and also for commoditie, to make Chimneys of some of them.

Of the Corinthia

Things that are made for common use (although they are placed in all proportion and measure) are much commended; but not admired. But things that are not used, if they were made for some cause, and well proportioned, shall not onely be commended of most men, but also wondered at. Therefore this building following, which representeth a Temple, shall first be made of strong rusticall manner, as you see, and of such height as the place and situation requireth; but it must not be higher then 2. mens length: On which flat or Pavement, a man shall goe upon, beginning at the step A. standing within the entrie, and going by to B. then it shall be flat where the Temple shall have a broad walke, with a leaning round about. The which Temple shall be elevated from the walking or Pavement, till you come above the height of the Podium, or leaning, 3. steps more: and to come to that, you must goe upon the step C. to the flat D. which shall be the height of the Podium, with another leaning, which shall be higher then the lowest. And from this flat, to the Pavement of the Temple, the sayd three steps shall be: the widenesse of this Facie shall be divided in 24. parts, and one of these parts shall be the thicknesse of the Colunne. The middlemost inter Colunne shall have 4. parts: those that stand on the sides, where the windowes are, shall be 3. parts: and where the niches shall be, they shall each of them have a part and an halfe, so shall the 24. parts be distributed. The same Stilobato, as is without at the Podium, shall also be made vnder the Colunne, of which Pedestall, the height without the Plinthus, the Base shall be 3. parts. The height of the Colunnes, with Bases and Capitals, shall be of 3. parts and an halfe. The Architrave, Frise, and Cornice, shall be a fourth part of the Colunne, as it is sayd of others: and the members also divided in 4. sorts, the widenesse of the Gate shall be 3. parts, and the height 7. parts and an halfe, which is about 2. foure squares and an halfe: and this is done, for that by reason of the distance, they seemed shorter to a mans sight, then these that are below. The widenesse of the windowes shall be one part and an halfe; but the height shall be more then 2. foure squares, because of the sayd shortening. The bredth of the niches shall be one part, and the height of 3. bredths, for the same reason: the order that the Fastigium holdeth, shall be like the Pedestal in height, and the Cornice the fourth part of the sayd height: and the other, where the Kettell or Lanthorne riseth by, is also of the same height, which shall be so much more then halfe round, as the Proiecture shall cover the Cornice. On the 4. corners of the Temple, for the more beautifying, you may make 4. Piramides: the height whereof (without the Stimen) shall be as the eyes are at the beginning of the Fastigium: and the Scima like the Fastigium: which Fastigium shall be made by the like rules, as are spoken of before, of the Temple of Dozica. The parts vnder the Temple, shall be for certayne Oratozies, called Confessionals, whereof I have seene many vnder the high Altar.

Of the Corinthia

Although in these our dayes, men make no Arches Tryumphant of Marble or of other Stones, neuertheless, which any great personage entereth into a Towne, they vse to make Arches tryumphant for to welcome him in, which they set in the fayrest places of the Towne, adozned and painted in most curious maner. Therefore, if you will make an Arch after the Corinthia maner, the proportion and measure shalbe, that the light shalbe of two sourses, and one sixt part: the thickenesse of the Columnnes shall be the 5. part of the widenesse of the Dooze or light: The height of the Pedestals shalbe of thre Columnnes thicke: and the height of the Colonne shalbe of ten parts and an halfe. The Epistilie, Sophoze, and Cornice, are together the fourth part of the height of the Colonne: and so from vnder the Arch, to vnder the Architrave, there shall hang a roole of two Columnnes thickenesse in height, and the lessening thereof vnder, shalbe drawne vp to the Center of the Arch. Touching the particular members, as the Pedestal, Base, Capitall, Architrave, Frase, and Cornice, you shall obserue the rule befoze set downe: the bredth of the Arch, with the Pilaster, shalbe halfe a Colonne. The inter-Colonne must be of a Colonne and an halfe. The Niches are a Colonne broad, and the height thre, for a standing Image to be placed in them. The height of the second order shalbe made thus: the Colonne without Pedestal, shalbe set in the vpper part in the Cornice in thre parts, and one of those parts shalbe the height: but of that height there shalbe sours parts made: one shalbe the Cornice aboue; the diuiding whereof, may be drawne out of the Chapter of Dozica, altering the members. The height of the Bases stand eleuated aboue the Cornice the thickenesse of a Colonne below, and that is, for that the vsiecture of the Corona darkeneth the rest of the Bases netherward. The Cornices shall giue out, as you see them in the Figure. The height of the Fastigium shall be made by one of the rules set downe in the Dozica. This present Figure doeth partly resemble the Arch at Ancona: but with great reuerence, in regard of such a workeman, I haue brought the measure into one generall rule, that euery man may easily put such measure in vse.

Of the Corinthia

AS much as need required, I haue spoken of Corinthia; although a man might speake of diuers kindes of ornaments: but it is needfull to speake of the ornament of a Chimney, because of the dayly vse thereof, so that a man cannot bee without it: for not onely in great, but also in small Chambers men vse to make fire, where, in such straight places, they set such Chimneyes within the wall, whereon a man may make diuers ornaments after the Corinthia manner. But if you make them in this forme, then the widenesse must be taken, according to the situation of the place: and the Pilaster shall be made of the sixt part of the widenesse; but of the eighth part the worke will be smaller: the which Pilaster or Antepagmentum, together with the Supercilium, shall bee deuyded like the Architrave of the Corinthia. This Frise above, because it is grauen, shall be made a fourth part greater then the Supercilium. The Cornice, together with the Capitals of the Putiles, shall hold as much as the Supercilium, and the same deuyded in thre, as it is sayd of the Cornice, in the Corinthia. The breadth of the Putiles, or Ancones (as we say) above, shall be like the Pilaster, but beneath, which reacheth down to the opening, they shall be one fourth part smaller; and vnder them there hang out two leanes, as you see in the Figure: which Proiecture shall bee referred to the pleasure of the workman. To make or leaue the ornament above, there consisteth not much therein: and this inuention shall serue not onely for a Chimney to beautifie it withall, but also for a dooze, or other things, and the Frontispicie thereon will agree well with it, when you vse it for a dooze.

Of the Corinthia

In a Hall or a great Chamber there is a great Chimney required, proportioned according to the distance, the which needeth a great conuergance; therefore, if a man will make the Dodiglions sufficient for such a bearing out, hee must make two places on the sides: but in such a case (I mean) he should make two flat Columnes, and before them round Pillars, not close to the other, in such maner, that betwene them both the place for the Columnes must be, and in this maner you shall adorne them. As I sayd in the beginning of this Chapter, the Corinthian maner had her beginning from a mapd, of the Colone of Corinthia: therefore I haue placed a mapd here, in stead of a Colonne: the height and bredth of the opening, being made according to the place, the height shall be diuided in nine parts, and one of those parts shall be for the heads of the mapds, and the whole Figure being formed and swaddled, as you see: then the flat Colonne or the Pillar shall be of the same proportion, obseruing the measure before set downe. Upon the Colonne, the Architrave, Frieze and Cornice shall be set: which height, together, shall be the fourth part of a Colonne lying, measured after the rule also sayd, from the Cornice upwards, to the place; and the height thereof a man may adorne in this maner, as in the Figure: and who doubteth that this inuention might not serue for a Dore, making such a Colonne against the wall, and specially before the Gate or Dooze of a Court, or place of triumph, and such like?

The end of the Corinthia maner of building.

The ninth Chapter.

Although *Vitruvius* speaketh of foure maner of Columnes, as Dorica, Ionica, Corinthia and Thufcana, giuing hereby vnto vs almost the first and simple maner of ornaments of Architecture: neuertheless, I haue added one to the sayd foure, as (almost) a fift maner of Pillar, composed of the others aforesayd, moued thereunto by the authoritie of Romane worke, which we may see with our eyes. And, in trueth, the workemans foresight ought to be such, that as occasion serueth, he may make many things by the sayd simple and compound worke, respecting both the nature and the subiect. And therewithall the workeman sometimes (to whose iudgement many subiects may be referred) shall be abandoned and left by *Vitruvius* counsel, that could not conceaue all; whereby he should be brought into a straight, and compelled to do, as he seeth cause: (I meane) for that *Vitruvius*, in my opinion, speaketh not at all of this Composita, by some called, Latina, and by others, Italica; which the old Romanes, peraduenture, being not able to goe beyond the inuention of the Greekes, finders of the Dorica, after the example of men, and of the Ionica, resembled to women, and the Corinthia, after the forme of maydes, of the Ionica and Corinthia made a composition, piecing the Volute of the Ionica, with the Echino in the Capitall Corinthia; and these they vsed more in Arches tryumphant, then in any other things: which they did with good foresight, for that they tryumphed ouer all those countries, fro whence the sayd worke had their beginnings: and so they might well at their pleasures, as commanders ouer them, set these orders together, as they haue done in the great building of the Romish Coliseo. And hauing therein placed the 3. orders one vpon the other, viz. Dorica, Ionica and Corinthia, they placed Composita about them all, which, by euery one, is called so: although, as men may perceyue, the Capitalls are almost Corinthia. But it was an excellent iudgement, in my opinion, of them, that hauing placed this order in the highest part of the Coliseo, which being farre off from mens sight, men should haue seene, if they had set the Architraue, Freese and Cornice of the Ionica and Corinthia about the Columnes, that such worke, by long distance of time, would haue prooued bad: but placing the Mutiles in the Freese, they made the worke rich, and it holpe the Proiecture of the Corona; and withall, it wrought another effect, which was, that the Architraue, Freese, and Cornice, seemed to be one Cornice alone, by meanes of the Modiglians that were set in the Freese, for that they seemed great, obseruing their proportion.

The height of this Colonne, Composita, shall, with Base and Capitall, be of 10. parts: the Base shall be of halfe the Colonne thickenesse; and it shall bee made Corinthia, with the measure set downe by the Corinthia: and this is yet seene in the Gate of the Arch tryumphant of Ticus, and Vespasian, in Rome. You may make the Colonne chaneled, as you doe the Ionica, and sometime like the Corinthia, make the Volutes somewhat greater then the Caulicoli of Corinthia: which Capitall you see in the Arch aforesayd, and is set downe here in Figure; for the Architraue, Freese and Corona, if it stand farre from mens sight, then the Architraue shall bee as high as the Colonne is thicke about: the Freese, wherein the Mutiles are, shall bee of the same height. The Cimatie of the Mutiles shall be of a sixt part: the Proiecture of the Mutiles shall be like the height. The height of the Corona, with her Cimatie, holdeth as much as the Architraue, and that denided in 2. parts, one shall bee the Corona, the other the Cimatie; the Proiecture thereof, shall be like the height: and this is a common rule, although that in the Figure ensuing, marked C. you may see the members and measures of that, which is in the Coliseo aforesayd: and for that this Colonne is the slenderest of all others, therefore the Pedestall ought to bee seemelier then the rest, following the common rule: the height thereof shall be a double bredth, that is, flat, and of that height there shall be eysht parts made, one for the Base, and one for the Scima: but of the particular members you may take the example here on the side, in the Figure; which, altogether, are proportioned according to the Pedestals of the aforesayd Arch tryumphant: and so, being a Colonne of ten parts, the Pedestall shall also be ten parts in it selfe, proportioned after the Colonne. And although men make all Pedestals in Perpendicular, yet in Athens, a most ancient Colonne, there are some, that are somewhat lessened in the upper part, which I discommend not.

Of the Composita

For that ancient workemen have used diuers mixings of worke, therefore I will not set downe those that are best knowne and composed, for that the workeman may chuse out of them such as he thinketh will serue his turne best. The Capitall hereunder set, marked T. is composed of Dorica, Ionica, and Cozinthia: the Abacus and Cimatie is Dorica: the Chine and Strike, is Ionica: the Astragal and Leaves, are Cozinthia, as also the Base with the two Thorus, is Dorica: but by the 2. Scottes, and the Astragals, as also, because of the beautifulnesse thereof, it sheweth to be Cozinthia; which things are in Trekeuere in Rome: the Capitall X. and also the Base, are of 2. kinds, Dorica and Cozinthia. The Abacus of the Capitall, and also the Base, is Dorica; but the Base, by meanes of the liuelinesse of the worke, may be named Cozinthia, and so are the Leauies of the Capitall of Cozinthia: but for that the Abacus is square, and all the other members round: therefore you shall cut the Rose vnder the Abacus in the 4. corners, as you see it in the Figure. The Capitall A. with the monstrous hoyle, in place of Caulicules, may be called Composita, and is in the Basilio del foro transitorio. The strikes of the Colunne are different from others, as you may see them beside the A. The Base X. is Composita, and is in Rome: the Capitall is mere Cozinthia, and is at the 3. Colunnes, beside the Colleso. The Capitall C. is composed of Ionica and Cozinthia; and is in an Arch triumphant in Verona. The Capitall D. is in the same Arch, on some flat Colunnes. The Base Y. is Composita, with the Astragals; which standeth vpon the vppermost Thorus, and is of Antiquitie in Rome.

Of the Composita

You see not many Arches tryumphant made of Composita, and the most part are made of pieces, taken out of other buildings: neuer thelesse, hauing shewed a generall rule for them; therefore I will not set downe any other inuention of Edifices of that kinde: for the prudent workeman, as necesse requireth, may helpe himselfe with the inuention s aforesayd, changing them into Composita. But I will shew two orders of Chimneys of each sort of worke; the one within the wall, & the other without. This Chimney, which should stand cleane within the wall, if you will make it in a small place, the height shalbe no higher then to a mans shoulders, that a mans eye and sight may not be hurt by the fire: and the widenesse shalbe according to the bignesse of the place wherein it should bee set. The height vp to the Architrave, shalbe deuided in 4. parts, one shalbe the bredth of the Antepagmentum or the Pilaster, wrought in such maner as you see it here set downe. And in this Composita, (because it is fræer then the other) I haue made this Pilaster very much differing from the rest, neuer thelesse, taking a part of this inuention from an ancient scoule, which is at S. Iohn de Lateranes in Rome. The Architrave shalbe of halfe the bredth of the Pilasters: the Cimatie of the first part: the rest shalbe deuided in 7. whereof 3. parts shalbe for the first Facie, and 4. for the second. The Afragalus shalbe made of a halfe part, taken betwene both the Facies. The Fræse, because it is cut, shalbe made the fourth part higher then the Architrave: the Cornice is the height of the Architrave, and there shalbe 7. parts made of it: 2. for the Cimatie vnder the Cozona: other 2. for the Cozona: and one for the Cimatie thereof. The 2. that remaine, are for the Scima; and the Proiecture of all shalbe like the height. But if you make the Pilaster of the first part of his height, and the other members diminished accordingly, it will be much moze seemely, and specially, if the worke bee of small forme. For the ornaments aboue the Cornice, you may chuse whether you will make them or not; that is referred to the workeman.

Of the Composita

A Man may make other ornaments of Chimneys of this Composita worke, & in diuers formes as this, because it is more licentious then the other maner of building: and for a changing of the other forme, you may also make this by this rule. The height of the Architrave being of a reasonable mans stature, you shall deuise the same in 3. parts, whereof one shalbe for the bredth of the Pedigions or Rolles: Vitruuius calleth them *Prothyides*. The height of the Pedestals shalbe as high as if they were to sit vpon. The order above the Pedigions, which holdeth no rule at all, shalbe two parts and an halfe of the bredth of the Pedigions. And so; that also I haue sayd, this maner is without rule, therefore the leaues and other parts, shalbe referred to the workman. Men may also sometimes set the Dorica and the Ionica, and sometimes the Corinthia above the Pedigions: and so; that the funnell, which recepueth the smoke, is wyde, therefore you may make the small order above it, which will giue it a fayer forme then the vsuall, which goeth like a *Pyramides*, or sharpe vp.

Of foure maner of Simmetries.

The Workeman is to haue a great iudgement, because of the diuersitie of composition in Ornaments of building, for that there are some places in Architecture, of the which there may, almost, certayne rules be giuen, for they are no accidents that happen contrary to our opinions, for euery day we see some Columnes, that with their different positions, shew different measures in themselves, according to the places where they stand. These alterations are so made in buildings in 4. wayes, that is, setting the Columnes almost in an Inule, without any companion to helpe it epyther on the sides or behind. These certaynely beare a great waight, and in their height they goe not aboue the aforesayd rule: the example hercof is in the first Colunne marked A. but if you place them against the wall (though they be round) by the which being vnderholden and holpen, a man may make another thickeesse higher aboue the same: the example thereof is in the Colunne B. Also drawing alone two third parts from the wall, they may yet a thickeesse or wall go higher then the other, for that you see the like in some buildings, that rise to nine thicker & a halfe, and most in the Colises of Rome, in the Order of Dorica, as it is shewed in the 3. Colunne C. but they are more holpen when they haue Pillasters on the sides, which bearing all the waight, geue the workeman meanes to make the Columnes more seemely, and so slender, that they may be sayd rather to be placed there to fill a roome for beautifying, then for strength. You may also draw a Colunne two third parts out of the wall, and on each side set halfe a Pillar, which will helpe the Colunnes so well, that you may make another thickeesse aboue: and in this case, the Architrane, Frieze and Cornice may beare out vpon the round Colunne, yea although it were flat, because the halfe Pillars would hold the Architrane, &c. on the sides: but vpon one Colunne alone, it is vicious to make such worke bearing out, for the other parts besides should be abandoned without any helpe. This example you see in the Colunne D. But when the Colunnes haue any waight to beare by, without the helpe of another, and shall haue fit Intercolunnes, it shall not be thought meate to excede order, yea, although they haue Storey vpon Storey to beare by: it is reason that they should be made better, that the worke may be more durable: and although the Pedestall be a great helpe to raise by Colunnes, neuertheless, if the Colunnes be high inough, I would thinke it better if the Colunnes had them not, specially in the lowest Storey, but in the third and fourth Storey with reason. Podiums and Pedestals also serue to raise by Colunnes, which the old Romanes obserued in Theaters and Amphitheaters.

But touching the setting of Colunne vpon Colunne, there are diuers reasons: The first is, that the Proiecture of the Pedestals of the Colunnes placed aboue, should go no farther out, then the thickeesse of the vndermost Colunne, and this should be a most certayne reason: but for that the second Storey should lessen much from the first, and would serue no more for any other Storey, considering the great lessening ensuing, another reason, and more to the purpose, is this: That the flat of the Pedestall ought, at least, to be in Perpendicular with the Colunne below, and to set the Colunne aboue this Pedestall, lessened a fourth part from that which standeth vnder, as well in thickeesse as in height: so this rule agreeth with that of Vitruuius in Theatrum: which figure is aboue the Colunne A. and if you will not lessen the Colunne so much, then you must make the vppermost Colunne as thicke as the nethermost is in the vppermost part: but in this case, the flat or massy part of the Pedestall would be broader then the nethermost Colunne is thicke below: neuertheless, those of the Theater of Marcellus worke that effect. The example hereof is in the Colunne B. and these three reasons are probable inough. But the ancient Romanes, in the great Edifice of the Coliseo, made the Colunne Ionica, Corinthia and Composita all of one thickeesse, and the Dorica, vnder all the other, they made thicker, about the twentieth part. And this (in my opinion) they did by good aduice: for if they had lessened all the Colunnes the fourth part, one aboue the other, the last, in so great a building, by reason of the great distance, would haue shewed very small, which we now see to be of good correspondence, by reason of the height. The shewing of this is in the Colunne C. And as the Colunne aboue the Colunne D. is lesse then that which standeth lowest one fourth part: for that, if a man hath a reasonable house to make of 3. Storeys, so I would not thinke it amisse, that a man should lessen euery Storey the fourth part, according to Vitruuius aduice: but if the building be high, then you were better obserne the Order of the Coliseo, that the Storeys Dorica, Ionica and Corinthia, may each bee about one height, but the Storey aboue increase in height about the fifth part: and this is so (as I haue sayd) because of the great distance: which part, by meanes of the great distance, seems to be of the height that the rest are: and although that the shewing of these Colunnes is Doricall, yet it is so in all sort of Colunnes.

Of Bricke.

Having spoken of so many and divers Ornaments of Stones, it is requisite, that it should also shew, to how they are to be placed in worke; and specially, when a man is to mixe hard Stones & bricke together, which requireth great diligence and Arte: for that bricke are like flesh in a piece of worke, and hard Stones like the bones to knit and hold them together: which two things, if they be not well and fastly bound together, they will, in time, decay: and therefore the foundation being made in such manner as the place affordeth, it is requisite, that the workeman should make ready all the hard Stones, and also the bricke, with the rest of the stuffe belonging thereunto, and so should come to lay and ioyne the hard Stones and the bricke together, all at one time: and it is requisite, that the hard Stones should be set so farre within the wall: which doing, the worke will be strong and continue hard. The example hereof is seen in the other side, by the figure A. where it is also shewed, how a man may make places well high, without feare. And if you have Pedestals with Columns to set upon them, where hard and soft Stones are mixed together, if the hard Stones be not well ioyned with the soft, as you see in the figure B. the worke will not continue long. And if the Columns be of divers pieces, some of them (that is the least) shall goe deeper into the wall, to hold the other the faster. But if the Columns be of one piece, then they would stand, at least, a third part within the wall; but the Bases and Capitals must enter much more into the wall, and above all the Corons and other Cornices, which beare farre out from the wall. The innermost part that is brought, must counterwaile that which is without; that it may beare it selfe: but if at the same time a man will make any worke or facade upon the Stones, then it is requisite, that the workeman, before he begins to lay any worke above the ground, should make ready all his Stones, together with the other stuffe belonging thereunto: and so laying and knitting the Stones with the bricke together, I say, that he shall doe well to set some of the Stones so deepe into the wall, that they may hold the other pieces together by force, ioyning well in, as you see it in the figure C. that in time they may not rype and breake asunder one from the other. But that the wall, made of bricke, should not sinke, and sinking, should breake the thinnest parts, by reason of the waight above, it is necessary to haue bricke well burnt, and moztet well tempered, & betwixt the Stones little moztet, & wel layd and ioyned one upon the other: And above all, such worke would not be made by any force, nor waight upon waight, to be packt in haste, but you must let it rest somewhat from lay to lay: for if a man will worke in haste, and set great waight upon it, it is most certayne, the wall will sinke, and the Stones being not able to beare the waight, will breake; but if it be made with leysse, then the stuffe will be as it should be: nevertheless, I would alwayes more commend the worke that is wholly bound in the wall, then that which is ioyned together or covered; and specially, in my opinion, men should not make them in walles that stand outward, for that the houses which haue bene made so in former time, by ancient workemen, and were covered over with Marble and other fine Stones, are now seene all without Stones before, and nothing but the wall of bricke, that stand behind them, standeth still: but those buildings, where the hard Stones are bound and ioyned into, and with the bricke, are yet standing: nevertheless, if you will make such worke simple, I thinke this the surest way, although some workemen, in divers places of Italy, haue made some building, with simple walles, leaving places in them for hard Stones to be put in, and after, at another time, haue put in such Ornaments: nevertheless, for that such things are not well fastened in the wall, but in a manner backt, you may in many places see the pieces fall, and euery day more and more decay.

Of Doores of Wood, and of Metall.

The tenth Chapter.

AS I thinke, I haue sufficiently spoken of the Ornaments belonging to building of Stone, now I will speake of Doores that shut the houses: whether they be of Wood or Metall, I will set downe some Figures thereof: of the hookes I will say nothing, for all the world knowes them well enough: neuerthelesse, those that were vsed in ancient time, as you see them in the Figure *A*. were easilier to be opened and shut, then those which are now vsed in all Countries, as in the Figure *B*. But whether these Doores are of Wood or Metall, their Ornaments shall be made in such maner, that the fayrer the Ornaments of Stone are, the Ornament of the Gate also shall bee correspondent, that they may be one like the other; and to the contrary, if the Ornament bee slender, then you shall make the Doore of Wood or Metall thereafter, which is to be referred to the workeman: and to giue you a shew of such Ornaments, you shall here see siue maners of Ornaments, which, for the most part, are taken out of Antiquities.

Of the Frames of Doores

If men make Doores, Gates, or Leaves (as we terme them) all of one piece, so that there needeth in that case neither wood nor yron vnto them, they make the bookes of the same piece of Metall. But those that are made of wood, and then covered ouer with Copper of reasonable thickenes, which, if it bee of flat plates, you must fasten one vpon the other, and yet, although they be well ioyned & ynd, or nayled together, neuer thelesse, the nature of wood is such, that it will shrinke or swell, as the time of the yeere is drie or moyst: if therefore you will make such a doore, that shall be covered ouer with Copper, yron, or any Metall, you see the surest way here in the side, in the figures A. and B. for wood neuer wareth longer, but remaineth still in the same forme; which is referred to the workeman, to make them thicke or thinne, as hee will, according to the waight that they shall beare, and you may also fill the spaces of the same wood. And so; that all the ancient doores or goings throug, are commonly square, onely those of gates of Townes, or tryumphant Arches, which are roost: neuer thelesse, in our dayes many doores are made round about, peraduenture for more strength; and also, so; that in some cases they become the houses well, whereof I haue shewed a figure, and so; that, in trueth, a man cannot conceaue all things: so; many accidents happen to a workeman at such times when he is to deuise some new worke.

Of Ornaments of Pictures within and without the houses.

The eleventh Chapter.

That I may not leave out any kinds of Ornaments, whereof I giue not some rule for instruction, as well in Pictures as other things, I say, that the workeman ought not onely to take care of the Ornaments of stone or marble, but also of the Paynters worke, to set out the walles withall: and it is requisite, that he should prescribe an order therein, as Surueyor of all the worke: for this cause, that some Paynters haue bene workemen good enough, touching the handling of their worke, but for the rest, of so little vnderstanding, that desiring to shew their skill in the placing of the colours, haue disgraced, and sometime spoyled a Story of a house, for want of consideration how to place the Pictures in the same. Therefore if they haue a Forefront or Facie of a house to paynt, it is certayne, there is no opennesse to be left, where ayre or lantshap is to be made, for those breake the building; and of a thing that is massy and close, they transforme it into an open weake forme, like a ruinous and vpperfit building. Also there should be no personages nor beasts coloured, vnlesse it were to trim and decke doores, wherein there are mens personages: but if the owner of the house, or the Paynter, desire colours, that the worke may not be broken nor spoyled, a man may couer a hackled wall ouer with cloth, and therein paynt what he will: and also, after the maner of tryumphs, a man may hang on the wall Garlands, and strings of Leaues, and Fruits, Flowers, &c. and also Shields, Trophies, and such things as are to be stirred: but if you will paynt the walles with firme matter, then you may fayne things of marble or other stones, cutting therein what you will: you may also beautifie some figures in Niches, with metall, and so the worke will remayne firme, & worthy commendation of all those that know good worke from bad. And the Author rehearseth diuers excellent workemen, whome (for breuitie sake) I will omit, that onely vsed to paynt nothing else but white and blacke in houses, and yet so excellently well, that it made men wonder to behold them. A man may also, with good reason, make and set forth certayne openings in walles of lodgings, round about the Courts, and make ayre, lantshaps, houses, figures, beasts, and such like things, as hee will in colours. Also, if a man hath Chambers, Halls, or other places, about the ground within, to paynt and set forth, then a Paynter, in maner of Architecture, may make openings to see through them, as the place is: for about the sight a man must make nothing but ayre or skyes, roofes, high hills, and the vpper part of houses: and if you place figures also about the sight, a man must see vnder them, and not the ground whereon they stand. And if the Paynter will make a Hall or any other, or further roome perspective-ly, he may, ouer the going in, with order of Architecture, make it to shew further then in effect it is. And this, *Balthazar* (a man excellently well learned in Architecture) did, in beautifying the Hall of *Augustin Gynse*, a Marchant of Rome, where, in that sort he set out some Columnnes, and other Architecture to that purpose: so that *Peter Aretino*, a man also skilfull in Paynting and in Poesie, sayd, that there had not bene a perfitter Paynter then he in that house, although there is worke also in it of *Raphaels* owne doing. And when the walles are paynted, and if you will haue the rooffe also done, then follow the steps of Antiquitie, making things that are called Grootes, which, for that you may make them as you will, shew well therein, as Leaues, Flowers, Beasts, Birds, and other mixed matter. If a man maketh any clothes or apparell of figures, or which are made fast on them, therein a man may doe as he will. But if a Paynter will make any figures according to the life, in a rooffe of a house, then he must be very skilfull, and much exercised in Perspective worke, and very iudicious to chuse such things as are fittest for the place, and rather heauenly flying things, then earthly things, with such Arte, that he must shorten the figures so (although they bee monstrous) that when men stand a conuenient distance off from them, they may resemble the life. Which thing is excellently well made in *Lorette Mantua*, and other places in Italy, by diuers workemen: yet skilfull workemen in our time haue shunned such shortening, for that (in truth) it is not so pleasing to the eyes of the common sort of people. Therefore *Raphaels* *Durbin*, whom I will alwayes name Diuine, for that he neuer had his fellow, (I say no more) in this thing, as men iudged of him when he was to paynt the rooffe of *Augustin Gynse* his Gallery, shunned shortening as much as he could: for when he came to the highest part of the rooffe, and there meant to make the banquet of the gods, heauenly things, and such as serued to the purpose for a rooffe, taking away the harshnesse of shortenings, set forth a cloth of azure colour, made fast to the strings or Garlands, as if it had bene a thing to bee stird, and therein made the banquet so seemely and so workemanlike, that the Gallery was rather esteemed for a preparation to a tryumph, then a playne paynting made vpon a wall. Therefore the workeman, that ought not to be vnskilfull in Perspective worke, should not indure, as being Surueyor ouer all the workemen in the building, that any thing should bee made therein, without his counsell and aduice.

Of flat Roofes, and the Ornaments thereof.

The twelfth Chapter.

Although in the Netherlands they use not to decke the Chambers in the Roofes with wooden worke, nevertheless, when a house without is made wholly after the old maner, it were unfit that the Roofe should not be agreeable, as also the Bedseeds, Bankes, &c. And which is more, I would say, that each place should be stuffed and suted within, with things fitting to that which it sheweth outward. I say then, If the Roofe be high, then the deuisions to be wide of space, and rising or bearing out well: and if a man will beautifie it with Paynting, it must bee well done, and conformably paynted, according to the greatnesse and distance thereof. It ought also to be made of light and browne colours: and in the middle of the field you must set a gilt Rose: but if a man will colour it, then the field must be blue, as piercing, but the Roses must be bound with some worke or branches, that they may not seeme to hang in the ayre: and the Cornices which close vp the fouresquare or other fields, must bee well gilt, or beautified with the same colour: but if so bee the Roofe is not high inough, then you must make the worke thinner and smaller, as also the paynting: and that you may understand it, I haue set two figures to them you, which, notwithstanding, are all one: the one of bare wood, the other paynted, as I sayd before. And this Order I obserued in the Roofe of the great Librarie in the Palace of Venice, in the time of the Prince Andreagrati, because the Roofe was lower then it should be, in respect of the widenesse and length of the Hall, and I made it of thinne worke, for the reason aforesayd.

The Timber worke of the ceiling aforesayd,

The Ornaments and Garnishing of the same worke,

Another maner of Sieling.

74
therefore these Mazes and Knots, are set in Figure.

Lastly, our Author speaketh of Armes, to shew how a man shall make, colour, and place them, according to state, workmanship, or nature: that thereby a man may perceiue of what stocke, or seed whence it is deriued: for, saith he, wee see that in former times men made & figured Armes in their maiesty, Bishops in Pontifical Robes, Captaines armed, and euery man in such habite, as best fitted his calling and condition. And so he will haue men to make & colour armes, that are to be set by, by on, or before houses, with beasts, birds, &c. gold, silver, blue, red, greene, and blacke colours: but no metall vpon metall, nor colour vpon colour. But for that workemen here in this Country make no Armes after their owne pleasures, we will let them passe, & in place thereof set downe a figure of Letters, the which the workeman hath occasion many times to cut, or place about Gates, Doores, in Frames, and other tables, therein to set names, titles, deuices, or other superscriptions, at the pleasure of the owners, or to know a Palace, or any other common places of office, or other wise. Neuertheless, for that here there are writing workes set to fill the place, I will set the Figures of the Armes, which he hath made after the Letters, that the Worke may bee complete. The workeman, having no knowledge of learning, should be much troubled, to seeke farre and nere for one that should write them for him: and although that he hath them in writing, neuertheless, for want of knowing the proportions, they may be spoiled in working, and so bring his worke in contempt; as also those that draw them for him: Therefore, although they are drawne by Lucas Pacioli, Geofrey Tory, and Albertus Durer, who, neuertheless, agree not altogether, therefore I will set these hereafter downe for a common rule, following our Author, who (letting passe all superstition) hath brought the Columns & Pedestals into a due measure: by whose authoritie, I should almost say, that a man may make these letters greater or smaller, according to the orders of Columns; but to write the Symetry, or not, if I may not digresse too far out of the way, I will follow Vitruuius, where hee saith, that a Ionica Columne is 9. parts high, and by shewing of diuers Authors, this forme of Letters is also found in Ionica, and so I leaue them of 9. parts: and whether a man would make them by Corinthia or Composita order of 10. parts, it would not be amisse, for as the Corinthia is most bled for the slenderesse, so these Letters, for the most part, are made of 10. parts: by the Dorica and Tuscan, they are made of eght. By that reason thereof, it were not much to bee contented, considering the grossenelle of the worke; also, according to Vitruuius writing, a man may alter the Symetries, as it is sufficiently shewed in other places: for vpon some occasions, they are greater & smaller, yea, and shew altogether faile to that they are. To learne easily to make these letters, first, you must make a perfect foursquare, and set it in as many parts as you wil giue vnto the letters: but if they be of 6. 7. 8. 9. or 10. parts, more or lesse, the smallest draught shall be the third part of the thickest, and the grosse draught the halfe. The corners shall, at least, haue as much Proiecture as the thickest of the letter taken with the Compasse. But although one letter is within the foursquare, and the other without, you may see in the figure, where you may set the Compasse to draw the round: you may set

the O. of the same measure that you set the Q. The taylor of the Q. is a quarter and a halfe of a foursquare, and sinckes a halfe foursquare; some make it shorter. I will not uphold these letters to be the best, but euery man take them he liketh best: it is also no need to take so much paynes with euery small letter: but it falleth out oftentimes, that a man is to make them a set, or size, more or lesse, high; which a man shall neuer bring to good passe, without following a sure proportion.

Printed for *Robert Peake*, and are
to bee sold at his Shop, neere Hol-
borne Conduit, next to the
Sunne Tauerne. 1611.

THE FIFT BOOKE:

Of diuers maners of Temples,

The foureteenth Chapter.

Although wee see and find diuers formes of Temples and Churches in Christendome, as well ancient as moderne, yet for that I haue formerly promised to shew some Orders thereof, to accomplish the number of my Bookes, therefore I will intrate of them, and set downe twelue seuerall maner of Temples, with their grounds and measures: and for that the round forme is the perfectest of all others, therefore I will begin with it: but though in our time, whether it be by reason of small deuotion, or cruelty of men, there are no more great Churches begun to be made, and that men finish not them which in former time haue bene begun, therefore I will make mine so small, as they may passe in reasonable maner, for that with small cost, they might in short time be made. The Diameter of this ground shall be as long as high, according to the Figure of the Circle, that is, of 60. foote. The thicknesse of the wall shall be the fourth part of the Diameter, that is, 15. foote, that a man may easily make the Chappels within it: which Chappels shall be 12. foot broad. The Niches betweene the Pillars shall bee foure foote broad: the other in the Entrie, and of the three Chappels, shall be sixe foote and a halfe broad: and to spare charges of stone and lime, the great Niches shall be made without the Chappell: the bredth whereof shall bee 15. foote. This Chappell is eleuated from the earth at least fise steps; and if it were higher, it were not amisse: for the earth in time riseth, so that men goe downward into many old Temples and Churches, whereunto, in former time they ascended vpwards: but this Stayre would alwayes be vneuen, according to *Vitruuius* writing, speaking of Temples, where he sayth: that as a man with his right foote begins to clyme vp, he may, with the sayd right foote, step vpon the pauement of the Temple. Touching the foundation, a man cannot sayle, if hee maketh it deepe and broad inough: but the least bredth that a man can lay, is this: that a man should from the Diameter of the thicknesse of the wall, make a perfit fouresquare, and the Diagonus of this fouresquare shall be the bredth of the foundation vnder the wall. And so, I thinke, *Vitruuius* writeth, where he speaketh of foundations. But touching the Stofes of foundations, in fast or hard ground, and also in watry ground, I neede not shew it here, because euery man knowes it.

Of diuers formes of Temples

Having shewed the ground of this round Temple, this Figure sheweth the body of the Temple, both without and within, so; that it is purposely made broken, to see both. The inner part of the Temple is made after the maner of Corinthia. The whole height from the Pavement below, to the Roofe above, is 60. foot; whereof 30. foote are for the Kettle or round rooffe: the rest netherwards, shall be divided in 5. parts and an halfe; whereof one part shall be for the Cornice, Frieze and Architrave. The foure parts and an halfe resting, shall be the height of the Columnes, with Bases and Capitals, whereof altogether, you shall finde the particular measures in my fourth Booke, in the Corinthia. The Pitches betweene the flat Pillars, shall be 10. foot high: the other shall be of 15. foot high. The hole above the Rooffe, shall be the seventh part of the wideness of the Diameter of the Temple: above, upon that hole, there may bee a Lanthorne made, stoppt with glasse, or it may be left open, whereat there will come in light enough to the middle of the Temple, so; that the Chappels haue light enough at their windowes: the top of this Temple will best bee covered with Lead: the Cornice without, shall stand like that within, but much greater of members, because it standeth in the weather. Touching the Doores, you finde them sufficiently set downe in my fourth Booke.

Although the ground of this Temple following is round also, yet it hath an alteration by the foure bearings out, which are three Chappels, and also the going in of the same fashion. The Diameter of this Temple is 48. foot: the thickenesse of the wall is a seventh part of the Diameter. The Chappels are 14. foot in fouresquare, with out the Pitches. The other 4. Pitches or small Chappels shalbe 9. foot broad: the fouresquare Chappels haue their light on the sides, but the light of the Temple above in the Roofe, shall be wide the fift part of the Diameter, with a Lanthorne vpon it, as it is sayd of the other: you shall goe by to this Temple also with five staires, and for that the corners without the Temple lye alwayes soule, I thinke it were not amiss to make a fouresquare wall about it, as high as the going by, that people may not so easily come to it.

Of diuers formes of Temples

Here you see the Chappel standing by right (whereof the ground is on the other side) which sheweth as well within as without, because it is as if it were broken. The height within, is like the Diameter, that is, 48. foot. The halfe shall be for the halfe round rooffe, and the hole about for the light, as I sayd before, shalbe twice the fifth part of the Diameter; whereon there shall be a Lanthorne, made with glasse, as the Figure sheweth, and the Rooffe without, covered with Lead, or other stuffe. From the Rooffe neitherwards, the Cornicement shall be made of two foot and an halfe high, formed like Finishe of the Arch of the Theater of Marcellus, in the fourth Booke and the seventh Chapter, Folio 37. and shall serue for Capitals, vnlesse it be the Plinthis with the Cimatic, which shall serue for Corona. The Pilasters are broad 4. foot and an halfe. The great Chappels are 21. foot high. The smallest Chappels shalbe 13. foot and an halfe high, halfe round about. About those 3. square Chappels, and ouer the going in, there may be flat couers, somewhat falling downe, to boyd the water: a man may also make steps within the thickenesse of the wall, to goe by, and an yron or stone rable, to rest or leane vpon. The Temple may be covered with such stuffe, as may best be provided: but Lead would be the surest.

After the round Figure, which is the perfectest, the best are the Duale, that is, like an Egge; therefore I haue made a Temple of that fashion: which Temple shalbe 46. foot broad, and 66. foot long. The thickenesse of the wall shall be 8. foot, & within it the Chappels shall stand; and although they be not too large, yet a man needs not cut them off. The widenes of the 2. greatest Chappels, holds 20. foot and an halfe; within the which are two Pitches, each 4. foot broad. The Columnnes shall bee a foote and an halfe thicke, and the halfe Columnnes accordingly. The spaces betwene the middlemost Columnnes shall be 7. foot and an halfe: the other shall contayne 4. foot and one fourth part. These two Chappels shall each of them haue 3. windowes: the middlemost shalbe 6. foot wyde, and the other on the sides each three foot. The Chappell with the high Altar, shalbe 10. foot broad, and 6. foot farre in the wall, with Pitches, like the great, and a windowe above the Altar, of 6. foot wide. The 4. other Chappels shalbe a halfe Circle, 10. foot wyde, hauing the like Pitches also, and a windowe of 4. foot wyde, above the Altar. And so; that this Chappell hath light inough of it selfe, it might suffice for the whole Temple: but to make it lighter, there may be windowes made above the Chappels. This Temple shall also go by fine steps: the doore shalbe sixe foot wyde, and shalbe beautified with 4. Pillars, after the Corinthia maner: the going in shalbe like the Chappell with the high Altar.

Of diuers formes of Temples.

This Figure ensuing, sheweth the Duale Temple within, which from the Panement to the Roofe, shall be as high as broad, that is, of 36. foot: from the Panement, till you come above the Cornice, it shall be 23. foot: which height divided in five, one part shall be for Architrave, Frase and Cornice: the other 4. parts shall be for the height of the Pillars, which separate the Chappels. The particular measures hereof you finde in my fourth Booke, in the order of Corinthia; so that this Temple is made of such worke. The height of the round Columnes shall be 12. foot. The Architrave, that holdeth by the Arch, is 2. foot. The Gate (as it is sayd in the ground) shall be beautified with foure flat Pillars, of such so;me and measure, as those that stand within the Temple; and also with such Cornicements: the Gate or Dooze shall have an Arch standing byon two Pillars, betwene the flat Pillars: the Roofe of this Temple may be beautified, as you see it in the Figure; and richlyer also, making the Windows about the Cornice, hanging downewards, as you see, and couer the Temple with Lead, which is best: and so the windows shall be preserued well ynough.

Although this forme is five cornered, which in Building is not so handsome, therefore within I have made it of ten corners. The Diameter of this Temple is 62. foot long: the Diameter of the Lanthorne is 12. foot: the five great Chappels are 15. foot in fouresquare, without the three Niches, which are ten foote wide. The small Chappels are 15. foot broad, and goe 4. foot into the wall, to the halfe Circle, which is, 13. foot wide. The great Chappels shall have two windowes, and the small one: the widenesse of the doores is 7. fot and an halfe. The Gallery without, shall be 10. foot broad, and 24. foot long. The 4. Pillars thereof, shall be 2. foot fouresquare. The middlemost spate betwene the Pillars, shall be 10. foot, and the other 2. spaces shall be 4. foot. The sides of the Gallery shall have a leaning place made with Balusters: In the sides of the Gates, there shall stand 2. payre of winding Staires, to goe by upon the Portall, and also round about the Temple. This Temple is 9. foot eleuated from the ground, and it may be made hollow vnderneath.

Of diuers formes of Temples

Although this Temple is shut, yet I will shew the measure within; it is as high as broad within, that is, 62. foot. The Lanthorne is also as high as broad to the Cornice: the Roofe is of halfe a Circle. The roofof the Temple is also halfe a Circle, high 31. foot, the rest netherwards. The Cornice shall haue two foot and an halfe, formed like the Impost of the Theater of Marcellus, in the fourth Booke, in the order of Ionica, marked T. Folio 37. This Cornice shall be set without, like the innermost, but greater. The fouresquare Pillars of the Portall, are 14. foot high, with Bases and Capitall, Dorica. The Architraue is halfe the thickenesse of the height of the Pillar: about the Arch, the Cornice is the fourth part lesse then the great, but of the same forme, and shall serue for Capitall vpon the Pillars. About this Cornice, there shall be a place best-high, made with Iron Balusters. The two pieces about this Temple, shew the Chappels within: and that with the crosse, sheweth the greatest Chappell, whereof the light is 25. foot. The other piece marked L. sheweth the lesse Chappell, which is also 25. foot high: the Pillars that separate the Chappels, are thre foot broad: the height is 19. foot: and there shall be a Cornice made, which shall goe round about the Temple, seruing for Capitalls vpon the sayd Pillars; which forme shall be made after the Dorica Temple, but a little altered: the Cornicement, vpon the Lanthorne, may be made with Architraue, Freese and Cornice.

The ground of the Temple following shalbe fixe coznerd, being in Diameter 25. foote: and the wall 5. foote thicke. The widenesse of the Chappels are 10. foote, and stand 4. foote within the wall. The widenesse of the Piches is 2. foote. The Dore of the Temple is 5. foote wide, adozned with double Pillars, which are a foote and a quarter thicke. The going by is 5. Steps, or more if you will, yet breuen. Each Chappell hath a Window, of foure foote and a halfe broad, which will bring in light enough, although there be no Lanthorne. On the 6. cozners without the Temple, there shalbe flat Pillars made, of 2. foote and a quarter broad, coozning out a little. And if you would make the Temple greater, and for want of Stones you could make it no thicker Columnnes: then you might make it Corinthia, or Ionica, or Dorica, if you will: and then you may helpe your selfe with Pedestals.

Of diuers formes of Temples

Now I haue shewed the ground of the 6. cornered Temple, & must shew it standing by right, and also describe it, as well within as without: for although the Temple be wholly closed by, yet I haue let a Chappell aboue ouer it, to see it within, for that they are all five of one forme; and the going in also is of the same forme. But touching the outermost part, I say, that the height from the pavement below, till you come about the Cornice, shall be 18. foote. The Cornice round about the Temple, shall be made of a foote and a halfe: but the members of the sayd Cornice shall be made according to the Chapter of Dozica, so that it shall also serue for Capstall upon the Pillars, at the 6. corners. Touching the Plinthus with the Cimatie, for that it shall serue for a Corona, it shall go but right through about the Pillars, as you may see in the Figure. The Portall before shall be beautified with round Colammes, & with flat Counterpillars: where of the middlemost Intercolammes (or spaces betwene the Colammes) shall be 7. foote and a halfe. The Colammes shall be a foote and a halfe thicke: but the space betwene each 2. Colammes, and Pillars, shall be halfe a foote: these sayd Colammes shall be 8. foote and three fourth parts high. The Capitals shall be Dozica: but the Bases, because they stand below at the foote, in the rayne and

the wind, and also for that they should be the Bases for the flat Pillars, and the great Pillars, going about the Temple on all sides, therefore they shall be made Tulcana. The height of the Archtraue shall be a foote, whereon the Arch shall stand: and the Dooze shall be adorne as you see it in the Figure. The going in shall be 5. steps at the least. The Roofe shall be covered with a thing, which in those Countreys lasteth long, and is easy to be had, otherwise it were best to be of Lead: and this is touching the worke without. To speake of the inward part; it is sayd, that 1. Chappell serueth for all: the breadth of these Chappels hold each of them 10. foote: and in height 12. foote and a halfe, and enter 4. foote into the wall: on each side they haue a Niche, which is 2. foote broad: about the Altar there is a window, which is 4. foote and a halfe broad: and 7. foote high. The Cornice within the Temple shall stand of the same height that the outermost doth, and shall also be of the same figures: for the Plinthus with the Cimatie, shall also go right through, round about the Temple, without bearing out about the Pillars: otherwise a man may make them much slenderer then they that stand in the rayne and the wind. You may also make the Bases after Dozica: and although all the other Temples shewed before, haue their heights within, like the breadth of the Diameter. so shall this, neuertheless, though it be so small, be halfe a Diameter more higher, that is a Diameter and a halfe, which is seuen and thirty foote and a halfe.

Although those aforesayd, and some Temples following, haue no Steeple for Bels to hang in, as the Christians vse to haue; nor any Vestries, nor other places for men to withdraw themselves in: yet they must, neuertheless, be handsomely made without, but so, that men may go through the Temple into them: all which subjects and inuentions shall not want in my other Booke. The ground of this Temple is 8. square: whereof the Diameter within shalbe 43. foote: and the wall 8. foote. The Chappels are 12. foote wide, and stand 6. foote within the wall. These Chappels are of halfe a Circle, and the other 3. with the going in are 4. square. Each Chappell hath 2. Niches, which are 4. foote broad. The 3. windowes in the halfe Circles are 4. foote broad: the other 3. with the Columns are 11. foote wide. The Dooze is 5. foote wide. In the middle of the Temple a man may set an Altar, covered with a Tribune, upon 8. Pillars. The Diameter hereof shalbe 12. foote long: and if you will make this Temple greater, you may make it more late:

Of diuers formes of Temples.

The Figure hereunder serueth for the 8. square ground, afoze set downe, and is the sayd Temple as it is without. From the highest step to the byp. rmost part of the Conice, it is 21. foote and a halfe, which is the halfe of the innermost height. The Conice shall contayne 2. foote, diuided as in the Chapter Dozica; and shall also beare out eue the Pilasters, without the Plinthus, as in the Figure. You shall also set a simple Base vnderneath thze fourth parts of a foote high. The breadth of the Pilasters at the corners, shalbe of 3. foote: and those that stand inwards shalbe but 2. foote broad. The Dooze is 5. foote wide, and shalbe 13. foote and a halfe high. The Ornaments of this Dooze you find in the fourth Booke, by the Ionica, Folio 38. The maner of the wideneke is sufficiently sene in the Figure: if you will haue moze light in the Temple, then you may make a hole aboue, and that to bee covered with glasse, poynt-wise, agaynst the rayne.

According to this innermost Orthographie, the Cornices and Pillars are of some height like the innermost: from the Cornices upwards, the rooffe is a halfe Circle: the 3. greatest Chappels are roofft with Arches, and are 18. foot high. The round Columnes shalbe thre quarters of a foot thick, and the halfe accordingly, and shall be five foot and an halfe high: the Architraue, whercon the Arch comes, shall also be thre quarters of a foot: the inter-Columnes in the middle, shall be foure foot and an halfe, and on epyther side two

foot and an halfe. The Chappels of halfe a Circle, shall also be 18. foot high: the pitches of all the Chappels shalbe ten foot high: the Tribune that should stand in the middle with the Altar, is figured above: and from the ground to above the Cornice, it is 18. foote high: the Cornicement thereof is thre foot: the rest is for the Pillars, where, on the sides, you may make Pilasters with Arches, and all Dorica worke, as well within as without. The Tribune is of a halfe Circle.

Of diuers formes of Temples.

Although this ground without is square, yet within it is 8. cornerd, whereof the Diameter within is 65. foot, and the wall 16. foot. The going in of all the Chappels, is 12. foot, and the wall there, is 3. foot and an halfe thicke. The corner Chappels shalbe 16. foot square within: the Niches with Altars, shalbe 12. foot broad: the 4. open, and two blind windowes, shalbe 3. foot and an halfe: the two lesser Chappels shalbe 22. foot long within, without the Niches. The Niches shalbe 10. foot broad: the windowes shalbe 6. foot wide: the Portall without, is 27. foot long, and five foot wide: right ouer against the flat Pillars stand round Columnes, which are one foot and 3. quarters thicke. The dooze is 6. foot wide: the Portall within, is almost like one of the small Chappels. You may also set a high Altar in the middle, with a Tribune, whereof the Diameter is 20. foot: the Pillars are three foot and an halfe thicke: the flat Pillars at the corners are three foot broad.

This is the Orthographic of the aforesayd ground, of the egypt cojnerd and fouresquare Temple, which is the Figure as it is without, whercof I will describe the height: and first, from the Pavement, to the highest part of the Coznice, it is 22. foot and an halfe: the height thereof deuided in sixe parts, one shall be for the Architrane, Fræse and Coznice, the other five parts are for the Pillars, which being two foot and an halfe broad, yet they are not so long, because they stand two together, and little rayled by. The measure of all together, you may find in the order of Ionica, in the fourth Booke. Above this Coznice standeth the Tribune, whercoon there shall stand a Lanthorne, to giue light into the middle of the Temple, whercof you may easily finde the measure, with the small foot that standeth in the ground. The round Columnes befoze the Postall, shalbe 13. foot high: the Architrane is a foot: aboue the Arch, the Coznice shalbe the thickenesse of a Colonne below, deuided as in the Capitall of Dorica. The Frontispicie riseth to the Architrane of the Temple: the going by is of sixe Steps: the small figure marked with A. is one of the Chappels without, which comes thzee foot out of the wall: the windowe whercof is 10. foot high, beside the light aboue the Coznice, and aboue it is halfe round, covered as you see.

Of diuers formes of Temples.

Now I haue shewed the ground and Orthography without of the Temple in square, I will also describe the 8. cornered Temple within, & set it here beneath in Figure. And here you see how men going by the Stappes which are figured in the entry of the ground, go by to & saye walke. The height of this Temple within is almost like all the Temples before set downe, and also which are found in Antiquities, that is, as high as broad, which forme is taken out of the Circle. The round Roofe, as for the halfe Circle, occupieth the one halfe, and of the other halfe downwardes there shall be 6. parts made, whereof one part shall be for the Architrave, Frieze and Cornice, which shall be made after the Dorica: the other 5. parts are for the wall with the Pillars, which also are 2. foote and a halfe broad, like the outermost, but for Capitall and Base, like the Dorica. The measures both of Capitalls, Bases, Architrave, Frieze and Cornice, you shall also find in the aforesayd fourth Booke, in the Order of Dorica. The breadth of the going in of all the Chappels is 12. foote: but the height of the sayd Chappels is 24. foote. The 4. greatest Chappels which stand in the corners are 14. foote within, square, with their Pillars, with Arches upon them. The height of all the Pitches, as well of those that are 10. foote broad, as those of 12. foote, shall all be 15. foote high. The Lanthorne shall hold 13. foote in Diameter: and the rest the Architecto, shall easily find with the small foote.

This ground standing hereunder may be named crosse-wise, whereof the principall place in the middle containeth 48. foot in Diameter. The 4. Pitches, with the 4. goings through, are each 10. foot broad; but the goings through are 15. foote long. The foure small Temples hold in Diameter 36. foote; and their Pitches, and Windows, (wherein you may place Altars) and the Doores are each five foot wyde. The 4. places within the 4. corners, may be dwellings for Priests, & other Church Officers, and are 16. foot square: about them, you may place foure Towers, and go vp into them through the Stayres. The foure round founnes may be Wellies, and other places for men to withdraine themselves. This whole square, without inclosing the innermost round Temple, containeth on all sides 88. foot. The principall going in shall haue 9. steps, and the Dooze may also be greater then the other two in the sides.

Of diuers formes of Temples

From the ground befoze shewed, here standeth the Orthography of the sayd Temple with one of the sides that is befoze, although a man should set them out all foure, at least thre, in this maner. The height of the first Storey, beginning at the highest step of the going vp to the vppermost part of the Cornice, shalbe 38. foote; which height, divided in 6. parts, one shalbe for the Architraue, Fræse and Cornice, and this shall inclose the whole Temple round about. From this first Cornice, to the second of the middle Temple, it shalbe 13. foote: of this height you shall make 5. parts: whereof one shall be for the Fræse, Cornice, and Architraue. The same great part of the Cornices shall also serue for the Lanthornes of the 4. least Chappels: which Lanthornes within shall contayne 8. foote in Diameter. The 3. Order agaynst the 4. Towers shall haue but a flat Facie, right like the soote of the greatest Lanthorne which standeth vpon the round roofe. The sayd Lanthorne within shall hold 10. foote in Diameter; and the height without the Kettle Stone shalbe 16. foote: this height divided in 5. the one part shalbe for the Cornicement of this Lanthorne, and the other shall be Corinthian Pillars. The fourth Order of the Towers shall also be of the same height, and beautified with the same Cornicement: and although that from this Cornicement netherwards, the Order of the Towers stands not very handsomely, because they are forced to yeld to the Cornicement of the Temple; yet according to Antiquity, it is a fault to be borne withall. The vppermost parts, which in no sort are tyed to any thing, shalbe as high as the thicke- nesse of the sayd Towers. The 5. part of that height shalbe for the Cornicement, and the rest, for the Columnes, made after the Ionica. About the Cornice the leaning place shalbe made, with the round rases, as you see.

Hereunder followeth the Orthographie of the aforesayd Temple within, that is, the halfe of the 3. Temples. And for that the middlemost Temple should receiue moze light then from the Lanthornes, as the other also doe by the windowes below, it is requisite to make the Cornice without higher then the innermost, that a man may, almost, receiue the light perpendicular-wise, as you may consider it in the Figure. From the Pavement, to the highest part of the Cornice, it shalbe 44. foot. The Cornice (because there are neyther Columnes noz Pillars about) a man may make ballard, and at his pleasure, so it haue not much bearing out, that it may not take away the sight of the roose. The Cornice shalbe a foote and a halfe high, and may bee made according to the Capitall of Dozica. The height of all the Piches are all 15. foote: about the Piches, there shall a Facie goe round about the whole part of the Temple, as well the small Temple as the great. About the Facie the halfe round roofes of the 4. Chappels shall stand. About these 4. Chappels there shalbe a playne, made a little hanging, to cut off the water, with a place brekthigh round about, where, by the Stayres, a man may go thzough to the Towers: and if that this Temple standeth in any open place, then there will be a faire walke aboute it; you must be carefull that you let no snow lye vpon it, soz it toketh in and harteth the roose. The Doozes on the sides haue also 9. steps, although they stand not marked in the ground: and as these and the like houses stand so high, or not so high, from the earth, a man may well make them places of deuotion, or other wise. We see commonly, that round about the Churches all corners lye full, which is vnciuill soz sanctified places: therefore I would thinke god, that it should be walled round about as high as the steps, that it might not be so ready soz people to goe in, and that it were hallowed soz a Church-yard. The Towers that should stand behind in this halfe, because they stand not vpon this Diameter, and also soz lesse cumber, soz that men may conceiue how they are placed: therefore they are not set downe in this Figure: and what there wanteth moze, it is referred to the discretion of the workeman, who, in building thereof, shall find many accidents which a man cannot write noz remember all at once:

Of diuers formes of Temples.

Although the aforesayd Temple is shew'd to bee cross-wise, neuerthelesse, this that is heere set downe is much liker: and first, I will speake of the first going in, which shall serue for all the rest, for that they are all of one forme. The widenesse is 30. foot, and the length 37. foot. The wall is seven foot thicke: in the middle, on eyther side, there are two Piches, which shall each of them be tenne foot broad. The Doore is eght foot wyde: the going through, to goe into the Circle, is 22. foot wyde. The Pilasters there, are seven foot thicke: the Piches, foure foote. Within the Pilasters the stayes shall stand to goe vp, and that the Pilasters should bee the faster to beare the Tribune, in the foure corners, behind against the Pilasters, you shall make these eght cornerd Chappels, of 18. foot in Diameter, and the wall is foure foot thicke. The Piches, Doores, Windows and blind windows, shall be five foot wide. The corners of the Temple without, haue their flat Pillars of thre foot broad: the going vp is of five steps.

The Orthographic without of the foure cornerd crosse Temple, is hereunder set doونه, and is 44. foot broad at the going in; and the height from the ground to the Coznice is 30. foot: the Coznicement is five foot: the rest re-
 seth for the Pillars, which should be Ionica. The second story is 22. foot high: which height shall be divided in
 five parts, one shalbe for the Coznicement, and the other five for the Coznithia Columnes. These two stories the
 Temple shall haue, whereof you shall haue the measure in the fourth Booke. The rooſe shalbe 10. foot high, but here
 in the Land where it bloweth, rayneth, and snoweth much, it may stand much higher. Aboue the vpper part of this
 Frontispicie or Rooſe, there shall be a Coznice of two foot, whereon the Kettle or the round Rooſe shall stand, hauing a
 Lanthorne vpon it, which is 10. foot high, without his cover. The part marked C. sheweth the corner or rose with
 in, and the other marked L. sheweth one of the 4. cornerd Chappels: and although these 5. steps, for a going vp, stand
 onely to this Dooze, they should also be made to the other two doozes on the sides: and the ornament of the doozes, you
 shall find in the aforesayd Booke, in the order of Ionica.

Of diuers formes of Temples

Having shewed this square crosse Temple without, now here followeth the part within, as if it were Diame-
 ter like, cut euen in 2. parts. And first, speaking of the middle whereon the Tribune standeth, there is from one
 of the Corners of the Pilasters, to the other, 30. foot. From the pavement below, to the highest part of the Cornice, it
 is also 30. foote. The height of this Frise, Architrave, and Cornice, is 5. foote, and this shall goe round about the
 Temple within. Upon this Cornice the Arches rest which beare up the Tribune. About the Arches there is a great
 Facie, and from thence vppwards it is 15. foote high. The Cornice shall be 2. foote: but shall not beare much ouer or
 out, not to let the rooffe. From this Cornice netherwards, to the Facie, there shall be 8. diuising windowes made, of
 7. foote square, as you see it in the Figure. The Lanthorne shall be 5. foote wide. From the pavement, to the
 hole of the Lanthorne, it shall be 77. foote high. The place where the high Altar standeth, is right ouer agaynst the prin-
 cipall going in. In the great square there may be an Altar Table set: and aboue it there shall be a great round
 window, as also aboue all the 4. Doores. I neede not write any thing of the second side: for by the ground and this
 Figure you may easily conceiue it. And although I say nothing here of Towers, yet there may 2. at the least, be set a-
 boue the Chappels in the corners: also, as in many other places it is shewed, the workeman, vpon good occasion, may
 alter some things: for although that in Italy, and here in these Countreyes (where the sunne shineth much) men desire
 small windowes for coldnesse: neuertheless, those that dwell Southward, where it is rumatike, and many times close
 weather, may, according to the situation, make the windowes great, and giue more light to the Temple, without
 breaking Order, as it is sayd in the fourth Booke of the Venetian houses.

As I promised in my fourth Booke, so I have shewed diuers fashions of Temples, viz. round, Quale, or Crosse wise, fouresquare, five cornerd, sixe cornerd, egypt cornerd, and crosse-wise, not onely after the maner of the Ancients, but also setting for Christians, in such fozmes as are at this day made in Italy, and else where, whereby I thought I had sufficiently performed my promise: but for that Temples or Churches are made here in these countries crosse-wise also, like Raphaels ground (of S. Peters Church in Rome) in my third Booke, therefore I will set two or thre more of that fozme here, therein following the maner of the Ancients. The greatest going through, or walke in the middle of the Church, is 30. foot wide: the thre Chappels of halfe Circles, besides the 2. smallest walkes, are 25. foot wide, and shall stand somewhat without the wall. The Diameter of the Tribune is 36. foot: the foure small Tribunes, or round Kofes, are in Diameter 21. foot, but they shall not come out of the rooffe. The crosse-worke hath a doze on eyther side, and the 3. halfe Circles are each of them 25. foot wide. The hindermost halfe Circle, where the high Altar standeth, is 31. foot wyde. Besides the Quier, there are two egypt-cornerd Aeftries, being 21. foot in Diameter. Besoze, at the greatest going into the Temple, is the middlemost doze, 12. foote wyde, and the 2. small dozies 6. foot. On the sides, the Towers are 27. foot wyde: within the Bayzes, there stands a wyde gate to draw by the Bels. And although this Temple hath many steps or Bayzes, you may make lesse.

Of diuers formes of Temples

This is the Orthographie of the ground aforesaid, whereof the first Cornice standeth 62. foot high: which height divided in five parts, one part shall be for Cornice, Fræse, and Architraue, and the rest shall bee for the flat Pillars, which shall be five foot broad, and of Dorica worke. The middlemost dooze is 24. foot high: the two smaller on the sides shall be 12. foot high. The great and the small doozes also shall be beautified with some workes, as you see in this Figure, taking the particular measures out of the Dorica order, in my fourth Booke. The elevation of rising vp in the middle, shall to the upper part of the Cornice be 25. foot; and the Cornice thereof shall be the fourth part lesse then the other Cornice vnder it, made after the forme of the Dorica Chapter. The Frontispicie is fiftene foot high, aboue it stands the cover of the Kettle, with this Lanthorne vpon it, the measure whereof, a man may take out of that before. Below, vpon the first Cornice, besides the middlemost bearing vp, you shall make a Basement of five foot high; aboue that Basement, you must place the two Towers, which are 42. foot and an halfe high, making the Cornice the fourth part lesse then the other, formed after the Dorica Chapter. The third order shall be the fourth part lesse then the second, and the Cornice thereafter: the fourth order shall also be a fourth part lesse then the third, and the Cornice thereafter. The places best-high, aboue these Cornices, shall be foure foot high: and from the Liff, to the point of the Pyramides, there are 36. foot. You may double the windows out of my fourth Booke.

The Figure following sheweth the aforesayd Temple within, whereof the length and bredth is set before in the ground: but here I will speake of the height. The Cornice shall stand high, & be as great as the uttermost, that is, the sixt part of 52. foot, but shall be more after the Ionica manner. The flat Pillars shall also be Ionica: the Impost which beareth the Arches, shall also be Ionica; whose forme, touching the measures, you shall find them all together orderly in my fourth Booke: all the Chappels shall haue their light of themselves, as you see. Above the Chappels, the Roofe shall be broken like a Dome, therein to make an ouall round hole, that it may yeeld more light: and that the Tribune may haue more light then from the Lanthorne, you shall, from the couer vppwards, make a Frese with a List, and therein also make round holes for light. This small closed figure, standing alone, about the Temple, sheweth one of the side doores of the Temple, in the crosse wayke, whereof the doore is 10. foot wyde, and 20. high. The Architrave, Frese and Cornice, under the couer or Roofe, although the Pillars are broken after another manner, with the List of the Portall, shall neuertheless agree with the Cornicement that goeth round about the Temple. And although it is not here shewed how the wydest space of the walke betwene the Pillars and the rose is, and how that the small:st walke is not so high roofed, nor the forme of the small Kettles and Vekries are not shewed, yet the workeman may imagine it by the ground: for he that undertaketh such a piece of worke, must not be vnskillfull.

Of diuers formes of Temples.

This Temple following is 30. foote wide in the middle. The crosse woꝝke, and also the Tribune, together with the high Quier, shall each of them containe 20. fot. The Arches which beare the Tribune, shalbe 24. foote wide. The Pillars on the sides, where the Piches stand, shalbe 5. foote broad. Each side of the Crosse woꝝke is 38. fot long, and shall each of them haue a Doꝝe. The part befoze the high Quier, towards the Altar, is 4. square. The Pillars with the Piches, befoze the halfe Circle of the high Altar, are 5. foote broad, and stand from other 24. fot. The Piche or halfe Circle is 23. foote wide. In the 2. corners on the sides of the high Quier, there are 2. Ueltries, which shalbe 17. foote wide in 4. square. From the Tribune to the principall going in, there shall stand 5. Chappels on epyther side, which shalbe 15. foote within 4. square. The walles betwene both shall bee 4. foote thicke. The windowes shalbe 6. foote wide, and there Altars shall stand. The wall at the Dooꝝes shall bee 4. foote thicke, and on the sides where the Piches stand, 5. foot. Here befoze there shall come a Gallery of 14. foote broad, and of 68. foote long. The Piches shalbe 8. foote broad. On the sides of this Portall the Towers shall stand, and shall stand as broad out at the sides, as the crosse woꝝke. The Diameter within the Towers is 18. foote: and although they be 8. square, they may also be made 4. square. The winding Stayes stand in the thickenesse of the wall.

Touching the raising vpright of the sayd Temple, first I will speake of the Portall, which with the helpe of the fourth Booke, and through the ground, you may find the particular measure of this Order. The Portall aboue shalbe flat without rooꝝe, to take no light away in the Temple. From the Pauement, to the top of the Cornice which goeth round about the Temple, it shalbe 47. foote high. The Archuraue, Fræse and Cornice, are 5. foote. The 2. Order containeth 37. foote: and their Cornicements shall bee a fourth part lesse then the other: the same heights and Cornices shall also serue for the second Order of the Towers, and shalbe a fourth part lesse then the second Order; and the Cornice shall also lessen the fourth part: aboue there shall stand a small rising or elevation, whereon the Kettle shall rest.

The Figure aboue the closed Temple, marked with A. sheweth the inner part of the 5. Chappels. The height from the pauement to the vpper part of the Cornice is 27. foote: the Cornice shalbe 4. foote thereof, made like a Capitall Doꝝica. The other vppermost Cornices shalbe as high as the outtermoꝝt; and betwene this first and the second Cornices, there shall Ionica flat Pillars stand; betwene them the windowes shall bee made. The other figure aboue that aforesayd, marked B. sheweth the Tribune, the Quier and the sides of the crosse woꝝke, with the open and the blind Dooꝝes. Though the one side (which was purposely broken) you may see the Ueltries within. The Cornice vnder the Arches, which beare the Kettle, is like the other Cornice which goeth round about the Temple. The Cornice which is aboue the Arch, and comes vnder the Kettle, shalbe bassard. The Lanthorne must bee made according to the other Lanthornes afoze the wꝝd. The other part marked C. is one of the Dooꝝes on the sides, and is in that maner couered round. The Doꝝe is 9. foote wide, and 18. foote high.

Of diuers formes of Temples

Although that in the Netherlands there are very fayre Temples made, as the maner in these dayes is, not onely with thre fles or walkes in the body, but also fine: my meaning is not to write of such great Temples, for that each Towne hath her chiefe Church: but these are onely to make such Churches in places, where, by chance, the Churches are decayed, because in these dayes, men could hardly make them by againe in great forme; and so this end I set this last figure here, which is playner then the other. It shalbe 36. foot wyde, and 54. foot long. At each end before and behind, there shall stand halfe a Circle of 24. foot in Diameter. This halfe Circle where the high Altar standeth, hath two windowes, each 6. foot wyde. The dooze to enter into the Temple, shalbe 8. foot wyde. In the crosse of the Temple there shall stand two Chappels, being 18. foot long, and 12. foot broad. The windowes behind the Altar shall be five foot wyde; all the great Piches are also five foot wyde, and the small thre foot. The Columns are two foot thicke: the inter-Columns in the middle, are 6. foot, and the other on the sides are 3. foot. The 4. Piches within the body, are beautified with round Columns standing in the wall. Without the Temple there is a Portall of 10. foot broad, and 52. foot long. The high Pilasters shalbe 6. foot broad, as counterforts; and the other shalbe thre foot broad. Within the thickenesse of the wall there shall stand two payre of winding Staires: and although this Church hath no Towers, yet you may make them on it, as the other were.

This Figure within is good to vnderstand, and from the Pavement to the first Cornice, it is 21. foot high, where of the Cornicement is a fift part: the other is for the Ionica Columnes. The Pedestall of the Piches shalbe the fift part, whereon there stand Columnes of Corinthia. The Frontispicies are three foot above the Postall, may bee blind windowes above may also be opened. The Chappels of the high Altar, marked A. haue small Piches of 7. foot and an halfe high. The fouresquare above the Altar, is for a table, broad 10. foot, and high 12. foot. The Temple without hath a Doricall Cornice, as high as the innermost. The part of the second order hath Pillars, and Cornices vpon them of two foot, which Cornices shal be made according to the Imposit of the Theater of Marcellus, in the fourth Book: and so that above on the side, in the rooffe or couer, there is 3. foot of roome to spare, there may be a leaning place made, both for an ornament, and also for ease: the couer may be covered ouer with Lead.

Here endeth the fift Booke: And this also is the end of the whole worke of Sebastian Serlius; Translated out of Italian into Dutch, and out of Dutch into English, at the charges of Robert Peak e.

Printed at LONDON, by Simon Stafford. 1611.
