The tubers of the bitter cassava attain a length of three feet. They can be converted into bread or cakes. The volatile poison of the milky sap is destroyed by pressing the grated root in the first instance, the remaining acridity being expelled by the heating process. The starch, heated while in a moist state, furnishes the tapioca of commerce. Cassava is abundantly cultivated in Brazil and Venezuela —especially at Caraccas, where the singularly uniform temperature throughout the year is only 60 deg. to 70 deg. Fah. It is a very exhausting crop, and stands in need of rich soil and manuring. The propagation is effected by cuttings from the ligneous part of the stem.

The soil destined for manioc must not be wet. In warm countries the tubers are available in about eight months, though they continue to grow afterwards. The growth of the plant upwards is checked by breaking off the buds. The bitter is the more productive of the two species. The yellowish tubers attain sometimes a weight of 30 lbs. They do not become soft by boiling, like the Aipi or sweet manioc.

The sweet species, though a native of tropical South America, extends as far south as the Parana river. The root is reddish and harmless, and can be used, unlike the bitter species, without any further preparation than boiling as a culinary esculent, irrespective of its starch being also available for tapioca.

From the roots of the two species many food products are obtained, among others, coarse cakes made by rasping and pressing the root, which are cooked on a hot plate. The fecula, heated on hot iron plates, becomes partially cooked, and agglomerated in small, hard, irregular lumps, and in this form is known as tapioca. This substance, partially soluble in water, forms a nourishing food, much appreciated in Europe.

Farina of manioc in its crude form is often seen at Brazilian tables, but is more frequently mixed with water and baked in thin cakes, in this state forming the bread of the poorer classes. It thus forms a nourishing and cheap food; and it is to be regretted that in Europe the vendors should palm off potato-starch and other similar substances for the more delicate and agreeable cassava and tapioca.

Manioc meal is produced on an extensive scale in the province of Santa Catharina, where they employ improved machines for preparing it, especially in the settlements. These producers supply the markets of the capital and of the other provinces. The foreign export of manioc meal in 1845 was 145,722 alquieres. Manioc is the staple article of food for the whole population. There are more than 14,000 manufactories, and the total production is calculated at upwards of 500,000 alquieres. In abundant years the meal and fecula fall as low as 1 or 2 milreis the alquiere, but in years of scarcity often rise to above 8 milreis. The foreign export was for some time checked by a tax of 2 milreis imposed on each sack exported, but this tax was abolished in 1865.

There are two modes of preparing the root—the wet and the dry process. In the first, the grated root is put into water for four or six days, and afterwards kneaded with water, and pressed to extract the juice. The fecula which remains is sifted and baked in earth ovens, some fresh manioc paste, which has fermented, being always added. There are no less than fourteen varieties of the manioc distinguished in the province of Amazonas, some of which mature in six and others in twelve months.

The dry process is carried on as follows:—The manioc is rasped by hand, water added within, and then put to be pressed; afterwards dried, sifted, and subsequently baked. In making the starch, the deposit in the water is left for some time to allow the starch to settle down; it is washed three times, dried in the sun, and is then fit for sale.

The carima, or fine, creamy starch, is prepared by softening the puba manioc in water, after which it is strained and pressed in a sieve, and made into little balls, in which shape it comes to market, although sometimes reduced to farina. It is used in gruels and other food preparations, according to the custom of each locality.

The exports of tapioca from Brazil were 200,725 bushels in 1868, and as high as 332,823 bushels in 1866. In 1871 the exports were about seven million litres, valued at £26,050. The value of the imports of farinaceous substances from Brazil (nearly all tapioca) have been as follows in the last nine years:—

1863	£4,193
1864	5,413
1865	6,404
1866	8,024
1867	13,812
1868	15,188
1869	8,974
1870	12,960
1871	14,092

Twenty years since about 11,000 cwt. of tapioca used to be imported annually from Brazil, now we only receive about half that quantity.

At Santiago, one of the Cape Verdes, the crude farina of manioc costs about 1*s.* 6*d.* the decalitre, and when prepared fetches as much as 10*d.* the pound. One estate, the Praia Rei, on the island of St. Thomas, West Coast of Africa, produces about 150,000 litres of farine of manioc. In Angola, 150,000 lbs. are manufactured annually. At Mozambique, the Portuguese also prepare a good deal, which is sold for export at 2½ to 3½ francs the decalitre (17½ pints); dried slices of the root are sold in great quantity in the markets at 5*d.* to 5½*d.* the decalitre.

The common mess of the Balonda Africans is porridge made of the manioc. The meal is stirred into boiling water; as much as can be moistened is put in, one man holding the vessel, and the other stirring the porridge with all his might. It is very unsavoury, and no matter how much one may eat, two hours after he is as hungry as ever. When made thin it is like starch made from diseased potatoes.

Eastern Starches.

The water lilies are much used by the Chinese for food. The seeds of *Netumbium speciosum* provide an excellent meal, used like gruel, and the sliced roots furnish a species of arrowroot. The root of *Nymphœa alba*, in Sweden, and of *Nymphœa lotus*, *edulis* and *rubra*, are used for food in Egypt and the East. The starch from the roots of *Sagitaria sagitifolia* is employed by the Chinese, and from the *Alisma Plantago* by the Kalmucks.

At the Paris Exhibition, in 1867, arrowroots were shown in the Indian department from Sarun, from Palhully, from Dacca, from Dehra Doon, North Malabar, Penang, and Singapore. Although not so stated, I presume most of these would be from *Maranta* and some few from *Curcuma* and the Palms.

The *Maranta arundinacea*, a native of America, was introduced into India about 1840, by Mr. Elphinstone, and is now cultivated in several of the provinces, especially in the Presidency of Madras. It takes twelve or fifteen months to attain its full development. About a year, with good irrigation, brings the plant to maturity in the East, and the roots then contain the maximum of fecula. Thus after twelve months' culture they will afford 16 per cent. and subsequent yields were found on careful investigation by a good botanist (M. Lepine, of Pondicherry) to be—

Months.	Per Cent.
14	15
15	14
16	12
17	11
19	10

The fecula is obtained from the underground shoots, which are white, fleshy, about nine inches long by one and a half to two inches in diameter. They contain about twenty per cent. of fecula, but by the rude processes of rasping and washing not more than twelve per cent. on the average is obtained. Arrowroot is in extensive use in India, and some is also shipped to Europe.

The root of *Curcuma rubescens* yields a starch like arrowroot. In Travancore it forms a large part of the diet of the inhabitants, but has never been tried much in Bengal.

C. angustifolia yields an arrowroot in Tikor, Benares, and Madras; and *C. leucorrhiza* in Berar. Specimens of these may be seen in the India Museum.

The wild ginger plant, which furnishes starch, grows everywhere in the district of Chittagong; it is very difficult to eradicate from land, as the smallest root, or piece of a root, that has an eye, will spring up again. The plant dies off in December. A rough experiment was made with this root by the Civil Assistant-Surgeon of Chittagong, Dr. W. B. Beatson, and the yield was estimated at an ounce of starch from one pound of the root. The experiment, however, was not precise enough to be satisfactory, and he was inclined to think that the yield would be much larger, for the microscope shows the root to be loaded with starch granules. The supply of the root being inexhaustible, any quantity of starch might be extracted from it yearly and become a valuable article of commerce.

There would be no expense for cultivation, and, allowing for the cost of digging the root, and manufacturing the starch, by bruising and macerating the root in water, and drying the deposit, the product would be cheaper than Arracan rice, which is largely exported to Europe to be used, not as food, but in starch manufacture for laundry purposes, stiffening fabrics, etc.

It is not easy to decide whether the wild arrowroot plant found in Cuttack is identical with the cultivated arrowroot. A cup of arrowroot made of the one is not distinguishable from one made of the other—except, perhaps, by a slightly earthy taste observable in the wild arrowroot, which is easily accounted for by its imperfect preparation. The cultivation and more perfect manufacture of the garden arrowroot have been comparatively recently introduced into the province, so that it is neither generally grown nor its produce used by the natives. It is made from plants of his own growing by a native Christian of Khundittur, who sells his produce among the European residents of Cuttuck, his price being a little under 6d. per lb. This arrowroot is of excellent quality, and the process of manufacture is as simple as can be. The tubers are taken up in the cold season, washed, put into a large wooden mortar, and mashed. The mash is then taken out and well washed in cold water, the water drained off, and set to stand in flat vessels, in which it deposits a large proportion of the starch, which is re-washed in cold water and set to dry in the sun. The wild arrowroot, know in the bazaars as "Palooa," grows abundantly in the jungles of the district. It is collected in the cold season by the Sahars, the tubers pounded and washed, and the sediment dried in the sun. By these people it is eaten and sold for the manufacture of what is called "Abheer" in the Jumbulpore, and, to a less degree, also in the Cuttuck district; the wild arrowroot is made into cakes, or boiled with milk, and thus used as an article of food.

(*To be continued.*)

Parliamentary and Law Proceedings.

Alleged Adulteration of Pea Meal.

An action has recently been brought in the Birmingham County Court to recover damages alleged to have been sustained by the death of fifteen pigs, caused by eating adulterated meal supplied by the defendant. Evidence was given that the stomachs of the dead pigs presented symptoms of irritant poisoning. Dr. Hill, the borough analyst, said that he had analysed a portion of the meal, and had been unable to detect any trace of poison; but that there was some sand present, to which, perhaps, the inflammation was due. For the defence chemical evidence was given by experts that the meal contained no poison. The judge decided in favour of the defendant, expressing an opinion that the deaths resulted from the improper manner in which the food was given.—*Birmingham Gazette.*

Misuse of a Liniment.

At an inquest held at Preston on Tuesday, April 1, the inquiry related principally to the nature of the instructions sent out with a liniment. According to the evidence of the wife, deceased had been to Dr. Lonie on a Friday for treatment for rheumatism. The doctor gave him some medicine and a liniment, which lasted him till the following Monday. Dr. Lonie again saw him on that day and said that he had a "pleurisy stitch;" that he was not to have any more medicine of the kind he had been having, but fresh medicine with a sleeping-draught for the night. Deceased's son was sent for the medicine, to whom it was given by an assistant without verbal instructions, and deceased took what he thought was the mixture first and the draught afterwards. He immediately commenced to vomit, and medical assistance was called in. He died a fortnight afterwards. It would appear that the assistant, in the absence of instructions, supplied the messenger with some medicine and a lotion as before. The bottle containing the liniment was produced; it was labelled "poison," in rather small type, with instructions that its contents should be applied outwardly. The wife could not, and deceased did not, read the instructions. According to the evidence of the medical man who conducted the *post mortem* examination, there was extensive disease of the heart, but no evidence of poison. Some discussion followed as to the propriety of the assistant giving the medicine without communicating with Dr. Lonie, and the jury returned a verdict of "Death from natural causes."

Reviews.

The Forms of Water in Clouds and Rivers, Ice and Glaciers. By John Tyndall, LL.D., F.R.S. London: H. S. King and Co.

This little book forms the first volume of 'The International Scientific Series;' a series intended to include a number of inexpensive treatises by distinguished men in England, America, Germany, and France on the results of modern scientific research. A glance down the list of authors is sufficient to satisfy one of the scientific value of these works: Huxley, Carpenter, Lubbock, Tyndall, Balfour Stewart, Lockyer, Wurtz, Odling, Berthelot, are men so eminent, each in his own branch, that the mere statement of their names guarantees at once the character of this new series. To those who have read Tyndall's former writings, it is unnecessary to say much about the style of the little volume he has just given to the public. But for the information of some who are as yet unacquainted with Tyndall as an author, we may state that they will find him throughout writing with a freshness, forcibleness, and perspicuity, that enable even the unscientific reader to grasp his meaning with ease, and make him to wonder at finding a subject of much difficulty at once interesting and intelligible. As might have been anticipated, the greater part of the book is devoted to glaciers. Tyndall's name is now so firmly associated with his Alpine investigations that we should naturally expect to hear something new on this subject, when he writes on 'Forms of Water.' There appears, however, to be little that could be called new by a well-informed man; old facts are well connected and seasoned occasionally with new. The reader is invited to be an imaginary companion to the author in his Alpine tours and work on the glaciers. After giving a little preparatory information necessary to enable him to understand what he will see on his tour, he is led at once to the Mer de Glace, with him to make careful measurements of the rate at which the "frozen rivers" are irresistibly but quietly winding down from lofty peaks to the valleys below. The remarkable resemblance to the motion of a river is established in a most satisfactory manner; not only does the ice-stream, retarded by friction on its bed, move more slowly in its lower than in its upper parts, but retarded by the rubbing of the rocky sides, the lateral portions are outstripped by the central, or to use terms commonly applied to a flowing river, the current is strongest in the centre. And further, where the bed of the glacier curves, it has been established by numerous measurements that the part of quickest motion lies nearer the *convex* side of the curve, the resemblance here to the movement of a running stream being most remarkable.

The production of "crevasses," "moraines," and the many other remarkable appearances on the glacier are explained in a most lucid manner, and throughout the interesting and vivid descriptions of scenery are scattered little morsels of science, put in so simple and pleasing a form that the most ordinary reader would scarcely be tempted to "skip them to go on with the story."

As an example of one of these little passages, perhaps rather a choice one, we may mention the explanation of how icicles are formed. At first sight, the formation might appear readily explicable and the matter too trivial to deserve any profound meditation, but the true explanation is founded on facts not so universally known and the true philosopher does not consider any natural phenomenon unworthy of his consideration. It is found that the sun's heat-rays may pass through air of icy coldness unabsorbed, and yet falling on snow cause it to melt: the mountaineer finds himself scorched by a burning sun and yet treading on thawing snow, and if temporarily sheltered from the sun's direct radiation, he finds himself in air of numbing chilliness. Imagine, then, the sun shining on a sheet of snow upon a roof, the snow is melted whilst the frosty air around may be many degrees below the freezing point, the water trickles from the melting snow and hangs in drops from the eaves beneath, here sheltered from the sun's radiation it is exposed to the chilling effect of the cold air and is rapidly refrozen; the next drop trickles down over this solid drop and attaches itself below, adding to the length of the ice pendant, drop after drop causing its further growth in length and thickness until the mature icicle is produced.

Having mastered the appearances and facts from a visit to the glacier, we are then informed briefly how the remarkable semblance in the movement of solid ice to that of liquid water has been accounted for. Ice is brittle, a sudden blow or strain will break it like glass, how then can a long column of ice move down rugged slopes, now narrowing as it is embraced by the walls of a chasm, now spreading and filling the interval between its wider banks, or as the author well figures it, at one time resembling "a plate of ice laid flat," at another, "a plate fixed on edge," and invariably throughout its downward course adapting itself most wonderfully to the irregularities of the surface over which it passes. Passing over explanations, only mentioned to be refuted, we find a satisfactory clue to the true one in the fact that ice is melted not only by heat, but also by pressure, and regealed when the pressure is removed. By powerful pressure in suitable moulds ice can be made to take any form we please; it is plain then that the lower parts of the glacier partially melted by the pressure of the upper portions assume temporarily a plastic condition, and hence their remarkable power of conforming to the unevenness of the rocks below.

Such is a brief and somewhat imperfect outline of the interesting little volume,—a few preliminary paragraphs leading to the subject of glaciers, a very real, though imaginary visit to these vast "ice-streams," during which the author explains in a simple manner what is known, chiefly what he himself has discovered by careful experiment and observation, about these interesting though long-neglected natural phenomena; and then a reference in conclusion to the evidences of former wide-spread "glacial action" visible in many parts of the United Kingdom.

This little book is well calculated to remove much of the deplorable ignorance of natural phenomena and their laws shown by the otherwise well-educated of the present day, as it cannot fail to be intelligible and interesting to any thoughtful reader, and will serve as a model of the way in which we should search into the processes in constant operation around us and unravel their laws. May many more such "Romances of Fact" be written to counteract the evil influence of the too numerous "Romances of fiction."

Grundlagen der Pharmaceutischen Waarenkunde einleitung in das Studium der Pharmacognosie. Von Dr. F. A. Flückiger. pp. v.; 133, and 104 illustrations. Berlin: J. Springer.

This book does infinite credit alike to the pharmaceutical profession of North Germany, to the public, and to its author—to the two former because it implies a state of technical education, and a recognition of the necessity of it, to which we in England are strangers. By this book pharmacy is reckoned a learned profession, requiring long and patient training. The pharmacist is a man of science, fully conversant with not only the names and medicinal properties of his drugs, and with their more salient chemical properties, as all English pharmacists are supposed to be, but also with the minute structure of such as are derived from the vegetable kingdom, and, further, with the life history, morphology, and physiology of the plants from which they are derived. With such a man of high culture imaged in his mind, Professor Flückiger has written a book worthy of his own high reputation, and quite unlike any English book. By diligent compilation from the works of English botanists and pharmacists, and the various papers from all sources published in this Journal, it would be possible perhaps to make something like it. But such a book would lack the unity of plan which characterizes Professor Flückiger's, and above all would not be, as our author's book is, an A B C guide to the pharmacological workshop. The professor insists upon the pharmacist possessing as intimate a knowledge of his drugs as the physician and surgeon must know of their medicinal properties, and of the anatomy and physiology of man and other animals. He would have him know, in fact, all that the advanced vegetable anatomist and physiologist knows, and more. It is evident that a book thus written is likely to be a very different thing from a book written for a more or less decided "cram," such as most English textbooks are. It is, in fact, simply an introduction—a guide book—to downright hard work in one small department of the vast field of pharmacology, and is very largely an elementary treatise on vegetable anatomy and physiology, having as its object to lead the student to the investigation of the natural chemistry by which pharmaceutical substances are elaborated. In giving this to the pharmaceutical student, our author has placed within the reach of an ordinary botanist a novel and most valuable work; in truth, saving a few pages, the book is a botanical treatise, combining the better qualities of the larger works of Schleiden, Mohl, and our own Henfrey. For the earlier portion the botanist will be all the better, although it must be confessed that these portions are the least complete and valuable. The bibliography, to mention one point only, is extremely deficient. English works—with two exceptions, those of Pereira and Royle and Headland—are not alluded to, and Mr. John E. Howard's magnificent 'Quinology' is wholly ignored, whilst continental names of lesser note are included.

The author's strong point evidently is vegetable structure, and he works at this as few but Germans do, with an infinite amount of painstaking, and avails himself of all the aid that chemistry will afford. The illustrations are about the most valuable portion of the book to the ordinary reader, who, for example, merely wishes to learn something about the structure of medicinal roots, woods, and barks. They are singularly well chosen and admirably drawn. The drawings illustrating the author's descriptions of various modifications of cell structure are cases in point. Take for instance the scalariform vessels of *Rhizoma Filicis*; no essential portion of the structure is omitted, nor on the other hand is the drawing encumbered by exceptional details. The markings of the vessels, with all their regular irregularity, so to speak, are shown to the life. The boldly diagrammatic figures in the following page of the "*Porencanalen*" and "*Steinzellen*" (felicitous expression this) of China bark are the best we have seen of such structures, whilst the drawings on page 38 of similar stone cells (stellate cells of Hassal) seen by polarized light are simply exquisite; but we differ from the author in advising the use of balsam instead of glycerine, as used by himself.

Roots, tubercules, stalks, wood bark, fruits, seeds, leaves, and flowers, are all described at greater length than we can possibly follow here, and each section is copiously illustrated whenever such illustration is necessary, and always from official plants. Take, for instance, the portion relating to the latex vessels (our author includes some doubtfully latex vessels in his term milchsäfte); we have first a drawing of the semi-vessel, semi-cell of Jalapa, then of the fig, and three different figures of the milk system of dandelion root, these latter showing the varied character of the vessels, and to some extent also their development. But the best figures in the book, and this is not easy to say in the face of the admirable figures of stomates and seeds of certain umbellifers immediately preceding them, are those of stems and roots distributed very freely between pages 55 and 88. The first on which we light is that of cascarilla bark, where the characteristic stone cells are very accurately drawn, and the binary cell contents carefully distinguished.

Other illustrations, however, surpass this. To take the best in the book, there are *Aconitum napellus*, transverse and vertical, *Actæa spicata*, with the various structures carefully shown, but in the case of aconite imperfectly described, sections of cinchonæ, sassafras, etc., and above all, an unequalled section of *Lignum quassiæ*. The one distinguishing feature of these illustrations is their general fidelity to nature. There is no attempt made to show every detail, clearly impossible of performance, but every effort is made to produce a drawing that shall show the general appearance of the structure. We submitted them to a tolerably severe test. Turning the book upside down, we tried how many of the drawings we could name, and were surprised to find that where a name could be ventured upon, the object being not always sufficiently well studied by us, the right name was hit upon. There are a few exceptions to the general excellence of the illustrations, however,—notably in the case of starches. In one case, calabar bean, the drawing is execrable in execution and hardly faithful to fact. The next drawing (103) errs the other way; it is too artistic, but is otherwise very good, and would probably give a novice a better idea of the appearance of starch by polarized light than any other drawing with which we are acquainted.

The author's remarks on certain cell-products, as raphides, starch, inulin, fats, and the perplexing protein compounds are interesting, and so far as we can see quite to date, albeit some portion may be open to discussion. This, however, cannot be done here.

Taking the book as a whole, there can be but one verdict, that it is incomparably superior to anything we have in England, and that the pharmaceutical student who wishes to begin at the foundation, and make it safe, in raising the superstructure of his business education, would find it worth while to learn German, in order to read it. There is one point more in which the book differs from our usual textbooks,—one which will commend it to the attention of every histologist, whether his work lie chiefly in the animal or vegetable kingdom,—and that is the admirable list of reagents, and running commentary thereon, with which the author concludes his book. Many of them are old friends, some two or three are new to us, one at least is novel of application—namely, cupric tartrate, which Ritthausen proposes as a test for albumen in living cells. Of those that are new to us it is not fair to speak by way of criticism, nor fair to the author to extract his novelties and lessen the interest of his book to any great extent. We recommend them one and all to the careful study of the experimental botanist and histologist.

Obituary.

JOHN GARLE, F.S.A.

"On the 7th instant, at his residence, Chiselhurst, John Garle, Esq., in his 59th year." Such is the pith of a paragraph which, under the formality characteristic of the first column of the *Times*, presented a special interest to many of its readers who are connected with the Pharmaceutical Society. Mr. Garle joined the Society at its formation, his name occurring in the first list of members, published in 1841. Since that time he has laboured lovingly and faithfully in its interest, serving the Society as a member of the examining board from the time of the institution of that body down to the present year. It is no exaggeration to say that his kindly disposition and amiable qualities greatly endeared him to his friends and colleagues, by whom his loss will be most seriously felt.

Notice has also been received of the death of the following:—

On the 25th February, 1873, Mr. Thomas Hall, Pharmaceutical Chemist, Newcastle-on-Tyne. Mr. Hall had been a member of the Pharmaceutical Society since 1853.

On the 19th March, 1873, Mr. William Fingland, Chemist and Druggist, of Thornhill, Dumfriesshire.

On the 7th April, 1873, Mr. John Hopwood, Chemist and Druggist, of Burnley.

Notes and Queries.

[335.]—BLACKFRIARS OINTMENT.—Will any correspondent favour me with a formula for "Blackfriars Ointment?"—E. JONES.

[336.]—COUGH PILLS.—*C. P.* wishes for the formula for "Sir Astley Cooper's Cough Pills."

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

THE BENEVOLENT FUND.

Sir,—Mr. Clark is, no doubt, prepared to answer a question or reply to comments upon his letter, which is in reality a bill of indictment against the present and past administration of our Benevolent Fund. I would therefore ask him how he reconciles the declaration of his "having long since resolved to withhold his mite, etc.," with the fact of his name appearing to an annual subscription of 5*s.* in the Calendars 1871 and 1872? Without some explanation this appears to be a chronometric error, and if so, it is a bad beginning from a correspondent claiming to put others right.

The Pharmaceutical Society is arraigned as "deaf to the voices around, and hoarding up money." If by this is meant that the Pharmaceutical Council is deaf to those in need, the accusation strikes at the root of benevolence; and is so grave that, in the interests of true charity, Mr. Clark ought to merge from a mere assertion and proceed to proof forthwith. If he be able to produce such proof he will earn the thanks of contributors and recipients; whilst should he fail, justice to the Fund would demand of him a withdrawal as public as the calumny would be flagrant.

It may be that his judgment on pharmacists of the present day would prove as little warranted as that he pronounces against those of former days. Few will deny he pays a sorry compliment to the founders and early supporters of the Fund. Their aim was to provide for a less fortunate brother a haven in which he could rest after an unprosperous though hard-fought career. Their scheme was to invest £10,000, and to grant annuities—thus secured—as interest upon capital. It is now written of them, "They doubted the generosity of the men of to-day."

Many of them are gone from us, but our annuitants live and *will ever live*, the embodiment of their wise, their generous sympathy, reverencing their memories when this sneer is forgotten, or let us hope, repented of. Against the present efforts of the Council to grant annuities and temporary aid from the Benevolent Fund, a counter-proposition is set up by Mr. Clark, and here it is,—"The members in each town should unite their subscriptions, taken away from the Benevolent Fund, to relieve the destitute of their own neighbourhood."

It is only fair to the proposer of this scheme that we should test the working of it touching his own City of Leicester, thus:—Amount of Benevolent Fund subscribed in Leicester as stated in 'Calendar,' 1872, £1 11*s.*; 1873, £1 16*s.* 6*d.* The amount of subscriptions thus taken from the Benevolent Fund and available for the relief of the destitute in Leicester would amount to £3 7*s.* 6*d.* for twenty-four months. Calculating the exact form or amount of relief this sum would provide by the most sagacious management, it cannot bear comparison with the fact that the Benevolent Fund, under the old and abused system, has provided for the widow of a chemist whose application came from Leicester, through the Society's local secretary, Mr. Cooper, and was recommended by another Leicester chemist, an annuity of £30 since 1865—amounting at the present time to upwards of £220.

Those who advocate breaking up the integrity of our Fund and substituting for it a federalizing relief system, must furnish more convincing statistics. And let me add, before the Pharmaceutical Council is adjudged unworthy to represent, or incompetent to interpret, the sentiments of their fellow-subscribers, it must—and more especially the Benevolent Fund Committee must—be put upon its trial. Fortunately the Fund possesses in the person of our Secretary, an officer whose warm interest and indefatigable energy on behalf of our less fortunate brethren no one can gainsay. I have understood he has ready, and would gladly produce, full particulars of every case that has been presented to him, together with the decision of the Council thereon. This material, and the opportunity of reviewing the proceedings of Council at the annual election of annuitants have always been available, and it would, many will conceive, have been fairer to have first tested the value of criticisms at such a meeting, before attacking a benevolent fund which is virtually the property of the needy and the last remnant of their hope. Mr. Clark has elected to bring his charge for discussion and proof in the columns of our Journal. He *may* convince us that a donor to our Benevolent Fund does, by the fact of his election as a member of the Council, lose one of his senses, becoming deaf to the voices around; but at present I believe that the Council will meet him in his capacity of accuser without fear and without reproach.

A SUBSCRIBER TO THE FUND.

Sir,—I was delighted to learn from such good authority as Mr. Sandford, in your last number of the Journal, that every deserving applicant to the Benevolent Fund has received relief.

Is it possible that in the whole country there are only thirteen needy druggists or druggists' widows at the present time who are willing to accept £30 per annum? Then, Drugs for ever! and, Hurrah for the pestle and mortar! Or, on the other hand, is the sum to be received so small that it is not worth having?

The annual subscriptions to the Benevolent Fund appear to be—

London members more than . .	£400
Country members (about) . . .	500
Then, interest on £13,000 . . .	400
	£1300

Why not distribute this sum annually? Why, with an income of £1300, is only £400 spent? Mr. Sandford instances the late Mr. Waugh's approval of the conduct of the Council in this matter. But that which was only proper caution some years since is scarcely applicable at the present time. There is not much danger of the subscriptions decreasing, and I have omitted the donations altogether.

At any rate, sir, pray leave it to the discretion of subscribers, whether their money should be funded or spent at once. Let the Council act boldly in this matter, and leave the result to the Giver of increase.

J. B. B.

PHARMACY IN IRELAND.

Sir,—I cannot allow Mr. Anderson's letter to pass unnoticed, as in many points he is far from correct. In the commencement of his letter he says, "A great amount of misunderstanding exists in the minds of the English chemists regarding the state of pharmacy in Ireland, especially with regard to the position of the chemists and druggists there." I shall be glad to learn what is the misunderstanding regarding the state of pharmacy, and what "especially as regards the position of the chemists and druggists there." If he alludes to their social position being lower than that of their English brethren, he makes a great mistake, as it is equal to theirs, if not higher. Again he says, "the Irish chemists must not be confounded with those bearing the same name in England;" by this we must infer that they are not so competent. Here, again, Mr. Anderson is at fault. The Irish chemists, as a body, are *fully* as competent as their English brethren. He goes on to say, "The pharmacists proper are those who have given up the practice of medicine and devoted themselves to retailing of drugs and dispensing of prescriptions." If such is the case, St. Patrick must have banished them with the snakes, as there are none to be found now.

I do not agree with Mr. Anderson about the examinations. Men who have been in business for years would scarcely be inclined to read up for so difficult an examination as the Major examination of the Pharmaceutical Society.

If, at the passing of the Pharmacy Act, the Modified examination was considered qualification enough for membership of the Pharmaceutical Society and the dispensing of prescriptions in England, why should not the same rule apply here?

The Society of Chemists and Druggists, at their last meeting, approved in the main of the draft Bill proposed by the Apothecaries' Hall. I was one of the deputation which waited on the Apothecaries' Company, and we arrived at a perfect understanding about the examinations. The deputation submitted that having been five years in business and served a proper apprenticeship, should be considered qualification enough without *any* examination. The Governor and Court did not agree with this, and, as near as I can remember, the Governor (Dr. Collins) said the examination they would propose for chemists in business would be almost nominal; that so far as the gentlemen constituting the deputation, as well as numbers more in the trade were concerned, they would have no hesitation in dispensing with examinations; but the public must be protected, and he knew that there were those in business to whom it would not be safe to entrust the dispensing of prescriptions, and he suggested an examination similar to the Modified of the Pharmaceutical Society.

The apothecaries are certainly alive to the necessity for some change; the chemists have not neglected pointing it out to them, and if the Pharmaceutical Society endorses Mr. Anderson's opinions, we must go in for "Home Rule" in matters pharmaceutical; and though our Society is young it is *strong*, and in this matter the members will certainly pull together.

J. T. HOLMES.

30, *Upper Baggot Street, Dublin,*
April 14th, 1873.

EXAMINED AND UNEXAMINED ASSISTANTS.

Sir,—Allow me, through the medium of your columns, to draw attention to what I think an apparent slip in the Pharmacy Act, viz. the non-prohibition of branch businesses of registered chemists and druggists being conducted by unqualified men. A registered druggist, as I understand the Act, is quite at liberty to open as many shops as he pleases, and, so long as his own name is exhibited, he may conduct them by his senior apprentices, or it may be by non-examined assistants, paying a personal visit perhaps once or twice a week, or even less frequently. Some may say that such is quite legitimate, and argue thus:—The responsibility rests with the owner, and therefore he is as much justified in employing an unexamined assistant in his branch shop as in his principal; but I would meet this with a decided negative, holding, as I do, that it is quite as important that such a business should be conducted on the principles of qualification as that of a registered chemist (deceased) whose executors are held liable for the conducting of such business on these principles, if they choose to carry it on. Again, on the other hand, it may be argued that there is no temptation to follow such a course as stated; in reply to which I have just to say that very little proves a temptation to the meagrely-remunerated druggist. Were such an apparent small slip filled up, I am satisfied it would go far to increase further the safety of the public, and at the same time render greater justice to those young men who have thrown themselves into the field at an early hour fully equipped for their calling.

Edinburgh, April, 1873. FAIR PLAY.

W. G. is requested to communicate full particulars respecting the name and address of the person referred to, accompanied by his own name and address, in confidence, to the Registrar, 17, Bloomsbury Square.

W. Macnaught.—The Paris 'Codex' is published by Messrs. Baillière of the Rue Hautefeuille, Paris, but it could be obtained through Messrs. Williams and Norgate, Dulau, Trübner, or any respectable foreign bookseller.

"*Veterinary.*"—Blaine's 'Veterinary Art.'

X. Y. Z.—Much would depend upon the circumstances of the case. Consult a respectable solicitor.

H. W. (Belfast) and "*Cerasum.*"—We believe Messrs. Southall, Son, and Dymond, of Birmingham, are prepared to supply the article in question.

"*Cicuta.*"—(1.) The Adulteration Act was printed in the PHARMACEUTICAL JOURNAL for Sept. 28, 1872, p. 252. (2.) We cannot undertake to say what the decision of a magistrate upon the point would be.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Betts, Mr. J. Waugh, Mr. Bradford, Mr. Gerrard, Mr. Jones, Mr. Fairlie, Mr. Houghton, Mr. Macnaught, Messrs. Tyrer and Co., Mr. Symons, A. G. P., H. B., "Cicuta," "An Assistant."

SUGGESTED ADDITIONS TO THE PHARMACOPŒIA APPENDIX.

BY A. W. GERRARD,

Pharmacist, Guy's Hospital.

The following preparations are suggested as possessing sufficient merit to entitle them to a place in the proposed Appendix to the British Pharmacopœia. All of them have been prescribed for some time past by the physicians and surgeons of Guy's Hospital, and some of them by those of St. Bartholomew's Hospital, and they have been found to be highly useful and efficacious remedies.

GLYCERINE OF BELLADONNA.

Take of—

Extract of Belladonna ...	1 ounce.
Glycerine	1 fluid ounce.

Mix the glycerine gradually with the extract in a Wedgwood mortar.

This is a very useful preparation, and one which I believe would soon become a favourite with the medical profession.

SOLUTIONS FOR HYPODERMIC INJECTION OF ATROPINE, MORPHIA, AND QUININE.

For some time past different prescribers have been using solutions of these alkaloids for hypodermic injections of different strengths, and prepared by different methods. Being organic products, the solutions are liable to undergo change, developing a confervoid growth, the prevention of which is an object yet to be attained, and for which a series of experiments on the solubility and keeping properties of the various salts of the above, both organic and inorganic, are required.

My experience with the acetate of morphia has been that the stronger the solution is made the better it keeps. Some samples of the salt I have found would not entirely dissolve. This, I believe, was due to unconverted morphia, a defect of manufacture, which I have remedied by the careful addition of acetic acid until dissolved, and afterwards of a small quantity of dilute solution of ammonia until slight turbidity was produced, and then filtering. This ensures a neutral preparation. The following formula is a good one:—

Take of—

Acetate of Morphia	1 drachm.
Warm distilled Water	6 drachms.

Dissolve and filter.

LIQUID EXTRACT OF SENEGA.

To be made after the usual method for liquid extracts, namely, by maceration and percolation.

This class of preparations is now regarded with much favour, and I believe the future of English pharmacy is destined to witness a large increase in the number. I consider the above one of the best and most elegant; it has a pleasant, peach-like odour, and the characteristic sweetish bitter taste in a high degree.

OPIUM SUPPOSITORIES.

The only suppository in the Pharmacopœia containing opium is the compound suppository of lead, which contains acetate of lead as well as opium. I think it is desirable to add one containing opium simply, as it is frequently prescribed; and for this purpose I would advise the extract to be used, as being less irritating, more quickly absorbed, and forming a suppository of more uniform strength than the powder.

RESIN OF COPAIBA.

In a recent number of the *Lancet*, Dr. Wilks speaks highly of this substance as a remedial agent, and remarks that he should like to see it have a place in the Pharmacopœia, as it is at present found in but few chemists' shops.

NOTES ON INDIAN SIMARUBEÆ.

BY ALFRED W. BENNETT, M.A., B.SC., F.L.S.,

Lecturer on Botany, St. Thomas's Hospital.

(*Continued from p.* 802.)

There is a good review of the order by Planchon in Hooker's 'London Journal of Botany,' 2nd series, vol. v. The Indian species may be thus classified:—

Tribe I.—SIMARUBEÆ.

Ovary deeply divided.

1. AILANTHUS, *Desf.*

Lofty trees with alternate, unequally pinnate leaves. Flowers small, polygamous, bracteolate, in terminal or axillary panicles. Calyx 5-cleft; lobes equal, imbricate. Petals 5, valvate. Disc 10-lobed. Stamens 10 (in the hermaphrodite flowers 2–3); filaments short or elongated, not scaly. Ovary 2–5-partite; styles connate; ovules solitary in each cell, semi-anatropous. Fruit samaroid; samaræ 1–5, with very large membranous wing, 1-seeded. Seed pendulous, sparsely albuminous.

The genus is confined to Tropical Asia and Australia; and includes 4 species.

1. *A. glandulosa*, Desf. Act. Ac. Par. 1736, p. 263, t. 8; DC. Prodr. i. 89. A lofty tree with very large unequally pinnate leaves, frequently exceeding a foot in length; the leaflets very numerous, shortly stalked, pubescent or subglabrous, very coarsely toothed at the base. Flowers small in much branched panicles. Stamens with elongated exserted filiform filaments, several times longer than the anthers. Fruit of about three membranous linear-oblong samaræ, about 15 lines long by 4 lines broad. Seed near the centre of the samara, about 2 lines by 1 line.

A native of China, generally distributed over Northern India, but probably introduced. Apparently destitute of useful properties either in the wood or bark, but frequently planted in India for the sake of its magnificent foliage, which is also the ordinary food of one of the Chinese silkworms, *Bombyx Cynthia.*

2. *A. excelsa*, Roxb. Cor. i. t. 23; Fl. Ind. ii. 450; DC. Prodr. i. 89; W. & A. Prodr. 150; Wight, Illust. i. t. 67. A tree 60 to 80 feet high, with unequally pinnate leaves, a foot or more in length, the leaflets very numerous, on long stalks, very coarsely dentate, very unequal at the base, and, as well as the petioles, glandular hairy. Flowers larger than in *A. glandulosa*, on longish pedicels, in large, lax, often very much branched panicles. Petals ovate-lanceolate, commonly reflexed. Stamens with very short filaments, about half the length of the anthers. Samaræ larger than in *A. glandulosa*, 2 inches by ½ inch, strongly

veined, blunt or pointed at both ends, copper-red, always much twisted at the base.

Indigenous in South India; extensively planted in North Western India, as far north as Sahamupoor. A variety, *A. imberbiflora* is found in Queensland. The aromatic bark is used by the natives in dyspepsia. Dr. Wight mentions that in the Circars the bark is regarded as a powerful febrifuge, and as a tonic in cases of debility. The wood is soft, white, light, and not durable, but is used for catamarans, and made into sword-handles and sheaths for spears in Western India; the pith is large, and not much used. The roots throw up abundant suckers, and the tree has therefore been employed in the plantations made to clothe barren stony hills near Nice.

3. *A. malabarica*, DC. Prodr. ii. 89; Wight, Ic. t. 1604; W. and A. Prodr. 150; Thwaites, Ceyl. Pl. 69; Rheede, Mal. vi. t. 15. A lofty tree with very large leaves; the leaflets very distant, on long stalks, the two sides of the midrib very unequal, nearly or quite entire, the margin often thickened and wavy, nearly glabrous, much lighter beneath. The flowers as in *A. excelsa*, but rather larger. Stamens with very slender exserted filaments many times as long as anthers. Samaræ large, broadly linear, 2½ inches long by ¾ inch wide, rounded at both ends, reddish, not twisted.

Malabar; Travancore; Ceylon; also in Cochin China. The bark has a pleasant and slightly bitter taste, and is given in cases of dyspepsia, and is also considered a valuable tonic and febrifuge. It yields a fragrant resin known as "Muttee-pal" which may become valuable as an article of trade. Reduced to powder, mixed with milk, and strained, this resin is given in small doses in dysentery, and also in bronchitis, and is reputed to be an excellent remedy, chiefly owing to its balsamic properties. The fruit, triturated with mango, and mixed with rice, is reckoned useful in cases of ophthalmia. Wight states that the bark is rough and very thick, and studded with bright garnet-looking grains, apparently of a resinous nature, which do not dissolve in either alcohol or water. Mr. Broughton, the Government Quinologist, reported upon this resin as follows:— "The resin, as commonly met with, is dark brown or grey in colour, is plastic, opaque, and has an agreeable smell. It contains much impurity. The pure resin is very soft, having the consistence of thick treacle; and this is doubtless the reason why it is always mixed with fragments of wood and earth, which make it more easy to handle. The sample which I examined contained but 77 per cent. of resin, the remainder being adulterations. Alcohol readily dissolves the resin, and, on evaporation, leaves it as a very viscous, transparent, light brown semi-liquid, which does not solidify by many days' exposure to a steam heat; when burnt, it gives out a fragrance, and hence it is sometimes used for incense. The perfume is, however, inferior to that produced by many other resins employed in the concoction of the incense employed in Christian and heathen worship. The peculiar consistency of the resin would enable it to be used as a substitute for Venice turpentine for many purposes, though its price (6 rupees for 25 lb. in the crude state) forbids an extensive employment."

2. Samadera, *Gært.*

Larger or smaller trees, with glabrous habit and simple leaves. Flowers hermaphrodite, in very long-stalked axillary or terminal umbels. Calyx small, 3–5 cleft, imbricate. Petals 3–5, much larger than the calyx, coriaceous, imbricate.* Disc large, conical. Stamens 8–10, included in the corolla, with a small scale at the base. Ovary of 4–5 distinct carpels, free; styles free at the base, more or less united above; stigmas acute; ovules solitary, pendulous. Fruit of 1–5 large, dry, compressed 1-seeded drupes, with a narrow wing on one side.

This genus includes only three species, two of them natives of the Indian Peninsula, Malacca, and Ceylon, the third of the island of Madagascar.

1. *S. indica*, Gært. Frut. ii. t. 156; Wight. Ill. t. 68; W. and A. Prodr. 151; Hook. Ic. Plant. t. 7; Planch. in Hook. Jl. Bot. v. 562; Thwaites, Ceyl. Pl. 70.—*Niota pentapetala*, Poir. Encycl. iv. 490, DC. Prodr. i. 592; *N. tetrapetala*, Wall. (not of Lam. DC.); *N. Lamarckiana*, Blume; *Vittmania elliptica*, Vahl. symb. iii. t. 62. A small tree, 30–35 feet, with stout branches. Leaves fleshy, 8 inches long by 3 inches broad, or larger, elliptic-lanceolate, blunt, with short thick petioles. Flowers yellowish-white, numerous, in dense umbels, on short pedicels surmounting a very long peduncle, equalling the leaves in length. Calyx small, thick, ciliated, persistent in fruit. Petals narrowly oblong, often apiculate. Stamens double the number of the petals; filaments very long, with a scale at the base. Ovary usually of four distinct carpels. Fruit large, 1½ inch by 1 inch, oval, coriaceous, quite glabrous, smooth or slightly reticulated.

Western Peninsula and Ceylon. Colonel Drury, in his 'Useful Plants of India,' says that this tree grows abundantly in Travancore and Cochin, and is propagated easily from seeds. The bark, known as "Niepa" bark, has febrifugal properties, and is used by the natives for this purpose. An oil is extracted from the kernels of the fruit, which is extensively used in rheumatism on the western coast, and is procurable in the bazaars. In erysipelas the bruised leaves are applied externally. The seeds are strung together, and tied round children's necks as a preventive of asthma and affections of the chest. The following directions for the use of the bark, known as "kharinghota," are given in the *Technologist*:— "*Decoction as a febrifuge.* Take six ounces of rasped wood, three pints of water, boil over a slow fire until reduced to one pint, and strain. *Dose.* Two ounces to be taken three times a day. It may be given in all stages of fever. When taken during a febrile paroxysm, it should be given in three-ounce doses. It abates the severity of the symptoms, shortens the paroxysm, and hastens the cure. Sometimes nausea and vomiting occur after taking the dose. This will rather favour the recovery of the patient than otherwise. In such cases the dose should be lessened to one ounce, and repeated at greater intervals, or it may be given during the paroxysm only. In recent cases the fever is generally speedily subdued by the decoction. An infusion of the wood may at all times be used as a general tonic, and it is a perfect substitute for the infusion of quassia in the following form:— Take two drachms of the rasped wood, one pint of boiling water; infuse for two hours in a covered vessel, and strain. *Dose.* One ounce as a bitter tonic to improve the appetite and invigorate the system. It is of a light lemon colour, and a good vehicle for the administration of iron, iodide of potassium, etc."

* Erroneously described as valvate in Bentham and Hooker's 'Genera Plantarum.'

The wood is light, but durable, and is used for shoes and other articles. It takes a good polish.

2. *S. lucida*, Wall.; Plant. As. Rar. ii. t. 168; Planch. in Hook. Jl. Bot. v. 562. Very closely allied to *S. indica*, and perhaps only a variety. Leaves a lighter green, sometimes larger, and with longer petioles. Umbels almost sessile, or with the common peduncle much shorter than the leaves. Fruit smaller than in *S. indica*, pear-shaped, dark brown, glabrous, beautifully reticulated, with a very narrow wing.

Eastern Peninsula and Andaman Islands. Nothing is known about its properties; it has probably been confounded with the former.

(*To be continued.*)

SULPHOVINIC ACID AND THE SULPHOVINATES.*

BY M. BERTHELOT.

I. *Reaction of Sulphuric Acid upon Alcohol.*

The reaction of sulphuric acid upon alcohol gives rise to very varying products, according to the temperature at which it occurs.

(1.) If the two bodies, previously cooled, be gradually mixed, avoiding any rise of temperature, and keeping the whole at about 0°C., no reaction is at first produced; but under the influence of a prolonged contact, a peculiar sulphovinic acid is gradually formed, the salts of which differ from those of the ordinary acid, into which they are transformed under the influence of boiling. This acid, first noticed by Svanberg, and met with since by Gerhardt and myself, has been recently contested by Erlenmeyer, but, I think, wrongly. That author, not having operated with sufficient precautions, obtained, in fact, the ordinary acid in two different ways, so that he compared the salts of one and the same body. The existence of these special sulphovinates, which are more unstable than the ordinary sulphovinates, may be one of the causes of the spontaneous alteration in the commercial salts. I shall, therefore, point out further on how their production they may be avoided.

(2.) Mixture of concentrated acid and absolute alcohol, in equivalent proportions, without special precautions, gives rise to great disengagement of heat and the production of ordinary sulphovinic acid. The quantity of this acid immediately formed varies according to the mode of mixture; that is to say, according to the degree of local heat and the relative proportions in contact, and whether the acid or the alcohol is poured into the other.

For example, upon mixing without precaution one part by weight of concentrated acid with five parts of alcohol, I have found that at the end of one hour 10 per cent. of the acid was changed into sulphovinic acid, and at the end of twenty-four hours, 26 per cent. On the contrary, upon mixing carefully one part by weight of concentrated acid and two parts of alcohol, scarcely any was etherified at the end of one hour, and a very small percentage in twenty-four hours, although the excess of acid compared with the preceding experiment might be expected to favour the combination. Be that as it may with these preliminary phenomena, under the influence of time the combination proceeds to a fixed limit, which it does not appear to pass. Thus, at the ordinary temperature, concentrated acid and absolute alcohol yield for 100 parts of sulphuric acid the following proportions of sulphovinic acid:—

At the end of 40 hours	56·0
„ „ 90 „	59·0
„ „ 147 days	58·8

The reaction is greatly accelerated by a suitable heat. In fact, if the temperature of such a mixture be kept at 100° C., 56 per cent. of sulphovinic acid may be obtained in four hours. It is necessary, however, to avoid the prolonged use of such a temperature, since, at the end of ten hours, there would remain but about 42 per cent. This retrograde action is due to a slow formation of ordinary ether, produced at the expense of the sulphovinic acid, and which tends to regenerate the sulphuric acid.

(3.) The production of ordinary ether becomes very plentiful if the temperature be raised to about 145° C.; at about 160° or 170° C., in consequence of a more complex reaction, even ethylene is formed. Although within these limits of temperature sulphovinic acid always exists in the mixture, in consequence of certain equilibriums between that acid, ether, ethylene, free sulphuric acid, alcohol, and water, it is advisable carefully to avoid such complications in the preparation of sulphovinic acid.

It is therefore necessary to raise the temperature, to about 100° C., and maintain it for a short time, in order to provoke the formation of sulphovinic acid under its most stable form; but the temperature should not be raised too high, nor should the mixture be kept too long at 100° C.

II. *Reaction of Water upon Sulphovinic Acid and its Salts.*

The influence of water upon the production of sulphovinic acid and its salts is illustrated by the fact that when equivalents of strong sulphuric acid and alcohol are mixed together, the production of the acid does not pass a certain limit, 59 per cent. This limit is due, as in the formation of other compound ethers, to the presence of water, a necessary product of etherification. In an inverse sense water will decompose pure sulphovinic acid, and the decomposition will stop precisely at the same limit as the reciprocal combination. Between these four bodies, alcohol, sulphuric acid, sulphovinic acid and water, there is thus produced a certain equilibrium precisely as in the formation of other compound ethers.

But the limit is not always exactly the same for the same equivalent relations, probably because the bibasic organic acids, which might be compared to the sulphuric acid,—such as oxalic, succinic and tartaric acids,—form at the same time two compounds, a neutral ether and an acid ether, a fact which I have verified. Consequently, in these cases, the acid standard is diminished 66 per cent. of its original value when equivalent quantities are used. Whereas I have ascertained that concentrated sulphuric acid only forms one compound with alcohol, an ethereal acid, to the exclusion of neutral sulphuric ether, which is not produced under these conditions; also that the standard of the acid is only lowered 29·5 per cent.

But if the limit be not the same, the general phenomena remain alike. Between the four bodies, acid, alcohol, acid ether, and water, there is produced

---

* Abstract from a letter to M. Bussy, President of the Paris Society of Pharmacy (Journ. de Pharm. et de Chimie [4], vol. xvii. p. 257).

a certain equilibrium. The proportions of this equilibrium do not appear to be affected by temperature, at least if it be not such as to produce new compounds, as ordinary ether or olefiant gas. In fact, the limit of the reaction (with equivalent quantities) in the cold, after some weeks, being 59 per cent. of sulphovinic acid, I have found 56 per cent. after a few hours. Although the absolute sameness of these limits has not been established, because of the slow formation of ordinary ether, yet the analogy of the ethers formed by organic acids and the preceding figures tend to show their identity.

The limit of equilibrium,—that is to say, the proportion of sulphovinic acid,—is also modified by the relative proportions of the four bodies. Water, in particular, after a time decomposes sulphovinic acid. Consequently the presence of an excess of water at starting lowers the limit of etherification; it also retards the combination. This is shown by the following figures:—

Nature of Mixture.	Per cent. of Sulphuric Acid etherified after a contact of 40 hours.	90 hours.	20 days.	147 days.
$SO_4H + C_4H_6O_2 + \frac{1}{3}HO$*	56·0	57·4	59·0	58·8
$SO_4H + C_4H_6O_2 + 1\frac{1}{3}HO$	13·2	21·2	41·2	54·8

Alcohol containing 25 per cent. of water yielded, at the end of a month, only 8 per cent. of sulphovinic acid, showing that the presence of water is an obstacle to the combination of the sulphuric acid with the alcohol.

On the other hand, if water be added to sulphovinic acid, or to a sulphovinate, there is decomposition and reproduction of alcohol and acid, slowly in the cold, rapidly at 100°C.,—in all cases inevitable, —until the equilibrium is established between the opposing actions. These are the principal facts in the preparation and preservation of the sulphovinates.

Finally, it may be remarked that sulphovinates are more slowly decomposed in solution than sulphovinic acid. It is in consequence of this slowness that solutions of sulphovinates can be evaporated to crystallization without being spoiled. But the salt should not be kept too long in a state of solution.

The decomposition of sulphovinates in solution presents a peculiar feature which is worth pointing out, namely, that when once commenced it is gradually accelerated. The resulting sulphuric acid takes up an equivalent portion of the base and sets free an equivalent portion of sulphovinic acid, and this latter is much more rapidly decomposed by water than the neutral sulphovinates. In the evaporation, the alcohol being given off, each equivalent of sulphovinic acid releases two equivalents of free sulphuric acid; two equivalents of sulphovinic acid quickly result from the reaction of this sulphuric acid upon the dissolved sulphovinate, and they in their turn are changed by the action of water into four equivalents of free sulphuric acid: the reaction once commenced being thus accelerated in geometrical progression.

These phenomena occur as well during evaporation by heat as a simple keeping of a solution; more slowly, indeed, in the latter case, but always certain. Hence the utility of maintaining solutions of sulphovinates either in a neutral state or slightly alkaline during evaporation or preservation; this may be done by adding to the solution a little neutral carbonate or bicarbonate, which will remain in the mother-liquors after crystallization. The presence of the alkaline salt retards the decomposition, without, however, preventing it altogether.

* Concentrated acid is here taken, which usually contains one-third or more of water.

I do not know whether the neutral sulphovinate, once isolated in a crystalline state, can be preserved. At ordinary temperatures, if the crystals were anhydrous, free from water of crystallization, perhaps it might be. But hitherto this result has not been attained. All the known sulphovinates contain water of crystallization; and I have found that they all undergo change after a longer or shorter time, sometimes after even years.

The alteration always progresses in the same manner; some of the crystals commence to effloresce; they become acid, and the whole mass then quickly undergoes decomposition. The mechanism of this alteration appears to result from the chemical action of water; it is due to a commencement of separation, however slight it may be, of the water of crystallization from the salt which is eliminated by efflorescence. While the crystals preserve their chemical nature and solid state intact they are stable; but the least trace of water of crystallization separated by efflorescence attacks the neighbouring crystals; after a certain time it there sets sulphuric acid free and leads to the cycle of successive decompositions described in connection with solutions. I do not think this fatal cycle can be avoided completely; but it can evidently be retarded by only preserving crystals which are well freed from the mother-liquors, and keeping them in a place having an invariable temperature.

NEW SOURCES OF ETHYL- AND METHYL-ANILINE.

BY JOHN SPILLER, F.C.S.*

In the process of manufacturing the Hofmann violet by the action of ethylic or methylic iodide upon rosaniline or one of its salts, there is always produced a considerable quantity of a dark-coloured resinous or pitch-like substance, which has received the name of "Hofmann gum." This by-product varies in amount and consistence according to the shade of violet simultaneously produced, being much more abundant when the iodide is employed in large proportion for the purpose of obtaining the bluer shades. It has hitherto received no technical application, but accumulates as a waste-refuse in the Aniline Dye-Works where Dr. A. W. Hofmann's process is used.

Whether obtained by the ethylic or methylic reaction, the properties of this body may be briefly summarized as follows:—It is easily fusible in boiling water, and very nearly of the same gravity, for it sinks or swims with the slightest current, being itself all but insoluble in that liquid. In dilute acids (sulphuric and hydrochloric) it is freely soluble, giving dark-brown liquids, from which the gum may be again thrown down unchanged by neutralizing with alkali. Alcohol and benzol dissolve it freely, especially when heated to nearly the boiling temperature; and glacial acetic acid likewise holds it in solution, being precipitated, however, on dilution with water.

During the past year a great number of experiments have been made upon various descriptions of Hofmann gum, varying in their origin and quality according to the amount and nature of the iodide concerned in their production. The results naturally divide themselves into two series, according as they happen to be ethyl or methyl derivatives, but there appears to be a perfect parallel between the two cases; and as much interest attaches just now to the economical production of methyl-aniline, the

* From the Proceedings of the Royal Society.

work has rather extended in the direction of the *methyl* gums.

Without further preface, I may state that the object of this note is to announce the fact that these gums furnish a large quantity of methyl-aniline by destructive distillation. After the Hofmann gum has been kept fused for some time to drive off nearly the whole of the enclosed water, it is charged into an iron still, either with or without the addition of roughly powdered charcoal, and then submitted to a greater heat over a coke fire.* An oily body of nauseous odour soon commences to come over, and the distillation may be safely carried on until the product amounts to half the weight of the gum originally employed. Small quantities of water and ammonia commonly appear, together with a little permanent gas; but practically the oil and residual pitch may be said to be the sole resultants of the operation. This oily body is methyl-aniline, and when purified by rectification in glass retorts becomes nearly colourless, boiling at 200° C., and rising only a few degrees above that point towards the end of the distillation. Not only does it possess the peculiar odour so characteristic of methyl-aniline, but the oil has the required boiling-point as stated above, and the remarkable property of forming permanently liquid compounds (not crystallizable) with any of the ordinary acids. When acted upon with arsenic acid, at or near the boiling-point of the mixture, it furnishes a violet of somewhat red shade, which may be employed as a dye; and the oil gives colours of various tints when treated with other oxidizing agents, according to the usual reactions of methyl-aniline. The red-violet from the arsenical melt may, after purification, be converted into the bluer shades by the Hofmann process, when a new generation of gum is again observed.

The specific gravity of the methyl-aniline oil has varied a little in different operations, but keeps within the ranges of 0·95 and 0·97. It is probable that this trifling variation may be ascribed to admixtures of dimethyl-aniline, due in part to the introduction of higher methylated products into the crude gum employed in these experiments.

By operating in a similar manner upon the *ethyl* gums the corresponding ethyl-aniline has been obtained, the boiling-point of which was higher and not so definite (205°-210° C.) as in the case of the oil already described.

By way of conclusion, and as giving further proof towards establishing the identity of the new oils with ethyl- and methyl-aniline respectively, it may be stated that they fail to give Girard's blue when heated with rosolic acid or rosaniline, but take the peculiar course of changing slightly towards violet, and then suddenly becoming decolourized,—reactions almost without parallel in the history of the tinctorial aniline derivatives.

PROFESSOR TYNDALL ON LIGHT.†

(*Continued from p.* 830.)

The question which we have now to answer experimentally is this: Is the eye as an organ of vision commensurate with the entire range of solar radiation? Is it capable of receiving visual impressions from all the rays emitted by the sun? The answer to this question we find to be "No." On both sides of the spectrum there is a copious outflow of rays which are incompetent to excite vision. Beyond the violet end of the spectrum this vast efflux of rays, entirely useless as regards our present powers of vision, is so copious and varied as to be able to form an invisible spectrum five or six times as long as the visible one. If the theory of evolution be true, then there are in store for man visual inspections far grander than he has yet experienced. These eyes of the future should find beyond the violet the actinic rays which produce chemical effects, rays which produce the decomposition of carbonic acid in plants, and which have so great a power in all the processes of vegetable and animal life.

These ultra-violet rays or waves, though incompetent to stir the optic nerve to vision, are able to agitate the molecules of certain substances so as to shake them asunder and produce chemical decomposition. All photography is founded upon such chemical actions; but there are special substances on which these ultra-violet rays exert a special power. They darken the white salts of silver; and, by permitting a spectrum to fall on paper properly saturated with a solution of such salts, the chemical action reveals the existence and the extent of the ultra-violet spectrum. One of the earliest, if not the very earliest attempts of this character was made by the celebrated Thomas Young, who photographed in this way the rings of Newton; thus proving that these invisible rays obeyed the principle of interference exactly like the visible ones.

As a general rule, bodies either allow the passage of light or they generate it. To use technical terms, they transmit the light or they absorb it, reducing it to darkness. This absorption, however, is not annihilation of the light; it is, in fact, a conversion of it into heat. But there is a third case in which the light is neither absorbed nor reduced to darkness, but transformed into light of another kind. Now, Professor Stokes, who has long occupied the chair of Newton in the University of Cambridge, and who is one of those original workers, who, though not widely known beyond scientific circles, really constitute the core of science, has demonstrated this change of one kind of light into another, and has pushed his experiments so far as to render the invisible rays visible. A piece of paper moistened with sulphate of quinine, when introduced into the portion of the spectrum beyond the violet, renders the non-luminous rays which lie there luminous. By the use of violet glass in cutting off the great mass of the luminous rays, we obtain a light rich in these invisible rays, and this light may be thrown upon the screen and the presence of such rays demonstrated by the paper covered with sulphate of quinine.

[A sheet of paper, moistened with sulphate of quinine, was introduced into the spectrum beyond the violet. Immediately a bluish tint appeared where previously none had been. The light from the electric lamp was then suffered to pass through a sheet of violet-coloured glass, and the experiment was repeated with the spectrum thus obtained. By the use of another sheet of paper a beautiful green hue was produced. A sheet of paper properly prepared, on which a rose with leaves appeared in outline, was placed in this light, and immediately the rose assumed a delicate blue tint, while the leaves showed an exquisite emerald green.]

These effects are due to the quality possessed by the sulphate of quinine and by other bodies, of changing the rapid vibrations of the rays beyond the violet into slower vibrations, and thus rendering the non-luminous rays luminous, and also changing one kind of light into another. Fluorescence is the name given to these effects. The human eye is a beautiful instance of this fluorescence, as Dr. Bence Jones has shown; and there is, no doubt, some substance in the crystalline lens analogous to the sulphate of quinine in its action.

The next question before us is, is radiation capable of diffusing heat? The same apparatus with which the diffusion of light has been shown will also serve to show the diffusion of radiant heat. I first cause an image of the carbon points to fall on the screen. By drawing out the lens the image contracts, but its intensity increases. If now I place some paper in the focus of the image formed the paper will smoke.

* A mixture of pulverized iron borings, kaolin, and syrupy silicate of soda forms an excellent lute for fixing on the head of the still, as it withstands a high temperature without softening.

† Abstract of a series of lectures delivered in the Cooper Institute, New York, and reported in the *New York Tribune*.

I will now cause the rays to converge to a focus, by the aid of a concave mirror. The mirror, silvered in front, is placed in this tin camera behind the electric lamp. A cone of rays, reflected, passes through the aperture in front, closed by a window of rock salt, and forms a focus outside the camera.

If I place paper in the focus formed by this mirror it will ignite. Zinc placed in it will not only fuse but also burn and vaporize. Magnesium will do the same.

Even such refractory metals as copper and silver will be fused on being brought within the focus. The same effects may be produced by the concentration of purely radiant heat. For this purpose convex lenses are employed to convey the purely radiant heat proceeding from the carbon points. Even a lens of so cold a substance as ice may be employed for this purpose. I have here a lens of ice brought to such a shape by being rubbed in a mould. At the focus to which the rays are brought by means of this lens, paper may be ignited and metals fused, and gun-cotton may be exploded.

This mode of concentrating the rays of heat—namely, by lenses—is the same as that first employed by the celebrated Academy of Florence. But the employment of a lens of ice is something remarkable. It was performed by Scoresby in the Arctic regions with solar light. It has, however, never before been performed with artificial light. The lens may be cold, as the ice is, and yet transmit sufficient heat to ignite various substances. This looks odd, but it is easy of explanation when we reflect that it is only those rays that are absorbed that produce the impression of heat. I shall now endeavour to ignite a diamond by the heat radiated from the carbon points. This experiment is a difficult one, and requires great caution. The diamond, as you see, is suspended in a jar. The jar is filled, by displacement, with oxygen; and the diamond is then brought within the focus of the light from the mirror.

Looking at these effects, the question naturally arises, What constituent of the radiation produces them? I introduce a cell of alum in front of the aperture of the camera, causing it to interfere with the light passing from the mirror to the focus. As you observe, the light remains as it was, but upon placing, as I now do, some gun-cotton in the focus, it shines brightly, but does not explode. As soon, however, as the alum cell is removed, the gun-cotton explodes.

This experiment shows us that there must be some constituent of the beam of light which, being transmitted, produces the calorific effect. What is this constituent? If we bring the light to a focus by means of the mirror within the camera, and then cut off all light, certain effects will follow which will give us a clue. Chemical combination exerts an enormous influence on the luminiferous ether. Every person in this brilliant audience is radiant with these rays, and the reason why we cannot see them is that the vibrations are too slow to awaken sensation in the retina. The atmosphere, which is a mechanical mixture of nitrogen and oxygen, is a practical vacuum to the passage of heat rays. When the atmosphere is dry there is an enormous reduction of temperature because of the amount of heat radiated by the earth into space. The elementary bodies, such as oxygen, hydrogen, chlorine, bromine, etc., are remarkably transparent to the rays of heat. Let us see what will result from using with our apparatus iodine dissolved in bisulphide of carbon.

By means of the iodine solution employed in this manner, we may intercept all the luminous rays of the spectrum and then examine the calorific rays alone. I now place a piece of paper where the focus of light was, and, as you observe, it instantly ignites.

I will now employ a sheet of platinum, coated with platinum black, instead of the paper used in the first experiment. Platinum, with its surface thus prepared, acts in regard to the invisible heat rays just as the sulphide of quinine paper did to the invisible light rays. A visible image of the carbon points appears on the surface of the platinum. The temperature of the air surrounding the glowing platinum has nothing to do with this circumstance of heating. The air at the focus may be of a frosty temperature, since no heat is communicated to it from the mirror. The heat raises the platinum to a white heat while not affecting the air. This, of course, is owing to the fact that while the air cannot absorb the heat rays, the platinum can and does. Still keeping the solution of iodine in bisulphide of carbon in front of the camera, and thus cutting off all the luminous rays, I will now proceed to burn at the perfectly dark focus paper and several of the metals.

What agent produces these effects? Let us heat a platinum wire by means of the voltaic current. The wire soon reddens, and finally glows with a white heat. Dr. Draper, to whom I am glad to pay a tribute of respect, has shown by prismatic analysis of the light emitted by the glowing wire that the light at first is a pure red. As the glow augments the red becomes more brilliant, but at the same time orange rays are added to the emission. Augmenting the temperature still further, yellow rays appear beside the orange, after the yellow green rays are emitted, and after the green come in succession blue, indigo, and violet rays. To display all these colours at the same time the platinum wire must be white-hot: the impression being in fact produced by the simultaneous action of all these colours on the optic nerve.

Let us reason backward from this experiment of Dr. Draper. At the beginning, and even before the electric current had acted at all upon the wire, it emitted invisible rays. The vibrations or waves causing these were too long and too slow to excite vision. What becomes of these waves? They are not destroyed, but their intensities are augmented as the shorter are introduced. It is the wave amplitude and not the wave length which determines the intensity of heat as well as of light and also of sound. The rule is that the square of the maximum velocity of the wave determines its intensity. All these waves existed simultaneously. Without such a provision there could be no sun. There cannot be light rays without dark rays also being found. This, Herschel's great discovery has shown. How shall we discover these dark rays? The human eye is delicate as regards the visual rays. But when we come to other rays, not capable of exciting visual impressions, the eye will not suffice, and we must employ an instrument of greater nicety.

I notice in the poetry of Emerson many allusions and expressions which find their application. For instance, he speaks at one place of the discontent felt by the human mind for what we may call the statical condition. Like an organic growth is the growth of science. Something seems an end, but when that end is reached the process does not stop, the bud expands and opens and fruit is born; and so in science, an investigation of a certain subject discovers facts which in the investigator's own and others' hands ripen into yet greater discoveries. In 1821 Seebeck of Berlin discovered that heat applied at the junction of two metals of unequal heat-conducting power soldered together at one end, the other extremities of the bars being connected with a galvanometer, would give rise to electric currents. Oersted, Nobili, and others caught at the idea and turned it to account in constructing a thermometer on this principle, by means of which most delicate changes of temperature may be determined. I place the instrument here and cast an image of the galvanometer dial on the screen. On approaching it with the hand the heat of the latter incites a current which deflects the needle and its image on the screen.

With this instrument we may discover the seat and intensity of the invisible rays of heat in the spectrum. This is done by carrying the thermo-electric pile through the spectrum many successive times, and recording its indications. The chart above the screen represents the range of the heat rays.

By this and other modes of experiment it has been shown that the heat radiated from the non-luminous portion is seven or eight times as great as from the luminous or visible.

The effects of the invisible rays in nature may now be instanced. The action of the sun on the tropical ocean results in warming the waters and vaporizing a portion for the production of rain and snow. It is the dark rays which accomplish these results. The light rays go deeper down. The non-luminous rays go but a short distance below the surface. Rivers are liberated by these same invisible rays. To enable you to see more clearly that it is the dark and not the light rays which produce these effects, I reflect the beam from the electric lamp by a mirror, and mark by a stick the place of the luminous focus. Now, placing the thermo-electric pile in this focus, you see the image of the needle deflected on the screen. Let us now cut off the light. Placing the pile where the focus of light was, the needle is still deflected though no light is at the focus.

By means of the Nicol's prisms we may polarize heat as well as light. They are introduced, and, when rotated to the proper angle with each other, polarization occurs. This polarized heat may be transferred to the thermo-electric pile, and its existence and amount shown by the deflection of the galvanometer needle.

The same effects may be produced with radiant heat as with light. Radiant heat is like light, capable of reflection, refraction, polarization both plain and circular, and double refraction. I will now cut off the light, and when I introduce a sheet of mica, the needle which previously was at zero will be deflected 90°.

(*To be continued.*)

RECENT PROGRESS IN WEATHER KNOWLEDGE.*

BY ROBERT H. SCOTT, F.R.S.,

Director of the Meteorological Office.

The prediction of the seasons, for any considerable period in advance, is of course a problem whose solution must affect the most important social interests, inasmuch as all the operations of agriculture are necessarily dependent on the varying character of the weather. Recently, in order to afford some practical information as to the effect of the weather on growing crops, an agitation has been set on foot for the organization of a system of telegraphic agricultural weather reports, in order, by a knowledge of the prospects of the harvest, to be able to regulate the price of grain. The late Commander Maury took an active part in this movement, and the question was mooted at the International Statistical Congress at St. Petersburg last summer.

Meanwhile, in the course of last summer, a commencement was made in England of giving intelligence as to the probable growth of crops, by adding six inland stations to the list of those which furnish information for the daily weather report.

Our recent experience of the rainfall of 1872, which was almost unprecedented and certainly unexpected, both as to its amount and continuance, is a fair illustration of the very moderate pretensions which even the most practised meteorologists can make to a knowledge of the probable character of the weather for even two months in advance. Abundant notes are now being received as to the concomitant phenomena of unusual drought during parts of last year in other regions of the earth, and as to the abnormal relations of barometrical pressure over north-east Europe on the one hand and Iceland on the other; but none of these facts throw any light, hitherto discoverable, on the causes of our exceptional weather.

Numerous instances might be cited of the failure of prophecies of weather based on the popularly-received signs, such as the shining of the sun on Candlemas Day, evidencing that the principles on which such prophecies depend are not mathematically correct. It is, nevertheless, undeniable that the movements of birds of passage are apparently directed by a prescience of the coming character of the weather; generally, their arrival may be attributed to the fact that they herald the approach of conditions of weather which have already set in in their home. Changes of weather ought to bear mathematical treatment as well as any other statistical facts, and consequently attempts have been made to apply mathematical reasoning to experience of the seasons, in order to test whether these popular ideas have or have not, any real basis of truth.

The most recent contribution to knowledge in this direction is a paper by Wladimir Köppen in the Russian Repertorium für Meteorologie, vol. ii., "On the Sequence of the Non-periodic Variations of Weather, investigated according to the Laws of Probability." The discussion is prefaced by the remark that while weather study has made great progress owing to the development of telegraphy, its results are mainly of utility to the seaman, but remain comparatively valueless for the farmer, while the advantage to be derived from a foreknowledge of the weather is as great in the one case as in the other.

Köppen has examined into the chance of a change of weather at any time, and he finds that *the weather has a decided tendency to preserve its character.* Thus, at Brussels, if it has rained for nine or ten days successively, the *next* day will be wet also in four cases out of five; and the chance of a change decreases with the length of time for which the weather *from* which the change is to take place has lasted.

In the case of temperature for five-day periods the same principle is found to be true; for if a cold five-day period sets in after warm weather, the probabilities are two to one that the next such period will be cold too; but if the cold has lasted for two months, they are nearly eight to one that the first five days of the next month will be cold too. The chance of change is, however, greater for the five-day periods than for single days. Similar results follow for the months, but here, again, the chance of change shows an increase.

In the instance we first cited, that of rain, the result is *not* that if it once begins to rain the chances are in favour of its never ceasing; all that is implied is, that the chances are against its ceasing on a definite day, and that they increase with the length of time the rain has lasted. The problem is similar to that of human life: the chance of a baby one year old living another year is less than that of a man of thirty.

The practical conclusion from all this is, that although it is known that a compensating anomaly for all extraordinary weather exists somewhere on the earth's surface,—*e. g.* the very common case of intense cold in America while in this country we have a mild winter, which was most strikingly true last January,—there is no reason, as yet ascertained, to anticipate that this compensation will occur at any given place in the course of a year. In other words, when definite conditions of weather have thoroughly established themselves, it is only with great difficulty that the courses of the atmospheric currents are changed.

Attempts have not unfrequently been made to predict the seasons for a long period in advance, but without much success hitherto. One great cause for failure is, that accurate meteorological records do not extend beyond the beginning of the century at more than a few stations, and for these the local influences cannot be altogether eliminated. Thus, it is hardly possible to say what has been the approximate temperature of these islands for more than twenty years,—a period far too short for the definite recognition of a cycle. The shortest of these cosmical cycles which has been determined is the sunspot period of $11\frac{1}{9}$ years according to Wolf, and there are indications of far longer periods, such as 33 years or even $69\frac{1}{3}$ years, according to Hornstein.

* Abstract of a Lecture delivered at the Royal Institution of Great Britain, Friday, February 14th, 1873.

At the last meeting of the British Association at Brighton, a paper by Mr. Meldrum, of the Mauritius, was read, in which he showed that the cyclones for which that district of the Indian Ocean enjoys an unenviable notoriety have been more frequent in some years than in others, and that these years of maximum frequency occurred at intervals of about 11 years, coinciding with those of maximum sunspot frequency. This agreement is most important, and it has been abundantly corroborated by an examination of the rainfall at such stations in the southern hemisphere as are available. This has been carried out by Mr. Lockyer, in 'Nature,' as well as by Mr. Meldrum. The results, for the comparatively short period to which they refer, are most striking, as they are sufficient to show that a periodicity is traceable in the weather of the Indian Ocean which is eminently suggestive of a close relationship between the changes which take place in the sun's surface, and the phenomena of our own atmosphere.

But, why has not this periodicity, if it exists, been detected long ago by an examination of European records, which are far more complete than any existing for the Indian Ocean? The answer to this is twofold: in the first place, we are preeminently in the district of the variable winds, and our storms are not nearly so regular in their character as those of the Mauritius, where almost the sole type of storm is the true tropical cyclone, with its concomitant rainfall. It is next to impossible in this country to keep an accurate record of all the several storms which pass over us. The existence of conjugate storms is not unfrequent; two and even three systems of disturbance being traceable at the same time within the area of the United Kingdom. Are these one single storm or several? and how should they be counted in a catalogue? Rain also cannot be taken as a sign of the frequency of storms in a year; for although we know that warm winters are invariably wet and stormy, it cannot be asserted that the all but constant rainfall of the early part of last year was in any way related to storms.

There is, however, in the second place, a far deeper reason for the non-discovery of these cycles in any chance series of rainfall records. The sun passes through phases of greater and less activity, and the terrestrial phenomena corresponding to the epochs of the former character are excessive evaporation in some parts of the globe, and consequent excessive precipitation in others. It must therefore be ascertained in what districts we are to look for the one and for the other of these phenomena respectively. The fact of the mutual compensation of anomalies will show that it is not imposssble that the years of maximum rainfall at the Mauritius may be years of great dryness here. In fact, it cannot yet be said where the maximum solar effect is produced. Mr. Lockyer has pointed out that we must aim at attaining a thorough knowledge of the movements and changes of our own atmosphere, and then seek to establish a connection between them and other cosmical phenomena, such as terrestrial magnetism, the relation of which to the state of the sun's surface was pointed out by Sir E. Sabine twenty years ago.

With Weather Telegraphy and Storm Warnings the name of Admiral Fitzroy will always be associated. This country, however, was not the first to issue telegraphic weather intelligence to its seaports; for in the year 1860, when the possibility of introducing such a system was being discussed here in London, the step had actually been taken in Holland, at the instance of Prof. Buys Ballot. At the present time there is not a single European country, except Greece, which has not its own meteorological organization. In most cases telegraphic weather reports are published in the newspapers, while the example set by Le Verrier, about 1858, of the publication of a lithographed daily bulletin, has been followed by our own office, more than 600 copies of whose charts are issued daily to subscribers and for exhibition at seaports. Of late years Russia, too, has commenced the publication of a lithographed bulletin.

To see weather telegraphy on its grandest scale, we must cross the Atlantic, where, under the direction of Brigadier-General Myer, no less than three charts are issued every day by the Chief Signal Office of the United States at Washington. This undertaking is rendered possible by the fact that the whole organization is military, and that its efforts are almost entirely concentrated on the preparation of these reports, while the telegraphic system of the States is placed at the disposal of the Signal Office for a certain space of time every day. By this means it is possible to publish the chart and report simultaneously in all the principal cities of the States. At the outside, £4000 a year is spent in this country on weather telegraphy, while the vote for the Signal Office, or, to use its familiar designation in the *New York Herald*, for "Old Probabilities," in the United States, is no less than 250,000 dollars, about fourteen times as much.

In our system of stations the first thing noticeable is, that we are entirely exposed to the westward, the direction from whence most of our storms come, and that we have little prospect of improving our condition in this respect. Proposals have been made to moor vessels off our coasts, having telegraphic communication with the shore, and to use them as floating observatories. A trial made with H.M.S. "Brisk," at the entrance of the Channel, resulted in a total failure. The proposal has just been resuscitated in the United States by Mr. Morse, who proposes to moor buoys out at sea with observing turrets on them. The Portuguese Government intend to establish a reporting system between the Azores and the mainland, and an application has been made to the Meteorological Committee to contribute towards the expense, who at once replied that they would be ready to assist in this particular development of weather telegraphy to the extent of their powers.

Comparison between the 8 A.M. reports from Angra do Heroismo in the Azores and from Valencia has been made for the last $2\frac{3}{4}$ years, and there is not a single instance in which the progress of a storm from the Azores to these islands can be traced; the two barometrical curves pursue their respective courses almost entirely independently of each other, and so far from it being true, as has been asserted, "that no country would benefit by this intelligence (from the Azores) so much as Great Britain," the *primâ facie* evidence afforded by the diagrams is, that the balance of advantage to be gained by the proposed connection would fall to the Azores. It, however, is undeniable that it would be a great advantage to us to know daily what were the atmospheric conditions over the district of the Atlantic where the islands in question are situated.

Our experience of the value of Transatlantic reports has not been satisfactory. For three years reports have been received daily (free) from Heart's Content, through the liberality of the Atlantic Telegraph Company, but they have not been of much practical value; partly because the station was badly placed for wind observations, being in a land-locked bay, and partly because *uncorroborated reports from distant stations cannot be trusted.* Accordingly, when the committee were asked to pay for the transmission of the reports, they at once decided to discontinue them.

We now come to the practical portion of our subject, the actual *forecasting of the weather.* The only great principle which has been established of late years has been the entire dependence of the wind, as to both its direction and its force, on the barometrical gradient, and not on the absolute height of the barometrical column. This principle is known as Buys Ballot's law. The law is—"Stand with your back to the wind, and the barometer will be lower on your left hand than on your right." As a simple result of this fertile generalization, we find that there is no danger of a gale, unless the gradient, or difference between barometrical readings over a given distance, exceeds 0·6 in. per 50 miles in the district where the gale will be felt. The attempts which have been made to establish a numerical relation between the gradients and the wind-force have not yet been satisfactory, owing chiefly to the difficulty of eliminating the local conditions which affect the wind. We are also unable, as yet, to say what interval of time elapses between the establishment of the gradient and the setting in of the corresponding wind, and, on the whole, it must be said that, if we trust to the barometer alone, we shall not have sufficient warning of the approach of a gale.

There are several valuable deductions which follow from Buys Ballot's law. The wind may move either against or with watch-hands, and the former is the more usual direction of gyration. The former of these motions is termed cyclonic, and takes place round a barometrical minimum; the latter, anti-cyclonic, and takes place round a barometrical maximum. The weather depends on the relative positions and characters of these areas of defect and excess of atmospherical pressure, and the wind systems connected with them.

(*To be continued.*)

POISONOUS PROPERTIES OF THE RED BUCKEYE.*

The red buckeye (*Æsculus Pavia*, Lin.), a Sapindaceous plant which has its habitat in the Southern States of America, is there generally looked upon as a poison, and farmers frequently attribute the death of stock to their having eaten some part of the plant. Mr. E. C. Batchelor has therefore made some experiments with the seeds, the results of which he has recently given in his inaugural essay upon taking up his degree of graduate in pharmacy at the Philadelphia College. So far as his researches have gone, they show that the seeds are possessed of decided poisonous properties, residing chiefly in a glucoside found in the cotyledons. The symptoms following its administration are similar to those of strychnia poisoning.

The seeds which are from 1 to $1\frac{1}{2}$ inches long, and $\frac{3}{4}$ to 1 inch in diameter, lost 25 per cent. of their weight in drying. The testa, constituting 17 per cent. of the seed, has no odour, but an astringent and slightly bitter taste. It yielded 3 per cent. of a dark reddish-brown resin, tannic acid, some colouring matter, and a minute proportion of tasteless long prismatic crystals.

The cotyledons have a slightly disagreeable odour and an amylaceous taste, slightly sweet at first, then bitter and acrid, with a peculiar and lasting drying effect in the fauces. They yielded by successive treatment a fixed oil (about 5 per cent.), a tenacious green mass, cane sugar and syrup ($2\frac{1}{2}$ per cent.), and a glucoside. The latter was obtained in light yellowish-brown shining scales, possessing a peculiar heavy odour, and an extremely bitter and acrid taste, with a very persistent drying effect on the fauces. Boiled with dilute hydrochloric acid it was converted into glucose and a compound obtained from a solution in alcohol in small yellowish-white tasteless odourless crystals having an acid reaction. The glucoside was insoluble in ether or chloroform, soluble in cold alcohol, more so in hot, freely soluble in water, yielding a frothy solution acid to litmus. Valerianic acid was obtained by distilling it with sulphuric acid.

The new glucoside differs from Argyræscin and Aphrodæscin found by Rochleder in *Æsculus Hippocastanum*. Sulphuric acid gives a rich yellow solution which a drop of water changes to a reddish-purple; upon raising the temperature purple flocks are deposited, and the odour of fatty acids is evolved. Its aqueous solution is not precipitated by acetate or subacetate of lead or baryta water. Less than half a grain administered to a full grown cat caused uneasiness in fifteen minutes, and alternate fits of stupor and muscular spasms, which lasted three days.

Besides the foregoing substances, the cotyledons yielded a minute quantity of a crystallizable acid, and 12 per cent. of starch. The seeds yielded 12 per cent. of ash, a qualitative analysis of which showed the presence of aluminium, magnesium, potassium, sodium, and iron (trace) as bases, and carbonic, hydrochloric, and phosphoric acids.

* Abstracted from the *American Journal of Pharmacy* [4], vol. iii. p. 145.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

A complimentary dinner was given on Thursday evening, at six o'clock, in McLean's Hotel, St. Vincent Street, by the President, Vice-President, and Council of the Glasgow Chemists and Druggists' Association, to the President, Vice-President, and Secretary of the Pharmaceutical Society of Great Britain, on the occasion of their first official visit to Scotland. Mr. Thomas Davison, President, in the chair; Mr. John Jaap, Vice-President, croupier.

The following gentlemen were present:—Mr. Haselden, President of the Pharmaceutical Society; Mr. Williams, Member of the London Council; Mr. Bremridge, Secretary and Registrar of the Pharmaceutical Society; Dr. Cowan, Professor of Materia Medica, Glasgow University; Dr. Simpson, Professor of Medical Jurisprudence, Glasgow University; Mr. Baildon, President of the North British Branch; Mr. Gilmour, Vice-President of the North British Branch; Mr. Mackay, Honorary Secretary of the North British Branch; Mr. Young and Mr. Ainslie, Edinburgh; Mr. McDonald (Glasgow Apothecaries' Company); Mr. Stanford, British Seaweed Company; Mr. Daniel Frazer, Member of the London Council; Mr. Rait Partick; Mr. Currie, Sauchiehall Street; Mr. Currie, Eglinton Street; Mr. Battie, Dumbarton; Mr. Duncanson, Stirling; Mr. Kinninmont; Mr. Fairlie; Mr. Greig; Mr. Whyte; Mr. Dun, etc. etc.

The Vice-President of the Pharmaceutical Society was unavoidably prevented from being present at the dinner.

Thirty-two gentlemen sat down to dinner. A fine band, under the charge of Mr. Adams, was in attendance, and played appropriate airs.

The Chairman, after giving the usual loyal and patriotic toasts, proposed the toast of the evening,—"The Pharmaceutical Society of Great Britain, coupled with Mr. Haselden, President, and Mr. Bremridge, Secretary."

In heartily welcoming the deputation—on the occasion of its first official visit to Scotland—to the good old City of St. Mungo, now in magnitude the second in the empire, the Chairman commented upon the desirability of the President and Council of the Pharmaceutical Society—it being a representative body—occasionally visiting their constituents as such, to enable them far more accurately to learn what was thought in remote places regarding the various matters brought under their consideration. He particularly referred to two points in which pharmaceutists of the commercial metropolis of the north were specially interested. These were, first, "That the true interests of the medical profession, as well as those of pharmaceutists and the general public, demand that the duties of the prescriber and pharmacist should be as far as possible separated." Second, "That when physicians and surgeons really find it necessary to keep open shop, they should at least be required to have a qualified dispenser." The necessity of the first point the chairman regarded as self-evident. With regard to the second point, the chairman said—"If the physician or surgeon requires to keep open shop, it is surely right that the person who dispenses in that shop should be a qualified person. It seemed altogether a strange procedure that laws—however well they may be made with the view of protecting the public, should apply only to the trained pharmaceutists, while mere boys, ignorant alike of pharmacy and elementary education, are permitted, under the wing of a medical practitioner's name, freely to dispense and sell the most poisonous agents. If the Parliamentary Committee who watch over such matters would feel assured of the support they would receive from Glasgow, he was sure they would not be long in being up and doing. The opportunity might soon occur in the introduction into the House of Commons of some bill on medical reform; and what greater boon could be conferred on pharmaceutists throughout the country than by pressing on the attention of Government the points he had named. Great advances had undoubtedly of late years been made in the position of pharmaceutists throughout the country, and certainly these had been chiefly attained through the instrumentality of the Pharmaceutical Society. He hoped, then, that new efforts would yield even greater advantages in the future."

Mr. Haselden and Mr. Bremridge, who were very well received, replied on behalf of the Pharmaceutical Society, commenting upon the desirability of belonging to the Society, and expressing the great desire, not only of themselves, but of the Council and Members of Committees, and of the Parliamentary Committee in particular, to do all that was possible for the benefit not only of members of the Society, but of all chemists and druggists throughout the kingdom; and concluding by returning thanks in eulogistic terms for the very cordial reception they had received, both at Edinburgh and Glasgow, as from every one with whom they had had the pleasure of associating from the moment of their arrival in Scotland.

The toast, "The Council of the Pharmaceutical Society in London," was proposed by Professor Simpson, and replied to by Mr. Williams and Mr. Frazer.

Mr. Stanford, in an able speech, gave the next toast, "The Medical Profession," which was ably responded to by Professor Cowan and Professor Simpson, both of whom made interesting speeches.

"The North British Branch of the Pharmaceutical Society" was proposed by Mr. Currie, and replied to by Mr. Baildon, President, and Mr. Gilmour, Vice-President.

"The British Pharmaceutical Conference" was proposed by Professor Cowan, and replied to by Mr. Williams.

"The Honorary Secretary of the North British Branch of the Pharmaceutical Society," proposed by Mr. Kinninmount, and replied to by Mr. Mackay.

"The Glasgow Chemists and Druggists' Association," proposed by Mr. Mackay, and replied to by Mr. Clarke, Secretary, and Mr. Fairlie.

"The Drug Trade in Glasgow," proposed by Mr. Williams, and replied to by Mr. McDonald (Glasgow Apothecaries' Company).

"The Chairman," by Mr. Young, replied to by Mr. Davison.

"The Croupier," by Mr. Ainslie, replied to by Mr. Jaap.

The *réunion* was entirely a success, everything passing off well, each one present seeming determined not only to please but to be pleased.

THE ANNIVERSARY DINNER.

It has been decided that the Annual Dinner of the Pharmaceutical Society, in connection with the presence in London of many members of the trade to attend the Annual Meeting, shall take place as before at the Crystal Palace, on Tuesday, the 20th of May next. The following is a list of the Stewards, from whom tickets can be obtained by those desirous of being present on the occasion:—

Atherton, John Henry	...Long Row, Nottingham.
Atkins, S. R....	...Salisbury.
Attfield, Professor ...	...17, Bloomsbury Square, W.C.
Baiss, A....	...102, Leadenhall Street, E.C.
Barker, W. R.	...143, New Bond Street, W.
Barnes, J. B....	...1, Trevor Terrace, Knightsbridge, S.W.
Barron, Frederick ...	...2, Bush Lane, Cannon Street, E.C.
Bathe, Robert Samuel	...10, Lisson Grove, N.W.
Baynes, James	...24, Waterworks Street, Hull.
Baynes, James, jun. ...	...17, Bloomsbury Square, W.C.
Beddard, John	...46, Churton Street, S.W.
Bell, R. E.	...161, East Street, Walworth, S.E.
Bentley, Professor ...	...17, Bloomsbury Square, W.C.
Betty, S. C.	...6, Park Street, Camden Town, N.W.
Billing, Thomas	...86, King's Road, Brighton.
Bird, Augustus	...Wood Lane, Shepherd's Bush, W.
Bottle, Alexander... ...	...37, Townwall Street, Dover.
Bourdas, Isaiah	...7, Pont Street, Belgrave Square, S.W.
Brady, Henry Bowman	...29, Mosley Street, Newcastle-on-Tyne.
Bremridge, Elias	...17, Bloomsbury Square, W.C.
Brierley, Richard... ...	...44, Market Street, Stalybridge.
Brown, William Scott...	...113, Market Street, Manchester.
Burbidge, Thomas ...	...16, Coleman Street, E.C.
Butt, E. Northway ...	...13, Curzon Street, Mayfair, W.
Carteighe, Michael ...	...172, New Bond Street, W.
Cornish, Henry Robert	...24, Market Place, Penzance.
Cracknell, Charles ...	...217, Edgware Road, W.
Davenport, J. T.	...33, Great Russell Street, W.C.
Deane, Henry	...Clapham Common, S.W.
Down, Dr. J. Langdon H.	...39, Welbeck Street, Cavendish Square, W.
Evans, Henry Sugden...	...60, Bartholomew Close, E.C.
Faulconer, R. S.	...272, Walworth Road, S.E.
Flux, William	...3, East India Avenue, Leadenhall St., E.C.
Francis, George Baggett	...5, Coleman Street, E.C.
Frazer, Daniel	...113, Buchanan Street, Glasgow.
Gale, Samuel...	...338, Oxford Street, W.
Garner, Thomas	...75, Allan Road, Stoke Newington, N.
Garratt, J. C.	...Rugby.
Giles, R. W.	...52, Royal York Crescent, Clifton, Bristol.
Goss, Samuel...	...Barnstaple.
Greenish, Thomas... ...	...20, New Street, Dorset Square, N.W.
Groves, Thomas B. ...	...80, St. Mary Street, Weymouth.
Hampson, Robert... ...	...205, St. John Street Road, E.C.
Harvey, Charles	...Giltspur Street, E.C.
Harvey, Edward	...6, Giltspur Street, E.C.
Haselden, A. F.	...18, Conduit Street, W.
Hemingway, Walter ...	...20, Portman Street, W.
Herring, John B.... ...	...40, Aldersgate Street, E.C.
Hills, Thomas Hyde ...	...338, Oxford Street, W.
Hodgkinson, William ...	...127, Aldersgate Street, E.C.
Hopkin, William King	...16, Cross Street, Hatton Garden.
Horner, Edward	...20, Bucklersbury, E.C.
Howden, Robert	...78, Gracechurch Street, E.C.
Hughes, John	...York Glass Co., West St., Finsbury, E.C.
Huskisson, H. O.... ...	...17, Swinton Street, W.C.
King, C. T.	...Tenter Street, Little Moorfields, E.C.
Kitchin, Archibald ...	...Whitehaven.
Lansdown, George ...	...3, Warwick Street, Charing Cross, S.W.
Lescher, F. Harwood ...	...60, Bartholomew Close, E.C.
Lockyer, George	...208, Deptford High Street, S.E.
Lynch, Thomas	...171A, Aldersgate Street, E.C.
McCulloch, Frederick ...	...13, Hart Street, Covent Garden, W.C.
Mackay, John	...119, George Street, Edinburgh.
Mackey, J. B.	...2, Bouverie Street, E.C.
Maltby, Joseph	...Lincoln.
Martin, T. C.	...11, Aldersgate Street, E.C.
Martindale, William ...	...University College Hospital, W.C.
Matthews, William ...	...12, Wigmore Street, W.
Mee, George	...79, Grosvenor Rd., Highbury New Park, N.
Morson, T. N. R.	...38, Queen Square, Bloomsbury, W.C.
Moss, John	...17, Bloomsbury Square, W.C.
Newbery, Lionel	...37, Newgate Street, E.C.
Paul, Dr.	...17, Bloomsbury Square, W.C.
Pound, Matthew	...60, Leather Lane, E.C.
Preston, Alfred	...88, Leadenhall Street, E.C.
Radley, W. Valentine ...	...74, Market Place, Sheffield.
Redwood, Professor ...	...17, Bloomsbury Square, W.C.
Roach, Pope	...8, St. James's Street, S.W.
Robbins, John	...372, Oxford Street, W.
Rossiter, Frederick ...	...20, George Street, Hastings.
Sandford, George Webb	...47, Piccadilly, W.
Savory, C. Harley ...	...143, New Bond Street, W.
Schacht, G. F.	...7, Regent's Place, Clifton, Bristol.
Schacht, William... ...	...6, Finsbury Place South, E.C.
Schweitzer, J.	...79, Pavilion Road, Sloane Street, S.W.
Shaw, John	...24, Great George Place, Liverpool.
Skinner, Thomas... ...	...Cirencester.
Smith, Nathaniel... ...	...Cheltenham.
Southall, William ...	...17, Bull Street, Birmingham.
Stacey, S. Lloyd	...300, High Holborn, W.C.
Starkie, R. S....	...4, Strand, W.C.
Stoddart, William W....	...Bristol.
Sutton, Francis	...Bank Plain, Norwich.
Thompson, John	...10, Aldersgate Street, E.C.
Tupholme, J. T.	...1, Coleherne Terrace, West Brompton, S.W.
Turner, John...	...Aylesbury.
Twinberrow, J. K. ...	...80, Wigmore Street, W.
Umney, Charles	...40, Aldersgate Street, E.C.
Walker, William Henry	...Southport.
Warner, Richard... ...	...20, Charterhouse Square, E.C.
Warrick, R. B.	...Old Swan Lane, Upper Thames St., E.C.
Watts, W. Manning ...	...32, Lower Whitecross Street, E.C.
Wavell, John...	...Ryde, Isle of Wight.
Wiggin, J.	...34, St. Matthew's, Ipswich.
Wilkinson, William ...	...263, Cheetham Hill, Manchester.
Williams, John	...16, Cross Street, Hatton Garden, E.C.
Wimble, Alfred	...62, Upper Stone Street, Maidstone.
Wood, C. H.	...300, High Holborn, W.C.
Wootton, A. C.	...44, Burghley Road, N.W.
Wright, G. H.	...103, Borough High Street, S.E.
Wyman, John	...122, Fore Street, E.C.

Tickets for the dinner may be obtained up to Thursday, May 15, from any of the Stewards, or from the Honorary Secretaries, Messrs. RICHARD BREMRIDGE and MICHAEL CARTEIGHE, 17, Bloomsbury Square, W.C. In order to make the necessary arrangements and prevent discomfort, members and their friends are requested to make application for their tickets *at once*.

The Pharmaceutical Journal.

SATURDAY, APRIL 26, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

JUSTUS VON LIEBIG.

An diesem Apparate ist nichts neu als seine Einfachheit und die voll-kommene Zuverlässigkeit welche er gewährt: "in this apparatus there is nothing new but its simplicity and thorough trustworthiness." Such were the words of LIEBIG when announcing to the world his practical creation of organic chemistry. The man himself speaks out in this sentence. "Simplicity" and "trustworthiness" were not less the characteristics of the method than of its author. Versatile as was his genius, and various as were its products, he never proved false to those twin-requisites of science.

"Servetur ad imum
Qualis ab incepto processerit et sibi constet,"

was as much his motto as that of the Roman sage; and whether his work lay in the laboratory or in the lecture-room; in the domain of agriculture or in that of popular education, it combined, in a degree seldom matched in the history of inductive research, the "simplicity" and the "trustworthiness" which are at once the symbol and the test of truth.

In another part of the Journal we have entered, with sufficient fulness, into the narrative of LIEBIG'S personal career. The "exceeding great reward," which is the meed of chivalrous self-devotion in every honourable life service, was not denied him,—probably few *savants* of modern times have lived to reap a richer harvest of recognition. But of him, as of every great pioneer of science, it may justly be said, "his works do follow him," and long after the experiments, theories, and writings associated with his name have lapsed into obscurity, the impulse which he gave to chemical investigation will be felt for good. In a preeminent degree he was, what the first of living French chemists designated him—"a master of scientific initiative"; and even when his generalizations turned out to be premature, or when his inductions proved incomplete, he never forfeited the admiration of the scientific world for the fertility of resource which had suggested them, or for the candour with which he brought them into the critical foreground. Even when the judgment of contemporary *savants* was adverse, not a few of them have been known to share the sentiment of CICERO—*Errare malo cum* PLATONE *quàm cum istis vera sentire.*

"The verdict of foreigners," says MADAME DE STAEL, "is that of a contemporaneous posterity;" and, if the saying be true, the reputation of LIEBIG, when measured by the standard of English appreciation, will be great indeed. Who of us, in school-boy days, has not revelled in the 'Familiar Letters on Chemistry,' and passed to the severer enjoyment of those beautiful researches by which he made science the handmaid of husbandry and the prescriber of food in its universal application to human wants? Even in the very process of enriching our knowledge with his pregnant teaching the intellectual faculties were stimulated and strengthened by the severe, yet simple, logic by which his conclusions were reached; and in studying, for example, his treatises on agriculture, we reaped a mental harvest in the exercise, and felt the wholesome discipline of what BACON calls 'the Georgics of the mind.' But, passing from personal to public obligations, what Englishman will withhold his tribute of gratitude to the chemist who first taught how crops grow and how the exhausted earth may be reinvigorated; what food is best adapted for the frigid, the temperate, or the torrid zones; what principles control the development and renewal of the tissues; how life may be most agreeably prolonged, and death most effectually kept at bay?

With the votaries of our own profession in particular LIEBIG'S must ever be an honoured name. His contributions to pharmacy, though eclipsed by the more brilliant additions he has made to physiological and agricultural chemistry, are none the less substantial and enduring. It was in the pharmacist's laboratory that he made his first researches; it was under pharmaceutical auspices that his scientific genius received its earliest nurture. To his dying day he never forgot his young associations; and all throughout his career he showed the keenest interest in the progress and in the perfecting of pharmaceutical science. In conjunction with his relative GEIGER he produced a handbook of pharmacy which marks an epoch in the history of the art, and indirectly, by analyses and experiments innumerable, he gave an impulse to pharmaceutic method and manipulation which will never cease to be felt. But in this, as in so many other fields, the bequest of his example is his most precious donation to posterity; his "simplicity" and "trustworthiness" will be cherished as a κτῆμα εἰς ἀεί, as a heritage for ever. Chemistry may be revolutionized; her processes may be indefinitely improved upon; her findings reach a profundity and comprehensiveness undreamt of in contemporary philosophy. But among the votaries to whom she is indebted for the new life on which she appears to be entering, and who have sacrificed their energies to her welfare, she will ever cherish, with a fondness reserved for few, the name of JUSTUS VON LIEBIG.

APPOINTMENTS UNDER THE ADULTERATION ACT.

We learn from the *Lancet* that Dr. A. Hill has been appointed Public Analyst for Warwickshire; Dr. Stevenson, Professor of Chemistry at Guy's Hospital, and Dr. Sutton, have been appointed for the Shoreditch District; and Dr. E. B. Truman, Analyst to the Borough of Nottingham, has been also appointed Public Analyst to the County of Nottingham.

NOTTONIA GRANDIFLORA AS A REMEDY IN HYDROPHOBIA.

At a recent meeting of the Royal Horticultural Society, the subject of the application in the neighbourhood of Bombay of *Nottonia grandiflora* as a remedy in hydrophobia was brought forward, and a reference made to the statements of Major Wheeler in the *Times* not long since, to the effect that six men under his charge having been bitten, an infusion of the stem of the plant was administered to five who recovered, the sixth who refused to take it having died. To Dr. A. Gibson is due the credit of having introduced the properties of this plant to notice in India. It is a succulent belonging to the Compositæ, and is found in dry rocky places in the Madras Peninsula. The following notes on the administration and its effects is from the Pharmacopœia of India. "About four ounces of the freshly gathered stems, infused in a pint of cold water for a night, yield in the morning, when subjected to pressure, a quantity of viscid greenish juice, which, being mixed with the water, is taken at a draught. In the evening, a further quantity of the juice, made up into boluses with flour, is taken. These medicines are directed to be repeated for three successive days. From official documents placed at the disposal of the Editor by Dr. Gibson, it appears that the remedy has been tried in numerous cases, but as at the time of the infliction of the wound, caustic was applied locally in the majority of cases, it is difficult to determine how far the *Nottonia* operated, if at all, as a prophylactic. Further trials may solve the question."

PRELIMINARY EXAMINATION.

We are requested to state that the list of persons who were successful in passing the Preliminary Examination on the 7th instant will be published in the Journal of next week.

PROPOSED REVISION OF THE FRENCH PHARMACY LAWS.

A Committee of the French National Assembly having been appointed to consider the state of the laws relating to the exercise of medicine and pharmacy has reported in favour of their revision. The National Assembly, however, in a recent sitting decided not to act on the proposition of the Commission.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

April 16th, 17th, and 18th, 1873

Present—Messrs. Allchin, Barnes, Carteighe, Cracknell, Davenport, Edwards, Gale, Ince, Linford, Martindale, and Southall.

Dr. Greenhow was present on the 18th on behalf of the Privy Council.

MAJOR EXAMINATION.

Eleven candidates were examined. *Four* failed. The following *seven* passed, and were declared duly qualified to be registered as "Pharmaceutical Chemists:"—

*Watmore, James ....Wokingham.
*Adams, Frank ....Brighton.
Roberts, William Henry ....Bath.
Stansby, Charles John ....Derby.
David, John ....Newport, Mon.
Lincoln, John Thomas ....King's Lynn.
Crisp, Frederick Arthur ....Clapham.

MINOR EXAMINATION.

Sixty-nine candidates were examined. *Thirty-one* failed. The following *thirty-eight* passed, and were declared duly qualified to be registered as "Chemists and Druggists:"—

*Feaver, John ....Truro.
*Fox, Charles Edward ....London.
*Bolton, Felix Palmer ....Dover.
*Wallis, Owen ....Hastings.
Baines, Arthur ....Alsager.
Luke, Tom ....Penryn.
Branson, Frederick Woodward ...Northampton.
Keeble, Sam Henry ....Leeds.
Southerst, Marshall ....Haslingden.
Laverack, William Henry ....Bradford.
Equal. { Davis, Benjamin ....Leamington.
Equal. { Thompson, Thomas ....Knaresborough.
Peach, Richard Walter ....Billinghay.
Smith, James William ....Cambridge.
Neale, William ....Woodbridge.
Balkwill, Joseph ....Kingsbridge.
Hargrave, Spencer ....Manchester.
Teebay, John ....Preston.
Waring, Albert Wynne ....Bedford.
Pickard, Henry ....Barnstaple.
Herbert, Samuel ....Bristol.
Brewitt, Alfred ....Spalding.
Bolt, Richard Tanton ....Tavistock.
McCormick, Frank Henry ....Cheltenham.
Equal. { Hopkinson, Stephen ....London.
Equal. { Lucas, Joseph Michael Mark ......Gravesend.
Equal. { Hulme, George ....Longton.
Equal. { James, John ....Hereford.
Equal. { Lord, John Edward ....Rawtenstall.
Hutchinson, George ....South Shields.
Clifford, Thomas Andrews ....Chelsea.
Ransom, Thomas ....Spalding.
Sherriff, George ....South Norwood.
Richardson, Thomas Plowman ...Blackburn.
Holroyd, Arthur ....Hull.
Bateman, Fred. Augustus Newton.Great Yarmouth.
Robinson, James Hedley ....North Shields.
Cowley, Henry Williamson ....Nottingham.

The above names are arranged in order of merit.

* Passed with Honours.

PRELIMINARY EXAMINATION.

The undermentioned Certificates were received in lieu of this Examination :—

Certificate of the Law Society of the United Kingdom.

Howard, Robert ....Clitheroe.

Certificate of the University of Cambridge.

Naylor, William A. H. ....Manchester.

Certificate of the University of Oxford.

Villar, Arthur ....Staplegrove.

EXAMINATIONS IN EDINBURGH.

April 15th and 16th, 1873.

Present—Messrs. Ainslie, Aitken, Buchanan, Gilmour, Kinninmont, and Young.

A deputation from the London Council, consisting of the President, Vice-President, and Mr. Williams, accompanied by the Secretary and Registrar, was also present.

Professor Maclagan attended on the 16th on behalf of the Privy Council.

MAJOR EXAMINATION.

Four candidates were examined. *Three* failed. The undermentioned passed, and was declared duly qualified to be registered as a "Pharmaceutical Chemist:"—

Hyne, Harry ....Bristol.

MINOR EXAMINATION.

Twenty-one candidates were examined. *Twelve* failed. The following *nine* passed, and were declared to be duly qualified to be registered as "Chemists and Druggists:"—

*McCallum, Hugh ....Berwick.
Huggins, Robert..................Southampton.
Hudson, Frank ....Clitheroe.
Graham, William Woodrow ...Dalbeattie.
Stuart, Thomas Peter Anderson.Dumfries.
Paterson, Stephen ....Edinburgh.
Whitelaw, James ....Glasgow.
Lawson, John Robert............South Shields.
Miller, Kenneth ....Wick.

The above names are arranged in order of merit.

MODIFIED EXAMINATION.

Nine candidates were examined. *One* failed. The following *eight* passed, and were declared duly qualified to be registered as "Chemists and Druggists:"—

Cokayne, James ....Newark.
Colledge, William Robert ... Newbiggin-by-the-Sea.
Darling, William ....Manchester.
Fenton, William ....London.
Gallagher, James ....Edinburgh.
Hellowell, John ....Huddersfield.
Lawson, Robert ....Glasgow.
Paterson, William ....Glen Lean.

---

* Passed with Honours.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

The Edible Starches of Commerce, their Production and Consumption.*

BY P. L. SIMMONDS.

(*Concluded from p.* 833.)

Under the name of "Beychundee" a starchy product is prepared by the Gonds and sold in the bazaars of Jubbulpore. It is not an arrowroot, but bears some resemblance to it when pounded. It is obtained from the stem of some wild jungle plant.

In Akyab a kind of arrowroot, called by the natives Rembowah, is prepared from a root called Pemban-oo, obtainable in large quantities, and sold at four rupees the maund. It may probably be Penda-loo (*Batatas edulis*), but is most likely to be Pen-bwa (*Maranta*). Starch is obtained in Travancore, from the round yam (called Chana in Cochin), *Arum Rumphii*, or *Amorphophallus campanulatus*. Imitation sago is made, in Mergui, from *Tacca pinnatifida*.

In Ceylon there was found great difficulty, at first, in inducing the people of the villages to plant the cassava and arrowroot. While only 50 lbs. of tapioca were made by the natives in 1852, 66,000 lbs. were supplied at 1856; so with arrowroot, the production increased from 50 lbs., in 1852, to 6,900 lbs., in 1856; and now, instead of importing arrowroot, exports are made from Ceylon.

In India a fecula is obtained from the young roots of the Palmyra palm (*Borassus flabelliformis*, Linn.), which serves as food to the natives. This palm is very extended over India, and is one of the most interesting trees for study, from the numerous products obtained from it. At Goa they prepare a farina and fecula from the wild palm. Sago is obtained from *Caryota urens*, in Mysore, and pearl sago, tapioca, and tapioca flour were sent to the Paris and other Exhibitions from Mysore, Singapore, and Penang.

The trunk of the Japan fern-palm (*Cycas revoluta*, Thunberg) is rich in sago-like starch.

In a paper which I read before the Society in 1861, "On the Trade and Commerce of the Eastern Archipelago," I gave the following details on the manufacture and commerce of sago.

"Singapore is at present the chief place of manufacture and the principal mart for granulated sago and 'sago flour,' as it is termed in commerce, but which is, in fact, the fecula, or ungranulated starch. The granulated fecula, or sago, of a dirty brown colour, used to be exported from the Archipelago in small quantities, but when the trade to Europe was thrown open, in 1814, the Chinese of Malacca began to prepare a superior starch, known in commerce under the name of pearl sago.

"There are four or five species of palms which yield sago; those most cultivated are, however, the *Sagas Konigii* and the *Sagus lævis*. These palms are found in every part of the Malayan Archipelago and Philippines as far as Mindanao, wherever there is a genial soil for them, and this consists of a marsh or bog, composed of decayed vegetables, near the sea. They are most abundant in the eastern parts of the Malay Archipelago, at the Moluccas and neighbouring islands, with New Guinea and Borneo, and in the Philippines at Mindanao. In all these sago is more or less the bread of the inhabitants. These palms propagate themselves by lateral shoots as well as by seed, and they die after producing fruit.

"The sago tree, when cut down and the top severed from it, is a cylinder about 20 inches in diameter, and from 15 to 20 feet in height. The contents would, therefore, be nearly 26 bushels, and, allowing one-half for woody fibre, there will remain 13 bushels of starch.

---

* Lecture delivered before the Society of Arts, March 26, 1873, Mr. T. Greenish, F.C.S., M.R.C.S., in the chair.

"It may give some idea of the enormous rate of this produce, if it be considered that three trees yield more food-matter than an acre of wheat, and six times more than an acre of potatoes. It is far from being either so palatable or nutritious as it is prolific, and is never preferred, even where it is most abundant, to rice.

"All the raw sago manufactured at Singapore is brought from islands to the eastward, principally from the north-west coast of Borneo and the north-eastern of Sumatra, with its adjacent isles, from Siak to Indragari, but a considerable portion comes from places more than 1,000 miles distant."

This article is very easily prepared for exportation in its raw state; the tree is cut down, then the pith or cellular tissue is taken out and made up into bundles. In this form some 20,000 tons are annually imported at Singapore, where it is prepared by the Chinese, who clear the meal or farina from the fibres of the pith, or cellular tissue, when the flour is either made up for exportation in its natural state, or is granulated into pearl sago.

The imports of sago have steadily increased in England since the abolition of the duty which was formerly levied.

In 1830 the import and consumption of sago in the United Kingdom was only 3,000 cwt.; in 1841 it was 52,000 cwt.; in 1850, 90,000 cwt.; in 1860, 179,825 cwt.; in 1870 the aggregate of sago and tapioca received from Singapore was 344,000 cwts., of the value of £283,541.

In Singapore tapioca manufacture has been very successful, but the crop is said to entirely exhaust the soil in five years.

From Penang as much as 10,000 cwt. of tapioca and arrowroot is shipped annually to Great Britain and the United States.

In the colony of Labuan the sago traders have largely increased their business, owing to the Sultan of Borneo having removed some of the obstructions to the transit of sago in the neighbouring rivers, and it is not improbable that this island may yet become the centre of the sago manufacture of the Eastern Archipelago. In 1867 sago was imported into Labuan of the value of £9,811; in the following year the trade increased one hundred per cent., the value of the imported sago being £19,841, and the process of manufacture added £8,764 more to the value of the sago.

In Celebes all the inhabitants feed upon sago of a very coarse quality, which may be said to grow spontaneously, affording abundance of subsistence to the inhabitants. The sago plantations are situated in the valleys between the mountains, in swampy ground. There are several kinds of sago-trees, some of which will not produce any useful fecula or starch for the first sixteen years. It is collected from trees of eight years up to thirty-two or thirty-five years of age, after which the tree becomes perfectly hollow, and rots away from the top downwards. A sago-tree of ten years' growth will be about 27 feet high, and from 5 to 8 feet girth at the bottom, and is continually yielding its crop. When the substance of the edible sago is 3 to 5 inches thick they cut it, and this will be in two or three months, according to the nature of the soil, and the oftener it is cut the faster it grows.

Australian Arrowroots, etc.

Attention has of late years been much directed to the production of arrowroot in several of the Australian colonies, facilities having been afforded by the culture and distribution of the several plants from the excellent botanic gardens of Melbourne, Sydney, and Brisbane.

Canna Achiras (Gillies) native of Mendoza, is one of the few extra-tropical Cannas eligible for arrowroot cultivation.

C. glauca (Lin.), and *C. coccinea* (Roscoe), yield, with some other Cannas, the particular arrowroot called *tous les mois*. *C. flaccida* (Roscoe) of Carolina is probably also available for arrowroot.

C. edulis (Edwards), the Aderia of Peru, is one of the hardiest of the arrowroot plants, for seeds, even if many years old, will germinate, and are commonly called Indian shot.

This species has been extensively introduced into Australia, and, according to Baron Müller, yields an excellent starch at Melbourne, Western Port, Lake Wellington, Ballarat, and other localities, from plants supplied by the Melbourne Botanic Garden.

The Rev. Mr. Hagenauer, of the Gipps Land Aboriginal Mission station, obtained 220lbs. of arrowroot from one-eighth of an acre of this Canna. The gathering of the roots in Australia is effected about April. The plants can be set in ordinary ploughed land. Captain James Hall, of Hastings, also prepared starch largely from this root. The starch grains, it is well-known, are remarkably large.

Maranta nobilis appears to be the species chiefly cultivated for arrowroot in New South Wales. There were seven exhibitors of arrowroot from it at Paris in 1867: Mr. E. S. Hill, Mr. D. L. Waugh, Mr. John Higgins, Mr. E. W. Rudder, Mr. W. C. Hetherington, Melville, Mr. G. T. Lodis, Wiley Flat, near Singleton, and Mr. H. Moss, Shoalhaven; the last three received bronze medals for their products.

In 1870 there were 84 acres of land under arrowroot in New South Wales, from which 13,567 cwt. of arrowroot was obtained, being 18,251 cwt. less than was made in the previous year from only 31 acres of land.

From Queensland, 26,368 lb. of arrowroot, valued at £548, were exported in 1869, the first shipment of a few packages having been made in 1860.

Good arrowroot used to be made in Norfolk Island, while it was a convict settlement, but I am not aware whether the production is maintained since the Pitcarn Islanders have been transferred there.

Arrowroot is made from *Zamia angustifolia* in the Bahamas, etc.

Under the local name of Coonti an arrowroot is prepared in Florida from the fecula of *Zamia integrifolia*. A fecula was also formerly prepared in Florida by the Indians from the saw palmetto *Chamœrops serrulata*.

Arrowroot prepared in Queensland from *Encephalartus* (*Zamia*) *spiralis* was shown in 1872 at the London Exhibition.

At the Paris Exhibition, in 1867, starch made from the seed of the bean tree, or Moreton bay chestnut (*Castaneospermum Australe*), was shown by the New South Wales Commission and Mr. T. Bawden, of Grafton, Clarence River district, which was highly commended. The seeds are said to be abundant, and the manufacture inexpensive. This large tree is found in abundance in the bushes from the Macleay River south to Cape York to the north. On examination under the microscope of the samples I obtained there, I feel convinced that this starch is not from a leguminous seed at all, but is merely a fraudulent substitution of cassava starch under a new name.

Mr. C. Moore, the colonial botanist, also exhibited it, and received a bronze medal from the Paris jury for this new starch. I should like to have the point cleared up as to there being any *bonâ fide* production of this leguminous starch in the colony.

Starches of the Pacific Islands.

A considerable production and commerce is carried on in various feculas in many of the Pacific Islands. One or two species of *Arums* especially are utilized. *Arum macrorhizon*, Linn., grows wild in Tahiti, and the rhizomes are occasionally eaten, but the *Arum esculentum*, Linn., the *Colocasia esculenta* of Ray, known under the name of *Taro*, is that most largely cultivated and esteemed for its starch, which is an article of food of prime necessity. The natives enumerate no less than thirteen varieties. The rhizomes range in weight from two to four pounds, but there is great variation, some varieties producing very small roots and others very large. They contain much fecula combined with a bitter principle, which is dissipated by heat. In preparing the starch, care has to be taken not to rub the pulp on the sieve with the hand, or a blistering effect will be produced. The yield of starch is as much as 33 per cent.

Another plant, largely cultivated, is the *Tacca pinnatifida*, Forster, which is indigenous to the sandy shores of the South Sea Islands, and is known in Oceanea, but especially in Tahiti, under the native name of *Pia*. This plant is, however, now widely diffused. It is met with in China and Cochin China, according to Loureiro. It is cultivated in the Moluccas, Arracan, and other parts of India, and at Zanzibar. It is found in large quantities in Cook's Archipelago, the Hervey Islands, at Raiatea, Huahine, Bora-Bora, Maupiti, the Hawaiian Islands, the Samoas, Tonga, the Feejee Islands, etc. The tubercles have much resemblance to the potato, but unlike that root the fecula is found chiefly in the centre and not towards the exterior. The proportion of starch yielded is 30½ per cent.

There is a large consumption of this starch in Tahiti, especially for children and invalids, and a considerable export of it under the name of arrowroot. The principal part of that which enters into commerce is made in the islands of the adjoining archipelago, Raiatea, Huahine, Bora-Bora, and Maupiti, where it can be purchased for 3*d*. to 3½*d*. per lb. In the Hervey Islands it is sold at 2*d*.; and Tubuai and Raratonga produce it even cheaper. At Tahiti it retails, or did a few years ago, at 4½*d*. to 5*d*. per lb.

From it the main supply of the Feejee arrowroot is prepared. The Tacca starch is much valued in medicine, and particularly esteemed in cases of dysentery and diarrhœa. Its characteristics are readily recognized under the microscope. A Tacca occuring on the Sandwich Islands yields a large quantity of the so-called arrowroot exported from there. Other species, including those of *Ataccia* (*Tacca*) *integrifolia*, occur in India, Madagascar, Guinea, and Guiana, all deserving tests in reference to their value as starch plants.

Starch is made from several species of yam (*Dioscorea sativa* and *bulbifera*), but it is difficult to extract, owing to the ligneous character of the roots, which require to be soaked in water for two days before rasping, and the bitter principle has to be removed by washing and torrefication.

A few other starches are obtained. The cassava or manioc is never sold or cultivated, although its starch used to form a common aliment mixed with that of the *Tacca*. From the bread fruit (*Artocarpus incisa*) about 17 per cent. of fecula is obtained.

African Arrowroots.

On many parts of the West African coast arrowroot and cassava are grown and prepared. The Canary Islands, Liberia, Lagos, Sierra Leone, and other districts produce it, but not in any quantity for shipment.

The Cape Colony and Natal—especially the latter—have given much attention to arrowroot production. *Maranta arundinacea* is the species grown. I have not the recent statistics of the acreage under arrowroot in Natal, but in 1864, from 226 acres, the quantity obtained was 2,347 cwt. It is chiefly in the counties of Durban, Victoria, and Tugela that the cultivation centres, but the quantity varies considerably, for 61 acres in Tugela, yielded 1,220 cwts.; 66 acres in Victoria, 639 cwts.; and 98 acres in Durban, 488 cwts. In 1866, 2,835 cwts. were produced.

The prices ruling in the colonial market in 1867 were 30*s*. to 40*s*. per cwt., but it realised 67*s*. 6*d*. in some instances. The freight to London was 45*s*. per ton.

I was a little puzzled for some time at the incidental mention of Madagascar arrowroot in this country, as it is scarcely an article of commerce, but I have traced out that 7 cwt., valued at 35*s*., were sent from the east coast of Madagascar to the Mauritius in 1868, and 552 cwts. 2 qs. 17 lbs. of starch of other kinds, valued at £286. *Canna indica*, a native of India, has been introduced and naturalised in the Mauritius, and the *Maranta arundinacea* is also grown there, exhibitors of this arrowroot having sent samples to the Paris Exhibition in 1867.

I have thus skimmed over the surface of this wide and interesting field of inquiry, contributing my mite towards the general fund of information which is so useful on commercial topics, and I trust it will lead to some discussion and added information on the character, quality, and uses of the various starches touched upon.

CHEMICAL SOCIETY.

Thursday, 17th April, 1873; Dr. Odling, F.R.S., President, in the chair.

When the usual business of the Society was completed, the President called upon Dr. Debus, F.R.S., to deliver a lecture "On the Heat produced by Chemical Action." During his discourse the speaker considered the relation existing between the chemical affinity of the metals and the amount of heat they develop during oxidation or combination with chlorine, iodine, etc., and also the various interesting conclusions which may be drawn from the thermic results obtained by the solution of salts, especially noticing that, in double decomposition taking place in solution, those compounds are always produced which develop the greatest amount of heat.

The meeting finally adjourned until Thursday, 1st May, when papers will be read "On Zirconia," by Mr. J. B. Hannay, and "On a New Class of Explosives," by Dr. H. Sprengel.

Parliamentary and Law Proceedings.

Misuse of a Liniment.

In a reference to a report published last week at p. 837 under the above head, and taken from a provincial newspaper, we are requested by Dr. John Lonie to state that "the liniment was taken about midnight on February 24th, and the person's death took place on Saturday, March 29th, 1873."

Charge of Embezzlement against a Druggist.

At the Wincanton (Somerset) petty sessions, on Monday, April 14, John Robinson, chemist and druggist, who for many years had acted as postmaster at Bruton, was committed for trial on a charge of embezzlement. The hearing of the case occupied a considerable time, but the facts are briefly as follow:—A young woman named Jane Hill deposited £6 in the Post Office Savings Bank at Bruton last December. As her book was not returned in the usual manner, after repeated applications to prisoner, she wrote to the Comptroller of the Savings-bank department, and an inquiry was set on foot. This resulted in prisoner's apprehension on the charge named above. When he was first confronted by the Government inspector, he was preparing some medicines, and at once mixed up and drank some chemicals, which were supposed to have been of a poisonous character, and he became seriously ill. He was committed for trial. Defendant has been a tradesman in Bruton many years, and had brought up a large family most respectably.—*Pulman's Weekly News.*

Prosecutions under the Adulteration Act.

At the Glasgow Central Police Court, on Friday, April 18, Daniel Gibson, butter merchant, was charged with having in his shop sold two half-pounds of American butter, which butter was knowingly mixed with other matters so as to increase its weight, contrary to the provisions of the Act to prevent the Adulteration of Food and Drink. The sanitary inspectors proved seeing the butter in Gibson's window, and, suspecting something wrong, bought two separate half-pounds, at 5*d*. per pound, which were handed, sealed up, to Dr. Thorpe, the city analyst, for examination. Dr. Thorpe said that he had very carefully analysed one of the samples given him (the other, still sealed up, being produced in Court) and found 19·5 per cent. of curdy and farinaceous matter, and 19·4 per cent. of water. For the defence a number of butter merchants were called, who considered the butter good, as American; and it was proved that two samples from the same kit had been given to Dr. Wallace for analysis. Dr. Wallace said he had analysed them, and found in one 1·1 per cent. of curdy matter, and in the other 1·5 per cent. There was also salt and water which he did not estimate. There was no farinaceous matter in the samples. The magistrate held that there were great difficulties in the way of comparing the analyses, and as to whether the different samples were the same butter; but he was satisfied that a guilty knowledge of the adulteration on the part of Gibson had not been proved. The case was then dismissed.—*Glasgow Herald.*

At the Clerkenwell Police Court, on Friday, April 18, Charles Deveson, a dairyman living in the Hornsey Road, appeared in answer to a summons which charged him with having adulterated milk for sale. The inspector of nuisances stated that he went to defendant's shop and purchased a quart of milk, and told him it would be analysed. When examined the milk was found to be adulterated, the analyst being of opinion that two-thirds of it was water; the look of the milk would show that it was not pure. In cross-examination he stated that the lactometer could "easily be cheated." The magistrate imposed a fine of £5 and costs.—*Times.*

Review.

CONTRASTS. Dedicated to the Ratepayers of London. Strahan and Co. 1873.

"Ignorant impatience of taxation" is a phrase which probably owes more of its vitality to alliteration than to truth, and it is a question whether it be not more correct to say that to ignorance is due the patience with which taxation is borne. For in the book which under the title of 'Contrasts' is dedicated to the London ratepayer, there is enlightenment amply sufficient to cause him to reverse the original dictum. Written by a man who, unlike the needy knifegrinder, has a tale to tell, and who persists in telling it in his own deliberate fashion, there is a tone about it which prepares the reader to give credence to the startling "contrasts" that are occasionally placed before him, because he feels that if the author should not be always correct in his conclusions he is at least well informed in his subject. And that it is no new theme with him there is evidence in the fact that we recognize a considerable portion of one section of the work as having appeared anonymously some four years since in the pages of a now defunct magazine to which the author occasionally contributed. As there were some rather surprising statements in the original article, we have been curious enough to compare them with those given in the book, and find that they are substantially the same, and we suppose therefore that their correctness has not been impeached.

Out of so much that is of the greatest interest to the heavily taxed ratepayer it is difficult to make a selection, but perhaps the following will present parochial relief in a new light to some of our readers. A dock-labourer, earning 18*s.* per week, is from some cause thrown out of work. He has a wife and four young children, and after various struggles they have to go into the workhouse. Our author says—"Instead of admitting them, it would have been better policy for the guardians to have said to the man, 'My dear fellow, give yourself no further uneasiness about your family. You say you can earn 18*s.* a week; go and smoke your pipe, loaf about the streets, spend your time in the public house or anywhere you like .... Your money will be paid you regularly every Saturday till work becomes plentiful again.'" The reason given being that on an average every man, woman, or child in the workhouse costs the ratepayer 10*s.* a week. Some forcible contrasts are drawn between well managed industrial schools and orphanages, where the cost ranges from £13 to £15 a child, and the pauper schools at Anerley, Plashet, and Hanwell, where the average is £25 a head annually. And many a ratepayer who has to struggle to keep the wolf from the door would endorse the words of the report attributed to a Holborn ratepayer who had been deputed to visit the Hanwell Schools.

But although rather hard upon parochial authorities, including the vestry, with its characteristic debate of three hours upon the material of a beadle's button, some contrasts are drawn in which they appear in a favourable light, and it is shown that the guardians—and ratepayers too—have suffered pretty considerably through the legislation following the *Lancet* investigation of workhouse infirmaries. An attempt is made to test the justice of the outcry against workhouse infirmaries by comparing the proportion of recoveries in them with those in hospitals. Putting aside ordinary cases,—because since the hospitals receive a larger proportion of acute cases, they would naturally have a larger proportion of deaths,—reference is made to the statistics of the lying-in wards, and it is found that the mortality in the lying-in charities is five times greater than in the workhouse infimaries. To quote an extreme instance, our author states that during the six years the model wards in a well-known hospital were open—in the building of which everything that skill could suggest had been lavished,—the mortality averaged about one in twenty-three, while during the same time in eleven metropolitan workhouses there were 2,413 deliveries without one death. But in answer to the public panic, Mr. Gathorne Hardy's Act was passed, and now we have the Metropolitan Sick Asylums to use, to look at, and to pay for. A footnote calls attention to the fact that patients confined in workhouse infirmaries are attended by women.

Other contrasts are presented in extracts from the original charters of some of our public hospitals, public schools, and livery companies, and the manner in which those institutions are managed at the present day; showing how money enough to relieve all our necessitous sick and educate all our poor children has been diverted from its original purposes. One hospital, originally endowed for very similar purposes to our present sick pauper asylums, with its cost of £800 per bed, is contrasted with another that cost £30 per bed. The enormous cost of education in our endowed charities is compared with that of education of at least equal quality in well-managed schools. But room will not allow the enumeration of all the topics dealt with. The book itself should be read by every person interested in the subject.

Obituary.

JUSTUS VON LIEBIG.

The forebodings respecting Baron Liebig have been but too painfully realized, and about the time on Friday afternoon when the lines in last week's Journal announcing his dangerous illness reached the hands of some of our readers, that great chemist breathed his last. Few names of scientific men are nearly such familiar "household words," even in their own country, as that of Liebig is throughout the civilized world. The general public in this country is more than usually appreciative of the great loss science has suffered, while amongst men of scientific training pharmacists are peculiarly interested from the fact that the deceased spent a portion of his youth in a pharmaceutical establishment, and was an Honorary and Corresponding Member of the Pharmaceutical Society of Great Britain.

Born in 1803 at Darmstadt, Liebig studied in the Gymnasium of his native city. From his earliest years he had shown an aptitude for natural science, especially chemistry. At the age of fifteen, therefore, his father placed him in a pharmaceutical establishment at Pappenheim. At the end of a year, however, he proceeded to the University at Bonn, and from thence to Erlangen, where he took his degree of Doctor of Medicine.

About 1822, while not yet of age, he was sent to Paris at the expense of the Grand Duke of Hesse, where he prosecuted his studies and was received on friendly terms by the most celebrated French chemists. How vivid an impression was made upon the young student by the kindness which he received in Paris, was shown in an address delivered by him before the Bavarian Academy of Sciences, nearly half a century afterwards, and at the close of the dreadful war between his own country and France. "When I went to Paris to study chemistry," he said, "accident drew Alexander von Humboldt's attention upon me, and a recommending word of his induced Guy-Lussac, one of the greatest chemists and physicists of his time, to propose to me, a youth of twenty, to continue and complete under his assistance an investigation of mine; he placed me in his private laboratory as pupil and assistant; the whole course of my life was thereby decided. Never shall I forget the kindness with which Arago, Dulong, and Thénard met the German student; and how many of my German compatriots might I name, who, like myself, thankfully recollect the active assistance in the pursuit of their scientific studies given to them by French *savants!*"

The "accident" that drew Humboldt's attention to Liebig was a memoir which, in 1823, he communicated to the French Academy of Sciences, entitled 'Sur l'Argent et le Mercure fulminant;' and one result of his labours in Guy-Lussac's laboratory was an 'Analyse du Fulminate d'Argent,' published in their joint names. Humboldt did not cease to be interested in his young countryman, and chiefly by his recommendation Liebig was appointed Professor Extraordinary of Chemistry at Giessen at the age of twenty-one. Two years afterwards he became Ordinary Professor of Chemistry in the same university. Here, with the assistance of the Government, he so developed the teaching of practical chemistry and raised the renown of the school, that the laboratory was sought by students from all parts of the world, and some of his pupils,—such as Will and Fresenius, Hofmann, Playfair, Blyth,,—have in their turn won world-wide reputations.

But the professorial chair did not absorb all Liebig's energies, and memoirs that may be numbered by hundreds, and in every one of which his ability and industry were made increasingly manifest, came from his pen. In 1837 he attended a meeting of the British Association, where he read a paper on the Composition and Chemical Relations of Uric Acid, which attracted considerable attention, and, at the request of the Association, he undertook to draw up two reports, one on Organic Chemistry, and another on Isomeric Bodies. The matured result of this engagement appeared in 1842, as a Report on Organic Chemistry applied to Physiology and Pathology, which was published in the British Association Reports of that year. His 'Familiar Letters on Chemistry in its Relations to Physiology, Dietetics, Agriculture, Commerce, and Political Economy' rapidly passed through several editions in England and America, and were also translated into Italian. In their English form many persons in this country first became acquainted with the author's views upon the chemistry of agriculture, which have in recent years so powerfully influenced farming operations. In these letters also he put forth his views upon the Food question, and described the preparation of the aqueous extract of meat with which his name is now so widely associated. Doubts as to the correctness of his conclusions and misunderstandings as to what he really did say having arisen, Liebig in a recent communication to this Journal, and probably nearly the last that came from his pen, defended his views with all his old force and clearness. Another important subject dealt with by Liebig was Fermentation, and in a memoir read before the Academy of Bavaria he disputed the theory of the eminent French chemist Pasteur as to its origin; a translation of this memoir, sanctioned by the author, was published in this Journal. Pasteur took up the challenge, at a meeting of the French Academy, and the subject has been there discussed with a heat unusually scientific, and has developed so many ramifications as to make it almost impossible to follow them. Liebig also assisted Poggendorf in his 'Dictionary of Chemistry' and Geiger in his 'Manual of Pharmacy.' But we cannot enumerate the various productions of his pen. He is said to have been the sole author of nearly three hundred memoirs, and from thirty to forty were issued jointly with other chemists, such as Dumas, Guy-Lussac, Mitscherlich, Pelouze, Pfaff, Rose, and Wöhler. Many of them appeared in the *Annalen der Chemie und Pharmacie,* of which he was a joint-editor.

Recognition of the value of his scientific labours came to him from all quarters. Professorial chairs, both in this country and on the Continent, including that at Heidelberg vacated by the death of Gmelin, were offered to him, but were declined, until in 1852 he accepted office in the University of Munich. In 1840 he was chosen a foreign member of the Royal Society and received the Copley medal. In 1845 he was made a baron by the Grand Duke of Hesse-Darmstadt. He was also elected an honorary or corresponding member of most of the learned societies in Europe and America.

The final honours were paid to Baron Liebig in a public funeral which took place on Sunday last. He was buried at Munich, where it is intended to raise a monument to his memory.

DR. H. BENCE JONES, F.R.S.

It is our painful duty this week to record the death of two distinguished men whose lives were devoted to the advancement of chemical, medical, and pharmaceutical science, and who, by the countenance and support they gave to the Pharmaceutical Society in its early days, contributed to its successful progress and permanent establishment. Thirty years ago it was no small benefit to the struggling but rising Institution in Bloomsbury Square, that such men as Liebig and Bence Jones were among those who, by their presence as visitors in the then recently formed laboratories of the Society, tended to stimulate and encourage the little band of working students, some of whom have since attained to eminence in their profession. The visit of Professor Liebig to our Laboratory, his inquiry into all the operations in progress by the students, and his instructive remarks and explanations on every subject brought under his notice, must be fresh in the memory of those who were present on the occasion. Although less prominently, yet more frequently, about the same time, Dr. H. Bence Jones, then rising to eminence as a chemist as well as physician, visited the laboratories of the Pharmaceutical Society, and often carried on experiments and investigations there with his friend Mr. Fownes, who occupied the chair of chemistry in the Institution. The working laboratory of the Pharmaceutical Society was at that time a new and unique institution in this country, the establishment of which was soon afterwards followed by those of the College of Chemistry under Professor Hofmann, and the Birkbeck Laboratory at University College under Professor Fownes. In all these provisions for the advancement of chemical knowledge Dr. Bence Jones took a deep interest, indicating his attachment to this department of science, and his thorough knowledge of chemistry and aptitude for chemical investigation were applied especially in the direction of physiology and therapeutics. For many years he had a chemical laboratory in his house, and an accomplished chemical assistant constantly engaged in carrying out his investigations. After the premature death of his friend Professor Fownes, Dr. Jones became one of the editors of Fownes's 'Manual of Chemistry,' with which his name has been so long associated. For many years he has taken an active part of the management of the Royal Institution, and continued to act as its Honorary Secretary until ill-health obliged him to resign. As a man of science and fellow of the Royal Society he has occupied a high position, and as physician he has had an extensive practice, yet with his many professional engagements he has found time for literary and other pursuits. Not only has he written the well-known biography of Faraday, but he has often given his attention to pharmaceutical subjects, being an advocate for the simplification of medicines, and for giving them a less repulsive character than they have hitherto generally possessed. Dr. Jones died on the 20th inst., after a long and latterly severe illness.

Notice has also been received of the death of the following:—

On the 15th of April, 1873, Mr. John Owles, Pharmaceutical Chemist, of Yarmouth, aged 67. Mr. Owles was a Justice of the Peace, and had been a Member of the Pharmaceutical Society since 1842.

On the 17th of April, 1873, Mr. John Fells, Pharmaceutical Chemist, of Clapham. Mr. Fells had been a Member of the Pharmaceutical Society since 1853.

On the 28th of March, 1873, Mr. Henry Stephen Duggan. Mr. Duggan was a Member of the Pharmaceutical Society from 1841 to 1866, in which latter year he retired from business. He died at his residence near Hereford, in his 57th year.

On the 15th April, 1873, Mr. John Hubert Fryer, Chemist and Druggist, of Tavistock Street, Plymouth.

On the 17th of April, 1873, Mr. Nicholas Bickford, Chemist and Druggist, of Exmouth, Devon.

We are requested to state that the date of the death of Mr. William Fingland was incorrectly given last week. It should have been 19th of March, 1872.

Notes and Queries.

COD-LIVER OIL IN COMBINATION WITH IRON.—An emulsion is by far the best method of incorporating cod-liver oil with other medicines. Iron is often introduced. This is easily done by adding a soluble salt to the mixture. In the following formula a concentrated solution of pyrophosphate of iron is used, which keeps well, and is a very useful addition to the list of cod-liver oil mixtures.

THE BENEVOLENT FUND.

Sir,—In a letter published in your Journal last week signed "*J. B. B.*," the annual subscriptions to the Benevolent Fund are stated to be, from "London members more than £400, country members (about) £500;" making together £900.

I should be glad to see that amount reached, but turning to the balance sheets published in the PHARMACEUTICAL JOURNALS, Vol. I., Third Series, p. 945, and Vol. II., p. 929, I find that in 1870 the whole annual subscriptions amounted to £586 16*s.* 9*d.*, and in 1871 to £594 3*s.* 6*d.* The statement of 1872, to be published next month, will show an advance, but will still be considerably less than the sum put down by *J. B. B.*

GEORGE W. SANDFORD.

Piccadilly, April 21*st*, 1873.

Sir,—I felt rather pleased on the 12th to read Mr. Sandford's reply to my remarks in the Journal of the previous week; but although I entertain a high opinion of his judgment, I must still differ from him. Mr. Sandford advocates the principle of paying annuitants by the interest of invested capital; I believe in the devotion of *subscriptions* to the same purpose. I hardly fancy that chemists would allow their subscriptions to fail of meeting the wants of any number of deserving annuitants of their own body. The large missionary societies of the present day allow their many agents to depend for sustenance upon annual subscriptions; I fancy it would be safe for us to imitate them. They do not wait to do noble work until they shall have invested capital at about 3 per cent., sufficient to give them income enough for their purpose.

Anyhow, I have the opinion of the Editor of the Journal with me, as the leading article of January 6th, 1872, p. 551, will prove; for there we read, "that annual subscriptions should be devoted exclusively to relieve the wants of present applicants,"* and not to swell an already enormous fund.

And now to reply to a letter in the Journal of to-day by a "Subscriber;"—since he has my name, it would have given me pleasure to have known his, and I think he would have been wiser to have given it. With regard to my trifling donations in 1871 and 1872, I am afraid I was then perhaps slightly careless concerning the appropriation of donations; but since I found that so large a percentage was added to capital, I considered other objects more deserving. The words "long since" were used to denote that my opinions had not been formed from letters, recently in the Journal, of writers entertaining my views. In reference to "Subscriber's" second paragraph, I will state the first case that occurs to me. Some time since we had two annuitants to vote for; three to choose from, who were all approved. Could we have taken £30 from that year's subscriptions, as well as from those of following ones, that third person might have been made happy.

A change in the right direction, I am glad to say, has occurred; for I find that at their last meeting the Council voted £110 to the relief of applicants, whilst in 1871 the whole sum devoted was the paltry amount of £77.

My friend is hardly just in charging me with sneering at

---

* Our correspondent is not justified in drawing this inference from the passage in question. In its entirety it stands thus:—"There are two plain facts that cannot be too well understood. A sum of £12,000 is invested in our Benevolent Fund, and at this we rejoice. The interest provides for twelve annuitants, *but* there are thirteen. One annuity is therefore paid out of the annual subscriptions, which should be exclusively devoted towards meeting the numerous claims for temporary assistance. £1000 is therfore urgently required as an investment, in order to allow the operations of the charity to flow in their proper channel."—ED. PHARM. JOURN.

the founders, for whilst, at any rate, I honour them for their self-denial, I only differ concerning the wisdom of the use to which they applied their contributions.

The argument in the next clause is somewhat absurd; for if facts prove that the present system has proved favourable to this locality, they will equally show that my system would have answered just by that much the more favourably to other localities.

In the last paragraph of "Subscriber," he insinuates that I am attacking the present Fund, with the design of taking away the property of present recipients. By no mens is this the case; my aim is solely to prevent the continual increase of a fund already somewhat unwieldy.

In conclusion, I trust that with a little forbearance on both sides, much good will accrue to the Fund by the sharp discussions concerning its best use.

WALTER B. CLARK.

Leicester, April 19th, 1873.

Sir,—With others, my thoughts have been directed to the above question. I cannot agree with all Mr. Clark's views, or fully realize Mr. Sandford's reply. The impression given by Mr. Sandford is that all applicants have been elected or relieved.

If my memory serves me correctly, before the election takes place, the Council makes a selection and recommends four or five candidates they believe most worthy of relief. Two are elected, two or three are unsuccessful; perhaps these receive a small grant each. In addition, there are the other applicants from which the Council made their selection,—what becomes of them? Do they each receive a small grant? Are they one and all a sort of unrecognized annuitants of a second scale, waiting their turn to be elected to the recognized permanent list?

The permanent fund has now increased sufficiently for a more liberal course being adopted. Five or even six annuitants might be elected annually at an annuity of £40 instead of £30, and yet leave a surplus.

I do not think the permanent fund is sufficiently large to discontinue any further increase, but would like to see it increased for some years.

J. B. B. gives the annual subscriptions at £900 in round numbers; let 10 per cent. of this be added, with all life subscriptions, legacies, and donations, to the permanent fund. By this means more present help would be given to the necessitous; the permanent fund still increasing, and when sufficiently large, any surplus funds might go to form an orphanage or some other charitable institution.

I have been tempted more than once to withdraw my subscription from the Society and give it to one of the unsuccessful candidates, but have not done so, seeing that our management is economical.

The income, according to *J. B. B.*, arising from £13,000 is very small: other benevolent societies invest in ground rents, or place the money on mortgage and receive 5 per cent. on their capital. T. J. W. T.

TINCTURA AURANTII RECENTIS.

Sir,—With regard to Dr. Symes's remarks on this preparation at page 821 in your last issue, I beg to state that I did not claim to be the originator of the idea of making it with the fresh peel, but I first suggested its introduction into the Pharmacopœia (see PHARM. JOURN., Vol. XI., 2 ser., p. 604).

WM. MARTINDALE.

University College Hospital, April 23rd, 1873.

[*** Dr. Symes appears to have overlooked the fact that the discussion he criticized had exclusively reference to the introduction of certain preparations into the Pharmacopœia Appendix. Mr. Martindale's remarks on tinct. aurant. rec. are obviously to be understood in that sense, and not as indicating that this preparation is any novelty.—ED. PHARM. JOURN.]

PHARMACY IN IRELAND.

Sir,—Having been personally engaged in the practice of pharmacy in Ireland for several years back, I have read with considerable interest the communications of your correspondents Messrs. Alex. Anderson and J. T. Holmes on that subject; and as the statements set forth by the former gentleman are very much what I have found to be fact, I cannot refrain from writing a few lines, not only in support of those statements, but also by way of reply to Mr. Holmes's letter in your issue of the 19th instant. Not that I judge Mr. Anderson incompetent to reply on his own account, but writing as I do from the midst of Irish pharmacy, my facilities for acquiring a correct knowledge of matters must be greater than his can be, writing as he does from the opposite side of the channel. That a great amount of misunderstanding does exist in the minds of English chemists with regard to the position occupied by chemists and druggists in Ireland is a fact beyond dispute, and one which I have experienced over and over again while conversing with chemists on the sister island; but an explanation of it is not far to be looked for, if we do not descend to the puerile interpretations of Mr. Holmes about *social* position, but hold to the matter of their position as *pharmacists*, which is evidently that meant by Mr. Anderson. Now the chemist and druggist of Great Britain has until very recently been allowed to pursue the duties of his calling as dispenser of physicians' and surgeons' prescriptions without any legal interference, much in the same manner as any ordinary tradesman, and he seems to have formed the impression (on what grounds it is not my present business to show) that the present chemist and druggist in Ireland is now much in the same position that he himself was previous to the passing of the Pharmacy Act. Now this is quite a mistake, and it is here the misunderstanding exists, for the Irish Apothecaries' Company has been a legally-constituted body for many years, having received its first act of incorporation in 1791. It possesses the power to enforce examinations, and of course prohibits all persons from entering the practice of pharmacy (that is, to keep open shop) until they have first obtained a diploma of competency from their Society. Such being the case, we have two sets of pharmacists in Ireland, if, indeed, the second can justly be called by that name at all; the first, being the licentiates of the Apothecaries' Hall,* "are the only persons who can legally keep a shop for the compounding and vending of medicines, and are the only practitioners in Ireland who can recover for medicines prescribed by themselves or furnished on the prescriptions of others." The second is a class of persons who keep open shop for the wholesale or retail only of drugs, having no legal authority to dispense a single prescription. This is evidently the class referred to by Mr. Anderson, when he states that much misunderstanding exists in England regarding their position; and I believe it to be also the class referred to by Mr. Holmes, when he states that they are *fully* as competent as their English brethren. May I be allowed to ask from whence do they attain to this competency, since they have never been trained to the most important part of a pharmacist's duty, namely, the correct dispensing of a physician's prescription. Mr. Anderson states that the Irish apothecary is the Irish pharmacist proper. Such is fact, beyond doubt; and if Mr. Holmes will look into his extract given of Mr. Anderson's letter, he will find that the statement he makes and that made by Mr. Anderson are entirely different, and that such a class of pharmacists does exist as Mr. Anderson states, namely, licentiates of the Apothecaries' Hall, who, having recognized the fact that the practice of medicine and that of pharmacy ought to be vested in separate individuals, have accordingly given up the former (which they legally possess) and devoted themselves to the latter. I can assure Mr. Holmes is no fallacy, and am prepared to give him the names of at least four such within a circuit of half a mile from where I now write, and that in one of the largest and most flourishing towns in Ireland; and such will be found to be no petty shopkeepers.

I trust your readers will now comprehend a little more clearly the position of the chemist and druggist in Ireland (not the licentiate apothecary), when they will be able to judge for themselves with what amount of justice Mr. Holmes founds his claim that they, as a body, should, on a *nominal* examination, be admitted to the privileges that have been the just and legal right of the apothecary for upwards of eighty years, and to gain which he has had to expend no small amount of his time and money. Such would seem to us to be indeed "injustice to Ireland." And of one thing we feel confident, namely, that the Pharma-

* See 'Digest of History and Legal Rights of the Irish Apothecary,' published with list of members.

ceutical Society, as a body, will be no party to the bringing about of any such a state of matters; and let us believe that our Irish Apothecaries' Company will be alive to the interests of its members, as also its duty to the Irish public.

I leave Mr. Anderson to reply to those parts of Mr. Holmes's letter that more immediately concern himself.

Belfast, April 21st, 1873.

Pharmacy in Queensland.

Sir,—May I ask how it is that we do not see any advertisements for assistants for Queensland, although greatly needed, according to the statement made by Messrs. Burgoyne, Burbidges, and Co. in last Saturday's Pharmaceutical Journal. Doubtless what they say is correct, but perhaps it may be accounted for if the Queensland chemists give but small salaries, although competent men are required. I have been looking out for an engagement abroad, but do not intend taking one unless a liberal salary is given me.

An Assistant.

A few Remarks on the Brighton Early Closing Meeting.

Sir,—It seems from the opinions expressed at the above meeting, that the majority think something should be done to shorten the hours of labour. If the chemists would agree to issue circulars to their customers (and give them away over the counter also) stating that they would close at a certain hour, after which time necessary medicines would be supplied at the shop or side door at an extra charge, say 25 per cent., I think they would soon find a solution of the difficulty, and one that would repay them for the accommodation. I have seen it carried out with success. Of course the same hour would not do for all neighbourhoods.

Mr. Armitage thinks we should close earlier, and stated that where the assistants work late they have time allowed in the daytime; it may be so in Brighton, but he would find it very different in other towns.

Mr. Glaisyer's remarks may be true, but there are many assistants who do not feel satisfied with merely passing an examination; they wish to confirm their work by keeping up in the different branches of study, and if overworked, can hardly feel fit to apply themselves as they ought.

We are coming to the time when these things will have to be done, and it is only putting off the evil day. Assistants are getting scarce, and the coming ones will not like long hours after paying a lot of money to pass examinations, especially for the present wretchedly low remuneration. It is necessary that the employer and employed should agree on the matter, if they wish to work happily together; for, after all, the principal should remember his assistants are independent of him to a certain extent, and by combining might effect what they require, at great inconvenience to himself. I hope such a proceeding will never be necessary, and feel sure the majority of assistants have sense enough not to wish to try it without great pressure were put upon them. Chemists' assistants, like other animals, require fresh air, besides time for study, a thing many masters seem to forget. I hope to see the day when they will be treated as well as drapers' assistants, both in time and remuneration.

Every labourer is worthy of his hire; and I am sure no one works harder for or is more worthy of his pay than the chemist's assistant.

C—ford.

A Caution.

Sir,—Will you be good enough to caution your readers against the wiles of a designing lady. I do not refer to either of the three who are now disturbing the harmony of the Council, but to one who affects to know but little of English or English ways. She introduces herself as the representative of a French house which has recently brought out a new kind of night-light, called by them "Self-generating Oil Gas-lamp." It is made of metal resembling tinned iron, and in shape is like the half of an egg-shell, which has been cut in two transversely. A small piece of glass tubing passes through the bottom, and is fastened by means of resin. She knows the names of all the leading English chemists, and tells her intended victim that she has been particularly requested by one or two chemists, well known to himself, to call on him. If he takes the bait and purchases, he will find to his cost that the "new invention" is perfectly useless, and the existence of the firm a myth. She has evidently taken in the Pharmaceutical Journal, as also she has your obedient servant,

Silas Daniel.

Ramsgate, April 16th, 1873.

J. Jones.—Where the "hardness" of water results from the presence of carbonate of lime, the process known as "Clark's Process" for softening water has been successfully adopted. It consists in adding a suitable proportion of lime, which combines with the free carbonic acid which previously held the carbonate in solution, and is precipitated, together with the other carbonate of lime originally present.

"*Inquirer*."—No person who was not of full age and had not been, for a period of three years prior to the passing of the Pharmacy Act, actually engaged and employed in the dispensing and compounding of prescriptions as an assistant to a chemist and druggist, and who did not, before the 31st of December, 1868, forward to the Registrar appointed under the Act certificates to that effect in accordance with Schedule E, is entitled to pass the Modified examination.

Pharmaceutical Women.—Referring to Mr. H. J. Lutwyche's letter on the subject of pharmaceutical women, F. A. L. expresses an opinion that it is a most unfair and ungallant thrust at the ladies; and the advice he offers in the matter is, that one who seems to evince so much capability in the best manner of preparing for table the popular vegetable of which he speaks should no more let his talents as a *chef-de-cuisine* be thrown away in a pharmacy, but should give them full opportunity of expanding by taking up the profession of a man-cook, as by so doing he would not only benefit himself, but would make way for such ladies who prefer the operations of pharmacy to the boiling of vegetables. As regards the "many occurrences" which Mr. Lutwyche thinks make a pharmacy unfit for women, F. A. L. thinks they would not see greater horrors (?) in a chemist's shop than they would in their capacity as nurse or doctor.

[*** We think that the discussion of this question should now cease, at least as far as our "Correspondence" columns are concerned, until after the Annual Meeting.—Ed. Ph. Journ.]

W. White.—Professor Flückiger's new work may be obtained for 12*s*. through Messrs. Asher, of Bedford Street, Covent Garden.

"*Cruciferæ*."—(1) *Ballota nigra* (Labiatæ). (2) *Alliaria officinalis* (Cruciferæ).

"*Inquirer*."—The persons you mention would obtain tickets upon application.

"*Inquirer R*."—(1) The Minor is entirely a *vivâ voce* examination. (2) No.

C. N. C.—The provisions of the Adulteration Act, which are intended to prevent admixtures for increasing either the bulk or weight, constitute only one portion of the Act. It also applies to admixtures of anything injurious or poisonous, and this section of the Act would probably often apply to articles that are intentionally coloured.

C. G. B.—Probably Attfield's, Roscoe's, or Fownes's Manual of Chemistry would suit your purpose, either of which could be obtained through a respectable publisher.

The following journals have been received:—The 'British Medical Journal,' April 19; the 'Medical Times and Gazette,' April 19; the 'Lancet,' April 19; the 'London Medical Record,' April 16; 'Medical Press and Circular,' April 18; 'Nature,' April 19; 'Chemical News,' April 19; 'Gardener's Chronicle,' April 19; the 'Grocer,' April 19; 'Journal of the Society of Arts,' April 19; 'Grocery News,' April 19; 'Produce Markets Review,' April 19,

Communications, Letters, etc., have been received from Mr. L. V. Rees, Ms. T. Tipping, Mr. Clayton, Mr. J. R. Jackson, Mr. E. Keating, F. A. L., "A Constant Reader."

THE PHARMACY OF THE UNITED STATES' PHARMACOPŒIA.

BY WILLIAM MARTINDALE, F.C.S.,

Dispenser, and Teacher of Pharmacy to the University College Hospital.

The fifth decennial revision of the 'Pharmacopœia of the United States of America' is the work of a committee appointed by a Convention held for that purpose at Washington in May, 1870. As it has attracted some attention from pharmacists on this side of the Atlantic,—especially the Galenical, or more correctly the pharmaceutical, as distinct from the chemical portion of it,—a survey of this part of the work from our point of view may be of interest to British pharmacists generally.

As compared with the previous edition, the "scope of the work has been extended rather than abridged," without, as is stated, at the same time "losing sight of the conservative character necessarily pertaining to a National Pharmacopœia. Such a work must necessarily follow in the wake of advancing knowledge; it is no part of its mission to lead in the paths of discovery. It should gather up and hoard for use what has been determined to be positive improvement, without pandering to fashion or to doubtful novelties in pharmaceutical science." How far the committee has been guided by such an apprehension of its duties will remain to be seen; that it *has* been so guided is evident, for, although in the United States the different syrups of the phosphates are in such large demand, there is not an official process given for making one of them.

In this edition of the work 82 new preparations have been added, and 7 contained in former editions have been omitted from it. Four entirely new classes of preparations have been introduced into it. These are respectively—*chartæ* 2, *glycerita* 5, *suppositoria* 9, *succi* 2. In addition to these Galenical preparations, 22 fluid extracts, 5 solutions, 2 tinctures, 4 troches, and 6 ointments have been added to the previously existing classes. Towards the end of the preface there is a little self-laudation about the anxious thought and research the committee has given to the revision, and complaint is made, no doubt justly, about the meagreness of the details which characterized the majority of the reports submitted to it, as generally presenting criticism rather than amendment in the old processes, and in the cases of new medicines indicating but little their mode of preparation. Then follows this significant *finale*:—"The committee would recommend, in view of subsequent revision, that the reports of medical and pharmaceutical bodies which are interested in the perfection of our national standard, should be made full and explicit in details, and leave to the committee the task of verification and testing rather than that of original investigation." This ought to be a timely hint to those interested who are keeping in view the next complete revision of our 'British Pharmacopœia.'

Therapeutics are apparently more closely studied in America than with us; and, although the practice of medicine may be yet quite empirical, still, if truth be arrived at by such means, it is a great boon to suffering humanity. With regard to the pharmacy in the present work, this must speak for itself as much as possible in what I have to state.

The troy ounce—printed as one word, *troyounce*—and its submultiple, the grain, are the only weights used; the terms *pound*, *drachm*, and *scruple* are not used in the formulæ, these weights being replaced by their equivalents in troyounces or grains. The measures are the old *wine pint* (of sixteen fluidounces), and its submultiples the fluidounce, fluidrachm, and minim. The term *gallon* is not used in the formulæ. Their fluidounce is about one-twentieth greater in capacity than ours; it weighs, of distilled water at 60° F., 455·7 grains. The Fahrenheit thermometer is employed, and a *gentle heat* is defined at any temperature between 90° and 100°. We have the somewhat equivocal expression "a moderately warm place" employed, in which to macerate the fluid extracts; the temperature of this is not mentioned.

The following instructions are given for conducting *percolation* or the *process of displacement*,—they are nearly the same as those given in the previous edition. The process is defined as:—

"The kind of filtration . . . ." which "consists in subjecting a substance or substances, *in powder*,* contained in a vessel called a *percolator*, to the solvent action of successive portions of a menstruum, in such a manner that the liquid, as it traverses the powder in its descent to the recipient, shall become charged with the soluble portion of it, and pass from the percolator free from insoluble matter. When the process is successfully conducted, the first portion of the filtered liquid, or *percolate*, will be nearly saturated with the soluble constituents of the substance treated; and, if the quantity of menstruum be sufficient for its exhaustion, the last portion will be nearly destitute of colour, odour, and taste.

"The percolator should be either conical, or nearly cylindrical with a conical termination at the smaller end, and provided internally with a porous or colander-like partition or diaphragm, resting transversely immediately above its neck, for the support of the powder. Ordinary glass funnels, varying in capacity from one to eight pints, are to be preferred for most of the operations requiring percolation in this Pharmacopœia; but percolators may also be made of earthenware or tinned iron, especially of the latter material when required of large size. Tinned iron, however, should not be used when the liquid acts chemically on the material. In the several formulas in which percolators are used, their form and material will always be designated when there is a preference in these respects. In cases in which these variations of the instrument are indifferent, the term percolator simply will be employed. When a funnel is used, a circular piece of muslin or of lint, pressed into the neck by means of a cork with notched sides, forms a good diaphragm; but in all cases a similar piece of muslin, moistened slightly with the menstruum, should be interposed between the diaphragm and the powder, to prevent the passage of the fine particles of the latter. The substance to be subjected to percolation, after having been reduced by sifting to a uniform powder of the fineness indicated in the formula, is to be put into a basin with the specified quantity of the menstruum, and the two rubbed together until the powder is uniformly moistened. A portion of the powder is now to be carefully placed upon the diaphragm, prepared as above directed, and pressed gently until the muslin, resting against the sides of the percolator just above the neck, is covered with a uniform layer. The remainder of the powder is then to be transferred to the percolator, and compressed evenly and firmly, and the levelled surface covered with a circular piece of moistened muslin or paper, so that the liquid poured upon it may penetrate equally, and not disarrange the powder. The percolator being now properly supported, with its neck in a bottle previously marked for the quantity or quantities of liquid to be percolated, the menstruum is to be poured on the muslin until the space above is nearly filled; and

* These italics are mine.

a layer of it must be constantly maintained above the powder, so as to prevent the access of air to its interstices, until all has been added, or until the requisite quantity of percolate has been obtained. If the fineness of the powder and its arrangement in the percolator have been properly attended to, the percolate will pass out, by drops, with greater or less rapidity, according to the size of the percolator; but if, by reason of accidental imperfection in the powder, or in the packing, the liquid pass more rapidly than this, the neck of the percolator should be obstructed by means of a cork until the requisite slowness has been attained. When the dregs of a tincture are to be subjected to percolation, after maceration with all the menstruum, the liquid portion should be drained off, the solid portion packed in a percolator as before described, and the liquid gradually poured on until all has passed the surface, when, immediately, a sufficient quantity of the original menstruum should be poured on to displace the absorbed liquid, until the prescribed quantity of the tincture has been obtained.

"*Fineness of Powders.*—As different degrees of fineness are necessary in powders, according to their nature and mode of treatment, the special degree required is designated in the several formulas.

"For this purpose the terms very fine, fine, moderately fine, moderately coarse, and coarse are used; the powder passed through a sieve of eighty or more meshes to the linear inch being designated as *very fine*; through one of sixty meshes, *fine*; through one of fifty meshes, *moderately fine*; through one of forty meshes, *moderately coarse*; and through one of twenty meshes, *coarse*."

Substances that are likely to swell much after packing, although they may have been moistened previously with the menstruum, are generally ordered to be packed in a conical percolator, *e. g.* four troy-ounces of bitter orange peel in moderately fine powder, moistened with two fluid ounces of diluted alcohol, are directed to be packed in a *conical* percolator, and diluted alcohol *q. s.* added, that the required product, 32 fluid ounces, may be obtained. A *cylindrical* percolator is ordered to be used for the preparation of tincture of aconite, the powdered root of which is not liable to swell under the influence of alcohol.

Mr. Ince once cynically remarked that French pharmacy, judged by the Codex, might be summed up in one word—*sugar;* American pharmacy might be summed up in—*percolation.* The process undoubtedly has many advantages over simple maceration, but the committee rides its hobby too far when it directs *bitter orange peel* to be used in the state of "*moderately fine powder*" to enable it to be percolated in making the tincture. What aroma or flavour,—for which it is generally used,—such a tincture will possess our readers may judge for themselves. The process of percolation which has been described above can be conducted with cleanliness and little chance of contamination, yet with doubtful economy. But the principal objection, as I hope to show more fully hereafter, is the difficulty of getting the drugs into a sufficiently fine state of powder without, in many cases, their undergoing great deterioration, and also much likelihood of contamination in the process of powdering. The Committee of Revision having come to the conclusion that the percolation of a drug in any state, except in the finest powder possible for it to be percolated, does not exhaust it, has therefore ordered the drugs to be used in that condition only. But as the powdering of many substances will necessarily have to be done on a large scale, such processes will be the means of throwing the preparation of these medicines into the hands of manufacturers, who will be distinct from retailers and dispensers of medicines. The same may be said of a great number of the Galenical preparations, the fluid extracts more particularly. This, although in many cases the division of labour may tend to perfection, will not, I think, be in the interest of the pharmacist and the public. The pharmacist likes a home-made preparation on which he will stake his professional and business integrity; the public also will suffer, for, owing to the competition in trade, and there being no tests easily devisable for the strength and purity of such preparations, the public, through the retail pharmacist, will often be supplied with what is comparatively worthless.

The principal solvents employed in making the preparations are:—

1. *Water.*—"Natural water in the purest attainable state." Excepting in rare cases where it is absolutely necessary to have distilled water, common water is directed to be used for all Galenical preparations, even for making the decoctions, infusions, tinctures, extract, and fluid extract of the cinchonas, where one would have thought the use of distilled water was clearly indicated.

2. *Distilled Water.*—This is directed to be used in making most of the chemical preparations.

3. *Alcohol.*—"Spirit of the specific gravity 0·835,"—that is, absolute alcohol with 15 per cent. of water; it is 57·5, O. P., and is therefore a little stronger than our *rectified spirit.*

4. *Diluted Alcohol.*—"Alcohol mixed with an equal measure of distilled water," sp. gr. 0·941. This is absolute alcohol with 61 per cent. of water. It is weaker than our *proof spirit* which contains 51 per cent. of water.

5. *Stronger Alcohol.*—"Spirit of the specific gravity 0·817,"—absolute alcohol with 8 per cent. of water.

6. *Glycerin.* Sp. gr. 1·25.—This is the same as our official glycerine. It is largely used as a solvent, mixed with alcohol and water in various proportions, in making the fluid extracts and a few other preparations; and as much depends upon its purity, the following qualitative tests are given:—"When mixed with twice its bulk of cold sulphuric acid it does not produce a brown colour. When diluted with water it affords no precipitate with hydrosulphate of ammonium, ferrocyanide of potassium, nitrate of barium, oxalate of ammonium, or nitrate of silver."

7. *Acetic Acid.* Sp. gr. 1·047.—This contains 36 per cent. of the monohydrated acid, and is slightly stronger than our *acidum aceticum*, which contains 33 per cent. only. In making the *aceti*, diluted acetic acid, 1 to 7 of distilled water is employed; but *distilled vinegar*, it is stated, may be substituted for it in making these preparations.

8. *Sherry Wine.*—This is used as a solvent in all the *vini*, but no definition is given of it or of *Port Wine*, which is also official.

These, or mixtures of them, are the solvents generally used: their strength should be borne in mind in making any comparative investigations as to the merits of their preparations in comparison with our own. The new favourite, which, like several of the articles in the materia medica list, is a "peculiar"*

* It is difficult to conceive how the term "peculiar" is at all descriptive of the substances to which it is applied. Camphor is said to be "a *peculiar* concrete substance;" amylic alcohol "a *peculiar* alcohol;" guaiac resin "a *peculiar* resin;" yeast "a *peculiar* insoluble product of fermentation;" musk "a *peculiar* concrete secretion;" creasote "a *peculiar* substance;" and castor, spermaceti, and yellow wax are all "*peculiar.*"

one, has been referred to. It is a mixture of alcohol, glycerin, and water, generally in the proportions of 8 parts fluid of alcohol, 3 of glycerin, and 5 of water.

(To be continued.)

RECENT PROGRESS IN WEATHER KNOWLEDGE.*

BY ROBERT H. SCOTT, F.R.S.,

Director of the Meteorological Office.

(*Concluded from p.* 849.)

A storm may be produced by an increase of pressure as well as by a decrease, and some most destructive storms—most destructive because they hardly give any warning of their approach—are caused by an increase of pressure on the eastern shores of the North Sea, while a depression is advancing over these islands. The storm of February 6, 1870, which levelled the harbour works at Wick, belonged to this class. Their direction is south-easterly.

Almost all our storms are related to barometrical depressions, and not to elevations. The reason of this has yet to be explained by mathematicians. If, therefore, we knew about an advancing depression, the shape (including gradients in all directions), direction, and rate of motion, and whether the disturbance was increasing or diminishing in intensity, we should be able to form a fair judgment as to what parts of the coast would be most likely to feel a gale, and from what points of the compass. There is hardly one of these particulars of which we can gain a sufficient knowledge until the storm is well upon us, so that the issue of warnings to our exposed western and northern coasts will ever be a matter of great difficulty and uncertainty.

As regards the direction of motion of storms, we have some progress in knowledge to report. Professor Mohn, in his Storm Atlas, has assigned for a few storms the direction and rate of advance, and has shown how both these elements are modified as the storm moves across Scandinavia into Russia. An English meteorologist, Mr. Ley, has also paid attention to the subject; and in his recent work, 'The Laws of the Winds in Western Europe,' has given charts of the mean paths of depressions for certain months of the year.

Both these investigators refer the direction of motion to the distribution and condensation of vapour in the atmosphere; and Mr. Ley maintains that the depression itself is generated by excessive rainfall, and that its advance is due to the same cause. We are hardly prepared to admit the truth of this statement in its entirety; the area covered by our daily weather reports is too small for us to be able to test the matter thoroughly, and but few of the foreign stations give either vapour tension or rainfall. Moreover, the magnitude of the depressions affords an argument against their being simply due to the condensation of vapour; for on November 22, 1869, barometrical readings were reduced to the extent of nearly an inch from what they had been on the 21st, over an area of about 200,000 square miles. To take a recent instance, on the 20th of January, the deficit of atmospherical pressure amounted to about $\frac{1}{20}$th of its total amount over the United Kingdom, the readings ranging between 28·0 and 28·5, instead of between 29·5 and 30·0.

We know that the direction of motion is ruled very much by the position of the areas of high pressure, which are of considerable superficial extent, and, as a rule, are not subject to much motion of translation. The depressions appear to skirt round these areas of high pressure, and not to advance into them. As an illustration of the effects of an area of high pressure on our weather, it may be remarked that one of the worst signs for us of the danger of a south-westerly gale is to find the barometer over the south of France high and rising.

The simplest idea of the general motion of these areas of depression is, that they follow each other in the main stream of air, which sweeps round the permanent area of low pressure near Iceland, much in the same way as eddies in a running stream. Many of the depressions appear to be modified in their character by the contour of the land. More than once a storm which has apparently struck the land about Valencia, travelled northwards until it found an opening in the coast-line, such as Donegal Bay, and then crossed to the Irish Sea, or else skirted round Ireland and crossed the Lowlands of Scotland.

In some cases which we are as yet quite unable to anticipate the disturbance changes the direction of its motion entirely, and returns for a time on its former path. This was in a marked way the case with the storm of April 21, 1872, which came down over Ireland, between Valencia and Armagh, swept round along the north coast of France up to Havre, recoiled and passed north of Portland and Falmouth to the south of Ireland, and eventually travelled out to sea across Ireland, nearly in the direction along which it had arrived. Such a storm as this sets us quite astray, and makes our warnings quite wrong. Another circumstance which complicates the study of storms is, that depressions increase or decrease in their intensity, and of the rate of this change we are quite ignorant.

Of storms which are mainly due to a rise of pressure, one, in February, 1871, may be selected for an illustration. This depression advanced from the westward, but hardly assumed the character of a storm until the morning of the 10th of February, when its centre lay over the north of England. Now, between the 9th and 10th the barometer over the North Sea had risen briskly, so that when the new depression came it found the conditions favourable to high gradients and south-east gales on its eastern side. Its appearance was quite unexpected; for even at 6 p.m. on the 9th there were little signs of it, and, moreover, its force at 8 a.m. on the 10th was moderate compared with its fury later in the day. The centre finally passed over London, and the whole phenomenon passed on to the Continent, where it is untraceable, in consequence of the absence of reports, owing to the war.

Easterly gales are, on the whole, difficult to foresee; they come with little warning; and this is not solely attributable to the deficiency of information from Eastern Europe, for since we have received warnings from that region, we have hardly had an instance of a warning which preceded the gale. In most instances the easterly storm was on the north side of a depression travelling eastwards, and began first at our western stations. Such was the storm of Sunday, Feb. 2, which set in as an east gale at Pembroke, and subsequently extended to stations lying to the eastward. Some of these easterly storms do apparently advance from the eastward, and to this class belongs the fearful storm of Nov. 12-13, in the Baltic. The ravages of this storm were mainly caused by the fact, that a continuance of westerly winds had dammed back the water at the Skager Rack, and then, when the wind chopped round to east, the narrow channels between the Danish Islands could not discharge the water quickly enough. The unavoidable result was an inundation.

What are now the signs of a storm, and when do we issue warnings? We are perforce driven to use the barometer mainly, as it is an instrument more closely related to the direction and force of the wind than the thermometer, and one whose daily range is trifling; but if we trust it alone, we shall hardly ever be certain about a storm, and the thermometer will not help us much. We have other signs, such as shifts in the direction of the wind, increase of sea, and all the manifold local indications given by the character of clouds and the transparency, etc., of the air, invaluable as collateral information, but requiring a practised eye to discern them.

If it were possible to place the meteorological office, with its present telegraphic facilities, on the west coast of Ireland, we might fairly hope to foretell five-sixths of the storms which strike us. On two separate occasions the lecturer, being in that district knew perfectly well from the look of the sky that a storm was coming some hours

* Abstract of a Lecture delivered at the Royal Institution of Great Britain, Friday, February 14th, 1873.

before the barometer began to fall, and consequently long before the office in London could issue warnings.

Some storms do not give even so much warning. That of Feb. 10, 1871, is one instance, and that of Nov. 22, 1872, when the 'Royal Adelaide' was lost on Chesil Bank, is a recent case. On that day at noon the telegraphic reports showed an apparent improvement in the weather on that of the previous day, so the drums on our south coast were lowered. At night the gale came, and of course the comments on the office were not favourable. But one of our best sea observers, Captain Donkin, who was out in that gale, being asked whether he had anticipated the storm from the look of the sky, answered :—

"With respect to the weather on the 22nd November, I may say that at noon I was standing in towards the land, between Falmouth and Plymouth, and a pilot cutter came alongside, and if I had had the least apprehension of such a gale as followed being near at hand, I should have taken a pilot and gone into Plymouth. The appearance of the weather at the time was fine, though the glass was falling, though not low at the time for S.W. wind and unsettled weather."

This will show that we cannot foretell all storms by means of telegraphy. We are beginning to recognize other signs of disturbance of the atmosphere generally as indications of a storm, but these can hardly as yet be considered as scientifically exact. Among these may be mentioned the circumstance which Professor Mohn has noticed, that warning of south-westerly gales for the coast of Norway is given by a rise of temperature at Dovre at a height of 2100 feet above the sea. In these islands we have little prospect of availing ourselves of this source of information, as our telegraphic stations are all at low levels.

Another principle is that pointed out by Mr. Meldrum, that storms are generated between two currents of air flowing in opposite directions, the easterly winds being on the polar side of the westerly.

It may seem a comparatively simple matter to say whether or not a warning was issued in time ; but it is really not so easy a matter, as storms are exceedingly local, so that two observers situated close to each other may differ seriously as to whether there has been a gale or not. Every effort has been made to keep a check on the correctness of warnings for the last three years ; that is, on whether or not intelligence of gales has been given in time to be of practical service to seamen. The result has been for the years 1870–71, that 46 per cent. of the warnings have been followed by gales, and about 20 per cent. in addition have been justified by the occurrence of strong winds after they were hoisted, showing a total percentage of successful warnings of nearly 70 per cent. For the first six months of 1872 the percentage of gales for which warnings were issued in time has risen above 60, and the total percentage of successes to nearly 80, owing to the postal telegraphic arrangements having gradually become more perfect, and the exchange of information with the Continent being now more regular.

THE PRESENCE OF ALCOHOL AND ACETIC ACID IN MILK.*

BY M. A. BÉCHAMP.

The author on a former occasion attempted to show that milk necessarily contains microzymes, which, by a purely physiological action, produce the agents of spontaneous coagulation. From the known action of microzymes in general, he concluded that besides lactic acid, coagulated milk must also contain alcohol and acetic acid ; but if so, why should not milk contain them physiologically? The present note has for its object to show that cow's milk does, at the moment of being drawn from the cow, contain both these bodies ; and, subsidiarily, that, the same cause operating before and after coagulation, alcohol and acetic acid ought to augment in the coagulated milk.

Fresh milk was added to a slight excess of oxalic acid, and immediately submitted to distillation in a chloride of calcium bath, the temperature of which was maintained at 120° C. Nineteen twentieths of the milk were distilled; the clear liquid had always an acid reaction, and to it was added excess of pure carbonate of soda. Little more than one-tenth was then collected, which was concentrated by distillation and rectification over carbonate of potash. In the case of coagulated milk it was thrown upon a filter and the whey collected and distilled as above.

A pretty considerable quantity of fresh milk was operated upon to obtain a measurable quantity of alcohol. This was distinguished (1) by burning with the characteristic flame; (2) by its oxidation products when treated with a mixture of bichromate of potash and sulphuric acid ; (3) by the formation of crystallized acetate of soda ; (4) by the formation of acetate of silver.

Acetic acid was obtained from the sodic residues from which the alcohol had been separated. It was distinguished principally by the formation of acetate of soda, which salt crystallized under its usual form down to the last drop. No trace of any of the acids superior to acetic acid was ever found.

The same phenomena have been met with in the alcohol and acetic acid of milk coagulated spontaneously while sheltered from the air. Butyric acid, or other volatile acid homologues, which are products of the decomposition of albuminous matters, were sought for, but none were found ; crystals of acetate of soda being formed down to the last drop.

This being the case, it was an interesting point to ascertain whether alcohol and the volatile acids are present in milk coagulated by lamb's rennet. M. Béchamp found alcohol, acetic acid, and a little caproic acid.

In order to decide whether the results permitted of generalization, alcohol and acetic acid were sought for in ass's milk. The animal was milked close to the laboratory and the milk distilled. Like that from the cow it was found to contain alcohol and acetic acid. M. Béchamp, therefore, ventures to assert that these bodies exist in the milk of all herbivorous animals, but that of carnivorous animals requires investigation.

Some estimates were made of the amount of alcohol and acetic acid present in fresh milk, in order to compare them with the quantities present in coagulated milk. The alcohol was indirectly determined by the acetic acid yielded by its oxidation, and this acid and that already formed in the milk were determined by a titrated solution of caustic soda. The proportions of alcohol and acid were found to vary very considerably.

The author does not think that the alcohol and acetic acid are, in the same sense as other chemical elements of milk, products of the milk-secreting organism ; he is rather of opinion that they are formed in some way in the mammary gland, by the action of microzymes upon the glycogenous matters of the milk, the evidence being that they exist only in small and variable quantities, which are increased naturally outside the udder, without the intervention of organic ferment other than microzymes.

The author considers that these results accord with the generalizations he has drawn from former investigations. The microzymes of every origin that he has studied possess the same power of forming alcohol and acetic acid, not only from glycogenous matters, but also from substances which are not convertible into sugar, such as tartaric, citric, muric, and lactic acids. These same microzymes engender alcohol and acetic acid in ripening fruits, producing it in greater abundance if, by bruising, the cells which contain the microzymes are broken, and they come into more immediate contact with the juice. M. Béchamp also considers that the theory of Liebig as to the alterability of albuminoid matters in the phenomenon of fermentation is a great chemical and physiological error. He says that in the fermentation of eggs and the souring of milk the albuminoid matters remain intact, and preserve all their essential properties.

The Pharmaceutical Journal.

SATURDAY, MAY 3, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE THIRTY-SECOND ANNIVERSARY OF THE PHARMACEUTICAL SOCIETY.

ON the first page of this week's Journal will be found the official notices in reference to the Anniversary Meetings of the Pharmaceutical Society for 1873. The Annual General Meeting of the members of the Society is to be held on Wednesday, May 21, at eleven in the forenoon, when the Report of the Council for the year will come under the consideration of the meeting. Until it is published, speculation as to what topics for discussion may be found in it would be useless, though probably the Council will see fit to follow the precedent of last year by ordering a copy of the Report to be sent to each member previous to the Annual Meeting. One subject, however, will doubtless appear in it,—the admission of women as members of the Society,—and this will be certainly one of the subjects discussed at the Annual Meeting, since Mr. HAMPSON has given a notice of motion that raises the whole question.

Should the Bye-laws which have now been under consideration at two meetings of the Council be confirmed at its meeting next week, a Special General Meeting of the members will have to be held at the close of the Annual Meeting, for the purpose of considering, and, if thought proper, confirming and approving such new or altered Bye-laws as may be submitted by the Council.

The Conversazione will, by the kind permission of the Lords of the Committee of Council on Education, again be held in the South Kensington Museum, and it is, as usual, to take place on the evening of the same day as the Annual Meeting. Tickets of admission may be obtained by all Members, Associates, and Apprentices or Students of the Society; and in order to obviate unnecessary trouble, a ticket has been sent to each member residing in London. Any other person connected with the Society, or Registered Chemist and Druggist, will have a ticket forwarded to him upon application to the Secretary at 17, Bloomsbury Square.

With regard to the Annual Dinner in connection with the Anniversary, which is to take place at the Crystal Palace on the evening of the previous day, we are requested to say that the tickets are now ready, and may be obtained from the Honorary Secretaries or any of the Stewards. A list of these gentlemen was printed in these columns last week, and is repeated in the advertising section of the present issue, with the addition of a few names which were then inadvertently omitted and a list of the Committee.

THE ADULTERATION ACT IN RELATION TO CHEMISTS AND DRUGGISTS.

THE action now being taken throughout the country under the Adulteration Act has given rise to a number of questions relating to the business of the chemist and druggist; and we have received numerous inquiries from provincial correspondents as to the scope and operation of the Act. A letter of this kind will be found in the "Correspondence" columns of the present number, and we must confess that it raises a question of some difficulty. So far as the wording of the Adulteration Act goes it might perhaps be maintained that it does not apply to cases such as that mentioned by our correspondent any more than to cases of substitution, which have been supposed to be placed entirely outside the provisions of the Act by the definition therein given of adulteration as being either the mixture with any articles of food or drink or any drug, of any injurious or poisonous ingredient or material, or of any other substance, with intent fraudulently to increase their weight or bulk. But though this may be a technical defect in the framing of the Act, we are disposed to consider that the sale of articles sophisticated by substitution or of inferior strength, would certainly be contrary to the spirit as well as the intention of the Act.

It may, however, be pointed out that the Pharmacy Act renders it a punishable offence for any person to "compound any medicines of the British Pharmacopœia except according to the formularies of the said Pharmacopœia;" and although the term "laudanum" is not in fact a pharmacopœia term, it is still so widely understood as indicating the tincture of opium of the Pharmacopœia that we should feel much doubt as to the safety as well as the propriety of deviating from the formula therein prescribed.

EXTRA-OFFICIAL PHARMACEUTICAL HONOURS.

WE quote the following extra-official utterance from a Staffordshire newspaper which has been kindly forwarded to us by a correspondent:—

"Mr. ——, son of Mr. ——, of ——, passed on Tuesday the examinations of the Pharmaceutical Society of Great Britain, gaining two certificates of merit and highly complimented in chemistry."

To those familiar with the conditions of the examinations it will be evident that certificates of merit are not granted as stated, but the name and address that we suppress appear a considerable way down in a recent Minor examination list. We quite agree with our correspondent that such an "impudent fabrication" deserves exposure.

FROM the *Neues Repertorium für Pharmacie* we learn the twenty-fifth anniversary of the connection of Dr. FRESENIUS with the Chemical Institute and Laboratory at Wiesbaden is to be celebrated in the early part of May by a festival, at which many of his former students will attend. An influential committee has been formed to make suitable arrangements, at the head of which is Professor NEUBAUER, for many years a colleague of Dr. FRESENIUS.

Transactions of the Pharmaceutical Society.

PRELIMINARY EXAMINATION.

The following is the result of the Preliminary examination, held on the 7th April:—

England and Wales.

Three hundred and sixty-one candidates presented themselves for examination, of whom *one hundred and seventy-four* failed. The following *one hundred and eighty-seven* passed, and have been duly registered as Apprentices or Students:—

Equal.
Bradley, Joseph Bourne .... Dudley
Wood, Charles Henry .... London

Playford, Robert Henry .... Horsham

Clarabut, Frank Stone .... Folkestone

Blythe, William Graves .... Goole

Thornton, John .... Aldridge

Equal.
Fowler, Edwin .... London
Ottey, Thomas .... Wycombe

Rogers, Oliver .... Upper Norwood

Laxon, Matthew .... Wisbeach

Roughton, William .... Loughborough

Equal.
Ballard, John Spencer .... Hereford
Dingle, James Hender .... Penzance

Equal.
Cæsar, Julius .... Cosham
Mainwaring, George William ... Dudley

Ronca, Alfred .... Upper Norwood

Equal.
Baker, William Brain .... Banbury
Loan, James .... Oxford

Dobson, George .... Kingswood

Equal.
Morgan, Thomas William ...... Hereford
Vinson, William .... Lewes

Tutton, James .... Northampton

Equal.
Thomas, James .... Rhyl
York, Thomas .... Cambridge

Equal.
Curtis, Thomas .... Holbeach
Furness, Thomas .... Chesterfield
Hibbins, Thomas Henry .... Stamford

Equal.
Finney, Arthur Cook .... Gainsborough
Wakefield, John .... Birmingham

Sharp, John .... Sunderland

Equal.
Chifney, George Pearmain ...... Mildenhall
Cresswell, Henry Peter .... London

Equal.
Kerry, Ebenezer .... Hastings
Thomas, John .... Carmarthen
Wallace, George William .... Sunderland

Equal.
Hall, James George .... Norwich
Wilkinson-Newsholme, Geo. T. Huddersfield
Sutcliffe, George Hargreaves ... Bacup
Wellburn, John .... Scarborough

Equal.
Worsley-Benison, Frederic Hy. Chepstow
Heading, Herbert Henry .... Ely
Hurst, Charles Herbert .... Littleborough

Equal.
Smithson, Thomas Henry .... Bradford (Yorks.)
Williams, David .... Swansea

Equal.
Jackson, William Hodgkinson .. Crediton
Leslie, John Morrison .... (Port Elizabeth)

Equal.
Hind, Thomas .... Lincoln
Shilton, Stephen .... Cockermouth
Summerhill, Thomas Henry ... Wolverhampton

Dix, Frederick .... Lynn

Equal.
Davies, Owen .... Llanelly
Lapthorn, George .... Taunton
Read, John Henry .... London
Sykes, Henry .... Huddersfield

Williams, Robert Edwin .... Cheltenham

Equal.
Hewat James C. .... Chertsey
Oldham, Frank .... Wisbeach

Holloway, Edwin Arthur .... Leominster

Equal.
Bolton, Joseph Hook .... London
Phillpot, Arthur .... Plymouth

Harris, George .... Moseley

Equal.
Pritchard, Richard .... Llandovery
Rickinson, Valentine .... West Hartlepool
Woodland, John .... Rochester

Equal.
Davies, Thomas .... Liverpool
Tunley, William Henry .... Guernsey

Smith, William Octavius .... Gosport

Equal.
Davies, Hugh .... Liverpool
Merrikin, William .... Boston
Howell, Edmund .... Oxford

Equal.
Gain, Edmund .... Southsea
McConnal, Allan .... Dudley
Wright, Robert .... South Shields

Equal.
Brewer, John .... Blackburn
Cockcroft, Alfred .... Richmond (Yorks)
Mitten, Flora .... Hurstpierpoint
Smith, Charles Albert .... Gosport
Soutter, David .... Grimsby
Thompson, John Henry .... Southampton

Lowdell, Frederic .... Brighton

Equal.
Cumber, Henry .... Guernsey
Dove, George .... Sherburn
Mears, Henry .... Bridgwater
Mitchell, Charles Archibald ... London
Snoxell, Samuel .... Guildford

Greathed, William Thomas W. Doncaster

Equal.
Blackwell, Josiah .... St. Austell
Crook, Herbert .... Gravesend
Gilkes, William Henry .... Banbury
Gregson, James Kenyon .... Blackburn
Story, George Arthur .... Bourne

Equal.
Bulcock, John Wardle .... Clitheroe
Cooley, Walter Bromley .... Wolverhampton
Hartill, Ambrose .... Lower Gornal
Mays, Robert Man .... South Shields
Wilson, Henry .... Rhyl

Barrat, Reuben .... Kingston-on-Thames

Equal.
Dobson, George Turner .... Holsworthy
Elborne, William .... London
Garner, Thomas .... Boston
Rumsey, James Window .... Crickhowell
Sibthorp, Stephen Shurmer ..... Liverpool
Smith, William .... Grantham
Thompson, Thomas .... Bedworth

Equal.
Lee, William Walter .... Wandsworth
Williams, John .... Oswestry

Equal.
Ashmead, John Stubbings ...... Clifton
Wilson, John Thomas .... London

Equal.
Collis, William Blow .... Arundel
Golding, Frederick James ...... Bath
Lovely, Ernest .... Shepherd's Bush
Smith, Frederick Adolphus ...... Macclesfield

Equal.
Boyden, John Augustus .... Wisbeach
Craske, Thomas Augustus ...... Tunbridge Wells

Equal.
Allatt, Arthur Edward .... Bradford (Yorks.)
Elliot, Joseph .... York
Heynes, William Henry .... Woodstock
Hornby, Henry G. .... Leeds

Everard, Horace .... Leicester

Equal.
Berrill, Robert Andrew .... Doncaster
Billing, John Henry .... Liverpool
Coles, Joseph .... Rye
Eddy, John Miller .... Plymouth
Hinds, William .... Coventry
Isaac, John Percy .... Sevenoaks
Phillips, John James .... Hyde
Sampson, George .... Chesterfield

Equal.
Brisley, George .... Margate
Gleadowe, John Webster .... Boston
Thomason, Thomas Watson ... Birmingham
Wild, George Frederick .... Hyde

Smith, Henry .... Holbeach

Fawn, Frederick Charles .... Bristol

Equal.
Bennett, Isaac Booth .... Hyde
Clarke, George .... Newport, Mon.
Foster, James Edward .... Bridgwater
Hayes, James Roberts .... Lynn

The questions for examination were as follows:—

Time allowed: Three Hours.

LATIN.

Translate into English two at least of the Latin sentences and answer the questions:—

1. Ariovistus ad postulata Cæsaris pauca respondit; de suis virtutibus multa prædicavit; transisse Rhenum sese, non suâ sponte, sed rogatum et arcessitum a Gallis; non sine magnâ spe, magnisque præmiis, domum propinquosque reliquisse.

2. Ita prœlium restitutum est, atque omnes hostes tergaverunt, neque priùs fugere destiterunt, quàm ad flumen Rhenum millia passuum ex eo loco circiter quinquaginta pervenerint. Ibi perpauci, aut viribus confisi, transnatare contenderunt, aut lintribus inventis, sibi salutem repererunt.

3. Coque Succum per sextam horæ partem et cola. Huic adjice Saccharum et liqua. Denique ubi Syrupus refrixerit, Spiritum admisce.

4. Capiat cochlearia duo magna statim; iterentur post horam, si tussis accreverit.

5. How many declensions of Latin substantives are there, and how are they known? Give examples.

6. To what questions do the Nominative, Genitive, and Accusative Cases severally answer? Give one example in Latin for each.

7. Decline the adjective *æger*.

8. Give the endings, singular and plural, of the Present Tense, Indicative Mood, First and Fourth Conjugation, Passive Voice.

9. Parse "Natus est Augustus consulibus Cicerone et Antonio.

ARITHMETIC.

10. A gentleman dying left £45,247 between two daughters; the younger was to have £15,000, £1500, and twice £15, what was the elder sister's fortune?

11. If the salary of an officer be £48 per annum, what should he receive for 232 days?

12. If £100 gain £5 interest in 12 months, what sum will gain £20 in 8 months?

13. Multiply $430\frac{6}{10}$ by $18\frac{2}{7}$.

14. Divide 715 by ·3075.

ENGLISH.

15. In the structure of words what is a prefix? Give examples of words having Latin prefixes.

16. Give the Past Tense and Past or Complete Participle of the following Irregular Verbs:—*Eat, chide, drive, lead, see, shake, slink, spin, ride, rive.*

17. What is meant by the *root* of a word? and illustrate by two examples.

18. What form of expression besides the Nominative Case may be the subject?

19. What is the result of two negatives coming together? and correct the following:—Nobody did me no good.

20. Write from fifteen to twenty-five lines upon *one* only of the following subjects:—

A. Good Writing.
B. Arithmetic.
C. Pride.

ERRATUM.

Page 852, col. 2, line 38, *instead of* "Neale, William," *read* "Neale, John."

BENEVOLENT FUND.

SUBSCRIPTIONS RECEIVED DURING APRIL, 1873.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The Seventh General Meeting of the session was held at the Museum and Library, Bristol, on Friday, April 4th.

The President, Mr. Townsend, occupied the chair, and briefly introduced Mr. Carteighe, of London, who delivered a lecture, of which the following is an abstract:—

On the Diffusion and Occlusion of Gases.

BY MICHAEL CARTEIGHE, F.C.S.

Dalton's experiments on the diffusion of gases, published in 1801 and 1803, were explained and referred to by way of introduction to Graham's more exhaustive researches on the subject.

The experiments of the latter physicist and chemist on free diffusion, diffusion through porous septa, *e. g.* plaster, graphite, etc., were shown, and the methods demonstrated by which the velocity of diffusion and diffusion volumes of the more important gases were determined.

The now well-known law, viz. that the volume of a gas diffused in a given time is in an inverse ratio to the square root of its specific gravity, *i. e.* the lighter the gas the greater its diffusibility, was explained, and the experimental data upon which it is founded exhibited by diagrams. The lecturer then defined atmolysis or air analysis, and showed the experiment by means of which the volume of oxygen in atmospheric air can be increased from 21 to 25 per cent. by the passage of a slow current of air through a series of tobacco pipe stems, owing to the superior diffusibility of the nitrogen. Similarly the more diffusible hydrogen of electrolytic gas can be in great part separated from the less diffusible oxygen.

The nature of diffusion and its bearing upon the constitution of matter were explained in the following terms:—

The pores of artificial graphite appear to be so minute, that a gas in mass cannot penetrate the plate at all. Molecules only can pass; and they may be supposed to pass wholly unimpeded by friction, for the smallest pores that can be imagined to exist in the graphite must be tunnels in magnitude to the ultimate atoms of a gaseous body. The sole motive agency appears to be that *intestine* movement of molecules which is now generally recognized as an essential property of the gaseous condition of matter.

According to the physical hypothesis now generally received, a gas is represented as consisting of solid and perfectly elastic spherical particles or atoms, which move in all directions and are animated with different degrees of velocity in different gases. Confined in a vessel, the moving particles are constantly impinging against its sides and occasionally against each other, and this contact takes place without any loss of motion, owing to the perfect elasticity of the particles. If the containing vessel be porous, like a diffusiometer, then gas is projected through the open channels by the atomic motion already described and escapes. Simultaneously the external air is carried inwards in the same manner, and takes the place of the gas which leaves the vessel. To this atomic or molecular movement is due the elastic force with the power to resist compression possessed by gases. The molecular movement is accelerated by heat and retarded by cold, the tension of the gas being increased in the first instance and diminished in the second. Even when the same gas is present both within and without the vessel, or in contact with both sides of our porous plate, the movement is sustained without abatement,—molecules continuing to enter and leave the vessel in equal number, although nothing of the kind is indicated by change of volume or otherwise. If the gas in communication be different, but possess sensibly the same specific gravity and molecular velocity, as nitrogen and carbonic oxide do, an interchange of molecules also takes place without any change in volume. With gases opposed of unequal density and molecular velocity, the permeation ceases to be equal in both directions.

The movement of gases through the graphite plate appears to be solely due to their own proper molecular motion, quite unaided by transpiration. It seems to be the simplest possible exhibition of the molecular or diffusive movement. This pure result is to be ascribed to the wonderfully fine porosity of the graphite. The interstitial spaces appear to be sufficiently small to extinguish capillary transpiration entirely. *The graphite plate is a pneumatic sieve, which stops all gaseous matter in* MASS, *and permits* MOLECULES *only to pass.*

The permeation through the graphite plate into a vacuum, and the diffusion into a gaseous atmosphere, through the same plate, are due to the same inherent mobility of the gaseous molecule. They are the exhibition of this movement in different circumstances. In interdiffusion we have two gases moving simultaneously through the passages in opposite directions, each gas under the influence of its own inherent force; while with gas on one side of the plate, and a vacuum on the other side, we have a single gas moving in one direction only. The latter case may be assimilated to the former if the vacuum be supposed to represent an infinitely light gas.

We may speak of both movements as gaseous diffusion; the diffusion of gas into gas (double diffusion) in the one case, and the diffusion of gas into a vacuum (single diffusion) in the other. The inherent molecular mobility may also be justly spoken of as the diffusibility or diffusive force.

The diffusive mobility of the gaseous molecule is a property of matter fundamental in its nature, and the source of many others. The rate of diffusibility of any gas has been shown to be regulated by its specific gravity, the velocity of diffusion varying inversely as the square root of the density of the gas. This is true, but not in the sense of the diffusibility being determined or caused by specific gravity. The physical basis is the molecular mobility. The degree of motion which the molecule possesses regulates the volume which the gas assumes, and is obviously one, if not the only, determining cause of the peculiar specific gravity which the gas enjoys. If it were possible to increase in a permanent manner the molecular motion of a gas, its specific gravity would be altered, and it would become a lighter gas.

It is conceivable that the various kinds of matter, now recognized as different elementary substances, may possess one and the same ultimate or atomic molecule existing in different conditions of movement. The essential unity of matter is an hypothesis in harmony with the equal action of gravity upon all bodies. We know the anxiety with which the point was investigated by Newton, and the care he took to ascertain that every kind of substance—metals, stones, woods, grain, salts, animal substances, etc., are similarly accelerated in falling, and are therefore equally heavy.

In the condition of gas, matter is deprived of numerous and varying properties with which it appears invested when in the form of a liquid or solid. The gas exhibits only a few grand and simple features. These, again, may all be dependent upon atomic or molecular mobility.

If we imagine one kind of substance only to exist—ponderable matter—and further, that matter is divisible into ultimate atoms uniform in size and weight, we then shall have one substance and a common atom. With the atom at rest, the uniformity of matter would be perfect, but the atom possesses more or less motion, due, it must be assumed, to a primordial impulse. This motion gives rise to volume. The more rapid the movement the greater the space occupied by the atom, somewhat as the orbit of the planet widens with the degree of projectile velocity. Matter is thus made to differ only in being lighter or denser matter. The specific motion of an atom being inalienable, light matter is no longer convertible into heavy matter. In short, matter of different density forms different substances—different inconvertible elements, as they have been considered.

Moreover, these more or less mobile, or light and heavy forms of matter, have a singular relation connected with equality of volume. Equal volumes of two of them can coalesce together, unite their movement, and form a new atomic group, retaining the whole, the half, or some simple proportion of the original movement and consequent volume. This is chemical combination. It is directly an affair of volume, and only indirectly connected with weight. Combining weights are different, because the densities, atomic and molecular, are different. The volume of combination is uniform, but the fluids measured vary in density. This fixed combining measure weighs 1 for hydrogen, 16 for oxygen, and so on with the other elements.

This hypothesis admits of another expression. As in light we have the alternative theories of emission and undulation, so in molecular mobility the motion may be assumed to reside either in separate atoms and molecules or in a fluid medium caused to undulate. A special rate of vibration or pulsation originally imparted to the portion of the fluid medium enlivens that portion of matter with an individual existence, and constitutes a distinct substance or element.

Again, molecular or diffusive mobility has an obvious bearing upon the communication of heat to gases by contact with liquid or solid surfaces. The impact of the gaseous molecule upon a surface possessing a different temperature appears to be the condition for the transference of heat, or the heat movement, from one to the other. The more rapid the molecular movement of the gas, the more frequent the contact, with consequent communication of heat. Hence, probably, the great cooling power of hydrogen gas as compared with air or oxygen. The gases named have the same specific heat for equal volumes; but a hot object placed in hydrogen is really touched 3·8 times more frequently than it would be if placed in air, and 4 times more frequently than it would be if placed in an atmosphere of oxygen. Dalton, many years ago, ascribed this peculiarity of hydrogen to the high "mobility" of that gas.

The passage of gases through colloid septa was next considered, and the rates of passage of certain gases through india-rubber compared with those of ordinary diffusion. These are shown in the following table:—

	Rates of Passage through India-rubber.	Diffusion Velocities.
Nitrogen	1·00	1·01
Marsh gas	2·15	1·34
Oxygen	2·55	·95
Hydrogen	5·5	3·80
Carbonic acid gas	13·58	·81

Gases may be partially separated from one another by passing through india-rubber just as, by passing through a porous plate and the stems of tobacco pipes, a partial analysis of mixed gases can be effected.

Oxygen passing through india-rubber two-and-a-half times more rapidly than nitrogen, it was demonstrated that by passing air through an india-rubber bag into the vacuum of a Sprengel exhauster, such air contained two-and-a-half times more oxygen than was originally contained in it.

The gases which pass most freely through india-rubber being those most freely absorbed by it, the process was defined as being due to—

1. The solution of the gas in the rubber.
2. The diffusion of the gas as a *liquid* through the thickness of the rubber.
3. The evaporation of the liquefied gas from the internal surface of the rubber.
4. The diffusion of the evaporated gas into the internal space.

There exist, therefore, three modes of gas transmission through a solid or semi-solid septum:—

1st. By a sufficient degree of pressure gases may be forced bodily, *i.e.* in masses, through the minute channels of a porous septum, or, in other words, may pass through such a septum by transpiration, of course, in the direction only of the preponderating total pressure.

2nd. As the channels of a porous septum become more and more minute, their resistance to the bodily transmission of gas becomes greater and greater, and the quantity of the gas forced through them less and less, until at last the septum is absolutely impermeable to transpiration under the particular pressure. But such a septum of which the individual capillary channels are so small as to offer a frictional resistance to the passage of gas greater than the available pressure can overcome, nevertheless, presents a considerable aggregate of interspaces through which the diffusion proper of gases, consequent on their innate molecular mobility, can take place freely in both directions.

3rd. A septum may be quite free from pores of any kind or degree of minuteness, and so far be absolutely impermeable to the transmission of gas in the form of gas. But it may, nevertheless, permit a considerable transmission of certain gases by reason of their prior solution or liquefaction in the substance of the septum. And while the mere passage of gas by transpiration or diffusion through a porous septum would take place in thorough independence of the nature of the material of the septum, in this last considered action, the transmission would take place by virtue of a sort of chemical affinity between the gas and the material of the septum. The selective absorption of the gas by the septum being a necessary antecedent of its transmission, it may be said that the gas is transmitted *because* it is first absorbed. Of course, in certain transmissions, two, or all three modes of action may come into play simultaneously.

The lecturer then explained the permeation of ignited platinum and iron to hydrogen and other gases, and the special property possessed by the former metal and palladium of allowing the hydrogen of coal gas to pass through them, while the marsh gas and other constituents were left behind. Graham's most interesting discovery that metals readily absorb those gases which they freely transmit, led to the consideration of the occlusion of gases.

Occlusion of Gases by Palladium and other Metals.

The absorption of hydrogen by ignited platinum, of oxygen by ignited silver, and of carbonic oxide and hydrogen by iron were referred to, and the evolution of these gases by again heating the respective metals in a vacuum was shown by means of a Sprengel pump. The evolution of five times its volume of hydrogen by meteoric iron, from the Lenarto fall, when heated in vacuo, seems to prove the highly condensed nature of the atmosphere in which this gas was absorbed. The spectroscope has shown that hydrogen is one of the constituents of the atmosphere of the sun and other heavenly bodies, and it is an interesting fact that we are able to extract the hydrogen from meteoric iron by heating in the vacuum of a Sprengel exhauster.

The lecturer then referred to the enormous amount of hydrogen absorbed by palladium, amounting in some cases to 980 times its volume, and mentioned the following three principal methods by which that metal can be charged with and freed from hydrogen:—1, by being heated and cooled in an atmosphere of the gas; 2, by being placed in contact with zinc dissolving in acid, *i. e.* with hydrogen in the act of evolution; 3, by being made the negative electrode of a battery. Correlatively, the charged metal can be freed from its occluded hydrogen: 1, by heating it in air or vacuo; 2, by acting on it with different feebly oxidizing mixtures; 3, by making it the positive electrode of a battery.

A piece of palladium wire was made the negative electrode of a battery for a minute or two; it was then dried and heated in a glass tube connected with a Sprengel exhauster. Gas was rapidly evolved, collected in the receiver, and shown to be pure hydrogen.

The lecturer also showed the ingenious experiment devised by Mr. Chandler Roberts, in which two slips of palladium foil, varnished on one side, are made to curl and uncurl as they become alternately the negative and positive electrodes of a battery, or are alternately charged with and discharged of hydrogen on the unvarnished surfaces.

It was explained that the curling and uncurling were due to the alternate expansion and contraction of the foil by its occlusion and evolution of the hydrogen, produced by the electrolysis of the water.

The lecturer concluded by referring to the nature of occluded hydrogen. That hydrogen is the vapour of a highly volatile metal has frequently been maintained on chemical grounds; and from a consideration of the physical properties of hydrogenized palladium Graham was led to regard it as a true alloy of palladium with hydrogen, or rather hydrogenium, in which the volatility of the latter metal was restrained by the fixity of the former, and of which the metallic aspect was equally due to both its constituents.

Although the occlusion of upwards of 900 times its volume of hydrogen was found to lower appreciably the tenacity and elective conductivity of palladium, still the hydrogenized palladium remained possessed of a most characteristically metallic tenacity and conductivity. In further support of this conclusion as to the metallic condition of the hydrogen occluded in palladium, may be mentioned Graham's singular discovery of its being possessed of magnetic properties, more decided than those of palladium itself, a metal which Faraday proved to be "feebly but truly magnetic." Operating with an electro-magnet of moderate strength, Graham found that while an oblong fragment of electrolytically deposited palladium was deflected from the equatorial by 10 degrees only, the same fragment of metal, charged with only 600 times its volume of hydrogen, was deflected through 48 degrees. Thus did Graham supplement the idea of hydrogen as an invisible incondensable gas by the idea of hydrogen as an opaque, lustrous, white metal, having a specific gravity between 0·7 and 0·8, a well-marked tenacity and conductivity, and a very decided magnetism.

NORWICH CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of the above Association was held at the Society's Rooms, on Friday, the 25th inst., Mr. Henry Thompson in the chair.

In opening the meeting, the Chairman said, although it was with great reluctance that he had undertaken the office of chairman, he could not but feel great pleasure in being called upon to fulfil such a pleasant task as that which had called them together on the present occasion. His own experience now extended over a considerable period of time. He was one of the oldest members of the trade in Norwich, and he had seen some of the body rise to eminent positions. He hoped that amongst the students to whom he should have the pleasure of presenting prizes, there would be some who would rise to even higher degrees of eminence than those he had then in his mind. The Secretary then read the report, stating that during the past session 53 meetings of classes had been held, namely, in Botany, 6; Chemistry, 33; Materia Medica, 7; Pharmacy, 7. Although the attendance had been small (only averaging eight throughout), a great deal of attention had been shown and considerable progress made. In consequence of this attention and regularity, the Council had decided to purchase four prizes with the funds so liberally placed at their disposal for this purpose by J. D. Smith, Esq., instead of three, as originally announced, and had awarded them as follows:—To Mr. De Carle and Mr. Woolnough (equal), Attfield's 'Chemistry.' Mr. Bayfield and Mr. King (equal), to the former, Barber's 'Companion to Pharmacopœia,' and to the latter, Wanklyn's 'Water Analysis.' Taking the report given by Professor Attfield on the results of the examinations as a criterion, the members had every reason to be satisfied with the teaching which had been kindly given by Messrs. Nuthall, Caley, Corder, Butler, and Mason.

The *vivâ voce* Examination in Botany, Chemistry, Materia Medica, Pharmacy, and Prescriptions, undertaken respectively by Messrs. Nuthall, Mason, Corder, Hill, and Fox, only brought four competitors into the field, and the result was—First prize, Mr. King, Miller's 'Chemical Physics.' Second prize (two), Mr. Tooke, Hofmann's 'Modern Chemistry,' and Fergusson's 'Electricity,' and Mr. Woolnough, Lindley's 'School Botany.' The examiners appeared to have been particularly well satisfied with the proficiency shown in Prescriptions, Chemistry, and Botany.

The prize (Valentin's 'Chemistry') offered by the Vice-President (Mr. E. Nuthall) for competition between the students of his own class, was contested for by seven candidates, and fell to Mr. Woolnough, with a total of 86 out of 100 marks. In deciding between the merits of the respective candidates, Professor Attfield took occasion to speak of the work done in a way satisfactory to the Society, and still more so to Mr. Nuthall, who had taken such pains to bring about this result. Professor Attfield said, "Permit me to add that these questions and answers give evidence of thoroughness of teaching. The progress that has been made is at least sound and lasting. In these days when mere 'preparation' for the examinations established by law is nowhere so unblushingly rampant as in British pharmacy, it is refreshing to an educator to meet with such illustrations of good training as those you have placed before me."

The Secretary then said that three students had passed the Minor examination during the past session, one of whom (Mr. Tooke) took the honourable position of first with honours, thereby gaining the prize of books given by T. Hyde Hills, Esq.

The Chairman then distributed the prizes to the successful candidates, at the same time making very encouraging and appropriate remarks. Before the meeting concluded, he (the chairman) wished to say a few words with respect to the small attendance mentioned in the report, which had unfortunately been the burden of their complaint since the starting of the Association. He had been at some pains to find out the cause of this inattention, with a view of learning if there was any other reason for it than the reluctance of many of the youths to submit themselves to a regular course of study, and he was bound to say that complaints had reached him that the courses of the classes were not such as appeared to promise good results. He had thought at the time that such complaints had arisen from the carelessness or ignorance of those who made the complaint, and such opinion was now thoroughly confirmed by the evidences of good teaching that they had before them that night. After alluding to the great advantages for study now provided by that and similar associations, he promised all the support he could render, both in person and purse, and concluded by inviting both the successful and unsuccessful candidates to sup with him on Tuesday, the 29th inst.

The meeting closed with a cordial vote of thanks to the examiners, and to Mr. Thompson for his able conduct in the chair. There was but a limited attendance.

HALIFAX CHEMISTS AND DRUGGISTS' ASSOCIATION.

The last meeting of the season was held on Thursday April 24, 1873; Mr. Jessop, President, in the chair After the minutes of the last meeting had been passed and a holiday on Whit Tuesday decided upon, Mr. B. Shaw moved the following motion, viz.:—"That it is desirable to form a Library of Medical and Dispensing Works suitable for reference out of the surplus funds of the Association." He stated that he happened to be in the same predicament as the Chancellor of the Exchequer was, with a surplus and the problem how best to dispose of it. The motion he proposed, he thought would be one good method of meeting the difficulty. He did not know the experience of others in the trade, but he himself found obscure points arose in dispensing which required clearing up. He had been occasionally applied to in difficulties of this kind, and while he was at all times willing to render any assistance in his power, as no doubt others in the trade were, he thought it would be more reliable to have a selection of works bearing upon dispensing to refer to. It need not be large by way of commencement, some one or two dozen volumes, and he would suggest the following half dozen as suitable, viz. 'Selecta è Prescriptis,' Beasley's 'Formulary of Medicines,' Squire's 'Companion to the British Pharmacopœia,' Attfield's 'Chemistry,' Squire's 'Hospital Pharmacopœias,' and the 'Throat Hospital Pharmacopœia.' The following more comprehensive works might afterwards be added, viz. Gray's 'Supplement,' Parrish's 'Pharmacy,' Hoblyn's 'Dictionary of Medical Terms,' Bentley and Redwood's 'Abridgment of Pereira's Materia Medica,' and Taylor's 'Jurisprudence.' He suggested also a printed "Chart of Antidotes to Poisons" for the use of the members, to be suspended in a conspicuous place in the shop for easy reference.

Mr. Hebden seconded the motion, which was carried unanimously.

Mr. J. B. Brierley moved that the following be appointed a sub-committee to select the books, appoint a librarian, draw up rules for the town and country members, and report to the next meeting, viz.—Messrs. Jessop, Brook, Hebden, Dyer, and Shaw.

This was seconded by Mr. Blade and carried.

The President then drew the attention of the meeting to the great advance made by the railway companies on the carriage of drugs, etc., and suggested a sub-committee be appointed to take such steps as may be deemed advisable to lay before the directors their strong objections to the high rates now charged. He had been informed on good authority, that if they took the subject up firmly they might probably get a reduction of half the recent advance. Mr. Hebden moved, and Mr. Brierley seconded that Messrs. Jessop, Dyer, and Farr be appointed to undertake the duty.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION AND SCHOOL OF PHARMACY.

A meeting of the Council of this Association was held in the rooms, 37, Blackfriars Street, on Tuesday evening, April 22nd, for the purpose of presenting the prizes in the various classes. The President, Mr. W. S. Brown, occupied the chair, and there was a good attendance of students.

The Chairman in opening the proceedings called on Mr. Siebold to read his report.

Manchester School of Pharmacy Report for the Session 1872—1873.

To the President and Council of the Manchester Chemists and Druggists' Association.

Gentlemen,—The first session of the Manchester School of Pharmacy commenced on October 8th, 1872, and terminated on April 16th, 1873. Three courses of lectures were delivered, viz., 25 lectures on Pharmaceutical Chemistry, on Tuesdays from 8 to 9 P.M.; 25 lectures on Materia Medica and Practical Pharmacy, on Fridays from 8 to 9 P.M.; and 15 lectures on Botany, on Fridays from 9 to 10 P.M. The number of students were 36 for the chemistry course, 31 for Materia Medica, and 29 for Botany, amounting to a total of 96 entries. Of the 44 students who availed themselves of the instruction provided, 23 attended all the three courses, 6 attended two, and 15 one course only. The attendance was very good and regular, the average number of absentees not exceeding four of whom two were prevented by uncontrollable circumstances from attending during the greater part of the session. The chemical lectures were illustrated by experiments as far as the present limited accommodation permitted, and it appears to me highly desirable that the necessary provision should be made for more extensive experimental teaching in future.

Questions and problems were regularly given to be worked out at home, and the answers supplied enable me to state that about 50 per cent. of the students have derived a real and lasting benefit from the lectures, whilst the remainder have failed to do so, partially owing to their own indifference and carelessness, and partially on account of their great want of rudimentary education. Of about one-third of all the students, I can fairly say, that they have given me the very greatest satisfaction. Most of our students never attended a course of scientific instruction before, and but few of them can boast of a sufficient amount of thoroughly sound school-training, which is so very important in the study of science. Taking these circumstances into consideration we may look upon the first session of our young school of pharmacy as a gratifying and encouraging success. In point of numbers our success has been very great indeed, and has proved that in a large provincial town like Manchester, a school of pharmacy can exist and flourish without any extraneous support whatever. When you did me the honour of appointing me as lecturer on Chemistry, Materia Medica, and Botany, and of thus placing into my hands the entire management of this school, I entered upon my duties with a sense of great responsibility, yet very cheerfully, and with a full anticipation of success. I had not forgotten the failure that attended our previous efforts to found a school of pharmacy in connection with Owens College; but teachers as a rule overrate the preliminary knowledge of our assistants, and their lectures are consequently not properly understood and appreciated. Being strangers to pharmacy, their teaching does not prove of sufficient practical value and applicability to the young pharmacist, or to the student preparing for the Major or Minor examination. So far Chemistry has generally been taught to pharmaceutical students in the provinces by scientific chemists possessing little or no knowledge of pharmacy, whilst the teaching of Materia Medica has generally been entrusted to medical men who have lectured on Pharmacology rather than on Pharmacognostics, just as if their pupils were students of medicine instead of students of pharmacy. Can it be a matter of surprise then that even in the largest provincial towns the efforts to establish schools of pharmacy have ended in failure. I do not hesitate to assert that the success of our newly-established school in Manchester is mainly, if not entirely, due to the fact that a practical pharmacist has filled the post of lecturer, and that this conviction is shared by the students whom I have had the pleasure of instructing. I will now resume my report, from which I deviated in favour of a subject which I believe merits serious consideration and a full discussion.

On Wednesday, March 19th, and on the following Wednesday, competitive examinations were held in chemistry, materia medica, and botany. The questions submitted are annexed to this report. Fourteen candidates competed for the chemistry prizes, fifteen for the materia medica, and twelve for the botany prizes. The awards were as follows:—

Chemistry.

1st prize to Mr. Arthur Joseph Pidd.
Equal. { 2nd „ to Mr. Frank Hudson.
2nd „ to Mr. Blacklock.

Materia Medica.

1st prize to Mr. John Blacklock.
2nd „ to Mr. Edward Gardner.

Botany.

1st prize to Mr. J. J. Macauley.
2nd „ to Mr. S. Challiner.

The answers supplied by nearly all the competitors were highly creditable, and bear testimony to the zeal and industry of their authors.

I trust that our future educational efforts will be crowned with ever-increasing success, and that our young school will ere long grow into an important and permanent centre of pharmaceutical education.

Chemistry Questions.

1. What is the difference between sulphates, sulphites, and sulphides?
2. If a mixture of six volumes of oxygen and four volumes of hydrogen be ignited by an electric spark, what will be the composition of the resulting gas?
3. How is acidum sulphuricum tested for impurities?
4. Write the notation for phosphate of sodium and pyrophosphate of sodium, and state how they can be distinguished by testing.
5. How much sulphate of magnesium, $MgSO_4 7H_2O$, will be required to make sixteen ounces of magnesiæ carbonas, B.P. $(MgCO_3)_3MgO, 5H_2O$. $Mg = 24$; $S = 32$; $C = 12$.
6. Give a full explanation of the process for making iodide of potassium, and state how it may be tested for impurities and adulterations.
7. How can potassæ citras be distinguished from potassæ tartras?
8. The specific gravity of acidum hydrochloricum, B.P., is 1·16. How much water will be required to reduce an acid of 1·19 sp. gr. to the Pharmacopœia strength?
9. Explain by an equation the mode of making ammoniæ carbonas.

Materia Medica.

1. How is scammony tested for impurities and adulterations?
2. State how the presence of opium may be recognized in a mixture?
3. How can true Vera Cruz jalap be distinguished from Tampico jalap?
4. How are the leaves of *Cynanchum argel* distinguished from senna?
5. How would you test powdered rhubarb for turmeric?
6. Name the plants from which the following drugs are obtained, and also their natural orders and habitats:—Althææ Radix, Hemidesmi Radix, Digitalis Folia, Uvæ Ursi Folia, Guaiacum.
7. Essential oils are often adulterated with spirits of wine; how would you detect that adulteration?

Botany.

1. Name and define the different kinds of underground stems.
2. State all the distinguishing features of exogenous and endogenous plants.
3. What is a perianth?
4. Give definitions of the terms raceme, corymb, and umbel.
5. What are hypogynous, tetradynamous, and monadelphous stamens?
6. Give a brief description of the leaves of *Atropa belladonna*.

The President then presented the prizes (consisting of standard works on chemistry, materia medica, and botany) to the successful competitors. He said it was highly gratifying to the Manchester Chemists and Druggists' Association to receive such a Report from Mr. Siebold. He need not say the establishment of these courses of lectures had received the most anxious deliberation of the Council. A previous attempt had ended in failure, mainly, he believed, for the reasons stated by Mr. Siebold, that the lectures given were not adapted to the requirements of the classes. The Association had been singularly fortunate in securing the services of a gentleman so able and at the same time so willing to undertake the duties of lecturer. Mr. Siebold had made a very great sacrifice of time, and, he believed, also a pecuniary sacrifice, as in all probability the private teaching of pharmaceutical students might have been more remunerative to him than his present office. He, the Chairman, believed that to Mr. Siebold was due the fact that the Manchester School of Pharmacy occupied a position this session unsurpassed throughout the provinces. The success of the classes was a subject of which the Association may be proud. He hoped that at no distant day they might be in a position to provide a complete course of laboratory instruction. This depended entirely on the more general cooperation of the chemists of the district. If the funds were provided, members might rely on their being spent in the promotion of that which he was not ashamed now to speak of as The Manchester School of Pharmacy.

Mr. J. T. Slugg said he would congratulate the losers as well as the winners of the prizes. The knowledge which all had an opportunity of gaining, and which, as Mr. Siebold had said, so many of the students before him *had* gained, was itself a prize. He would also congratulate Mr. Siebold on having so entirely gained the respect and confidence of his class; with these he was in a position to secure the progress of his pupils. He contrasted the advantages now offered to pharmaceutical students with those available when he was an apprentice forty years ago, and urged young men to seize these opportunities. He believed it was Lord Brougham who said, if he were only a shoeblack he would try and be the best shoeblack in the parish. Let every one feel that though he be only a druggist, he will try and be the best druggist in the country.

Mr. Siebold then briefly thanked the speakers for their kind and complimentary remarks, and the meeting terminated.

HULL CHEMISTS' ASSOCIATION.

At the last meeting of this Association, held at the Cross Keys Hotel, the President, Mr. Anthony Smith, in the chair, the question of the botanical class for the ensuing session was considered, and it was arranged that the President, Vice-President, and Secretary wait upon Mr. Niven, the curator of the Botanic Gardens, and make the necessary arrangements. The decision arrived at by the committee and Mr. Niven was that the class should commence on Wednesday, May 7th, at 7 A.M., and continue weekly for twenty weeks, the fee for which will be 10*s.* 6*d.* The annual examinations in connection with the chemistry and materia medica classes have been conducted by Mr. H. J. Parson, M.P.S., during the last week, and the competition for prizes resulted as follows:—Senior chemistry, Mr. D. P. Roberts; junior chemistry, Mr. J. T. Morley; senior materia medica, Mr. D. P. Roberts; junior materia medica, Mr. H. T. G. Wood.

LEEDS CHEMISTS' ASSOCIATION.

The sixth meeting of the present session was held in the Library, Church Institute, on Wednesday, March 19th, 1873, Mr. R. Reynolds in the chair.

The Chairman placed upon the table 'Pharmacopœia Germanica,' and 'Transactions of the American Pharmaceutical Association.' It was announced that the "Year-Book of Pharmacy' had been received as a donation to the library, and resolved that the thanks of the society be given to the Committee of the British Pharmaceutical Conference for the same.

Mr. E. Brown gave a brief review of the published 'Proceedings' of the American Pharmaceutical Association, remarking that the office of President of the Association was not without its toils as well as its honours, as this voluminous work testified, it becoming the province of the President to compile the transactions. The book is well and clearly printed, and is large for circulation to the members of an Association, numbering little over nine hundred. The Association seems to be very methodic in its operations, committees and sub-committees being appointed to each branch of its affairs; politico-pharmacy, commercial-pharmacy, scientific-pharmacy, and executive or shop-pharmacy, have each their organizations. Each state and city contributing to the association has or is its microcosm of the whole Union, in fact many pages of the 'Proceedings' are but official reports of the routine of arrangements, and that to an extent we were not prepared to expect in our Transatlantic brethren; but when we come to the actual reports of meetings, it is manifest that however much system pervades the conduct of the American Pharmaceutical Association, there is all the energy and freedom of a vitalized body in their transactions. The long distances between the several centres of operation, and the keen distinctions perceptible to the American mind, are quite adequate to solve what appears like so much red tape; but which, however cumbrous it may seem, bears useful fruit for the well-being of the constituency that organized it.

The 'Proceedings' report some instances of careful and scientific research, but are much more largely comprised of the results of practical observations and testings in regard to articles of every day use in the drug store and at the dispensing counter. The Americans suffer more even than we do from chronic inventopathy. "Something new" has charms with them more potent far than "established" remedies have with us, so that on their shelves there is a perpetual Sir Roger de Coverley in process,—the last but one of recent concoctions is already on the trams to the oblivious region of dead stock, having been displaced by the very last feat of ingenious admixture.

The class of articles that takes the first place in this panorama-medicamenta is elixirs, preparations of the cordial kind, sweet, spirituous, aromatic, and medicated, contrived so as to gratify the palate rather than to benefit the patient. The proprietors of these compounds introduce them to medical men, who, prescribing them, so induce a demand on the pharmacist and hence on the proprietor.

Much inconvenience arises from this oft introduction of new remedies, and the dispenser has not unfrequently to tax his ingenuity to devise a substitute for an article as foreign to his stock as might be the potions and perfumes indulged in by the Grecian gods. There is a species of honesty, however, in this practice of substitution that merits commendation. The dispenser in such a case sends to the prescriber, acquainting him he is minus the article prescribed, and asks what is to be used in its place, or if the doctor is out of reach, he makes the best guess he can, and afterwards informs the doctor of the deed. Necessity, it has been said, has no law; in these instances it may be said the rather to become law. The circumstances of the American pharmacist are in these affairs in many respects so unlike our own that we must not hastily condemn. To us, nevertheless, these practices carry a moral, on which each one may ruminate as experience suggests.

Not inaptly following observations on new remedies, we have reports on the drug market, and here is named as a "drug," *proprio nomine*, condurango, that so recently was the golden balm, now lying in discarded parcels begging a customer.

Professor Parrish's remarks on pharmaceutical education are well worthy our regard. They bear on the value of a sound general education prior to technical instruction, and urge that, where practicable, an advanced education before entry on the duties of the drug store and laboratory will, in the long run, place its possessor at a great advantage, even where he runs to or through the last of his teens before he manipulates with the mortar or the retort. There is here support for not lowering the standard of our Preliminary examinations. At the same time, Professor Parrish was as well aware as any one in this country, of the difficulties in the way of what he saw to be so desirable, and because he saw these practical difficulties, he asserted that the advantages of a classic education in the drug trade can be had only by a favoured few.

In the report of the committee on adulterations, our American friends make no suppression of names of the firms whence the examined articles are had,—a course we should not be ready to commend, one that, while it savours of open fairness, may be equally the cloak for much that is contrary to what is fair and open. In a very comprehensive report on seidlitz powders, it becomes manifest that these powders are for the most part *measured* in America, and consequently that they differ much in weight. Their composition, however, proved more uniform than might be expected, collected as they were from so many sources.

Turning from American to British pharmacy, Mr. Brown commented on the getting up and merits of the 'British Year-Book of Pharmacy,' remarking that brief marginal notes or headings in some departments would add to its value as a book of reference. The book does not take the same position as the American 'Proceedings,' is not a report only of an association, so it must not be compared with it on like grounds; yet as a means of information, the 'Year-Book' is far the more comprehensive. He then directed special attention to articles in the 'Year-Book' on German opium, placing on the table a sample of English opium, produced in Kent; also to articles on gum arabic, pepsine, tannin and glycerine, glyceroles of vegetable extracts, etc., commending the book to those present. In the course of his remarks, Mr. Brown referred to Messrs. Harvey and Reynolds' manual, entitled 'Notes on New Remedies,' which, he said, was quite abreast of the times in the matters treated of. He then gave a formula for the preparation of tinct. aurant. recent., a sample of which he also exhibited, adding some observations on the desirability of there being other dilutions of spirit than *proof spirit* for pharmaceutical use. Mr. Brown also drew attention to the utility of the tragacanth and glycerine mucilage, recently noticed in the PHARMACEUTICAL JOURNAL, and placed on the table samples of the mucilage and of several emulsions formed by its admixture with cod liver oil, castor oil, almond oil, etc.

An interesting discussion followed, in which Messrs. Reynolds, Teesdale, and others present took part, and on the motion of Mr. Reynolds, seconded by Mr. Yewdall, the best thanks of the meeting were given to Mr. Brown.

The seventh meeting was held in the Library, Church Institute, April 10th, 1873. The President, Mr. E. Brown, in the chair. The minutes of former meeting having been read and confirmed, Mr. Elfendale, hon. sec., read a short paper upon "Our Society." In the discussion which followed the reading of this paper, the President, Mr. Abbott, and Mr. S. Taylor repressed their opinions upon the questions introduced, and on the motion of Mr. Abbott, seconded by Mr. E. S. Payne, Associate, the thanks of the meeting were given to the author. This was the last meeting of the present session.

SUNDERLAND CHEMISTS' ASSOCIATION.

The annual meeting of the above Society was held on Wednesday, April 23rd, at the Palatine Hotel.

The report of the Council was read by the Secretary, and the balance-sheet by the Treasurer, showing a small balance in favour of the Society. The following officers were elected for the ensuing year—President, Alderman Thompson; Secretary, J. J. Nicholson; Treasurer, R. Robinson. Council—Messrs. J. Harrison, D. B. Sharp, H. Thompson, T. Nasbet, C. S. Lord, J. Mitchinson, H. Turnbull, T. Burn, J. Priestly, W. Sayer.

After the conclusion of business the members adjourned to a supper, provided in the Palatine Hotel.

Parliamentary and Law Proceedings.

The "Chlorodyne" Dispute.—Browne v. Freeman.

(*Before the Lord Chancellor for the Master of the Rolls.* —April 28, 1873.)

This was a bill filled by Dr. Collis Browne for an injunction to restrain the defendant, a chemist in the Kennington-road, from issuing certain advertisements and publishing certain testimonials in support of his assertion that his, and not Dr. Collis Browne's, is the original and only genuine chlorodyne. It was the third suit between the parties. The plaintiff began to supply the public with chlorodyne in 1855, having invented it, as he stated, in 1846, and used it with success in his practice in the East. The first bill was filed in May, 1862, to restrain the defendant from using the name of chlorodyne as descriptive of a medicine prepared by himself; but on the defendant putting in an answer, claiming to have discovered his preparation in 1844, and denying that he had ever advertised it, except as Freeman's chlorodyne, the plaintiff dismissed his bill. The second bill was filed in December, 1862, to restrain the defendant from advertising his own preparation as "the original chlorodyne, manufactured by the inventor, Richard Freeman." On the 11th of January, 1864, Vice-Chancellor Wood dismissed this bill on the ground that, as far as the name of chlorodyne went, the plaintiff had, by acquiescence in the use of it by other persons, lost the right to treat it as his own trade mark, and that the defendant had not actually represented that his chlorodyne was of the manufacture of the plaintiff; but as his Honour disapproved the course pursued by the defendant, he dismissed the bill without costs. There was no appeal from this decision. The rivalry between the parties was not decreased by this decision, for in December, 1871, the present or third suit was brought in consequence of some advertisements issued by the defendant, one of which was as follows:—

"The original chlorodyne and only genuine invented by Richard Freeman, pharmacist, entitled by the decision of Vice-Chancellor Sir W. Page Wood, January 11, 1862, to the sole right to use the word 'original' as a prefix to 'chlorodyne,' which decision was confirmed July 12, 1864." The plaintiff also complained of the defendant's representing that genuine chlorodyne is only sold under the protection of Government authority, with a stamp bearing the words "Freeman's Original Chlorodyne," and that without such stamp no chlorodyne is genuine; and that several testimonials to the efficacy of chlorodyne as a remedy for various disorders which were really given in favour of the plaintiff had been appropriated by the defendant and printed on the wrappers of his bottles.

Sir Richard Baggallay, Q.C., Mr. Fischer, Q.C., and Mr. B. B. Rogers, appeared for the plaintiff; Mr. Southgate, Q.C., and Mr. Stirling for the defendant.

The Lord Chancellor, stopping Mr. Southgate, said the advertising had gone on since 1864, and the plaintiff had lost by his acquiescence any right he might formerly have had to ask the Court whether the defendant's misrepresentation of the decree of Vice-Chancellor Wood did not amount to contempt of Court. It appeared to him that the suit was virtually concluded by the decision in the former suit that the plaintiff had not an exclusive right to the use of the word chlorodyne. The defendant's calling his preparation the original did not, as the Vice-Chancellor thought, amount to a representation that his preparation was in fact the manufacture of the plaintiff; and the words "only genuine," which were the only new feature in the present suit, merely involved a slander of the plaintiff's property, which might or might not be actionable; but, if actionable, would not be so as a mere trade assertion that one man's article is better than another's. Nor could his Lordship see any ground of complaint as regards the testimonials used by the defendant. He should, therefore, dismiss the bill. He might be impressed in the same way as the Vice-Chancellor was with regard to the conduct of the defendant, but he could not approve the course pursued by the plaintiff of filing another bill after the point had been substantially decided against him; so that the bill would be dismissed with costs.—*Times.*

Charge of Culpable Homicide again st a Doctor's Assistant in Glasgow.

At the Glasgow Circuit Court, on Saturday last, April 26, Robert Taylor M'Donald was chaged with culpable homicide, in so far as on the 14th January last, being employed as a dispenser of medicines by Thomas Smith, Cowcaddens Street, and having been requested by Jessie Stewart, otherwise Kean, to supply her with a halfpenny-worth of salts, or Epsom salts, and a halfpenny-worth of cream of tartar, which she had been sent to purchase for the now deceased Margaret Brown, warehouse girl, he "wickedly, recklessly, ignorantly, and culpably" sold her two packets containing binoxalate of potash, otherwise called salt of sorrel, and the said Margaret Brown having taken the contents of the packets, became ill, and died about half an hour afterwards. The prisoner, who had been liberated on bail, took his place in the dock, and pleaded not guilty. He was defended by Mr. Cooper. The first witness called was—

Mrs. Esther Brown, who deponed—Margaret Brown, the deceased, was my daughter. She was 17 years of age at the time of her death, and was in the employment of Messrs. Howat, Brown, and Co. On the morning of 14th January, she left for her work about eight o'clock. She was then well, and generally enjoyed good health. Nothing had occurred to vex her.

Jessie Stewart or Kean deponed—I worked with Margaret Brown at Howat, Brown, and Co.'s. On the morning of the 14th January I called for her at her mother's house, and we went out together. On the way she gave me 1*d.*, and told me to buy for her a halfpenny-worth of salts, and the same quantity of cream of tartar. I went to Dr. Smith's shop in Cowcaddens, and asked for the salts and cream of tartar. I think the prisoner was serving in the shop. He took something out of a clear bottle which he removed from one of the shelves. He put the medicine on a piece of paper and made it up into a parcel. I did not see him make up the other parcel. He took it from some place, but I cannot say where. One of of the parcels, I cannot say which, he labelled. He weighed the stuff that he took out of the bottle. The parcels were both white paper. On reaching the warehouse, I gave the parcels to Margaret Brown, who mixed the contents in a can of water and drank them about ten o'clock. The stuff in the parcels was white, like baking soda. Margaret drank all the stuff except a "wee drop" at the bottom of the can, and immediately said these were the queerest salts she had ever taken. About ten minutes afterwards she became ill and vomited, and died that forenoon.

Cross-examined by Mr. Cooper.—The medicine was lumpy—harder than baking soda. Maggie broke down the pieces with her scissors, and mixed them in water. On the 15th January, an officer took me in a cab to Smith's shop. I saw a man standing behind the counter. I was asked if that was the man, and I said I was not very sure. He was not the man. Another man came in afterwards, but I was not sure whether it was him. On another occasion I was taken to the shop by an officer, and was shown a packet taken out of a drawer. I was asked whether the packet I got from the man before was bigger or smaller, and I said I thought it was about the same size. (Shown the prisoner.) I am not sure that the prisoner is the man.

Sophia Mitchell or Fotheringham—I worked beside the deceased. On the 14th January last she showed me two white paper packets, and said they contained cream of tartar and salts. I afterwards saw her drink the contents of the packets, which had been dissolved in a can of water. She became ill about half an hour afterwards.

Margaret Horn, forewoman to Messsrs. Howat, Brown, and Co.—Margaret Brown worked under my charge. I saw her at her work on the morning of the 14th, when she appeared to be in her usual health and spirits. I never heard her complain of illness. About eleven o'clock she came to me and said she was "awful bad." She looked pale and sickly. She put up two mouthfuls of white froth. She said, "I took a dose of salts, and have been sick ever since." She died that forenoon. She was not a girl that I would think likely to take anything to injure herself.

Alexander Horn, foreman in the employment of Messrs. Howat, Brown, and Co.—I saw the deceased after death. Margaret Brown was a cheerful girl. She was six years in our service, and I am not aware that she had had a day's illness during that time.

Superintendent Brown, Central District, spoke to taking Jessie Stewart to Dr. Smith's shop on 15th Jan. Dr. Smith was then in the shop, and on entering she said she thought it was that gentleman who supplied her. Witness explained his object in calling, and Dr. Smith said he had not been in the shop in the morning. The girl then said she did not know that it was him. About twenty minutes afterwards the prisoner came in, and she said she thought he was the man. The prisoner said he did not recognize Jessie Stewart, but that he remembered selling to a girl a halfpenny-worth of cream of tartar and a halfpenny-worth of salve about the same hour in the morning. He said he had not sold any Epsom salts.

Dr. James Dunlop read the report of a *post mortem* examination of the body of Margaret Brown made by Dr. Samuel Moore and himself. The reporters, after describing minutely the internal and external appearances of the body, said there was no indication of preexisting disease, and their opinion was that she had died from the immediate effects of a large dose of irritant poison.

Cross-examined by Mr. Cooper—Two drachms of salts of sorrel might prove fatal to a person taking them, but not certainly fatal if proper medical treatment were obtained. In a French case, one and a half drachm proved fatal in an hour. He was not able to say how many drachms of salts of sorrel might be given for a halfpenny.

By the Court—Salts of sorrel is sometimes mistaken for cream of tartar.

Interrogated—Supposing a person in general good health were to take by mistake two drachms of salts of sorrel, and within fifteen minutes were to be seized with vomiting and illness, would you consider that a probable result of taking the two drachms?—Yes.

You would not be surprised to hear of the death of a person who had taken two drachms?—I would not.

Would a mixture of it with Epsom salts have any effect at all on its operation?—I think not. It is so rapid in its action.

Dr. Samuel Moore coincided in the report subscribed by Dr. Dunlop and himself.

Dr. John Clark read the report of an analysis of the stomach, etc., of the deceased, as made by himself. He was able to trace salts of sorrel in the stomach and bowels, but not in the liver or spleen. He had no doubt death was caused by the deceased taking salts of sorrel. The quantity which he found would not cause death; but taken in connection with what might be presumed to have been absorbed or given off in vomiting, it would prove fatal.

By the Court—In its powdered state, salts of sorrel is sometimes mistaken for cream of tartar. Two drachms of salts of sorrel might prove fatal.

Dr. James Ormiston Affleck—I have had occasion to observe the action of irritant poison. The smallest quantity of salts of sorrel which I know to have produced death is three drachms. I think two drachms quite capable of producing death.

James Miller, packing clerk in the employment of Messrs. Howat, Brown and Co.—Salts of sorrel is occasionally used in our warehouse for taking ink stains out of cloth. It is kept in my desk, and when necessary to be used it is applied by William Smith and myself. No one else is ever employed to do so. I keep the desk containing the salts of sorrel locked. The deceased had no access to it.

Dr. Thomas Smith—The prisoner was in my employment for a year, quitting it on the 30th of March last. He came to the shop about eight o'clock in the morning, and I went to it about ten o'clock. On the 14th January last, he opened the shop as usual, and I found him there about ten o'clock. He was the only person who dispensed medicine that morning (shown two pieces of paper). The larger paper would contain twopence worth of salts of sorrel, and the smaller one a pennyworth or a halfpenny-worth. We sell two drachms of salts of sorrel for a halfpenny. In a previous case the prisoner made a mistake while in my service. An order was given for 3 oz. of sal volatile, instead of which he gave 3 oz. of liquid acetate of ammonia.

The prisoner, in his declaration, said he was a native of Aberdeenshire, and was 24 years of age. He remembered selling a halfpenny-worth of cream of tartar to a girl on the 14th of January, but he was sure he did not supply her with any salts, and what he sold did not contain oxalic acid.

Several witnesses were called for the defence, but no point of interest was brought out.

Counsel having been heard, Lord Ardmillan summed up, giving it as his opinion that the point for the jury was whether the prisoner was "guilty" or "not guilty," and believing that the circumstances in no degree justified a verdict of "Not proven."

The jury, after a short absence, returned with a verdict of "Not Proven," by a majority of one.

The accused was thereupon dismissed.—*Glasgow Herald.*

Review.

My Garden, its Plan and Culture; together with a General Description of its Geology, Botany, and Natural History. By Alfred Smee, F.R.S. Second Edition. London: Bell and Daldy. 1873.

When, in the closing year of the sixteenth century, Queen Elizabeth visited Sir Francis Carew, at Beddington, that worthy knight, knowing her Highness's weakness for cherries, led her to a tree on which, by a cunning manœuvre, the ripening of the fruit had been retarded for at least a month after every other cherry in England had disappeared. The prim old young lady, surrounded by her courtiers, while daintily picking the ripe black fruit, or pausing to examine the first orange trees ever cultivated in England, which were grown in that garden, must have admired the beauties by which she was encompassed. But it is doubtful whether she looked upon a fairer scene than the Garden in the same parish which is the theme of the book before us. Probably its author is of the same opinion, and not satisfied with limiting the enjoyment of its charms to himself and his visitors, he has sought to share it with the public so far as carefully minute description and lavishly abundant illustration can impart it. Jonathan Tyers, who was lessee of Vauxhall for the greater part of the eighteenth century, after maintaining those gardens as a place in which "debtors, lords, and thieves" might run riot, retired to another garden at Denbigh, in which he designed an "awful and tremendous view" of the Valley of the Shadow of Death, in order to terrify libertines from their evil courses. But Mr. Smee's garden-pictures are of a very different kind, and the score of full-page illustrations in this book have rarely been excelled, either for the beauty of the scenes they depict, or the manner in which they are engraved on wood and printed.

But to speak of the book itself. It commences with a history of the district in Celtic, Roman, Anglo-Saxon, Mediæval, and modern times. It next describes the geology in a chapter where there are some interesting remarks as to the water supply from the chalk; the rising of the Bourne; and also upon the effect of the Croydon sewage experiment. Then comes the planning of the garden,—not the least interesting part of the book, as it is a subject the author has studied *con amore*,—and this is followed by a chapter on the principles of gardening. These principles are laid down in rather a gossipy manner, and sometimes a considerable latitude is required in construing the scientific information upon which they are based. For instance, in reference to dialysis, the reader is informed that "crystalloids—such as alkaline salts—pass through a layer of membrane, impervious to water, *as though it had no existence*;" and an epiphyte is said to encircle another plant and "pump out by dialysis all its salts." Again, we read, "the changes which take place in the interior of plants are caused by the action of light, which enables them to reduce the carbon products . . . . from the carbonic acid of the atmosphere," which is only part of the truth. Another chapter is devoted to garden tools and freely illustrated; in fact too much so, for there is nothing extraordinary in Mr. Smee's watering pot, or wheelbarrow, or several other of his tools, that makes them worthy of a woodcut. A good hint as to garden labels is to have the name embossed in sheet lead by printing on it with ordinary type. Frames and glasshouses are next treated of, and a "poor man's house" of extremely simple construction is described. With the exception of a well-written chapter by Miss Smee on the "Gardens of All Nations," the remainder of the book is taken up with short descriptions of the numerous living things in the garden, both animal and vegetable. Roses and aphides, blackbirds and blind-worms, ducks and duck-weeds, cabbages and butterflies, are all included within the range of the author's jottings, and the descriptions are in most cases assisted by well-executed woodcuts.

Our limits do not allow of an attempt to enter into a detailed description of this portion of the book, but there are one or two things worthy of note. The great impulse which has been given to horticulture in recent years—due in no small degree to the labours of the late Mr. Loudon—has not only improved and increased the number of varieties of indigenous plants, but it has caused nearly every land the sun shines upon to be searched for new treasures. Edward I.'s fruiterer's bill included only pears, apples, quinces, medlars, and nuts, and amounted to but £21 14s. 1½d. from Whit Sunday to November. Mr. Smee's garden contains more than three hundred varieties of the apple alone, and at least five times that number are known. In the fifteenth century, the English kitchen garden contained little besides cabbage, lettuce, spinach, beetroot, trefoil, bugloss, borage, celery, purslaine, fennel, smallage, thyme, hyssop, parsley, mint, a species of turnip, and small white onions; but the author of "My Garden" enumerates more than an equal number of salad plants alone, to say nothing of numerous legumes, roots, and tubers, cabbages, marrows, aromatic herbs, etc.

We may quote here the description of a process devised by Mr. Smee, Jun., for obtaining the delicate odours of pinks and other flowers. "He uses a glass funnel, with the narrow end drawn to a point. In this funnel he places lumps of ice with salt, by which a very low temperature is produced. The funnel is supported on an ordinary retort stand, and placed near the flowering plants, when water and the ethereal odour of the blossom are deposited on the exterior of the glass funnel, trickling down to the point, and droping at intervals into a glass vessel below. The scent thus obtained is very perfect and interesting, but is apt to become sour in a few days, unless some alcohol is added. . . . To obtain the odour in perfection, the blossom must be in its prime."

With Mr. Smee a standard rose is tabooed—one cannot wonder at it after seeing the picture of his pyramids—and he has evidently little liking for geometrical beds and ribbon borders, with their "inevitable geranium." Campbell sang—

"Ye field-flowers! the gardens eclipse you, 'tis true,
Yet, wildlings of nature, I dote upon you;"

and in the author he would have found a kindred spirit, for there appears to be as much care devoted at Wallington sometimes to the introduction of a wild plant as to the cultivation of those more popularly prized. But the student of nature invariably enjoys beauties which are passed over by ordinary eyes. Many a reader of Mr. Smee's beautiful book will be surprised to find how much food for study there is in a garden, and after perusing it to the last page will be able to understand the feeling which prompted the motto on the first—*Μεγάλα καὶ θαυμαστὰ τὰ ἔργα σοῦ, Κύριε ὁ Θεὸς ὁ παντοκράτωρ.*

BOOK RECEIVED.

Botanical Companion to the British Pharmacopœia. By Hyman Marks. Dublin: Fannin and Co. 1873.

Obituary.

Notice has been received of the death of the following:—

On the 2nd April, 1873, Mr. William Lingwood, Chemist and Druggist, of Edwardes Terrace, Kensington.

Notes and Queries.

SYR. FERRI ET QUINIÆ IODIDI.—In reply to *A. E. J.*, who asks for a reliable formula for Syr. Ferri et Quiniæ Iodidi, we insert the following, the second of which is from Dorvault's 'L'Officine:'—

Quiniæ Iodidi	gr. j
Acid. Acet. Dil.	♏ iij
Syr. Ferri Iodid.	℥ j.

M.

Place iodine, 5 parts, and iron wire, 2 parts, in water, 20 parts. Allow the reaction to go on until the colour disappears; filter, and mix with simple syrup, 1120 parts; then add sulphate of quinine, 1 part, dissolved in q. s. of dilute sulphuric acid.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Benevolent Fund.

Sir,—I have to thank Mr. Clark for his reply to my former letter, and to assure him that his wishes concerning me shall be gratified.

His allusion to forbearance convinces me that he is a courteous disputant, I only regret he has put the right thing in the wrong place. Forbearance more properly was due to the fund at which Mr. Clark has attempted to aim a deadly blow,* and in defence of our fund I shall strike out as vigorously as I am able.

He clears up what appeared some slight inconsistency in his previous dealings with the fund by an explanation that "his opinions had not been formed by the recent correspondence," they had in fact existed "for a long time," but were rendered inert by, "perhaps, a slight carelessness concerning the appropriation of the donations." No fair penitent could confess her shortcomings in a more self-excusing apologetic strain; but from a doctor of charity could we not have looked for more explicit and seemly credentials?

I presented figures in my first communication, which demonstrated how utterly Mr. Clark's pet local relief scheme would have failed in his own city of Leicester. The figures are not disputed; but the argument founded on them is declared "somewhat absurd," and for this reason, because the greater the failure there, the greater the success elsewhere.

This is a staggerer!

Misfortune is ever in our midst heeding not whatever limits we may define, nor is it in the habit, if my recollection is correct, of inquiring into the state of district relief funds before it casts its gloomy shadow on a household, in which, as in its lair, lurks the gaunt spectre destitution, a veritable social beast of prey, ready to spring upon the feeble, the sick, the aged. Hence true charity has ever boasted of her universality.

On the other hand what does Mr. Clark propose? A system (if so it can be termed) to work somewhat in this fashion: Want comes upon a chemist and druggist living in one of these local spheres of amiability, let us say in the district of Benevolentia-sine-Nummo, for there are many such. Is relief given or is he spurned? Neither the one nor the other. The poor man is left with want as his companion, and he is presented with a potfull of flattering unction which he may, if he possesses much philosophy, apply to his soul; for does it not suffice him to know, that whereas he is poorer, others are just so much the richer? possessing his share in addition to their own. "O charity, what blunders cannot be committed in thy name!"

Will Mr. Clark, if he has nothing better to say for his system, unite with us in consigning it to the depths of Erebus?

I met the censor's proposition with figures, I shall meet his own selected case with facts.

That I may not by any possibility misrepresent him, I quote his words—"Some time since we had two annuitants to vote for, three to choose from who were all approved. Could we have taken £30 from that year's subscriptions and from those of following years, that third person might have been made happy."

Here we behold the writer who, a fortnight ago, railed against annuities now complaining that the Council did not elect three instead of two candidates. I am pleased to see that Mr. Clark no longer conceals his liking for annuities. I may mention to him that, however desirable it may be to grant annuities, their number must be limited by circumstances. I am informed that the Council will, next October, grant at least two additional ones, and I should calculate, that by carrying on his votes to the approaching election, last year's third candidate is certain to succeed.

Ah! but during these long months of expectancy how has it fared with him? What have the Council done? It appears to me two courses were open to them. They might have assured Mr. K. that though he was left out in the cold the others felt all the warmer for it; or they might have been mindful of their duties as almoners, and given aid to the extent of their power.

On reference to the Benevolent Fund accounts, I see the Council from July 1872, to April 1873, that is within ten months, voted £35 to him.

Thus, according to the scale laid down by Mr. Clark, that a person can be made happy for £30 a year, the third candidate has been rendered even more than happy; and that by the method he proposed, by sums of money taken from the year's subscriptions. One is tempted to ask if it is by such ignorance of facts that hostility to the Benevolent Fund can prevail? Can this be the case, which, when challenged to proof, the accuser puts forth to convict the Council of a dereliction of duty? It really is so, and I am yet unconvinced that the Council is deaf to voices round, but if facts are truth, the accuser is blind to both.

I know too well what I am writing about to feel one moment's uneasiness for our present annuitants; they are in a position of security against all contingencies; it is based on the elegant simplicity of Government securities, which fact, like the meat in the soup, is the making of it.

I rather feared that a check to the influx of subscriptions and donations might be possible, if strictures such as I have endeavoured to answer had been left unnoticed; and I trust the facts cited may have drawn Mr. Clarke and myself more into unison of thought, and guided both of us to the same conclusions.

A Subscriber to the Fund.

* "I would ask in the name of all that is right and charitable, that members in each town should unite their subscriptions, taken from the Benevolent Fund, to relieve the destitute poor of their own neighbourhood."

The Pharmacy Act, 1865.

Sir,—Within a radius of one mile from my shop, I should say there are no less than forty or fifty small grocery and provision shops, the proprietors of which carry on a certain amount of trade, which I think ought to be strictly and exclusively confined to us, viz., the vending of medicinal substances and preparations bearing the names of paregoric, Godfrey's cordial, etc., containing no opium nor any ingredient comprised in the second part of Schedule A of the Pharmacy Act; thereby they keep outside the operation of the law.

I think this matter ought to be thoroughly investigated, and a stop put both to the sale of drugs by unregistered persons, and also to wholesale firms supplying the above-mentioned persons with the articles alluded to.

A Registered Chemist (by Exam.).

Leeds, April 25th, 1873.

A Question Respecting the Adulteration Act.

Sir,—A chemist in the country who sells a gallon or two of laudanum per week, in small quantities of from 1*d.* to 1*s.* worth, applied to me for information respecting the Adulteration Act. His proportion for making it is 8 oz. opii to the gallon of proof spirit, and as B. P. formula orders 12 oz. to one gallon, he is afraid when an inspector is appointed under the Adulteration Act, he possibly might be found in error. He asked for my opinion, and as I could not enlighten him as to whether making laudanum of weaker strength than B. P. was adulterating it, I promised I would try to get some information, and if I should not be trespassing on your kindness too much, I should feel obliged if you would give me the information in order to satisfy my country friend, who has been in the habit of selling laudanum of that strength for twenty years. The reason he has not made it hitherto in accordance with B. P. form, was from fear that his customers might be injured if it were stronger, as many are ignorant and would be unable to read a caution label if the strength was altered. Quaerens.

April, 1873.

A Trade Grievance.

Sir,—I trust you will find a few words on a commercial subject affecting the trade not out of place in your Journal. The gradual rise in every department of labour, material, and fuel, has so seriously affected the producers of proprietary articles that they are very generally raising their prices to the trade. The special hardship to the retailer is that the profits are fixed, not by themselves, but the proprietor or maker. If an ordinary article rises in cost, we put the increase on the selling price of the article, and thus the public, as should be the case, pay the increased value; but in the case of patent medicines and proprietary articles the price is fixed and advertised to the public. One finds now constantly in patent medicine invoices first one article and then another marked "maker's price advanced." I may mention Ridge's Food, Dinneford's Magnesia, Rowland's Kalydor, Lamplough's Saline, and many others, of which the selling price remains the same. I have in view a one shilling article which used to be invoiced at seven shillings and has gradually expanded to ten—where will it stop? I have no fault to find with any proprietor raising the price of his article to a remunerative amount; but why should the retailer bear all the burden of increased wages, extra cost of fuel, and advanced value of bottles? It is not fair—it is not reasonable. The producer should as has been done in the instances of Bond's Ink, and Du Barry's Revelenta, raise the selling price of the article, it would then be a question entirely between themselves and the general public. The remedy is in our own hands; it is true the proprietor advertizes and creates a demand for his goods; but how largely is he aided by the efforts of the retailer, who exhibit in their windows, expose upon, and push, over their counters these goods, to the detriment often of legitimate trade. I would advise all retailers to discourage and discountenance in every way the sale of articles which are raised in price to them, without a corresponding increase on the price charged to the public. I think this would tend to stop this alarming rise, and that producers would find out what good friends they have had in the great body of the trade, who stand between them and the public.

Wm. Barron.

Cheltenham, April 29th, 1873.

Pharmacy in Ireland.

Sir,—I would not again have troubled you with any opinions of mine on pharmacy in Ireland, had not your correspondent Mr. Holmes accused me of being incorrect in many of my statements. I did not refer to the social position of the chemists and druggists of Ireland when I compared them with those of the same name in England and Scotland, but to their position as pharmacists. If the Irish chemists are so fully competent, as Mr. Holmes asserts they are, why does he not say how, where, and when they have gained that experience so necessary in the correct and efficient dispensing of physician's prescriptions? I have yet to learn how any one can be competent to dispense physician's prescriptions who has never dispensed one in the whole course of his experience. If an Irish chemist were asked if he could dispense physician's prescriptions, I am afraid he could give no better answer than that given by the Scotchman who, on being asked if he could play the violin, replied, "I dinna ken; I ne'er tried." I should be very happy to think that my experience of Irish chemists was exceptional; but mere assertions can never convince any one.

There are apothecaries to be found in Ireland, who devote themselves strictly to pharmacy, and abjure prescribing as rigidly as any first-class pharmacist in London. I could mention one of the most flourishing towns in Ireland where the dispensing is entirely done by such men, and I think Mr. Holmes could find many such in Dublin.

I might for Mr. Holmes' benefit (I hope no one else requires the information) mention, that the Modified examination was never considered qualification enough for membership of the Pharmaceutical Society; it was merely instituted as a compromise with those who had been long enough in the business to give them a vested interest.

Can the Irish chemist claim any such vested interest? Were the proposed Act as it at present stands to become law, he would be no better—no worse.

Alex. Anderson.

277, *Oxford Street, W., April 24th*, 1873.

Pharmaceutical Curiosities.

Sir,—Although the above is rather a hackneyed subject for a letter, I cannot forbear sending you a few specimens collected in this neighbourhood. The chemist here must be viewed as a superior being by the common folks, or they would never so severely task his sense of gravity, and if one should unfortunately express surprise at anything they ask for, they would probably say you had not "passed your diploma" (the expression of a native in reference to my examinations).

What would our examiners think of "oil of lily," "oil of Exeter," or "oil of cabbage?"

A day or two ago I got an inquiry for "black oil of snails."

Scarcely able to maintain my gravity I inquired what it was to be used for, but my customer was too wide awake to let me know *that*.

I asked if it was not the green oil she wanted, meaning to give her ol. virid., but she persisted in saying that it was black, and left the shop observing that she did not expect she should be able to get it about here! Can ignorance go further?

Well, lately I have been looking over an old recipe-book of a *registered chemist*, and under the head of "definitions" I find the following:—

"Cort. Granatur—Pome Granate bark."

"Os. Sepiæ—Scuttle bone."

"Lignum—Chips."

Further on iron filings and ferri carb. are given as synonymous terms, and then we are told that "pioloygneous acid" is another name of acetic acid!

On another page "amaris" is defined as meaning "bitter," and on another I catch sight of "syrup of madenhare."

But, really, it is too bad to pull a brother in the craft to pieces so; and as I fear I am occupying too much of your space, these "specimens" must suffice for the present, but I promise to send you more ere long.

J. Bower Williams, A.P.S.

Kingswinford, April 2nd, 1873.

P.S.—The person referred to dispenses with B. P. form.

J. Farmer.—Pyroacetic spirit is acetone, and pyroxylic spirit is wood naphtha.

A. Kinninmont is thanked for his letter and inclosure.

G. S. T.—Apply at Apothecaries' Hall.

M. A. M. (Yeovil).—We agree with you thinking that such a practice as that you refer to would be very objectionable, and we are disposed to think that the instance you refer to must have been accidental. However, we have made inquiries respecting it, and will communicate further with you when we have the result.

J. H. T.—The Act 29 & 30 Vict., c. lxiv., specifically prohibits the use of methylated spirit, or any derivative thereof, in the manufacture, composition, or preparation of any article whatsoever, capable of being used either wholly or partially as a beverage, or *internally as a medicine*. On this ground we should not consider the use of methylated spirit in the case you refer to would be legally an adulteration, although the preparation would not be strictly in accordance with the directions of the Pharmacopœia.

Mr. T. Collice.—Your letter has been forwarded to our correspondent.

The following journals have been received:—The 'British Medical Journal,' April 26; the 'Medical Times and Gazette,' April 26; the 'Lancet,' April 26; the 'London Medical Record,' April 23; 'Medical Press and Circular,' April 25; 'Nature,' April 26; 'Chemical News,' April 26; 'Gardener's Chronicle,' April 26; the 'Grocer,' April 26; 'Journal of the Society of Arts,' April 26; 'Grocery News,' April 26; 'Produce Markets Review,' April 26; 'Practitioner' for May; 'Journal of the Women's Educational Union' for April; 'Doctor' for May; 'Journal of Applied Science' for May; 'Practical Magazine,' Parts I.—IV.; 'American Chemist' for April; 'Mineral Water Trade Review' for April; 'Sanitarian' (New York) for April; 'Canadian Pharmaceutical Journal' for April.

Communications, Letters, etc., have been received from Mr. Jenkins, Dr. Collins, Mr. Barron, Liebig's Meat Company, Mr. Lowe, Mr. Walker, Mr. Ekin, Cacoethes Scribendi.

CINCHONAS.*

BY JOHN ELIOT HOWARD, ESQ.

At a recent meeting of the Linnean Society the author referred to a former treatise in the Report of the Botanical Congress in London in 1866, in which he expressed the opinion "that every well-defined region of the Andes has its own prevalent and characteristic cinchonæ, generally found in varied aspects, and incapable of being reduced to any one typical form." Mr. Howard thinks that the number of so-called species is already far too great, and that if every well-defined kind be held to be a species, the number of these might soon amount to *hundreds* at the very least. Moreover, it appears that these species produce great variety of forms from the same seed. This was illustrated by a number of specimens of cinchonæ from Mr. Howard's stores. Amongst these two totally diverse forms were shown, which had originated from the seed obtained from the capsules of one botanical specimen from the East Indies. One of these was the *C. Bonplandiana*, var. *angustifolia*, the celebrated kind which yields about 10 per cent. of sulphate of quinine; the other was a different sort of *C. Bonplandiana*. This could not well be the result of cross-fertilization, but rather of accidental variety. Mr. Howard showed another specimen (sent from the East Indies) of a supposed hybrid between the *C. succirubra* and the *C. officinalis*.

Arranged in the room were more than a dozen luxuriant plants grown from one small parcel of seed of *C. calisaya* sent from Mr. Broughton, in April of last year, exhibiting an average growth of perhaps two feet, and in some cases a great divergence from the usual form of the leaf of this species, which, however, from Dr. Weddell's account,† seems also to be the case in different forms of the *C. calisaya* in Bolivia. Is this the result of cross fertilization? or of an innate tendency to vary within certain limits? Mr. Howard thinks that the present is a favourable opportunity to ascertain these points. He would admit, as different species, only those forms in which there is a manifest incompatibility in the organs of reproduction, shown by sterility, or else by the production of true hybrids marked as such by instability, and a tendency to revert to one or other of the parents. Where there exists perfect facility of union, and fruitfulness in the progeny, he would regard the varying forms as simply different races: and consequently the distinctions drawn from the shape of the leaf (*cordifolia*, *ovata*, and so forth) are unsatisfactory and misleading when made the basis of *species*. Mr. Howard reviewed two works recently published in France, one by Dr. Weddell called 'Notes sur les Quinquinas,' the other 'Nouvelles Etudes sur les Quinquinas,' by J. Triana, both of which he considered had advanced greatly our knowledge of the genus, and remarked, in the first of these, points of gradual approximation to his own views.

In the course of his observations on the red bark, Mr. H. drew attention to some information which had reached him in regard to the management of this tree in India, and the different modes of cultivation by mossing, etc., none of which seemed able to change the habit of this species to produce more cinchonidine than quinine. A discussion arose in reference to the best method of propagation and cultivation of these plants in India, in which some gentlemen interested in the plantations took part, and the President made some concluding remarks, in which he alluded to the like variability of form exhibited in some other trees.

* Abstract of a paper read at a meeting of the Linnean Society, May 1, 1873.

† "If we compare the leaves, the typical form of which is a very obtuse obovate-oblong, we shall find that some are oblong-lanceolate and pointed, or even oval or elliptical, and of varying consistency and colours."

NOTES ON INDIAN SIMARUBEÆ.

BY ALFRED W. BENNETT, M.A., B.SC., F.L.S.

Lecturer on Botany, St. Thomas's Hospital.

(*Concluded from p.* 843.)

3. PICRASMA, *Blume*.

Trees or shrubs with very bitter properties. Leaves unequally pinnate. Flowers small, unisexual or polygamous, in axillary panicles. Calyx very small, 4–5-toothed. Petals 4–5, valvate, very often persistent and enlarged after flowering. Disc thick. Stamens 4–5, not scaly, hairy. Ovary 3–5-partite, free; styles free at the base and apex, but united in the middle; stigmas simple; ovules solitary, erect. Fruit of 1–3 fleshy coriaceous drupes. Seed erect, albuminous.

About six species, distributed over tropical continental Asia, the Eastern Archipelago, Japan, the West Indies, and Brazil.

1. *P. quassioides*, Benn. Plant. Jav. Rar. 198; Planch. in Hook. Jl. Bot. v. 573; *Nima quassioides*, Ham. *Simaba quassioides*, Ham. in Don Fl. Nepal, 245. A large scrambling shrub, with stout, often spotted, branches, and very bitter bark. Leaves a foot or more long, unequally pinnate; leaflets 9–15, obovate, acuminate, serrate, the lowest pair much smaller and stipulæform. Flowers small, green, polygamous, in axillary branching, pubescent panicles. Calyx-segments 5, small, imbricate. Petals 5, ovate or obovate, valvate, persistent, and much larger in fruit. Stamens 5; filaments strap-shaped, as long as the petals, villose. Fruit of 3–5 rather membranous drupes, about the size of a pea, each containing one erect seed.

North-Western India; Eastern Himalayas; Nepal; South China. The bark is very bitter, and is used in native medicines as a tonic and stomachic. It is imported into Bengal from the hills, and is sold under the name of "Bharangi." The root is, according to Royle, as bitter as the Quassia of the West Indies.

2. *P. javanica*, Blume Bijdr. Fl. Nederl. Ind. 247; Benn., Plant. Jav. Rar. 197, t. 41; Planch. in Hook. Jl. Bot. v. 573. A moderate-sized tree. Leaves of 3–7 leaflets, much thicker and often larger than in *P. quassioides*; leaflets ovate or obovate, quite entire, with a thickened margin, ending abruptly in a blunt point. Flowers in axillary often rather dense panicles. Calyx-segments, petals, and stamens 4; the petals persistent, much enlarged, and greatly thickened in fruit. Drupes strongly reticulated.

Eastern Bengal; Khasia Mountains; Malaya; Java. The form from the Khasia Mountains has smaller leaves, and approaches more nearly to *P. quassioides* in habit. Bennett's *P. nepalensis* (Pl. Jav. Rar. 201), "Brucea arbor," Wall. Cat. 7499, from Nepal, is undistinguishable. This tree is everywhere known to the Javanese as an intense bitter; in the western parts of the island its name is "Ki-pait," literally "bitter wood;" in the eastern parts "Patty-lallar" or "fly bane." It is used as a remedy against worms, and in cutaneous eruptions.

3. *P. andamanica*, Kurz. Enum. And. iv. A tree with very smooth branches, closely resembling *P. javanica.* Leaves unequally pinnate; leaflets 5 inches long by 2½ inches broad, oval, rounded, and often unequilateral at the base, acuminate, entire, scarcely thickened at the margin, thinner than in the last species. Panicles axillary, rather lax. Calyx-segments, petals, and stamens 4; one or more of the petals of the male flowers with two large glandular dots. Fruit unknown.

South Andaman Islands. Properties unknown.

4. Brucea, *Mill.*

Bitter trees or shrubs. Leaves very large, unequally pinnate. Flowers very small, in a large number of very small cymes arranged in axillary panicles. Calyx minute, 4-partite, imbricate. Petals 4, minute, linear, imbricate. Disc 4-lobed. Stamens 4, inserted beneath the disc; filaments naked. Ovary deeply 4-lobed, or carpels 4, entirely free; styles nearly or quite distinct. Drupes 4, entirely free, ovoid, somewhat fleshy. Seed solitary, exalbuminous.

This genus includes six species, distributed over Tropical Asia, Africa, and Australia. Although partaking of the bitter properties of the order, I am unaware of any species being used officinally, except the African *B. antidysenterica*, already alluded to.

1. *B. sumatrana*, Roxb. Fl. Ind. i. 449; DC. Prodr. ii. 88. A shrub with bitter and somewhat fetid properties. Leaves often more than a foot long, covered with a dense yellow pubescence, especially in the veins and beneath; leaflets numerous, very coarsely dentate, the lowermost pair sometimes again pinnate. Panicles axillary; rachis very long, yellow-pubescent, the minute flowers collected into rather distant small cymes, usually hermaphrodite. Calyx very minute. Petals longer than the calyx-segments, linear-obovate. Stamens 4, inserted beneath the disc; filaments short, not exceeding the petals in length. Ovary 4-lobed. Drupes 4, 1-seeded; 2 lines long by 1½ lines broad, black.

Eastern Peninsula; Assam; South China; Ceylon; Eastern Archipelago; Philippines; Tropical Australia.

2. *B. mollis*, Wall. Cat. 8483. A bitter shrub. Leaflets larger than in *B. sumatrana*, 3 inches long by 2 inches broad, lanceolate, acute, entire, pubescent or nearly glabrous. Panicles axillary; rachis pubescent or nearly glabrous; secondary cymes often many-flowered. Petals linear, longer than the stamens. Drupes 4, much larger than in *B. sumatrana*, 4 lines long by 3 lines broad, ovoid, brown.

Sikkim; Bhotan; Khasia Mountains; Silhet.

5. Eurycoma, *Jack.*

Small trees with bitter bark. Leaves very large, coriaceous, pinnate, with entire leaflets. Flowers polygamous, in much branched sub-terminal hairy panicles. Calyx minute, 5-toothed, valvate. Petals 5, induplicate-valvate. Disc absent. Stamens in male and hermaphrodite flowers 5, smaller in the latter; filaments attached to the base of the petals. Ovary 5-partite, free; styles 5, connate; stigmas distinct. Drupes 3–5, stipitate. Seed solitary, pendulous, exalbuminous.

Two or three species, confined to the Eastern Peninsula, Eastern Archipelago, and the Philippine Islands. Like the last, the species of this genus do not appear to have been used medicinally, although possessing the properties of the order.

1. *E. longifolia*, Jack. in Roxb. Fl. Ind. (ed. Wall.) ii. 307. DC. Prodr. ii. 86; Planch. in Hook. Jl. Bot. v. 584. *E. merguensis*, Planch. l. c. *E. tavoyana*, Wall. M.S. A tree with very large leaves, a foot or more long, having a large number of coriaceous elliptical acute leaflets, much lighter beneath. Panicles large, spreading, and much-branched, the rachis and pedicels covered with a rufous glandular pubescence. Calyx-segments minute, elliptical, glandular-ciliated. Petals four times as long as calyx-segments, lanceolate-ovate, 2 lines long, ½ line broad, very finely pubescent within and without. Filaments broad, half as long as petals, glabrous, with a ligulate ciliated appendage at base. Drupes hard, ovate, ½-inch long by ⅓-inch broad. I am unable to distinguish Planchon's *E. merguensis*, from the specimen in the Hookerian herbarium, by the alleged character of the filaments; and in other respects it precisely resembles the typical form.

Eastern Peninsula; Andaman Islands; Eastern Archipelago; Philippine Islands.

2. *E. apiculata*, nov. sp.—Leaves very long; leaflets elliptical, ending in an abrupt apiculus, dotted on the lateral veins beneath. Panicles compound, denser than in *E. longifolia*, the rachis and pedicels slightly hairy. Calyx-segments small, ovate, acute, hairy without, but not glandular. Petals ligulate, very narrow, 3 lines long by ½ line broad, glabrous. Filaments very short, ¼–⅓ as long as petals, glabrous, not appendiculate. Fruit unknown.

Penang.

6. Suriana, *Lin.*

Leaves simple, entire. Flowers hermaphrodite. Calyx 5-partite, imbricate, persistent. Petals 5, imbricate. Disc inconspicuous. Stamens 10, of two unequal lengths, 5 sometimes barren. Ovary of 5 free carpels; styles basilar, filiform; ovules 2 in each carpel, lateral. Fruit of 5 or fewer carpels, covered by the persistent calyx, indehiscent, each 1-seeded. Seed ascending, exalbuminous.

1. *S. maritima*, Lin. gen. no. 581; DC. Prodr. ii. 91; W. and A. Prodr. 361. Branches thick, covered with a velvety pubescence. Leaves linear-spathulate, obtuse, velvety. Flowers rather large, terminal, buried in the leaves. Petals yellow, equalling the calyx in length.

The only species, found on all tropical shores. An insipid shrub, with no known useful properties.

7. Harrisonia, *Brown.*

Glabrous spiny shrubs, with compound unequally pinnate or unifoliolate leaves. Flowers arranged in cymes, bracteate, hermaphrodite. Calyx small, 4–5-fid. Petals 4–5, longer than the calyx. Disc hemispherical. Stamens 8–10; filaments with small scales at the base. Ovary globose or 4–5-lobed, 4–5-locular; styles connate or distinct at the base; ovules solitary, pendulous. Fruit consisting of from 2–5 small globose berries. Seed solitary; albumen sparse.

Three to four species, distributed over the Eastern peninsula, China, the Archipelago, Tropical Australia, and Tropical Africa. Of no known useful properties.

1. *H. paucijuga*, Benn. Plant. Jav. Rar. 202, t. 42. *Lasiolepis paucijuga*, Benn. l.c. *L. Bennetii*, Planch. in Hook. Jl. Bot. v. 570. A woody shrub, with

sharp, short, recurved spines (apparently metamorphosed stipules) especially on the lower part of the branches. Leaves unequally pinnate; leaflets 5–9, ovate, entire or crenate, glabrous; rachis broadened between the leaflets. Cymes terminal, of from 8–20 flowers. Calyx persistent; segments very small. Petals lanceolate, glabrous. Filaments longer than the petals, five rather shorter than the other five, all glabrous, with a hairy scale at the base. Styles completely united, hairy. Fruit surrounded by the persistent calyx, of from 2–5 pyrenes. A specimen in the Hookerian Herbarium, from Madura, "Herb. Hort. Bot. Cal. no. 1794," with the leaves trifoliolate, appears distinct, but is too imperfect for determination.

Eastern Peninsula, South China, Java, Philippines.

Tribe II.—Picramneæ.

Ovary entire; 2–5-celled.

8. Balanites, *Delile.*

Spiny small trees or shrubs. Leaves bifoliolate, coriaceous; leaflets entire. Flowers green, in small axillary cymes. Calyx-segments 5, imbricate, deciduous. Petals 5, imbricate. Disc thick, conical. Stamens 10; filaments naked, not appendiculate. Ovary globose, 5-locular; ovules solitary in each loculus, pendulous. Fruit a large, fleshy, oily, 1-seeded drupe. Seed pendulous, exalbuminous.

Two species, one a native of Tropical Asia, the other of Tropical and Northern Africa and Syria.

1. *B. Roxburghii*, Planch. in Ann. Sci. Nat. Ser. iv. t. ii. p. 258. *Ximenia ægyptiaca*, Roxb. Fl. Ind. ii. 257; Wight, Ic. 274. A small tree, 20 feet high, with glabrous or puberulous branches, ending in very strong, sharp, ascending spines. Leaves of two elliptical or obovate, puberulous, entire, coriaceous leaflets. Cymes 4–10-flowered. Sepals and petals ovate, velvety, pubescent. Filaments filiform-subulate. Fruit large, woody, angular, more than an inch long, 1-celled, 1-seeded.

Bombay, Deccan, Sikkim, Eastern Peninsula. Closely allied, if not identical with, *B. ægyptiaca* of North Africa. The flowers are very fragrant. We learn from Col. Drury that the nut is covered with a soft, pulpy substance like soap, bitter to the taste, and with an offensive, greasy smell. The nut itself is very hard, and is used in fireworks. For this purpose a hole is drilled in it, the kernel extracted, and the shell filled with powder; when fired, it bursts with a loud report. In Africa, the wood, which is very hard and of a yellow colour, is used for making furniture, also for firewood. An oil is extracted from the seeds. The unripe drupes are bitter and violently purgative, but when ripe are eaten without any unpleasant consequences. The ryots use the bark medicinally for their cattle. This is one of the few trees which flourish on black soil. Royle, in his 'Himalayan Botany,' remarks that it is interesting to find this plant in the country about Delhi, and in the Dowab as far as Allahabad, especially on the banks of the Jumna, as it serves, with other plants, to show an analogy in the Flora of this part of India with that of Egypt. This was first discovered by Dr. Roxburgh as belonging to the Indian Flora, when he suggested that it should be formed into a new genus rather than be referred to *Ximenia*, and described it as common on the driest and most barren parts of the Circars. It is found only in similar situations in the north of India, and is one of those plants which show the great uniformity of vegetation over a great extent of the plains of India, where he has no doubt [illegible] indigenous. M. Delile supposes that the fruit of this shrub is the "Persea" of the ancients, the "lebakh" of Arabian authors.

A NEW VARIETY OF OPIUM.*

BY P. CARLES.

The author reports that he was requested to determine the value of a specimen of a new variety of opium which has been met with in commerce for some time, and which was said to be obtained from Persia. This opium occurs in the form of conical cakes weighing about a pound avoirdupois, partially covered by the remains of poppy leaves. It is free from seeds of Rumex; its odour differs from that of Smyrna opium, being rather comparable to that of green coffee, and when it is heated an odour of chocolate is exhaled. It is soft like ordinary fresh opium, the softness being due to 5·6 per cent. of moisture. When well dried it is easily powdered, but it is slightly deliquescent. The paste is of a fawn colour, and does not darken upon exposure to the air; and when examined by the naked eye or with the aid of a glass appears fine and very homogeneous. It mixes freely with cold water, without requiring to be much worked up in the liquid, which it only slightly colours.

Whilst Smyrna opium usually yields 49 per cent. of aqueous extract, this variety yields 52 per cent. In this operation it always presents a remarkable peculiarity: when two-thirds of the water has been evaporated in a water-bath, successive crystalline crusts are formed in such a manner that if the liquor be left to cool, a nearly solid mass results, in consequence of the interlacing of the crystals. By treating such a product with water M. Carles separated 1·10 per cent. of pure narcotine.

An analysis of the crude opium, according to the method of Fordos, gave as the mean of two operations —morphine, 8·40 per cent., narcotine, 3·60 per cent., that is to say, a smaller proportion of morphine than that indicated in the Codex as the yield of Smyrna opium.

The facility with which this opium dissolves in water, its deliquescence in air, etc., led M. Carles to suspect its adulteration with honey or glucose. This was rather difficult to decide, as Magnes-Lahens has stated that such a body is present in normal opium, or at least in that from Smyrna. Experiment showed that both varieties evidently reduced the cupric solution, but it was a question whether this reduction was due exclusively to glucose. Fermentation alone would appear to the author capable of accounting for it, considering the multiplicity of products that are contained in opium, a certain number of which belong to the glucose family, and reduce the blue liquor. Parallel experiments were made with the cupric solution and with fermentation. Smyrna opium gave off few bubbles of carbonic acid, and the so-called Persian several cubic centimetres; but there was no concordance between these results and those furnished by the Fehling test, which tends to corroborate the author's suspicion. In any case, M. Carles considers this variety of opium to differ notably from that which was described by Guibourt under the name of Persian opium.

… OF PROPYLAMINE.

In *L'Union Médicale*, March 22, M. E. Perret gives a method of preparing propylamine "always pure and good," a good deal of what has been sold under that name being apparently nothing more than stinking ammoniacal compounds of different kinds. The proceeding consists in setting in fermentation the digestive apparatus of cows, calves, sheep or oxen (after having cut it up and washed it) with four or at most six times its weight of water, and one-fifteenth of carbonate of potash or dry soda, at a temperature of 59° to 64·5° F. during thirty-two to thirty-six hours. The magma is passed through an open wire sieve, and to the liquid obtained is added half its volume of caustic soda (soap-makers' lees at 40°). The mixture is then put into a retort and distilled very slowly. The methylic gas escapes first in great abundance, and the mass swells up considerably; the heat is moderated, and, this reaction ended, propylamine mixed, very slightly however, with methylic and ammoniacal gases, passes over. It is wholly contained in the first eighth part; that is to say, if there be eight parts of the solution, all the base will be in the first part. It is now saturated with hydrochloric acid and the filtered solution is evaporated to dryness. The dry hydrochlorate is pounded with three times its weight of caustic soda (lees at 40°), then distilled in a retort provided with a tube which reaches the surface of distilled water placed in the recipient. The propylamine dissolves in this, and saturates the water; and, when the bubbles pass off at the surface of the water without being dissolved in it, the recipient is changed and fresh water is employed. This solution is clear, limpid, and has an ammoniacal odour, accompanied by a smell of brackish water, which is extremely unpleasant, but passes off quickly. It furnishes all the reactions described by Wertheim, who in 1850 made a research on this base; it crystallizes well with acids, forming definite salts with four equivalents of water. The salts—sulphates, hydrochlorates, and gallates—crystallize with the greatest facility in prisms of four flattened planes, and in brilliant needles. They have no odour, and a fresh flavour which is not disagreeable.

SULPHOMOLYBDATE OF AMMONIA AS A TEST FOR SOME ORGANIC COMPOUNDS.†

BY J. H. BUCKINGHAM.

Among the latest tests for the detection of morphia, a solution of sulphomolybdate of ammonia will be found the most delicate. The beautiful blue colour which it gives when dropped upon that alkaloid, is indeed a striking reaction. It will give, however, a characteristic colour, not only with morphia, but also with many other organic principles.

One of the peculiarities which I noticed while making my experiments was, that when allowed to stand for any length of time in contact with the compound, the solution always became blue. This colour was light or dark, according to whether or not the solution, when first applied, gave a characteristic colour. This change is due to the oxidation of the solution, as all salts of molybdic acid or its compounds, when heated in contact with air, will finally turn blue. This, however, is hastened by the contact of some organic matter or any deoxidising agent.

This test may be prepared by mixing eight grains of molybdate of ammonia with two drachms of sulphuric acid (chemically pure). The milky solution is then heated until it becomes clear, care being taken not to raise the heat too high, or a change will take place.

This solution should be made fresh every time it is wanted for use. Small quantities should be used, as different results may be obtained by increasing the quantities. The following are the reactions with some of the most important alkaloids and other principles.

1. Those which at first produce no colour, but afterwards change to a light blue.

Alkaloids, etc.	First Colour.	Second Colour.	Final Change.
Quinia	Colourless	. . . .	Light blue.
Quinidia	Do.	. . . .	Do.
Cinchonia	Do.	. . . .	Do.
Asparagin	Do.	. . . .	Do.
Strychnia	Do.	. . . .	Do.
Atropia	Do.	. . . .	Do.
Caffeia	Do.	. . . .	Do.

2. Those which at first produce a characteristic colour, and afterwards, with exception of meconin, change to a dark blue.

Alkaloids, etc.	First Colour.	Second Colour.	Final Change.
Santonin	Light purple	. . . .	Dark blue.
Menispermia	Light yellow	. . . .	Do.
Solonia	Yellow	. . . .	Do.
Veratria	Yellow green	Dark brown	Do.
Meconin	Light green	. . . .	Light blue.
Codeia	Green	. . . .	Dark blue.
Narcotina	Yellow green	. . . .	Do.
Phloridzin	Dark blue	. . . .	Permanent.
Salicin	Purple	Blue, then brown red	Dark blue.
Morphia	Dark red	Purple	Do.
Digitalin	Crimson	Purple	Do.
Brucia	Brick red	. . . .	Do.
Aconitia	Light yellow brown	Brown	Do.
Piperina	Brown red	. . . .	Do.
Berberina	Purple	. . . .	Do.
Cubebin	Crimson.	. . . .	Do.

This test gives an easy and delicate method of distinguishing between strychnia and brucia, and also for detecting the adulteration of quinia with either salicin or phloridzin. The first colour produced may be regarded as the real reaction, as the final change is due to deoxidation.

SYNTHESIS OF MARSH-GAS AND FORMIC ACID, AND THE ELECTRIC DECOMPOSITION OF CARBONIC OXIDE.*

BY SIR B. C. BRODIE, BART., D.C.L., F.R.S.,

Late Waynflete Professor of Chemistry in the University of Oxford.

In connection with the investigation on the electric decomposition of carbonic acid gas referred to in a previous communication to the Society, I was led to submit a mixture of hydrogen and carbonic oxide gas to the action of electricity in the induction-tube, the mixed gases being circulated through the tube by means of an apparatus which I will not now describe. A contraction was soon observed to have taken place, which at the end of an hour amounted to 10 cubic centimetres. The rate of contraction steadily diminished, and during the fifth hour of the duration of the experiment amounted to only 2 cubic centimetres. The experiment was stopped, and the gas analysed with the following results in two several analyses:—

I.		II.	
Carbonic oxide	61·65	Carbonic oxide	61·35
Hydrogen	32·16	Hydrogen	32·34
Marsh-gas	6·14	Marsh-gas	6·31
	100·00		100·00

* From the *Medical Record.*

† From the *American Journal of Pharmacy.*

* From the Proceedings of the Royal Society.

A small quantity (about 2 per cent.) of nitrogen was also contained in the gas, together with a trace of oxygen, which have been omitted from the calculation.

The result of this reaction is expressed in the following equation :—

$$CO + 3H_2 = CH_4 + H_2O.$$

This fundamental experiment, which constitutes the basis of a new method of chemical synthesis, susceptible of the most varied applications, and of peculiar interest in reference to the explication of natural phenomena, was commenced by me on the 10th of January last at Oxford, in the laboratory of my friend and successor in the Chair of Chemistry, Professor Odling; and two analyses of the gas were completed, and the results attained in the course of a week from that date.

In a similar experiment made with a mixture of hydrogen and carbonic acid gas, a contraction also occurred, attended with the formation of water. The gas which resulted from the experiment was found to consist (after the absorption of carbonic acid) of hydrogen and carbonic oxide, together with a little marsh-gas. Traces of oxygen and nitrogen were also present. Minute drops, too, of an oily liquid appeared in the tube. This liquid, after the conclusion of the experiment, was dissolved in a small quantity of water. The solution was strongly acid and had a pungent taste. It reduced an alkaline solution of terchloride of gold and an ammoniacal solution of nitrate of silver.

These reactions are the characteristic properties of formic acid, of which we may infer the synthesis to have been effected according to the equation

$$H_2 + CO_2 = H_2CO_2.$$

I may avail myself of the present opportunity to place on record the following important facts in reference to the action of electricity on carbonic oxide gas.

When pure and dry carbonic oxide is circulated through the induction-tube, and there submitted to the action of electricity, a decomposition of the gas occurs, attended with a gradual and regular contraction, which, in the form assumed in my experiments, occurred at the regular rate of about 5 cubic centimetres in an hour. Carbonic acid is formed, and simultaneously with its formation a solid deposit may be observed in the induction-tube. This deposit appears as a transparent film of a red-brown colour, lining the walls of the tube. It is perfectly soluble in water, which is strongly coloured by it. The solution has an intensely acid reaction.

The solid deposit in the tube, in the dry condition before it has been in contact with water, is an oxide of carbon. Samples, however, made in different experiments do not present precisely the same composition; but nevertheless they appear to belong to a certain limited number of forms which repeatedly occur, and may invariably be referred to the same general order or system. This system is, or appears to be, what I may term an homologous series of "oxycarbons," of which the unit of carbon with the weight 12 may be regarded as the first term, and of which the adjacent terms differ by an increment of carbonic oxide (CO) weighing 28, precisely as homologous series of hydrocarbons differ by the increment CH_2 with the weight 14.

I have succeeded in identifying by analysis two at least of these substances, namely, the adjacent terms C_4O_3 and C_5O_4. From this point of view these peculiar bodies are members of a series of oxycarbons analogous in the oxycarbon system to the series of hydrocarbons of which the unit of carbon is the first and the unit of acetylene C_2H_2 is the second term, the oxycarbon C_4O_3 being represented in that series by the hydrocarbon crotonylene C_4H_6, and the oxycarbon C_5O_4 by the hydrocarbon valerylene C_5H_8.

STEARATES OF SODA, AND THEIR EMPLOYMENT IN PHARMACY.*

BY ÉMILE REEB.

As many practitioners disapprove of the liniments which have fatty bodies for their basis, it has been proposed to substitute them by soaps and recently by glyceroles. The former, however, require too much time in their preparation by the pharmacist, and the latter have the inconvenience of containing an organic body (starch) subject to alteration, causing a change in the glycerole itself. The author has, therefore, sought to obtain a substance combining the qualities of the soaps and the glyceroles. This he believes he has found in the stearates of soda; that is to say, in definite compounds of the fatty acid, deprived of the other products of saponification, such as the oleate and other fatty salts of soda. It has also the advantage of allowing exact measurement in its use.

For several years past pharmacists at Strasbourg have with advantage employed stearate of soda in the preparation of opodeldoc. While investigating the subject more fully, M. Reeb's attention has been turned to the neutral stearate hitherto used, and also to the bistearate of soda which has not yet been employed.

These two compounds have the property of dissolving in boiling alcohol of 95°, and forming upon cooling a transparent jelly of the appearance and consistence usually sought for in opodeldoc. But to obtain this result it is necessary that certain proportions should be maintained, for if the quantity of stearate be too great, the jelly, instead of being transparent, becomes milky, full of crystallizations, or even opaque.

The following table shows the maximum proportions necessary to obtain a firm transparent jelly, melting easily at the temperature of the hand. It will be seen that a smaller proportion of the bistearate is required than of the neutral stearate.

	Stearate.	Bistearate.	Caustic Soda.	Alcohol 95°.	Glycerine.
Opodeldoc . . .	2·50	1·50	—	1·00	—
Iodized Soap .	2·00	—	2·00	1·00	—
	—	1·50	2·50	1·00	—
Stearated Glycerine	4·00	3·00	—	—	1·00
Iodized Glycerine	6·00	5·00	—	—	1·00

The preparation of the bistearate requires less caustic soda; 50 grams of caustic soda are sufficient to convert 500 grams of stearic acid into bistearate of soda, but at least 180 to 200 grams are required to produce the same quantity of the neutral stearate. Moreover, being less soluble in the cold than the neutral stearate it is better suited for this class of preparations.

The stearate of soda alone is not sufficient for the preparation of iodized soap; an addition of caustic soda is required, or else the jelly is not formed, and the stearate of soda is deposited from the alcoholic solution in a pulverulent form. The cause of this has not yet been ascertained, but the author thinks it to be attributable to a physical cause rather than to a chemical reaction.

The property which glycerine possesses of being easily absorbed by the skin, induced M. Reeb to attempt the preparation of a gelatinous mass with stearate of soda and glycerine in the place of alcohol. Using the proportions given in the preceding table, he obtained a compound having similar properties to glycerine, and of the consistence of opodeldoc. Increased proportions of the stearate gave products more and more firm up to the consistency of ordinary soap without diminishing their transparency.

In the preparation the powdered stearate is mixed in a mortar with the glycerine. It is then heated to the melting point, the active principle added as a concentrated solution, and the whole strained through cambric and left to cool. The author claims for it the advantage over

---

* From *L'Union Pharmaceutique*, vol. xiv., p 68

soap or glycerine of starch of melting at the heat of the hand; that it is free from an organic body liable to decompose like starch; and that it does not irritate the skin like the alcoholic preparations.

PROFESSOR TYNDALL ON LIGHT.*

(*Continued from p.* 847.)

We have employed as our source of light in these lectures the ends of two rods of coke rendered incandescent by electricity. Coke is particularly suitable for this purpose because it can bear intense heat without fusion or vaporization. It is also black, which helps the light; for other circumstances being equal, as shown by Balfour Stewart, the blacker the body the brighter will be its light when incandescent. Still refractory as carbon is, if we closely examined our voltaic arc, or stream of light between the carbon points, we should find there incandescent carbon vapour. We might also detach the light of this vapour from the more dazzling light of the solid points and obtain its spectrum. This would be not only less brilliant but of a character totally different from the spectra that we have already seen. Instead of being an unbroken succession of colours from red to violet, the carbon vapour would yield a few bands of colour with spaces of darkness between.

What is true of the carbon is true in a still more striking degree of the metals, the most refractory of which can be fused, boiled, and reduced to vapour by the electric current. From the incandescent vapour the light, as a general rule, flashes in groups of rays of definite degrees of refrangibility, spaces existing between group and group which are unfilled by rays of any kind; but the contemplation of the facts will render this subject more intelligible than words can make it. Within the camera is now placed a cylinder of carbon hollowed out at the top to receive a bit of metal; in the hollow I put a fragment of the metal thallium, and now you see the arc of incandescent thallium vapour upon the screen. It is of a beautiful green colour. What is the meaning of that green? We answer the question by subjecting the light to prismatic analysis; here you have its spectrum, and it consists, as you see, of a single refracted band. Light of one degree of refrangibility, and that corresponding to green is emitted by the thallium vapour.

We will now remove the thallium and put a bit of silver in its place. First observe the arc of silver; it is not to be distinguished from that of thallium; it is not only green, like the thallium vapour, but the same shade of green. Are they then alike? Prismatic analysis enables us to answer the question. It is perfectly impossible to confound the spectrum of incandescent silver vapour with that of thallium. Here are two green bands instead of one. Adding to the silver in our camera a bit of thallium we obtain the light of both metals, and you see that the green of the thallium lies midway between the two greens of the silver. Hence this similarity of colour. But you observe another interesting fact. The thallium band is far brighter than the silver bands; indeed, the latter have wonderfully degenerated since the bit of thallium has been put in. They are not at all so bright as they were at first, and for a reason worth knowing. It is the resistance offered to the passage of the electric current from carbon to carbon that calls forth the power of the current to produce heat. If the resistance were materially lessened the heat would be materially lessened, and if all resistance were abolished, there would be no heat at all. Now thallium is a much more fusible and vaporizable a metal than the silver; and its vapour facilitates the passage of the current to such a degree as to render it almost incompetent to vaporize silver. But the thallium is gradually consumed; its vapour becomes less and less; the resistance rises, until finally you see the two silver bands as brilliant as they were at first. The three bands of the two metals are now of the same sensible brightness.

We have in these bands a perfectly unalterable characteristic of these two metals. You never get other bands than these two green ones from the silver, never other than the single green band from the thallium, never other than the three green bands that you have just seen from the mixture of both metals. Every known metal has its bands, and in no known case are the bands of two different metals alike. Hence these spectra may be made a test as to the presence or absence of any particular metal. If we pass from the metals to their alloys we find no confusion. Copper gives us green bands, zinc gives us blue and red bands; brass, an alloy of copper and zinc, gives us the bands of both metals, perfectly unaltered in position or character. But we are not confined to the metals; the salts of these metals yield the bands of the metals. Chemical union is ruptured by a sufficiently high heat, the vapour of the metal is set free and yields its characteristic bands.

The chlorides of the metals are particularly suitable for experiments of this character. Common salt, for example, is a compound of chlorine and sodium; in the electric lamp it yields the spectrum of the metal sodium. The chlorides of lithium and of strontium yield in like manner the bands of those metals. When, therefore, Bunsen and Kirchhoff, after having established by an exhaustive examination the spectra of all known substances, discovered a spectrum whose bands did not correspond to any known bands they immediately inferred the existence of a new metal. They were operating at the time upon a residue obtained by evaporating one of the mineral waters of Germany. In that water they knew the new metal was concealed, but vast quantities of it had to be evaporated before a residue could be obtained sufficient to enable ordinary chemistry to grapple with the metal. But they hunted it down, and it now stands among chemical substances as the metal rubidium. They subsequently discovered a second metal, which they called cæsium. Thus, having first placed spectrum analysis on a safe foundation, they demonstrated its capacity as an agent of discovery. Soon afterward Mr. Crookes, pursuing this same method, added to the list of metals the thallium which yielded that bright monochromatic green band.

This relates to chemical discovery upon the earth, where the materials are in our own hands. But Kirchhoff showed how spectrum analysis might be applied to the investigation of the sun and stars, and on his way to this result he solved a problem which had been long an enigma to natural philosophers. A spectrum is pure in which the colours do not overlap each other. We purify the spectrum by making our slits narrow and by augmenting the number of our prisms. When a pure spectrum of the sun has been obtained in this way it is found furrowed by innumerable dark lines. Four of them were first seen by Dr. Wollaston, but they were afterward multiplied and measured by Fraunhofer with such masterly skill that they are now universally known as Fraunhofer's lines. To give an explanation of these lines was, as I have said, a problem which long challenged the attention of philosophers.

Now, Kirchhoff had made thoroughly clear to his mind the principles which linked together the emission of light and the absorption of light; he had proved their inseparability for each particular kind of light and heat. He had proved for every specific ray of the spectrum, the doctrine that the body emitting a ray absorbed with special energy a ray of the same refrangibility. Consider then the effect of knowledge such as you now possess upon a mind prepared like that of Kirchhoff. We have seen the incandescent vapours of metals emitting definite

* Abstract of a series of lectures delivered in the Cooper Institute, New York, and reported in the *New York Tribune*.

groups of rays; according to Kirchhoff's principle those vapours if crossed by solar light ought to absorb rays of the same refrangibility as those which they emit. He proved this to be the case; he was able by the interposition of a vapour to cut out of the solar spectrum the band corresponding in colour to that vapour. Now, the sun possesses a photosphere, or vaporous envelope; doubtless mixed with violently agitated clouds; and Kirchhoff saw that the powerful rays coming from the solid or the molten nucleus of the sun must be intercepted by this vapour. One dark band of Fraunhofer, for example, occurs in the yellow of the spectrum. Sodium vapour is demonstrably competent to produce that dark band; hence Kirchhoff inferred the existence of sodium vapour in the atmosphere of the sun. In the case of metals which emit a large number of bands, the absolute coincidence of every bright band of the metal with a dark Fraunhofer line raises to the highest degree of certainty the inference that the metal is present in the atmosphere of the sun. In this way solar chemistry was founded on spectrum analysis.

I have now to make plain to you if I can, through the analogy of sound, the physical meaning of emission and absorption. I draw a fiddle-bow across this tuning-fork and it immediately fills the room with a musical sound; this is the radiation or emission of sound from the fork. A few days ago, on sounding this fork, I noticed that when its vibrations were quenched, the sound seemed to be continued, though more feebly; the sound appeared to come from under the table, where stood a number of tuning-forks of different sizes and rates of vibration. One of these, and one only, had been started by the fork, and it was one whose rate of vibration was the same as that of the fork which started it. This is an instance of the absorption of the sound of one fork by the other. Placing two forks thus near each other, sweeping the bow over one of them and then quenching the agitated fork, the other continues to sound. Placing a cent piece on each prong of one of the forks we destroy its perfect synchronism with the other, and then no communication of sound from the one to the other is possible. I will now do with light what has been here done with sound. Placing a tin spoon containing sodium in a Bunsen's flame, we obtain this intensely yellow light, which corresponds in refrangibility with the yellow band of the spectrum. I will send the white light from our lamp through that flame, and prove before you that the yellow flame intercepts the yellow of the spectrum, producing to all intents and purposes a dark Fraunhofer's band in the place of the yellow.

Mentally as well as physically every age of the world is the outgrowth and offspring of all preceding ages. Science proves itself to be a genuine product of nature by growing according to this law. We have no solution of continuity here. Every great discovery has been duly prepared for in two ways; first, by other discoveries which form its prelude, and secondly, through the sharpening by exercise of the intellectual instrument itself. Thus Ptolemy grew out of Hipparchus, Copernicus out of both, Kepler out of all three, and Newton out of all the four. Newton did not rise suddenly from the sea level of the intellect to his amazing elevation. At the time that he appeared the table land of knowledge was already high. He juts, it is true, above the table land as a massive peak; still he is supported by it, and a great part of his absolute height was the height of humanity in his time. It is thus with the discovery of Kirchhoff. Much had been previously accomplished; this he mastered, and then by the force of individual genius went beyond it. He replaced uncertainty by certainty, vagueness by definiteness, confusion by order; and I do not think that Newton has a surer claim to the discoveries that have made his name immortal than Kirchhoff has to the credit of gathering up the fragmentary knowledge of his time, of vastly extending it, and of infusing into it the life of great principles. Splendid results have since been obtained, in relation to which both England and America have played an honourable part; but, splendid as they are, they are but the sequel and application of the principles established in his Heidelberg laboratory by the German investigator.

I have now come almost to the end of my task in this city, and, indeed, in America. My desire has been to show you, with as little break of continuity as possible, the past growth and present aspect of a department of science, in which have laboured some of the greatest intellects the world has ever seen. My friend, Professor Henry, in introducing me at Washington, spoke of me as an apostle; but the only apostolate that I intended to fulfil was to place, in plain words, my subject before you, and to permit its own intrinsic attractions to act upon your minds. In the way of experiment, I have tried to place before you the best which, under the circumstances, could be provided; but I trust that each experiment has had a distinct intellectual value, for experiments ought to be the representatives and expositors of thought—a language addressed to the eye as spoken words are to the ear. In association with its context, nothing is more impressive or instructive than a fit experiment; but, apart from its context, it rather suits the conjurer's purpose of surprise than that purpose of education which ought to be the ruling motive of the scientific mind.

And now a brief summary of our work will not be out of place. Our present mastery over the laws and phenomena of light has its origin in the desire of man to know. We have seen the ancients busy with this problem, but, like a child who uses his arms aimlessly for want of the necessary muscular exercise, so these early men speculated vaguely and confusedly regarding light, not having as yet the discipline needed to give clearness to their insight, and firmness to their group of principles. They assured themselves of the rectilineal propagation of light, and that the angle of incidence was equal to the angle of reflection. For more than a thousand years—I might say, indeed, for more than fifteen hundred years subsequently—the scientific intellect appears as if smitten with paralysis, the fact being that, during this time, the mental force, which might have run in the direction of science, was diverted into other directions.

The course of investigation as regards light was resumed in 1100 by an Arabian philosopher named Alhazan. Then it was taken up in succession by Roger Bacon, Vitellio, and Kepler. These men, though failing to detect the principle which ruled the facts, kept the fire of investigation constantly burning. Then came the fundamental discovery of Snell, that corner-stone of optics, as I have already called it, and immediately afterward we have the application by Descartes of Snell's discovery to the explanation of the rainbow. Then came Newton's crowning experiments on the analysis and synthesis of white light by which it was proved to be compounded of various kinds of light of different degrees of refrangibility.

In 1676 an impulse was given to optics by astronomy. In that year Olaf Roemer, a learned Dane, was engaged at the Observatory of Paris in observing the eclipses of Jupiter's moons. He converted them into so many signal-lamps, quenched when they plunged into the shadow of the planet, and relighted when they emerged from the shadow. They enabled him to prove that light requires time to pass through space, and to assign to it the astounding velocity of 190,000 miles a second. Then came the English astronomer, Bradley, who noticed that the fixed stars did not really appear to be fixed, but described in the heavens every year a little orbit resembling the earth's orbit. The result perplexed him, but Bradley had a mind open to suggestion, and capable of seeing, in the smallest fact, a picture of the largest. He was one day upon the Thames in a boat, and noticed that as long as his course remained unchanged the vane upon his masthead showed the wind to be blowing constantly in the same direction, but that the wind appeared to vary with every change in the direction of his boat. "Here,' as Whewell says, "was the image of his case. The boat was the earth, moving in its orbit, and the wind was the light of a star."

You will immediately understand the meaning of Bradley's discovery. Imagine yourself in a motionless railway train with a shower of rain descending vertically downward. The moment the train begins to move the rain-drops begin to slant, and the quicker the train the greater is the obliquity. In a precisely similar manner the rays from a star vertically overhead are caused to slant by the motion of the earth through space. Knowing the speed of the train, and the obliquity of the falling drops, the velocity of the drops may be calculated; and knowing the speed of the earth in her orbit, and the obliquity of the rays due to this cause, we can calculate just as easily the velocity of light. Bradley did this, and the "aberration of light," as his discovery is called, enabled him to assign to it a velocity almost identical with that deduced by Roemer from a totally different method of observation.

Up to his demonstration of the composition of white light, Newton had been everywhere triumphant—triumphant in the heavens, triumphant on the earth, and his subsequent experimental work is, for the most part, of immortal value. But infallibility is not the gift of man, and, soon after his discovery of the nature of white light, Newton proved himself human. He supposed that refraction and dispersion went hand in hand, and that you could not abolish the one without at the same time abolishing the other. He maintained this opinion to the end of his life, and thus retarded the progress of subsequent discovery. Dolland at length proved that, by combining together two different kinds of glass, you might abolish the colour and still leave a residue of refraction; and he applied this residue to the construction of achromatic lenses—lenses which yield no colour, which Newton thought an impossibility.

But Newton committed a graver error than this. Science, as I sought to make clear to you in our second lecture, is only in part a thing of the senses. The roots of phenomena are imbedded in a region beyond the reach of the senses, and less than the root of the matter will never satisfy the scientific mind. We find, accordingly, in this career of optics the greatest minds constantly yearning to pass from the phenomena to their causes—to explore them to their hidden roots. They thus entered the region of theory, and here Newton, though drawn from time to time toward the truth, was drawn still more strongly toward the error, and made it his substantial choice. His experiments are imperishable, but his theory is dead. For a century it stood like a dam across the course of discovery; but, like all barriers that rest upon authority and not upon truth, the pressure from behind increased, and eventually swept the barrier away. This, as you know, was done mainly through the labours of Thomas Young and his illustrious French fellow-worker, Fresnel.

In 1808 Malus, looking through Iceland spar at the sun reflected from the window of the Luxembourg Palace in Paris, discovered the polarization of light by reflection. In 1811 Arago discovered the splendid chromatic phenomena which we have had illustrated by plates of gypsum in polarized light; he also discovered the rotation of the plane of polarization by quartz-crystals. In 1813 Seebeck discovered the polarization of light by tourmaline. The same year Brewster discovered those magnificent bands of colours that surround the axes of biaxial crystals. In 1814 Wollaston discovered the ring of Iceland spar.

All these effects, which, without a theoretic clue, would leave the mind in a hopeless jungle of phenomena without harmony or relation, were organically connected by the theory of undulation. The theory was applied and verified in all directions, Airy being especially conspicuous for the severity and conclusiveness of his proofs.

The most remarkable verification fell to the lot of the late Sir William Hamilton of Dublin, a profound mathematician, who, taking up the theory where Fresnel had left it, arrived at the conclusion that at four special points at the surface of the ether-wave in double-refracting crystals the ray was divided not into two parts, but into an infinite number of parts; forming at these points a continuous conical envelope instead of two images. No human eye had ever seen this envelope when Sir William Hamilton inferred its existence. Turning to his friend, Dr. Lloyd, he asked him to test experimentally the truth of his theoretic conclusion. Lloyd, taking a crystal of arragonite, and following with the most scrupulous exactness the indications of theory, cutting the crystal where theory said it ought to be cut, observing it where theory said it ought to be observed, found the luminous envelope which had previously been a mere idea in the mind of the mathematician.

But while I have thus endeavoured in these lectures to illustrate before you the power of the undulatory theory as a solver of all the difficulties of optics, do I therefore wish you to close your eyes against any evidence that may arise against it? By no means; we leave it to others to shrink from the contemplation of truth because it may be for the moment disagreeable. You may urge, and justly urge, that a hundred years ago another theory was held by the most eminent men, and that, as the theory then held had to yield, the undulatory theory may have to yield also. This is perfectly logical, but let us understand the precise value of the argument. In similar language a person in the time of Newton, or even in our time, might reason thus: "Hipparchus and Ptolemy, and numbers of great men after them, believed that the earth was the centre of the solar system. But this deep-set theoretic notion had to give way, and the theory of gravitation may in its turn have to give way also." This is just as logical as the first argument. Wherein consists the strength of the theory of gravitation? Solely in its competence to account for all the phenomena of the solar system. Wherein consists the strength of the theory of undulation? Solely in its competence to disentangle and explain phenomena a hundred fold more complex than those of the solar system. Be as sceptical, if you like, regarding the undulatory theory; if your scepticism be philosophical, it will wrap the theory of gravitation in the same great doubt.

Nevertheless this great theory of undulation, like many another truth, which in the long run has proved a blessing to humanity, had to establish, by hot conflict, its right to existence. Great names were arrayed against it. It had been enunciated by Hooke, it had been applied by Huyghens, it had been defended by Euler. But they made no impression. And, indeed, the theory in their hands was more an analogy than a demonstration. It first took the form of a demonstrated verity in the hands of Thomas Young. He brought the waves of light to bear upon each other, causing them to support each other, and to extinguish each other at will. From their mutual actions he determined their lengths, and applied his determinations in all directions. He showed that the standing difficulty of polarization might be embraced by the theory.

After him came Fresnel, whose transcendent mathematical abilities enabled him to give the theory a generality unattained by Young. He grasped the theory in its entirety; followed the ether into its eddies and estuaries in the hearts of crystals of the most complicated structure, and into bodies subjected to strains and pressures. He showed that the facts discovered by Malus, Arago, Brewster, and Bort were so many ganglia, so to speak, of his theoretic organism, deriving from it sustenance and explanation. With a mind too strong for the body with which it was associated, that body became a wreck long before it had become old, and Fresnel died, leaving behind him a name immortal in the annals of science.

(*To be continued.*)

The Pharmaceutical Journal.

SATURDAY, MAY 10, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, *17, Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary, 17, Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE COUNCIL REPORT.

PROBABLY before, or at least as soon as, the present number of the Journal is in the hands of our readers, a copy of the Council's Annual Report will have been sent to all members of the Society, and consequently although the official publication of this document will not take place until the Anniversary Meeting on the 21st inst., it will not be out of place for us to refer to its more prominent features now that the trade in general is more directly affected by the proceedings of the Society than was formerly the case.

In the first place we may state that though the Report of this year is remarkable for its brevity, it is by no means wanting in matter of deep interest and importance. Moreover it may be inferred that the conclusions arrived at as the result of the Council's labours have been such as to command general approval, since the Report opens with a declaration of the advantage ensured by full representation in the governing body of different shades of opinion. We believe that with the exception of those whose occupation would be gone if they did not, under the semblance of criticism, carp and cavil at all that is, there will be few who will fail to appreciate the soundness of the principle involved in the declaration just referred to—few who will not regard its practical recognition as amply compensating for that retardation of results inseparable from the ordeal of discussion which measures must pass through more slowly, when different shades of opinion are represented, than when the governing body is of a more paternal form.

Passing from generalities to particular points in the Report, it must be noticed that there is no decrease in the financial well-being of the Society, while there has been a considerable increase in the numbers of Members, Associates, and Apprentices.

In regard to legislative measures, the Council has the satisfaction of reporting that the Government proposes to act upon its representations as to the desirability of relieving dispensers of medicine from that interference with their daily avocations which results from liability to serve on juries. In like manner, its remonstrances in reference to the wording of a portion of the Adulteration Act resulted in an amendment of the clauses complained of. Lastly, the appointment of several Pharmaceutical Chemists as analysts under this Act may be regarded as the most effectual recognition of the views submitted to the Local Government Board by the deputation from the Council last year. In all these cases it will be evident that the Council has been zealous in furtherance of the interests of the trade in general, and that its action in this direction has been no less successful than its vigilance has been constant.

Passing over the references made in the Report to prosecutions under the Pharmacy Act, and to the late revision of the Registers, as well as to the subject of Provincial Education, which has been found too vague to admit of any organized system being adopted at present, we may mention that the account given of the steady increase in the number of subscribers and amount of subscriptions to the Benevolent Fund, as well as of the mode in which the Fund has been applied, will be calculated, together with the recent discussion on this subject, to augment still more the ranks of its supporters.

Last, though not least, we must refer to the action taken by the Council in regard to the Examinations. The nature of the revised regulations will be fresh in the memory of our readers, and it would be superfluous to dwell either on their importance or on the propriety of seconding the endeavours of the examiners by such regulations, as that requiring candidates for the qualification to carry on the business of a Pharmacist to be of the full age of twenty-one years, and to produce certificates of having been employed for three years by a Pharmaceutical Chemist or Chemist and Druggist, and in dispensing and compounding prescriptions.

JOHN STUART MILL.

THE scientific world will hear with profound regret that Mr. JOHN STUART MILL died of erysipelas on Thursday at Avignon. The blow is all the more poignant because unexpected. Three weeks ago Mr. MILL was in London, and, to the eye of his most intimate friends, seemed in the enjoyment of his wonted good health. The full significance of the loss which his death entails upon science it will take long to realize. His mind, sensitive as it was to so many points of scientific and social interest, was active and prolific to the close. Thirty years have elapsed since his "System of Logic: Ratiocinative and Inductive," marked an epoch in the history of research, and it has now assumed a permanent place in the library of the *savant* and on the bookshelves of the student. Mr. MILL was much more than an abstract reasoner, or an analyst of mental processes. He had made solid acquisitions in science; and while still a lad—he was never at either public school or university—he had earned a high reputation as a botanist, adding not a few varieties and even species to the existing classifications of the British Flora. His controversies with WHEWELL, DE MORGAN, and SPENCER gave evidence of his intimate familiarity with the latest inductions in physics, mathematics, and physiology; while he was an ardent and effective advocate of the addition of scientific subjects to the traditional *curricula* of school and college.

Perhaps the most perfect academic oration ever pronounced was his address to the students of St. Andrew's University on the occasion of his becoming their Lord Rector in 1867. He surveyed the whole realm of culture; and while speaking respectfully of the old subjects of university education, he insisted on the claims of chemistry, physics, and social science to a place in the academic programme. His writings have done more to form the intellectual habits of the rising generation of professional men than those of any other philosopher; and his influence, beautifully catholic and enlightened in all its phases, will be remembered as operative for good at a time when the tendency to "division of labour" was encouraging a narrow specialism in every department of professional life. His many-sided accomplishment and his dispassionate spirit of inquiry were at once a rebuke and a lesson to the self-satisfied expert and "the giant with one idea;" while his large tolerance of every variety of belief—so long as the belief was honest and intelligent—was the characteristic feature of a mind that took nothing on trust and gave a candid and patient hearing to every well-accredited arrival from the fields of scientific research. His loss is of more than national concern. Not only in the country in which he died, but in Germany, Italy, and on the other side of the Atlantic, it will be felt as that of an intellectual guide and pioneer in all that affects the advancement of sound philosophy and the progress of civilization.

THE DINNER AT THE CRYSTAL PALACE.

As the time fixed for ascertaining the exact number of those who will be present at this gathering is next Thursday, the 15th inst., and this is the last opportunity we shall have for reminding our readers of the fact, it may be useful to mention that each Steward is requested to report on that day to the Honorary Secretaries the number of tickets disposed of. Those desirous of obtaining tickets should therefore make application for them as early as convenient before that time. We may add, that there is every reason to believe the Dinner will in no respect fall short of the success attained last year.

THE APOTHECARIES' COMPANY, DUBLIN, AND THE ASSOCIATION OF CHEMISTS AND DRUGGISTS OF IRELAND.

We are informed by the Governor of the Apothecaries' Hall, Dublin, that he has received a communication from the Secretary of the Association of Chemists and Druggists of Ireland, disclaiming on behalf of the members of the Society any responsibility for a letter which appeared in our "Correspondence" columns on the 19th ult., and repudiating the interpretation in that letter of words attributed to Dr. Collins. As there appears now to be a general disposition to cooperate in securing for qualified pharmacists in Ireland a more satisfactory status than they have hitherto occupied, it is to be hoped that nothing will arise to mar the good feeling at present existing between the Apothecaries' Company of Ireland and the druggists of that country.

POPPY CULTURE IN CHINA.

The cultivation of the poppy and the manufacture of opium in China continue to increase, and the quality to improve, judging from the reports of the British Consuls. At the same time it is considered highly improbable that the Chinese product will ever interfere to any extent with the Indian. We read that "the extension of poppy cultivation in Sechuen, Yunnan, and other provinces, cannot but indicate a corresponding increase in the consumption of native opium; but it is improbable that the native growth will ever seriously affect the consumption of the Indian import. Once accustomed to the superior flavour and potency of the latter, no opium-smoker would dream of preferring the native variety, which, in fact, is employed almost exclusively for purposes of adulteration, or consumed by the poorer classes, and relinquished even by them the moment they can afford the higher price of the Indian drug."

The collection of the opium is effected in a very similar manner to what it is in India, the incisions in the poppy-heads, however, instead of being made longitudinally, are transverse, being cut round the entire circumference. "After the collection of the opium, the heads are gathered, and from the seeds they contain, an oil is extracted, which is used in lamps, and is sold for about 3*d.* per lb. An English acre of ground will, in a good year, produce 110 lbs. of seed, which will yield about 50 lbs. of oil."

It is said that the poppy was introduced into the Niuguta district about ten years ago, from the north, the quality now grown being superior to any other of native production.

PHARMACY IN BAVARIA.

The total number of Bavarian pharmaceutical students at the three universities during the recent winter session was—at Munich, 54; Erlangen, 17; Würzburg 34: total, 105. Besides these there were 26 students belonging to other countries. The population of Bavaria is under five millions. If these numbers be compared with those of pharmaceutical students in this country, it will be evident that much remains to be done before England will be on a level with Continental countries in the matter of pharmaceutical education.

It will be seen by an advertisement in another part of this Journal that the office of Dispenser at University College Hospital will shortly be vacant, through the resignation of Mr. William Martindale.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

May 7th, 1873.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

MR. W. SCOTT BROWN, VICE-PRESIDENT.

Present—Messrs. Atherton, Baynes, Betty, Bottle, Frazer, Greenish, Hampson, Hills, Owen, Radley, Sandford, Savage, Schacht, Shaw, Stoddart, Sutton, Urwick, and Williams.

The minutes of the previous meeting were read and confirmed.

Finance Committee.

The report of this Committee was received, and sundry accounts were ordered to be paid. The sum of £2500 new 3 per cents. was ordered to be purchased on the General Fund account. The Auditors' report was read, and the accounts presented were accepted. The audited financial statement was ordered to be published in the usual way.

Mr. Urwick moved that the statement of accounts marked B, prepared by the Finance Committee, and accepted by the Council, be also published. He saw no reason why these accounts should be withheld from the members at large, the Council being only the representatives of the members, and the fullest information being due to their constituents. These details showed what each department was doing, and how its operations affected the position of the Society, and when the question had been mooted of getting rid of some of these departments, it was very desirable that the fullest information should be afforded. The Journal had been valued at £5000 for some years past, and yet, by the accounts published, there appeared to be a considerable loss upon it each year, which was absurd. In the detailed accounts, however, credit being given in the Journal account for the cost of Journals supplied to the members, and postage charged to general account, a very different result is brought out.

Mr. Betty seconded the motion. He said that it was an acknowledged principle that the position of any society, and more especially an important one, must ever be strengthened or weakened by the state of its finances; and he trusted that the accounts which the Council had already accepted, as prepared by the Finance Committee with the aid of a professional accountant, would be published for the information of the members of the Society. Unless very strong reasons were shown to the contrary, they should hesitate before passing a resolution which would put the seal of secrecy upon the real financial position of the Society. The reason why the Committee had in the first instance proposed that the accounts should be presented in another form was this:—it was apparent that in their present form they did not represent the true financial position of the Society at any given time, inasmuch as they merely recorded payments and receipts of money. This is especially illustrated in the Journal department, from the figures relating to which no member of the Council had ever been able to gather the true financial position of the Journal. These more extended accounts, however, give a statement of assets and liabilities, showing the actual loss or profit. It was unfair to charge the Journal account not only with £990, the cost of the Journals supplied in return for subscriptions to the Society, but also with £528 annually for the postage of the same. The Council really adopted this principle at its last sitting by requesting the Finance Committee to credit the Laboratory account with the cost of the education of Bell Scholars; because, although no actual cash passed, there was value received. The question then was whether the old method should be still followed of only giving the receipts and expenditure, or whether the full details apportioned in the manner referred to should be given. He had heard it said that these accounts were confusing, and possibly in this instance they might require explanation; but he might say that there was not a figure which could not be substantiated at the annual meeting either by the Finance Committee, or by the professional accountant whose services had been obtained. Of course, taking five quarters of one account and six quarters in another, the statement must appear somewhat involved on the first occasion, but that would not occur again. There was always a little difficulty during a state of transition, but on the whole he believed it would be a wise act to vote for the publication of the whole details. The cashier was now engaged in going through the books to show the exact amount on which interest had been charged under various heads, and to verify the statements made by the Secretary, on which the amounts charged had been calculated.

Mr. Savage thought it would look very strange to publish two financial statements, one signed by the Auditors and the other not, and showing different results.

Mr. Urwick said the difference was caused by the different principle on which the accounts were made out. For instance, the Auditors gave no credit for the cost of supplying the Journal, but the Committee had done so, and thus produced a different result.

Mr. Savage said he did not in the least object to the fullest details of the accounts being given, but such accounts ought to be presented in so clear a form that everyone could understand them, and in the proposed statement there were many items which he believed would be very difficult of explanation. He proposed, therefore, that the accounts should be published as before on the present occasion, and that, with present experience to aid them, the accounts should be presented next year in an amended and more detailed form. He was not opposed to any amount of details, but he did object to the publication of an imperfect statement.

Mr. Schacht agreed very much with what had fallen from Mr. Savage, and advised the postponement of the fuller statement for another year.

Mr. Betty said the Auditors would never sign a statement of accounts containing estimated amounts, and therefore they would be in the same position next year.

Mr. Williams did not think some of the items, such as rent, interest, etc., apportioned to different departments, were based on such exact calculations as they should be before publication, and feared they would create confusion.

Mr. Schacht proposed the insertion of the word "estimated" in the title of the accounts, and after a considerable amount of discussion, it was decided to put the motion in the following form:—

> "That the statement marked B, with the addition of the word 'estimated' before the words 'Financial statement' be published."

A ballot was demanded, the result being that ten votes were given for and ten against the motion.

The President was thereupon called to give a casting vote, which he did against the motion, saying he believed the detailed accounts as presented would only cause some misunderstandings and difficulty of explanation.

The Amended Bye-Laws.

The Solicitor attended at two o'clock, when the amended bye-laws were put and confirmed in legal form, and a resolution was passed for holding a special meeting of the Members at the conclusion of the Annual Meeting on the 21st inst., to submit them for approval and confirmation by the Society.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Adams, Frank ....Bodiam.
Crisp, Frederick Arthur ....Clapham.

David, John ....Newport, Mon.
Hyne, Harry ....Bristol.
Lincoln, John Thomas...........King's Lynn.
Roberts, William Henry ....Bath.
Stansby, Charles John ....Derby.
Watmore, James ....Wokingham.

Several members, associates, and apprentices who had paid their subscriptions since April 30th, were ordered to be restored to their original status in the Society on payment in each case of a nominal fine. The same course was taken with a former member on paying his arrears of subscriptions and a nominal fine.

ELECTIONS.

HONORARY MEMBER.

Henry Watts, Esq., B.A., F.R.S., was elected an "Honorary and Corresponding Member of the Society."

MEMBERS.

Pharmaceutical Chemists.

The following Pharmaceutical Chemists were elected Members of the Society :—

Adams, Frank ....Bodiam.
Butterfield, Edward ....Brighton.
Candy, John William Gilbert...London.
Crisp, Frederick Arthur ... .Clapham.
Diaper, Albert ....Upper Norwood.
Furmston, Samuel C., jun. ......London.
Hills, Walter........................London.
Hyne, Harry........................London.
Jones, Moses.......................Swansea.
Kendall, Edward Basnipp ......Lincoln.
Lincoln, John Thomas...........King's Lynn.
Parker, John Samuel .. ..Horbling, Folkingham.
Pretty, Charles.....................London.
Roberts, William Henry ....Abergele.
Stiles, Matthew Henry ....Doncaster.
Taylor, John William ....Lincoln.
Thorn, John James ....London.
Watmore, James ....Wokingham.

Chemists and Druggists.

Atkinson, John.....................Wilmslow.
Atkinson, William ....Skipton.
Heward, William ....Beverley.
Kennedy, Alexander ....Tillicoultry.
Rees, John James ....London.
Richards, Samuel ....Tavistock.
Strawson, Vincent ....Liverpool.

ASSOCIATES.

The following, having passed their respective examinations, and being in business, were elected "Associates in Business of the Society:"—

Minor.

Askew, John........................Carnforth.
Bannerman, Charles Alexander. Lytham.
Bell, Richard Edward .. ..Walworth.
Bonnett, Frederick ....Swansea.
Brown, George Matthew.........Southsea.
Burn, Henry ....London.
Carr, George ....Sheffield.
Cartwright, William Bryan......Stratford.
Cordley, William Bains ....Colchester.
Earee, Edwin Thomas ....South Croydon.
Francis, Charles Ernest ....Hulme.
Freestone, Robert Henry ......Bristol.
Greatrex, Thomas James.........Liverpool.
Little, Henry ....London.
Marshall, Austen ....Waltham Abbey.
Sandy, Frederick William ......Walworth.
Saunders, Ernest Clement ......Detroit, U.S.A.
Stubbs, Tyson ....Deal.
Walton, William Henry ....Hull.
West, William .... Bradford.
Whitelaw, James ....Glasgow.

Modified.

Barrow, Francis Clark...........Barrow-in-Furness.
Bates, John Freer..................Didsbury.
Biggleston, Edwin Radford......Canterbury.
Bond, Edward .... Reading.
Burdon, Thomas Austin ....Spennymoor.
Clayton, Daniel Thomas ....Grimsby.
Collett, Charles B. ....Exeter.
Lorimer, John ....London.
Moule, William.....................Redditch.
Murphy, John ....London.
Orme, Alfred John ....Birmingham.
Smith, John Charles..............London.
Turton, Randolph Culwick ......South Lambeth.

The following, having passed their respective examinations, were elected "Associates of the Society:"—

Minor.

Baines, Arthur ....Alsager.
Balkwill, Joseph ....Kingsbridge.
Baxter, William, jun. ....Wisbeach.
Bradshaw, John ....Runcorn.
Branson, Frederick Woodward .Northampton.
Clifford, Thomas Andrews ......London.
Davis, Benjamin ....Leamington.
Edward, William Wales ....Aberdeen.
Fox, Charles Edward ....London.
Graham, William Woodrow ...Dalbeattie.
Herbert, Samuel ....Bristol.
Hodges, Edwin Goodall ....Bristol.
Jenkins, Thomas Morgan ......Merthyr Tydvil.
Kitchen, William...................Kendal.
Laverack, William Henry ......Bradford.
Luke, Tom...........................Penryn.
Lucas, Joseph Michael Mark...Gravesend.
McCullum, Hugh... ....Berwick.
McCormick, Frank Henry ......Cheltenham.
Miller, Kenneth ....Wick.
Neale, John ....Woodbridge.
Paterson, Stephen.................Edinburgh.
Richardson, Thomas Plowman. .Blackburn.
Robertson, John ....Plymouth.
Scott, Thomas Alexander ......London.
Sheriff, George ....South Norwood.
Smith, James William ....Cambridge.
Smithard, Herbert Henry ......Guernsey.
Teebay, John........................Preston.
Wallis, Owen........................Hastings.
Waring, Albert Wynne ....Bedford.
Watson, Horace, jun. ....Laceby, Grimsby.

Modified.

Coates, Richard ....Croydon.
Colledge, William Robert......Newbiggin-by-the-Sea.
James, Henry ....Ross.
Speight, Robert.....................Lincoln.

APPRENTICES OR STUDENTS.

The following, having passed their Preliminary examination, were elected "Apprentices of the Society:"—

Albright, Alfred ....Bootle.
Allison, Edward Arthur ....Hull.
Beach, William Henry...........Penkridge.
Beeby, John ....Falkirk.
Chadwick, John ....Accrington.
Collinson, Frederick William ...Alnwick.
Crowden, Francis ....Keswick.
Eardley, James Furnival.........Hulme.
Gibson, Robert James ....Glasgow.
Harrison, James ....Sunderland.
Howard, Robert ....Clitheroe.
Husband, John Cecil ....Berwick-on-Tweed.
Ingham, Thomas Whittaker ...Rawtenstall.

Jones, David William ....Llandilo.
Law, William Thorburn ....Falkirk.
Miller, Alexander Kenneth......London.
Morgan, Augustus Kinsey ......Newport, Mon.
Naylor, William Arthur H. ...Manchester.
Newbould, John Benson ....Liverpool.
Pasmore, Walter Frank .. ..London.
Pittuck, Frederick W............Helburn-on-Tyne.
Ronca, Alfred ....Upper Norwood.
Savage, John Welch ....Wells.
Sanderson, Thomas Eastwood...Darlington.
Weighill, Thomas Armstrong ...Sunderland.
Will, William Watson .. ..Montrose.

Library, Museum, and Laboratory Committee.

The Report of this Committee was read, including a draft of the Annual Report to be presented at the ensuing Annual Meeting, which, with certain amendments, was received and adopted.

The following books were ordered to be purchased:— Valentine's 'Qualitative Chemical Analysis,' Tome's 'Dental Surgery,' 'Throat Hospital Pharmacopœia,' and 'Skin Diseases Hospital Pharmacopœia.'

A chemical balance was also ordered to be purchased.

Report of Examinations.

The North British Branch.

The President read the report of the deputation which recently visited Edinburgh, expressing generally their satisfaction with the new premises and arrangements, and making certain suggestions for the conduct of the Society's affairs and business in that city. The report was ordered to be entered on the minutes.

The Board of Examiners.

The Secretary reported the death of Mr. John Garle, lately one of the Board of Examiners, and the President also reported the resignation of Mr. Ince in accordance with the advice of his medical attendant.

A resolution was passed accepting the resignation of Mr. Ince, and expressing the thanks of the Council for his many years' services on the Board of Examiners.

Benevolent Fund.

The Report of the Committee was read, recommending the grant of £10 to a Registered Chemist and Druggist in distressed circumstances, and also a similar grant of £10 to the widow of a deceased member. The Report was received and adopted.

The Conversazione.

The minutes of the Committee appointed to make arrangements for the forthcoming Conversazione at the South Kensington Museum, were read and approved.

The Secretary reported that he had received a communication from the Royal Botanical Society granting admission to Professor Bentley's class during the ensuing season.

Certificate of Cambridge University accepted by the Board of Examiners in Scotland in lieu of the Preliminary examination of

Adams, Joseph ....Edinburgh.

Errata.

Page 866, col. i. *for* "three hundred and sixty-one" *read* "three hundred and sixty-two."

For "one hundred and eighty-seven" *read* "one hundred and eighty-eight."

In the result of the Preliminary examination, p. 867, "Raynor, Charles Thomas, of Leicester," omitted, should be equal with "Barlow" and "Corden," lines 24 and 25.

Page 867, of towns at which examinations were held, Leicester should read "5 | 2 | 3."

Page 869, *for* "Salisbury, Madge, James C., 10/6," *read* "Lymington, Madge, James C., 10/6."

Provincial Transactions.

THE NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

A Special Meeting of this Association was held on Monday, May 5th.

The President, Mr. Hester, said the purpose of their Association was the education of its members in pharmaceutical knowledge, and their preparation for the various examinations they had to pass. That they had not failed in their purpose was conclusively shown by the fact that last month two of their members passed the Minor in such a creditable manner, one passing in honours and the other close upon the stars. Both those gentlemen he warmly congratulated, reflecting, as they did, such credit upon the Association. Last week, too, he also noticed with great pleasure the name of one of their number very high up on the Preliminary list; and he had no doubt many others, stimulated by these examples, would go on working till they had also become successful. Nor must they forget that the simple passing of an examination was not their destination, but only a resting-place upon the road. After the Secretary had read the minutes, etc., he should call their attention to a subject which doubtless was present in their minds,—that of a botanical ramble.

Mr. Druce then read the minutes of the previous meeting and a list of donations, including a very interesting and useful series of prescriptions, which contained some specimens of foreign prescribing, through Mr. Evans, from Mr. Babb, of Taunton. Messrs. Sandall and Maxwell, who had kindly acted as examiners, had sent in the result of the late examination:—

Assistants' Examination—Botany.

The President's Prize ....Mr. Owen Wallis.

Apprentices' Examination—Materia Medica, Pharmacy, and Botany.

The Secretary's First Prize ......Jno. Cross.
„ Second Prize......Lewis J. Bird.

The prize offered by Mr. Sutton was postponed.

It was then arranged to have a Botanical Ramble to Olney and Turvey on May 27, 1873.

UNITED CHEMISTS AND DRUGGISTS' SOCIETY OF IRELAND.

The monthly meeting of this Society was held on Monday evening, at 12, Grafton Street.

Mr. J. A. Ray was moved to the chair.

The minutes of the last meeting were read and confirmed, after which the honorary secretary (Mr. W. Hayes) read communications from members of the trade in Cork, Belfast, Armagh, Athy, Warrenpoint, etc., approving the objects of the Society and offering their cooperation.

Mr. C. R. C. Tichborne, Ph.D., F.C.S.L., M.R.I.A., was elected Honorary Member of the Society.

The following gentlemen were elected Members:—Messrs. H. N. Draper (Bewley and Draper) and W. Dobbyn, Belfast.'

The following were elected Associates:—Messrs. Cottingham Walters, J. Beggs, and T. C. Kelly.

After some discussion on certain letters which have appeared in the PHARMACEUTICAL JOURNAL, and other business, the meeting adjourned

BRIGHTON ASSOCIATION OF PHARMACY.

At a meeting of the Brighton Association of Pharmacy, on Friday, May 2nd, at the Hanover Lecture Hall; Mr. W. D. Savage, President, in the chair, the subject of Civil Service Trading was introduced for discussion by Mr. T. Higham.

Having given Professor Rogers's idea of cooperation, he endeavoured to show that trading, as carried on by the Civil Service servants at the present time, is not cooperation at all, as any friend can borrow a ticket and avail himself of its privileges. For many reasons he considered the practice unjust to the ordinary retail trader, and he believed that similar principles of injustice applied to themselves would be stoutly resisted by them, but he hoped the time was not far distant when the very enviable salaries of the officers of the Civil Service would revert to the National Exchequer, and so be shared by the public at large. He then argued that the present system of introducing proprietary articles was not desirable, as it tends to lower the standard of skilled labour by employing porters and errand boys in their production instead of properly qualified assistants. He regretted that the efforts of retailers to cope with these evils had not met with the success they deserved on account of a want of proper organization amongst themselves, and he proposed several remedies to meet the difficulty.

In the discussion which followed Messrs. Savage, Barton, Armitage, Ettles, W. H. Smith, and others took part. Civil Service trading was decidedly objected to because civil servants had many advantages over ordinary retailers, on account of their positions as servants of the State, so that retailers were very heavily handicapped in competition with them. An opinion was also decidedly expressed that all cooperative stores ought to pay property and other taxes, so as to be placed on an equality with other trading bodies, and not on a level with charitable societies. The question was also raised as to who would be responsible for cases of poisoning, etc., that might be expected to arise from the fact of their mixing up groceries, wine, and other trades with the very responsible duties of pharmacy.

A hearty vote of thanks having been given to Mr. Higham, the Chairman called on Mr. W. H. Smith to exhibit a new Laboratory Gas Burner (Wallace's Patent) which was shown to be capable of melting copper wire in the open flame, and by a small arrangement at the tap would produce a luminous, a Bunsen, or a kind of blowpipe-flame at pleasure.

The meeting then concluded by passing a vote of thanks to the Exhibitor.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, 1st May, 1873; Dr. Odling, F.R.S., President, in the chair.

After the usual business of the Society had been transacted, three memoirs were read. The first, by Dr. H. Sprengel, "On a new class of Explosives," gave an account of some new explosives, consisting of two liquids inexplosive by themselves, but which when mixed and fired with a detonating charge, are as effective as nitroglycerine. In the discussion which ensued Professor Abel, of the Royal Arsenal, Woolwich, drew attention to the great difference produced by variations in the mechanical state of the explosive. The other papers were "On Zirconia," by Mr. J. B. Hannay, and "A Note on Pyrogallate of Lead and on Lead Salts," by Mr. W. H. Dewing.

The meeting was finally adjourned until Thursday, the 15th May, when a lecture "On Isomerism" will be delivered by Dr. H. E. Armstrong.

PARIS SOCIÉTÉ DE PHARMACIE.

HYDROCHLORATE OF TRIMETHYLAMINE.

At the meeting of this Society on the 2nd April, M. Petit said that in operating upon twenty-five litres of herring-brine he had obtained 30 grams of hydrochlorate of trimethylamine and 45 grams of chloride of ammonium. An estimation of the chlorine had given 37 per cent., a quantity agreeing with that required by theory; whilst the chlorhydrate obtained by M. Wurtz in decomposing iodide of tetramethylammonium by lime gave 53 per cent., a figure corresponding with the formula of hydrochlorate of monomethylamine.

M. Wurtz said that in the reaction of lime upon tetra methylammonium the three compound ammonias are pro duced, and certainly trimethylamine.

M. Guichard exhibited some large crystals of benzoic acid produced by the slow action of sulphide of carbon upon benzoin, and suggested that sulphide of carbon might present some advantages in the purification of resins.

Dr. de Vry remarked that there were some resins which were not dissolved by sulphide of carbon, instancing that of *Podocarpus cupressina*.

ESTIMATION OF CINCHONAS.

Dr. de Vry communicated some new results obtained by M. Oudemans, Professor at the École polytechnique of the Netherlands, respecting the variations in the rotatory power of an active substance being dependent upon the vehicle in which it is dissolved. Thus cinchonidine, which rotates a beam of polarized light to the left, manifests a very varying degree of energy, according to whether it is dissolved in absolute or dilute alcohol. The same is the case with cinchonine, the dextrogyrous power of which varies between rather wide limits, according as it is dissolved in alcohol or chloroform. In making comparative experiments upon the same body, therefore, it would be necessary always to employ the same solvent. Dr. de Vry also alluded to some unsatisfactory results he had obtained with various cinchonas, in the estimation of sulphate of quinine by the process recently published by M. Carles,—a cinchona which by the usual process yielded 8 per cent. of alkaloid, only yielding him 3·8 per cent. by M. Carles's process.

M. Vigier said that he had frequently adopted the process of M. Carles, and always with good results, and attributed Dr. de Vry's want of success to some defect in the mode of operating.

Dr. de Vry said that to determine the value of a cinchona the rotatory power of the total alkaloids it contained should be determined. If the rotatory power be to the left and with great intensity, the cinchona is good for the manufacture of sulphate of quinine. If the deviation be but slightly to the left, or more particularly if it be to the right, it is unsuitable.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Public Health Bill.

A Bill with the above title was introduced into the House of Commons on the 21st March by Sir Charles Adderley, read a first time, and ordered to be printed. It has now been issued, and among its provisions are the following :—

Clause 3 extends the provisions of the Nuisances Removal Act, 1863, to unwholesome tea and to all milk of any animal suffering from any contagious or infectious disease, as defined by the Contagious Diseases (Animals) Act, 1869, or from any tubercular disease, the person selling the same is, on conviction before a justice, to be liable to a penalty not exceeding *twenty pounds*, and the refunding of the purchase-money.

Clause 5 provides that on complaint made by a medical officer of health, or by any inspector or other officer of a sanitary authority, a justice may grant a warrant to enter any building or part of a building, or other place in which there is reasonable ground for believing that any diseased, unsound, or unwholesome food is kept or concealed, and to search for, seize, and carry it away.

Clause 6 adds to previous definitions of "nuisances," any inhabited house or building without an adequate supply, or access to an adequate supply, of wholesome water ; any inhabited house or building admitting rain or other water so as to be injurious to health ; any well or pump, public or private, likely to be used by human beings for drinking purposes, or for the preparation of human food, the supply of water from which is unwholesome and injurious to health ; any pool, ditch, gutter, watercourse, privy, urinal, cesspool, drain, or ashpit, injurious to health, and any drain inlet not properly trapped ; and any animal kept in such a situation as to be injurious to health.

Clause 13 relates to returns from medical officers of health and poor law medical officers respecting sickness within their respective districts, and as to sickness under treatment in or in connection with any institutions within their respective districts established for the treatment of the sick, and maintained wholly or partly by voluntary subscriptions, or by endowments, or grants from the Consolidated Fund, or by local rates.

Clause 26 provides that "Every sanitary authority shall cause the water supplied for drinking or domestic purposes within its district, whether by itself or by any waterworks company or by any other person, to be analysed at such times and by such person as the Local Government Board may direct. For the purpose of obtaining samples of the water so supplied, any analyst or duly authorized officer of the sanitary authority may enter upon any lands occupied by such waterworks company or person so supplying water and may take and carry away samples of the water so supplied, and any person refusing admission to or obstructing any such analyst or duly authorized officer as aforesaid in the performance of his duties under this section shall, in addition to any other punishment to which he may be subject, be liable to a penalty not exceeding *forty shillings*."

On Thursday, May 8, Sir Charles Adderley moved the second reading of the Bill, and it was intimated that the Government were favourable to the measure, but it was opposed on the ground that it was inexpedient until the laws relating to public health were consolidated, and the discussion was eventually adjourned.

Trade Marks Registration Bill.

A Bill providing for and regulating the Registration of Trade Marks,—a subject concerning which we continually receive requests for information,—was brought in on the 21st of April, when it was read a first time and ordered to be printed. It has been drawn up by Mr. Arthur Peel and Mr. Chichester Fortescue.

The Bill provides that any person who is entitled to the exclusive use of any lawful trade mark, and any person who intends to adopt and use any trade mark which can be adopted for exclusive use by him as a lawful trade mark, may (subject to certain exceptions), whether he is a British subject or not, and whether he is resident or carrying on business or using such trade mark in the United Kingdom or elsewhere, register such trade mark under its provisions. Upon the registry of a trade mark, and so long as such registry remains in force, the registered owner of such trade mark is to be deemed entitled to the exclusive use of such trade mark so far as regards the description of goods to which it is appropriated in the register. No person, however, is to be entitled to have any trade mark registered which in the opinion of the Board of Trade is not or cannot become a lawful trade mark ; or is the name of a person or style of a firm only, unaccompanied by a mark sufficient to distinguish it from the same name or style when used by another person or firm ; or is identical with a trade mark appropriated to the same class of merchandize and belonging to a different owner, and already registered or received by the registrar for registry ; or so nearly resembles such trade mark as to be likely to deceive.

Application for registry is to be made in a prescribed form, and facsimiles of the proposed trade mark are to be deposited with the registrar, who, after examination and publication, is to register the applicant as owner of that particular trade mark. Such registration, however, is to be dependent upon the payment of a fee (five pounds), and only to be in force so long as an annual payment (one pound) is made. If the owner of any registered trade mark fails to pay the annual fee within one month after it is duly demanded by the registrar, the registrar is empowered to strike it out of the register. If within three months after such demand the owner pays the annual fee to the registrar, together with a prescribed additional fee, the registrar may restore such trade mark to the register. If after the lapse of three months and not more than twelve months the Board of Trade be satisfied by the owner that the nonpayment of the fee arose accidentally, or from circumstances beyond the control of the owner, it may make an order restoring such trade mark to the register ; but at the expiration of twelve months from such demand, if the trade mark is not meanwhile restored to the register, the registered owner of such trade mark shall be deemed to have abandoned and to have lost his right to the exclusive use of such trade mark for the description of goods to which it is appropriated in the register.

The registrar of trade marks, on the original registry of a trade mark, and at any time while the registry of such trade mark remains in force, is, on application, to give to the registered owner a certificate, certifying that the trade mark therein specified is at the date of the certificate duly registered.

A person is not to be entitled to have registered more than one trade mark appropriated to the same description of goods ; and various provisions are made for joint proprietorship, transfer, changes of address, additions to trade mark, etc. Falsification of the register, obtaining registry by false representation, and forgery of certificates, are misdemeanours under the Act, punishable by fine and imprisonment, and the necessary proceedings may be conducted in the manner prescribed in the Summary Jurisdiction Acts.

PROSECUTION FOR THE SALE OF ADULTERATED VINEGAR.

At the Blackburn Borough Police Court, on Wednesday, April 30, Mr. John Thomas Hall, chemist and druggist, was summoned on three charges—firstly, for selling on the 25th January last, to Mary McGrath, a cough mixture composed of opium and adulterated with hydrochloric acid; secondly, for selling on the 10th February last, to Superintendent Robert Eastwood, a cough mixture adulterated with hydrochloric acid; and thirdly, for selling to Superintendent Robert Eastwood, on the 10th February last, half a pint of vinegar, the same being adulterated with hydrochloric acid.

Mr. Potts, chief constable, conducted the case for the prosecution; Mr. Clough appeared for the Cambrian Vinegar Company, of Leeds.

The case had its origin in a prosecution, at the Liverpool Spring Assizes, for manslaughter of a child (reported at p. 798), in which the grand jury failed to return a true bill, but called the attention of Mr. Baron Pollock to evidence that tended to show that the vinegar used in a cough mixture which was given to the deceased was adulterated with hydrochloric acid. The judge concurred in the remarks of the jury, and expressed a hope that they would lead to an investigation. Mr. Potts, the chief constable, stated that he had therefore caused to be purchased from the defendant a quantity of vinegar and a quantity of the cough mixture. Both were analysed, and both were found to contain hydrochloric acid. The defendant had declared that he had received the vinegar used in the cough mixture from the Cambrian Vinegar Company, Leeds, and through the chief constable of Leeds, before the case was reported in the newspapers, samples of vinegar were obtained from that company, as for an intending purchaser, consisting of the highest and lowest standards of vinegar. These were analysed at Leeds and Blackburn and found to be unadulterated. Samples of vinegar were also obtained from other customers of the Company, which had been in stock prior to the death of the child, and found to be pure. Mr. Potts then went to the defendant's shop to get a sample of the original vinegar with which defendant said he had prepared the cough mixture. Defendant said that he had finished all the vinegar used in the preparation of the cough mixture. Ascertaining that the defendant had received six casks out of one of which he said he had obtained the vinegar used in the preparation of the cough mixture, he went with Superintendent Eastwood into the defendant's cellar, and there saw a cask marked with the initials of the Company. They saw a quantity of vinegar drawn from that cask. It was analysed, and found to be perfectly free from hydrochloric acid or any deleterious ingredients. He could not tell whether the cask had been previously opened. The defendant accounted for the absence of the casks that he had received from the Company by saying that he had sent them back. That statement was not true, as on the 18th January six casks were sent to him by the Brewery Company, and only one of these casks had been sent back. Mr. Potts said that the difference between the vinegar obtained from the Company's cask, and that alleged by the defendant to have been taken out of the Company's cask, and which was poisonous, could be detected even in the taste. The defendant had stated distinctly that the vinegar he gave to Superintendent Eastwood first, was taken from the same cask as that mixed with the cough mixture was taken from. Notwithstanding the fact that defendant discovered at the inquest that the vinegar, which he alleged was obtained from the Company, was adulterated, he had since that given three successive orders to the Company for the same quality of vinegar.

Some medical evidence was given as to the state of the stomach of the deceased child; and the mother deposed to the purchase of the cough mixture at the defendant's shop.

Professor Railton, analytical chemist, said, on Saturday, the 8th of February, he received from Dr. Martland a jar containing the stomach and other parts of the intestines of a child. The stomach was inflamed. He found an ounce and three-quarters of liquid matter, and on analysing the contents of the stomach he found 26 grains or 3·4 per cent. of hydrochloric acid. He also found thirty-eight hundreds per cent. of morphia, equal to about four grains of opium, in the whole contents of the stomach. He also found a quantity of acetic acid, saccharine matter, and gum. Hydrochloric acid would inflame the stomach. The stomach would not have been found in an inflamed state if the tincture of opium had alone been there. The presence of the acid would be excessively injurious. The mixture ought to have been entirely free from hydrochloric acid.

The Mayor—Would the hydrochloric acid be put in separately?—Witness said hydrochloric acid would be put into the mixture in order to obtain a solution of the morphia of the opium, and to get the most out of the latter. Manufacturers of vinegar would not use hydrochloric acid unless they were great rogues.

By the Mayor—A certain quantity of sulphuric acid was put into vinegar, but that was allowed by law. But no hydrochloric acid was allowed to be put in. The latter acid was put in to represent acetic acid. There was hydrochloric acid in this case to represent 50 per cent. of acetic acid.

The Mayor—Is there not a great deal of vinegar made out of acetic acid?—Witness—Yes; vinegar is dilute acetic acid.

Mr. Potts—But acetic acid has no relation to hydrochloric acid?—Witness—Not the slightest.

The Mayor—There must be no hydrochloric acid?—Witness—Not the slightest.

By the Mayor—There must be no hydrochloric acid in vinegar.

By Mr. Potts—Every bottle of it must be free from that acid. Out of threepence worth of hydrochloric acid 50 gallons of the stuff called vinegar could be prepared. No manufacturer in his senses would use that quantity. He received from Superintendent Eastwood on the 10th February, a bottle of cough mixture. He analysed a portion of that, and found 4·20 per cent. of hydrochloric acid in it. That was substantially an equal proportion to the liquid found in the stomach of the child, with the addition of a little water. On the 10th February he received from Superintendent Eastwood a bottle of vinegar, which he had carefully analysed. He found in the vinegar 4·6 per cent. of hydrochloric acid, 94·9 per cent. of dilute acetic acid, and 0·5 per cent. of sulphuric acid. The 4·6 per cent. of hydrochloric acid ought not to have been there at all. He had analysed samples received from Leeds, from the Company's brewery, and from tradesmen, and found them all free from adulteration. He had also analysed the sample obtained at Mr. Hall's shop, and it was free from adulteration, and was pure vinegar.

By Defendant—Could not say what was the quality of the vinegar obtained from Leeds. He knew nothing about where the samples came from when he analysed them, or what quality they were, or what the analysis was for. He merely returned the analysis as he found it.

Mr. Potts said the vinegar obtained from Leeds was of the highest and lowest brands.

Superintendent Eastwood said he was present at the coroner's inquest on the 10th of February, and the defendant gave evidence. He then stated that the cough mixture was composed of vinegar, treacle, sugar, oxymel of squills, and tincture of opium flavoured with mint, and that he made it himself in quantities of two gallons at a time. He said he put an ounce and a half of laudanum to the two gallons, and that these were all the ingredients he put in. Subsequently witness obtained some of the cough mixture from the defendant, and took it to Mr. Railton, and also a quantity of vinegar, which Mr. Railton had stated contained hydrochloric acid. On the 2nd April he went with Mr. Potts to the defendant's shop, and asked him if he had any of the vinegar out of which the cough mixture had been prepared left. He said he had not. Witness said that he wanted a pint of vinegar, and accompanied the defendant down the cellar when he went to draw it. He saw the defendant draw the vinegar from a cask that was branded with the initials C.V.C. (Cambrian Vinegar Company.) Mr. Railton had sworn that that vinegar was pure. Defendant said the vinegar of which he had made the cough mixture was not drawn from that particular cask, but from one of six that he had got from the Company since the inquest was held. Defendant, when asked to account for the other casks, said he had sent them back. He at the same time showed the invoices, showing that the Company had sent him six casks on the 18th January. According to those invoices, defendant's statement as to his making the cough mixture out of the casks sent on the 18th of January could not be true.

Mr. James Brodie said he was manager for the Cambrian Vinegar Company, at their branch establishment, Leeds. He had done business with the defendant in several cases. The copy (produced) was a correct copy of the invoice sent to the defendant on the 18th January last. The six casks would be sent to the defendant on the 18th January, the same day as the invoice. The Company had got one of the casks back. The others had not been sent back. They always acknowledged the receipt of casks. The Company brewed five qualities of vinegar. They did not use any hydrochloric acid in the manufacture of their vinegar. If they did use that acid, he would know, as it would be his business as manager to direct that it should be put in. On most days he superintended the making of the vinegar and the general work. They had no hydrochloric acid on the premises. They had never had. Richard Milford, the brewer at the works, would know what was put into the vinegar. There was no adulteration whatever in the vinegar sent to the defendant on the 18th of January. He was quite certain of that. The company had never at any time—either on the 18th of January or any other date—supplied to any one vinegar adulterated with hydrochloric acid. Defendant's statement that he had made the cough mixture out of vinegar supplied by them had considerably damaged the company's trade.

Richard Milford said he was the brewer at the Cambrian Company's Vinegar Works, Water Lane, Leeds. It was his duty to attend to the process of making the vinegar. He had never at any time put hydrochloric acid into the vinegar. They had no hydrochloric acid on the premises. He saw the vinegar made, and it was pure brewed malt vinegar, and was not at all adulterated with hydrochloric acid.

By the Mayor—The vinegar was diluted, and different ingredients were used, such as sugar and raisins. Nothing that was deleterious was used.

By Mr. Potts—Nothing that was poisonous or corrosive was ever used in the preparation of vinegar at the Company's works.

The Mayor asked Mr. Railton whether in such a mixture as that described, any chemical action might take place that would produce hydrochloric acid.

Mr. Railton—Certainly not; the chlorine is wanted.

Mr. Clough addressed the Bench in behalf of the Cambrian Vinegar Company, and contended that the evidence adduced proved that the vinegar which had been procured by the defendant from the Company did not contain any deleterious ingredients.

The defendant did not offer any defence, and after a few minutes' consultation,

The Mayor said the Company was entirely exonerated from any blame in the matter. (Addressing defendant): We are very sorry that such a case has been brought against you. I was very much struck with the ignorance you have shown with respect to the nature of medicines. You must know that it is necessary for you to understand what you are dealing with as medicine. My advice to you would be, never to make another cough mixture until you thoroughly understand the constituent parts of it. I should also recommend you to pass an examination before the Chemical Society. We have decided to fine you £5 and the costs in one case, and the other cases are dismissed.

Mr. Potts asked for costs of three analyses, being 10*s.* 6*d.* an analysis.

The Bench granted the application.

Mr. Hall, who had stepped from the box, got up again, and asked the Bench to grant him a case for a superior court.

The Mayor—The best thing you can do is to let the matter drop.

Mr. Hall—I am entirely innocent of it.

The Mayor—It will be the cheapest and the best to let the thing drop.

Mr. Hall then left the box.—*From the Blackburn Times.*

Adulteration of Quinine with Quinidine.

At the Liverpool Police Court, on Wednesday, April 30, William Henry Rowlands, chemist, 195, Vauxhall Road, was summoned for selling a quantity of quinine which was adulterated. The Deputy Borough Solicitor, Mr. Atkinson, prosecuted.

A Corporation officer, named Robinson, said that on the 28th March last he visited the defendant's shop and asked for twenty grains of the purest quinine. The defendant said he did not keep any but the best quality, and gave the witness a packet labelled "quinine sulphate," for which he paid him one shilling. The witness then told the defendant that he was going to take it to the public analyst, and the defendant said he could not get a living by selling genuine drugs; and that the article he had sold was "quinidine," the second extract from the red Peruvian bark.

Dr. Brown, the borough analyst, who was called, said that the article in question contained a considerable amount of an alkaloid of bark, which was not quinine at all. "Quinidine" was not injurious to health, but it would increase the bulk and materially decrease the value.

The defendant pleaded that what he had sold was a mild tonic, and was not detrimental to health.

Mr. Aspinall (magistrate) asked how it was that only one druggist had been summoned? He thought it would have been better to have sent inspectors to half-a-dozen shops in various parts of the town, when they would probably have found matters much the same in each case.

Mr. Atkinson replied that the course suggested had been adopted, and the defendant's was the only case in which any adulteration had been detected.

A fine of 10*s.* and 9*s.* 6*d.* costs was imposed, Mr. Aspinall remarking that it was very gratifying to find that this was the only case.—*Liverpool Daily Post.*

Prosecution under the Adulteration Act.—Important Decision.

On Friday, May 2, at the Clerkenwell Police Court, Mr. William Rance, a dairyman and cowkeeper, Islington, was summoned before Mr. Barker, by an inspector appointed by the Vestry of St. Mary, Islington, under the provisions of the Act to amend the law for the prevention of adulteration of food and drink and of drugs, to answer complaints "for that he, being a dairyman and milk seller, did, on the 31st March, unlawfully sell a certain article of food and drink (to wit, milk), knowing the same to have been mixed with another substance, with intent fraudulently to increase its bulk, and without declaring such admixture to the purchaser thereof before delivering the same to the purchaser, contrary to the Act," etc. Mr. John Layton, vestry clerk, of Islington, attended for the prosecution; Mr. Ricketts defended Rance.

The inspector stated that he had purchased the milk at Mr. Rance's shop, and paid 3*d.* for a quart. Dr. Tidy analysed it with the following result :—Specific gravity of milk, 1024; cream, 3·8; total solid per 1000, 84·0; fat (butter), 14·6; casein (cheese), 23 = 37·6; sugar, 39·2; salts, 7·2 = 46·4.

Mr. Ricketts, in both cases, submitted that the milk was known as skim milk, and that, though the cream was removed, that was not an adulteration. He further contended that the defendant had not fraudulently increased the bulk of the milk for the purpose of defrauding the purchaser.

Mr. Barker asked if this case was not similar to one he dismissed, in which the Vestry of St. Luke's were the prosecutors.

Mr. Ricketts said it was, for then it was shown that the milk sold was known as skim milk.

Mr. Barker said that since the case was first before him he had paid particular attention to it, and he came to the conclusion that he could not convict. What the intention of the legislature was it was not for him to say, but he must deal with the case as it stood. By the 3rd section he found that any person who should sell any article of food or drink, or any drug, knowing the same to have been mixed with any other substance with intent fraudulently to increase its weight or bulk, and who shall not declare such admixture to any purchaser thereof before delivering, to be the same and no other, shall be deemed to have sold an adulterated article of food, or drink, or drug, as the case may be, under this Act. Construing these words literally and strictly, as he was bound to do, he did not think he should do right in convicting the defendant. He then dismissed the summons.

Mr. Layton said that after that judgment he should have to ask for a case for the decision of the judges in the superior courts.

Mr. Barker said that for the present he should not grant a case, but Mr. Layton could, if he pleased, apply in writing, as the Act laid down.

On Saturday, Mr. Layton again appeared before Mr. Barker, and said that he had to ask for a case, and he now formally put in his reasons for so doing. The case was applied for in consequence of a resolution of the Vestry, passed on Friday night, the Vestry having determined, should the decision of Mr. Barker be upheld by the court above, to consider the Adulteration of Food Act a dead letter, and at once to discharge their analyst and inspectors and refuse to put the Act in force. At the meeting of the Vestry on Friday night it was stated that the Adulteration Act had been passed on the ground that the vestries had failed to use the permissive laws previously in existence, and now the legislature had given them an Act which, should Mr. Barker's decision be upheld, would be perfectly useless to them. If the law as laid down by his worship was to be carried out the Vestry felt that they should be acting in the dark. If the Act was not to be carried out, or if it had not given the court power enough, then it was not worth the paper it was written upon.

Mr. Barker remarked that this was not the first Act that was not worth the paper it was written upon.

Mr. Layton referred to the first Act of Parliament, in which the word "pure" was used, and he contended that both Acts of Parliament bore on the case. The court had held with Mr. Ricketts that because the cream was taken away from the milk that it was milk still, and that it was not adulterated; but his contention was that reducing the strength of any article was an adulteration within the meaning of the Act.

Mr. Barker said he had decided the case on the facts as submitted to him in the evidence, and had decided that there had been no ingredient added fraudulently to increase the weight or the bulk of the article sold.

Mr. Layton said he might refer the magistrate to the case of cinnamon. There was a process in existence by which all the good of the spice might be extracted, and then the remainder was sold as chips, there being no goodness left in it. He further contended that the presumption of the Act was that if any person went into a shop to purchase an article, he was bound to get what he asked for, and that in a pure, unadulterated state.

Mr. Barker said he would not discuss the matter further then, nor would he then grant the case. He would look through the evidence, and give his decision next week.—*From the Echo and Standard.*

Reviews.

JOURNAL OF THE CHEMICAL SOCIETY: with Abstracts of Chemical Papers published in other Journals. Van Voorst. 1872.

The bulky volume now before us is something more than the journal of a learned society. It contains, indeed, the transactions of the Chemical Society, with all the papers and lectures read before it, but it also presents us with a tolerably adequate account of a year's progress in chemistry in the world at large. It is now rather more than two years since the Chemical Society commenced the task of publishing abstracts of all the original papers bearing on chemical science which appeared in English or foreign periodicals. Dr. Williamson, then the president of the society, was, we believe, the leader of the movement. It appeared to him, and to many other English chemists, that it would conduce much to the advancement of science if those engaged in scientific work could be supplied as early as possible with a condensed account of the original papers published in our own and foreign journals. Every branch of science now-a-days progresses with such rapid strides, and results are so voluminous, and they appear in so many languages, that it is only with the greatest difficulty that either the teacher, the investigator, or the manufacturer can keep abreast of modern discoveries and improvements. This difficulty presses especially on Englishmen. It is no use being blind to the fact that the greater part of scientific work is done on the Continent. For one original investigation published in England probably ten appear in Germany and France, and these foreign papers are quite inaccessible to most English readers. In Germany the necessity of collating the scattered publications of scientific work has long been recognized; their painstaking 'Jahresbericht,' giving short abstracts of the papers of each year, is a work well known. But the volumes necessarily appear so long after the date of the papers which they report, that they furnish rather a past than a contemporaneous history. We may feel proud, then, that our own Chemical Society, by its issue of monthly abstracts, is at the present time supplying more complete and useful reports of chemical science than have hitherto been produced.

The volume before us is made up of the bound monthly numbers of the past year, and is furnished with a copious index both to authors and subjects. The papers and lectures read at the meetings of the Society are many of them of great interest; in addition to these we have in this volume about eleven hundred abstracts of papers which have appeared in other journals. We have examined the volume somewhat carefully, and find that nearly forty periodicals are regularly abstracted, and as some of these, from the second references given, evidently republish papers from other periodicals, the extent of literary surface which comes under contribution is even more extended than at first appears. The periodicals drawn from are German, French, Italian, American, and English; the first two largely predominating. The matter is very methodically arranged. First comes the section of physical chemistry, then inorganic, mineralogical, organic, animal physiology, vegetable physiology and agriculture, analytical, and technical. The titles of the sections sufficiently indicate the wide range of subjects included. The journal is under the editorship of Mr. Watts, a name well known in the literary departments of science. The task of preparing the abstracts is performed by a body of gentlemen whose names are given, and whose initials are appended to their respective work. There is also a large and influential publishing committee which exercises a general superintendence of the journal.

So vast an undertaking as this could not be carried on without great expense. We understand that the British Association has made a grant of £100 to the journal, and that a special subscription has been raised among the fellows of the Society and other friends of science to ensure a trial of the scheme. We hope that as the monthly numbers of the journal get better known the appreciation of the public will relieve the Society of any further financial anxiety. For ourselves we cannot think the library furniture of any active student of science can be complete without the journal and abstracts published by the Chemical Society.

The West Riding Lunatic Asylum Medical Reports. Edited by J. Crichton Browne, M.D., F.R.S.E. Vol. II. London: J. and A. Churchill. 1872.

This is the second annual instalment of a series which promises to be of much value to the practitioner in general and the medico-psychologist in particular.

In no department of the healing art has more progress been made than in the diagnosis and treatment of lunacy. The old system of torture and physical restraint—a relic of those early Christian times when the lunatic was regarded as the victim of demoniacal possession, out of whom the devil had to be scourged—would, if repeated now-a-days, draw down upon the practitioner the vengeance of the law. The cruel apparatus, without which no asylum was held to be complete,—the hobbles which prevented locomotion; the bath of surprise into which the maniac suddenly found himself descending through the treacherous floor, and thereafter immersed to the chin; the travelling of strong-kneed keepers over the chest of the recumbent patient till his ribs were fractured without any external sign,—all these devices are now things of the past, and replaced by a system at once rational, humane, and often efficacious.

Yorkshire, under the auspices of the shrewd and genial Tuke, led the way in this philanthropic revolution, and his traditions are being worthily sustained and developed by the able and energetic physician who presides over the West Riding Asylum. Among other services to the cause of medico-psychology, in theory and in practice, Dr. Crichton Browne, for the last three years, has incited his staff to the observation of such phenomena in his patients,—their special diseases, the treatment by which they seem to benefit, the therapeutic agents which experience has shown to be most efficacious,—as, when clearly recorded, would be of use to the profession at large. These records have been fasciculated in two successive volumes, and constitute a substantial and enduring addition to medical literature. On the principle of *vires acquirit eundo*, the second volume is a distinct improvement on its meritorious predecessor, and, if the ratio of progress be, as we have every right to expect, maintained, the series will be looked for from year to year with progressive curiosity and interest.

In the present volume the articles which will have most attraction for the pharmacist are, Dr. Wilkie Burman's on 'Conia, and its use in Subcutaneous Injection;' Dr. S. Mitchell's on the 'Effects of Ether and Nitrous Oxide combined;' and Dr. Maziere Courtenay's on 'The Use of Opium in the treatment of Melancholia.' All these contain fresh and thought-inspiring matter, and should be studied in view of the approaching revision of the 'British Pharmacopœia.'

Other papers in the volume, of more than average ability, are the editor's on 'Cranial Injuries and Mental Diseases,' which ought to bring its author into court as a medical witness on all occasions when damages are sought from railway companies for obscure injuries to the brain; the 'Mental Symptoms of Ordinary Disease,' by Dr. Patrick Nicol; the 'Electric Treatment of the Insane,' by Dr. Clifford Allbutt; and 'Impairment of Language as the result of Cerebral Disease,' by the editor's father, Dr. W. A. F. Browne, late Commissioner in Lunacy for Scotland. This last is an exceptionally able paper, reasoned and written with much freshness, force, and effect. Throughout the volume, indeed, the literary features are unusually commendable, and reflect the highest credit on its accomplished editor and his trusty *entourage.*

BOOKS RECEIVED.

Report on the New or Fifth Decennial Revision of the United States' Pharmacopœia to the Medical Society of New York. By Edward R. Squibb. New York: Appleton and Co. 1873.

Manual for Medical Officers of Health. By Edward Smith, M.D., LL.B. (Lond.), F.R.S. London: Knight and Co. 1873.

Obituary.

Notice has been received of the death of the following:—

On the 23rd of April, 1873, Mr. William Judd, Pharmaceutical Chemist, of Bath Street, Leamington. Mr. Judd had been a Member of the Pharmaceutical Society since 1859.

On the 2nd of May, 1873, Mr. John Handcock, Chemist and Druggist, of Ossett, near Wakefield. Mr. Handcock had been a Member of the Pharmaceutical Society since 1870.

On the 1st May, 1873, Mr. William Taylor, Chemist and Druggist, 120, Oldham Road, Manchester.

On the 5th May, 1873, Mr. James Bell, Chemist and Druggist, of Broadgate, Grasmere, Westmoreland.

On the 5th of March, 1873, Mr. Thomas Sherlock, Chemist and Druggist, of St. Helen's.

Notes and Queries.

ADHESIVE PLASTER.—M. Eng gives the following formula for the preparation of an adhesive plaster in *L'Union Pharmaceutique*:—

Powdered Gum Dammar	560 parts.
Oil of Sweet Almonds	140 „
Castor Oil	70 „
Glycerine	30 „
Aniline Red	q. s.
Spirit of Ether (equal quantities of ether and spirit	225 to 240 „

The first four ingredients are to be heated in a copper vessel until the resin is fused, the aniline red then added, and when the mixture has half cooled, the spirit of ether is to be poured in. An emulsive liquid is thus formed of the consistence of syrup. A layer is then spread on a material previously coated with mucilage of starch, flour, or isinglass. The court plaster so made is said to be strongly adhesive, bright and shining, and to be free from any irritating effect on the skin. It does not dry up like ordinary court plaster, contains no lead, and may be spread upon calico, silk, gutta percha, or paper. It also allows of the introduction of any substance soluble in alcohol or ether.

The Benevolent Fund.

Sir,—A letter in to-day's Journal seems to warrant me in again troubling you. Although not gifted with the power of writing in the sensational style of a "Subscriber to the Benevolent Fund," I will endeavour to be as concise as possible in my reply.

Since my explanation of my two trifling donations does not seem to have been credited, I will state more plainly the fact, that up to the time of sending my last five shillings, I was ignorant of the amount that was taken yearly from subscriptions and donations and added to the already large fund. My knowledge increasing, my sympathy with the appropriation of donations was not great. I have already stated that the words "long since," in my letter of March 29th, were used to denote that my opinions had not been formed by the writings recently found in the Journal.

I fancy "Subscriber" is a little hasty in calling my scheme a pet one, for if he will again trouble himself to refer to p. 800 of the Journal, he will find that I have another which I advocate, viz., the present system, minus any further accumulation of subscriptions; which improvement is already being, to some extent, adopted. If only carried out to the full, I am pleased to confess that, in my opinion, there would not be many wishing for the novel one.

But just a word in defence of the pet scheme. Can "Subscriber" not see that if Leicester has received more than she has subscribed under the present system, other towns must have received less, and therefore that it is manifestly unfair to judge of the pet scheme as a whole, by a case which is balanced by the surplus which would be in hand in other districts?

"Subscriber's" energy in defence of the Fund has led him into error, for he charges me with having *railed against annuities*. If your readers will kindly peruse my two former notes, I think they will agree with me that I only contended for the *immediate distribution of subscriptions*, caring little what form it took, being equally pleased in seeing either temporary relief granted, or regular annuities conferred.

In regard to Mr. K., should the Council still see fit to grant him £35 per year until elected an annuitant, my case in regard to him will fall to the ground. I fail to find, though, that they took the same course in regard to Messrs. Wilson and Watkins until elected.

Finally, I am sorry that my convictions in regard to the best use of benevolent subscriptions do not allow me to agree with the gentleman I have alluded to.

Walter B. Clark.

Leicester, May 3rd, 1873.

A Trade Grievance.

Sir,—*Apropos* with Mr. Barron's letter in last Saturday's Journal, I, in common with other chemists, have this morning received an elaborate counter-bill from a well-known firm, with an intimation that a supply would be forwarded on receipt of address. Imagining, in my innocence, that the increase of wholesale price of this firm's goods was to be followed by a corresponding advance in their retail prices, which they desired thus to advertise through their agents, I at once cast my eye towards that part of the bill, when, to my surprise, I found no such advance hinted at.

The conclusion to which I at once came was that the advance had been made, not on account of increase of value of ingredients, but in order to cover the expense of their advertising goods, to the serious detriment of the retailer; and that the wiser plan for us to adopt, in self-defence, will be, instead of clamouring for a supply of pretty pictures, to prepare and recommend our own toilet requisites to the total exclusion of others. That such must be the effect of the present rage for advancing the wholesale prices of various proprietary articles, while the retail are advertised as before, is self-evident, unless we are prepared to sacrifice a considerable portion of our returns to the exclusive benefit of the makers.

Query.—Why cannot we agree to act on the same principle as the wholesale dealers, and refuse to sell proprietary articles except at advanced prices in the same ratio?

May 6th, 1873. Equity.

In reference to Mr. Barron's letter on this subject, the representative of Mr. Henry Bond writes to say that he has not advanced the price of his marking ink.

Pharmaceutical Curiosities.

Sir,—If the subject is of any interest, allow me to add one or two of my experiences on the above subject. I have a sort of album of the original orders, and transcribe a few. Amongst the oils I find, in addition to those mentioned by Mr. Williams, oils of fhagone, St. John, beaver, and peacock, all of which are synonyms of ol. viride. I have also oils of Nero, hay, oakem, and Agmai, and by a note I see ol. amygd. dulc. is (or was) the article sold for each. "Purple plum spirit" (*i.e.*, archill) is another oddity I fancy, and the following are (to put it mildly) eccentric as to orthography. For instance,—

"Se. lot. za Juice."
"Turnasais" (Turner's Cerate).
"possits of past" [*sic*] (Phosphorus Paste).
"Qubruck Powder."
"Arse and asnel sope."
"Mulbry suryuph."

And finally,—

"Sa. la. monac."

I could give a long list of similar examples of "free and independent" spelling, but doubt if the information is worth the space it will occupy.

Tauro-gallus.

J. J. Anderson.—Apply at the Royal Veterinary College, Camden Town.

W. C. J.—The dose is large, but not excessive, nor so large as to justify the supposition that there was a mistake.

J. Dibbs.—The latest issue of the 'Medical Directory' is for 1873. It is published by Messrs. J. and A. Churchill, 11, Burlington Street, from whom you could obtain further particulars.

E. Ward Jackson.—You are recommended to communicate the facts of your case to one of our medical contemporaries.

Mr. Baildon is thanked for his communication.

"*Cinchona.*"—(1) 1873. (2) Both the works mentioned are good ones, but we should give the preference to the illustrated edition of Bentham. (3) The subject is not specially mentioned in the synopsis of the examination, and it is probable that nothing would be required beyond what is implied in the identification of officinal plants, an intimate acquaintance with the functions and mode of arrangement of the different organs of plants, and a knowledge of the general principles of classification.

"*Arte et Labore.*"—A chemist and druggist, registered by virtue of his having been in business before the passing of the Pharmacy Act, 1868, may become, by election, a Member of the Pharmaceutical Society. For particulars apply to the Secretary, 17, Bloomsbury Square, W.C.

"*Inquirer.*"—We should recommend you to address your inquiry to the authorities of the Inland Revenue Office, Somerset House.

W. H. Burrell.—All advertisements should be forwarded to the publishers, Messrs. J. and A. Churchill, 11, New Burlington Street.

Inquirer (*Chemicus*) is referred to the regulation respecting anonymous communications.

Communications, Letters, etc., have been received from J. Dibbs, J. Abraham, P. Q., L., "Catta-fiord," "Tauro-Gallus."

THE PHARMACY OF THE UNITED STATES' PHARMACOPŒIA.

BY WILLIAM MARTINDALE, F.C.S.,

Dispenser, and Teacher of Pharmacy to the University College Hospital.

(*Continued from page* 863.)

Aceta.—First in the list comes *Acetum Destillatum.* It is directed to be made by taking eight pints of vinegar, and distilling until seven are obtained. It is not stated in the materia medica list from what source the crude vinegar should be prepared, but that used in the United States is generally made from cider. The distillate contains about 4·5 per cent. of monohydrated acetic acid, and is of the same strength as *acidum aceticum dilutum,* for which also, as I have previously stated, it may be substituted in preparing the official vinegars. It seems unfortunate that this should be allowed, because if dilute acetic acid possess any solvent and preserving action in making these preparations, over and above that of pure water, it possesses it *alone* and without the impurities which are contained along with it in distilled vinegar, such as alcohol, aldehyd, acetone, and acetic ether. These impurities may tend to complicate or obscure the action of that class of preparations when given for certain diseases. The additional cost, however, will, I suppose, commercially preclude the use of such a substitute almost entirely.

Acetum Opii, for which the synonym of "Black drop" is given, is prepared by macerating and percolating opium and nutmeg, both in moderately coarse powder, in diluted acetic acid, and adding a certain proportion of sugar. It contains about one grain of dried opium in six minims. How far it resembles its prototype will be difficult now to ascertain. The other *aceta*—those of lobelia, bloodroot, and squills are uniform both in strength (1 in 8) and in the processes of their preparation; they may be made by either process, percolation pure and simple, or maceration and expression. No addition of spirit is made to any of them.

Acida.—Of these, *acidum sulphuricum aromaticum* contains about one-third more acid than B. P., but less aromatics. The strong acid is mixed gradually with half the alcohol ordered, and allowed to cool. A tincture is made by percolation of the aromatics with the other portion of alcohol, and mixed with the acidulated spirit. This process will tend to the formation of much ethyl-sulphuric acid in the product even at first, which is probably an advantage, as I find that on keeping a little while the B. P. preparation contains it also.

Aloe.—Aloe purificata. This is made by melting socotrine aloes in a water bath, adding one-sixth of stronger alcohol, and straining through a fine sieve, which has just been dipped in boiling water; the strained mixture is then evaporated until it becomes solid on cooling. Socotrine aloes only is so treated, the object being to separate the mechanical impurities, but mere powdering and sifting will, I think, answer that purpose quite as well; the continued application of heat must be injurious to the product. I may here state that there are no *extracts* of aloes corresponding to the B. P. preparations.

Aquæ.—The aromatic waters—*aqua anisi, aqua cinnamomi, aqua fœniculi, aqua menthæ piperitæ,* and *aqua menthæ viridis*—are directed to be made by distilling the fruits, barks, or fresh herbs of these

respectively with water, or by the alternative process of triturating their oils with carbonate of magnesia, adding distilled water gradually and filtering through paper. *Aqua amygdalæ amaræ* is made by the latter process only. Orange-flower and rose waters are ordered to be distilled from the fresh flowers or petals, or in the case of rose water, the petals may be used pickled with salt. In the formula for *aqua camphoræ,* 120 grains of camphor are ordered to be rubbed, first with 40 minims of alcohol, then with half a troyounce of carbonate of magnesia, and lastly, with two pints of distilled water added gradually, and filtered through paper. Dr. Wood states* that camphor water thus made contains three grains of camphor in the fluid ounce; if so, it is an active preparation, and very different from that in the British Pharmacopœia, which does not contain above half a grain in the fluid ounce. With us, camphor water is generally used as a mere *placebo;* the United States' preparation would form a dangerous one. *Aqua acidi carbolici* is made by mixing ten fluidrachms of glycerite of carbolic acid with sufficient distilled water to make a pint. It will thus contain one part of carbolic acid in about sixty-four parts fluid. This will make but a weak lotion, if it be intended to be used as such, and as carbolic acid is soluble in about one-fourth the quantity of water, the utility of the glycerine in the preparation, or of the preparation itself even, is doubtful. A formula for hydrated carbolic acid, directing one part of water to be added to sixteen parts of the crystal, only liquefied by means of heat, would be a much more useful preparation than either the glycerite or the water of carbolic acid. Pharmacists will rarely keep the latter preparations made, and as they require their strength to be adjusted by the prescriber to suit the case he requires them for, pharmacopœial formulæ for them appear to be unnecessary. *Aqua creasoti* is prepared by agitating one fluidrachm of creasote with sixteen fluidounces of distilled water, and filtering through paper. Genuine English creasote is not soluble in four times this quantity of water, nor is it dissolved "wholly and readily in an equal volume of acetic acid," as is stated at p. 28. In the preparation of distilled water we are told to "take of water eighty pints. Distil two pints, *using a tin or glass condenser, and throw them away;*† then distil sixty-four pints, and keep them in well-stopped glass bottles." We have also a process given for making *aqua ammoniæ,* sp. gr. 0·960, direct from chloride of ammonium and lime, but none for *aqua ammoniæ fortior,* sp. gr. 0·900, this is found described in the materia medica list only. Why is not the other made from it by mere dilution?

Testa præparata—prepared oyster shell. Under the head of *Calcium* preparations we find this has a place. Crabs' eyes have departed from the realms of pharmacy, but oyster shells still find favour on the other side of the Atlantic, it appears.

Cerata.—For these we have ten formulæ. The *cerates* are still with them a class of preparations firmer in consistency than *ointments,* and all contain wax as an almost necessary ingredient. *Ceratum*—simple cerate, is composed of eight parts of *lard* and four of *white wax. Unguentum*—simple ointment, has two parts of white wax to the same quantity of lard.

---

* Wood and Bache's 'United States' Dispensatory,' 12th Edition, p. 1001.

† These italics are mine.

American lard, at least that imported into this country, contains less stearin than English lard, so that they may find the need of a firmer basis than pure lard, else I am of opinion that lard, when carefully prepared, is not surpassed by any factitious mixture of fatty substances as a general basis for ointments. *Ceratum cantharidis* corresponds to our *emplastrum cantharidis*, but it contains no suet. In preparing it, it is directed that on the addition of the cantharides, in very fine powder, to the melted basis, by the heat of a water-bath the mixture is to be kept in a liquid state for half-an-hour, stirring it occasionally while digesting, and afterwards constantly, until cool. This is an undoubted advantage, and will assist in the absorption of the cantharidin by the cerate; but, as cantharidin is a volatile principle, I think the temperature of the water-bath should have been limited. There is also *ceratum extracti cantharidis:* an alcoholic extract of the flies is first made, and mixed with a similar basis to the ordinary cerate—it is slightly weaker than this preparation. For Goulard's cerate we have two processes; we have the old London Pharmacopœia formula and an alternative one, in which, by using liniment of camphor and simple cerate, we get the same product by mere admixture. This is also an advantage, as it is an ointment very prone to become rancid,—it can thus be prepared extemporaneously without any difficulty. There are *cerates*—but not *ointments*—of both spermaceti and resin (synonym for the latter—"Basilicon ointment"), and also a *compound resin cerate*, which contains crude turpentine and flax-seed (linseed) oil. *Ceratum saponis* is a mixture of soap-plaster, yellow wax, and olive oil. *Ceratum sabinæ* is a mixture of the fluid extract of savine and resin cerate, heat being applied to drive off the spirit from the extract after its admixture with the melted cerate. *Ceratum zinci carbonatis* is precipitated carbonate of zinc and simple ointment, mixed thoroughly.

Chartæ.—Charta cantharidis corresponds to our *charta epispastica.* The whole of the ingredients are directed to be *boiled gently,* not *digested* merely, before straining and coating the paper with its layer of the basis. *Charta sinapis* has been referred to by Professor Redwood. Ninety grains of black mustard seed in powder are mixed with a solution of gutta percha in chloroform ($1\frac{1}{2}$ in 17 by weight), and painted on a piece of paper four inches square. It is sufficient for a much larger piece. Dr. Squibb states that it is probably an imitation of Mr. Crew's preparation (and Mr. Crew's most likely of Rigollot's). Benzine is used as a solvent of the gutta percha in the preparation of M. Rigollot's paper, as the odour of it is very evident on opening a new packet.

Collodium.—Simple *collodion* is prepared with stronger alcohol (sp. gr. 817) and stronger ether (sp. gr. 728), and contains about one-third more pyroxylon than the B. P. preparation. My experience with the preparation, when required for surgical purposes, has been that one-third *less* than the B. P., not *more*, should be added of the pyroxylon if this latter be the right kind of nitrocellulin. It is stated that by long standing it deposits a layer of fibrous matter and becomes more transparent, and that this layer should be incorporated by agitation before the collodion is used. *Collodium flexile* has been borrowed from us; it is almost exactly the same as that in the British Pharmacopœia. *Collodium cum cantharide* is made by percolating cantharides with stronger ether and then with stronger alcohol: having reserved the ethereal product, the alcoholic percolate is concentrated to a small bulk by spontaneous evaporation; this is then mixed with the ethereal tincture, and pyroxylon added, with *Canada balsam* and *Castor oil,* to render its film flexible when applied.

Confectiones.—Of these there are five. *Confectio aromatica* is a mixture of *aromatic powder* (cinnamon, ginger, cardamom, and nutmeg) with clarified honey. *Confectio opii* is the same, with the addition of one part of powdered opium in about thirty-six of the product. *Confectio rosæ* is prepared with red rose petals in fine powder, sugar, clarified honey, and rose-water. *Confectio sennæ* is much the same as the British Pharmacopœia preparation without the extract of liquorice, but the figs and prunes are merely *digested* along with the purging cassia and tamarind, not *boiled* previously, as it is directed they should be in our process.

Decocta.—The general process of making these is to take one troy ounce of the bruised drug and boil "in a pint of water for fifteen minutes, strain, and add sufficient water through the strainer to make the decoction measure a pint." In *decoction of logwood* the fluid is boiled down to one-half its bulk, and in the *compound decoction of sarsaparilla* the ingredients are boiled for fifteen minutes, and digested for two hours more at 200° F. *after* ebullition, not *before* as in the British Pharmacopœia.

Emplastra.—Emplastrum plumbi is the basis of eleven out of the seventeen official plasters. This lead plaster contains less oil than ours; more minute directions are given for its manufacture than in B. P., but we are not told how, or when to separate, or what to do with, the glycerine that is formed during the process. *Emplastrum resinæ* is a mixture of lead plaster and resin,—*emplastrum saponis*, of lead plaster and sliced soap, the soap being previously brought to a semi-liquid state with water, then added to the melted lead plaster and boiled to a proper consistence. *Emplastrum aconiti* is prepared by mixing an alcoholic extract of aconite root with resin plaster,—*emplastrum arnicæ*, with an alcoholic extract of the flowers and the same basis,—*emplastrum belladonnæ*, by mixing resin plaster with an alcoholic extract of the dried leaves of belladonna. This latter is made by maceration and percolation, and the subsequent distillation and evaporation of the product thus obtained. *Emplastrum assafœtidæ* is directed to be prepared by dissolving assafœtida and galbanum in alcohol, straining, adding lead plaster and yellow wax, and evaporating to a proper consistence. *Emplastrum galbani* contains galbanum, crude turpentine, Burgundy pitch, and lead plaster. *Emplastrum picis Burgundicæ* and *emplastrum picis Canadensis* are merely these resins with the addition of yellow wax; *emplastrum picis cum cantharide,* a mixture of Burgundy pitch and cerate of cantharides. *Emplastrum opii* is made with the extract of opium, Burgundy pitch, and lead plaster. *Emplastrum ferri* is the same as ours—the so-called subcarbonate of iron being used in its preparation. *Emplastrum hydrargyri* and *emplastrum ammoniaci cum hydrargyro* are also much the same as B. P. A mixture of Burgundy pitch and powdered tartar emetic forms *antimonial plaster*, and ammoniacum dissolved in diluted acetic acid, strained and evaporated to a proper consistence, makes the *ammoniac plaster.*

(To be continued.)

CINCHONA CULTIVATION IN ST. HELENA.

BY OSWALD A. READE.

Having recently had a few idle days in the island of St. Helena, I took the opportunity of making some inquiries respecting the result of the attempt to introduce and cultivate cinchona there.

The experiment was commenced rather more than four years since at the recommendation of Governor Elliot who then had charge of the island. The plants were at first placed under the management of Mr. Chalmers, formerly of Kew Gardens, but he had left the island a few weeks previous to my visit. Everyone I spoke to in Jamestown respecting them informed me that they were a complete failure; but as very few had actually seen them, I resolved to go to Diana's Peak where the attempt had been made.

Diana's Peak is the highest point on the island, being nearly 3000 feet high and six miles distant from the town. The south-east trade-winds laden with moisture condense in almost perpetual clouds about the peak, and people living near the base of it informed me that there had not been a fine day for two months. The roads were in such a wretched condition that I was obliged to give up my first excursion in despair, and renew the attempt two days later, though they were then not much better. Steep clayey paths seldom trodden by anything save cattle, into whose tracks we sank over boot-tops, led the way to the foot of the peak. At some remote period steps have been cut out of the rock to enable people to reach the summit, but many of them have been worn away and those which remain are thickly covered with succulent lichens, which render the climbing tedious and dangerous, especially near the summit, where the path, which is only two or three feet wide, is bounded on either side by precipitous slopes. It is along side paths leading from the one I have described that the cinchonas are planted; everything around them betokens rich and luxurious vegetation; tree ferns and their smaller brethren rise everywhere, interspersed with cabbage trees and wild fuchsias springing from a thick carpet of mosses, the whole bound together with brambles and some scrophularious creeper. The past generations of these have left a layer of rich peat, kept moist with the continual clouds and rain, which has formed a good natural bed for the cinchonas.

Originally, more than 1000 were planted out from the hothouse where they were raised, but less than 300 now remain. I was informed by the man who at present has charge of them, that when first planted out they made great progress and throve well, especially *C. succirubra*, some of the leaves of which measured 19 inches long by 15 broad, before the plants were twelve months old. After the roots had penetrated through the layer of peat, however, many of them began to sicken and die, the heavy red clay which underlies it apparently not being suitable for them. It is to this I believe that the loss of so many of the plants is attributed.

Several species were tried, of these *C. succirubra* has succeeded much the best, and the trees of this species which are now alive look healthy and promising.

C. Condaminea also looks healthy, but the wood has grown spindly.

C. Calisaya has not done so well.

The average height of the trees is now about 8 feet. The trunks have formerly been protected for 2 or 3 feet from the ground with a thick covering of moss, but it appears to have been allowed to fall away lately.

The bark has been stripped off some of the dead plants and sent to the civil hospital here, where it was tried and pronounced to be equal in quality to that supplied through the wholesale houses.

It certainly seems as though the cultivation of the red cinchona would be a success in St. Helena, were it well looked after.

NITRATE OF ZINC AS A CAUSTIC.*

BY M. LATOUR.

Up to the present time nitrate of zinc has not been used as a therapeutic agent; yet its causticity approaches nearly that of chloride of zinc, which renders such important services in the surgical art. Less soluble than the chloride, it is still soluble enough to allow of the hope that its application as a caustic will give results sufficiently satisfactory to recommend it to the notice of surgeons, with whom it will rest to decide by clinical experience whether it will be of real service.

Preparation of Nitrate of Zinc.—Pure nitrate of zinc is easily prepared by dissolving commercial zinc, with the aid of heat, in nitric acid diluted with an equal volume of water. It is best to maintain an excess of zinc and to concentrate the liquor down to the production of an ochraceous precipitate due to the formation of a certain quantity of basic nitrate, which carries down the iron usually present in commercial zinc. Boiling water is added to dissolve the salt, and after cooling the liquid is filtered, then evaporated at a gentle heat until a slight ebullition takes place. It is now allowed to cool, when the solution forms a mass; finally, the salt is separated, broken into small pieces, and thrown on to a glass funnel to drain. Thus prepared, nitrate of zinc corresponds to a crystalline salt melted in its water of crystallization, part of which is driven off by a moderate heat. It contains three equivalents of water; it is not completely soluble in water in consequence of the formation of a small quantity of basic subnitrate of zinc, of no importance otherwise. It has the advantage over acetate of zinc of being less deliquescent, while its preparation is more easy and less costly. The salt so obtained is the basis of the following preparations:—

Paste of Nitrate of Zinc.—A caustic paste is prepared by dissolving 100 grams of the nitrate in 50 grams of water, and incorporating with the solution 50 grams of wheaten flour. The mixture is kneaded until perfectly homogeneous, and the result is a convenient paste which retains its humidity. It does not adhere to the fingers, moulds perfectly without contraction, and does not spread at the edges through attracting moisture from the air. When made into cylinders it must not be dried in a stove, or it becomes yellowish in colour and friable, through the oxidation of the gluten of the flour by the decomposition of the nitrate of zinc under the combined influence of heat and water. The paste may, however, be preserved in perfectly dry cylinders by placing it in a well-closed tin box, together with some pieces of quick lime, in such a manner as not to come into contact with the lime.

The preparation of this paste may be shortened by employing a saturated solution obtained by stopping the evaporation of the solution above described when it has, while warm, from 1·450° to 1·580° density; after cooling, its density is from 1·630° to 1·650° One hundred cubic centimetres of this solution would contain 113 grams of the zinc nitrate; a litre of saturated solution would contain 1·130 kilos, and require 555 grams of wheaten flour to form a homogeneous paste similar to that before described. Upon adding the flour to the solution, the mixture at first is liquid, but afterwards it gains consistence

* 'Journ. de Pharm. et de Chimie' [4], vol. xvii. p. 385.

through the hydration of the starch and gluten. The proportions given are the result of numerous experiments.

The saturated solution of nitrate of zinc is strongly caustic, and its coagulating property is intense. It is reported to have been successfully used in cauterizations by Dr. Clement, physician of the Hôtel-Dieu, Lyons.

Caustic Mixture of Nitrate and Chloride of Zinc.—Several attempts were made to combine the nitrate and chloride of zinc in a paste that should possess the advantage of suppleness, and of not contracting when spread over a surface, which is characteristic of that prepared from the nitrate. Such a paste was obtained; it remained soft, spread easily, and did not contract; but in consequence of the avidity of the chloride for water, the slough produced by it has not proved so clean as that produced by the nitrate alone. The following is the formula:—

Chloride of Zinc	50 grams.
Nitrate of Zinc	100 „
Water	80 „

Dissolve by the aid of heat the chloride and nitrate of zinc in the water and allow the solution to cool, when it will have a density of about 1·650°. 100 c.c. are then mixed with 75 grams of flour.

PROFESSOR TYNDALL ON LIGHT.*

(*Concluded from p.* 888.)

One word more I should like to say regarding Fresnel. There are things better even than science. There are matters of the character as well as matters of the intellect, and it is always a joy to those who wish to think well of human nature, when high intellect and upright character are combined. They were, I believe, combined in this young Frenchman. In those hot conflicts of the undulatory theory, he stood forth as a man of integrity claiming no more than his right, and ready to concede their right to others. He at once recognized and acknowledged the merits of Thomas Young. Indeed, it was he and his fellow-countryman, Arago, who first startled England into the consciousness of the injustice done to Young in *The Edinburgh Review*. I should like to read you a brief extract from a letter written by Fresnel to Young in 1824, as it throws a pleasant light upon the character of the French philosopher. "For a long time," says Fresnel, "that sensibility, or that vanity, which people call love of glory, has been much blunted in me. I labour much less to catch the suffrages of the public than to obtain that inward approval which has always been the sweetest reward of my efforts. Without doubt, in moments of disgust and discouragement, I have often needed the spur of vanity to excite me to pursue my researches. But all the compliments I have received from Arago, La Place, and Biot, never gave me so much pleasure as the discovery of a theoretic truth, or the confirmation of calculation by experiment."

This is the core of the whole matter as regards science. It must be cultivated for its own sake, for the pure love of truth, rather than for the applause or profit that it brings. And now my occupation is gone. Still I will bespeak your tolerance for a few concluding remarks in reference to the men who have bequeathed to us the vast body of knowledge of which I have sought to give you some faint idea in these lectures. What was the motive that spurred them on? What the prize of their high calling for which they struggled assiduously? What urged them to those battles and those victories over reticent Nature which have become the heritage of the human race? It is never to be forgotten that not one of those great investigators, from Aristotle down to Stokes and Kirchhoff, had any practical end in view, according to the ordinary definition of the word "practical." They did not propose to themselves money as an end, and knowledge as a means of obtaining it. For the most part, they nobly reversed this process, made knowledge their end, and such money as they possessed the means of obtaining it. We may see to-day the issues of their work in a thousand practical forms, and this may be thought sufficient to justify, if not to ennoble their efforts. But they did not work for such issues; their reward was of a totally different kind. In what way different? We love clothes, we love food, we love fine equipages, we love money, and any man who can point to these as the result of his efforts in life justifies those efforts before all the world. In America and England more especially he is a practical man. But I would appeal confidently to this assembly whether such things exhaust the demands of human nature? Given clothes, given food, given carriages, given money—is there no pleasure beyond what these can cover which the possessor of them would still covet? I need not tell such an assembly that there are joys of the intellect as well as joys of the body, or that these pleasures of the spirit constituted the reward of our great investigators. Led on by the whisperings of natural truth, through pain and self-denial, they often pursued their work. With the ruling passion strong in death, some of them, when no longer able to hold a pen, dictated to their friends the results of their labours, and then rested from them for ever.

Could we have seen these men at work without any knowledge of the consequences of their work, what should we have thought of them? To many of their cotemporaries it would have appeared simply ridiculous to see men whose names are now stars in the firmament of science straining their attention to observe an effect of experiment almost too minute for detection. To the uninitiated they might well appear as big children playing with not very amusing toys. It is so to this hour. Could you watch the true investigator—your Henry or your Draper, for example—in his laboratory, unless animated by his spirit, you could hardly understand what keeps him there. Many of the objects which rivet his attention might appear to you utterly trivial; and, if you were to step forward and ask him what is the use of his work, the chances are that you would confound him. He might not be able to assure you that it will put a dollar into the pocket of any human being living or to come. That scientific discovery may put not only dollars into the pockets of individuals, but millions into the exchequers of nations, the history of science amply proves; but the hope of its doing so is not the motive power of the investigator. It never can be his motive power.

I know what De Tocqueville says of you. "The man of the North," he says, "has not only experience, but knowledge. He, however, does not care for science as a pleasure, and only embraces it with avidity when it leads to useful applications." I wonder whether the great historian and analyst of democratic institutions would repeat these words to-day? What are useful applications? Is man's body alone to be the object and arbiter of what is useful? Is there no nakedness of the mind to be clothed as well as nakedness of the body?—no hunger and thirst of the intellect to satisfy? Surely no two terms were ever so much distorted and misapplied with reference to man in his higher relations than these terms useful and practical. Let us expand the definitions of these terms until they embrace all the needs of man, his highest intellectual needs inclusive. It is specially on this ground of its administering to the higher needs of the intellect; it is mainly because I believe it to be wholesome as a source of knowledge, and as a means of discipline, that I urge the claims of science upon your attention.

But with reference to material needs and joys, surely pure science has also a word to say. People sometimes speak as if steam had not been studied before James Watt, or electricity before Wheatstone and Morse, whereas, in point of fact, Watt and Wheatstone and Morse, with all their practicality, were the mere outcome of antecedent

* Abstract of a series of lectures delivered in the Cooper Institute, New York, and reported in the *New York Tribune*.

forces, which acted without reference to practical ends. This also, I think, merits a moment's attention. You are delighted, and with good reason, with your electric telegraphs, proud of your steam-engines and your factories, and charmed with the productions of photography. You see daily, with just elation, the creation of new forms of industry—new powers of adding to the wealth and comfort of society. Industrial England is heaving with forces tending to this end, and the pulse of industry beats still stronger in the United States. And yet, when analysed, what are industrial America and industrial England? If you can tolerate freedom of speech on my part, I will answer this question by an illustration. Strip a strong arm, and regard the knotted muscles when the hand is clenched and the arm bent. Is this exhibition of energy the work of the muscle alone? By no means. The muscle is the channel of an influence, without which it would be as powerless as a lump of plastic dough. It is the delicate unseen nerve that unlocks the power of the muscle. And without those filaments of genius which have been shot like nerves through the body of society by the original discoverer, industrial America and industrial England would, I fear, be very much in the condition of that plastic dough. At the present time there is a cry in England for technical education, and it is the expression of a true national want: but there is no outcry for original investigation. Still without this, as surely as the stream dwindles when the spring dries, so surely will their technical education lose all force of growth, all power of reproduction. Our great investigators have given us sufficient work for a time; but if their spirit die out, we shall find ourselves eventually in the condition of those Chinese mentioned by De Tocqueville, who, having forgotten the scientific origin of what they did, were at length compelled to copy without variation the inventions of an ancestry who, wiser than themselves, had drawn their inspiration direct from Nature.

To keep society as regards science in healthy play, three classes of workers are necessary: Firstly, the investigator of natural truth, whose vocation it is to pursue that truth, and extend the field of discovery for the truth's own sake, and without any reference to practical ends. Secondly, the teacher of natural truth, whose vocation it is to give public diffusion to the knowledge already won by the discoverer. Thirdly, the applier of natural truth, whose vocation it is to make scientific knowledge available for the needs, comforts, and luxuries of life. These three classes ought to coexist, and interact upon each other. Now, the popular notion of science, both in this country and in England, often relates, not to science strictly so called, but to the applications of science.

Take the electric telegraph as an example, which has been repeatedly forced upon my attention of late. I am not here to attenuate in the slightest degree the services of those who, in England and America, have given the telegraph a power so wonderfully fitted up for public use. Assuredly they earned a great reward, and assuredly they have received it. But I should be untrue to you and to myself if I failed to tell you that, however high in particular respects their claims and quality may be, practical men did not discover the electric telegraph. The discovery of the electric telegraph implies the discovery of electricity itself, and the development of its laws and phenomena. Such discoveries are not made by practical men, and they never will be made by them, because their minds are beset by ideas which, though of the highest value from one point of view, are not those which stimulate the original discoverer. The ancients discovered the electricity of amber, and Gilbert, in the year 1600, extended the force to other bodies. Then followed other inquirers, your own Franklin among the number. But this form of electricity, though tried, did not come into use for telegraphic purposes. There appeared the great Italian, Volta, who discovered the source of electricity which bears his name, and applied the most profound insight and the most delicate experimental skill to its development. Then arose the man who added to the powers of his intellect all the graces of the human heart, Michael Faraday, the discoverer of the great domain of magnets, electricity. Oersted discovered the deflection of the magnetic needle, and Arago and Sturgeon the magnetization of iron by the electric current. The voltaic circuit finally found its theoretic Newton in Ohm, while at Princeton, Henry pushed forward the course of experimental inquiry.

Here you have all the materials employed at this hour in all the forms of the electric telegraph. Nay, more; Gruss, the celebrated astronomer, and Weber, the celebrated natural philosopher, both professors in the University of Göttingen, wishing to establish a rapid mode of communication between the observatory and the physical cabinet of the university, did this by means of an electric telegraph. The force, in short, had been discovered, its laws investigated and made sure, the most complete mastery of its phenomena had been attained, nay, its applicability to telegraphic purposes demonstrated by men whose sole reward for their labours was the noble joy of discovery, and before your practical men appeared at all upon the scene.

Are we to ignore all this? We do so at our peril. For I say again, that, behind all your practical applications, there is a region of intellectual action to which practical men have rarely contributed, but from which they draw all their supplies. Cut them off from this region, and they become eventually helpless. In no case is the adage truer, "Other men laboured, but ye are entered into their labours," than in the case of the discoverer and the applier of natural truth. But now a word on the other side. While I say that practical men are not the men to make the necessary antecedent discoveries, the cases are rare in which the discoverer knows how to turn his labours to practical account. Different qualities of mind and different habits of thought are needed in the two cases; and, while I wish to give emphatic utterance to the claims of those whose claims, owing to the single fact of their intellectual elevation, are often misunderstood, I am not here to exalt one class of workers at the expense of the other. They are the necessary complements of each other; but remember that one class is sure to be taken care of. All the material rewards of society are already within their reach; but it is at our peril that we neglect to provide opportunity for those studies and pursuits which have no such rewards, and from which, therefore, the rising genius of the country is incessantly tempted away.

When the Pilgrim Fathers landed at Plymouth Rock, and when Penn made his treaty with the Indians, the newcomers had to build their houses, to chasten the earth into cultivation, and to take care of their souls. In such a community science, in its more abstract forms, was not to be thought of. At the present hour, when your hardy Western pioneers stand face to face with stubborn Nature, the pursuit of science for its own sake, is not to be expected. The first need of man is food and shelter; but a vast portion of this continent is already raised far beyond this need. The gentlemen of New York, Boston, Philadelphia, Baltimore, and Washington, have already reached that precise condition of well-being and independence when a culture as high as humanity has yet reached may be justly demanded at their hands. They have reached that maturity, as possessors of wealth and leisure, when the investigator of natural truth, for the truth's own sake, ought to find among them promoters and protectors. Among the many grave problems before them they have this to solve, whether a republic is able to foster the highest forms of genius.

You are familiar with the writings of De Tocqueville, and must be aware of the intense sympathy which he felt for your institutions; and this sympathy is all the more valuable from the philosophic candour with which he points out, not only your merits, but your danger. If I in no unfriendly spirit—in a spirit, indeed, the reverse of unfriendly—venture to repeat before you what this great historian and analyst of democratic institutions said of America, I am persuaded that you will hear me out. He wrote some twenty-three years ago, and perhaps would not write the same to-day; but it will do nobody any harm to have his words repeated, and, if necessary, laid to heart. In a work published in 1850, he says: "It must be confessed that, among the civilized peoples of our age, there are few in which the highest sciences have made so little progress as in the United States." He declares his conviction that, had you been alone in the universe, you would speedily have discovered that you cannot long make progress in practical science without cultivating theoretic science at the same time. But, according to De Tocqueville, you are not alone. He refuses to separate America from its ancestral home; and it is here, he contends, that you collect the treasures of the intellect, without taking the trouble to create them.

De Tocqueville evidently doubts the capacity of a democracy to foster genius as it was fostered in the ancient aristocracies. "The future," he says, "will prove whether the passion for profound knowledge, so rare and so faithful, can be born and developed so readily in democratic societies as in aristocracies. As for me," he continues, "I can hardly believe it." He speaks of the unquiet feverishness of democratic communities, not in times of great excitement, for such times may give an extraordinary impetus to ideas, but in times of peace. There is then, he says, "A small and uncomfortable agitation, a sort of incessant rubbing of man against man, which troubles and distracts the mind without imparting to it either animation or elevation." It rests with you to prove whether these things are necessarily so, whether the highest scientific genius cannot find in the midst of you a tranquil home. I should be loath to gainsay so keen an observer and so profound a political writer, but, since my arrival in this country, I have been unable to see anything in the constitution of society to prevent any student with the root of the matter in him from bestowing the most steadfast devotion on pure science. If great scientific results are not achieved in America, it is not to the small agitations of society that I should be disposed to ascribe the defect, but to the fact that men among you who possess the genius for scientific inquiry are laden with duties of administration or tuition so heavy as to be utterly incompatible with the continuous or tranquil meditation which original investigation demands. I do not think this state of things likely to last. I have seen in America willingness on the part of individuals to devote their fortunes in the matter of education to the service of the commonwealth, for which I cannot find a parallel elsewhere.

This willingness of private men to devote fortunes to public purposes requires but wise direction to enable you to render null and void the prediction of De Tocqueville. Your most difficult problem will be not to build institutions, but to make men; not to form the body, but to find the spiritual embers which shall kindle within that body a living soul. You have scientific genius among you; not sown broadcast, believe me, but still scattered here and there. Take all unnecessary impediments out of its way. You have asked me to give these lectures, and I cannot turn them to better account than by asking you in turn to remember that the lecturer is usually the distributor of intellectual wealth amassed by better men. It is not as lecturers, but as discoverers, that you ought to employ your highest men. Keep your sympathetic eye upon the originator of knowledge. Give him the freedom necessary for his researches, not overloading him either with the duties of tuition or of administration, not demanding from him so-called practical results—above all things avoiding that question which ignorance so often addresses to genius, "What is the use of your work?" Let him make truth his object, however unpractical for the time being that truth may appear. If you cast your bread thus upon the waters, then be assured it will return to you, though it may be after many days.

WOMEN'S RIGHTS.

The 'Collective Wisdom' has again rejected by a large majority Mr. Jacob Bright's proposal to invest the ladies with political powers and privileges; and for another year at least, the engaging 'Sex' is to be left out of the scheme of the British Constitution. We are bound to state that, in Blackburn at any rate, the female applicants for electoral rights have sustained this cruel rebuff with almost superhuman stoicism and composure. No mass meetings of householding widows and spinsters have, while we write, been advertised to assemble on the Market-place to demonstrate indignation against those brutal M.P.'s who have made the female claim to the franchise a subject of flippant jest, and by their votes have denied the demand. Mr. Beresford Hope, Mr. Bouverie and Mr. Leatham are still intact and unscarified. This exemplary forbearance under such affront is, in our opinion, evidence either that so self-controlled a section of our community is peculiarly qualified to exercise political influence, or—that these fair ones do not care a rap about it. Supreme heroism, or supreme indifference, are the alternative explanations of Woman's silence under the continuance of Woman's electoral disqualifications. We lean to the latter interpretation. There is absolutely no evidence that the housekeeping ladies of Great Britain really long and pine for the questionable gift of the parliamentary vote, or yearn to share with male humanity the onus and the shock of political conflict, the secrets and the sacrifices of party combination, or the frenzied joy and rage of party triumph and defeat. Why should Mr. Jacob Bright insist upon making the ladies this cumbrous present of a 'White Elephant?' But we need not ask why. It is the pressure of a small but masculine female coterie behind them that impels Mr. Jacob Bright and Professor Fawcett on their course. The hands that framed this Bill are ostensibly the hairy hands of Mr. Jacob, but the voice is the voice of Mistress Jacob. Mrs. Jacob Bright and Mrs. Fawcett, and the insurmountable Miss Becker, are the real movers in this agitation. They compose the Board of Directors of this Woman's Suffrage Association (Limited). The Mr. Jacob Brights and the Professor Fawcetts are but the meek instruments of the masterful female characters that rule their destinies. We do not blame them for pursuing with every show of zeal that work of championing female rights which they dare not, as we can conceive, evade. It is, however, testimony to the invincible force of female pertinacity directed to a given object that although the Englishwomen who want to be active politicians are a mere handful, that little group of strong-minded ones, with no countenance from their sex at large, and with nothing to back them but their own courage and fortitude, have so far progressed as to persuade more than a hundred and fifty members of Parliament to vote for woman suffrage. A full fourth-part of the House has already been 'nobbled' by Miss Becker and her sweet sisterhood, to say nothing of the considerable number who have been reduced to such a condition of fear and trembling that they dare not vote against the Bill, much as they inwardly object to its provisions, but stay away from the House in cowardly concealment when the subject is on. In fact, the political ladies are rife with hope that some year before long they will gain an absolute majority of votes in one of these annual divisions, and then, *væ victis*—woe to the members who have withstood their claims when the ladies get upon the electoral rolls! These fair anglers for statesmen boast that they have already got Mr. Disraeli in their baskets, and that Mr. Gladstone is on the point of being hooked, while other big fish are smelling at the bait. We do not profess to rejoice at ladies taking part in politics, unless they are prepared to take the whole tiresome business off the hands of men entirely; but if it must be, it must, and we trust we know how to accept inevitable fate.

The Pharmaceutical Journal.

SATURDAY, MAY 17, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE BYE-LAWS OF THE SOCIETY.

ON the occasion of the Anniversary Meeting next Wednesday, it will devolve upon the members of the Society who attend the Special General Meeting called for that day, to confirm the alterations of and additions to the Bye-laws which have for some months past been under consideration by the Council. The official notice which appeared last week as an advertisement sufficiently sets forth the particular nature of the alterations and additions to be submitted to the Special General Meeting, for the purposes contemplated by the Society's Charter of Incorporation as well as the Pharmacy Acts, 1852 and 1868. It may be as well, however, to recapitulate here more concisely what are the effects of the changes that have been made.

The first alteration is in clause 10 of section 1, and relates to the conditions under which forfeited status in the Society may be at any time restored by the Council; the payment of the current year's subscription, and of a sum ranging from the half of one year's subscription, up to five guineas being substituted in place of payment of all arrears, and a fine not exceeding half a guinea.

The second alteration is in clause 3 of section 3 and consists simply in the substitution of a permissive for a prohibitory form of stating how the Common Seal of the Society is to be used.

In section 4 the term "Regulation" is now coupled with the term "Bye-law" in regard to the "making, altering, and abrogating" provided for by this section, which is also declared to be applicable to regulations to be prescribed by the Society, in accordance with any statute. In clause 1 of this section there is little alteration beyond the insertion of the word 'regulation" in two places.

The alteration of section 9 by introducing the words "or oftener" empowers the Library, Museum, and Laboratory Committee to meet more than once in every month, as may be requisite.

It is in section 10, relating to examiners, examinations and fees, that the chief and probably the most important alterations have been made. In clause 1 of this section the plural number is substituted for the singular, since there is now more than one Board of Examiners; and while this clause also provides for the continuance of these respective Boards in office until the end of the present year, clause 2 provides that, instead of appointing examiners at the first ordinary Council meeting after the general meeting, the Council shall appoint examiners at its first meeting in December next, and every subsequent December, and that the persons so appointed shall, for the year to commence on the then following first day of January, constitute the Board of Examiners for England and Wales. By this alteration the new Council, from year to year, will have an opportunity of judging as to the fitness and efficiency of the examining Board before being called upon to appoint its members.

In clause 3 of this section the election in like manner of Examiners for Scotland, is provided for by alterations of the same nature as those applying to the appointment of Examiners for England and Wales.

The alteration in clause 4 provides for the meetings of the Boards of Examiners being presided over by either the President or the Vice-President of the Society, when they happen to be present, rather than by both.

The alteration of clause 5 consists simply in cancelling the exceptions to the limitations by age of elegibility for the office of Examiner, and consequently no person of the age of 65 can be made an Examiner.

By the alteration of clause 6, the time which must elapse between the appointment of any person as an Examiner and his ceasing to hold office as a Member of Council is now reduced from one year to six months, but in other respects the exceptions in this clause in favour of the President and Vice-President remain the same.

The only alteration in clause 7 is the substitution of the number fourteen for twelve as the maximum for the Board of Examiners for England and Wales. In clauses 8, 9, 10, and 11, there are no changes, and in clause 12, relating to the examination of persons desiring certificates of competent skill and qualification to be engaged or employed as assistants, as well as to the examination of persons desiring certificates of like qualification to exercise the business or calling of pharmaceutical chemists, the only alteration is the introduction of authority for the acceptance, in the Minor examination, of certificates of having been previously examined in the First examination, and for the acceptance, in the Major examination, of similar certificates of having been previously examined in the Minor examination.

The clauses 13, 14, 15—17, 18, and 19, of this section are unchanged, but an important alteration has been made in clause 16 by adding to it the provision that:—

"After the 31st day of December, 1874, no person shall be admitted to the Major or the Minor Examination who shall not have attained the full age of twenty-one years; and after the 31st day of December, 1876, no person shall be allowed to pass the Major or the Minor Examination unless he shall satisfy the Examiners that for three years he has been registered and employed as an Apprentice or

Student, or has otherwise for three years been practically engaged in the translation and dispensing of prescriptions.

"Persons who have passed the Minor Examination at least three months previously may be admitted to the Major Examination, and all other persons desirous of passing the Major Examination may make application to the Board of Examiners for special leave in that behalf."

THE BELL AND HILLS FUND.

Few of our readers in town or country will have forgotten that in 1869 the presentation of fifty guineas to the Pharmaceutical Conference by Mr. T. H. Hills, in his own name, and in memory of Jacob Bell, was accompanied by a suggestion that the sum of ten guineas should be applied for the purchase of books for the chemists' library at Exeter Those who have taken part in, or watched the proceedings of the Conference in subsequent years will know that the Executive Committee has, since that time, sought to give further effect to Mr. Hills' desire to promote pharmaceutical education, by making a present of books of the same value to the chemists' library in each town visited by the Conference. In this way the Fund had, in course of time, been nearly exhausted, when Mr. Hills last year, with characteristic generosity, supplemented his former gift with the sum of £200 (four Russian Bonds of £50 each).

At the Brighton meeting of the Conference it was unanimously decided, after previous consultation between the Executive Committee and Mr. Hills, that the grant of a sum of £10 for books to any local association in towns where the Conference met should be continued out of the interest arising from these bonds; and that the Executive Committee should from time to time, but not oftener than once in three years, decide when one-fourth of the investment should be sold out, and also decide upon the appropriation of such income, from principal and interest, by granting sums in aid of original research or for the cultivation of pharmaceutical science.

In our report of the proceedings of the Executive Committee of the Conference (p. 916) reference is made to a circular that has been issued in reference to the appropriation of this fund and the rules by which it is to be governed. The plan adopted is the same as that of the British Association, which has successfully promoted the accomplishment of much valuable work. The sum available during the next three years will be about £80, and on the 20th of this month the Committee will be prepared to receive applications for grants in aid either of any original research members of the Conference may desire to undertake in connection with pharmacy, or of the repetition of experimental work which might seem to require further corroboration or inquiry.

These applications must be addressed to the Executive Committee through the Secretaries of the Conference. They are to be accompanied by full particulars as to the proposed investigation and estimates of cost. In other respects the general conditions and rules laid down by the British Association in regard to grants have been adopted.

We trust that this scheme will be efficacious in contributing towards the doing away with that lack of original contributions to the progress of pharmacy, which is not only in itself a reproach to the followers of the art in Great Britain, but also tends to place them in a disadvantageous light as compared with the pharmacists of other countries.

TRADE MARKS' REGISTRATION BILL.

Now that the new Adulteration Act makes it especially desirable both for manufacturers, retailers, and for the public that there should be some trustworthy criterion of the genuineness of various commodities of daily use, the utility of trade marks for that purpose must be evident. But unfortunately trade marks have hitherto had no legal status, though the right to use them has always existed; and though by the Merchandize Marks Act the piracy of a trade mark, known in the market, is made an offence, as well as the false application of any genuine or forged mark, it is in any case necessary to show an intent to defraud.

It is only recently, by the decisions of the Courts that any property in a trade mark has been recognized, and even now the exclusive right to its use depends on its notoriety, while in any suit or prosecution it is still necessary to prove, not only the exclusive use of a trade mark, but also the period during which such use has continued, as well as its notoriety in the market. Frequently it is also necessary to prove that a purchaser has been deceived by the wrongful use of a mark.

The registration of trade marks as proposed by the Bill, of which we gave an abstract last week, would give the wanting statutory status, would prove ownership and furnish a record of the period of use, besides being in itself evidence of notoriety.

Such registration would give a trade mark, as such, an immediate legal character from the time of its first employment. The reference which it is intended that each trade mark shall bear to the register, would furnish at once the means of verifying the title of the person using it, and thus furnish direct evidence of the right to use, of the user, the notoriety of use, the exclusiveness of that right, and the priorities of employment by either of the several litigants.

The proposed Bill would also settle several other questions relating to trade marks and to the articles to which they are applied, such as their place of manufacture, the persons responsible for their manufacture, as well as for their genuineness and character.

Moreover, it would facilitate the prevention of piracies of British trade marks abroad; for although registration of trade marks has been adopted in various parts of Europe, in America, and several British colonies, with the best results, a remedy for such infringement has often been refused abroad in consequence of the absence of reciprocity to foreign manufacturers, from the English law not providing a means for registration of foreign marks here.

It appears, therefore, that the Bill now before Parliament is one calculated to be of great benefit to all classes of traders as well as to the public generally, and for these reasons the measure has our most cordial wishes for its success.

WOMEN'S RIGHTS.

Although some who claim to have a just estimate of the prevailing tendency of opinion believe there is no reason to expect the result of the demand for a pharmaceutical franchise for women will be much other than that lately experienced in St. Stephen's, it is not to be supposed that the defeat of those who contended for the electoral privileges of women will at all lessen the vigour of the assault that is now about to be made in the same cause within the British Parliament of Pharmacy. *Apropos* of the coming discussion of the question as to the admission of women into the ranks of the Society—some of our readers will regard with interest the extracted remarks from the *Blackburn Times*. (See page 906.)

Though we do not endorse either the statements or the opinions of our contemporary, we cordially sympathize with the supposed victims of ultra vigorous womenkind, and, as regards the latter part of the extract, we are instinctively reminded of a verse in the 'Nugæ Canoræ Medicæ,' where the Poet Laureate of the Edinburgh New Town Dispensary predicts—

> "An' when the leddies git degrees,
> Depen' upon 't there's nocht 'll please
> Till they hae got oor chairs an' fees,
> An' there's an en' o' you and me.
> For a' that ken the woman craiter
> Maun own it is her foremost faitur
> To tak' to lecturin' by natur';
> An' hoo she'll do 't ye sune' ll see."

THE CHICAGO COLLEGE OF PHARMACY AND PROFESSOR ATTFIELD.

The pleasure which all English pharmacists experienced in the successful result of the effort to show sympathy with the pharmacists of Chicago, while suffering from the effects of their almost unparalleled disaster, was to a great extent owing to the energy of Professor Attfield. This activity on their behalf was speedily recognized by the members of the College, and their appreciation was shown by a request from a few of them to Professor Attfield that he would sit for a portrait for presentation by them in the name of their fellow members to the College. In complying with this request, Professor Attfield stipulated that the cost of the picture should not exceed twenty-five guineas. The picture has now been finished and shipped to its destination. It is an admirable likeness, and represents the Professor sitting by a table, on which are placed some books, and in his hand some papers relating to the Chicago College Fund. It has been painted by Mr. E. N. Downard, a rising artist, several of whose pictures have been exhibited in the Royal Academy. A tablet, having the following words on it, is attached to the frame:—

> "Professor Attfield, F.C.S., Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain. A portrait painted for a few members of the Chicago College of Pharmacy and presented by them to this College in recognition of the generosity of British Pharmacists and the special efforts of Professor Attfield in largely aiding to raise the College from its ashes after the great fire of 1871.—E. N. Downard."

A replica by the artist may be seen for a short time in the Museum at 17, Bloomsbury Square.

THE CONVERSAZIONE.

In order to prevent inconvenience to the visitors to the Conversazione on Wednesday evening next, we are requested to say that the officials at the South Kensington Museum will not be able to take charge of hats on that occasion. Programmes of the music will be provided, and should be obtained by each visitor upon entering the museum.

The appointment of Professor Redwood as Public Analyst, under the provisions of the Adulteration Act, for the Parish of Clerkenwell and the Districts of St. Giles's and Holborn has been confirmed by the Local Government Board.

Professor Bentley will commence the Third Part of his course comprising Practical Demonstrations on Plants and Systematic Botany, at the Royal Botanic Society's Gardens, Regent's Park, on Friday morning, May 23rd, at 8 o'clock. Cards of admission may be obtained from Mr. Bremridge, 17, Bloomsbury Square.

We are informed that the control and analysis formerly exercised by the late Baron Liebig and his delegate, Professor Max von Pettenkofer, in connection with the "Liebig's Extract of Meat Company, Limited," will in future be carried out by the latter gentleman in conjunction with Hermann von Liebig, son of Baron Liebig, who has been accustomed to act as special assistant to his father.

Notice.—In order to include a report of the approaching anniversary proceedings of the Pharmaceutical Society in the number of this Journal for next week, its publication will be delayed until Saturday.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, NORTH BRITISH BRANCH, EDINBURGH.

The annual meeting of the North British Branch of the Society was held in St. Giles Street, on Monday, 12th May, at 12 o'clock, Mr. Baildon, President, in the chair.

Mr. H. C. Baildon made a few valedictory remarks as President previous to vacating the chair. He said: To the exhaustive report of the past session presently to be read by our Honorary Secretary, little remains for me to add. But I have the pleasing duty to perform of asking you to pass a cordial vote of thanks to those gentlemen who have so kindly contributed lectures at the various scientific meetings during last session, viz. to Professor Crum Brown, to Dr. Stevenson Macadam, to Dr. J. G. M'Kendrick, to Mr. Paton, and to Mr. Mackay. All these lectures have been extremely interesting and instructive, and they have upon the whole been well attended. The recent official visit of the President, Vice-President, and the Secretary of the London Council, accompanied by Mr. Williams, has been most gratifying to the Council and to the Board of Examiners of the North British Branch, and will, I feel satisfied, be attended with very beneficial results. You will, I am sure, be pleased to hear in connection with pharmaceutical education in Scotland, that our indefatigable Secretary has now completed arrangements which will enable our students to obtain tickets through him for each of the subjects required by them upon very moderate terms. During the last session no less than 14 took tickets for Dr. Stevenson Macadam's class, whilst 3 attended his practical, and 1 his analytical chemistry. Eleven tickets have now been issued for Professor Balfour's botanical class, and each succeeding year should add considerably to these numbers. I have now great pleasure in stating that if elected, my friend Mr. Young has consented again to place his valuable services at the command of the Society as President of our North British Branch,—we all know how well he has on two previous occasions filled the chair; and our friend Mr. Gilmour is willing, if elected, to continue in the vice-presidential chair, in preference to taking that of president this year, but we all look forward to his filling the higher office, which indeed nothing but his extreme diffidence has caused him for the present to decline. In retiring for the second time from the honourable position of President of the North British Branch of the Pharmaceutical Society, I wish to return my sincere thanks to the Council for the kindness and support which I have invariably received at their hands during my two years' term of office.

The following report was then read:—

Annual Report.

In this the Annual Report of the proceedings of the North British Branch of the Society, there can be nothing of more importance to the members generally, than the occupation of the new premises, in which have been carried on, since November last, the operations of the Society in Scotland.

The room which was set apart for the museum has been used for all the examinations. Though somewhat small, and scant in accommodation when many candidates were present, it yet has answered the purpose fairly. The same room has also been made available for the ordinary evening scientific meetings, which have, the Committee are glad to say, been on the whole well attended throughout the session now closing. It must be admitted, however, that practical experience, even during the short time the rooms have been in use, points to the necessity ere long of having more space both for examinations and meetings.

The second room, set apart as a library, has also been used as a reading-room. Here a visitors' book is laid on the table, and it is gratifying to know that since November last, when the rooms were opened, 432 names are entered as having, on various occasions, paid visits to the rooms. There have been twenty-two tickets issued for the library, and regularly used; but many of the young men who have gone to St. Giles Street have made use of many of the volumes, by remaining during several hours at a time reading books and examining specimens together.

The Council feel satisfied that the short experiment which has been made proves that it was a step in the right direction to give such opportunities to young men in town and from the country, who were really desirous of spending a portion of their time in reading and study. It is hoped that still greater facilities will be afforded in this respect, as the Council have it in contemplation to fit up a more extensive series of specimens for the special use of students.

It may also be here mentioned that while the rooms have been used for all the requirements of the Society, the Council, on an application from the Young Men's Chemists and Druggists' Association, had much pleasure in granting the free use of the rooms for the purpose of that Association holding their regular meetings for mutual improvement throughout the winter months, and at which meetings papers were read, and interesting discussions followed.

The Board of Examiners have not been idle, and they beg to state that since last report, the following candidates have appeared:—Preliminary, 175; Major, 13; Minor, 54; Modified, 24—in all, 264. Of these failed in Preliminary, 74; Major, 6; Minor, 23; and in Modified, 6—in all 109; giving roughly 41 per cent. of failures. The Council cannot but regret the large percentage of failures which have occurred in all the above departments. The questions, as a rule, which are set for the first examination are really so fair to the candidates, that it appears inexplicable how so many should fail; more especially as the bulk of those who come up for this examination are young and fresh from school, and who ought therefore to be quite conversant with Latin, arithmetic, and English, to the extent, at all events, required by the Board.

Great as has been the extent of failure in the past, it is much feared that a recent change carried out by the Board in London, will very much increase the percentage for the future. It may be frankly stated that the examiners in Scotland do not concur in some of these alterations, and are very desirous that the old condition of things in respect to partial failures should be at once restored. They feel strongly on this point, sharing as they do the fear—if not the conviction—that if the change referred to be continued, it will so militate against parties entering the business, that the supply, both of apprentices and assistants, may yet be seriously interfered with if the new system be adhered to. Some correspondence has already taken place between the two Boards, London and Edinburgh, which the Council hope may result in some satisfactory arrangement being made.

The annual statement of intromissions on the part of the Honorary Secretary and the Branch have been already rendered, accounts vouched, passed, and settled.

By a series of new bye-laws, already passed at the Council-table, and which it is expected will be confirmed by the Annual Meeting in London this month, provision has been made for electing examiners in December of each year, instead of June as heretofore. In accordance with this proposal it is intended that the present Board in England and Scotland will continue as already constituted until the end of the year, when the new appointment for one year, to be confirmed by the Privy Council, will then take place. The gentlemen at present comprising the Board in Scotland will thus retain their position until December, when the Board will be elected anew.

The Council had much gratification in having had the honour of receiving during last month a deputation from London. Ever actuated by a desire to assimilate the Branch here as much as possible to the Society in London, the Council are confident that from what the President, Vice-President, Secretary, and Mr. Williams saw while present at our examination, and the benefit derived from some hints which fell from Mr. Haselden as to the conduct of the examinations in London, much good will accrue; and it will always be a matter of pleasure to the Council here, to receive in future a repetition of such a visit from their friends in the south.

In regard to the election of Council in Edinburgh for this and succeeding years, it is proposed to make the number sixteen, or fourteen members along with President and Vice-President. Of this number ten will be balloted out each year, leaving six of the old members. The ten drawn shall, however, be eligible for re-election, while it will also be competent for any member of the Society at the Annual Meeting to propose, and if need be put to the vote, any new name he may wish to serve on the Council for the ensuing year. This mode of procedure will be more in accordance with the plan adopted in London, without the machinery and expense of voting papers. To give, however, a more general interest to the proceedings at the Annual Meeting, it has been proposed that in future, billets will be circulated in Scotland a fortnight before the date of meeting in Edinburgh, giving the result of the ballot; and in event of any member wishing to propose a member of Council he may do so, by writing to the Secretary, who will intimate the same to meeting. Vote will then be taken as to the new members. Intimation of the meeting will also be made on the cover of the Pharmaceutical Journal.

The Council are thankful that the Society now recognize the position which the Branch here ought to occupy, and are glad to find that as our wants become apparent and known, the London Council are ready to grant supplies as well as to meet our various requirements. The true feeling which has ever existed here, and has prompted from time to time an advocacy of our rights, has arisen from a desire that our affairs should be so conducted that the North British Branch of the parent Society in London, and established in Edinburgh, should occupy a position in the estimation of the medical and general public in all respects worthy of such a powerful organization as that of the Pharmaceutical Society of Great Britain.

The report was unanimously adopted.

Vote of Thanks to Lecturers.

Mr. H. C. Baildon moved a vote of thanks to those gentlemen who had been kind enough to deliver lectures during the past session.

The vote was cordially passed.

Election of President and Vice-President.

Mr. H. C. Baildon said he had great pleasure in moving that Mr. Young fill the presidential chair and Mr. Gilmour continue to occupy the vice-president's chair during the ensuing year. He hoped that Mr. Gilmour's extreme diffidence would not prevent him on a future occasion, though it had on this, from occupying the presidential chair.

Mr. Napier seconded the motion, which was then passed unanimously.

The Election of Council for 1873–74.

Mr. Mackay then reported that at a meeting of a committee of the Council and examiners held on Saturday, the following names were drawn by ballot as those of gentlemen who should retire this year, but be eligible for re-election:—Messrs. Fairgrieve, Noble, Napier, Heron, Davison (Glasgow), H. C. Baildon, J. Aitken, and Fairlie (Glasgow).

The following having been nominated were declared elected, other five who had been also placed in nomination having retired:—Messrs. Kemp (Portobello), Buchanan, W. Tait (of Duncan, Flockhart, and Co.), Fairlie (Glasgow), Davison (Glasgow), J. Aitken, Heron, and Baildon. These, with the President and Vice-President, will fill the ten vacancies on the Council.

Mr. Baildon then moved that their Honorary Secretary, should be re-elected. He knew of no one who could perform the duties of this office in the same efficient manner as Mr. Mackay did, and he hoped that he had many years of health before him, for this, amongst other reasons that he was sure so long as he had health they would have an efficient Secretary.

Mr. Young, the newly elected President, then moved a cordial vote of thanks to Mr. Baildon for his services during the past year. It had been a year of considerable work, and Mr. Baildon had bestowed a great amount of labour upon their concerns. He had given his services most cordially, and he was sure they were all conscious of how much he had adorned the chair.

The vote was cordially passed.

Mr. Baildon having acknowledged the compliment, expressed his satisfaction that he was succeeded by so able a gentleman as the newly elected President.

This closed the meeting.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Eleventh General Meeting was held at the Royal Institution on Thursday evening, April 24th, the President, Mr. E. Davies, F.C.S., in the chair.

The following donations to the Library were announced:—Current numbers of the 'Pharmaceutical Journal;' the 'Register of Pharmaceutical Chemists and Chemists and Druggists;' and the 'New York Druggists' Circular.' To the Museum—A specimen of "Guaranine," manufactured and presented by Messrs. Hopkins and Williams, of London.

The first paper read was on the

Action of Spirit of Nitric Ether upon Iodide of Potassium.

BY J. ABRAHAM.

Mr. Abraham said that, in consequence of an inquiry, he had made careful experiments on this subject, and found that the spirit of nitric ether made according to the Phamacopœia was, when perfectly fresh, *feebly acid.* If, in that state, it was added to a solution of iodide of potassium, decomposition was instantly apparent, the solution becoming *reddened.* If the iodide of potassium contained ten per cent. of carbonate of potash (perhaps less) this change of colour did not occur; and after the mixture had been kept some days, there was at most a slight yellow colour. He believed that carbonate of potash was often found in commercial iodide of potassium, and when such an article was used, the discolouration to which he referred might not occur. Even if spirit of nitre were made by another process, and were perfectly free from acid at first, it would soon become changed, and the effect on iodide of potassium would be what he had described.

In connection with this subject, Mr. Alfred E. Tanner said that the prevailing practice appeared to be, to add a certain quantity of alkali to the spirit of nitre previously to mixing it with the iodide, under the impression that the spirit of nitre should be neutral, but this was really not sufficient, for unless there was an excess of alkali present the iodide would still be decomposed, and where this discolouration was not present, it was owing to the alkali being added in sufficient excess to take up the iodide liberated. All nitrites decompose iodide of potassium, and the practice of ordering these two articles in combination is to be deprecated, inasmuch as they are quite incompatible.

A paper was afterwards read on

The Decomposition of Animal and Vegetable Substances.

BY GEO. F. CHANTRELL,

Hon. Sec. of the Microscopical Society of Liverpool.

The following is an abstract of the paper:—

To the sanitarian this subject is one of most vital interest, as decomposing animal and vegetable matters enter so largely into the pathology of contagion. One of the earliest developments of life to be noticed in water, in contact with animal and vegetable substances, is that of bacteria. The writer referred to the diverse opinions expressed by Dr. Burdon Sanderson and Professor Hallier as to whether bacteria are plants or animals; it was evident their place in nature was as the universal destroyers of nitrogenous substances, acting as the pioneers, if not the producers of putrifaction. He said, by a little investigation of the remarkable substance "yeast," much light would be thrown on the subject.

He then referred to the results of Dr. Lionel S. Beale's (the well-known microscopist) examinations of *yeast* under the 50th of an inch object-glass = 2800 diameters, who says the yeast-cell will be found to be composed of two kinds of matter, the one smooth, *transparent*, and external, closed at all points, known as the cell wall (formed material); the other soft, diffluent, also transparent, but apparently composed of *semi-fluid* matter (germinal matter or bioplasm). Professor Huxley says of this bioplasm that it is a substance which contains the elements carbon, hydrogen, oxygen, and nitrogen, that it is in all essential respects the substance which forms the chief part of the contents of the yeast-plant, that it is identical with the material which forms the chief part of the white of the egg, that, in fact, although this little organism is a *plant*, and nothing but a *plant*, yet that its active *living* contents contain a substance which is called protein, which is of the same nature as the substance which forms the foundation of every *animal* organism whatever. Mr. Chantrell then referred to an experiment he had made with a thin section of celery, which he had placed in an animalcule cage, with a drop or two of well-boiled distilled water, forming a film of water and celery, about the size of a well-worn threepenny piece; in course of twenty-four hours, he noticed that on the outside of the chlorophyll granules a film or mucus (bioplasm?) had formed, which, after a while came away, and at the same moment active bacteria were to be seen all over the field. He could not resist the conviction that this mucus or bioplasm was the source from which the bacteria arose; as far as the microscope showed, it was evident the material was identical, only that the bacteria had their own characteristic movements and the chlorophyll granules their own slower ones. Later on, the bacteria were in amazing quantities as also were developments of the bacteria into filaments and spirilla.

Fish roe and meat treated in a similar manner to the celery produced almost identical results, animal and vegetable substances alike developing bacteria, torulæ, spirilla, etc., etc.

In course of a number of experiments with *boiled* vegetables it was remarkable how soon ciliated infusoria appeared (treated in a similar way to the celery). In an experiment with a portion of the *Collomia grandiflora* seed, which was kept for some weeks in the animalcule cage, infusorial life was developed in a most remarkable manner, from bacteria up to paramecia; one form of the latter regularly *swarmed* for nearly six weeks, after which some of them began to alter in form, and soon there were no less than six different varieties. Unfortunately by neglect the colony dried up—by the addition of water, in course of a few hours *amœbæ* were observed to be developing from the dead matter. The remarkable results obtained in these and other investigations of vegetable tissues led to the treating of garden soil in a similar way, and in twenty-four hours as a rule, ciliated infusoria, besides other life, were found. There was also another reason that suggested this investigation, and that was the fact of charcoal having been produced from the carbonization of garden, arable, and pasture soils, which has been *patented* as a most efficient purifying material for the treatment of sewage of towns. In the examination of a sample of sewage sludge from Ealing Sewage Works (now being treated under Major-General Scott's Patent Clay and Lime process) in a similar manner to the experiment with celery, in a very few hours active infusoria appeared, and to that extent that the carbonization of this unpromising-looking substance suggested itself—and the result you have before you—a perfectly black charcoal, not a pure charcoal, but probably containing as much carbon as animal charcoal. In sewage under the microscope, infusoria can almost always be found. In the examination of boiled vegetables, under a power of 760 diameters, movement has been found in the chlorophyll granules as they disengaged themselves from the vegetable tissues; besides these granules are very minute germinal spheroids, mere greenish points which have their own characteristic movement; these same spheroids, have been observed in the body of the spirilla, and also in minute fungoid growth. Carefully made infusions of coal, marble, and gypsum show these same spheroids which develop into many strange forms which have been well affirmed by microscopists of note, both English and foreign.

Mr. Chantrell then quoted some extraordinary effects on a fine rose bush by the application of half an inch of coal dust in depth on the surface. A sickly plant in a very short time quite recovered itself, and the effect on the colour of the flowers was something marvellous. This account is given in the *Revue Horticole*. The only exception was, that the flowers of a *yellow* colour alone remained insensible to the influence of the coal. It has been said that vegetable charcoal has a similar effect. Are we to suppose in the case of the coal, that it is due to the presence of these minute organisms before described, and that these are taken up as food by the plant?

The writer then referred to Pouchet's account of the mode of origin of *Paramecium viride* from infusions of hay and Dr. Bastian's difficulty in getting the same results, until he found out that whilst he was making his infusions with hot water Pouchet was making *his* with cold water. Temperature has a marked effect on the character of infusorial life. The "proligerous" pellicle or *scum* which forms on the surface of decomposing infusions of animal and vegetable substances is one of the most interesting objects of study to the microscopist; and he would call especial attention to that strange production of nature, the *spirillum*. It constitutes a large portion of scum; it is a living, moving thread, always on the move, coiling and uncoiling constantly. Examine it under a high power; the small spheroids, of a greenish colour, may be discerned. In old scum these threads have been seen undergoing change, and afterwards these spheroids aggregate, and finally develop into *amœbæ*; these in their turn become *paramecia*, and after a time develop into planarian worms. These worms seem to extract from the water, as it were, the last of the nitrogenous matter—old infusions generally finishing by a deposit of a substance like the lees of yeast, all active infusorial life having disappeared. The formation of scum primarily is thick and viscid, and after a while sinks to the bottom, followed by a weaker one—which in its turn sinks—and a third and fourth one, according to the strength of the decomposition. Each time the smell is reduced; nature by these means purifies the water.

Mr. Abraham said that it was an exceedingly difficult thing to trace the changes which took place in microscopic objects in fluids. That a new object was found in place of one which had been previously there was not a proof that one had been changed into the other. Mr. Chantrell might, however, be perfectly correct, and no doubt objects had been described as distinct animals which were the same in different stages of growth. With respect to the bacteria, it should be remembered that they were exceedingly minute, so minute that he believed no structure had yet been observed in them. He had looked at them with a $\frac{1}{15}$th-in. object-glass, magnifying 2000 diameters, and had seen none. A paper had been read some time ago before the Liverpool Microscopical Society, in which Mr. Metcalfe Johnson, of Lancaster, expressed his opinion that certain minute objects became animals or vegetables according to the circumstances in which they were placed. Some still more advanced authorities resolved vital force into chemical force.

A discussion on the subject of the paper followed, in which the President, Dr. Cook, and Mr. Tanner took part.

A vote of thanks to Mr. Chantrell for his valuable and interesting paper, proposed by Mr. Mason and seconded by Mr. Tanner, was unanimously carried.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The annual business meeting of the Association was held in Anderson's University, on the evening of Wednesday, the 23rd April; Thos. Davison, Esq., President, in the chair.

The minutes of previous meeting having been read and adopted, the Secretary then gave his annual report, after which the Treasurer presented his financial statement.

Secretary's Report.

"In accordance with an old established custom, it becomes my duty, to-night, to lay before you a statement (which shall be brief) of what has been done during the session that is now about to expire.

"I cannot speak definitely as to the number of our members, many of those who were members last session, I believe, have left the city, without, however, notifying your Secretary of the same. If I might be allowed to give a rough guess I should say that the probable number will be between 70 and 80, a number less by about 20 than that of last of session, but this can be accounted for by the formation of the 'Assistants' Association' about that time, which robbed us of several members, and also by the fact of a few of our members getting situations in other parts of the country. While on this point I may be allowed to allude to the loss that the Association has suffered in the departure of Mr. Jas. L. McMillan from Glasgow to fill a situation abroad. It will be remembered that this gentleman gave several valuable papers to the Association during the last two or three sessions.

"Including the present there have been six meetings of the Association this session. Our first meeting, as most of you are aware, was honoured by the presence of Mr. Samuel Chapman Betty, Member of the Pharmaceutical Council, London, who came to Glasgow specially to deliver the inaugural address of your Association.

"We must not forget to express the indebtedness of your Association to Dr. John Clark, Glasgow, who delivered an able and interesting lecture on the 'Oxides of Hydrogen' on the occasion of our second meeting, and to Mr. James Stitt, who kindly favoured us with a lecture on 'Phosphorus;' nor must we forget to record the obligation that we are under to Mr. Weir for his short lecture on 'Health,' and to Mr. Fairlie for his excellent paper on 'Artificial Silicates.'

"The principal features of the past session have been the issuing of a retail price-list, the formation of an 'Assistants' Branch' of the Association, and the complimentary dinner on the occasion of the official visit of the President, Vice-President, and Secretary of the Pharmaceutical Society to Glasgow.

"In regard to the price-list, we have every reason to congratulate ourselves on the success that has attended the labours of the committee appointed to carry out that matter.

"We cannot, of course, say that every chemist and surgeon in the city is closely following the prices contained in the list, but that the majority are endeavouring to adopt it to the utmost of their power we believe to be a fact.

"The demand for the price-list has quite exceeded our expectations. The first issue of 300 copies was very soon exhausted, applications for them being received from different parts of the country, including England; and as inquiries still continued to be made for them, the committee thought it advisable to have a second edition printed. This allowed of certain alterations in, and numerous additions to the list being made.

"As it was thought that most of the towns in the west of Scotland of any importance would most likely before long adopt the Glasgow price-list (as was instanced a short time since by the chemists of Greenock), your Committee have had 400 printed this time, copies of which may be had from Mr. Jos. A. Clarke, convener of Price-List Committee, price 1*s.*

"In connection with this matter I may say that an advertisement has been inserted in the Pharmaceutical Journal, and also in the *Chemist and Druggist.*

"In regard to the Assistants' Branch very little can be said, and your Council regret that that little is not of a very encouraging nature. On the 19th February, 1873, a meeting of assistants was called to consider the advisability of forming a branch association. The attendance was small, but it was moved, seconded, and agreed to, that a branch association should be formed. Office-bearers and committee were then appointed. On the 19th March a second meeting was called, but as there were not more than half a dozen presented themselves, there was no business done. I cannot attempt to account for the want of interest shown by the assistants and apprentices in this matter. One would naturally have supposed that they would have hailed the formation of such an association with delight, and instead of giving it the "cold shoulder," would have given it their hearty support.

"In reference to the complimentary dinner given in honour of the visit to Glasgow of the President, Vice-President, and Secretary of the Pharmaceutical Society, your Council have very much pleasure in being able to report that the occasion came off with very great *éclat.* About forty gentlemen sat down to dinner. Among the number were (besides the deputation from London) Messrs. Ainslie, McKay, Baildon, Young, Gilmour (Edinburgh), Duncanson (Stirling), Stanford (British Seaweed Company), Professors Cowan and Simpson, etc., etc.

"Your Council cannot allow the session to close without expressing in the strongest language their great indebtedness to Mr. John Currie, of Sauchiehall Street, for his generosity in conducting that class for pharmaceutical students; and they feel certain that those students who were regular in attendance at the class will corroborate the statement that Mr. Currie was thoroughly master of the subjects that it was his self-imposed duty to impart to his pupils, and which he did in a most able and agreeable manner; and they trust that they will have the honour of his advice and assistance in connection with classes during the coming session.

"Through the liberality of that very liberal gentleman, Mr. Jas. McDonald, of the Glasgow Apothecaries' Company, and Mr. Rait, of Partick, your Council were enabled to offer two prizes in connection with Mr. Currie's class, and which, as many of you are aware, were carried off by Messrs. Wallace and Cleghorn.

"There is one subject more that I wish to touch upon, and then I have done, and that is, the Annual Festival. Your Committee have much pleasure in being able to state that it has been a success. After paying all expenses, there was a balance of three pounds in the Treasurer's hands. At the first glance it would appear that, this year, the festival had been a great success financially. But in case it should cause you to be less energetic on the occasion of our next festival, I desire to remind you that, with one exception, the services of those who took part in the concert were gratuitous. Had each of those gentlemen who gave their services on that occasion been paid, say, two guineas, I fear that the chancellor of your exchequer would have pulled a very long face to-night when giving you his budget."

Treasurer's Report.—1872–3.

The Secretary's and Treasurer's Reports having been adopted, the following motions were brought forward :—

The President, having vacated his chair, moved—"That the following alterations and additions be made in the Rules :—Rule 1, instead of 'and shall have for its object the mutual improvement of its members, the better education of assistants and apprentices, and the general advancement of the interest of the profession and trade ;' to read thus—'And shall have for its object the study of the science of chemistry, and other collateral sciences having a bearing upon pharmacy.'"

The President briefly stated his reasons for making this motion, it being simply to remove the Association from the burden of taxation. This having been seconded and agreed to, he then moved the following as a new rule :—"No part of the Society's funds shall be applied by way of dividend, gift, donation, or bonus to any of the members." This was also agreed to.

Mr. Fairlie then moved—First, "That the Council take steps to procure another place of meeting, in some central part of the city, which could be opened at certain hours as a reading-room, and used as a class-room, and for the meetings of the Association in the evenings." Second, "That the Secretary be instructed to convene a joint-meeting of the Council, and the Committee of the 'Assistants' Branch' early in September, to arrange the business of the session, including Syllabus of Lectures, Essays, Discussions, Classes, etc."

Both the motions were seconded by Mr. Murdoch, and finally adopted. The election of Office-bearers and Council was then proceeded with. The retiring President (Mr. Thos. Davison) declining re-election, Mr. John Currie (Sauchiehall Street) was elected President. Mr. Wm. Whyte, Vice-President, Mr. Jos. A. Clarke, Secretary, Mr. William McKenzie, Treasurer. Council —Messrs. Daniel Fraser, Thos. Davison, Alex. Kinninmont, John Black, John Fenwick, Arch. Paterson, R. T. Dun, Robt. McDonald, Jas. M. Fairlie, W. S. Galbraith, R. Brodie, G. Garry. Auditors—Messrs. J. Hunter and J. Foster.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Meeting of the Executive Committee.

A meeting of the Executive Committee of the British Pharmaceutical Conference was held on Wednesday, May 7th, at 17, Bloomsbury Square. The chair was taken by Mr. Daniel Hanbury, and there were also present—Messrs. Clayton, Williams, Schacht, Attfield, and Moss. The minutes of the previous meeting were read and confirmed.

Year-Book.—The Secretary (Professor Attfield) reported that upon seeking to make arrangements, directly after the meeting at Brighton, for the issue of the annual volume he found that the printers required an advance on former prices of 7½ per cent. for the greater part of the printing, paper, etc., and 8 per cent. on the binding. Upon inquiry he became convinced that the proposed increase was a reasonable one and ventured to allow it without troubling the members of Committee to assemble and decide the point. In September, Mr. C. H. Wood announced to the Executive that he had completed his portion of the MS. of the volume. Professor Attfield had also prepared by that time a list of the names and addresses of the 2000 members of the Conference, an alphabetical list of the towns with the resident members, and a complete report of the transactions of the Conference at the ninth annual meeting at Brighton. In compiling the latter he had been much assisted by the reports published in the Pharmaceutical Journal, and by the kindness of the authors of papers and speeches. The proof sheets were corrected as they came from the printers, the first part by Mr. Wood, and the second by himself and Assistant-Secretary. The volume was published at the end of December.

Honorary Members.—The Secretary reported that he had officially communicated with the gentlemen who had been elected honorary members of the Conference at the Brighton meeting, and had since received the acknowledgments of those gentlemen.

Bell and Hills Fund.—Professor Attfield reported that he had purchased and had had bound ten guineas' worth of books, selected by himself in accordance with the wishes of the Brighton Chemists' Association, and had presented them to that body in the name of the Committee. The Association had acknowledged their receipt in highly appreciative terms.

Finance.—Professor Attfield reported that in November and December last he issued 1760 circulars requesting members to forward their subscription. About 1100 subscriptions were forwarded in answer. In February, 660 members were again asked for their subscriptions—210 responded ; in April the remaining 450 were a third time requested to remit and to that date about 50 or 60 had done so. Of the 400 defaulters, 57 were three or more years in arrear ; 114 owed for the current and previous and the previous year, and 229 for the current year only. With regard to the members who had not paid subscriptions for three or four years, the Professor said they were mostly gentlemen who resided in towns where the annual meetings were held, and who probably had not intended to subscribe to the Conference for more than the one year of their temporary interest in the association. Many members, however, who had avowedly joined for one year only, and who had not promptly paid the following year's subscription, had been induced to continue membership on being appealed to by the Secretary or after receiving the various circulars issued during two or three years. The 57 members now alluded to had not responded to such appeals, and he proposed that to such members a special letter should be sent drawing attention to the rule respecting defaulters, and stating that if no answer were received within a given period (say ten days) the name of the member applied to would be struck off the roll by the Executive Committee.

Mr. Clayton approved of the efforts of the Secretaries to induce members to retain their interest in the Conference, but thought that when such endeavours met with no response the connection should be severed.

Mr. Williams concurred in this view.

Professor Attfield said that as Secretary he fully appreciated and even fostered temporary interest in the Conference, of course also hoping that it might merge into permanent interest ; but when men answered neither circulars nor letters year after year continued appeals would probably become troublesome to such members themselves and certainly gave useless trouble to the staff.

The course proposed by the Secretary was ordered to be adopted.

Number of Members.—In answer to a question from the Chairman, the Assistant-Secretary said that the total number of names on the books was 2071, including 17 honorary members and about 60 candidates for membership.

Bell and Hills Fund.—Mr. Benger (Secretary) reported that he had written to five or six prominent members of the Conference with the object of obtaining suggestions as to the best method of appropriating the money which Mr. Hills had confided to the Executive Committee for the promotion of pharmaceutical education and the cultivation of original research and pharmaceutical science generally. The following was a summary of the answers he had received:—

Mr. Reynolds thought that the Committee meeting in May might draw up a set of rules, and immediately afterwards invite special attention to the subject by directly laying it before their leading members and by offering a statement to editors for publication in the usual way. There was no reason why a subsequent committee in June should not make grants that might be applied for by individuals; but at all events before the annual meeting took place members should be invited to name special subjects of considerable extent or importance, and if these required combined energies and involved expense, the Committee would aid with their advice, and as in the case of individual workers with grants from the fund. With respect to the ten-guinea grant of books Mr. Reynolds thought that although the Pharmaceutical Society was prepared to contribute to libraries, there was an inherent merit in Mr. Hills' original gift for provincial libraries that should preserve it alive. As to medals, to trust to a medal having no money value was not desirable, and he was against giving medals.

Mr. Groves thought that no other stimulus than desire for distinction was necessary to induce members to undertake absolutely new work, but the equally useful labour of checking and revising the labours of others who, perhaps, had been in haste to be original was not so attractive; the fund, therefore, would be well applied in repeating experimental work whenever experimental corroboration might seem desirable. The French societies nominated commissions to test the conclusion of almost every pharmaceutical writer in France. Some reputations might disappear in the process, but in the interests of truth such consequences should not be regretted.

Mr. Tichborne thought the Fund should be entirely devoted to Pharmaceutical science. He thought (*a*) researches might be undertaken with a view to the expurgation of useless preparations from the British pharmacopœia; (*b*) that a prize should be offered for an essay on the perfecting of official formulæ, for although this was a matter which should be encouraged by the Medical Council, it was also a subject of national importance; (*c*) another prize might be offered for a natural history of the materia medica; (*d*) an essay was wanted on the best disinfectants and the mode of using them; (*e*) also one on the economy of alcohol in tinctures and other pharmacopœial preparations; (*f*) investigations might be made on the application of the spectroscope, microscope, and other physical instruments to pharmacy. The prizes should not be too small, or good men would not compete.

Mr. Brady, Mr. Williams, Mr. Benger, and Professor Attfield concurred in the opinion that the best mode of procedure would be to follow, with modifications, the course pursued by the British Association, which had for many years granted money in aid of researches in science.

Mr. Benger submitted the draft of a circular, including rules relating to the application of the Bell and Hills Fund. After some slight alterations, Mr. Schacht moved and Mr. Williams seconded a resolution which was carried unanimously—"That the statements and rules now read be printed and distributed in the manner suggested."

Annual Meeting, 1873.—Professor Attfield reported that the usual blue list had been revised and a copy forwarded to each member. He had for some time been in correspondence with the officers of the local committee in Bradford, and he anticipated that the meetings in September (Tuesday, the 16th, and Wednesday, the 17th) would be thoroughly successful.

Annual Meeting, 1874.—Professor Attfield said that at the next meeting of the Committee it would be necessary to consider the question of the place of meeting for 1874. The British Association had decided on assembling at Belfast in the autumn of that year. Hitherto the Conference had met in the same town as the Association, on the Tuesday and Wednesday immediately preceding the Association days, a course which benefited both bodies to about the same extent as regarded increased attendances at the respective meetings,—though that extent of benefit was more important to their own gathering than to that of the Association, which mustered twenty times their number—and it was to be hoped that this convenient and favourite course might be possible next year. It was true that Belfast was a long way off, and that ninety-nine hundredths of the members resided in England and Scotland, still distance need not prevent a successful meeting being held if local support were strong. Unfortunately, party feeling in pharmacy was somewhat stirred in Ireland just now by prospective legislation, and might become more so, and it was important that a neutral body like the Conference, which was open to all comers, and which was established not only "for the encouragement of pharmaceutical research," but also "for the promotion of friendly intercourse and union amongst pharmaceutists," should not take any step which might be one of apparent sympathy with a portion only of the followers of pharmacy or its branches. He had during the past six months corresponded on the subject with some of the members of the Conference residing in Ireland, and would state the results at the next meeting of the Committee.

The Committee decided to meet again on Thursday, May 21st.

PHILADELPHIA COLLEGE OF PHARMACY.

The annual meeting was held at the College Building March 31st, 1873. Thirty-five members present. Dillwyn Parrish, President, in the chair. After some routine business had been transacted, Professor Proctor read, on behalf of the committee of deceased members, a memoir of Professor Edward Parrish; and after a number of expressions of the deep and affectionate regard in which he was held, the memoir was directed to be published in the Journal, whence the following abstract is taken:—

Edward Parrish was born in Philadelphia on the 31st of May, 1822, in Arch Street below Fourth, and was the seventh son of the late eminent physician and surgeon, Dr. Joseph Parrish, and Susanna, daughter of John Cox, of Burlington, N.J., both members of the Society of Friends. He was educated in the Friends' School in Philadelphia, where he is said to have been well instructed in elementary studies, and to have acquired a fair knowledge of the higher branches and the classics. He early manifested an aptitude for scientific pursuits, and in the year 1838 entered as an apprentice the pharmaceutical store of his brother Dillwyn. He is reported to have been attentive and faithful in the discharge of his shop duties and responsibilities. Availing himself of the favourable opportunities afforded in the store and at the College of Pharmacy, near by, he acquired an excellent knowledge of his business, for which his taste and inclination were well adapted. His first course was under the instruction of Professors Franklin, Bache, and Joseph Carson, and his last under Professors Carson and William R. Fisher, in the session 1841–42. In the spring of 1842 Edward Parrish took his degree in pharmacy in the Philadelphia College, having written his thesis on "Statice Caroliniana," published in Vol. XIV. *American Journal of Pharmacy.*

In 1843 he purchased a drug store, previously conducted by George W. Ridgway; here he continued business until 1850. During this period he contributed several papers to the Journal, and in 1848, in connection with his assistant, W. W. D. Livermore, a paper on "Collodion," the first notice of that preparation occurring in the Journal, the discoverers at Boston not having published their process. During the same period he married Margaret, daughter of Uriah Hunt, of Philadelphia, who continued his closest friend and companion until her death, a few months before his own.

In the autumn of 1849 he gave his first course of instruction in Practical Pharmacy to 14 students.

Soon after this time he removed and entered into business with his brother Dillwyn, his "Practical School" being better accommodated and gradually increasing in importance, was addressed to pharmaceutists as well as to medical students. In furtherance of his school he determined about this time to take a course of practical instruction in analysis in the laboratory of Professor Booth, and afterwards a medical course in the University of Pennsylvania.

Feeling the need of a text-book for his class, he decided to write a book addressed to medical and pharmaceutical students, and in the year 1855 he published the first edition of his "Introduction to Practical Pharmacy."

In 1857 his lecture on "Summer Medical Teaching in Philadelphia," after speaking of his earlier efforts in establishing his "School," he says: "Twenty-three courses of lectures and practical exercises have since 1849 been given to an aggregate of 299 medical students, drawn from nearly every State in the Union, and from British America. After near eight years' experience as teacher of this speciality, I need offer no apology for giving some general conclusions I have arrived at in regard to its utility as a branch of medical education, and the best means of imparting it." Again he says: "In claiming the position of a pioneer in this sort of teaching [in the U.S.], I do so with the confident belief that the time is approaching when its importance will be fully recognized, and when the education of the physician will be universally regarded as incomplete unless he has enjoyed the advantages of a more or less thoroughly practical teaching in pharmacy."

These extracts will show that Edward Parrish had made considerable advance as a teacher in imparting instruction to medical students before subsequently entering our faculty, and had carried on his school with an enthusiastic belief in its usefulness and efficiency.

The pharmaceutical meetings of the College (an offshoot from the interest awakened by the Pharmacopœia Committee of Revision of 1840) were frequently attended by Edward Parrish after he graduated; and, although his written communications to their proceedings were not numerous, he often gave interest to them by his practical remarks and by the exhibition of attractive objects. Being a ready speaker, he delighted on these occasions to bring forward subjects for discussion, and often without preparation added greatly to their interest. His genial manners, and earnest desire to render these meetings open to all who would come —members, students, or strangers—assisted in prolonging their existence after they decreased in importance, from the cessation in great measure for several years of the experimental essays, which in the beginning had given character and importance to their transactions.

Edward Parrish early determined to pursue a scientific career, aspired to a position in the schools, and was deeply impressed with a belief in his ability to teach. When the chair of Materia Medica was vacated in 1850 by the retirement of Dr. Carson, he was a candidate for the vacancy, but the traditional influence of the idea that that chair was best filled by a physician, led to the election of Dr. R. P. Thomas. In the Spring of 1864, however, on the death of Dr. Thomas, he was elected to fill the vacancy, as Professor of Materia Medica, and continued in that office till 1867, when he exchanged chairs with Professor Maisch, and, assuming the duties of the Professorship o Practical Pharmacy, more in accordance with his inclina tion and habits, continued until his decease to lecture annually to increasingly large classes.

Professor Parrish was always popular with the students; his free and open manner, the interest he took in the class individually and collectively, and, above all, his good delivery as a speaker, rendered him a favourite and gave him influence. For several years prior to his death other engagements had trenched greatly on the time required by his professorial duties, but in 1871 he was relieved from these, and had his life been spared there is no doubt that his career would have been increasingly useful as a teacher of practical pharmacy.

Edward Parrish was elected a member of the Philadelphia College in 1843, became a member of the Board of Trustees in March, 1845, and was elected to the Secretaryship of the College in 1854, and continuing that office until he entered the Faculty, in 1864. In 1847 he was one of a committee of fifteen members to report on the Pharmacopœia previous to the convention of 1850, and in 1859 and 1869 he acted on similar committees previous to the conventions of 1860 and 1870. He was also a delegate to the Pharmacopœia Convention of 1860 for Revising the Pharmacopœia, and in 1869 was one of three delegates appointed by our College to the International Pharmaceutical Congress of Paris, but was not able to to attend. In 1850 he was elected a member of the Publishing Committee of the College, and continued in it until 1870. He contributed frequently to the Journal during this period, and to the *Druggists' Circular, N.Y.*

Professor Parrish became a member of the American Pharmaceutical Association at its first meeting in Philadelphia, in 1852, was elected Recording Secretary at the Boston meeting, in 1853, First Vice-President in 1866, and President of the Association at the meeting of 1868. He acted on many of its committees, assisted in the revisions of the Constitution and other labour, and, when present, always took an active part in the discussions. A number of papers and reports, scattered over the twenty volumes of Proceedings, mark the interest he manifested in this way in the advancement of pharmacy.

His ready pen was always at command to bring together in order the results of reflection and inquiry, whether these related to the ethics of pharmacy, the bye-laws of the Association, or the advantages of education, general or special. Moreover, though not himself possessed of an inventive genius, he delighted in new inventions or improvements in pharmacy, and was always ready to encourage their authors, and to be the means of spreading a knowledge of them by tongue or pen.

In 1858 Professor Parrish made a hurried trip to Europe, but limited his travels to England and Scotland, with a brief tour to Paris, Strasburg, and the Rhine, availing himself of the opportunity to make acquaintance with pharmaceutists and their institutions. In a series of letters published in 1859, in the *American Journal of Pharmacy*, he gave some of the results of this voyage.

About this period he published a little book entitled "The Phantom Bouquet," which treated of the art of skeletonizing leaves and other parts of plants.

In the year 1864 the project of establishing a collegiate institution under the direction of the Society of Friends, which had long been entertained by some of its members, culminated in obtaining the Act of incorporation of Swarthmore College, and the purchase of a farm site of 93 acres in Delaware Co., Pa. Deeply impressed with the importance of more thoroughness in education and with the newer views in regard to the manner and means of educating the youth of both sexes, he gave the subject deep attention, and, entering the field in 1862, became one of the most successful pioneers in the work of advocating the claims of Swarthmore to those who held the means for its completion; serving as Secretary to the Board of Managers from December, 1864, until the completion of the building in 1868, when he was officially declared the first President of Swarthmore College, and continued in office during nearly two years.

On the several occasions when legislative encroachment on the best interests of pharmacy needed resistance, or when legislative aid and protection were to be sought, Professor Parrish took an active and efficient part; and on the passage of the Pharmacy Act of 1872 he was one of the five commissioners appointed by the Mayor of Philadelphia to carry the law into effect. The labour incident to the organization of the Board, and the subsequent service required in the examination of numerous assistants seeking registration under this law, protracted till late in July, doubtless had some influence in undermining his health, not yet recovered from the severe shock it had received by the sudden death of his wife, and probably contributed to his approaching end.

In the following month (August, 1872) the Government of the United States, desiring to settle some difficulties with certain Indian tribes, in the direction of peace, appointed Professor Parrish and Captain Alvord as commissioners. In entering upon this last act of his life he was advised by his family, who believed his health would be benefited by the journey. But the unforeseen exposure incident to a long and rough stage ride through the wilderness proving too heavy a tax on his impaired vitality, and before he could fully accomplish his mission of peace, he fell a victim to the climate, in the 51st year of his age.

Edward Parrish possessed social qualities of a high order: his conversational powers were good, his information on ordinary subjects general, his interest in modern progressive ideas considerable, and he was never happier than when his friends were around him in the family circle interchanging ideas.

His home instincts were strong: his wife and children ever occupied a prominent place in his plans and arrangements; for them no sacrifice was too great, no pleasure too rich, no necessity too expensive; and whether fortune smiled on him or frowned, he was the same kind and liberal husband and father, the same sympathetic brother and friend. There was nothing mean or contracted in his nature, and in business his competition was unmarked by bitterness or personality.

Professor Parrish was by nature ambitious of distinction among his fellows, yet his yearnings after power or place were influenced by a spirit at once mild, benevolent, and lovable. His intellect, which was clear and forcible, he had cultivated by reading and conversation. Had it been steadily concentrated in the line of his profession, it would have led him to honours far higher than those to which he attained; but by directing his attention to too many objects, his efforts lost in power and thoroughness what they gained in variety and popularity.

Although originality was not a prominent trait among his mental characteristics, his mind was active and ready; he was quick to catch ideas when presented, manifested much excellence of judgment in adapting them to his purposes, and it was generally with graceful acknowledgments that he rendered tribute to others when occasion required. It was in his manner of grouping and classifying facts, and of lucidly presenting subjects to his readers, that his personality was most deeply impressed on his literary labours in pharmacy.

Nature had endowed him with a gift of speech well adapted to the platform, and some of his ablest efforts have been introductory and valedictory addresses. As a teacher of pharmacy in the lecture-room, he loved to array the leading facts in generic groupings on the blackboard, using the more prominent individual substances for special comment on the table, often bringing in anecdote to enliven his subject. Less happy as a manipulator than as a speaker, Professor Parrish trusted more to his ability to convey his meaning by figures of speech than to annoying and often troublesome demonstrations by practical experiments; nevertheless he was conscious of the important and valuable aid derived from object-teaching and the exhibition of actual processes; and in his last course introduced several important improvements in his methods of illustration.

As a business man, his mind was too much given to outside matters to push his interests by close personal attention, and they not unfrequently suffered from too much devotion to other objects and interests wholly disconnected with his own personal advantage.

Professor Parrish was known among pharmaceutists abroad, but more especially in England, chiefly through his writings, which are held in much esteem, and the Pharmaceutical Society of Great Britain and the British Pharmaceutical Conference have each shown their appreciation of him by honorary memberships; whilst at home, besides being in membership with various societies, his name is as a household word among the members of the pharmaceutical and medical professions.

Professor Parrish leaves four sons and a daughter to keep green his remembrance and to imitate his virtues.

A letter was read from Mr. Charles Bullock, resigning the office of Secretary, which he had held for many years.

The following were elected as officers for the ensuing year:—

President, Dillwyn Parrish. 1*st Vice-President*, William Procter, jun. 2*nd Vice-President*, Robert Shoemaker. *Treasurer*, Samuel S. Bunting. *Recording Secretary*, William J. Jenks. *Corresponding Secretary*, Alfred B. Taylor. *Publishing Committee*, Thomas S. Wiegand, John M. Maisch, William Procter, jun., James T. Shinn, Charles Bullock. *Editor*, John M. Maisch.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Shop Hours' Regulation Bill.

This Bill, which has been introduced by Sir John Lubbock, and has on the back the names also of Mr. Thomas Hughes, Mr. Morley, and Mr. Mundella, contains some provisions of great importance as affecting pharmacists. It proposes to extend the provisions of the Workshops Acts, 1867 to 1871, with certain amendments, to shops kept open for the sale of goods, in the same manner as if such shop were a workshop.

By clause 4 it proposes that no child, young person, or woman shall be employed in any workshop or shop on Good Friday or Christmas Day; and that there shall be allowed to every child, young person, and woman employed in a workshop or shop not less than four whole holidays or eight half-holidays in every year (exclusive of Good Friday and Christmas Day).

The term "young person" is for all the purposes of the said Act to be deemed to include every apprentice, whether male or female, who has attained the age of thirteen years and has not attained the age of twenty-one years.

The term "employed" is defined to mean occupied under a master or parent, whether for wages or not for wages, in any manual labour exercised in or incidentally to the sale of any article in a shop; and the term "shop" is to include any building, room, warehouse, or premises in which any article is sold or exposed or offered for sale, and any buildings or premises, whether open or enclosed, which adjoin a shop or communicate therewith otherwise than by a public highway or thoroughfare, and to or over which the occupier of the shop, or the person by whom any child, young person, or woman employed in the shop is employed, has a right of access or control.

The Workshop Acts, 1867 to 1871, are, in their application to shops as defined in this Act, to be subject to the following modifications:—(1) On some week-day in every week every shop to which this Act applies shall be closed during the whole of said day after the hour of two in the afternoon; and during the time when a shop is closed in accordance with this provision no child, young person, or woman shall be employed therein. If a shop has not been closed as aforesaid on some one of the first five week-days in any week, and it is not so closed on the Saturday in the same week, every child, young person, or woman employed therein during any part of such Saturday shall be deemed to have been employed in manner contrary to the provisions of the Workshop Acts, 1867 to 1871. Subject to the provisions of this modification, children, young persons, and women may be employed in a shop on Saturdays in the same manner as on other days.

(2) A Secretary of State, on proof to his satisfaction that the exigencies of trade require the alteration, may, by order published in such manner as he thinks fit, give permission with respect to any shop or class of shops either generally or in any particular place for the employment of young persons or women for a period not exceeding fifteen hours on any market-day; provided that they are not so employed except between the hours of six in the morning and nine in the evening; that they are not so employed on more than one day in any one week; and that in addition to the time otherwise allowed for meals and rest, they are allowed half an hour for a meal after the hour of five in the afternoon.

Shops of the following kinds are excepted from the provisions of this Bill:—Any premises licensed for the sale of intoxicating liquors under the provisions of the Acts for the time being in force for regulating the sale of intoxicating liquors; any shop in which articles of food are sold for consumption on the premises; any bakehouse as defined by the Bakehouse Regulation Act, 1863.

The Bill is set down for second reading on the 20th May.

Weights and Measures (Metric System) Bill.

The Bill to establish the Metric System of Weights and Measures after a fixed period, which was read a first time at the beginning of March, has now been issued. Substantially, it appears to be the same as that introduced in 1871. It provides that the primary standards of the metre and of the kilogram, verified in relation to the original standards at Paris, and the derived standard unit of capacity, the litre, containing a kilogram weight of distilled water at its maximun density, weighed in a vacuum, together with their several multiples and parts, which are now in the custody of the Warden of the Standards, shall be the standard measures and weights of the metric system. It gives power to judges, etc., to order copies to be supplied, and extends to the metric system all provisions as to inspection of imperial standard weights and measures.

The principal units of the metric system, the "metre" the unit of measures of length, the "are" the unit of the measure of surface, the "litre" the unit of the measure of capacity, as well for liquids as for dry goods, and the "gram" the unit of weight, a thousand of which shall be and is the "kilogram;" with their decimal multiples and decimal parts, as well as the double and the half of the said units, are declared to be units, multiples, and sub multiples of the metric system.

A table is contained in the schedule annexed, in which are set forth, for all commercial purposes, the equivalents of the weights and measures therein expressed of the metric system and of the imperial system respectively; and such table is to be used for computing, determining, and expressing, in imperial weights and measures, weights and measures of the metric system, and in metric weights and measures, weights and measures of the imperial system.

Clause 7 provides that after the expiration of years from the passing of the Act, the imperial and all local or customary weights and measures shall be abolished; and every person who shall sell by any denomination of weights and measures other than those of metric weights and measures, authorized by this Act, is on conviction to be liable to a penalty not exceeding the sum of forty shillings for every such sale, and it also provides that penalties shall be inflicted upon persons using any other denominations of weights and measures in any return, price list, price current, or any journal or other paper containing price list or price current.

From the passing of the Act, and until the use of the metric weights and measures shall be made compulsory, it proposes that the said metric weights and measures are to be deemed and taken to be legal weights and measures, and as such may be used for all purposes whatsoever.

The second reading is set down for the 21st May.

Adulteration of Milk.

At the Liverpool Police Court last week Samuel Worthington was charged with having sold adulterated milk. Evidence was given by the inspector of nuisances that a quantity of milk, which had been purchased on the 28th of April on the premises occupied by the defendant, had been submitted to Dr. Brown, the borough analyst, who certified that it had been diluted by upwards of 16 per cent. of water. In cross-examination the witness who had purchased the milk admitted that he had not been served by the defendant, and it was contended that unless evidence could be given as to the intentional adulteration of the milk by the defendant there was no ground for a conviction. In support of this argument the case of *Core* v. *James* was cited, in which it had been decided at the Bolton Petty Sessions to inflict a penalty of £5 on the defendant for having used alum in the making of bread. The case, however, had been carried to the Court of Queen's Bench, and the conviction was quashed on the ground that no guilty knowledge on the part of the defendant had been proved. Although the action referred to had been taken under a different Act, it was urged that the same objection held good in reference to the present case. Mr. Raffles said that the Act would be useless if the defendant was not held responsible for what his wife or daughter did in a case like the present. The question was simply whether a man whose name appeared above the door of a shop was to be answerable for what was done by anybody who served on the premises. His opinion was that in such a case the occupant of a shop was responsible. Some curious impressions, Mr. Raffles further observed, had got abroad regarding milk cases. He had read a short time ago that water mixed with milk did not constitute adulteration, but how that idea came to be entertained he did not know. In the absence of any further evidence, Mr. Raffles said that he would hold the charge proved. A fine of 20s. and costs was imposed.

William Simpson was summoned on a similar charge. In this case the milk had been purchased by one of the inspectors of nuisances from a shandry belonging to the defendant which was standing in the street. On the milk being analysed by Dr. Brown, it was found to contain 5 per cent. of water. For the defence it was pointed out that the defendant was on his way from the station when the milk was purchased, and as the milk had not been transferred from the railway cans the defendant could not have had any opportunity for adulteration. In consideration of the quantity of water mixed in the milk being so small, Mr. Raffles said he thought it would be sufficient to dismiss the defendant with a caution.—*Liverpool Albion*.

Adulteration of Bread.

At the Wandsworth Police Court a baker, of High Street, Barnes, was summoned for selling bread mixed with alum, which was injurious to the health of the persons eating the same.

The Defendant said he must plead guilty. He was not a baker, but he kept a foreman and trusted him. The flour was rather fresh, and customers had complained. The foreman put a little alum into the bread unknown to him.

Mr. Ingham said, *primâ facie*, he would take it that a baker knew what were the ingredients of his bread. He could not accept the defence unless it were proved. He fined defendant 20*s*. and 23*s*. costs, which included the analyst's fee of one guinea.

James Wilson, a baker, of West Fields, Barnes, was summoned for a similar offence.

For the defence a report in a newspaper was read, in which it was stated that flour was impregnated with alum which came out of the stones used in grinding corn.

Mr. Ingham said some stones might have a certain portion of alum in them, but to yield sufficient to be injurious to health a millstone would be required to be worn away. When a man carried on the business of a baker he must know whether his bread contained alum or not. He held that where a man carried on a trade which required skill he must have a knowledge of it.

The defendant was then fined 20*s.* and 23*s.* costs.

THE SALE OF ANNATTO.—ALLEGED IMITATION OF LABEL.

In the Vice-Chancellor's Court, on Monday, May 5th, the case of Fullwood *v.* Fullwood was heard. It was a motion to restrain the defendant from selling annatto in bottles bearing labels similar to the plaintiff's. The plaintiff, Richard Jackson Fullwood, of 24, Somerset Place, Hoxton, is a manufacturer of annatto. The plaintiff's trade mark was a stag with an olive branch, and his bottles were of different sizes, bearing labels of a light brown or grey colour, having under the trade mark the title—"To Farmers and Dairymen. R. J. Fullwood and Co.'s Highly Approved Fluid Extract of Annatto for Colouring Cheese and Butter." The defendant, Henry Fullwood, is a nephew of the plaintiff, and a manufacturer of annatto under the firm of "Henry Fullwood and Co." The plaintiff alleged that the defendant, who had formerly carried on his business at Kingsland, had recently removed to No. 1, Somerset Place, Hoxton, a few doors from the plaintiff's premises, and had adopted labels and bottles similar to his. The defendant's labels bore at the top the device of the Royal Arms, and the following title:—"For Colouring Cheese and Butter. H. Fullwood and Co.'s Concentrated Liquid Extract of Annatto for Farmers and Dairymen." The plaintiff accordingly now moved for an injunction as above mentioned.

The Vice-Chancellor said that the Fullwood family had, it appeared, been annatto manufacturers since the year 1785. The defendant had in 1870 set up in business in Kingsland. When he began business he called himself "H. Fullwood and Co.," the object of which, if it was a right object, was not altogether clear. When a man starting a business by himself added "and Company" to his name when he intended to trade alone, his so doing was a badge, to say the least, of unfairness. It was not quite a proper thing to do. The defendant's whole conduct showed a desire to become known as connected with the plaintiff's old-established firm of "Fullwood and Co." To complete the matter, in the spring of 1872 the defendant moved into the very street in which the plaintiff carried on his business. There was no shadow of a doubt that his object was to become known as Fullwood and Co., of Somerset Place. The public would not notice the difference between No. 1 and No. 24. His conduct was unfair and fraudulent, and such as the Court could not allow. If the defendant had kept away from Somerset Place, he might have carried on his business with impunity. But his Honour was satisfied that when the defendant removed his business into this street, so close to his uncle, he did so with the hope that the public might be led to confound the two businesses, and to further his object he had adopted bottles of the same shape as those used by his uncle, and labels very similar in appearance. Therefore, under all the circumstances of the case, he was of opinion that the plaintiff was entitled to an injunction.—*Grocery News.*

A DRUGGIST FINED UNDER THE VACCINATION ACT.

At the Preston Police Court, Mr. Edward Foster, chemist and druggist, of Friargate, Preston, was summoned, for the twenty-fifth time, for the non-vaccination of his child. The defendant appeared, by proxy, his representative being Dr. Dupré, of Manchester. Dr. Dupré contended that vaccination was impossible. They punished Mr. Foster now for the twenty-fifth time for refusing to do that which he could not do. The Lyons Society of Medical Sciences had appointed a committee, of which MM. Chanveau and Viennois were prominent members, to experiment upon the transmission of small-pox and cow-pox. From ample data they concluded that these diseases were perfectly distinct, the one from the other, and could never be transmuted the one into the other. The fact was that the vaccination movement was a money-getting swindle, and many persons connected with the Local Government Board made a fine thing out of it.

The Mayor said that the summons required the appearance of the child. It had not been brought, and the case would be adjourned for a week for its production.

HOSPITAL INQUIRY.

In the course of an inquiry by a committee of the Guardians of the Wandsworth and Clapham Union respecting two deaths that had taken place in the workhouse, it was incidentally stated by a nurse that she administered once two tablespoonfuls of ammonia and ether to one of the patients. In their report the committee state their opinion that the "lax and dangerous system of allowing a nurse to administer on her own judgment and responsibility ammonia and ether, or any other drug, cannot be too strongly condemned," and suggest that such a course might have been fatal in the case under inquiry. Ultimately it was decided to bring the facts of the case under the notice of the Local Government Board.—*From the Wandsworth and Battersea District Times.*

Obituary.

On the 8th of May, Mr. David Edwards, Pharmaceutical Chemist, died at his home, Glanmyddyfi, near Llandilo, South Wales. Mr. Edwards was a student in the Pharmaceutical Laboratory during the Session of 1871–2, where he was much esteemed by his tutors and fellow-students. He passed his Minor examination with honours in July, and his Major with honours in December, 1872. It is thought probable that his early death was in a great measure the effect of privations which he suffered in Paris during the siege and the civil war.

Correspondence.

"*Inquirer.*"—We think the assumption of the modified title you mention would be merely an evasion of the Pharmacy Acts, 1852 and 1868. According to section 12 of the former, any person unlawfully styling himself "pharmaceutical chemist" or "pharmaceutist" is liable to a penalty of £5; and the latter, clause 15, still more explicitly provides that any one who shall improperly use the title "pharmaceutical chemist, pharmaceutist, or pharmacist," shall be similarly liable. We think, therefore, you will clearly see that your informant must be grievously mistaken.

"*How to Kill Beetles.*"—Our correspondent is thanked for his communication, but inasmuch as we reprinted a paragraph recommending borax for the destruction of beetles just two years since, and its merits were then discussed by several correspondents (see Vol. I. p. 982, 1001, etc.), we think the proposed remedy is neither a novelty nor yet sufficiently forgotten to be brought forward as one.

"*A Subscriber to the Fund.*"—We have received your letter, but inasmuch as Mr. Clark has now virtually abandoned the ground which he first took in criticizing the administration of the Benevolent Fund, we think it undesirable to prolong this discussion.

*** We are compelled by press of matter to defer the publication of several communications, answers to correspondents, etc.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Pocklington, Sturton, J. Abraham, G. Brown, Wilkinson, Matthias, Learoyd, "A Cumbrian," "An Onlooker," "Boz," "Reader," "Ignoramus," "Live and Let Live," "Olim Juvenis," "Isca," G. C., H. G. R., R. T. C. D.

THE ANNUAL DINNER.

The Second Annual Dinner of the Members and Friends of the Pharmaceutical Society took place on Tuesday evening at the Crystal Palace. The chair was taken by Mr. A. F. Haselden, F.L.S., the President.

The President, in proposing the first toast, said it was one which always was, and he doubted not always would be, responded to most heartily in all assemblies of Englishmen—"The Health of Her Majesty the Queen." Having spoken so freely and fully on a previous occasion of the virtues which adorn Her Most Gracious Majesty, he would not detain his audience by recapitulating them, but would simply ask all present to drink in a bumper, "Health and Happiness to Her Most Gracious Majesty the Queen."

The toast having been drunk in the usual loyal manner,

The President briefly but forcibly proposed "The Health of the Prince and Princess of Wales, and the rest of the Royal Family," with the hope that it would be many years before the Prince was called upon to assume the cares and dignity of royalty.

Mr. W. Scott Brown, Vice-President, in proposing the toast of "The Medical Profession," referred to the attendance, so numerous as to give the assurance of a continuation of the annual gatherings so happily inaugurated twelve months since. At that period a dark cloud which had for a time overshadowed the whole nation was just passing away; and it had served to render more than ordinarily apparent the bright light of medical skill and devotion. Happily, during the past year and now, there was no dark background to give increased lustre; but the lamp of medical science burnt steadily, and needed not to be made apparent to those who were able to appreciate the benefits conferred on the sick and suffering. If, as had been said, gratitude consisted in "a lively expectation of favours to come," in no assembly could the toast which had been entrusted to him meet with a more ready or hearty reception than in that which he was addressing. Years ago a certain William Shakespeare described, in language which probably was familiar to all, a certain very useful body of men, and no doubt his words were appropriate at the time; but certainly, looking around him, he did not think they were quite so apt in the nineteenth century. Their obligations to the medical profession began with the earliest period of their existence, and in after years few, indeed, were so fortunate as not to be in a position to recall circumstances in which some member of the medical profession had interposed between them and the king of terrors a shield which, at any rate for a time, turned aside his darts; and when the last inevitable time arrived, it was one of the solaces of human existence to know that we should then receive all the alleviation of our condition which medical skill and benevolence could bestow. Yes, the medical profession was a truly noble one, and well had it maintained its character in this country. He need not recapitulate the great names which had adorned its annals in the past, and it would be invidious to mention only a few of those who adorned the present era, nor was it necessary to do so, as they were especially familiar to such an audience. During the past year a great deal had been heard about medical charities and their abuses, and this one fact spoke volumes for the medical profession, that, knowing as its members must have done of the abuses connected with the administration of many of these noble charities, which, abuses notwithstanding, were the pride of Englishmen, they still continued to render to them services of a priceless character, for which they could never be compensated except by the knowledge that they received the most cordial good wishes of every member of the community. Efforts were now being made to redress these abuses, and he hoped before long some well-devised scheme would be prepared, which, while preserving those noble foundations, would prevent the misapplications of them which were in reality unfair both to the medical profession and to their own body. Speaking as a country member of the Council, he was proud to be able to say that every year showed that a better and more cordial understanding was springing up between the medical profession and that body to which he had for many years had the honour to belong. He sincerely hoped that such cordiality would continue to increase, and that it would be fostered and encouraged by such meetings as the present. He begged to couple with the toast the name of Dr. Quain.

Dr. Quain, in returning thanks, said he felt it difficult to adequately acknowledge the very cordial welcome which the toast so eloquently proposed by Mr. Brown had secured. He rejoiced to think that the feeling of jealousy that once existed between their bodies was passing away. This he attributed to a better understanding of the functions and duties of the members of those bodies, and to a better and higher education, both of the members of the medical profession and of pharmacists. It was not difficult to remember the time when the practice of medicine consisted of the study of a few symptoms, of feeling the pulse, looking at the tongue, and prescribing a certain quantity of physic, more profitable, perhaps, to the practitioner than to the patient. Now, however, by the aid of physical science, the phenomena of life in health and disease were closely scrutinized. The stethoscope, the ophthalmoscope, the laryngoscope, the test glass, and the crucible were made use of, and thus an accuracy of diagnosis never previously dreamt of was obtained. So, too, with regard to pathology; by the aid of the microscope and its appliances, an immense advance in our knowledge of the nature of diseased processes had been made. There was still one branch in which there was great room for progress, viz., the treatment of disease. We want a better knowledge of therapeutics; and as therapeutical success must depend on the character of the agents used, we must look to pharmacists for help in this respect. This is the return we must ask for the favours to which Mr. Brown had alluded. He rejoiced to see the successful efforts which had been made in the promotion of education by the pharmaceutical body. These efforts may be traced in the character of their Preliminary, their Minor and Major examinations, and the result may be recognized in the published proceedings of their Council, their evening and other meetings, which afforded evidence of rare judgment, intelligence, and scientific knowledge. In wishing prosperity to the Pharmaceutical Society, he begged to connect the toast with the name of their present President, Mr. Haselden, the last of a list of distinguished names. He referred to the names of William Allen, Jacob Bell, John Savory, Peter Squire, Henry Deane, Thomas Morson, George Sandford, and others, who had rendered, each in his own way, valuable service to the Society and to pharmaceutical science,—of these gentlemen the present President was a worthy and successful follower. He saw a great future for the Society, for he saw in so large a body of educated men throughout the country, valuable allies of the medical profession, and he wished them all success.

The President begged to thank Dr. Quain, personally and on behalf of the Society, for the kind manner in which he had proposed the toast, and the company for the way in which they had received it. He was also grateful to the medical profession for the support which had been accorded by it thirty years ago, in the early days of the Society, not only morally but practically, by giving lectures freely and spontaneously, for which the Society had at that time made no settled provision. The advantages of the Society, of the education it bestowed, of the evening meetings, of the conferences, of such social gatherings as the present, and the conversazione, were obvious to all, and did not require to be more especially mentioned. Two years ago, in 1871, the first attempt was made at an annual dinner. There were at the same time two annual dinners going on, a small cloud being present which threatened to burst over us; it did not burst, but was quietly and gradually dispersed. So that in 1872 there was but one annual dinner, and that at the Crystal Palace, which was a success; and again, now, a repetition of the dinner, which, he trusted, had again been a success, and gratifying to them all. Although he took no credit to himself for the establishment of this dinner, yet he felt greatly pleased that it had been established whilst he occupied the presidential chair.

Mr. T. H. HILLS, in proposing the toast of "The North British Branch of the Pharmaceutical Society," said that, as he assumed every one there present was in the habit of reading the PHARMACEUTICAL JOURNAL, it would be unnecessary for him to enter into any particulars as to the labours of their friends in the north, since they would already have read the annual report which appeared in last week's Journal. But he could not propose this toast without making special reference to some of those who had been prominent in their endeavours to promote the objects of the Society in Scotland—Mr. Macfarlan, Mr. Mackay, and Mr. Frazer. Of Mr. Macfarlan, who was gone from them, he need only say, Peace be with his memory. Mr. Frazer also was most active in carrying out the best interests of the Society, and he regretted his absence that night. He also deeply regretted the absence of Mr. Mackay in consequence of domestic affliction, but he would take the opportunity thus afforded him to speak with more freedom of the great services rendered by Mr. Mackay for so many years as Honorary Secretary of the North British Branch. It was no exaggeration to say that John Mackay had done in Scotland what Jacob Bell had done here. However, there was a most worthy representative from Scotland in the room, Mr. Baildon, who had always taken the greatest interest in the Pharmaceutical Society, and therefore he begged to couple with the toast of "The North British Branch of the Pharmaceutical Society" the name of their esteemed friend, Mr. Baildon.

Mr. BAILDON, in responding to Mr. Hills' toast, said that he was very much pleased by the way it had been proposed by Mr. Hills, and for the very kind reception it had met with from the large assembly of pharmacists present. He remarked that the interests and objects of the North British Branch were one and the same with those of the parent Society, and that the Board of Examiners in Scotland were most anxious to conduct their examinations in strict accordance with the suggestions and regulations of the Council in London. Their students had now ample facilities for acquiring a scientific knowledge of pharmacy by attending the classes of the professors in the university, or by attending the lectures in the medical school, and he had pleasure in stating that they were availing themselves of these classes in increasing numbers every year. He regretted very much that owing to a domestic affliction his friend Mr. John Mackay was not present. The North British Branch were greatly indebted to him for the valuable services gratuitously rendered by him for a long period of years.

Mr. BETTY next rose to propose "The British Pharmaceutical Conference," "an association bearing the closest relation to the Pharmaceutical Society, and possessing the machinery to meet increased requirements for organizing and systematizing research." As our individual organisms depend for their healthy development upon conditions materialistic and intellectual, so must the due advancement of pharmaceutical culture ever be essential to pharmaceutical institutions. In speaking of the British Pharmaceutical Conference one of the great results flowing from its free and expansive genius might be referred to. It was not, and never was, an association exclusively of the Pharmaceutical Society, of any division of the United Kingdom, nor even of a continent: it had formed a bond of brotherhood between thinking labourers in science. In its earliest gatherings this catholic feeling found expression in the conviction that the Pharmaceutical Society had a mission, which was to become the representative of the interests and of the unity of their calling, and a mission in which it should brook no rival; and now that the Pharmaceutical Society had received its powers and its privileges, and had accepted together with them the responsibility of maintaining its position as an educated and examining body, it was to such an association as the Pharmaceutical Conference it could point to furnish proof truly of its progress and its influence, but essentially of its vitality. And whilst they might say, Long live the Pharmaceutical Society, they might add, May the Pharmaceutical Conference be coexistent with it,—that Conference which, born of their exigencies, might be said to have stepped forth, like Minerva from the brain of Jove, equipped for its task as the champion to do battle for the intellectual life of present and future pharmacy. The officers of the association included in their number some of the most illustrious names which adorned the ranks of pharmacy; but time only allowed of mentioning Mr. Brady, the present President, who, he regretted to say, was not present that evening. So long as addresses such as he and his predecessors had delivered were continued at the annual meetings, so long would the interest of the Conference be sustained, and of this he had no fear. He begged to couple with the toast the name of one of the officers of the Society, who had so zealously and with such talent laboured to place the Conference in the position it now held—the Secretary, Professor Attfield.

Professor ATTFIELD, on the part of the President and other officers of the Conference, thanked those present for their generous wishes for the success of the Conference, and acknowledged the compliment paid him by the association of his name with the toast. Every one of the present and past officers, he would venture to say, had been actuated by two motives—first to encourage an onward march into the untrodden regions of pharmaceutical research, and next to foster friendly feelings amongst pharmacists, and it was pleasing to know that very great success had resulted. But this state of prosperity was only in part due to the efforts of the officers. They must not forget the twenty pioneers who first cleared the way for the Conference ten years ago on the banks of the Tyne, nor the two hundred who enrolled themselves under its banners at the first annual meeting at Bath, nor yet the six hundred who joined its ranks in the ensuing years, before anything so tangible as the 'Year-Book' could be offered in return for support. Nor must the authors of papers be forgotten, for without them the annual meetings could not be carried on. Much of their success was also due to the labours of the local officers of the Conference in the towns where it held its meetings, and acknowledgement must also be made of the encouragement they had always received from kindred associations, especially from the Council and leading members of the Pharmaceutical Society of Great Britain, and the pharmaceutical press both of Europe and America. To these things as well as to the energies of the executive must be attributed the fact that their numbers had increased from twenty to twenty hundreds. As to the future success of the Conference he did not believe there was a gentleman present who felt the least doubtful on that point. The influences which had brought it to its present position were as vigorous as ever, if not more so. Any difficulties which might be met with by members in carrying out expensive researches were removed by the munificence of a gentleman whose name he need not mention, who had lately given the Association £200 with which to aid original workers. And with regard to the supply of such workers, he felt perfectly sure, that so long as the Pharmaceutical Society continued to promote that high class pharmaceutical education which it had provided for the last twenty-five years, there would be no lack of men who would engage in original investigations. Lastly, with reference to general support, he would say that the officers of the Conference would never rest satisfied until they knew that their annual volume, the 'Year Book,' was to be found on the shelves of every pharmacy in the British Empire.

Dr. RAMSEY proposed the health of the Stewards, which was briefly acknowledged by Mr. Carteighe, and this concluded the list of toasts, the remainder of the evening being devoted to friendly conversation.

THE ANNIVERSARY MEETINGS.

THE amount of space occupied by the reports of the several meetings which have taken place this week leaves no room for more than a few very brief remarks on some of the most prominent features of the week's proceedings.

Speaking of these in the order of their occurrence, it is with great gratification that we are able again to record the unqualified success of the Annual Dinner, and to add that the number of those present was considerably greater than last year.

In the discussion on the Council's Report at the annual meeting, Mr. ATKINSON PICKERING, still urged by that spirit of "dogged perseverance" by which he desires to be animated, again came forward in the cause of Provincial Education. While admitting that the trade was indebted to the Council for the influence it had exercised on recent legislation, he did not hesitate to declare his opinion that the executive body was wanting in its efforts to educate those who practise pharmacy. This he still regards as the primary duty of the Society. We have already attempted to show that he is in error in this respect, not only in his too literal interpretation of the Charter, but also in disregarding the altered position the Society now holds.

Mr. PICKERING complained that out of an income of £10,000 a year the Society gives almost nothing to further education in the provinces, and with strange inconsistency he prefaced this complaint by a pointed objection to the fact, that while the fees paid for attendance on lectures at Bloomsbury Square amounted to only £193 4*s.*, the expenditure on those lectures was £649 9*s.* 5*d.* We thoroughly agree with him in thinking there is here something radically wrong—something indeed that calls for speedy rectification; but we do not think a remedy would be found in carrying out a similar distribution of the Society's funds in country towns, nor do we concur with him in disregarding the fact that this expenditure of some £450 per annum is incurred mainly for the benefit of the provinces, and of students coming from the country.

We mention this fact not at all for the purpose of justifying the discrepancy between outlay and income for lectures, nor merely to show that the aid rendered by the Society to education of provincial students is really greater than it has credit for, but also for the sake of protesting against the continuance of a system which is inconsistent with the Society's present status, however much it might be appropriate, while the acquisition of competent skill by education, was, for the pharmacist, a purely optional thing.

It is impossible now to follow this subject further, although Mr. PICKERING'S declaration that the Society is not popular with the country members, because it compels their young men to undergo three examinations, and—as he says on their behalf—gives them nothing in return, betrays a state of mind which obviously renders this subject deserving of further earnest attention.

The next subject of interest which occupied the meeting was the question as to the right of women to be admitted into the Society. Mr. HAMPSON, in moving the resolution of which he had given notice, dwelt especially on the words of Lord BROUGHAM'S Act, providing that the word "person" should include women, while at the same time he objected to the Society being regarded in any degree as a private one. On these grounds he contended that, as women were free to become chemists, and be registered as such, they were equally entitled to become members of the Society. His seconder, Mr. BOSTOCK, based his support of the resolution chiefly on æsthetic considerations; and Mr. PICKERING, in proposing as an amendment that the consideration of the question should be adjourned *sine die*, did so mainly on the ground that when the Society was formed there was no intention to include women under the term "person." He also urged that, since the practice of pharmacy was so much less suited for women than many other occupations that were open to them, its adoption by women should not be encouraged by admitting them members of the Society.

Several of the other speakers failed to keep in view the distinction between the right of women to registration as chemists and druggists, and the question actually before the meeting, whether they should also be admitted members of the Society. Indeed it was only with some difficulty that the discussion was kept to the real point at issue. The necessity for observing this distinction was, however, insisted upon by Mr. SANDFORD, Mr. GILES, and Mr. BETTY, while Mr. FLUX, the Society's solicitor, pointed out that Mr. HAMPSON, in refering to BROUGHAM'S Act, had omitted the proviso as to the context of an Act being consistent with the extension of the term "person" to women. He also expressed his opinion that in regard to election of members, the Society possessed all the privileges of a private association, and eventually the amendment was carried by a considerable majority.

The remaining business of the meeting had reference to the bye-laws which were adopted after some discussion, but we must defer any remarks on this subject.

The Conversazione in the evening at South Kensington was attended by nearly 3000 visitors, and was in every respect as attractive and agreeable as it has always been hitherto.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

May 21*st*, 1873.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

MR. W. SCOTT BROWN, VICE-PRESIDENT.

Present—Messrs. Atherton, Betty, Bottle, Frazer, Greenish, Hampson, Hills, Owen, Radley, Sandford, Savage, Schacht, Shaw, Stoddart, Sutton, Urwick, and Williams.

Several members, associates, and apprentices who had paid their subscriptions since April 30th, were ordered to be restored to their former status in the Society, on payment in each case of a nominal fine.

The VICE-PRESIDENT asked if it was the rule for the Secretary to apply direct to all members who had not by the end of March paid their subscriptions to the local secretaries. He believed some members felt themselves aggrieved at having their names erased from the list without previously having a reminder.

Mr. SUTTON said he always informed gentlemen in his district who had not paid by a certain time that they must forward their subscriptions to the Secretary direct.

Mr. STODDART having spoken to a similar effect,

The PRESIDENT, referring to the minutes, said the resolution directed the Secretary to apply to all members who had not paid their subscriptions by a certain date.

Mr. SANDFORD said he believed there was a little misunderstanding on this matter. The resolution was passed in order to prevent the occurrence of a difficulty which had sometimes happened, of gentlemen losing their votes at the annual meeting in consequence of their subscriptions being retained in the hands of the local secretaries. The Secretary was therefore directed to apply personally to gentlemen who had not paid by the end of March, but he believed that was only intended to apply to gentlemen whose votes would be endangered by the nonpayment of their subscriptions, not to associates or apprentices.

The SECRETARY said that was certainly the understanding. The first week in January he sent to all local secretaries a list of members and associates in business, but he never sent out a list of apprentices and associates not in business, because they were very migratory, and it would be giving local secretaries unnecessary trouble. A circular was sent, in April, to members and associates in business who had not paid, and if this were not attended to, a second was sent, besides which the notice appeared constantly in the Journal.

Mr. SUTTON said he should be very glad if the local secretaries were relieved altogether of the duty of collecting subscriptions.

THE NEW BYE-LAWS.

The amended bye-laws were passed a third time by the Council preparatory to their confirmation by the General Meeting.

SHOP HOURS' REGULATION BILL.

Mr. BETTY asked if the attention of the Parliamentary Committee had been called to a Bill now before Parliament called the Closing of Shops Bill?

The SECRETARY said the Bill was set down for the 18th June, before which time there would be an opportunity of considering it.

The VICE-PRESIDENT said it was hardly possible for such a Bill to pass the House of Commons, but it would not do to assume too much, and therefore he had no doubt that the Parliamentary Committee would give their attention to it.

THE THIRTY-SECOND ANNUAL GENERAL MEETING OF THE PHARMACEUTICAL SOCIETY.

Wednesday, May 21*st*, 1873.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

The Thirty-second Annual General Meeting of the Members of the Pharmaceutical Society of Great Britain was held at 17, Bloomsbury Square, on Wednesday, May 21st, at twelve o'clock.

The SECRETARY having read the notice convening the meeting, the CHAIRMAN said :—

Gentlemen,—For the third time I find myself in the honourable position of Chairman at the Annual General Meeting—the thirty-second of our Society—and I venture to congratulate you upon the steady and prosperous condition which has been maintained up to the present time, and which, as regards the past year, the Report presented by your Council fully declares; it is always a pleasure to meet old friends, more especially when the sky is clear above, and there are no volcanic rumblings underground. The science of pharmacy steadily progresses, and the Pharmaceutical Society of Great Britain is highly esteemed on the Continents—East and West; but I am more particularly desirous of referring to home questions interesting to and affecting ourselves.

The appointment of a professional short-hand writer to attend at and report the proceedings of the Council is satisfactory to all concerned, and has in no way taken from the spirit and earnestness of the debates, whilst it has removed a great weight of responsibility from the members of the Committee who previously did that somewhat difficult work.

The alterations (coming into force in October, 1874) which have been made by the Council in the regulations for conducting the examinations are, in my opinion as a constant attendant and as chairman *ex officio* of the board, also from an examiner's point of view, not merely judicious but desirable. Statements respecting the examinations are partially current to which I should have wished, if possible, to have turned a deaf ear, but I could not. The opinion is entertained by some that the chances of passing are in favour of those who have attended the lectures and laboratory in Bloomsbury Square; for this I say most emphatically there is not the remotest foundation. As a rule the examiners know nothing of the antecedents of the candidates; on the contrary, it is somewhat notorious that young men from the provinces, who have never attended the lectures in London, and students from other schools, have been, numerically, the most successful in passing. Complaints have appeared in the "Correspondence" columns of the Journal against the manner of conducting the Preliminary examination; these strictures should not, as I take it, have been made against the mode prescribed for carrying out the examination, but that occasionally a superintendent has not performed that part of the duty imposed upon him as he should have done. It appears to me that the remedy for this would be to appoint certain towns as centres, where the writing of the papers should take place, and if required, that a member either of the London or Scotch board should be sent to superintend. It may be well, perhaps, to remind you that "Certificates of having passed the Local Examinations of the Universities of Oxford, Cambridge, or Durham, the Examination of the College of Preceptors, or of those of any legally-constituted examining body, previously approved by the Council, *provided Latin and arithmetic be included in the subjects*, are accepted in lieu of this examination;" but to give up our own and compel all to go to one of those Boards would be unwise and unfair. To have passed in silence over this, which has been so freely handled by correspondents, would have been a weakness on my part. How gladly and willingly would I, if I could, report upon improvement in the answers furnished by candidates, and consequent diminution in the number of failures.

As usual, early closing has engaged considerable attention in many localities during the year. I believe that, for the present, as much has been accomplished in that direction as could be consistently with our calling generally, and with the peculiarities of situation and the requirements of our patrons. I sincerely trust that those for whom the arrangements have been made may reap benefit in the way in which it was intended, taking advantage of increased opportunities for study, as well as relaxation from toil.

I cannot refrain from again touching upon the question of prices, a question almost daily in some way or other coming to the fore. The mere cost of an article should not decide the charge to be made, but rather the time, the skill, and the care employed, also the cost of education necessary to fit one for the office of dispenser, even if the cost of drugs, etc., were uniformly the same; but now that speculation in one shape or another is continually affecting the prices of the most important chemicals and drugs in use, this charge for qualification is more than ever necessary. The simplest plan would appear to be a fixed charge per dose, irrespective of the cost of material, supplementing with an increase for increased market value. Indeed, did nothing else suggest such a mode of proceeding, the increase in the price of everything, either pertaining to the business or otherwise, would almost enforce a consideration of the subject. Members should face this boldly by communicating and consulting with each other, put an end to low charges, and form a determination to work upon a fair and remunerative scale.

The number of subscribers to our Benevolent Fund increases. Some difference of opinion still exists as to the most desirable course to be adopted for its distribution—as it is, the deserving are not refused aid or neglected; although it is just possible that money has, upon a rare occasion, been badly made use of, still it is better that the undeserving should occasionally enjoy rather than any deserving be refused.

Provincial associations, I am glad to say, are increasing. There are now twenty-four which report their proceedings through the Journal, besides the North British Branch. Their prosperity seems to be good, if any estimate can be formed from the small number of applications for aid. I may be excused for repeating the language of the Report: "It must not be forgotten that under regulations at present in force, assistance can be rendered to local associations which are doing efficient work."

A deputation from the Council, of which I was one, paid an official visit to the North British Branch of the Society as recently as last month. I should be deficient in courtesy if I did not speak of the excellent spirit which exists in the North towards the parent Society in the South, and the great desire there is to promote in every way the interests of pharmacists generally. Towards your President, and the gentlemen who accompanied him, I cannot speak too strongly of the kindly feelings manifested and the unbounded hospitality.

I regret very much that death has been lately more than usually hard upon us, so much so that I dare not enumerate: but I cannot pass over two names;—the one, Mr. G. Waugh, so many years an honoured and valuable member of Council, and always a generous contributor to the Benevolent Fund; the other, Mr. James Garle, I believe one of the earliest members of the Board of Examiners and to the last, kind, patient, and careful.

In accordance with notice of motion, the question of admitting females as associates and members of the Society will be submitted to you after the Report of the Council has been received and adopted. I will simply remind you that it is not a question of admitting them to lectures or examinations upon which you will be asked to express an opinion, those points having been already settled; but whether it is desirable, whether it was originally contemplated, that our Society should admit them as members. You will vote upon this point, I am persuaded, with that discretion which you have so often shown, and whichever way it may be decided, the minority will bow to the expressed wishes of the majority. I sincerely hope that you will not follow the example of your Council, and place me in the unenviable position of having to give a casting vote.

Notice has been given in the Journal, that at the conclusion of the business of this Annual General Meeting, a Special General Meeting of the members of the Pharmaceutical Society will be held, for the purpose of abrogating or altering some or one of the bye-laws of the said Society, and of considering, and, if thought proper, of confirming and approving such new or additional bye-laws, etc., etc. You will, I am confident, in considering this matter, giving your earnest attention in the interests of the public and also of your Society, confirm the bye-laws or alterations as recommended by your Council.

A few words more and I have finished. Possibly you have observed the absence of my name from the list of candidates for the incoming Council; and it is due to you that I should offer some reason for my retirement. For fourteen years uninterruptedly I have been a member of Council, working ever—as I believe I have done and as I still hope to do—in the interests of pharmacy and the Pharmaceutical Society; but seeing that the number of Councillors residing in London must be limited, in order that the country may be fully and fairly represented, it seems to me desirable that such a one as myself should occasionally retire, if but for a season, and make way for others desirous of filling the office and enjoying the same honours,—beyond this I feel that I may be equally useful in another sphere, viz. the Board of Examiners.

Permit me now to thank you for the attention with which you have listened to me; my colleagues in Council, for their unwavering kindness and support; and our excellent and indefatigable Secretary and Registrar. With this it only remains that for the present I should say—

"Farewell! a word that hath been and must be
A sound that makes me linger; yet, farewell!"

The Report was taken as read.

REPORT OF THE COUNCIL.

In reviewing the proceedings of the past year the Council confidently believes that after full discussion on matters which from time to time have come under consideration, conclusions conducive to the general interests of the Society have been arrived at. It is indeed an advantage that different shades of opinion should be fully represented in the governing body, and in the reports published from month to month of the debates in the Council, these find full expression.

The financial statement is upon all occasions an important feature in the Annual Report. It will be observed that the income of the Society has in no way diminished during the past financial year, but exhibits an increase upon former statements, upon which the members may fairly be congratulated.

On reference to the Registrar's Report for the year 1872 of the number of members, associates, and apprentices of the Society, it will be seen that there was an increase of 90 members, 176 associates—86 in business, 90 not in business—and of 31 apprentices.

One of the most important duties of your Council during the past year has been the revision of the regulations for conducting the examinations. This subject was urgently pressed on the Council by the Board of Examiners, to whose judgment great deference is undoubtedly due in the matter. It was specially represented that, as on passing the Minor examination a candidate was entitled to registration as a chemist and druggist, and certificated as qualified to perform the most important duties of his business, it was essential that the examiners should have better proof of his practical acquaintance with dis-

We, the undersigned Auditors, have examined the Accounts of the Pharmaceutical Society, as presented in the Financial Statement and Benevolent Fund Account, and find them correct; and that there was standing to the account of the Society at the Bank of England on the 31st December, 1872 :—

		£	s.	d.	£	s.	d.
General Fund	New Three per Cents.	13,200	0	0			
Life Members' Fund		3,000	0	0			
					16,200	0	0
Benevolent Fund	Consols	12,700	0	0			
Pereira Memorial Fund		100	0	0			
					12,800	0	0
Bell Memorial Fund—Consols					2,050	0	0
Secretary's Casual Relief Fund—Consols					105	0	0
Hill's Prize Fund—Russian Bonds					200	0	0

FREDERICK ANDREWS,
FREDERICK BARRON,
WILLIAM HODGKINSON, *Auditors.*
EDWARD HORNER,
WILLIAM SQUIRE,

April 8th, 1873.

pensing than had sufficed when he only received from them a certificate of competence to take the rank of an assistant. In order to effect this, a small portion of the present Major examination will be, according to the new arrangement, transferred to the Minor. It is, however, extremely difficult to obtain, in the time which can be allotted to the examination of each candidate, satisfactory proof of his manipulative skill and practical knowledge. The Council, agreeing with the Board of Examiners, have framed a regulation, requiring each candidate to be of the full age of twenty-one years, and to produce certificates of having been employed for three years by a Pharmaceutical Chemist or Chemist and Druggist, and in dispensing and compounding prescriptions. This will come into operation in October, 1874. So deeply impressed, however, are the Council with the necessity for this alteration, that in order to give it greater weight, the same principle has been embodied in one of the new byelaws, to be submitted for confirmation and approval to a special meeting of the Society, convened for this day.

Full proof of a practical knowledge of dispensing and pharmacy having been given in the Minor examination, it ceases to be necessary to re-examine on these subjects, therefore "Practical Dispensing" and "Pharmacy" will no longer form part of the Major examination.

The importance of insisting on a youth passing the Preliminary examination before entering on his apprenticeship cannot be too strongly maintained; once apprenticed all his time is required to obtain *technical* education, and the possession of proper elementary education would therefore be an ultimate advantage to him as well as a means of advancing the general status of the trade.

The number of candidates who passed examinations during the year 1872 in England and Wales, as compared with the year 1871, is as follows :—

	1871.	1872.
Major	50	52
Minor	234	287
Modified	123	96
Preliminary	802	782

Since the institution of the Jacob Bell Memorial Scholarships in 1861, only three Senior Scholarships have been awarded, showing that the expectations of the founders have not been realized. The Council therefore determined to abolish the Senior, and in its place institute a second *Junior* Scholarship. They also revised the syllabus of the examination, and enlarged its scope with a view to test the candidates' abilities, industry, and range of education. Thus, *inter alia*, 'Virgil' has been substituted for 'Cæsar,' and one modern language—French or German, at the option of the candidate—has been added. These alterations to come into operation in 1874.

In the report last year it was stated that premises necessary for conducting the examinations and the affairs of the Society in Scotland had been obtained, and were being arranged: the Council has the satisfaction of stating that eligible premises are now occupied by the North British Branch of the Society. A deputation from the Council, consisting of the President, Vice-President; and the Secretary, accompanied by Mr. Williams, has paid an official visit to Edinburgh.

The Council, always solicitous to promote the usefulness of the library, has continued, with the assistance of the Committee, to supply new and suitable books for study and reference. The attendance of readers has been good during the day, and the Council has pleasure in observing that the evening attendance has also increased.

The museum of the Pharmaceutical Society is a most important feature of the establishment, and deserves every attention. There is probably no collection in existence more interesting to pharmacists than that accessible at all times to members and students in Bloomsbury Square. During the past year a new curator has been appointed for the museums, and certain changes have been carried out making him more directly responsible for the safe keeping and proper arrangement of the specimens therein contained. An herbarium is also in course of formation, which will prove useful to students. A catalogue is in preparation.

During the past session the evening meetings have been well attended, and subjects of great interest have been discussed.

The Parliamentary Committee has been much occupied with questions involving the interests of the Society and of chemists and druggists generally. Strong representations were made by your Council to the Solicitor-General, showing the great advantage to be secured to the public by leaving dispensers of medicine at their daily avocation rather than enforcing their absence therefrom by calling them to serve on juries. In compliance with these representations the Bill to amend the Juries' Acts, now before Parliament, contains an exempting clause for chemists and druggists.

Late in the last Session an Adulteration of Food and Drugs Act was passed rapidly, and almost silently, through the House of Commons, and but for the timely action of a deputation from this Committee, would have become law with most obnoxious penal clauses against tradesmen generally, and rendering druggists especially liable for offences over which they had no control. The Marquis of Salisbury, who had charge of the Bill in the House of Lords, and Lord Eustace Cecil, who had taken great interest in the question in the Lower House, at once acknowledged the oppressive character of these clauses and amended them by rendering a man responsible only for such acts of adulteration, or the sale of adulterated articles, as were committed knowingly and with intent to defraud. The Act has since given rise to certain communications with the Government respecting the appointment of analysts, and your Council has had the satisfaction recently of seeing several pharmaceutical chemists appointed by local authorities to the office, which appointments are now waiting the approval of the Local Government Board.

Several prosecutions against offenders under the Pharmacy Acts have been carried to a successful issue, and the Council has every desire to put a stop to the illegal sale and dispensing of poisons, as well as the false assumption of titles protected by these Acts.

During the past year applications have been received for the admission of ladies to the lectures delivered at the Society's house, to the course of practical instruction in the Society's laboratory, and for admission also into the ranks of the Society. The Council determined to admit lady students to the lectures, but not to the laboratory; and deferred the question of their admission to the ranks of the Society, in order that the opinion of the members generally might be elicited at the Annual Meeting.

In compliance with the requirements of the Act of 1868, section 10, one thousand two hundred and sixty-two registered letters were sent by the Registrar to those persons on the register whose addresses were doubtful, and six months having elapsed, second letters were sent to all who had not replied to the first; many addresses were thus corrected, but after a further interval of three months, the names of between six and seven hundred of those who had not answered were struck off the register—clearly showing the necessity for such a provision; at the same time the Council has power to restore the names of such persons on proper proof being given of the justice of doing so.

The Council cannot report any definite progress on the subject of Provincial Education. The scheme which early in the past year was submitted to the trade generally through the local Secretaries of the Society did not appear to enlist such general support as the Council considered necessary to warrant the attempt to carry it into effect. It is gratifying, however, to see that local efforts in this cause are still being made in many provincial centres, and the Council congratulates those who are exerting themselves with so much constancy and zeal. It must not be forgotten that, under regulations at present in force, assistance can be rendered to Local Associations which are doing efficient work.

A Conversazione was held last May at the South Kensington Museum, and the Council has made arrangements for a similar and, it trusts, equally agreeable *réunion*, to take place on the evening of the Annual Meeting.

The Benevolent Fund steadily increases in the number of subscribers and in the amount subscribed; at the same time there has been an increase in the number of applicants for relief, and notably from chemists and druggists and their widows; it is gratifying that assistance could be given, however much the necessity for such applications may be regretted. The amount of annual subscriptions in 1871 was £594 3*s.* 6*d.*, of donations, £74 7*s.* 10*d.*; in 1872, subscriptions, £749 2*s.* 6*d.*, donations, £84 13*s.* 6*d.* In addition to this, a legacy of £500 was received from the executors of the late Mrs. Lyon. Although as a matter of account it will not appear until next year, your Council cannot allow this opportunity to pass without recording publicly the generous gift of £100 from Mrs. Waugh, given at the express desire of the late Mr. George Waugh, who was for many years a member of Council, and always, from its commencement, an ardent supporter of the Pharmaceutical Society.

The Council desires to tender its hearty thanks to those gentlemen who have performed the responsible duties of Local Secretaries.

The following registers were placed before the meeting:—

Register of Members, Associates and Apprentices of the Society.
Register of Pharmaceutical Chemists.
Register of Assistants.
Register of Apprentices or Students, Under the Pharmacy Act, 1852.
Register of Chemists and Druggists, Under the Pharmacy Act, 1868.

Mr. J. O. Davis (Kilburn): Mr. President and gentlemen, it may appear presumption on my part in addressing this meeting; but my apology may be expressed in this fact, that I have been connected with the Society since its formation. The duty I have to perform is of a very simple character. I have read this Report very carefully and I shall move,—

"That the Report now read be received and adopted, and published in the Journal and Transactions of the Society."

The Report speaks for itself, and I have very great pleasure, therefore, in moving this resolution.

Mr. F. M. Rimmington (Bradford): I have great pleasure in seconding the resolution that has been proposed.

Mr. Atkinson Pickering (Hull): Whilst I am willing to admit that the Report, financially, is a success, I feel that, educationally, it is not so. Whilst I feel that we are indebted to the Council, and especially to the Parliamentary Committee, for their action with regard to exempting chemists from attendance on juries, and also with regard to the alterations which they have succeeded in getting inserted in the Adulteration of Food Act, clauses which might have been made very useful in the interests of trade, still there are subjects mentioned in this report which do not altogether accord with my way of thinking, and as a member of the Pharmaceutical Society, I feel that I should not be doing my duty if I did not state those points on which I dissent from the Report of the Council. In the first place, the financial statement is not to my satisfaction. I consider it too concise; and I cannot make out, from the statement which I have in my hand, what surplus income you have now in your possession. I see what surplus you possess on the year's statement; but comparing this annual statement with those of previous years, I apprehend that the sum stated here does not fairly represent the total sum that you have in your hands as surplus income. I see that during the past year you have again invested £2000 in the Three per Cents. You are aware, Mr. President, that last year I stated my dissent from the investment of money in this way, either with regard to the general funds of the Society or with regard to the funds of the Benevolent Fund. I consider it is a waste of money investing them in Consols, bringing in something less than three-and-a-quarter per cent., when you can invest in real securities, and securities quite as safe as Consols, which could be obtained, bringing in an income of four-and-a-half per cent. Were the money of the Benevolent Fund invested in a different way it would produce a much larger income. I think I might appeal to the members present whether they would invest their surplus earnings at three-and-a-quarter per cent., and whether they would be satisfied with such a percentage. I apprehend there is nothing to prevent the money belonging to the Benevolent Fund, and the money belonging to the General Fund, from being invested in real securities; and I apprehend in this large city there could be no difficulty in finding securities bringing in that amount of income. It is a source of pleasure to me to see that the laboratory has been conducted so successfully. The laboratory and many other things in connection with the Society are exceedingly creditable to it; but with regard to the lectures there appears to me to be something wrong, and something radically wrong. Of the ability of the lecturers I have no doubt whatever,—there cannot be two opinions as to their ability; but I see the fees amounted to £193 4*s.*, whilst the cost of the lectures was £649 9*s.* 5*d.* I cannot make out exactly from this statement the number of students who have contributed these fees; but I feel persuaded, from the smallness of the amount that has been received, that they cannot be a very numerous body; and yet I find, on turning to the report, there have been a larger number who have passed both the Minor examinations, the Modified examinations, and the Major examinations. Now these must have been prepared from some source or other, doubtless some by private study alone. But how is it that we see so many people advertising in the Journal offering to prepare young men to pass these examinations in so short a space of time? And how is it (that is what I should like to know) that young men give their preference to going to those—I do not use the word disrespectfully—who "grind?" Why is it they prefer going to those "grinders" to prepare themselves for examination when they have here everything which is calculated to give them a thorough scientific knowledge of their business? The lectures appear to me not to be a success. I regret that such is the case, and I should be glad if some explanation could be afforded to the members of the Society why it is so. It does not appear to be so with regard to the laboratory. Why should not the lectures be equally as successful as the laboratory? There is another subject, too, which is a sore point with me. Out of an income of £10,000 a year, I see the magnanimous sum of £10 granted towards furthering provincial education. Now I believe I am correct in stating that the country members of the trade contribute the larger proportion of the income of the Society; and when there is so large a surplus income as there is, I think the Council might, with this large surplus income, do more for the advancement of the trade than by investing it in Consols at 3 per cent. I apprehend that the founders of the Pharmaceutical Society had specially in view, judging from the first clause of its charter, the education of those who practise pharmacy and chemistry. I believe the very first clause in the charter states this; and yet we find there is less money annually granted for the furtherance of that object than there was twenty years ago, when Jacob Bell was living. I think the country members of the Trade are entitled to their fair share of the income of the Society. The Pharmaceutical Society, I can assure you, is not popular with the country members of the trade, and I will tell you why it is not so. They say you compel their young men to undergo three examinations, and that you give them nothing in return. You yourself, Sir—and I agree very much indeed with what fell from you in your opening remarks—have stated the desirability that the prices of drugs should be increased. How can you reasonably expect such a thing, when the next-door neighbour to a chemist can sell everything the chemist sells except poisons, and nine out of ten do not thank you for the trade of them? Dispensing, in the present position of pharmacy, occupies a very small portion of a country chemist's business. If I were to exempt twenty businesses in the country, I believe there are not more than twenty that could make a living by dispensing alone. I do not find fault with the education you are giving to the young men of the present generation; but it is quite possible so far to educate a young man as to give him in the country a distaste for the sale of those things, and the dealing in those things, by which he must get a living. I should have been better satisfied with the Pharmaceutical Society myself had I seen their anxiety to secure for the trade the entire sale of those things on which it compels men to pass an examination; and I think there would be no very great difficulty in obtaining an Act of Parliament for that purpose. If a young man be compelled to pass an examination here in all the articles mentioned in the British Pharmacopœia, surely, having been compelled to pass the examination in these things, it is not right that his next-door neighbour should be allowed to deal in the same things and undersell him. If articles of food in the British Pharmacopœia,—raisins, for instance, and similar things that might be mentioned,—were to be exempted, there could be no difficulty in obtaining an Act of Parliament that would confine to the educated man the sale of and the dealing in those things which he is compelled to pass an examination for. Were this done you would find the Pharmaceutical Society would occupy a far higher position in regard to the country members of the trade. I trust, Mr. President, that the incoming Council of the Pharmaceutical Society will endeavour to secure pharmacy for pharmacists alone. I trust the day is not far distant when the medical profession will be comprised within two classes, the prescriber and the dispenser. It is so on the Continent of Europe, and I do not see any reason why it should not be so in this country as well. I think I have stated reasons why this should be the case. In the present position of the trade, the country members find very great difficulty in getting apprentices, and very often difficulty in getting assistants. These examinations have acted as a bugbear; and many who are qualified by these examinations are endeavouring to enter the higher branches of the medical profession. If you give a young man in the country a distaste for the sale and dealing in of those things, which he must necessarily deal in to get a living, you are doing a great injury to that young man unless you secure to him a pharmacy pure and simple. He ought to have the sale of drugs entirely confided to his care; and unless you do this, the time is coming quickly when a great many of the country chemists will have to close their shops. Apprentices will not offer, young men will not do the work that is necessary to be done in a great number of country businesses. I see there is another subject contemplated, and that is, the admission of females as members of the Society. Perhaps it would be better for me to reserve any remarks upon that until it is brought before the meeting. I do not intend to move that this Report be not adopted, because I am sure that resolution would not be carried; but I am quite sure there are things left out of this Report which ought to engage the very serious consideration of the ensuing Council.

Mr. Mellin (Wimbledon): I quite concur in several remarks which Mr. Pickering has made, and I have myself found the same difficulty in getting both apprentices and assistants, because young men will not now go into the trade on account of the difficulties they have to go through. I think it is a great inconvenience and great expense to young men coming up to town to pass the examinations. Another remark Mr. Pickering has made is, that he thinks druggists ought to keep entirely to their trade. I quite agree with that, but in some cases they cannot help it, because the trade is very mixed. My business is entirely a dispensing business, and I do not do anything else; but in Hull I know they do a large trade in oil cake, and other things. There are a great many complaints in the country of druggists dealing in things that they ought not. People say, why should we not sell citrate of magnesia? you sell tea, coffee, paints, pickles, and so on. I did so when I was an assistant, and likewise sold blacking, and such things. I should be very glad indeed if we could keep the trade more select; but then we should have to reduce the number of chemists. In that way perhaps they might get an increase in prices.

Mr. Richardson (Leicester): I have very great pleasure in supporting the Report; and there is a suggestion which has often struck me, which I should like to see carried out as regards the publication of the Journal. I shall not enter into the elaborate question which has already occupied the time of the meeting, but on this question I feel very much. I think the country members want a little more than they at present get. It has often struck me that an abstract of the lectures might be published in the Journal. When I was a student in this Institution, there was no greater treat than coming to listen to these lectures, and copying them out, and writing them when I got home. I should feel the same pleasure in reading those lectures now, and I conceive it would be a very great advantage to young men in the provinces. I quite thought when our Journal was published weekly, we should have it very much better conducted than what we have. We do not get a sufficient amount of leading articles; I do not think the facts written about have been dealt with with sufficient vigour by the Editor of this Paper. When Jacob Bell edited the Journal, there was an immense amount of vigour. It appears to me as if they were ashamed of writing about the druggists, as we are generally called, and the articles that appear not only in the *Lancet*, but in the *Globe*, against the chemists ought to be repelled. As to one thing which Mr. Pickering mentioned, namely, the investment of the money both for the General and Benevolent Fund, I think he is quite wrong. I know the difficulty the Council have to contend with in the investment of money. In my private capacity I have several trusteeships, and I know there is no greater difficulty than to steer clear of the law in investing money. A gentleman who is here is going to make a speech, a great financial person, Mr. Giles, and he will give you a better idea of how to invest in railways or securities, and all these sorts of things than I can do. I question very much whether the Council would be justified in investing any money except upon Government securities. I think that they are quite right in maintaining the investments in Government securities.

Mr. Reid (Aberdeen): I had no intention when I came to this meeting of saying one word; I am here pretty much by chance, but I sympathize almost entirely with what Mr. Pickering has said; and therefore I think it is right that I should offer a few remarks, as we seldom have the opportunity of being here, and I think the gentlemen who represent the country districts ought to take the opportunity when they are here of letting their views be known in London. I do feel a considerable amount of misapprehension necessarily exists as regards the wants of the chemists and druggists in the country, especially in the very remote districts in Scotland from whence I come. It is not to be supposed that gentlemen who have been born, bred, and educated in London can know very precisely the state of the case as regards a business there. I do not, however, intend to enter into a general discussion of the subjects which have been raised here, but to confine myself rather to one item that is in this balance sheet, namely, a grant to a provincial Association of £10. Now Sir, I admit most completely that the question of provincial education is one which is surrounded by many difficulties. I quite agree that it is exceedingly difficult for the present Council, or any Council, to frame a code of regulations which would suit the very varied circumstances of our trade throughout the country. But I do think that if there is one thing which ought to press more upon the attention of our Council than another, it is that question of provincial education. I am sure that the country members here will sympathize with me when I say that we find ourselves drifting into a course, and we do not see where we are to land. In the place where I come from, and dozens of other places, attempts have been made, and a good deal of money has been spent in efforts which have been to a certain extent successful. We did it all ourselves, but did not fail to apply to the Council here for a grant of money. We like money in Aberdeen as well as in most places, and possibly many of us cannot afford to spend our money. Understanding that educational grants were given from this Council, we made an application; we had spent a considerable amount previously in erecting premises and buying apparatus, had engaged parties to lecture, and had got the whole thing in work, and what we wanted to have we put, it seems to me, in a simple sort of way. I come from a place which is a place of recognized importance, where gentlemen in the trade are known to be gentlemen, and who can be trusted with money. We applied for a grant or loan, I think, of £25. We made this application, and after a delay of several months (I do not know how it happens, but a delay of several months generally does happen before we get an answer) we got a document which contained ever so many questions, and ever so many things to answer; and we were asked to take, in point of fact, simply a loan for three years of £10. That is what in point of fact it was. We were asked to take £10 in that way. That is all very well. I quite admit that this Society must be careful how they spend money,—there can be no question about that. But is it a thing likely long to be tolerated by country members who are providing the funds, that we should have hundreds and thousands spent in London by way of supplementing this educational establishment, and that we should be starved literally all over the country? There surely is a way of doing something to show that you are willing to assist country members in doing what you can to educate their young men. It is impossible that the thing can go on like that. The real fact of the matter is that I believe, looking at my part of the country, if these things go on for a very few years longer, within the next ten or fifteen years the whole of the dispensing trade will go out of the hands of the chemists and druggists, and back into the hands of the medical profession, who at the present time have almost ceased carrying on dispensing at all. The result is very obvious. Unless some means are taken to place the trade in a position where a man can earn a living by it, it necessarily results that a man will not educate himself for it; and in all the small towns (not to speak of the villages, for there are even druggists in the part of the country from whence I come), there will not be a druggist to be found at all, so that the medical men will resume the practice that existed forty or fifty years ago, and dispense their own medicines. I do not say, however, that is a reason why I have risen to speak, but to urge upon the Council to devote their time to devising some scheme which will give to large towns, or to towns being the large centres of a district, a reasonable amount of money, and trust them at all events for a year or two to see if they produce good fruit, and if not, withdraw the grants. When you are sending papers to be answered categorically, it may give rise to considerable difficulty, and I do not much wonder that the loan of £10 was not taken. I believe many grants have been applied for, but several towns have said that they would not borrow £10 for three years. I would press upon the Council to look that matter in the face, because it is a most serious one. I believe it is the greatest difficulty the Society has to contend with, namely, the education of chemists in the country. It matters little to me, perhaps, but the rising generation will certainly feel it.

Mr. Vizer (London): I feel very great pleasure in rising this morning, because we meet under such exceptionally favourable circumstances, smiling faces around us on all sides, and no dark clouds in the future. The Report I look upon with great satisfaction, and I most heartily support it almost in its entirety. I would draw attention for a moment to the first paragraph, the sentiments of which are highly gratifying. Those dark clouds of which our President spoke so graphically last night have all vanished away, and now we see peace reigning in our midst. But, sir, will you allow me to say that I receive that paragraph—forgive me for saying it—with very profound satisfaction. I am not going to stir up dirty waters, but, if we had asked the Council to have passed a vote of thanks to the Defence Associations, which, for some two or three years, disturbed the equanimity of some of our friends, we could not have got a better vote than we have here,—the Council therein expressing the great advantage which has arisen from the different shades of opinion within that body. I therefore, sir, tender the Council the thanks of the Defence Associations which have now passed away, and, let us hope, never more to return. I thank them for this expression of satisfaction, because—and I do not think any gentleman will contradict my assertion—the existence of those varied opinions upon the Council is decidedly owing in a very great measure to the efforts of those Defence Associations. I want to, Sir, ask a question which no doubt is easily explained, respecting the third paragraph. In that paragraph we find it stated that the number of members, associates, and apprentices of the Society has increased 90 members and 170 associates. If I turn to the report which was published in the February number of the Journal, I cannot make the two tally. I simply bring it forward, because I think some explanation is needed. According to this report, which I hold in my hand, the total number of pharmaceutical chemists in 1872 was 31 less than in 1871, whilst the chemist and druggist members shows an increase of 80. By deducting the 31 decrease of pharmaceutical chemists from the 80 increase of chemists and druggists, I make 49 the absolute increase, instead of 90 as mentioned in the Report. Again, as regards the associates, I should make the number 151 instead of 170; thus 87 associates in business and 64 not in business. The total increase of the Society according to that reckoning, taking in 31 apprentices, would be 231 instead of 291, showing an error of 60 in the Report. I state this not only for explanation, but also with another motive, namely, because it confirms an assertion which I made here last year, and subsequently in the pages of the Journal, that our strength as a society of pharmaceutical chemists was decreasing rather than increasing. I consider it is the duty of the Council to look into this matter, or otherwise the time will come when we shall have the unpleasant duty of recording the death of the last pharmaceutical chemist of the Society. Another point I should like to draw attention to is the prosecutions which have taken place under the Pharmacy Act. We see that several such have taken place in order to prevent the illegal sale and disposing of poisons. I am perfectly aware of the difficulty with regard to that question. How far we can possibly prevent the sale of medicines by grocers and such like, is a question of great difficulty; but, at the same time, I do think that in any alterations which may at some future day be contemplated by Act of Parliament, some provision ought to be made for towns over a certain population where a chemist could be supported; leaving small towns only where drugs might be procured at the grocers or elsewhere. But that we should all have to compete, as we do now with every oilman and grocer, does seem to me very hard. The paragraph recording the increase of the Minor examinations I entirely endorse. I only wish one thing, as has been expressed by other gentlemen this morning, that there was a brighter prospect before our young men, the rising generation of chemists, but unfortunately it is not so. The Benevolent Fund is cause for great satisfaction. I think it is one of the most satisfactory parts of the Report, and thoroughly gives an answer to the complaints which have been made recently in the Journal upon the distribution of that fund. We see clearly by the Report that there is a considerable increase in it, which shows the confidence the members of the Society have in the Council, and the way that fund is distributed. Reference has been made in the Journal to the idea of disposing of the annual subscriptions to annuitants. Such a process would be an utter absurdity. To imagine that we could distribute any proportion of the annual subscriptions for granting annuities would be, I take it, dangerous to this Society and most deceptive to those who received them. It has, however, been stated that the religious societies act on that principle. I admit that fact. But, sir, do those gentlemen, who advocate the distribution of our funds upon that principle, consider the analogy between the two? There is not the most remote analogy. From what source do those societies draw their funds? Why, the wide world. They have subscriptions coming in from all parts of the world, whereas ours are limited to some 8000 or 10,000 members supposing every member of the trade subscribed. Then, again, there is another objection. Those societies make no stipulation with their agents. At any moment they can discharge them. If we take in an annuitant we cannot give him notice to quit unless, indeed, we follow the King of Dahomey's example, and send him on a message to departed friends. Another objection is the amount of subscriptions to our Benevolent Fund. The total sum raised last year was only £1896; whereas, take four of the leading religious societies which support their dependents. The income of the London City Mission last year was £40,000, and that of the Pastoral Aid Society £48,000. And if we go to a still larger example, the Church Missionary Society, or the Wesleyan Missionary Society, we have an income over £156,000 each. What comparison is there between the two? I therefore consider the Council have acted perfectly right in the way in which they have distributed this fund, and heartily support the Council, and the report which has now been moved.

Mr. Mumby (Gosport): I do not propose to trespass on your time, but I wish just to call attention to one fact; I do not propose to go at all into the general question of the Report and its adoption, but to refer to the fact which has been alluded to by the gentleman who has just sat down—namely, the prosecutions against offenders under the Pharmacy Act. One of the duties of the Council was to promote, and watch over legislation affecting the interests of members of this Society, and also to enforce the law made for our protection. I take it that so far as watching over legislation, the members have no fault to find with the Council, but I do not think we can speak with quite the same satisfaction of the way in which they have enforced the law in existence for the protection of members of the Society. Because, as I understand, if you submit a case to the Council with absolute evidence as to the violation of, so to speak, the title clauses of the Pharmacy Act, and can do that conclusively, they have no hesitation in ordering a prosecution. But (and this is the special point to which I wish to call the attention of the meeting) if, while the spirit and intention of the Pharmacy Act are distinctly violated, through the ingenuity of the persons carrying on the business, or through the defect of the Pharmacy Act itself, they are able to avoid any infraction of the title clauses, although openly violating the poison clauses of the Act, the Council decline to prosecute, and say that that is a question for the police. Now, gentlemen, what is the result of this caution, or rather want of caution? Why, simply this. The Council decline to interfere, because they say they consider it is no part of their duty to enforce these clauses, but it is the duty of the police; and the police do not trouble themselves about the matter. In fact, they perfectly ignore this point altogether; and thus the Pharmacy Act becomes simply a dead letter. It appears to me it is the duty of the Council to protect the members of the Society by enforcing the Pharmacy Act. If, while the title clauses are not infringed, still the spirit of the Act is openly violated, it is the duty of the Council to protect their members by prosecution. The case on which my observations are based is this. A person goes into the country and opens a business:—He does not adopt any of the titles allowed by the Pharmacy Act, but he puts up his name, A. B., we will say, and underneath he puts in very conspicuous letters, "Registered." To all intents and purposes he is carrying on the business of a chemist and druggist. He can dispense any prescription you like to take to him. Therefore I say he is to all intents and purposes carrying on the business of a chemist and druggist, although he does not call himself a pharmaceutical chemist, but simply "registered." He violates the poison clauses of the Act, but yet the Council refuse to prosecute,—at all events they have hitherto refused,—and a gentleman who came down to inquire into a case, said the person to whom I allude was sailing so close to the wind that the general clauses of the Act had not been infringed, but only the poison clauses, and it was a case for the police. If I am wrong I am open to correction. As this is the only opportunity we have of introducing these matters, I thought it right to submit this particular case to you. Certainly the reason the Council do not act in this matter cannot be on the ground of poverty, because the financial account is an extremely satisfactory one. They have invested £2000 in the Three per Cents, and still have a balance in hand of £850. But if that money were used occasionally to prosecute in a case such as I have mentioned, it would be for the benefit of the members at large. No doubt any one living in the locality, can, upon proper evidence, go before a magistrate with evidence as to the violation of these poison clauses, and obtain a conviction. But I say it is an extremely invidious thing for a member in the country to place himself in such a position, because it would be thought that proceedings were taken from some personal spite or ill feeling against the accused, and not simply to carry out a law which was passed for the protection of the chemists and druggists. Therefore, I say if the Council leave the prosecutions to the police, they will very likely have in a large number of small country places mere grocers and hucksters, and all kinds of persons, vending poisons. When a man opens a chemist's shop for the express purpose of carrying on business as a chemist and druggist, and violates the Act, I think it is a case in which the Council ought to interfere.

Mr. Bostock (Ashton-under-Lyne): One remark was made by Mr. Pickering to which I should like to refer. It appears that the fees from students amount to about £149, while the amount paid to the lecturers is £600, so that there is a loss of between £400 and £500. The important question to consider is how we can avoid that loss; and I think something ought to be done to remove that state of things. In the country we take young men for four or five years; they come to live in our families as our sons, and there springs up a kind of fatherly regard for them. Then in course of time comes a desire to go to London. I think a young man has not completed his education until he has been to the metropolis and seen a little life in London. But many of them obtain situations where they can. They cannot all be at the dispensing houses. Some take a position in wholesale houses, which close at six or seven o'clock. The question is what becomes of young men for the two or three hours afterwards. In Manchester we have excellent evening classes for the young men, which have been well sustained, and have paid their expenses. But I find in London this parent Society has no evening classes, which I think is a great misfortune. Some of the young men from my own establishment are in London, and they have nowhere to go. Some have joined the Good Templars, and I am very glad they have done so. What we want is, that they should be qualified for future life. We shall not live to carry on our businesses for ever; and unless these young men are qualified there will be no one to carry them on unless we educate them for it, and that can only be done by their pursuing a course of study. I think it desirable, if possible, to attract young men to this institution by having evening classes. Young men having obtained a taste for this business and shown some desire to fit themselves for future life, if you can encourage them to evening classes, keeping them out of the theatres of your city, you will assist in creating a better tone, and qualify them to take positions in the country. A great many members will leave the Society unless you do something like this. If you can devise any plan of giving evening classes I think you will make the Society more paying, and confer a great benefit both on the masters and the young men themselves.

Mr. Wilkinson (Manchester) said, anyone who read the fourth paragraph would suppose that there was not much alteration intended, but on looking at the Calendar it would be seen that there was much more than many would anticipate, and instead of its being slightly more stringent than before, it appeared to him that the new Minor examination was more severe than the old Major; but if a practical knowledge of dispensing were required before the Minor examination, it would not be necessary to re-examine on that subject for the Major.

Mr. W. S. Brown suggested that Mr. Wilkinson's remarks would come in better when discussing the amended bye-laws.

Mr. Wilkinson said he was quite willing to adopt that suggestion.

Mr. Humpage (London), having read the Report with a great deal of satisfaction, said, many of the remarks already made had been, in his judgment, so thoroughly brought before the Council, and canvassed and answered in the Journal, that it was almost needless to bring them forward again. It was quite manifest at two or three meetings that an impression was abroad that if upon the Council there were placed some gentlemen who understood the nature of the country business better than their London friends did, a different state of things would arise, and that many of the difficulties which were felt would be solved to everyone's satisfaction. Thereupon, a body of gentlemen were returned from the country, and he was sure they had given their very best consideration to the question. No one could read the report and see the number of attendances, recently given in the Journal, without seeing that those gentlemen had not regarded their position as a sinecure, but that they had gone into it as gentlemen who were prepared to do their best. And as they had found when they came to approach the difficulties which had been so graphically pointed out by Mr. Pickering, so these gentlemen on the Council, when they came to grapple with them, found that practically very great difficulties did exist, which, with all their judgment and determination, they could not successfully overcome. He regarded the Report as highly satisfactory on the whole; and looking at it in that way, he thought the whole trade ought to congratulate themselves upon it. No doubt they were not in a perfect condition, and they had many grievances. Much was said about the prosecution of parties who infringed the law, and of putting down those who undersold and kept their shops open late at night, and all that. He wished they could do it, but they could not. He thought it a very wise suggestion which had come from the chair, that each individual should in his own neighbourhood adopt such arrangements as were best suited to it, and endeavour to give to the body individually a *status* and power which it could not possess as a whole. Those in the west could not legislate for those in the east, but those in the east and in the west too could step out of their own business and call upon their neighbour, and reason with him either as to keeping open till eleven o'clock at night, or selling a mixture at 8*d*. for which he ought to charge 1*s*. 6*d*. They might say, "If you will do it I will do it; and a little private mark might be introduced which would obviate all difficulty as to prices." Then the answer would often be, "Oh, Mr. Jones will not agree to it." No; and if they waited until Mr. Jones would agree to it they would never do anything. If a person came in and asked the price of making up a prescription, and when they were told a fair price said it was very dear, that they could get it for so and so, he should reply, "I daresay you can, and have the chance of being poisoned into the bargain; but if you go to what you term a respectable chemist, such as Mr. So-and-So, I think you will find his price very much the same as mine." That was the way to do; not run down their neighbours and call them dirty fellows, or anything of that sort. Call them gentlemen, and treat them as gentlemen, and then they would be more likely to act as such. If they wanted to raise the whole body they must raise the individuals; a house could only be built by piling up brick after brick, and the same thing applied to a Society. This course had been pursued in some neighbourhoods, and it answered very well, as the till bore witness. In conclusion, he remarked that the subject had been very well discussed in the letters in the Journal, which were always interesting to read, more particularly, sometimes, the Editor's comments upon them. It was very easy to find fault, and raise objections, and no doubt there were objections and difficulties, but it was no use getting out of humour with them; if you could not throttle them, the only way was to "bolt" them.

Mr. Hustwick (London) said, there was one paragraph in the Report which seemed to have escaped the attention of the meeting so far, but which appeared to him a matter of considerable importance, he meant the paragraph relating to the evening meetings, which was dismissed in two and a half lines, simply stating that subjects of great interest had been discussed. That, no doubt, was the case; the meetings had been well attended, and the subjects had been of great interest, but in his opinion these evening meetings did not recur often enough, nor was there sufficient time when they were held for the subjects to be sufficiently discussed. They found that some of the provincial Associations held their meetings once a fortnight, or at any rate once a month, for eight months out of the twelve. For instance, there was the Liverpool Chemists' Association, whose proceedings were reported in the Journal twice a month for about eight months; and it appeared to him if Liverpool chemists could afford to spend so much time on pharmaceutical subjects, in a place like London, where everything interesting in the pharmaceutical world was to be found, it would be only proper to afford a little more time for such meetings than had been done. No doubt many gentlemen who attended these meetings must have been struck with the rapidity with which the time passed; a subject was no sooner abandoned by the original speaker than the discussion commenced, and the time appeared to be at an end, and it often occurred that the discussion on such and such a matter had to be postponed until the next meeting. When that happened to take place at the last meeting of the session, there was a period of something like five or six months would elapse before it came up again. He, therefore, hoped that greater facilities would be offered for the purposes of discussing matters of importance.

Mr. S. R. Atkins (Salisbury) wished to make one remark on the paragraph relating to the Preliminary examinations, in consequence of what fell from the President in his opening address. Everything which came from the chair deserved the most careful attention of every member, but in the paper he had the honour of reading at the Brighton Conference, he ventured to express a desire that the Preliminary examination would be taken out of the hands of the Local Secretaries, although having been a Local Secretary himself for many years, and having had long experience in conducting these examinations, he had no wish to retire from the work which he had cheerfully undertaken, and should be prepared most cheerfully to carry on. Still he entertained the opinion that it would be well if these examinations were taken out of the hands of the Local Secretaries, and in the place of them the Local Examinations of the three Universities, or of the College of Preceptors, or any other duly constituted body, were accepted. At any rate he was glad to find this matter was engaging the attention of the Council, though he could not for one moment endorse the remarks made in some correspondence which had appeared, that the Preliminary examinations had been conducted in a slovenly or improper manner. So far as his own observation went, and from what he had heard—and he had taken the trouble to obtain all the information he could—his impression was that they had been conducted honourably and fairly. At the same time he did think some change would have to be made, and he was glad to find that this subject had been and would be further considered. With regard to provincial education, he had been much struck with the force and good humour of the remarks made by Mr. Humpage, with regard to the extreme facility of finding fault, but the extreme difficulty of making useful suggestions. It was no difficult matter to do the first, nor was it an easy matter to do the second, and he was rather glad that the Council had not committed themselves to any definite scheme with regard to provincial education. He would not attempt to refute the admirable remarks made by the gentleman from Aberdeen; there might have been in the reply to that application a little want of wisdom, or perhaps a little red-tapeism, but he did feel that the country members, if they went into the Council, would have to face some very difficult questions, and if Mr. Schacht, a most able representative of the provincial body, had failed to find the exponent of that difficulty, other men might well feel the pressure of it themselves. He ventured to think that the true solution of the difficulty was this, that they themselves should become personally educated. If every pharmacist undertaking the responsibility felt it was his duty to train the young men under his charge, they would then relieve the Society of this which was really a very pressing difficulty. He should like to ask Mr. Reid whether he met with much response from the young men in Aberdeen, and whether they appreciated the privileges which had been so liberally furnished to them. For his own part, he must say that after he had, in his own humble way, for some years, endeavoured to create a love of study, and had furnished the means of study to those under his charge, his greatest difficulty had been to create a taste for it; and until that demand was made, and until the young men pressed forward, determined to utilize the opportunities already at their command, he could not be surprised that the Council hesitated before spending much of the Society's money in that way.

Mr. RANDALL (Southampton), said, he would only make a remark on two points: First, with regard to the country lecture question. There were two ways in which lectures might be viewed. Young men might want lectures in order to have nice scientific recreation, or they might want them for the purpose of real study, with a view to their approaching examination. He did not think it was the business of the Council to do more than give very small grants, at least, for lectures for mere scientific amusement, not because they were not important, but because that was not real education. Then, considering the matter with regard to lectures which could be so prepared as to qualify those who attended them, and studied afterwards for passing their examination, he contended that except in very large places such courses could not be given with any reasonable amount of assistance from the Society. He thought so, but they must look to schools where there were other things to be done as well, such as the school which existed in London, and in some universities. In his own locality there was the Hartley Institution, which was well known to all. Up to the present time they had there a gentleman, formerly a professor of chemistry at Birmingham, who was an exceedingly good teacher, and he gave a series of lectures. He generally had several assistants wishing to pass the Minor examination, and they had not been young men who objected to study; but they did not attend these lectures, simply because the scope of them was not what they wanted, and they found they could spend their time better in reading and working hard at home. He did not mean to say but what if there had been a course of lectures extending over three months, they might not have found benefit from them, but when the lectures were given in short courses, as a general rule young men would find they could spend the time better at home. One gentleman had suggested the publication of the professors' lectures, but he presumed those lectures consisted principally in reading from their hand-books, and making explanations of the experiments as they went along; at any rate that was his experience when he attended a course of seven months' lectures by Professor Graham at University College, and that was not at all the sort of thing which could be expected to be published. With regard to the Preliminary examination, he would say this: the Council was necessarily a little cautious in advancing, especially unless they were clearly given to understand by the members at large that they were desired to go faster,—he did believe that if Preliminary examination were not increased in difficulty, it would be found very soon that, excepting the Latin, boys of about the fourth standard of the elementary schools would be able to pass it with very little difficulty. Now it was not desirable that such lads should be introduced into the business, but unless this was to be the result, they must be exceedingly careful as to the sort of examination required. In these primary schools the boys were constantly being inspected and examined by the Government officer, and the master's salary depended to a considerable extent on whether they passed or not; they were kept constantly up to the mark. Unfortunately there was nothing of that sort in the schools above that grade, to which their scholars must go, because they wanted to learn Latin, and therefore he believed it to be a fact that in the elementary schools the teaching as far as it went was far more thorough than that given in what might be called the lower classical schools. It was very necessary therefore that the examination should be rendered more exact in the matter of English and arithmetic. The examination in Latin also he contended was much too slight,—it was scarcely a test at all. This did not at all touch the question of educating boys so highly that they would be above going into the business, but they must insist on a more thorough knowledge of English and the elements of mathematics being taught, and if they did so he believed they would not have so many failures, and he hoped therefore the Council would pull up a little in that direction; not so as to increase the expense of education, but to let the schoolmasters know that they should teach more thoroughly the subjects they professed to teach.

Mr. WHEELER (London) said, that, at a previous meeting, he had brought forward the question of the illegality of associations of traders dispensing prescriptions, and he understood from the Council that if the matter were left in their hands, something should be done. As it was not referred to in the Report, he should like to ask if anything had been done, and whether it was within their knowledge that prescriptions were actually dispensed at the Civil Service Stores in the Haymarket, containing Scheele's prussic acid.

The PRESIDENT said, the question had been under consideration, and he himself took a very prominent part in bringing it forward; but he was not supported to an appreciable extent by chemists outside, or by the members of the Council, to carry on any action against these stores. Otherwise, he should have done so very willingly. He believed that if any action was to be taken, there must be a more decided feeling manifested by the trade at large, so that it should be done in their names, rather than in that of the Council.

Mr. SUTTON (Norwich) wished to add one word on the question of provincial education. He said they had a little association at Norwich, carried on amongst the assistants themselves, which was commenced with the help of two or three of the principal chemists, and a small grant from the Society. The difficulty was, to know how to apply it; and that was the difficulty in which the Council often felt themselves; they did not know how to help these provincial societies to the best advantage, though they were perfectly willing to do so if they could. His experience of young men was, that they came and said they did not want to go through a very extensive course of materia medica, botany, and chemistry, but only to learn just enough to squeeze through the examination. It therefore came to this: How could you possibly help people who would not help themselves?

Mr. FLUX (the Solicitor), said he had been asked to say something with regard to the prosecution of offenders, with a special reference to the remarks made by Mr. Mumby. He believed he knew something of the case to which that gentleman referred, and in that case, as in nearly all others, the difficulty was to get satisfactory evidence. It must be borne in mind that any proceedings were proceedings for penalties, and they must have proof *strictissimus*. In that case he believed they had no inconsiderable difficulty in getting to direct evidence; but he believed. though he could not speak distinctly from memory, that evidence was now obtained, and; if so, there would be very little delay in prosecuting it with effect. But in the latter part of Mr. Mumby's observations he alluded to the cause of the great difficulty which the Council had in dealing with these matters. Those who brought forward cases of this sort, in nearly every case stipulated that their names were in no way to be disclosed; the result was that they in London had put into their hands a case, perhaps 100 or 200 miles distant, and none of the local gentlemen connected with the Society would be identified with it. He did the best he could, but to show the difficulties in the way, he might mention that he lately had placed in his hands what was said to be a class of cases in a large manufacturing town in the north. No local gentleman would give any assistance at all, so thinking he would act as economically as possible, he wrote to the chief constable of the county, pointed out that it was a public grievance, and a matter which the police might undertake, and that if they would not undertake it as a matter of police, they might do so under his directions, purchasing any articles he should direct, and keeping them according to his instructions. But from the police he got no assistance at all, rather the reverse: then, on sending from London a special agent to go round to the persons who had been named to him, and make purchases, what was the result? the messenger was scoffed at in nearly every instance, and had not the chance of obtaining the evidence that was required. In one or two instances he was even told that it was known a messenger was coming down from the Pharmaceutical Society to make purchases. If gentlemen would only be a little bold, and take up a position as representatives of the Society, make purchases on the spot, and instead of sending them to London in such a way as to break the links, which it was most important to preserve, keep them, and write to him for instructions, there would be no difficulty in getting a great many convictions in various parts of the country if that were thought desirable. It is very easy to get convictions for selling poisons if gentlemen would only take the matter into their own hands; they must get an article purchased, and in nearly every instance it would pass at once into the hands of a skilled gentleman who could prove that it contained poison, and then a summons before a magistrate, and proof of the purchase, and of the existence of the poison in the article purchased, would ensure a speedy conviction. It did not always follow that an article purchased as a poison really contained the poison, and therefore both proof of the purchase and of the presence of the poison was necessary. If proof of those two things were secured, he did not believe that there was any reluctance on the part of the Council to prosecute, although at the same time it was felt that the real mission of the Council was to point out how the thing could be done, and that chemists and druggists throughout the country ought to take a little trouble and put the law in force in their own localities. Anything with regard to the register must of course be done through the Society, and wherever there was evidence to warrant proceedings, they were always taken so far as he knew.

Mr. FRAZER (Glasgow) said the course taken in Scotland was this: there was there as there was in England a class of gentlemen called writers or lawyers, and another class called messengers-at-arms. Now, in Glasgow, there was the same delicacy felt by the local secretary as to prosecuting his immediate neighbour, so they employed an agent, who, under the instructions of Mr. Flux employed two messengers-at-arms to get the necessary evidence. They came to him, and he gave them some old prescriptions containing poisons; then they took them into the different shops and got them dispensed. Having thus got the necessary evidence, the case was brought into court, and there was no difficulty whatever. He did not see why the same thing should not be done in every town in England.

Mr. GILES (Clifton) said he should be very sorry to go so far as the gentleman in Glasgow did in employing messengers-at-arms to entrap a man in that way. Acting on the maxim *qui facit per aliam facit per se*, he should not like to do a dirty underhand thing for anybody, and what had been described was very similar to the action sometimes taken by the Excise, who having been participators in some possibly provable offence, convicted the party upon it. He should be very sorry to do that himself, and he did not think any member of an honourable trade should be guilty of such a thing, but what he thought they might very well do would be this: In discharge of their duty to themselves, and carrying out the Act of Parliament, he should not hesitate in going straight to any man whom he intended to trip up and telling him he understood he was doing so-and-so; that it was against the law and contravened his own privileges, and cautioning him that, if he continued it, he should take means to ascertain whether he did so, and to prosecute him for it. That would be perfectly manly and upright, but he did not like the idea of taking a prescription which he did not want, and getting it made up by a man who supposed it was really wanted, for the sake of prosecuting him afterwards.

Mr. FRAZER (Glasgow) said the men he had referred to were warned by the Secretary that they were breaking the law, and it was only after repeated warnings that steps were taken to prosecute them in the way he had mentioned.

Mr. SCHACHT (Clifton) said he had listened with the greatest pleasure in the world to the full expressions and discontent which had fallen from several gentlemen in reference to the small amount of work done by the Council in the matter on which he felt very strongly, namely, provincial education. His only object in rising now was to assure the meeting the Council had not been idle in their efforts to do something even if the results had been small. They had been very anxious to find if possible some scheme which should affect all cases arising within that scope of the subject, and a step had been taken by the putting forward of one scheme for general discussion. Unfortunately it did not elicit so much general approbation as he hoped, and they were obliged after a time to abandon it, but still some advance had been made in the general appreciation of the necessities of the case, and he hoped it might lead to some more practical work in the future. In the meantime he would ask all gentlemen interested in the question to express their opinions as practically and distinctly as possible, for this would immensely assist the Council in their work. There was one stumbling-block in the way of all schemes of this kind, that unless there were a general co-operation in one scheme it was of very little use. He himself naturally thought his own scheme a splendid one, but it did not meet with general approval, and that being so, it could not be carried into effect. At present it had received a great deal more criticism than approval. However little they might appear to be doing, they were very anxious to do more; and for himself he might say that nothing in the Report dissatisfied him so much as finding that they had funded £2,300. It seemed to him a most unfortunate fact that they had no process by which that very large sum could be made useful to the community who supplied it.

Mr. W. S. BROWN (Vice-President), in reference to the application from Aberdeen referred to by Mr. Reid, said when that application was first received in 1871, it was referred to the Committee, as usual. It asked for £25 for providing suitable apparatus for teaching chemistry, materia medica, and botany, and so on; and for an annual grant of £20 to assist in paying lecturers and providing materials, etc. That seemed rather a startling application; and the Committee, after consideration, advised the grant of a sum of £10 to aid in affording education to the young men at Aberdeen and the district. This sum was quite as much as could be expected in proportion to the amounts granted to other places, and was certainly not out of proportion to the sum received by the Society from Aberdeen. The largest number of members there at any time was twenty, and that had now diminished to about twelve. Under those circumstances, he thought the grant of £10 was quite as much as could have been reasonably expected. That grant was refused, and some eighteen months afterwards another application was made; this being referred to the Committee, they repeated their former offer, the cheque originally drawn being still in existence. It was again refused, and he did not think under these circumstances the good people at Aberdeen had any reason to complain.

Mr. REID said the facts, as stated by Mr. Brown, were quite correct, except that, as he had stated before, it was not an unconditional grant of £10, but, in point of fact, a loan of £10 to provide chemical apparatus, which was to continue the property of the Society, and to be redeemable at the end of three years. Looking at it in that point of view, they thought if they could get on without the £10 it was not a very large matter. Their object in making the application was to establish a principle which should govern the application of these large savings or accumulations in the hands of the Society, so that they might be made more available throughout the country. From the statement just made, it appeared as if Aberdeen had presumed to ask a great deal more than they were entitled to, in proportion to their subscriptions. He had not the figures with him, but in addition to the ten or twelve guineas per annum from annual subscriptions, he believed that as Aberdeen formed the centre for almost the whole of the north of Scotland, there was a very large sum sent up in the shape of fees for preliminary examinations—he should think several hundred pounds. The application they made for assistance was simply in order to set the Society going, and they had spent out of their own pockets four or five times as much. They had hired a suite of rooms, and engaged gentlemen to give senior and junior courses of lectures, extending over three months; and though these lectures were not supported to the extent they could heve wished, still they had about twenty-five students, twelve or thirteen in each class. There was no difficulty in Aberdeen, or any similar place, as he believed, in finding gentlemen who would give, partly from a desire to benefit their fellow-citizens, and partly in return for what remuneration could be afforded them, such courses of lectures as would enable the students to see their way and follow them up by a proper system of reading and study. He had no hesitation in saying that anyone who had attended the course he had mentioned would be enabled to carry on his education with very great facility. The great difficulty of finding a generally acceptable scheme had been referred to, and he thought that was the great mistake. It would be impossible to make a scheme suitable to all parts of the country; each district and county differed in its habits and customs; what suited one would not suit another, and therefore he thought it a pity to attempt to have one stereotyped scheme for all. If the Council would, as men of business, make such inquiries as they deemed proper with regard to the status, size, and requirements of any large centre of population which applied for a grant, and then give what they could afford, and take an account after twelve months had elapsed as to what use had been made of it, continuing it or not, as circumstances might dictate, he thought a great deal of trouble might be saved in endeavouring to devise a universal scheme. When it was known that there was a large surplus available, and that in London these classes were kept up by the Society at a loss of £400 or £500 per annum, it was hardly likely that the country members would remain satisfied so long as the accounts contained this item, "Grant for provincial education, £10."

Mr. Brown said the offer to the Aberdeen Society could not be properly characterized as a loan. At that time the regulation by which the Council were governed prevented the absolute grants of money, and the grant was made for the purchase of apparatus. Now Mr. Reid himself advocated the principle of the Society retaining some control over the grant so made, and that was all they proposed to do. It not unfrequently happened that these provincial societies had but a very ephemeral existence, and therefore it was a very proper condition that in case it were dissolved before the end of three years the apparatus should be returned to the Society.

The resolution for the adoption of the Report was then put and carried unanimously.

Mr. Hampson (London) was then called upon by the Chairman to move the resolution of which he had given notice as follows:—

> "That inasmuch as the Examiners of the Pharmaceutical Society are empowered by law to test the qualifications of persons—*female as well as male*—before the state permits them to be registered as persons fitted to 'keep open shop' to practise pharmacy, and as all persons having passed the Major and Minor examinations are eligible for admission into the Society, as members and associates, that they may exercise control and direction over the working of the Pharmaceutical Society, and have the benefit of its associative influence and protection, this meeting is of opinion that it is contrary to the plain intention of the statutes to refuse admission to female persons, who, having conformed to the legal tests of the Examiners and the regulations of the Society, may desire to become connected with the Pharmaceutical Society in the capacity of apprentices or students, or associates, or members."

He said: Mr. President and Gentlemen, I dare say this motion may not be as pleasant, in some respects, to speak upon as many others; and, perhaps, it may be unpopular; nevertheless, I feel bound, in duty to my own conscience and my own general principles, to present it to you. I do not think there is any apology required for its introduction, but am disposed rather to think one is required for the necessity of its introduction from those who have opposed female students having all the privileges of the Society in the same way as male students. I dare say many of you think that too much has been made of this question, simply because a few women are concerned. I quite agree in that opinion, inasmuch as I think, where principles are at stake, it is as important to see to the interests of a few persons, as of a large and powerful class. I desire, as much as possible, and I hope all speakers will follow me, to address myself strictly to the resolution. I do not want to see you wander off into any outside questions which may be accidentally connected with it; but I desire as much as possible to confine myself to the words of the resolution. There is one thing I feel bound to mention at this stage of my remarks, and that is, that our Editor has thought proper to introduce a political article into last week's Journal with a view to bias this discussion. I do think that is a most reprehensible course. The organ of this Society is in no way a political organ, and I do not think it is a right thing for an article of the kind to which I refer to be introduced. I shall not endeavour to define what is a woman's avocation or duty. I think the public and the women themselves will find that out. All that we have to do is to consider the relationship of persons, qualified under the Act of Parliament, with this Society. There is no doubt about this, that a certain number of female persons (as the Act terms them) are entering into the vocation of pharmacy; a number are getting their living by pharmacy, in London especially, and two or three have sought instruction here. I was exceedingly pleased that the Council allowed them to receive that instruction on the same terms as the other students; and I certainly did hope that when the legitimate consequences of that instruction came about by examination, that they would also receive the same reward and be entitled to the same privileges. The question is this: Have we any moral or legal right to keep women out from the Society? You remember that when the list of apprentices or students was brought before the Council for admission into the Society, the names of three ladies appeared on that list, and I can assure you the scene in the Council was something extraordinary. The names of those three individuals—and one them had stood at the top of the tree as regards the Preliminary examination—were separated from the rest, as if they had to go into quarantine, or had been affected with a plague. We had a separate resolution whether they should be admitted or not, and I am sorry to say I was not successful in procuring them admission. But I will just call your attention to clause 10 of the Pharmacy Act, 1852—"Every such person who shall have been examined by the persons appointed as aforesaid, and shall have obtained a certificate of qualification from them, shall be entitled to be registered by the registrar according to the provisions of this Act, upon payment of such fee or fees as shall be fixed by the bye-laws; and every such person duly registered as a pharmaceutical chemist shall be eligible to be elected as a member of the said Society; and every such person duly registered as an assistant shall be eligible for admission as an associate of the said Society, and every such person duly registered as a student or apprentice to a pharmaceutical chemist shall be eligible for admission into the said Society, according to the bye-laws thereof;" and also clause 20 of the Act of 1868—"Every person who shall have been registered as a chemist and druggist under this Act, by reason of having obtained a certificate of qualification from the Board of Examiners, shall be eligible to be elected an associate of the Pharmaceutical Society; and every such person so elected and continuing as such associate, being in business on his own account, shall have the privilege of attending all meetings of the said Society and of voting thereat," etc. I would also call attention to the bye-laws, which, when they pass, become a part of the Act, section 1, rule 2—"Persons qualified to be elected members, associates or apprentices, or students of the Society shall at a meeting of the Council be proposed and seconded by members of the Council. The qualification of the proposed member, associate or apprentice, or student shall be stated in a written resolution." Now, gentlemen, you will observe that the word "qualification" is very prominently brought out in the bye-law and in the Act. I take it to mean this: that qualification is a test of eligibility. If a person is qualified I suppose, and I think that it is natural to suppose that person is eligible. That is simply the ground upon which I move. Now women have been registered, both women who were in business before the passing of the Act of 1868 and also several who have passed their examination since, and I consider this registration to be a practical acknowledgment of the position I assume. We have tested their qualifications and so far we read the Act as assuming that there is no distinction to be made between a male and a female person in the Act. That so far is our interpretation of it. Our own solicitor I have no doubt will support me when I refer to Lord Brougham's Act, 13 & 14 Vict. sect. 4.—"That all words importing the masculine gender shall include the feminine unless there be an express provision to the contrary." Under that particular Act of Parliament I have no doubt our solicitor advised this Society to admit women to registration and examination. He would not move without authority, and I believe it was under his authority that they were admitted to examination. The Society has so far adopted this view, and I believe it is simply a matter of prejudice which prevents the Society taking the consequence of continuing this view and allowing women to become apprentices or students, associates, or members. There is a notion abroad something to this effect, that this is really a private society. It was a private society, I am free to admit, but it is no longer, strictly speaking, a private society. I believe that statement to be a most fallacious one. Our authority comes from the public, we have important public duties to perform, and I think, in our duty to the public, we should read the Act in a spirit of liberality, and that is the mode in which I should wish to read it. We cannot view the Act of Parliament as conferring power on a private society. It is a society of a public character; we have a Council which you elect periodically to represent you; we have members joining for the purpose of controlling that Council; and all the principal functions of the Society are of a public character. Do you suppose, gentlemen, that if the Council refused to elect a number of men to various grades in this Society, the Government would not step in and say that we were using our power badly. Do you think if we refused to elect a certain number of members coming from a particular town, or for some reason or other, that the Government would rest satisfied, and that there would be no remedy to set us right? I am quite sure that if there were a powerful class of men anxious to enter the Society, they would soon find a remedy. Then, if that be the case, I think we ought to be thoroughly just in this matter. It is a question of simple justice and common fairness. I think in excluding women in this way we are not dealing according to the great principle of English fair-play. We have been told that women must not do this, that, and the other, and many tell us they must not be chemists; but you cannot prevent them being chemists, and why should you prevent them entering the Society as men do? I will just mention two facts. We are constantly told that women must stay at home, and that is a very good thing, too, sometimes, but there are at this moment between two and three millions of women earning an independent livelihood, without masculine assistance, in this country. That is a grave statement, and we ought to ponder it well before we shut up this Society, and say we will shut this Society against them. A few weeks ago there were eleven situations offered in London for young women in the Post Office, and for those vacancies there were 1500 personal applications. Over a thousand were examined, each candidate being questioned and having to give evidence of a certain capacity. Now in the face of these facts we ought really to consider before we say we will not be fair and just and allow women equally to enjoy the privileges of this Society. Again, I cannot conceive that any dishonour would be done to us by the admission of women. If it be possible, it is highly improbable that more than a few women will distinguish themselves in pharmacy, but women do occasionally distinguish themselves in various ways, and if they do so in Pharmacy, would it not be an honour to us to have them as part and parcel of our body. I would conclude by repeating we shall do no dishonour to ourselves by admitting women, but shall be simply acting fairly at least to a few women who wish to join us.

Mr. Bostock (Ashton-under-Lyne) said that he hoped to spend the evening at South Kensington with many of those he saw around him, and each gentleman was invited to take a lady with him. The presence of ladies would add much to the agreeableness of the evening, and he must say he should not consider himself as a member of this Society in any way degraded if ladies, properly qualified, were admitted to membership. On the other hand, it would be an honour to the Society rather than a disgrace, to have ladies associated with them. There were many cases in which it was very desirable that women should be able to conduct the business of pharmacy. Sometimes the head of a business was removed, and if his wife or daughter could make a living by carrying it on, it was very desirable that she should do so. If they passed the examination they were entitled to become chemists and druggists, and why should they be denied admission as members of the Association. If they had gone through the course of study necessary to qualify them, which was not a very easy one, be thought their perseverance and industry should be rewarded by accepting them as members. They could not be kept out of the trade, and if they applied for admission as members of the Society, it should be our duty and our pleasure to allow them to join. He, therefore, had much pleasure in seconding the resolution. Men themselves would have thought it very hard if they were shut out from any ordinary rights of citizenship by the accident of birth, and what they would not like to have done to themselves they should not impose upon others.

Mr. Atkinson Pickering (Hull) begged to move:—

"That the question of admitting ladies as members, associates, apprentices, or students be adjourned *sine die.*"

He did so for several reasons, which were perfectly conclusive to his own mind, and he hoped it would be so to others. It was a matter of great doubt to him whether, when the rules and regulations of the Society were framed, the word "person" was ever intended to include the female sex, though, in strict legality, no doubt it did so; but the question was this, was it desirable that the women should occupy the position of pharmaceutical chemists? There were many callings which females could adorn with credit to themselves and advantage to society, such, for instance, as the duty of educating the rising generation. Again, he could understand how a young lady behind a draper's or silk-merchant's counter—— (cries of "question"). He contended he was speaking to the question.

Mr. HAMPSON said this was not the question.

The PRESIDENT said, he thought a great deal of time would be saved if the discussion were confined to the question,—members or not members. All the other parts of the question, as to admission to lectures, and so on, had been already settled; and if gentlemen would confine themselves to the real point of the resolution, it would simplify the matter very much.

Mr. PICKERING said, the regulations of the Society never contemplated admitting women to membership, and with that broad assertion, he was willing to leave the question in the hands of the meeting. He had intended to have gone at more length into the question, but he would simply say now that there were matters connected with pharmacy which it was not desirable that women should be connected with, matters which it was not delicate for them to listen to, and articles they would have to deal in which it was not fit that they should touch. That was especially so in the country trade. He therefore hoped the resolution would be rejected.

Mr. FRAZER (Glasgow) said he intended to vote for Mr. Hampson's motion, both on general principles and on the question of expediency. The general principle was this, that women were entitled by law, as was acknowledged, to have a field of labour, and he knew of no law restricting them to this trade or that; it was for the women themselves to choose their own trade. Referring to the concluding remarks of the last speaker, he would only say that if there was a particular description of work which ought not to be done by women, they knew who was to blame for it, and more the shame that it was so. They all knew that women were now employed to a large extent in the manufacture of articles which all chemists dealt in. Even within the last fortnight the President had visited one of the largest establishments in Scotland, where a woman was employed doing nothing else but manufacturing suppositories and pessaries. They had no right to restrain women from taking up any occupation which they desired. Then as to the question of expediency —he held that these examinations, which were now being made more stringent, would restrict the supply of assistants. He himself had put a dozen advertisements in three Glasgow papers, and yet failed to get one apprentice, and the same thing was occurring elsewhere. Young men, in fact, were leaving the trade in all directions, and some one must be found to supply their places. It had been said that if the men could not pass the examinations, how could the women do it? But the fact was, the young men could pass them, but they had so many other fields open to them that they did not think it worth while to spend the time and money which was required for these stringent examinations, and therefore he believed they would be driven to employ women who wanted a field for their labour; he should therefore have much pleasure in voting for the resolution.

Mr. BOOTH said he should support the resolution.

Mr. RANDALL said, a good many remarks which had been made were not strictly to the point. Some time ago the trade was divided between pharmaceutical chemists and chemists and druggists, and chemists and druggists claimed to be on the register. When that was conceded they said it was unfair, because they had only taken the first step, that they should be kept out from any share in the government of the Society, and then it was admitted that they must come in and be admitted to membership. At that time there was a little suspicion as to what might be the result, and it was asked whether they could insist upon coming in, or whether they might not be rejected by the Council by a sort of side-wind. He remembered very well that at that time it was stated as a legal opinion that though the Council might exclude individuals on account of some individual incapacity, they could not keep out a class or a large section, for that if they attempted to do so a *mandamus* would issue compelling them to elect. Now it appeared to him that women were exactly in that position; they had been admitted as pharmaceutical chemists, and it was now too late to keep them out of the Society. He would ask the solicitor to say why, if he had correctly stated what passed on the previous occasion, a *mandamus* would not lie in the same way on the part of those women who were refused admission. It seemed to him simply a question whether they would do it spontaneously or be compelled to do it.

Mr. SANDFORD, referring to Mr. Hampson's objection to the Journal having contained an article advocating certain opinions, said it was only fair that the Journal should admit all opinions. It had done so on this question, sometimes even admitting poetic effusions, sometimes in favour of the ladies, and sometimes against them. He himself had written one or two letters on the subject, and as it was important that all should have a fair opportunity of expressing their views, he could not go with Mr. Hampson in finding fault with the Editor on that score. With regard to Mr. Randall's observations, he, Mr. Sandford, had most emphatically asserted that men, being eligible, would have a right to come into the Society; but it was with a reservation that individual disqualifications might exist which would justify the Council in rejecting them. According to the principle laid down by Mr. Randall, they must elect anybody and everybody who was on the register. Mr. Hampson said that these women were qualified, and therefore eligible. Now, it was very true that there must be qualification before eligibility, but there might be a disqualification, and he thought in the case of women their sex was a disqualification. He could not help thinking that Mr. Pickering was quite in order in the remarks he was making when interrupted, he was only stating his objections to admitting women to membership. There was no objection to any one employing his wife, or any other woman if he thought proper, in his shop, but he did not wish the Society to encourage the employment of women in pharmacy. He was glad one gentlemen had reminded them of meeting the ladies that evening, and he should be delighted to do so on any such occasion; in fact it was out of respect to the ladies that he opposed this motion, and because he had the pleasure of the acquaintance of many women, some especially of the highest mental qualifications, who were utterly disgusted with the present movement. To show what change might be expected in women, he handed to the President the current number of *Punch*, representing Mrs. Dr. Mandragora Nightshade calling on a physician, when the housemaid, in great dismay, described her as a man in woman's clothes.

Mr. HAMPSON said this was not dealing with the question before the meeting.

Mr. SANDFORD said he was giving his reason for opposing the motion. He opposed it both on behalf of the Society and of the women themselves. Mr. Hampson referred to the scene at the Council Board when three ladies were proposed to be admitted as apprentices. He remembered that scene perfectly well, and could not see that there was anything very remarkable about it. A list was handed in containing twenty or thirty names, and amongst them were these three ladies; when the list was first read over and the motion made, that the whole should be admitted, he moved that the three ladies should not be admitted, and then their names were taken out and put on a separate list by themselves. Therefore, the amendment was perfectly in order, and there was nothing extraordinary about it. It was quite open to these ladies, if they felt aggrieved, to go to the Court of Queen's Bench, and get a *mandamus*, to try the question at once. The Council had not passed any resolution that women should not be admitted, but certain names having been submitted, they had rejected them. In like manner, he remembered some few years ago, a Miss Leech applied to be admitted as a member. He believed she had been on the register, because her father had been a chemist and druggist, and she had carried on the business for a time after his death. She afterwards became manager or housekeeper in an asylum, and applied to be admitted a member of this Society. He opposed her admission, and when she asked him what his objection was, he told her it was simply that she was Miss Leech; to which she replied very truly, that was not her fault. There were many other means of earning a living open to women, and he was opposed to encouraging them to enter a business where they would have, day by day, to deal in things which he should be very sorry for any near female friends of his own to have any knowledge of. He trusted, therefore, the meeting would entirely negative the proposition.

Mr. GILES thought it particularly desirable that the question should not be settled on a false issue, which was not at all unlikely to be the case. On the one side gentlemen might be influenced by chivalrous feelings and on the other by something like jealousy. Now, there was really no room for any jealous feeling, because competition was not a question of sex, but of the number of shops. This question had been advanced a certain stage by a measure the Council had taken in conceding what he considered the essentials, in admitting women to the lectures, and what remained was he believed in great measure a matter of sentiment. Now it was not their business to adjudicate upon the sentiments of other people, or to say what sphere of action women should occupy. Every gentleman might influence his own friends or relations in accordance with his own views; but at that moment he knew a young lady who was devoting herself to nursing, which many others had done, and he apprehended that in that vocation they would come into contact with many things which might be very offensive. At the same time he must say *puribus omnia pura*, and it was possible that women might find a proper place in pharmacy quite consistent with all delicacy. He feared that a great many would be influenced in voting upon this question by their individual disposition rather than by reason; but it appeared to him that ladies had received permission to enter the trade, and to qualify themselves for it, and that being done it could not be undone. For his own part, he should have hesitated a great deal before going so far as that, for he was pretty certain that when the Acts of Parliament were passed such a thing was not contemplated. During many hundreds of years there had been a certain kind of separation between the functions of the sexes, and their duties in ordinary life, which they must believe, if they had any respect for their ancestors, was founded on good reason. Still the circumstances of life changed, and in an overcrowded country things which were once fitting were no longer to be maintained, and they must be prepared to give to woman a more independent sphere of action. If they desired them all to be married they would to a certain degree be only adding to the difficulties which already existed, at any rate, many of them did not get married and therefore required some means of honourably and independently maintaining themselves. These facts must be looked in the face, and they must expect that the state of things, which he confessed he preferred, might have to give place to something different. He therefore thought the Society might have been excused if this question had been postponed for a time, but as this had not been done, and access had been given to the lectures, it simply became a question whether the Council were justified in excluding women from membership. He thought it was perhaps a doubtful question whether they had any right at law to exercise that power of selection. It appeared very much as if the Council's function in relation to the election of members was simply executive, and not judicial, but that was a legal question which could not be settled there, and he hoped they would not attempt it. He noticed, however, a difference in the expression which applied to people being entitled to registration, and to their being eligible for membership; that was a difference which must be left to legal acumen to determine the value of, but he did not think it followed that because a person was eligible that therefore the functions of the Council were executive. For instance, a person might be eligible to be commander-in-chief, but if she were a woman, though she had passed the requisite competitive examinations, he apprehended the answer would be—"You are eligible *quoad* the examination, but you are not eligible *quoad* your sex." He thought the best way would be for the ladies to go to the Court of Queen's Bench and get a *mandamus*, and then the question would be satisfactorily settled. If it were settled now by refusing them admission, it would still be left open for agitation until it was settled by a court of law. If they were obliged to admit them they must do so by all means, but if it was a matter of choice he should certainly prefer their not being elected.

Mr. SAVAGE said they seemed travelling a good deal beyond the record. It was admitted that they had no power to exclude ladies from passing the examinations, and the only question was whether they should be admitted to membership. He should be very sorry to have a lady dispensing in his shop, but at the same time, if there were ladies who wished to encounter any indelicacy that might occur, they had nothing to do with that. He did not believe there would be a dozen present themselves in forty years, but whatever the number might be, they must be above the average character, or they would not pass the examinations, and he did not see why they should be kept out in the cold.

Mr. LINFORD begged to propose, as an amendment, that the question be referred back to the newly-elected Council.

The question being raised whether Mr. Pickering's amendment had been seconded, Mr. MARSDEN said, he should be very glad to second it.

Mr. HUMPAGE remarked, there was one point of view from which this question had not been looked at. They were about to confirm an alteration in the bye-laws, the effect of which would be that, in future, after the close of 1866, no individual should be eligible for examination except after passing three years' apprenticeship. That was virtually what it amounted to. But if they voted for ladies being admitted, then these would have to undergo this three years' apprenticeship the same as the other sex. Now this he strongly objected to, because, as had been observed by Mr. Pickering, they would have to undergo a certain routine, and hear and see things which would entirely destroy the delicacy of any young lady. Let ladies assist their husbands if they thought fit, though he should not like them to do so, but that was a widely different thing to sanctioning and encouraging them to enter the business. It was said that, having opened one door, they should open the second, but he had no responsibility on that point, for he had never voted in favour of ladies being admitted, and he certainly should oppose the motion; not out of any disrespect to the ladies, but he did not want them as members.

The SOLICITOR said, that as silence was sometimes taken to mean assent, he was anxious that silence on his own part should not be deemed assent to the proposition contained in the resolution, as to the law of the subject. At the same time, he had not made up his mind upon it, but he had an impression, rather than an opinion, that if the ladies did go to the Queen's Bench for a *mandamus*, they would not be successful. He believed that the Society possessed all the privileges of a voluntary association, with regard to election to membership, so long as those privileges were reasonably exercised. In many clubs in London, ladies were absolutely excluded; that society was formed of gentlemen, and he was under the impression that if gentlemen chose so to continue it, the law would sustain them in so doing. Brougham's Act, which had been referred to, showed that the expression implying one gender should be held to include the other, "unless the context be repugnant thereto." And he believed that there would be no difficulty in finding in the charter sufficient in the context and in the sanction of the long usage from the commencement of the Society to the present day to warrant the exclusion of women from membership. He would also remind the meeting that when the last Reform Act was passed it spoke of persons and men; and the ladies' advocates went to one of the courts, with the Act of Parliament and with Brougham's Act in their hands, and contended that ladies were admitted to the franchise. The courts, however, held the contrary, and it seemed to him that the ruling in that case was strictly applicable to this one. He would point also to the difference between the admission to the register and the admission to membership. The register was simply a creation of the Act of Parliament, and all persons duly examined were bound to be admitted to it. But though the Act of Parliament gave the members of the body the privilege of going on the register, it did not give to those on the register the right of becoming members of the body. The body itself was the creation of the charter, and at the very beginning of the charter it would be found that certain gentlemen having associated themselves together for a certain purpose, they were to establish a fund for the relief of their widows and orphans; they did not find the word *widower* there. And that very sentence was repeated in the last Act of Parliament. He did not profess to have formed a strong opinion on this subject, for, until coming there, he never imagined that it would be seriously discussed in the sense in which it had been; but he did not wish to have it said that he sanctioned the idea that the law would compel them to admit ladies. If the matter was to be fought out in a court of law,—speaking as a lawyer,—he should prefer fighting on the side which he believed would win, and if he had his choice on which side he should be, it would not be on the ladies' side.

Mr. HILLS asked, if the meeting decided to admit ladies would there be any legal difficulty in doing so?

The SOLICITOR replied, that if the admission of ladies was voted, there was nothing to prevent a gentleman going to the court for a *mandamus* calling upon the Council to show cause why the ladies were admitted.

Mr. HILLS said he had given this subject a great deal of consideration, and he had taken a considerable time to make up his mind upon it. He had not voted against the ladies as yet, and as he had not heard anything to convince him that they ought not to be admitted he should vote in favour of the proposition.

Mr. WARD inquired what would be the consequence if a lady became a member of the Society, and carried on business, and afterwards took a husband, and changed her name. Would she be allowed to retain her maiden name on the register, or would it be altered to the married one?

The SOLICITOR said he had had to consider that question with regard to the register, when he advised as he should again, that the register ought to describe the individual by that individual's known name or designation for the time being; and that the register might have to be corrected in the same way as it would be if a gentleman

Mr. SCHACHT said, it seemed rather a bold thing for a

changed his name.

layman to utter an opinion which was in any sense opposed to that of a professional man, but he could not help thinking that Mr. Flux was quite correct in saying that he had scarcely given this matter sufficient consideration; and, curiously enough, the quotation he had made, seemed to him to bear against his conclusion. He said the usage in these matters very materially determined the conclusion arrived at, and that the context of that word which would seem to admit ladies, served to show that they would be excluded, because the usage would be against them. Now, he must have forgotten that usage up to the present time had not excluded women at all. He had seen numbers of cases in which women had been employed as pharmacists behind the counter, and it was not denied that they were quite at liberty by law to be recognised as pharmacists by being on the register. Further than that, the Society admitted them to a course of instruction, and surely those arguments would be quite sufficient, at any rate, to give them a *locus standi* in any court to which they might apply for a *mandamus*. It was also said, that if the Council thought it right to admit ladies to membership, it would be open to a man to apply for a *mandamus* to show cause why they had done so, but he apprehended that if they admitted any particular man, say John Jones, it would, legally speaking, it would be open to anybody else, Mr. Thomas Smith, to apply for a *mandamus* to compel the Council to show why they had admitted him. If the solicitor thought there was a legal difficulty in the way, which he did not see his way to giving an exact answer to, that was a very good reason they should adopt Mr. Giles's suggestion and postpone the matter for further consideration. He had always voted on the Council in favour of the admission of women, because he thought it was only just, and he could not help saying that if there were any doubt as to the justice of the matter, generosity should lead them to give way. They need not fear that there would be more than two or three at the most. Beyond that it must be remembered that now members of the Society had control over the whole trade to a certain extent, and if once women were admitted to the register he did not see they had any right to exclude them from their fair share of executive control over the occupation they had adopted.

Mr. BETTY (London) said, the subject logically and practically divided itself into two portions—one, the right of women to carry on the business of chemists and druggists, and the other, and the main question, whether they should be admitted to take part in the conduct of the Society, and form a portion of the governing body. This was a matter eminently fitted to be decided by public opinion, and therefore the Council had delegated it to the Annual Meeting, especially looking to what had been done in other kindred societies and to the feeling in the country at large. The question was being agitated for the admission of ladies to vote for members of Parliament, and when they found public opinion year after year decidedly averse to such an innovation it behoved them to very carefully consider before they went in opposition to the general feeling of public bodies throughout the country. He very much objected to the admission of ladies to the lectures, and had he not been accidentally absent should have voted against the motion on the Council; indeed he was much surprised to find that it had been carried. The French proverb *ce n'est que le premier pas qui coûte* was particularly applicable to all dealings with ladies. It did not so much matter how the negotiations were begun; they might be comparatively harmless; the difficulty was you could never tell to what lengths they might go afterwards. He very much objected to the mixture of the sexes in educational establishments, as he had himself seen what inconveniences—to use the mildest word—might have arisen therefrom. As a public body, therefore, he hoped they would be guided by the truly English feeling that the delicacy of an English lady should be above suspicion. When there was a mixture of the sexes at Eton, Harrow, Marlborough, and Rugby, then he would say, let them be associated together in the public school of pharmacy.

Mr. BURDEN (London) rose to address the meeting, but was met with so many cries of "Vote" that he resumed his seat.

Mr. ATKINS said, no doubt time was valuable, but he had come up at some personal inconvenience on purpose to hear this discussion, and he thought everyone ought to have an opportunity of expressing his opinion.

Mr. BURDEN thought this was one of the most important questions which could be debated, and he deprecated its being decided by mere passion or prejudice. He should be glad if it could be postponed until it could receive further consideration, and when everyone had expressed their opinion. He had been waiting for a long time to hear some solid arguments why women should not be admitted to practise pharmacy, but had not yet heard them. He believed that in many cases they would be much better fitted for such positions than young men. In the druggists' shops in Paris you constantly saw the wife assisting her husband.

Mr. Giles reminded the speaker that it was not a question of practising the business, but of membership in the Society.

Mr. Burden did not see how women could practise as druggists unless they were admitted to all the privileges of membership. They ought to be qualified to do everything which they might be called upon to perform.

Mr. Atkins said he must object, although time was valuable, to a vote being taken on this question without a full discussion, and the Annual Meeting was the only opportunity for provincial members to make known their views, except in writing, which many had not time for. The question as to the desirability of women entering the business was, it appeared to him, a question for the women to decide for themselves. He did not wish to speak in the least degree personally or offensively, but he believed a great deal of the opposition to this motion arose from an unwise feeling of jealousy. Mr. Sandford had said that there was a large sphere of labour open to women; but, with all due respect, it appeared to him that their sphere of action was very limited, at any rate an opinion existed, wisely or not, on the part of many women, that a certain section of their own business, being somewhat refined in character and light in its manipulation, was capable of being appropriated by them. It seemed to him that the whole argument had been conceded when females were admitted to the register. He did not pretend to prophetic power, but he believed they were only now attempting to resist the inevitable. The suggestion had been made—and received with approbation—that women should be driven to apply to the court for a *mandamus*, but if it came to that, would it not be much more chivalrous, honourable, and manly, to admit them without that? He would not say how he intended to vote, for he simply came to hear the debate, and though he had a natural feeling of conservatism, prompting him to say no, he wished only to be influenced by the force of argument.

Mr. Urwick (London) had no wish to see ladies enter the trade, but at the same time he would not oppose them if they thought themselves adapted for it. He was guided in this matter by the 10th clause of the Act, which said they were eligible to conduct business and to be pharmaceutical chemists. Ladies having come forward and passed the requisite examinations, it was simply a matter of justice to admit them to membership, leaving it to each individual who presented herself to stand upon her own merits, and judging in each case, as in the case of a man, whether there was any moral reason for rejection. They could not assume that ladies who passed their examination were going to conduct business in an improper manner, and as a pure matter of justice he should vote for the resolution.

Mr. Hampson, in replying to the adverse criticism which the resolution had received, said he had taken care to fortify himself with legal opinions, and he had authority to use the name of Mr. Hinde Palmer, Q.C., M.P., who distinctly coincided with the principles he had laid down. Two other legal opinions were in the same direction, all three gentlemen agreeing that women occupied exactly the same position as men in relation to the Society. With regard to the disagreeable nature of the business and the awful consequences of women being mixed up with these disagreeables, he could not share the fears which had been so eloquently expressed. Those women who passed the examination and carried on business themselves would very probably employ female assistants, and in such cases there could be nothing in any way derogatory to female modesty or propriety.

The President then put the amendment that the question be adjourned *sine die*, and declared it to be carried by a considerable majority.

Mr. Davis called for a division, but this was not pressed.

The President was then proceeding to put the amendment as a substantive resolution, when—

Mr. Wade said he had an amendment to propose—"That it is the opinion of this meeting that, the solicitor of the Society not being able to give a decided opinion on the meaning of the Act, it is the duty of the Council to obtain Counsel's opinion thereon."

Mr. Randall seconded the amendment.

The President said he could not consider that as an amendment to the resolution before the meeting.

Mr. Randall said that difficulty could be easily got over. He could put himself perfectly in order by moving to omit the words "*sine die*," and to substitute "for the purpose of obtaining Counsel's opinion on the point."

Mr. Wade seconded.

Mr. Giles wished to know what "the point" was.

Mr. Randall: The point whether women can legally demand to be admitted. He would not press the motion if the Council would undertake to do so.

Mr. Brown appealed to Mr. Randall whether it was worth while to press the amendment after the meeting had so decidedly expressed its opinion that the question should be adjourned. The Council was as yet an unelected body, but he had no doubt there would be some gentlemen on the incoming Council who would not let the question entirely rest; and there could be no doubt that before the Council brought it forward again they would take care to have an authoritative expression of opinion from the highest legal gentlemen. He hoped, therefore, the meeting would at once proceed to the important business they had still to transact.

After some further conversation, Mr. Randall said he must press his amendment, as he could not get a distinct understanding that the question would not be allowed to drop altogether. The amendment was therefore put, and lost by a considerable majority; and Mr. Pickering's motion being put was immediately carried.

Scrutineers were then appointed to examine the voting papers sent in for the election of gentlemen to the vacant seats at the Council, and the meeting was adjourned to eleven o'clock on Friday, to declare the result of the poll.

SPECIAL GENERAL MEETING.

The Secretary having read the notice convening the Special General Meeting for the purpose of abrogating or altering some of the Bye-laws of the Society, and of considering, and, if thought proper, confirming and approving the new Bye-laws submitted to the said meeting by the Council as follows:—

FIRST SCHEDULE. Present.	SECOND SCHEDULE. Proposed.
Section 1.	
Clause 10.	*Clause* 10.
All subscriptions for the current year shall become due upon election, and all annual subscriptions shall become due on the first day of January in every year; and if any Member, Associate, or Apprentice or Student, shall not have paid his annual subscription before the first day of May in any year, his name shall be omitted from the Register of Members, Associates, and Apprentices or Students of the Society, certified by the Council at the Annual Meeting.	All subscriptions for the current year shall become due upon election, and all annual subscriptions shall become due on the first day of January in every year; and if any Member, Associate, or Apprentice or Student shall not have paid his annual subscription before the first day of May in any year, his name shall be omitted from the Register of Members, Associates, and Apprentices or Students of the Society, certified by the Council at the Annual Meeting.

It shall be competent to the Council to restore any defaulter to his former status in the Society on payment of his arrears and any fine which it may be thought fit by the Council to impose, not exceeding half-a-guinea.	It shall be competent to the Council to restore any person whose name has been so removed to his former status in the Society on payment of his subscription for the then current year, and a sum not less than the amount of half of one year's subscription, nor exceeding five guineas, as for and in commutation of his arrears of subscription.

SECTION 3.

Clause 3.	*Clause* 3.
The Common Seal shall not be set or affixed to any deed, instrument, or writing whatsoever, unless in the presence of the Council of the Society, and in pursuance of an order or minute entered in their books.	The Common Seal may be set or affixed to any deed, instrument, or writing, in pursuance of an order or minute of the Council entered in their minute book, and in the presence of the President, or Vice-President, or two Members of the Council, and not otherwise.

SECTION 4.

BYE-LAWS.	BYE-LAWS AND REGULATIONS.
The making, altering, or abrogating any Bye-law shall be in the following manner:—	The making, altering, or abrogating of any Bye-law or any Regulation, to be prescribed by the Society, in accordance with any statute, shall be in the following manner:—
Clause 1.	*Clause* 1.
A written formula for any proposed Bye-law, or for altering or abrogating any Bye-law, being delivered by a Member of the Council to the Chairman, shall thereupon be read, and, if seconded and approved, shall be referred to two subsequent ordinary or special Meetings of the Council for confirmation, and then to a special General Meeting of the Members of the Society, and afterwards to the Privy Council, according to the provisions of the Statute, 1852, as amended by the Act, 1868.	A written formula for any proposed Bye-law or Regulation, or for altering or abrogating any Bye-law or Regulation, being delivered by a Member of the Council to the Chairman, shall thereupon be read, and, if seconded and approved, shall be referred to two subsequent ordinary or special Meetings of the Council for confirmation, and then to a special General Meeting of the Members of the Society, and afterwards to the Privy Council, according to the provisions of the Pharmacy Act, 1852, and the Pharmacy Act, 1868.

SECTION 9.

Clause 1.	*Clause* 1.
This Committee shall consist of not less than four Members, two of whom shall constitute a quorum. The Committee shall meet once in every month, and report from time to time to the Council.	This Committee shall consist of not less than five Members, three of whom shall constitute a quorum. The Committee shall meet once, or oftener, in every month, and report from time to time to the Council.

SECTION 10.

Clause 1.	*Clause* 1.
The Board of Examiners heretofore appointed shall continue in office until the first monthly meeting of the Council after the general meeting in the year 1869.	The Boards of Examiners respectively heretofore appointed shall continue in office until the end of the year 1873.
Clause 2.	*Clause* 2.
The Council shall, at the first monthly meeting of the Council after the general meeting in 1869, and in every subsequent year, appoint such competent persons as they shall think fit, to be examiners to conduct all such examinations as are provided for or contemplated by the Charter or by the Statute, 1852, and the persons so appointed shall constitute and be called the Board of Examiners for England and Wales.	The Council shall, at their first meeting, in December, 1873, and in every subsequent December, appoint such competent persons as they shall think fit, to be examiners for the year to commence on the then following first day of January, to conduct all such examinations as are provided for or contemplated by the Charter or by the Statute 15 and 16 Vict. c. 56, and the persons so appointed shall, for the period of their appointment, constitute and be called the Board of Examiners for England and Wales.
Clause 3.	*Clause* 3.
The Council shall, at the first monthly meeting of the Council after the general meeting in 1869, and in every subsequent year, appoint fit and proper persons in Scotland to be examiners, and to meet in Edinburgh or Glasgow, or such other place or places as the Council may think desirable, and to conduct there all such examinations as are provided for or contemplated by the Statute, 1852, and the persons so appointed shall constitute and be called the Board of Examiners for Scotland.	The Council shall, at their first meeting in December, 1873, and in every subsequent December, appoint fit and proper persons in Scotland to be examiners for the year to commence on the then following first day of January, and to meet in Edinburgh or Glasgow, or such other place or places as the Council may think desirable, and to conduct there all such examinations as are provided for or contemplated by the Statute 15 & 16 Vict. c. 56, and the persons so appointed shall for the period of their appointment constitute and be called the Board of Examiners for Scotland.
Clause 4.	*Clause* 4.
The President and Vice-President of the Society shall, *ex officio*, be members of the Boards of Examiners, and shall preside at all meetings of such Boards at which they shall be present.	The President and Vice-President of the Society shall, *ex officio*, be members of the Boards of Examiners, and either of them present at any meeting of either of such Boards shall preside thereat.
Clause 5.	*Clause* 5.
After the first day of January, 1871, the Council shall not appoint any person who has attained the age of sixty-five years at the time of the appointment to be an examiner, unless such person shall be the President or the Vice-President of the Society.	The Council shall not appoint any person who has attained the age of sixty-five years at the time of the appointment to be an examiner.
Clause 6.	*Clause* 6.
After the first day of January, 1871, no person shall be appointed an ex-	No person shall be appointed an examiner who at the time of appointment

aminer who at the time of appointment is, or who during one year prior to the time of appointment has been, a Member of the Council, other than the President or Vice-President; and the election of any examiner to be a Member of the Council shall vacate his appointment as an examiner.

Clause 7.

The Board of Examiners for England and Wales shall consist of not more than twelve nor less than eight Pharmaceutical Chemists, exclusive of the President and Vice-President of the Society. The Board of Examiners for Scotland shall consist of not more than eight nor less than four Pharmaceutical Chemists, exclusive of the President and Vice-President of the Society. The Council of the Society may from time to time appoint Professors of Science to assist either of the Boards of Examiners at any of their Examinations. Eight Members of the Board of Examiners for England and Wales, and four Members of the Board of Examiners for Scotland, exclusive in each case of assistant Professors, shall constitute a quorum.

Clause 12.

All persons who shall tender themselves to the Examiners for Examination in accordance with the Charter and the Statute, 1852, shall be examined in their knowledge of the Latin language, in English Grammar and Composition and Arithmetic, which Examination shall be called the First Examination.

Such of the said persons as shall desire Certificates of competent skill and qualification to be engaged or employed as Assistants shall be examined in the First Examination, and also in the translation and dispensing of Prescriptions, in Botany, in Materia Medica, in Pharmaceutical and General Chemistry, the Chemistry of Poisons and Posology, which examination shall be called the Minor Examination; and such of the said persons as shall desire Certificates of competent skill and qualification to exercise the business or calling of Pharmaceutical Chemists shall be examined in the Minor Examination, and in more extended knowledge of Botany, Materia Medica, the translation and dispensing of Prescriptions, Pharmacy, General Chemistry, the Chemistry of Poisons and Posology, which examination shall be called the Major Examination.

Clause 16.

All persons before registration as Apprentices or Students shall pass the First Examination, and shall pay a Fee of Two Guineas, whereupon they shall be registered as Apprentices or Students.

is, or who during the six months prior to the time of appointment has been, a Member of the Council, unless he shall within the said six months have been the President or Vice-President; and the election of any examiner to be a Member of the Council shall vacate his appointment as an examiner.

Clause 7.

The Board of Examiners for England and Wales shall consist of not more than fourteen nor less than eight Pharmaceutical Chemists, exclusive of the President and Vice-President of the Society. The Board of Examiners for Scotland shall consist of not more than eight nor less than four Pharmaceutical Chemists, exclusive of the President and Vice-President of the Society. The Council of the Society may from time to time appoint Professors of Science to assist either of the Boards of Examiners at any of their Examinations. Eight Members of the Board of Examiners for England and Wales, and four Members of the Board of Examiners for Scotland, exclusive in each case of assistant Professors, shall constitute a quorum.

Clause 12.

All persons who shall tender themselves to the Examiners for Examination in accordance with the Charter and the Statute, 1852, shall be examined in their knowledge of the Latin language, in English Grammar and Composition and Arithmetic, which Examination shall be called the First Examination.

Such of the said persons as shall desire Certificates of competent skill and qualification to be engaged or employed as Assistants shall be examined in or produce Certificates of having previously been examined in the First Examination, and shall be examined in the translation and dispensing of Prescriptions, in Botany, in Materia Medica, in Pharmaceutical and General Chemistry, the Chemistry of Poisons, and Posology, which examination shall be called the Minor Examination; and such of the said persons as shall desire Certificates of competent skill and qualification to exercise the business or calling of Pharmaceutical Chemists shall be examined in or produce Certificates of having previously been examined in the Minor Examination, and shall be examined in more extended knowledge of Botany, Materia Medica, the translation and dispensing of Prescriptions, Pharmacy, General Chemistry, the Chemistry of Poisons, and Posology, which examination shall be called the Major Examination.

Clause 16.

All persons before registration as Apprentices or Students shall pass the First Examination, and shall pay a fee of Two Guineas, whereupon they shall be registered as Apprentices or Students.

After the 31st day of December, 1874, no person shall be admitted to the Major or the Minor Examination who shall not have attained the full age of twenty-one years; and after the 31st day of December, 1876, no person shall be allowed to pass the Major or the Minor Examination unless he shall satisfy the Examiners that for three years he has been registered and employed as an Apprentice or Student, or has otherwise for three years been practically engaged in the translation and dispensing of prescriptions.

Persons who have passed the Minor Examination at least three months previously may be admitted to the Major Examination, and all other persons desirous of passing the Major Examination may make application to the Board of Examiners for special leave in that behalf.

The PRESIDENT moved—

"That this meeting do confirm and approve the proposed alterations in the Bye-laws in the sections numbered respectively 1, 3, 4, 9 and 10, by erasing therefrom the several portions of the said sections in that behalf appearing in the first schedule hereto, and substituting for the respective portions of sections so erased the several clauses and words in that behalf appearing in the second schedule hereto, and that the said alterations do take effect from the date of confirmation and approval thereof by Her Majesty's Privy Council."

The VICE-PRESIDENT, in seconding the motion, said he believed the alterations had been well considered, and that they were judicious and necessary. Many of them referred only to matters of detail, but others involved questions of some importance. It was for the meeting to express its opinion and to suggest any amendments; but unless some principle were violated, it was very desirable that no alteration should take place, as it would cause considerable delay and inconvenience. They had been very fully discussed in Committee and at the Council, and he believed they would be found in accordance with the best interests of the Society.

Mr. GILES, suggesting that the alterations should be considered *seriatim*,

The SOLICITOR read or described the various alterations.

Mr. GILES, with reference to section 4, clause 1, relating to the alteration of bye-laws, said he did not raise any objection, and he was aware that similar provisions existed in many other societies, but he was not quite sure whether it might not be useful to afford members outside the Council an opportunity of initiating a new bye-law if they desired.

The SOLICITOR said there was no alteration in this respect.

Mr. GILES said he was aware of that. He only threw out the remark for consideration at some future time.

Mr. GILES asked with regard to section 10, clause 12, whether the certificates referred to were certificates of qualification to be granted by other bodies.

The SOLICITOR said only as regards the Preliminary examination.

Mr. GILES said he might take that opportunity of saying that he hoped the Council would not lose sight of the desirability of dissociating themselves as much as possible from that Preliminary examination. It was not the object of the Society to constitute itself an examining body in *literæ humaniores*, but they should confine themselves as much as possible to technical matters.

The SOLICITOR having concluded reading the alterations,

Mr. HAMPSON said: Before the motion is put I must claim the liberty of moving an amendment, as follows:—

"That the altered Bye-laws be approved and confirmed, save and except clause 16, section 10."

I am exceedingly sorry to have to oppose this bye-law again, but I have opposed it, and I hope to oppose it until it is thoroughly exterminated, for the simple reason that it is not legal. I am warranted in that opinion by legal authority which I have obtained; I will read the section of the Act, 1868, clause 6, which is as follows:—"All such persons as shall from time to time have been appointed to conduct examinations under the Pharmacy Act, shall be, and are hereby declared to be Examiners for the purposes of this Act, and are hereby empowered and required to examine all such persons as shall tender themselves for examination under the provisions of this Act." Now, there the Examiners are "required;" there is no option; and under this clause any one can come up, of course, unless this bye-law passes; then it will stand in the way. There are other reasons besides legal reasons, but I think I ought to state this also with reference to the legal opinion that our own solicitor distinctly affirmed before the Parliamentary Committee, and I do not think I am committing any breach of privilege in stating boldly my opinions. I believe what occurs before the Parliamentary Committee and comes to the knowledge of the Council becomes, or ought to become, open to all the members. On these grounds, I say again, I do not think I am guilty of any breach of privilege in referring to this opinion, and I must again state what our own solicitor's opinion was. Mr. Flux distinctly told us that it was illegal, and that we had no power to cause an interval of three years to be placed between one examination and the other. If that opinion be correct we have no right to pass this bye-law; if we want to bring about such regulations let us go to Parliament and get the alteration in a straightforward way. I maintain that this is not a straightfoward way of making the alteration, it is opposed to the statutes, and I say it is unjustifiable to press it forward in this way. But besides that there is something to be said on the general question. I think it is very undesirable to make these hard and fast lines, and no evidence has been brought forward to show that they are necessary. The old bye-law has stood for a long time, and I believe it has borne good fruit. Why should we interfere in this manner, and say that a young man, a candidate, shall not pass his examination when it is most convenient to him. Why should we say a young man should not pass in two years or two and a half years? But this bye-law says no, you shall pass your examination at a certain time; that is to say, there shall be an interval of three years. Besides that there is another restriction in this bye-law. It affirms that any one entering the trade shall be three years with a chemist and registered, or engaged for three years in dispensing prescriptions. If this bye-law passes it will be constantly evaded, and besides that the three years with a chemist is no guarantee whatever. In the majority of shops even in the metropolis, the great centre of pharmacy, it would be no guarantee of capacity or practical training. Is it not patent to us all that numbers of tradesmen do not make any of their own preparations, but buy them all, and their stock is on their shelves? How, then, would a candidate obtain the knowledge of pharmacy? Again, the subjects of examination are all practical subjects. You have botany; surely, if there is any practical subject in the world it is botany; and the examiners ought to be able to tell whether a candidate knows anything of botany or not. So with dispensing—is it not possible to test the capacity of a dispenser in compounding emulsions or pills? There is scarcely a person in the room but would be able to tell in five minutes whether a man knew his business or not. Again, coming to chemistry, the new regulations impose increased stringency in the examination, giving the examiners the power of testing the candidates in their knowledge of chemistry, and all this is in a practical direction. Therefore I say there is no necessity for this term of apprenticeship. On these grounds, and especially on the ground of illegality, I must oppose this bye-law. Only this morning I received an opinion from a barrister on this question. He says: "It seems clearly contrary to the 6th section of the Pharmacy Act, 1868, which requires and empowers the examiners to examine all persons who shall present themselves. The proposed bye-laws would restrict this generally;" and he goes on to confirm this statement, and to say that it must be contrary to law. Why need we go and do things illegally? Have the examiners become so worthless that we must step out of our way in this surreptitious manner—I use the word advisedly—to press this bye-law on the Society? I believe the members generally scarce know what will be the consequence. Already there is a difficulty, as we have heard mentioned this morning, in getting assistants, and this will only be another barrier in the same direction. When evidence is brought forward to show that such a change as this is necessary, it will be quite time for us to consider whether we shall go to Parliament in a straightforward way and obtain a modification of the statute.

Mr. URWICK seconded the amendment, simply on the ground that it was a departure from the principle of the Act. The Act clearly pointed out the examiners' duties, viz., to examine every person who presented himself. It was the duty of the examiners to test the qualifications of the candidates. This new regulation would be putting a clog upon young men in compelling them to wait three years when they might be ready in two years or a little more. He opposed the alteration. He considered the bye-law ought to be in every respect in conformity with the statutes.

Mr. M. CARTEIGHE (London) was much astonished to see two gentlemen, members of the Parliamentary Committee and of the Council coming forward, and one of them bringing rival lawyer's opinions, and asking the meeting not to accede to the proposition, which appeared to have been carried by a very large majority of the Council. Did they suppose that the other members of the Council were blind to the interest of the Society, or that they deliberately shut their eyes for the purpose of acting unjustly towards the members? As a member of the Society, he must be pardoned for saying he thought it hardly desirable for a gentleman in office to publish business transacted in Committee. If that kind of thing were continued, there would be many difficulties constantly occurring, and he hoped future members of Council would, as in times past, consider the proceedings of Committees as being private. It was as easy to get a lawyer's opinion as to get up a petition. He remembered a gentleman's saying, after a petition had been obtained on a certain subject, that if he had a shilling a head, he could go round and get the same persons to sign another in the opposite direction. The value of a legal opinion depended entirely on the way in which the case was drawn. He did not profess to know anything about this as a question of law, but the examiners left it to the Council to consult their proper authorized officer, and to do what they thought desirable for the benefit of the candidates, by adopting such proceedings as would, in their judgment, improve the calibre of their men in what was always clamoured for—practical knowledge. It was all very well to say that a man's capacity could be tested in five minutes. He should like any of those present to try. If they were conscious how easy it was for a man to get up a certain kind of knowledge, even a certain kind of practical knowledge, they would not make such statements. Men would actually make up difficult emulsions, pills, and even silver them, and get a certificate, who still did not know their business; and the examiners felt they had no right to give certificates unless they carried—what they should carry—a certain amount of money value, and be a guarantee that every man who passed the Minor examination might be considered reasonably competent. It often happened now that employers would say to assistants, We do not care so much about the Minor examination; where have you been?—they each wanted some test of practical knowledge. If the examiner devote two hours to every candidate, in ninety-nine cases out of a hundred he would be able to pass an accurate judgment; but for that purpose they would require an enormous increase in the number of examiners, or the duties would be so heavy that no one would undertake them. The proposed alteration was asked for in the interest of the candidates themselves, in order that they might have ample opportunity to digest their knowledge, and so be better prepared to pass creditably. The great fault of the present system was, that many men got up their scientific knowledge too quickly, and while they came up thoroughly prepared in chemistry and botany, they often failed in a practical subject, because of some little technical matter which experience only could have made them familiar with. If such men had waited a little longer they would have passed with credit. Any man who was competent to pass under twenty-one should be infinitely more competent at that age; there could be no question of that. With regard to apprenticeship regulation, it must be remembered that the examiners were men who had taken some interest in the constitution of the Society; they had had something to do with the passing of the Pharmacy Act and with the old voluntary examinations which previously existed. They did not want to force on any bye-law, but simply, in accordance with the often-expressed wishes of the members, to make the examinations more practical. If Mr. Hampson were an examiner for twelve months he would find it much more difficult to discover the amount of a man's real knowledge than he supposed. Men might be, and he believed were, prepared for the examination who had never been in a chemist's shop at all. They wanted men having an honest, *bonâ fide*, practical knowledge of the various subjects. Believing they would assist in this direction, the examiners had proposed the new regulations, and he took it for granted that the Council consulted their solicitor and knew what they were about. Assuming that no breach of law was involved, he supported the bye-law, and was quite sure it would be beneficial both to candidates and employers, the latter of whom would in the course of time find they could obtain a better class of assistants.

Mr. ANDREWS (London) considered the new bye-law a wise one in every respect, and he had devoted a good deal of thought to the subject.

Mr. MELLIN said he should support the amendment. There were many young men apprenticed at fourteen or fifteen for three years, and if they could not pass their examination until they were twenty-one, they might be kept out of a situation for two or three years. Many were as well qualified at seventeen as others were at twenty-one; but he thought it quite right to insist on a three years' term of apprenticeship.

Mr. GILES said the greatest respect was due to the suggestions of the Board of Examiners and the decision of the Council, but at the same time it was a very fair subject for discussion, and Mr. Hampson was quite entitled to move his amendment. He did not attach much importance to the legal question; because, after all, they could do pretty much as they liked until they were disturbed, but he should put his vote in the hands of the Council; and if they felt they must ask for a vote in favour of the alteration, he should give it. At the same time there were objections. It was within their knowledge that there was a great difficulty in obtaining assistants able to pass the examinations, and they were considering how best to offer educational facilities to assist them; now this was raising up an artificial obstacle, it appeared to him, unnecessarily. A young man should, he thought, be allowed to pass when most convenient to himself; he was frequently controlled by circumstances, as to when he should come up to Bloomsbury Square and undergo a course of instruction, but when that was concluded he was best prepared to come up for his examination. He quite agreed that no young man ought to be allowed to conduct a business before he was twenty-one, but that was quite a distinct question, and the two ought to be separated. It would be much better to allow the examination to take place at any time, when most convenient, and introduce a clause restricting the age for opening a shop. What would be the use of this clause? What would it effect? In the majority of places which would confer this three years' qualification, a young man might never see a prescription from one year to another. Taking the chemists and druggists throughout the country, he did not believe the majority had a prescription once a month. He was very sorry for it, and always stood up for those members of the trade who were not doing the class of business they could wish, and he considered it a great mistake to set up a standard which would make it impossible to find men to fill useful and necessary positions. The object of the examinations was not to certify that the candidate was qualified to discharge all the duties which might devolve upon him, but that he was so far qualified that he was in a position to qualify himself. One of the most essential qualifications—good handwriting—did not appear to be considered at all.

Mr. CARTEIGHE said Mr. Giles could not have read the regulations.

Mr. GILES: If they did attend to handwriting, they failed most miserably in securing anything like a good standard; probably the standard was fixed rather low. Something must be left to the employer. The examiners did not certify that a candidate had two legs, but he should not like to have a man with a wooden leg in his shop. Still he could judge in that matter for himself. He repeated that he placed his vote at the disposition of the Council, remembering that even if this new rule were not found to work well, it could at any time be revoked.

Mr. COSSEY supported the amendment, and desired to endorse the sentiments expressed by the last speaker. A three years' apprenticeship would in no way ensure a qualification to dispense, whilst cases might occur, say of a person dying and having a son in the business not quite of age, in which a hard and fast rule would work great hardship. He thought some remarks which had been made as to the desirability of re-opening questions which had been fully discussed at the Council quite uncalled for, seeing that unless matters were to be considered at the General Meeting, it was a mere farce to bring them before it. No doubt the Council had done their best, but he could not consider it a mark of wisdom to go out of their way to propose prohibitory measures calculated to prevent young men entering the business.

Mr. WHEELER agreed with the remarks of Mr. Carteighe, and considered that an apprenticeship qualification was the only means of preventing the cramming system, under which a young man might pass an examination, though his practical knowledge might be almost *nil.*

The amendment was then put and lost, eight hands only being held up in its favour.

The original motion was thereupon put and carried.

Mr. URWICK proposed a vote of thanks to the President for his able conduct in the chair; desiring at the same time to express on behalf of the members generally what he knew was their feeling of gratitude for the long-continued and conscientious services rendered by Mr. Haselden to the Society. He was about to retire for a time from the Council, but he hoped before very long that he would resume the seat at the Board which he had so long and worthily filled.

The motion having been carried by acclamation,

The PRESIDENT said, I am very much obliged to you, Mr. Urwick, and to you, gentlemen, for the kindness you have shown towards me at all times. I have only one thing to add, that though I part with you as a Councillor, I do not leave you as a member of the Society.

This terminated the proceedings, which had lasted about five hours.

NORTH BRITISH BRANCH.

EDINBURGH, *January 29th*, 1873.

ADJOURNED MEETING.

Friday, May 23, 1873.

MR. A. F. HASELDEN, F.L.S., IN THE CHAIR.

The Scrutineers brought up their report as follows :—

SCRUTINEERS' REPORT.

We, the undersigned Scrutineers, appointed at the Thirty-second Annual General Meeting of the Pharmaceutical Society of Great Britain, do hereby certify that we have examined the voting papers committed to us, and report the following :—

Voting Papers received	1067
Disallowed from informality	10
Votes registered	1057

FREDERICK ANDREWS, *Chairman.*
JOHN LINFORD.
STANLEY FOWLER.
DAVID MORGAN.
JOHN MOSS.
WILLIAM GULLIVER.
J. M. HUCKLEBRIDGE.
GEORGE MEE.
THOMAS SHEPHEARD.

May 22nd, 1873.

The Chairman then declared the Council for the ensuing twelve months to consist of the following Members :—

COUNCIL.

ATHERTON, JOHN HENRY, Long Row, Nottingham.
BAYNES, JAMES, 24, Waterworks Street, Hull.
BETTY, SAMUEL C., 6, Park Street, Camden Town, N.W.
BOTTLE, ALEXANDER, 37, Townwall Street, Dover.
BROWN, WILLIAM SCOTT, 113, Market Street, Manchester.
FRAZER, DANIEL, 113, Buchanan Street, Glasgow.
GREENISH, THOMAS, 20, New Street, Dorset Square, N.W.
HAMPSON, ROBERT, 205, St. John Street Road, E.C.
HILLS, THOMAS HYDE, 338, Oxford Street, W.
MACKAY, JOHN, 119, George Street, Edinburgh.
OWEN, JOHN, 234, Upper Street, Islington, N.
RADLEY, WILLIAM VALENTINE, 74, Market Place, Sheffield.
ROBBINS, JOHN, 372, Oxford Street, W.
SANDFORD, GEORGE WEBB, 47, Piccadilly, W.
SAVAGE, WILLIAM DAWSON, 4, Park Road, East, Brighton.

SCHACHT, GEORGE FREDERICK, 7, Regent's Place, Clifton.
SHAW, JOHN, 24, Great George's Place, Liverpool.
STODDART, WILLIAM WALTER, 9, North Street, Bristol.
SUTTON, FRANCIS, Bank Plain, Norwich.
URWICK, WILLIAM WALKER, 60, St. George's Road.
WILLIAMS, JOHN, 14, Buckingham Street, W.C.

AUDITORS.

There being only the requisite number of Candidates (five) for the offices of Auditors, the Chairman declared the following duly elected for the ensuing twelve months :—

ANDREWS, FREDERICK, 23, Leinster Terrace, Hyde Park, W.
BARRON, FREDERICK, 2, Bush Lane, E.C.
HODGKINSON, WILLIAM, 127, Aldersgate Street, E.C.
HORNER, EDWARD, 20, Bucklersbury, E.C.
SQUIRE, WILLIAM, 5, Coleman Street, E.C.

The Scrutineers also handed to the President their report of the return for the election of Local Secretaries.

Votes of thanks were given to the Scrutineers and the Chairman, and the meeting separated.

Provincial Transactions.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The usual monthly meeting of the above Society was held on Wednesday, May 7th ; Mr. W. Ward, F.C.S., President, in the chair, when, after some preliminary business, a lecture was delivered by Mr. G. A. Cubley, M.P.S., on "Pharmaceutical Arithmetic." The lecture, which was of a most interesting character, was listened to with great attention, and Mr. Cubley was frequently applauded during its delivery ; the obvious practicability of his remarks being appreciated by a numerous meeting of members and associates. During the course of his remarks the lecturer alluded to the necessity of a good knowledge of arithmetic required in pharmacy, and which becomes year by year more important. He then entered into an examination of the weights and measures of the Pharmacopœia, the old apothecaries' weight, and the metrical weights and measures ; these he illustrated with comparative tables. The proportions of active ingredients in the preparations of the Pharmacopœia as there given were next alluded to and their great use shown. The case of mucilage under the head of Acaciæ Gummi being, however, said by the lecturer to convey a wrong impression, as it is stated in the Pharmacopœia to contain 1 part gum in 2½ mucilage, which, though right as regards weight is wrong by measure, for mucilage being a fluid would according to the Pharmacopœia be measured not weighed. The method of calculating the measure of a fluid, its specific gravity and weight being known, was then given, and the necessity of calculating the quantity of excipient used in pill masses shown.

He then proceeded to the use of arithmetic in prescriptions, and proved its especial use in those now becoming so frequent where a single dose is prescribed, and then so many doses ordered. He brought forward several peculiar instances and gave the various calculations required. After illustrating the mode of converting Fahrenheit degrees of temperature into Centigrade, and showing various easy methods of converting the various weights and measures into one another, the lecturer concluded with an appeal to the students of the Society to apply diligently to their arithmetical studies, not only for their own sakes in relation to business, but because life frequently was at stake whilst they were calculating.

At the close a vote of thanks, moved by Mr. Dobb and seconded by Mr. Malcham, was unanimously accorded to Mr. Cubley, which brought the meeting to a close.

Parliamentary and Law Proceedings.

HEAVY SENTENCE UNDER THE ADULTERATION ACT.

On Saturday, May 17, Henry Howard, a milk dealer, carrying on business at 270, Euston Road, appeared before Mr. Mansfield to answer the complaint of the inspector appointed by the vestry of St. Pancras to enforce the Adulteration Act.

From evidence adduced it appeared that on the 3rd instant, the inspector went to the defendant's shop and asked for a pint of milk. The niece of the defendant served him, and he poured the milk into bottles, which were sealed in the presence of defendant, and afterwards given to Dr. Stephenson, the analyst, who found it was half water, and he gave a certificate to that effect, but stated that in his opinion it was not injurious to health. On the 16th instant Mr. Hartley again entered the shop of defendant and asked for a pint of milk, which was served by the defendant's wife, but he was standing by her side at the time. The milk was placed in a bottle, sealed, and given to the analyst, who found that the milk was adulterated to the extent of one-fourth of water.

The defendant, in answer to the charge, said the inspector did not ask for pure milk, if he had done so he could have had it.

As this was the first prosecution by the parish the full penalty was not asked for.

Mr. Mansfield said he should not inflict the full penalty, but he hoped the vestry would proceed against every person offending against the Act. The defendant would have to pay a fine of £10 for the first case, £5 for the second, and 25*s.* costs.

The money was at once paid.—*Standard.*

ROBBERY OF DRUGS.

Frederick Tucker, who had been in the employ of Messrs. Herring and Co., manufacturing druggists, Aldersgate Street, for over twenty-one years, and had held the position of manager of the tincture department, and John Holland, a general dealer, living in Spitalfields Market, were charged on remand at the Guildhall Police Court, on Thursday, May 15, before Sir Benjamin Phillips and Alderman Owden, with stealing half a pint of essence of ginger, belonging to the prosecutors.

Mr. Humphreys (of the firm of Humphreys and Morgan) prosecuted on behalf of the Wholesale Chemists and Druggists' Protection Society ; and Mr. Buchanan appeared for the prisoners.

It appeared that Messrs. Herring found they were being robbed, but could not tell how, or by whom, so they employed the detectives to find out ; and Frederick Charles Brett saw Tucker leave his employers' premises, and go into a public-house in Jewin Street, where he met Holland, and gave him a bottle of essence of ginger. They had some gin together, and then parted. Brett stopped Holland in Bishopsgate Street, and questioned him as to what he had got about him, when he produced the bottle, and said that it was his medicine. He afterwards apprehended Tucker, when he admitted that he had given the other prisoner essence of ginger for his asthma. At his house several bottles were found, some of which were empty, and others contained chemicals such as Messrs. Herring manufactured.

The prisoners, by the advice of their solicitor, pleaded guilty, so that the magistrates might deal with them summarily, and that course was acquiesced in by the prosecution.

Sir Benjamin Phillips, having consulted Alderman Owden, sentenced them each to four months' imprisonment with hard labour.—*Evening Standard.*

The Shop Hours' Regulation Bill.

Sir,—I was greatly surprised at reading an article in this month's number of the *Chemist and Druggist*, commenting very strongly on the provisions of the above Bill; and as a reply to that journal would not appear for another month, will you kindly allow me space for the purpose?

In the first place, I cannot see how compelling chemists and druggists to close their shops at 2 P.M. for one day in the week would be "seriously affecting them," for at the present time in several towns the shops are closed early one night in the week, so it would only be adding a few more hours; besides, any chemist would be at liberty to supply medicines himself after closing time, or to keep a qualified assistant for the purpose. Now that the examinations are to be made more severe than ever, which of course will necessitate very close application to study, what could be more refreshing to the student than an afternoon's trip into the country, where he might study botany from real plants, and thus learn more in one afternoon than he could by a week's reading at home? As to closing at 9 other evenings, that certainly would not be "seriously affecting them," as 8 is the general hour now in most country towns, and even in London some of the principal chemists have agreed to close at 9 (as lately reported in this Journal); and as I said before, medicines urgently required could be supplied by qualified persons at any time. I hope the exigencies of our trade (or profession!) will never compel us to keep open shop on Christmas Day and Good Friday, when every other tradesman is holding holiday! If this Bill is made law, the public, of course, will soon become aware of it, and consequently come earlier for their goods. I am sure if any one tradesman would be more benefitted by it than another it would be the chemist, who has hitherto been working the longest hours of any. I think Sir J. Lubbock has taken a step in the right direction, and I trust he will not be influenced by petty representations. In conclusion, let me urge on all assistants and apprentices the necessity of prompt and united action in preventing this desirable privilege being taken from us. I hope the subject will soon be taken up by abler hands than mine.

Audi Alteram Partem.

May 17th, 1873.

Pharmacy Act, 1868.

Sir,—I quite agree with "Registered Chemist" that the system of wholesale firms supplying small grocers and costermongers with drugs, etc., should be investigated. For several miles around my shop, you can purchase from the above class of dealers a penny powder, box of pills, ointment, or paregoric, etc. The above are put up and sold by persons called wholesale druggists or manufacturers of pharmaceutical preparations. It is time such a practice was put a stop to,—but how are we to do it? I think by refusing to do business with such firms as are known to supply drugs to the above-mentioned dealers.

Boz.

Proposed Addition to the British Pharmacopœia.

Sir,—The pulv. glycyrrhizæ co. of the Ph. Borus., to which attention was directed by an article in *The Practitioner* about a year ago, has been found in many cases an excellent aperient.

When prepared with 2 oz. of ginger instead of 3 oz. of fennel, as ordered, I find that patients do not complain of the taste so much, and the medical man to whom I suggested this slight alteration finds it an improvement, and frequently orders the pulv. glycyrrhizæ co. prepared with ginger.

George Brown.

Sandown, I. W., May 12th, 1873.

An Inquiry.

Sir,—A public confession of ignorance, if not exactly conducive to a feeling of self-respect, is sometimes a necessary preliminary to the acquirement of knowledge; such—having completely failed to obtain the information I seek in the circle of my acquaintance—I fear it is in my case. This is my difficulty: I am familiar with analytical chemists, dispensing chemists, manufacturing chemists, but I don't know what a *consulting chemist* is; yet such is the title a gentleman who has recently opened what an auctioneer would describe as "commanding premises," not a thousand miles from Broad Street, has conferred on himself in letters of no common magnitude. Can you or any of your readers enlighten

An Ignoramus?

Pharmaceutical Curiosities.

Sir,—Mr. J. Bower Williams, A.P.S., has the honour to occupy a quarter-page of the Journal of the 3rd May, 1873. Such an advantage brings responsibility. He fulfils his by holding up to view,—

1st. A small exhibition of *popular* ignorance; and

2nd. A specimen of *trade* ignorance which may be taken as not the worst to be found, although such instances cannot possibly be numerous. *En parenthèse*, the remedy is already provided, for henceforth "vested rights" can only be possessed by the initiated.

But in reference to No. 1, I would say it is always possible for a teacher to expose the ignorance of his pupils. Chemists are teachers, and the general public are their pupils. For this reason many of the now absurd names for drugs are historical; *e. g.*, oil of Exeter, oil of swallows, and oil of earthworms, which are legitimate names of things formerly dispensed to the public as medicaments of value. The *things* are obsolete, but the *names* are not totally forgotten. Names of another class are equally absurd: take, for instance, the series of "copperas." The public retain the use of the terms, but the chemist, being a little in advance of his pupils, calls them sulphates according to their kind. It is probable that, for some time to come, the chemist will be asked for things under obsolete and corrupted names, and he will still continue to teach his pupils a more correct nomenclature, for he is in that department the only true pioneer.

I am happy to see that Mr. Williams is going "to send you some more ere long." Might I suggest his line to be—A research into the history of curious and old-fashioned names of medicaments, and their corruptions? I have no doubt many would feel pleasure in aiding in that pursuit, and in doing so, many a quaint old book might turn up to daylight again.

I will just add a specimen which will serve to indicate the occasion to be informed of the meaning of old terms, and then conclude.

THE COLOUR OF CANTHARIDES.

BY HENRY POCKLINGTON.

The colours and colouring matter of the thorax, head, and other portions of cantharides that bear the metallic green lustre so characteristic of these insects, agree so closely in origin and kind with those that formed the subject of my last paper* that it will be convenient to discuss the colouring matters without reference to any particular portion of the insect. As with the wing cases the colours of the thorax, etc., are in large part due to interference and in part to fluorescence. The persistent green colour referred to in my previous paper has been the subject of the later investigation of which I now propose to give the results.

Many readers of my former article have expressed their regret that it did not include any account of the mode of working followed in these inquiries, and have also intimated a desire that a more graphic method of charting the spectra should be followed in the paper, that non-spectroscopists may be able to follow the description better; I will endeavour as briefly as possible to meet their wishes in both respects.

As stated in my former paper, the instruments of which I make use, are a Sorby Browning micro-spectroscope, a small direct vision spectroscope adapted for use with the microscope, and capable of showing two spectra at once, and side by side to permit comparison; and a stand-spectroscope of moderate dispersion, giving a much longer spectrum than the micro-spectroscope, and working, on this account partly, rather better when bands occur in the blue or extreme green. A very simple and inexpensive arrangement will enable any of my readers to see absorption bands, and thus enable such of them as are not acquainted with the subject to understand what sort of things they are. Having closed the shutters of a room looking south, make a narrow slit in the shutter and place before it a small prism (the triangular pendant of a chandelier will do if nothing better be at hand, or failing this, three pieces of glass may be fastened into a cork so as to form a triangular bottle, and this, filled with water, or carbon bisulphide, will make a very good make-shift prism) with its thin edge at right angles to the length of the slit, and pointing downwards. A more or less pure spectrum will be projected on the opposite wall, or may be allowed to fall upon a white paper screen. If a bottle filled with dilute solution of the permanganate of potash be placed outside the slit so that the sunlight passes through the bottle, then through the slit and prism, the spectrum will be seen to be no longer "continuous," that is, the various "prismatic" colours will be no longer uniformly shaded the one into the other from red to violet, but there will be seen four (or five if the arrangements be very good) black bands crossing the spectrum, and the violet will be entirely missing. These are absorption bands, the spectrum being "discontinuous," with general absorption of the violet. These bands are, of course, due to the absence of certain colours that are absorbed by the solution in the bottle, and the rays of light that our senses translate into the colours being missing when the sunlight (or lamp-light) falls upon the prism, the prism simply disperses those that are present into their proper places in the spectrum, and leaves the other places blank, and the absence of light meaning darkness (that is, blackness) we have a spectrum of such colours as the incident light was composed of, crossed by black band spaces due to the absence of such colours as the incident light had been deprived of. That they are bands is due to the fact that the prism paints an infinite number of images of the slit, each image being of one colour, and when all colours are present, so exactly side by side that the most cunning eye cannot discern the piecing, any absent colours being represented by black portraits of the slit, their number side by side determining the width of the absorption band.

The production of the spectrum is due to the different amount of refraction that each constituent colour of white light suffers in passing through the prism, and this is connected with the wave-length of the rays in question, the short waves being most retarded in passing through the prism, and therefore the most refracted, and the long or red waves (those that vibrate least rapidly) the least retarded; thus each wave of the infinite number that composes the spectrum is differently affected by the prism. Out of this law arises the wonderful modern method of scientific inquiry known as spectrum analysis. The subject is one much too large for discussion here, and has only been introduced to this extent to clear the atmosphere of a misapprehension induced by an error in Mr. Stoddart's interesting paper on "Spectral Analysis adapted to Pharmacy," in this Journal for September, 1869, in which Mr. Stoddart, by a remarkable slip of the pen, refers the prismatic dispersion to this cause, that, "the red rays of the spectrum vibrate so weakly that they can only penetrate the thin edge of the prism. Those of greater intensity are capable of penetrating the thicker portions of the glass, and are thereby refracted at a greater angle."*

To meet the other desideratum I have charted the spectrum of the cantharides previously described in addition to the spectra of the new ones.

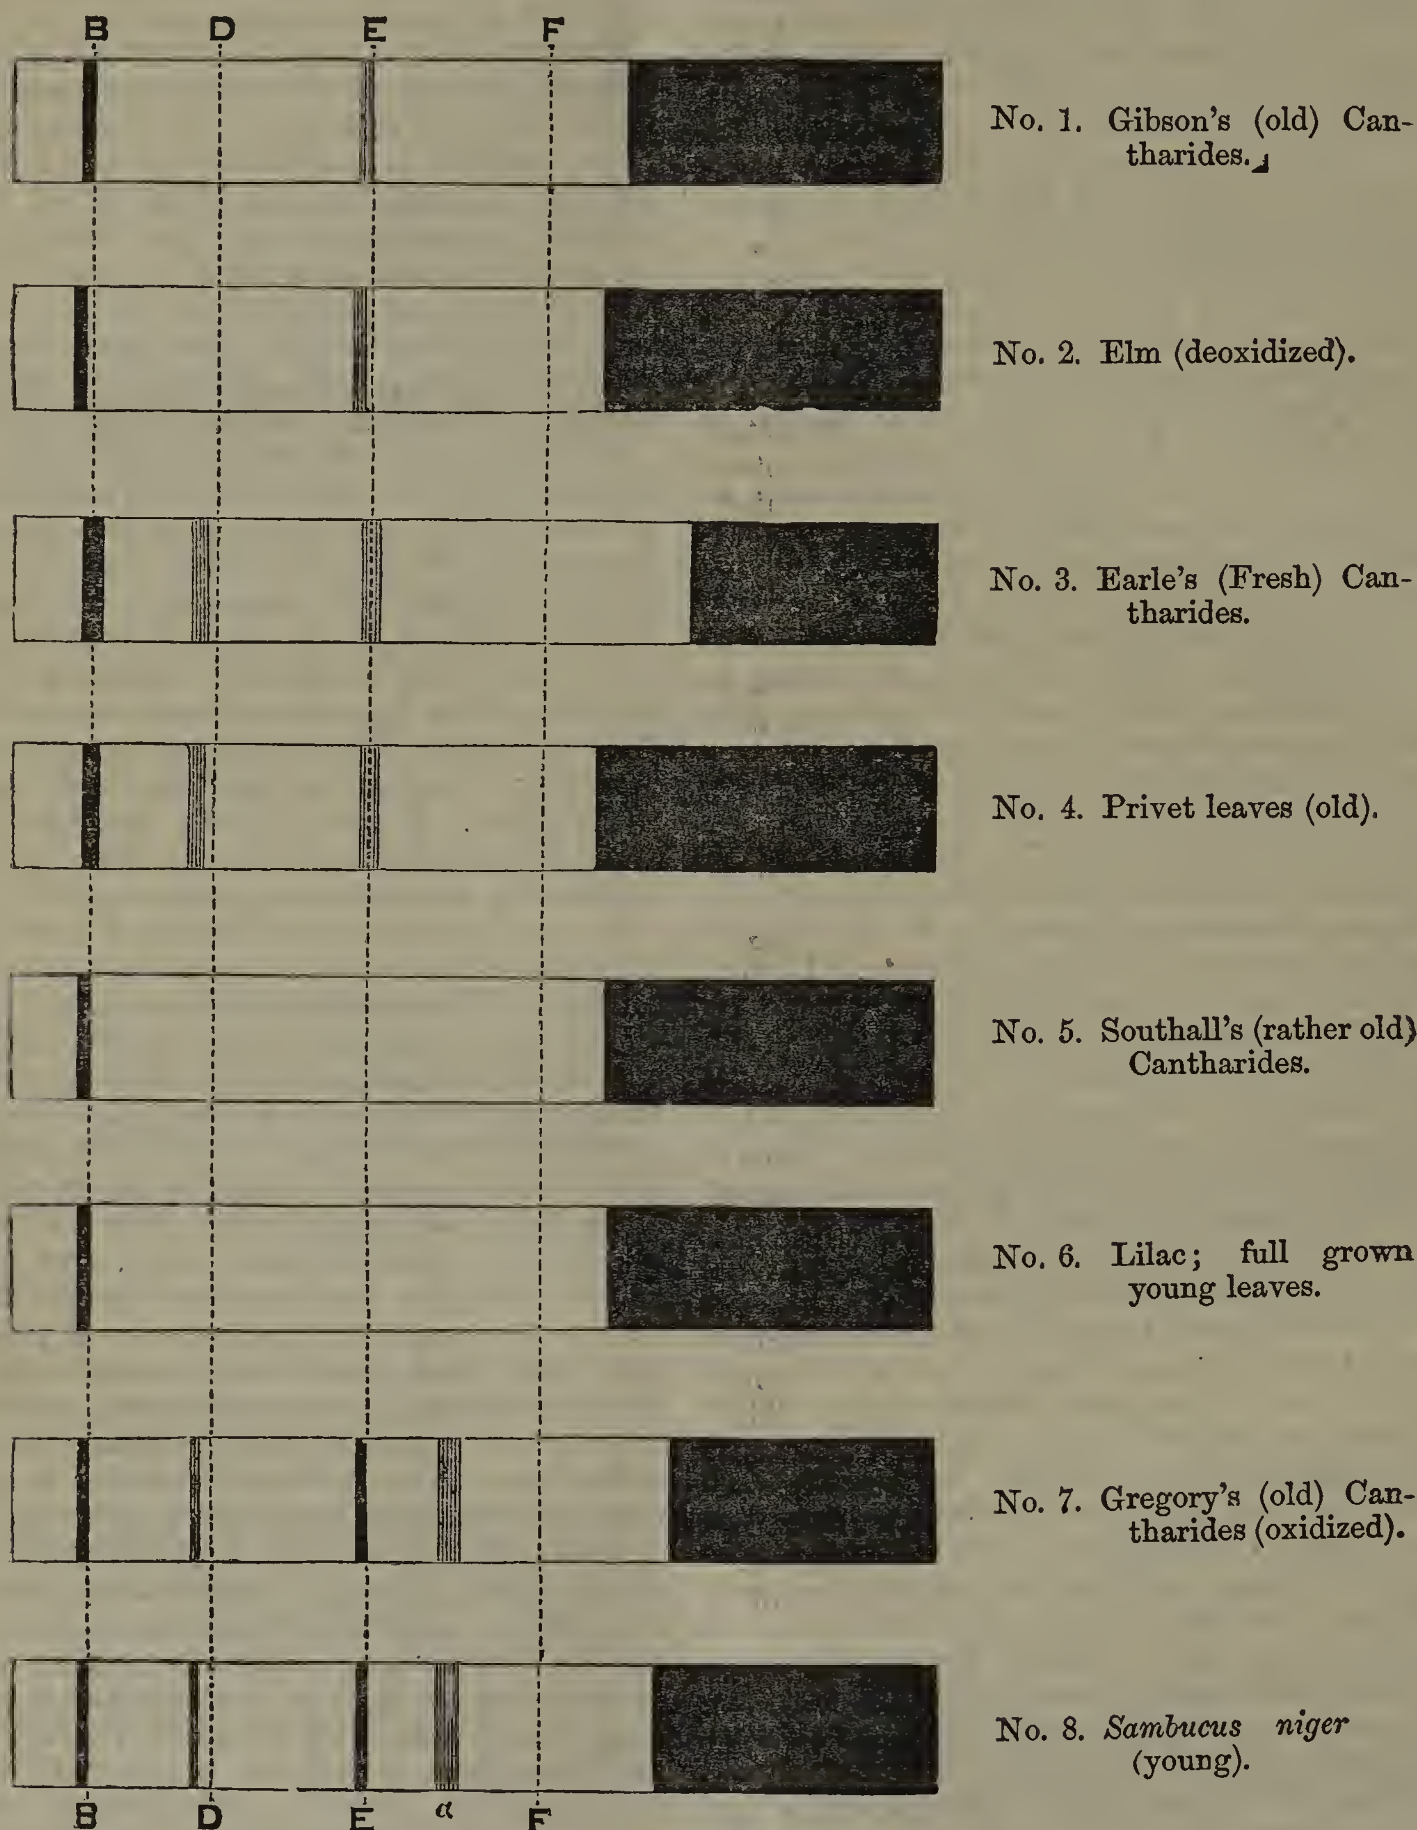
The green portions of the insects were carefully pulverized and macerated in cold ether, alcohol, and bisulphide of carbon for forty-eight hours. The solution was poured off and examined in a narrow test-tube placed before the slit of the instrument. In the other field was placed the interference spectrum, crossed by its twelve black bands, and the position of the absorption bands read off against these. If it be desired to chart them, a piece of paper may be ruled with faint pencil lines to correspond with the bands of the interference spectrum, and the absorption bands easily and exactly drawn to correspond with them. This mode of charting is exceedingly easy and permits of the greatest accuracy. If thought desirable, the position of Fraunhofer's lines may be compared with the interference bands and drawn on the chart to facilitate comparison by those who have not the Sorby plate. Before beginning work, and at frequent intervals, it is desirable to calibrate the instrument by comparing the sodium yellow bright line spectrum (there is only one bright "D" line in these small spectra) with the interference spectrum, to make sure that the two spectra lie truly side by side, otherwise the spectra will be inaccurately charted. The spectrum given by the simple solution of the colouring matter having been carefully charted, the

* PHARMACEUTICAL JOURNAL, 3rd Ser., Vol. III. p. 681.

* A moment's reflection, of course, leads one to see the fallacy of this. The sun shines as white light through the thickest plate-glass window equally with the thinnest of crown. Those who desire to pursue the subject may refer to Ganot's 'Physics' or Deschanel's 'Natural Philosophy.'

effect of certain reagents is tried, and if any effect upon the spectrum is produced, the spectrum is charted as before.

Thus, the normal spectrum of a certain specimen of cantharides is that charted in No. 3. The addition of hydrochloric acid removes the band from the orange and lowers the absorption of the violet. Protosulphate of iron restores the violet absorption but does not restore the band. The alcohol solution of twenty-eight hours' maceration does not give the band in the orange, but in forty-eight hours more this band is visible. If metallic sodium be added to the ethereal solution as in No. 3, and water added when the violent action of the metal has ceased, the water carries down all the colouring matter, but yields it again on the addition of any oxidizing agent. Caustic potash added to the alcoholic solution removes the band by continuing the absorption to the red end (that is, the



absorption of the extreme red is general), and intensifies the absorption of the violet. After having carefully examined the solutions, in this and many other methods giving more or less negative results, my attention was turned to the chlorophylls of the various plants on which the insects were likely to have fed, with a view to ascertaining the absolute identity of the chlorophyll of the plants with the chlorophyll-like green substance of the cantharides. This was a more difficult matter than would at first appear, because newly gathered and young leaves, such as one would gather now, give a very different spectrum from that of old leaves, especially if these latter be kept long and become thoroughly dried.

There is, for example, one notable reaction of young leaves which has not, so far as I know, been published. It is this: If an ethereal solution of the chlorophyll of, say, a young lilac leaf be acted upon by sodium or potassium in small quantities, and water added when the action of the metal has nearly subsided, the water will carry down a substance canary-amber by transmitted light and roseate-hued amber by reflected light, insoluble in ether but soluble in water, and giving only general absorption of the blue and violet, with enfeeblement of the green and extreme red, and a small quantity of a rose-coloured fluid, partially soluble in water and soluble in alcohol.

But with care it is possible to ascertain what are the probable changes that the colouring-matter of the cantharides will have undergone by taking note of the age of the specimen and its condition, and we may then submit the chlorophyll to similar conditions. Such has been the course followed in my investigation, and the charts illustrating this paper will show that the result is, that there is little room for doubt that the green colouring-matter of cantharides is chlorophyll, and derived from the food on which the insects feed. This is confirmed by the fact, that whilst the wing-cases contain only small quantities of it, the thorax and contents of the stomach contain considerable quantities, and that the latter contain also a substance soluble in water, which gives a spectrum in all cases similar to that given by a product of the chlorophyll that agrees with the green colouring-matter of the particular insect.

I have extended the inquiry to specimens of insects procured from different quarters, and, as will be seen from the spectra, they evidently have been gathered from off different feeding-grounds; and although the creatures may have been dead (like one of my specimens) these ten years, yet it is possible to tell off what plant they had lately dined.

Spectrum No. 1 is that described in my last paper, and is the one given by the ethereal solution. The cantharides were old and full of mites, having been kept as specimens by my friend Mr. C. P. Gibson, on account of their large size. Their spectrum does not quite agree with the normal spectrum of any leaf likely to be involved, but does agree with a deoxidized solution of the chlorophyll of young elm leaves; and the behaviour of the two solutions under the action of the different reagents runs very closely on all fours. No. 2 represents the elm-leaf spectrum. No. 3 is the normal spectrum of an ethereal solution made from some very fine and fresh specimens kindly given me by my friend Mr. Francis Earle. These cantharides give a band in the yellow and less absorption of the violet. The spectrum is precisely similar to that of old privet leaves allowed to macerate forty-eight hours in cold ether. In six hours each solution gives a single band in the red, and the alcoholic solutions equally agree.

If the alcoholic solutions be treated with liquor potassæ and agitated with carbon disulphide, the upper stratum of each is yellow amber and fluorescent. The ethereal solutions treated with sodium or liquor potassæ and water also agree, and each gives a spectrum agreeing with the aqueous solution of the stomach contents. The privet spectrum is shown in No. 4.

No. 5 represents the spectrum given by some small flies obtained from one of Messrs. Southall and Dymond's specimen materia medica chests, by the kindness of a medical friend. The spectrum is exceedingly simple, and agrees with that given by the chlorophyll of full grown young lilac leaves.

No. 7 is from the solution of some cantharides obtained in Hull. They were old, but in good preservation, and fine flies. The spectrum runs on all fours with that of elder leaves. The spectra given are from the ethereal solutions of the cantharides, allowed to remain in contact with chlorate of potash for some hours. The effect of this reagent is to partially remove the absorption from the violet end of the spectrum, leaving a broad feeble band in the blue, and is due to slow oxidation, and may be much more rapidly produced by passing nascent oxygen through the solution. The elder spectrum is from young leaves, and is the normal spectrum.

Other specimens of cantharides examined have fallen under one or other of these now described. I have probably said enough to show that the spectroscope does enable us to tell with tolerable certainty from what feeding-grounds the creatures were gathered and the source of a part of their colour.

NOTES ON THE MEDICINAL PLANTS OF THE RUTACEÆ.

BY JOHN R. JACKSON, A.L.S.,

Curator of the Museums, Kew.

The Natural Order *Rutaceæ*, as at present constituted—that is, including as tribes such groups as *Zanthoxyleæ* and *Aurantieæ*, which by former botanists have been dignified as Natural Orders—includes a great number of medicinal and economic plants; for besides such well-known articles as rue, buchu or barosma leaves, and cusparia bark, many others of less repute are brought together. We purpose to refer to those which, though being used by the natives of the countries in which they grow, are seldom seen except in museum collections in this country, and some not even there. In the tribe *Cusparieæ*, besides the genus *Galipea*, which is, of course, well-known as the source of cusparia bark, occurs *Ticorea*, two species of which are medicinal in Brazil. *T. febrifuga*, St. Hil., a tree of about twenty feet, has a very bitter and astringent bark, and is used as a substitute for cinchona in intermittent fevers. In the province of Minas Geraes it is known as *Quina* or *Folhas brancas*. The leaves of *T. jasminiflora*, St. Hil., also a tree about twenty feet high, growing in the same country, are boiled by the natives for the sake of the juice, which they value as a medicine. *Peganum Harmala*, L., is a powerfully disagreeable-smelling herbaceous plant, common in Southern Europe, Asia Minor, and throughout Scinde and the Punjaub. In Turkey the seeds are used as a vermifuge, and in the Crimea the Tartars collect them for the same purpose. In the Pharmacopœia of India it is stated that "these seeds have long held a place in Eastern materia medica as a stimulant, emmenagogue, and anthelmintic. Mild narcotic properties have also been assigned to them, and, according to Kæmpfer, delirium characterized by cheerfulness follows their use in some cases. Further investigations as to the properties of these seeds are desirable."

The European dittany (*Dictamnus albus*, L.), a plant sometimes cultivated in gardens for the sake of its handsome flowers and fragrant leaves, is well known for the abundance of volatile oil or resinous matter, which is secreted in such large quantities that the plant not only ignites on the approach of a lighted candle, but the air surrounding the plant becomes itself inflammable in hot weather. The root is resinous, bitter, tonic, and stimulating. *Monnieria* *trifolia*, L., a shrubby plant of Guiana and Brazil, has an aromatic and acrid root, much prized by the natives as a diaphoretic, diuretic, and alexipharmic. The leaves of species of *Adenandra*, a South African genus of plants, having the habit of the common rue, are used at the Cape for the same purposes as those of *Diosma*, while in Australia the leaves of some of the species of *Correa* are used as tea. They are handsome, shrubby plants, and are in cultivation in greenhouses in this country.

The genus *Zanthoxylum*, the type of the tribe *Zanthoxyleæ*, has a wide geographical range, and a variety of applications. In India the fruits of *Z. alatum*, Roxb., *Z. hastile*, Wall., and *Z. Budrunga*, DC., are all articles of the native materia medica. They are aromatic and pungent, and are said to possess stomachic and carminative properties. *Z. Rhetsa*, DC., a large spreading tree, growing on the mountainous parts of the East Indian coast, has its unripe capsules and small berries of a gratefully aromatic taste, somewhat like the skin of a fresh orange, the ripe seeds have a pungency somewhat like pepper, and the inner bark has an acid bitter taste. The name *Rhetsa* is said to signify in the Telinga language a committee, and alludes to the fact, that under the shade of this tree the hill people assemble to deliver discourses and to consider and discuss matters of public concern. In China the root of *Z. nitidum*, DC., is aromatic, and is used as a sudorific, emmenagogue, and febrifuge, the leaves also are used as a condiment on account of the volatile oil they contain. The fruits of *Z. piperitum*, DC., are known as Japan pepper, they are of an agreeable aromatic flavour. In the West Indies the barks of *Z. ternata*, Desv., and *Z. Clava-Herculis*, L., are regarded as antisyphilitic, and the bitter astringent leaves are used as a vulnerary. *Z. fraxineum*, Willd., is known in America as the prickly ash or toothache bush, from its reputation as a masticatory in curing toothache. The bark is officinal in the United States, and as seen in the shops is in small quills varying from a line or two to about an inch in diameter. It is of a darkish grey colour with occasional lighter patches and covered with fine transverse cracks, and in the younger pieces the prickles are sometimes remaining. It is light, brittle, and has at first a somewhat sweetish aromatic taste, which changes to a bitter acrid flavour; this acridity is extracted either by boiling water or alcohol. The bark is stimulating, producing a sense of heat in the stomach. It is also said to be a "powerful sudorific and diaphoretic, and to have been used successfully in paralysis of the muscles of the mouth." In chronic rheumatism it is very highly extolled, and is given in the form of a powder, a dose being from ten grains to half a drachm repeated three or four times a day. A fluid extract has likewise been prepared and administered in doses of from fifteen to forty-five drops. A favourite form of administration, however, is a decoction prepared by boiling an ounce of the bark in three pints of water until it is reduced to a quart, a pint of which should be taken in divided doses during the twenty-four hours. A tincture made from the berries is sometimes employed as a carminative in doses of ten to thirty drops, which can be increased if the stimulating effects are desired.

In New South Wales, *Geijera salicifolia*, Schott, a moderate-sized tree, is known as the "Balsam Capivi Tree," from the strong flavour of that balsam which pervades the bark. I am not aware whether or not it is used in medicine, but a good ink is said to be prepared from the bark. *Esenbeckia febrifuga*, Mart., or *Evodia febrifuga*, St. Hil., a native of the forests of Brazil, is remarkable for its extremely bitter bark, which is used as a tonic and febrifuge; while *Toddalia aculeata*, Pers., a moderate-sized shrub, widely dispersed through Tropical Asia, has considerable reputation as a stomachic and febrifuge, all parts of the plant being used. In India the bark of the root is officinal, and is used as an aromatic tonic and stimulant "in constitutional debility and in convalescence after febrile and other exhausting diseases." It is given in the forms both of tincture and infusion. The following notes on the value of *Toddalia* root-bark are from the 'Appendix to the Indian Pharmacopœia:'—"Strong testimony to the value of *Toddalia* root is borne by Dr. G. Bidie, who states that though he has not employed it as a febrifuge, he can speak with confidence as to its great value as a stimulant and tonic. Every part of the plant, he remarks, has a pungent, bitter taste and a pleasant aroma, but these qualities are most marked in the root. The dried root-bark is of a yellowish-brown colour, and retains its pungency and bitterness for a long time. The whole plant possesses active stimulant, carminative, and tonic properties; and he adds that he knows of no single remedy in which all these three qualities are so happily combined. This article possesses additional interest from having been identified by M. Guibourt with *Lopez root*, which formerly enjoyed considerable repute in Europe as a remedy for diarrhœa. Mr. Daniel Hanbury, from examination of genuine specimens of the root, confirms M. Guibourt's views." The natives also prepare a liniment by frying the root and green fruits in oil, which they consider good for rheumatism. The fresh leaves are likewise eaten raw in stomach complaints, and the ripe pungent berries make capital pickles. The bark, root, and leaves of *Murraya Königii*, L., a small East Indian tree, are used in native practice as a tonic and stomachic: the young leaves of this species, as well as those of *M. exotica*, L., are used to flavour curries. In Mauritius the latter are said to impart a flavour superior to that of bay-leaf, while in India they further have the reputation of aiding digestion.

The wood-apple tree, or elephant apple of India, *Feronia elephantum*, is the only species of the genus, and is common in India, Ceylon, and Java. The fruit is hard and woody, globose, about the size of a large orange; the pulp is used in India in cases of dysentery and diarrhœa. The leaves smell like anise, and are used in native medicine as a stomachic and carminative. A decoction of the unripe fruit is said to act as a powerful astringent, and the ripe fruit as an antiscorbutic. A gummy substance flows from the stem when wounded, which is used by painters for mixing with colours, also in dyeing and for making ink and varnish, as well as by bricklayers in preparing a fine kind of whitewash. This gum occurs in irregular, reddish-brown, semi-transparent tears; powdered and mixed with honey, it is used in dysentery and diarrhœa. The Bael fruit (*Ægle Marmelos*, Corr.) has been brought into notice in this country recently; it is imported in slices, dried, or in quarters or pieces with the rind still attached. The entire fruit is round, somewhat resembling a large orange. It is officinal in both the British and Indian Pharmacopœias, and is used in India "in atonic diarrhœa and dysentery; and in the advanced stages of those diseases, in irregularity of the bowels, and in habitual constipation, it is a remedy of much value." It is administered in the forms of a mixture and an extract: those prepared from the dried fruit, as seen in this country, are said to possess much less medicinal power than those prepared in India from fresh fruit. It will be needless to recapitulate all that has been said and written on the medicinal value of this fruit, as they will be fresh in the minds of the readers of the Journal, many of whom have likewise probably tested the article itself.

In concluding these notes it only remains to mention two or three plants, the properties of which are little known, but which are nevertheless reputed to be useful in their native countries; thus, for instance, *Hortia brasiliana*, Vand., is said to possess febrifugal properties and to be used in Brazil. The leaves and shoots of *Ptelea trifoliata*, L., a North American shrub, are used in infusion as an anthelmintic, and the aromatic fruits are said to be a good substitute for hops. *Casimiroa edulis*, a tree of Mexico, has a bitter bark, which, together with the leaves and seeds, are used as a medicine when burnt and reduced to a powder.

TOXIC EFFECTS OF TETRAMETHYLAMMONIUM AND OF TETRAMYLAMMONIUM.*

BY M. RABUTEAU.

In the course of some uncompleted researches upon the amines, or compound ammonias, the author made the following observations, which he deemed of sufficient importance to lay before the French Academy at once. Whilst the most diverse salts of the primary, secondary, and tertiary amines, from the methylamines to amiline and the phenylamines, are comparable in their physiological effects to other ammoniacal compounds, and would be, according to the author's experiments, muscular poisons in large doses, the salts in which all the hydrogen of the ammonium is replaced by alcohol radicals, such as the iodides of tetramethylammonium and tetramylammonium, appear to be poisons of the nerves of movement, completely analogous in their effects to those of curara. The following are the experiments upon which he bases his proposition :—

Iodide of Tetramethylammonium.—After having injected into the veins of a dog two grams of hydrochlorate of trimethylamine (chloride of trimethylammonium) dissolved in forty grams of water, without observing any other effect than a slight slackening of the circulation and lowering of the animal temperature, it was intended to inject into another dog the same quantity of iodide of tetramethylammonium. (This salt is but slightly soluble in water, which takes up scarcely one-twentieth of its weight at ordinary temperatures.) Scarcely, however, had one-fourth of the quantity entered the circulation, when the animal was greatly affected; the respiratory movements ceased nearly immediately. The heart, which was accelerated at first, afterwards slackened, not beating more than once in five or six seconds, till it stopped completely at the end of four or five minutes; consequently, some time after all respiratory movement had ceased and the animal had been reduced to an inert mass. It proved, therefore, to be a substance infinitely more active than the primary, secondary, or tertiary amines, which operated rather by paralysing the motor nerves than by paralysing, as do these latter salts, the muscular system, since the heart did not stop till after the suspension of the respiration.

Twenty-five centigrams of iodide of tetramethylammonium were injected with a Pravaz syringe in five places under the skin of the chest of a large dog. Immediately afterwards the cardiac beats were accelerated, salivation took place, the pupils were enormously dilated, respiration became difficult and painful. A thermometer which, introduced into the rectum, previously marked 39·2° C., rose quickly to 39·4° C. The animal was unbound, but could not move itself; it made vain attempts to drag along the ground; the posterior members were affected more than the anterior; it retained its intelligence, and was sensible to prickings of the parts least affected. The animal recovered at the end of about half an hour, from which it would appear the poison is quickly eliminated.

The symptoms were exactly similar to those produced by curara. These experiments were supplemented by others on frogs, which are described by the author, and which confirmed his opinion as to iodide of tetramethylammonium being an energetic poison, paralysing the extremities of the motor nerves, but not affecting sensibility or muscular contractility.

Iodide of Tetramylammonium.—This compound, which is pretty soluble in boiling water, is nearly insoluble in cold; so that it is necessary to inject into frogs at least twenty drops of a saturated aqueous solution at ordinary temperature, to cause death, which follows much more slowly than under the influence of but three or four drops of a saturated solution of tetramethylammonium at the same temperature. The symptoms observed were of the same order as those previously noticed, showing that the amylic compound is a poison of the same nature as the methylic compound. So that the salts of tetramylammonium and of tetramethylammonium, such as their iodides,—

$$\left.\begin{matrix}CH_3\\CH_3\\CH_3\\CH_3\end{matrix}\right\}NI \quad \text{and} \quad \left.\begin{matrix}C_5H_{11}\\C_5H_{11}\\C_5H_{11}\\C_5H_{11}\end{matrix}\right\}NI$$

are active poisons, whilst the hydrochlorate of trimethylamine—

$$\left.\begin{matrix}CH_3\\CH_3\\CH_3\\H\end{matrix}\right\}NCl$$

is not. The most striking point in these results is that the substitution of CH_3 for all the hydrogen of ammonium transforms a slightly active compound into an extremely poisonous one, operating similarly to curara. However, it should be remembered that the compounds obtained by treating the alkaloids with the hydriodic ethers produce analogous effects; thus iodide of methylstrychnium acts by paralysing the motor nerves.

Such are the results of the author's first researches, and if, as he thinks probable, the salts of tetramethylammonium, tetrapropylammonium, tetrabutylammonium, and those which correspond to the other alcohols, produce similar effects, he will have pointed out a new and very numerous group of curaric poisons.

* 'Comptes Rendus,' vol. lxxvi. p. 887.

THE COMPARATIVE THERAPEUTICAL VALUE OF SALTS OF PROTOXIDE AND SESQUIOXIDE OF IRON, AND ON A NEW SERIES OF TASTELESS IRON COMBINATIONS.*

BY J. L. A. CREUSE.

It is not my intention here to treat on the medical properties and uses of ferruginous compounds as a class; this has been done before me by more competent persons. My purpose is only to discuss the relative physiological and

* Read at the second annual meeting and published in the annual report of the Alumni Association of the College of Pharmacy of the city of New York.—*Amer. Journ. Pharm.*

chemical properties of the various iron combinations and describe a new series of tasteless ferruginous compounds.

Iron has been used in medicine, it may be said, from time immemorial. Metallic iron, green copperas, iron rust, carbonate of iron, bole armenia, etc., are mentioned in the oldest authors on medicine and pharmacy. It seems also that in former times little importance was attached to the peculiar form in which iron was administered. Some fifty or sixty years ago, however, a decided preference began to be shown for metallic iron, finely comminuted, and for the protosalts of iron. It was thought, then, that the easy solubility of those preparations in the stomach was a great advantage, and that theory gave rise to a number of officinal remedies like iron by hydrogen, Vallet's mass, protoiodide of iron, etc., etc., well known to all pharmacists.

But of late years, especially since the discovery of the citro-ammonical pyrophosphate of iron, by Robiquet, my old master, salts of sesquioxide of iron have been steadily growing into favour. It has been argued, with reason, that, since iron in human economy is invariably found in the shape of sesquisalts, such compounds should be preferred to all others whenever iron is indicated. I may add, also, that it is always in the form of sesquisalts that iron exists in all vegetable and animal substances which compose human food, and that metallic iron or its protosalts cannot be mixed with the simplest aliments without completely decomposing them. Protoxide of iron is as unyielding as it is unstable: when you have combined it with strong acids you can go no further with its salts: you can do nothing with them, not even an alum. Sesquioxide of iron, on the contrary, is a perfect Proteus; sometimes a base, sometimes an acid, it is always ready to enter some combination or other on the slightest provocation.

In a paper published some time ago I demonstrated that nearly all the insoluble sesquisalts of iron could be combined with the alkaline citrates, forming soluble and tasteless compounds, to which I gave the name of quadruple citrates.

Since then, further experiments have shown me that other vegetable salts, besides the citrates, possessed also the same property, and that not only the insoluble but also the soluble sesquisalts of iron could form similar combinations.

In other words, I may lay down this rule:—*All the salts of sesquioxide of iron, without exception, soluble or insoluble, form combinations with all the alkaline citrates, tartrates, and oxalates.* Such combinations are invariably green, whatever may be the colour of the iron salt; they are all soluble in water, nearly insoluble in alcohol; they are all free from ferruginous taste, all perfectly stable, and miscible with preparations of Peruvian bark without decomposition. In all of them the presence of iron is so disguised as not to be detected by chemical reagents, unless after the addition of strong acids or sulphuretted hydrogen, both of which destroy the combination.

In other papers I have described the soluble compounds obtained in combining the phosphate, hypophosphate, valerianate, and arseniate of iron with the alkaline citrates. In this I will merely describe the tasteless combinations of the alkaline citrates with iodide, chloride, sulphate, and nitrate of iron.

*Tasteless Iodide of Iron.**

This is, no doubt, the most important of the whole series, both therapeutically and chemically; therapeutically, because iodide of iron is admitted to be the best of all iron combinations; chemically, because all the reactions happening during its preparation are so remarkable and so easy to follow with accuracy as to be likely to give a key to the real composition of the rest of the series—a result which can hardly be obtained with any of the other similar combinations.

The salt is obtained in the following manner: 126·3 grs. (1 eq.) of iodine are first combined with metallic iron, in the usual way to obtain the protoiodide of iron; this is filtered, and 63 grs. ($\frac{1}{2}$ eq.) of iodine are dissolved into it. Then, a solution of 201 grs. (1 eq.) of citric acid saturated with a fixed alkali, such as potassa, for instance, is added by small portions to the sesqui-iodide of iron. The ferruginous solution which is at first of a ruby red colour and has a strong smell of iodine, becomes lighter by degrees, till, as the last drop of citrate is added, it takes a bright apple green colour; at the same time, all smell of iodine, all taste of iron have disappeared; the solution strikes no colour on starch paper, and gives no precipitate with either tannin or ferrocyanide of potassium. It may be then evaporated at a low heat, with gentle stirring, to dryness, when it gives a green mass formed of very small acicular crystals, looking somewhat like cauliflowers. It is tasteless, perfectly stable, unless exposed to direct sunlight, and may be exhibited, in the shape of syrup, elixir, solution, tincture, pills, etc. The dose of it need not be more than one-half of that of the protoiodide of iron, as it is absorbed much more readily.

Chemically, this iodide of iron seems to be a combination in which sesqui-iodide of iron plays the part of an acid and the alkaline citrate that of a base; but the subject requires further investigations before it can be decided with complete certitude.

The other alkaline citrates may be used instead of citrate of potassa; similar combinations may also be obtained with the alkaline tartrates, oxalates, and malates, but none are so tasteless, and especially none so *stable* as the one just mentioned.

I must add a few words on this subject which is a most important one, for the same remarks may be applied to all the other analogous iron combinations, pyrophosphate included. On reading the above process, some may think that, after all, the product is only a mixture of citrate of iron, iodide and iodate of potassium. But, aside of the fact that the different ingredients are not in proportion to form such combinations, chemical tests show that such is not the case. Citrate of iron, for instance, is of a ruby red colour and turns immediately ink black on the addition of tannin, while tasteless iodide of iron is bright green and is not coloured black by tannin, but only turned to a light purple hue, after some time. Iodide of potassium dissolves iodine freely; the new salt dissolves it but sparingly, unless when in a concentrated solution. Iodate of potassium is coloured red by solutions of morphia; no colouration is produced by them in solutions of the new salt. This last reaction is important, as iodate of potassium is deemed poisonous by some physicians.

Tasteless Chloride of Iron.

Sesquichloride of iron, the salt which enters into the preparation generally known as tincture of muriate of iron, has the property of forming combinations precisely similar to those of the sesqui-iodide. If an alkaline citrate be added to a solution of sesquichloride of iron, in the proportion of two equivalents of the former to each three equivalents of chlorine, a new salt will be obtained of a green colour, quite tasteless, and miscible with vegetable preparations such as infusions of bark, quassia, etc., without change or discolouration.

This tasteless muriate of iron may be dissolved in diluted alcohol in the proportion required by the Pharmacopœia of the United States; it forms, then, a tincture of muriate of iron, which is as superior to the old one as a civilized man is above a barbarian. Its effects, I know, from experience, are fully equal to those of the officinal tincture.

I cannot give the exact weight of citric acid required for a given quantity of the officinal tincture of muriate of iron, on account of the great variation in the strength and acidity of that preparation, but, on an average, 120 to 140 grains of citric acid saturated with either soda or ammonia

* The tasteless iodide of iron has been patented, but with no intention of interfering with any druggist who wishes to make it himself for his own dispensing.

will answer for one fluid ounce of the tincture. This is to be added to the iron solution before the alcohol, and the alcoholic strength of the tincture, when finished, must not be more than 30 or 40 p. c. instead of 70 p. c., as usual.

The sesquisulphate and the sesquinitrate of iron form also combinations precisely alike to those described above, but present no special interest to be entitled to more than a simple mention.

All these combinations, however, lack the property of coagulating the blood, and for that reason cannot be used as styptics in cases of hemorrhagia, etc. The old officinal preparations will have to be retained for external use, the only thing they are fit for in a civilized community.

THE OLIVE OIL TRADE.

The trade in olive oil in this country has been an interesting one, regarding it in its past and present characteristics. If we look at the statistics of the importation of this article in past years as compared with present, we are enabled to perceive the augmentation which has occurred in the trade, and the rapid progress it has made. We have some interesting figures before us bearing upon this subject, showing the amount of olive oil imported into this country during the years 1840–1870—that is to say, during three very important decades in our commercial history. As these figures have been prepared under official authority, their correctness cannot be brought into question. Commencing with the year 1840—say thirty years ago—we find that olive oil was imported into the United Kingdom to the extent of 8783 tuns, while in 1842 the amount had increased to 14,095 tuns. After this we note considerable fluctuations in the import, the amount having dwindled down in 1846 to 8534 tuns. In 1850, however, it increased, being in that year 20,784 tuns, thus showing a very considerable and rapid augmentation. In the few following years again we observe that the imports languished, but in 1858 they amounted to 25,121, at which amount they remained with more or less fluctuation for some time. The next important increase we find was in the year 1865, when the imports amounted to 32,005 tuns—the largest amount imported into this country during the period under notice. In subsequent years the imports have somewhat declined, as compared with 1865, according to the official statistics, although we have every evidence to show that the trade has been of late both brisk and healthy. Our readers will bear us out in this assertion.

Having thus considered the imports of olive oil as regards actual quantity, it will be next interesting to see what is their actual sterling value. Going back to the year 1856 we find that the computed real value of the olive oil imported into the United Kingdom amounted to the large sum of £1,124,755, while in 1865 it was no less than £1,684,852. Our readers will perceive from these statistics how important this branch of our import trade is, considered in regard to its actual sterling value, although it may be noted that during the few years subsequently to 1865, the amount has somewhat decreased. In 1870 it was £1,185,950. Chemists and druggists will assuredly view with interest the fact that merely one article of their stock-in-trade—an important article certainly, but not prominently so—is imported into this country annually to the extent of over a million pounds sterling. This is one of those satisfactory commercial facts which speaks for itself, and needs no comment from us.

The exports of olive oil from this country next invite attention. Going back to the year 1840 we note that these exports only amounted to the insignificant total of 517 tuns, which in the year 1845 had further decreased to the amount of 303 tuns. Subsequently, however, the exports seem to have increased, and were in the year 1854 1749 tuns, thus manifesting an increase of an important character. In the following year there was another considerable increase, the amount of the exports being 2203 tuns, after which they dwindled down again in 1858 to 587 tuns. From this time we observe continual fluctuations in the amount exported, sometimes the total showing a decrease, sometimes an increase, until, in 1870, we find the total exports reach the comparatively satisfactory total of 2168 tuns. With respect to the fluctuations in the trade of olive oil, interesting evidence is furnished by these statistics giving the exports of the article. Thus, while in the year 1845 the exports only amounted to 303 tuns, in the year 1870 they amounted to 2168 tuns—certainly a very large augmentation, and one which is pertinent in the way of comparison. It shows how much this branch of the trade is liable to fluctuation; how the exports are large one year and small another, and how it is not always easy to trace reliable causes of this commercial vicissitude.

Our readers will naturally feel an interest in the average prices of olive oil in past and present years. According to the official tables giving these prices, we find that in the year 1856, this oil, imported from Italy, fetched £51 10*s.* per tun, whereas the price of that from Morocco was £48 10*s.* In 1860 these prices had increased, the Italian oil being quoted at £59 7*s.* 6*d.* per tun, and the Morocco £55 11*s.*; and it will be observed that the latter had increased in value comparatively with the former. In 1865 the prices decreased, being as follows:—olive oil from Italy, £52 17*s.* 9d.; from Morocco, £49 6*s.* 8*d.* per tun. In the following year, however, the prices increased again to the extent almost of £5 per tun, which is to be accounted for by reason of the decreased imports. In 1868 the prices reached a very high point, viz. £68 3*s.* per tun for the Italian oil, and £63 for the Morocco; and we do not find these prices equalled in any other year during the period under notice. In the year following the prices diminished as much as £15 per tun—a not unimportant fact.

AN AIR BATTERY.*

BY J. H. GLADSTONE, PH.D., F.R.S., AND ALFRED TRIBE, F.C.S.

The authors describe a galvanic battery which is founded on a reaction that they brought under the notice of the Royal Society last spring.† They then showed that if pieces of copper and silver in contact are immersed in a solution of nitrate of copper in the presence of oxygen, a decomposition of the salt ensues, with the formation of cuprous oxide on the silver and a corresponding solution of the copper, while a galvanic current passes through the liquid from copper to silver. They stated that this was only one of a large class of similar reactions, and that it seemed desirable to examine more fully the history and the capabilities of the electrical power thus produced.

It was previously ascertained that the combination of the oxygen takes place only in the neighbourhood of the silver; and the following formulæ may serve to render the chemical change and transference more intelligible:—

Before contact—

$$m\mathrm{Ag} + \mathrm{O} + \mathrm{Cu}2\mathrm{NO}_3 + \mathrm{Cu}2\mathrm{NO}_3 + n\mathrm{Cu};$$

after contact—

$$m\mathrm{Ag} + \mathrm{Cu}_2\mathrm{O} + \mathrm{Cu}2\mathrm{NO}_3 + \mathrm{Cu}2\mathrm{NO}_3 + (n-2)\mathrm{Cu}.$$

This action is evidently a continuous one until either the oxygen or the copper fails. The oxygen of the atmosphere is practically unlimited in amount, but there is a difficulty in bringing any large quantity of it into contact at once with the silver and the dissolved salt.

To facilitate this, the silver plate should have a horizontal position just under the surface of the liquid in the cell; and, in fact, the authors convert it into a small silver tray, full of crystals of the same metal which rise in projections to the very surface. The copper plate lies

* Abstract of a paper read before the Royal Society, April 3 ('Transactions,' vol. xxi. p. 247).

† Proc. Roy. Soc., April, 1872, vol. xx. p. 290.

horizontally under it, separated, if need be, by a piece of muslin, and connection is made by a wire as usual. The vertical part of the copper plate, from a little above the liquid to the bend, should be varnished; otherwise solution principally takes place there, which causes the horizontal part of the plate to drop off. Holes are made in the silver tray with the view of shortening the communication between the air-surface and the copper plate and of facilitating the movements of the salt in solution. The solution itself may be contained in a shallow trough or saucer.

That dissolved oxygen is absolutely necessary for this chemical change had been already shown; but it was interesting to measure by a galvanometer the difference of the currents obtained by means of an ordinary, that is aërated, solution of copper nitrate, and one from which the air had been separated to the greatest possible extent. A Thomson's galvanometer was employed, which had a resistance of 2631·5 units at 18·3° C. Two cells were prepared with vertical plates and alike in all respects, except that the one contained an ordinary 6 per cent. solution of copper nitrate, and the other a similar solution which had been deoxygenized. Another experiment was made with a different pair of cells and an 11 per cent. solution. It was necessary to use the 1·99 shunt; and the following were the amounts of deflection:—

Time after immersion.	Expt. I.		Expt. II.	
	Oxygenized.	Deoxygenized.	Oxygenized.	Deoxygenized.
1 minute	78	14	130	11
4 minutes	72	9	90	8
12 „	68	6	75	6
49 „	—	—	58	3·5

The contrast is evident. That the deoxygenized solution does give a deflection at all is due partly to the difficulty of excluding air, and partly, perhaps, at first to the oxygen condensed on the surface of the silver plate. The effect due to the water itself is inappreciable. From the nature of the reaction it might be expected that the current would gradually diminish on account of the using up of the dissolved oxygen in the neighbourhood of the silver; such a diminution always does take place, at least after the first few vibrations of the needle. As might be expected, too, when the amount of action has run down considerably, the mere moving of the liquid so as to bring fresh parts of the solution against the silver augments the currents.

The same resulted from stirring up the crystals of silver in the tray so as to expose new surfaces. If the wire be disconnected for a time so as to allow the oxygen to diffuse itself from other parts of the solution, and connection then made, the current will be found as strong, or nearly so, as before.

A cell with the plates connected by a wire was placed under a bell-jar full of air over mercury. The mercury gradually rose inside, as might be expected from the absorption of the oxygen in the air.

The necessity of oxygen and the avidity with which it is taken up are both illustrated by the following experiment:—Two cells with horizontal plates were prepared alike in every respect, except that the first was filled with a solution simply deprived of oxygen, the second with a solution through which a stream of carbonic acid gas had been passed for some time. The first was placed in the air, the second in a vessel from which the air had been expelled by allowing carbonic acid gas to flow into it for an hour or two.

The deflections obtained were as follows, the 1·999 shunt being used and the temperature being 13·7° C.:—

Time after immersion.	In air.	In CO_2.
1 minute	165	76
5 minutes	135	62
10 „	135	58

As the cell in an atmosphere of carbonic acid gas showed nearly half as much action as that in the air, each cell was short circuited for twenty-three hours, with the expectation that any oxygen in the closed vessel would be used up; and, indeed, the most prominent crystals of silver in the cell in carbonic acid gas became reddened, while a cuprous deposit extended over the whole of the crystals in the other cell. When, however, the short wires were removed and the galvanometer interposed, the cell in the air gave a deflection of 136, practically the same as before, but that in carbonic acid gas, instead of showing a great decrease, rose to 80. It was then found that the vessel containing the latter slowly admitted air; so the contents were swept out by a fresh stream of carbonic acid gas, and it was made properly air-tight. After connection by a short wire for three days the galvanometer indicated a deflection of 20, that of the cell in the air being 110, temperature 10° C. As this showed a very great reduction of the chemical action, carbonic acid gas was again passed through the vessel for an hour or two; and after a connection of two more days the indication of the galvanometer was only 3, while the other cell gave 115, the temperature being now 10·5° C. The action, therefore, was at last reduced almost to nothing; and the original fault in the experiment brought out, perhaps more clearly than would otherwise be seen, how eagerly the solution will absorb even minute quantities of oxygen from the surrounding gas.

An important point to determine was the best strength of the copper nitrate solution. Six per cent. was generally preferred, for two reasons:—first, it gives about the maximum of effect—a solution four times as strong gives less than half the deflection, and a solution only a quarter as strong gives only two-thirds; secondly, a stronger solution than this 6 per cent. is apt to produce a deposit, not of pure cuprous oxide, but of a subnitrate, which was supposed to clog up the silver crystals to a greater extent.

Another point investigated was the best proportion between the areas of the metallic surfaces. Experiments were made with vertical plates, in which the silver was kept at a uniform size and the copper was diminished by covering it more and more with varnish; and another set was made in which the copper remained the same, while the silver plate was reduced.

The results may be thus exhibited:—

Proportion of surfaces.		Deflection.		
Silver.	Copper.	Expt. I.	Expt. II.	Expt. III.
1	0·25	24	23	—
1	0·50	28	27	—
1	0·75	31	30	—
1	1·00	33	32	28
1	1·33	—	—	28
1	2·00	—	—	32
1	4·00	—	—	30

The increase of the copper surface, therefore, has comparatively little effect.

Proportion of surfaces.		Deflection.		
Copper.	Silver.	Expt. I.	Expt. II.	Expt. III.
1	0·25	—	—	7·5
1	0·50	—	—	16
1	0·75	—	—	21
1	1·00	33	32	28
1	1·33	41	40	—
1	2·00	56	54	—
1	4·00	96	92	—

The increase, therefore, of the silver or negative metal causes an almost proportionate increase in the chemical action. This, doubtless, arises from the necessity of oxygen, and explains the value of the large surface exposed by the silver crystals in the tray.

The effect of heat on the action of this cell was examined; it increases the action greatly: thus an arrangement which gave a deflection of 40 at 20° C. gave one of

250 at 50° C.; and the augmentation was observed to be much more rapid in the higher than in the lower portions of this range of temperature.

If the formula given above for the reaction be a true one, it follows that every atom of copper deposited on the silver in the state of suboxide must be compensated by an atom of copper dissolved from the copper plate. This was proved quantitatively. In a cell that had been in action for a week the loss of the copper plate was 0·391 gram, while the suboxide deposited on the silver was found to be equivalent to 0·398 gram of metallic copper. This deposit of suboxide, though it soon forms apparently a complete covering to the silver, does not greatly diminish the action; it is probably porous, besides being itself a conductor of electricity. In some cases it was deposited in crystals sufficiently large to be seen by the naked eye, shown by a magnifying glass to be regular octahedra. The internal resistance of this battery is small.

The electrolytic power of the current was examined. One cell, the plates of which were about 2 inches in diameter, was found sufficient to decompose such metallic salts as the nitrates of copper, silver, or lead, copper sulphate or stannous chloride, in aqueous solution, when platinum was used for the negative electrode, and for the positive the same metal as existed in the salt experimented on. Six cells were sufficient to decompose dilute sulphuric acid slowly and dilute hydrochloric acid pretty quickly, copper electrodes being employed.

The theoretical interest of this battery lies mainly in the fact that it differs essentially from every other galvanic arrangement, inasmuch as the binary compound in solution is incapable of being decomposed either by the positive metal alone or by the two metals in conjunction; it cannot serve, in fact, as the liquid element of the circuit without the presence of another body ready to combine with one of its constituents when set free. Grove's gas-battery is essentially different if the oxygen and hydrogen condensed on the platinum plates play the part of the two metals; but it closely resembles it if hydrogen acts the part of the positive and platinum that of the negative metal; the dilute sulphuric acid, a hydrogen compound, will then be decomposed on account of the simultaneous presence of the oxygen, which can combine with the liberated hydrogen. Viewed in this manner, Grove's gas-battery is only a special case of the general reaction described in a previous paper; and the formula will be:—Before contact, $m\text{Pt} + \text{O} + \text{H}_2\text{SO}_4 + n\text{H}$; after contact, $m\text{Pt} + \text{H}_2\text{O} + \text{H}_2\text{SO}_4 + (n-2)\text{H}$.

The practical interest of the present arrangement lies in the fact that it is an approximation towards a constant air-battery. Should it ever come into use elsewhere than on the lecture table, it will probably be in the form of a combination of zinc and copper, with an aërated solution of zinc chloride; for that arrangement has an electromotive force six times that of the arrangement more particularly studied, and about three-quarters that of a Daniell's cell. The numbers representing the difference of potential between the two metals, which were actually obtained by means of an electrometer belonging to Sir William Thomson, were—

Silver and copper with deoxygenized copper nitrate	4
Silver and copper with oxygenized copper nitrate	8 to 11
Copper and zinc with chloride of zinc	62
,, ,, water	68
,, ,, Daniell's cell ...	83

Chloride of zinc is preferred to the sulphate, as it offers less internal resistance, and a solution of 20 per cent. is, on the authority of Mr. Herbert MacLeod, recommended as about the best conductor. A single cell of this description is capable of decomposing dilute sulphuric or hydrochloric acid, when copper electrodes are employed. The two metals might be arranged as in a Daniell's battery; the zinc would of course require no amalgamation, and the whole might be left for weeks or months without any attention. The oxide of zinc produced generally falls to the bottom of the vessel, and may be separated whenever it is thought desirable.

The power is thus obtained at a minimum of expense, for the oxygen which combines with the zinc costs nothing. Such a battery would appear to be specially adapted to cases where the galvanic current has to be frequently broken, as in telegraphy; for at each period of rest it renews its strength by the absorption or diffusion of more oxygen from the air.

THE MANUFACTURE OF PEPSIN.*

BY R. ROTHER.

With the important discovery of Mr. E. Scheffer, of Louisville, Ky., a new era was developed in the manufacturing interests of pepsin. The multitude of uncertain and mostly worthless preparations, erroneously called pepsin, have been swept from the market by the *bonâ fide* article, which alone merits the title, and is, in truth, the coveted desideratum, pepsin. This real, active, definite, and always reliable pepsin is most abundantly, easily, and expeditiously obtained by the process of Mr. Scheffer, which consists in precipitating it from its acidulated aqueous solution by saturation with chloride of sodium.

The history of pepsin will record an entire revolution through the agency of this simple method. The commercial interest will suffer a thorough change, as henceforth the exorbitant price of a comparatively worthless substance will be reduced to a very moderate rate, and then purchase a very superior article.

In the preparation of this substance the pharmacist ordinarily imagines an exceedingly unpleasant operation. But the sooner he disabuses his mind of this nauseous idea the greater will be the advantage to him. The process, however, is mere pastime, when compared to many less dreaded duties comprised in the routine of pharmacy.

Pigs' stomachs are the best sources of pepsin, and the yield of such a peculiar principle, exerting such a vast digestive power, is comparatively enormous, if the proper means are employed to secure it. The first consideration which requires attention is, that the stomachs must be fresh. The contents are then immediately removed, and the stomachs well cleaned by a judicious use of fresh water, so as not to waste the mucous membrane in which the digestive principle seems to reside. The second step consists in cutting them into moderately thin shreds by means of scissors. This done, they are macerated for two days in a large volume of acidulated water,—the more the better. However, one gallon of water, acidulated with half an ounce of muriatic acid, is ample for one stomach. At the end of this time the acid liquor is poured off, and the stomachs are again macerated for two days, with a similar quantity of acidulated water. This operation of macerating the stomachs can be performed three times with advantage, and even a fourth maceration will repay the effort. The liquids obtained from each maceration are immediately treated with about one-fourth their weight of common salt, and the precipitated pepsin, which accumulates in curdy flakes upon the surface of the liquid, is skimmed off with a ladle, collected on a muslin strainer and strongly pressed, to separate the most of the adhering water. The cake of yet moist pepsin is then mixed with a weighed quantity of milk sugar, the mixture spread out to dry, then weighed, and sufficient milk sugar added to make the final weight of the mixture equal to ten times the weight of the real pepsin contained in it, which is determined from the difference between the weight of the dried residue and the known quantity of milk sugar at first added. A source of error may, however, occur here, and the finished preparation be under

---

* From the *Chicago Pharmacist* for March.

strength, if the presence of a considerable quantity of chloride of sodium is not taken into account. The moist pepsin, after pressing, still retains over three times its weight of water, which can only be separated by evaporation; and as this water contains at least one-fourth of its weight of salt, the amount of this will perhaps equal half the weight of real pepsin present.

Therefore, the strength of the dried residue is best determined by means of an assay, and its final strength adjusted with the addition of milk sugar, so that ten grains of it shall at least dissolve 120 grains of coagulated albumen. In an extensive practice, with the necessary experience, this is not absolutely necessary, because the concentrated brine adhering to the pepsin can, in a great measure, be replaced by a much weaker saline solution, and afterwards pressed and dried. Most of the salty liquid can also be easily removed, by spreading the pressed pepsin upon abundant folds of bibulous paper, and allowing the liquid to be absorbed, and when quite dry mixing with the necessary amount of sugar of milk. Cold weather is the only proper season in which to undertake the manufacture of pepsin, as putrefied material is not at all serviceable, and in warm weather it is nearly impossible to prevent rapid decomposition.

It will amply pay any pharmacist to make his own pepsin, if he has a sufficient demand for it, because the process is so simple and inexpensive and the yield so plentiful. The product in saccharated pepsin, procured from six stomachs by means of four macerations, is as follows:—First maceration, 16 ounces; second maceration, 12½ ounces; third maceration, 8 ounces; fourth maceration, 4 ounces: total, 40½ ounces. The average yield of six stomachs by two macerations is 20 ounces, and where raw material is abundant only two macerations are usually performed, since it is difficult ordinarily to continue the process unaccompanied by putrefactive tendency. Thus it will be seen that, aside from labour, very little outlay is incurred; that the remuneration for extracting pepsin from six stomachs is twenty dollars, at the regular wholesale rates.

Several attempts were made to obtain pepsin in a concentrated liquid form, having the same strength as the saccharated. For this purpose the moist pepsin with adhering salt was dried, and then mixed with sufficient muriatic acid and glycerine to make the liquid weigh ten times as much as the pepsin employed. This did not give satisfactory results. The moist pepsin was then treated at once with acid and glycerine, without being first dried, the strength being adjusted from the data of the usual loss in water that moist pepsin sustains. This mixture, after long standing, did not form a clear solution; it filtered slowly and with great difficulty, and the remarkable fact was ascertained that the filtrate would not dissolve coagulated albumen. But the unfiltered liquid showed an undiminished activity when diluted and tested with albumen. Through this result it was found that if the liquid, be it acidulated water or glycerine, is increased to forty times the weight of the pepsin, a perfect solution can be made, which possesses the required activity, only it is but one-fourth as strong as the saccharated powder. No trial was made whether a pepsin freer from salt would make a more concentrated and perfect solution. But even this weaker solution, containing 2½ per cent. of real pepsin,—equal to 25 per cent. of the saccharated,—is perfectly stable, and for the purpose of making more dilute solutions of pepsin it is far preferable to the powdered.

In referring to a "pulverulent pepsin" met with in the American market, which has attracted considerable attention by its bitterness, the author states, that upon examination he has found this bitterness to be due to the presence of strychnia. An opinion to this effect had previously been expressed by Mr. A. E. Ebert at the meeting of the American Pharmaceutical Conference at Baltimore.

LIEBIG'S FIRST VISIT TO PARIS.

The following personal reminiscence of the late Baron Liebig is from the pen of Dr. Quesneville, and is published in the May number of the *Moniteur Scientifique-Quesneville*:—

"The editor of this journal had the happy privilege of assisting Liebig in his earliest researches—by washing his glasses and running to fetch the articles required by him—when, in 1822 and 1823, he came to Paris to perfect himself in the study of chemistry.

"Gauthier de Claubry, who is still living, and was then a man of considerable reputation and usually waited upon after the grand visit had been made to Thenard, presented Liebig to my father. At that time there was in Paris scarcely any place but the private laboratory in the Rue du Colombier where a chemist could work freely; that is to say, without a protector taking the half of his labour for chemicals used and apparatus borrowed. This laboratory was one of the appurtenances of the manufactory of chemical products which my father had purchased from Vauquelin and the heirs of Fourcroy. Gauthier de Claubry, who was acquainted with this laboratory, where Vauquelin, Chevreul, Serrulas, and himself had laboured and taught, mentioned it to Liebig, and it was in this commodious place that the illustrious chemist, newly arrived in the great city, prepared his first work on the fulminates.

"At this time I was twelve years of age, and it was I that carried to the great German the articles required for his experiments. My mother also conceived a great liking for him and charged herself with his firing. She filled his stove, and even fitted up at his hotel a fireplace *à la prussienne:* for the young chemist was not rich, and was completely without fuel in the middle of a most rigorous winter. Liebig laboured there one entire year, and when his memoir was finished he dedicated it to Thenard. Gay-Lussac was astonished by it, and requested Liebig to communicate to him his ideas: the second investigation was made in conjunction with Gay-Lussac and in his laboratory.

"But Liebig never forgot his early days in Paris and the assistance he received from my father, so that when he learned from Gerhardt, in 1840, that I had founded the *Revue Scientifique*, and that I had engaged the latter to abstract foreign memoirs for its pages, he wrote to me at once as follows:—

"'It will not be necessary to send you my journal by post, for, as I have already promised, you will receive proofs of all original memoirs before the numbers of the journals containing them are printed and published; in this manner you will be able to make these memoirs known to the French public four or six weeks earlier. This winter I have had the good fortune to count among my pupils six very clever young chemists; I have proposed to them to undertake together a thorough investigation of the fat bodies, and this work, commenced eight months since, is now nearly finished.'

"Liebig finished his letter with the following declaration, which it is curious to read in the present day:—

"'You may, my dear Quesneville, give provisional information as to the results, and I will send you the complete memoirs as soon as I can. You will see, though, that while they were occupying themselves at Paris in useless discussions on the theory of substitutions, we cultivated our field with organized forces. To-day we collect the fruit. Can you be astonished that I have taken so little part in these combats fought about theories so ephemeral, and that in my book I have not even spoken of them? It was because I would not draw off the attention of my readers towards matters so purely personal. In a couple of years they will not be spoken of, and the importance attached to them to-day will have vanished like a dream.'"

The Pharmaceutical Journal.

SATURDAY, MAY 31, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE MINOR EXAMINATION BYE-LAW.

THOUGH we had not space last week to comment on the discussion which took place on that most important alteration of the Bye-laws affecting the examinations, we take the earliest opportunity of referring to it, since it is highly desirable no misconception should continue to prevail on the subject.

Mr. HAMPSON'S opposition to clause 16 of section 10 of the amended bye-laws was based upon the ground that its provisions were illegal, and the arguments he brought forward in support of this view had been previously urged by him at the Council meetings on three separate occasions. He contended in regard to the Minor examination, that since the examiners are, by clause 6 of the Pharmacy Act, 1868, "required to examine all such persons as shall tender themselves for examination" under the provisions of the Act, it was not in the power of the Society to approve and confirm a bye-law requiring candidates for examination to satisfy the examiners that for three years they had been either apprenticed to the business, or registered students, or otherwise practically engaged in the translation and dispensing of prescriptions.

In taking this ground Mr. HAMPSON appears altogether to have overlooked the provision of a subsequent passage in the same clause to the effect that "the examination aforesaid shall be such as is provided under the Pharmacy Act (1852) for the purposes of a qualification to be registered as Assistant under that Act, or as the same may be varied from time to time by any bye-law to be made in accordance with the Pharmacy Act as amended by this Act" (1868). He appears to have ignored entirely the power thus given to vary the nature of the Minor examination, and of the requirements to be demanded of candidates by the examiners, and, as it seems to us, it is only by doing this that he has conceived the idea of "illegality" in regard to the new bye-law.

The passage above quoted clearly gives power to alter the Minor examination; and if we seek to ascertain what is to be the ruling principle of such alterations it may be learnt from the preamble of the Act, stating the expediency of chemists and druggists possessing competent practical knowledge of their business, and that they should be duly examined as to their practical knowledge. The object of the Pharmacy Act, 1852, was precisely similar, and the same may be said of the Society's Charter of Incorporation. With these facts before us it seems scarcely possible to comprehend how it can be argued that it is contrary to the intention of those who framed the Acts of Parliament for the examiners to require from candidates such evidence of their practical knowledge as would be reasonably afforded by the fact of their having been engaged in the business. This would be demanded by any one engaging an assistant; and surely it is not too much to ask before conferring a qualification to carry on business independently.

Taking into consideration these facts therefore, the groundwork of Mr. HAMPSON'S opposition vanishes, and the reason for it is entirely removed when it is remembered that the alteration he disputes was recommended to the Council by the Board of Examiners as a result of their experience, and as being necessary to render the examination more efficient as a test of practical knowledge.

Acting upon this recommendation the Council, after a long discussion, provided for the framing of amended bye-laws as to the examination, and instructed the Parliamentary Committee to consider the bye-laws in regard to the legal power they conferred. On the report of this Committee the alteration here more especially referred to was adopted, together with others. The bye-laws embodying these alterations were approved, in accordance with the provisions of the charter, at three meetings of Council, also by a Special General Meeting called for the purpose; lastly, in conformity with the statute, 1852, as amended by the Act, 1868, they are now in course of being submitted to the Privy Council for final confirmation, and in the event of their being so confirmed, they will have the same force as any portion of the original statutes themselves.

In the course of discussion on this subject several collateral issues have been raised, to which it is barely necessary to refer again here, excepting in the case of the argument Mr. HAMPSON founded on a supposed inconsistency in the opinion expressed by the Society's solicitor while the amendment of the Minor examination was before the Parliamentary Committee. Mr. HAMPSON'S letter, at p. 819 of this Journal, gives all the details, and we may confine ourselves to pointing out that the difficulty he there speaks of arose entirely from his own misconception. The distinction between the originally-proposed bye-law and the one now adopted is in no way subtle, but palpable and positive. The former—objected to by Mr. FLUX—proposed to require that every one admitted to the Minor examination should have been "registered or employed as an apprentice or student for at least three years previously," and in this form the bye-law would, as pointed out by Mr. FLUX, have varied from the intention of the Act that the examination should be freely open to all the world. However, in the bye-law as now confirmed, admissibility to the Minor examination is not thus specially limited, but is accorded also to those who have been *otherwise* for three years practically engaged in the translation and dispensing of prescriptions. A wider or more marked difference can scarcely be imagined; and Mr. HAMPSON'S confessed inability to comprehend it amply justifies the satisfaction he has expressed that his vocation is not that of expounding law.

The importance of a clear understanding on these points must be our excuse for dealing with them at such length; and before concluding we must add that while we feel sure those who have taken part in the consideration of this subject have freely given credit to Mr. HAMPSON for the sense of duty which compelled him to fight the question he raised as to the legality of the Council's proceeding, we cannot shut our eyes to the fact that, beyond the observance of courteous tolerance for opposite opinions, there has long since been no real occasion for continuing the discussion on the point.

The question has been thoroughly fought out, having been thrice decided in Council, and subsequently at a Special General Meeting of the Society. Discreet submission is therefore now the only loyal relation possible for the minority to assume towards the majority. It would indeed be an eminently unfortunate circumstance if the efforts of the Society towards improvement of the trade were to be hindered by the action of an irrepressible minority.

PHARMACY IN VICTORIA.

FOR some time past the pharmacists of Melbourne have been endeavouring to secure the passage of a Bill regulating the practice of pharmacy in the colony of Victoria, but hitherto their efforts have been rendered fruitless by changes in the Government. A vigorous effort is now, however, being made to pass the Bill during the present session. A deputation representing the Council of the Pharmaceutical Society of Victoria has waited upon the Chief Secretary to ask that the Government should take charge of a Bill prepared by that Society, and approved by the Medical Society of Victoria. Mr. W. JOHNSON, formerly, we believe, a student in the School at Bloomsbury Square, and now Government Analyst and President of the Victoria Pharmaceutical Society, explained the provisions of the Bill prepared by the Society, which is based upon the English Pharmacy Act, adapted as far as possible to meet the special requirements of the colony. The principal aim is to make it compulsory in future that all persons retailing poisons or dispensing prescriptions should possess a competent practical knowledge of their business. It provides that registered chemists and druggists only shall retail poisons, except in certain cases where, there being no registered chemist within four miles, a licence may be granted to a storekeeper. But all pharmacopœia preparations are to be of the B. P. standard, and such storekeepers are only to sell these preparations when they have obtained them from a registered chemist and druggist, whose signature the bottles or packages are to bear. The Bill also proposes to establish a board of pharmacy—consisting of five members of the Society (appointed by the Governor in Council) and the chief medical officer—to control all examinations and grant certificates of competency. Mr. FRANCIS, in reply, said that he had not had time to master the details of the Bill, but that it appeared to him to be of too sweeping a character. It might perhaps be advantageously applied to centres of population, such as cities, towns, or boroughs, but should not hastily be extended to the more thinly-populated districts. He promised, however, to give the subject careful consideration and communicate his decision to the Society.

We are informed that almost all the pharmacists in business in Melbourne have been educated in England; and it is hoped that the passing of such a law as that sketched out would give a great impetus to pharmaceutical education in the colony. The Pharmaceutical Society of Victoria has now been established fifteen years, and it numbers 71 members, 13 associates, and 1 registered apprentice.

MUSIC AND PHARMACY.

WE have been favoured with a programme of the "*Annual Commencement*" of the Massachusetts College of Pharmacy, Seventh Session, 1873–74, which is of so remarkable a character that we cannot do less than commend it to the notice of the schools of pharmacy of Europe.

The proceedings or as the programme terms them "*Exercises,*" commence with a musical overture, whereupon follows the VICE-PRESIDENT'S address, immediately succeeded by a "*Grand Pot-pourri from Robert le Diable.*" A statement of the progress of the College is followed by a "*Concert Waltz,*" and the *Conferring of Degrees* by a "*Polka Brilliante.*" The ceremony winds up with discourses on pepsine, liquorice, and mercurial ointment!

But are we not the victims of a hoax? The whole thing smacks of the last scene in the *Malade Imaginaire*, and we can fancy we hear the successful candidate returning thanks in the words of Molière,—

"Grandes doctores doctrinæ
De la rhubarbe et du séné,
Ce seroit sans douta à moi chosa folla,
Inepta et ridicula,
Si j'alloibam m'engageare
Vobis louangeas donare.
Et entreprenoibam adjoutare
Des lumieras au soleillo,
Et des etoilas au cielo,
Des ondas à l'oceano,
Et des rosas au printano.
Agreate qu' avec uno moto
Pro toto remercimento
Rendam gratiam corpori tam docto."

REGULATION OF THE SALE OF INTOXICATING DRUGS IN INDIA.

THE Calcutta correspondent of the *Times*, in a recent letter, says that the spread of habits of intemperance among educated native Indians has alarmed both the orthodox and reforming parties of Hindoos. Brandy kills off the rich absentee Hindoo zemindars in Calcutta at a rate which the native papers lament, while the Mussulman seems to prefer opium and other drugs. The Bengal Legislature has just passed an Act to bring the cultivation and preparation, as well as the sale, of intoxicating drugs under the Board of Revenue, and to enable it to make more stringent rules for licences. It is further stated that the dispensaries kept by natives in and around Calcutta are frequently used as places of carousal, brandy being supplied on the premises during the night. So frequently are the police in league with the liquor sellers, that an order has been issued upon the subject.

With such a questionable association of dram drinking and drug selling in vogue it is not surprising that some of the natives are not altogether satisfied as to the superiority of European physic, and we learn from the *Pall Mall Gazette* that the Hakims, or practitioners of the old Indian system of medicine, have made a stand against the supersession of it by the European pharmocopœia which has of late years been rapidly taking place, and that a company of them lately opened an "Indo-European Medical Hall," where only native drugs are to be sold.

It is not quite fair, however, to credit the Europeans with the introduction of drinking customs into India. Baboo Rajendra Lal Mittra has recently shown by numerous quotations that the practice of drinking ardent spirits has been common in India from the earliest ages, though denounced by Menu and other sages. We reproduce one of these quotations as an illustration :—

"In the time of Kálidâsa drinking seems to have been very common, for we find in the 'Sakuntalâ,' the superintendent of police, who was no other than the king's brother-in-law, proposing, like an English policeman, or cabby, to spend the present offered him by the fisherman who recovered the lost ring, at the nearest grog-shop.

"*Fisherman.*—'Here's half the money for you, my masters. It will serve to purchase the flowers you spoke of, if not to buy me your goodwill.'

"*Januka.*—'Well, now, that's just as it should be.'

"*Superintendent.*—'My good fisherman, you are an excellent fellow, and I begin to feel quite a regard for you. Let us seal our first friendship over a glass of good liquor. Come along to the next wineshop, and we'll drink your health.'"

As the date of Kalidasa's drama of 'Sakuntalá' is variously attributed to the three or four centuries nearest the commencement of the Christian era, the custom may fairly by this time be looked upon as a native one.

ALUM AND NITRE AS POISONS.

Some unusual cases of poisoning are reported from the Continent. In one case, which occurred at Liége, a man, aged 57 years, being troubled with gastric pains, sent to purchase some Epsom salts, and took about thirty grams of the substance supplied in a glass of cold water; eight hours afterwards he died in great suffering. Under the supposition that the pain was caused by the action of the salts, no medical assistance was obtained until shortly before death. At first it was thought that salts of sorrel, delivered by the pharmacien in mistake, had been the cause of death, and in the chemical examination of the contents of the stomach oxalic acid was consequently first sought for, but was not found. After a long and tedious operation, the analyist came to the conclusion that death had resulted from the swallowing of a large quantity of alum (sulphate of alumina and potash), probably in the calcined state. In the other case a Zouave who had obtained some nitre, which he had taken in water, was found in a state of violent delirium. Pacified and put to bed in the hospital, he shortly afterwards became insensible, the pulse grew weaker and weaker, and he died within two hours of his removal to the hospital. At the *post mortem* examination, the potash salt was found in the blood and the urine. The quantity of nitre delivered by the pharmacien he estimated to be about thirty grams, quite a harmless dose, in his opinion, and one that he expressed himself ready to take at any time.

USES OF THE GENUS VINCA.

The two species of periwinkle (*Vinca major* and *V. minor*) which grow in the woods and thickets of this country are not valued for any medicinal or economic properties, though they are known to be bitter and astringent. The last named species, however, is, in some parts of Continental Europe, used as a vulnerary, to stop hæmorrhage and in other branches of medicine. From a correspondent in Mauritius we learn that a kind of tea, made from the leaves of *V. rosea*, L., acts like a charm in the cure of indigestion and dyspepsia; and further, that a decoction made from the roots is invaluable for the cure of dysentery. In Bourbon the plant is known as saponaire, and is grown in gardens. We are told that fever is still raging over the whole of the Mauritius, which is not to be wondered at, considering the filthy state of Port Louis, and the general neglect of proper sanitary measures.

Mr. C. H. Wood, F.C.S., Editor of the 'Year-Book of Pharmacy' issued by the British Pharmaceutical Conference, has been appointed Quinologist to the Government of India on the Sikkim Cinchona Plantations.

The Leeds Local Government Board have appointed Mr. Thomas Fairley, F.C.S., Public Analyst for the Borough of Leeds, subject to the approval of the Local Government Board. Mr. Fairley is also analyst to the Yorkshire Agricultural Society, and was recently Chemical Lecturer to the Leeds School of Medicine.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, 15th May, 1873; Dr. Odling, F.R.S., President, in the chair.

When the formal business of the Society was terminated, Dr. H. S. Armstrong, delivered a most able and comprehensive lecture on "Isomerism," pointing out that the generally received position theory was incompetent to explain many reactions which took place in the formation of metameric and isomeric substances. He suggested that the investigation of the thermal properties of compounds would establish facts which might ultimately enable us to obtain some insight into the matter.

After a lengthened and animated discussion the meeting was adjourned until Thursday, 5th June, when papers will be read "On the Dioxides of Calcium and Strontium," by Sir John Conroy, Bart., and "On Iodine Monochloride," by J. B. Hannay; and a new ozone generator will be exhibited by Mr. T. Wills.

PHARMACEUTICAL SOCIETY OF VICTORIA.

The fifteenth annual meeting of the members of the above society was held in the Melbourne Athenæum on Friday, March 21, Mr. W. Johnson, President, in the chair. About twenty members were present.

The President said that the Society had been going along very quietly during the past year—almost too quietly. Its financial position, however, was most satisfactory.

Mr. Bosisto, honorary secretary, read the annual report of the Council of the Society, from which the following passages are extracted:—"It will be in the recollection of members that in last year's report it was stated that a Pharmacy Bill had been prepared by your Council, and that conferences and correspondence with the Medical Society had made it alike satisfactory to both societies; also, that the Bill so prepared had been presented to the then Attorney-General, who promised that it should receive his careful consideration. A change of Government occurring since then, your Council last July wrote to the present Attorney-General, inquiring whether the Pharmacy Bill would be introduced during that session of Parliament, and received the following reply:—That 'the Attorney-General will give the matter his attention at the earliest moment on which the state of public business will permit.' The last busy session having terminated, your Council count fully on its early introduction during the forthcoming one. In consequence of the Pharmacy Bill having been delayed in its progress, the Society's operations have not been extended. Your Council have been desirous to commence the republishing of the 'Transactions,' but, not knowing to what extent the funds would be required for a private bill should the Parliament refuse to take up this subject of legislation upon public grounds, deem it prudent to defer this matter. It has been suggested by your President that for the time being a copy of the English *Chemist and Druggist* should be forwarded monthly gratuitously to each member, having an addendum of your Society's proceedings and other matters of interest. Should this meet with a favourable response from members, it will be carried out forthwith. During the past year the roll of members and associates has been extended. Your Council regret that they have been compelled to refuse some of the applications, but, exercising care in the granting of the Society's diploma, they hope it will give some guarantee to the profession and to the public of competency on the part of those who hold it. The subject of early closing having been brought before your Council during the year, both by members and non-members, they took the initiative, and called two meetings of chemists and druggists. The attendance was not so great as was expected, but those present entered into its consideration with due regard to the employers, *employés*, and the demands of the public. It was shown that the special peculiarities of a chemist's business, together with the demands upon it being different in each district, placed the subject of final closing at a given hour each day out of the question; but your Council earnestly advise the adoption of a liberal consideration by employers to the employed, and also by the public to those engaged in the calling of a chemist and druggist."

The financial statement showed—Receipts during the year, £112 19*s.*; balance at the end of 1871, £78 4*s.* 5*d.*: total, £191 3*s.* 5*d.* Expenditure during the year, £51 16*s.* 2*d.* Balance in bank and in hand at end of 1872, £139 7*s.* 3*d.*

Mr. Wragge disapproved of the suggestion in the Report as to the *Chemist and Druggist*. The financial resources should be husbanded, as they might have to push the Pharmacy Bill through Parliament as a private measure.

Mr. Bosisto said it was well known that a Pharmacy Bill was required. Chemists had the lives of the public in their hands almost as much as the medical profession had. The rising pharmacists of the colony should be compelled to be educated up to a certain standard.

It was decided not to adopt the President's suggestion comprised in the Report as to the *Chemist and Druggist*.

On the motion of Mr. Blackett, seconded by Mr. Wragge, the Report and balance-sheet were adopted.

Mr. G. Lewis moved, "That it is desirable that a Benevolent Fund should be established in connection with the Pharmaceutical Society."

Mr. W. Ford seconded and Mr. C. R. Blackett supported the motion, which was adopted unanimously.

The Council were instructed to prepare rules for the management of the fund, and submit them to the next annual meeting.

Mr. Lewis moved that the Council be authorized to direct the treasurer to pay £25 to the credit of the Benevolent Fund.

Mr. J. C. Jones seconded the motion.

Mr. Bosisto moved the addition of the following proviso to the motion:—"Provided that the funds of the Society are not required during the year for the purpose of a private Pharmacy Bill." The cost of the Bill, if passed through Parliament as a private measure, would be £300.

The motion, with the amendment added, was carried.

It was also resolved that the trusteeship of the funds be left in the hands of the officers of the Society for the current year.

Mr. Wragge moved that a special meeting be called to consider the desirability of increasing the number of the members of the Council.

Agreed to.

The following members of the Council retired by effluxion of time:—Messrs. Bosisto, Ford, Wragge, and Irvine. They were now candidates for re-election, and Messrs. Guthrie and Plunkett were also candidates. A ballot was taken in connection with the four vacancies, and the retiring members were re-elected.

Messrs. Kingsland and Long were re-elected auditors.

A vote of thanks was passed to the President for his services during the past year.

AMERICAN NATIONAL ACADEMY OF SCIENCES.

At the tenth annual session of the American National Academy of Sciences, recently held in Washington, the President, Professor Henry, who is also executive head of the Smithsonian Institution, called attention to the fact that there is a rapidly increasing appreciation of abstract science in the United States, in proof of which he mentioned that in supplying vacancies in the learned institutions of the country effort is made to obtain men who to skill in teaching join talents for original research. He also alluded to a liberal grant made last session by Congress ostensibly for practical results, but which will nevertheless tend to advance knowledge. Besides these illustrations, he recounted the following instances of individuals who had sought to promote the progress of science by generous gifts. A gentleman of Massachusetts, Mr. John Anderson, has presented to Professor Agassiz an island off the coast of New England, valued at 100,000 dollars, besides 50,000 dollars in money, for the establishment of a school of investigation in natural history. Mr. James Hamilton, of Pennsylvania, lately left a bequest to the Smithsonian Institution for the promotion of science. Dr. J. M. Toner, of Washington, has devoted his fortune to the establishment of a series of lectures to encourage "the discovery of new truths" for the "advancement of medicine." Professor Tyndall, before leaving America, placed in the hands of trustees the sum of 13,000 dollars to advance science in that country by assisting students in prosecuting their studies in Europe. A citizen of San Francisco has given land valued at 140,000 dollars to the Academy of Natural Sciences of that city. Part of the income derived from the bequest of the whole of his property by the late Alexander D. Bache to the cause of science has been devoted to a series of observations to obtain data for the preparation of a magnetic map of the United States, and another portion to the delineation of sun spots, lunar prominences, and the lunar surface. The results of these expenditures are to be published in a series of memoirs.

The members of the Academy removed by death during the past year were five:—Professor John Frazer, of the University of Pennsylvania, a successful teacher in the chairs of natural philosophy and chemistry, and many years editor of the *Franklin Journal;* Professor James Coffin, of Lafayette College, in Pennsylvania, who acquired an extended reputation by his labours in the line of meteorological computation, mathematics, astronomy, and physics; Dr. John Torrey, a celebrated botanist, and for many years Professor of Chemistry and Botany in the New York College of Physicians and Surgeons, and Professor of Natural History in the College of New Jersey; Dr. William Stimpson, of Chicago, a naturalist of high standing; and Professor Hadley, of Yale College, philologist.—*Abstracted from the Athenæum.*

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Thursday, May 22nd.

The Adulteration Act.

Lord E. Cecil asked the Attorney-General whether, having reference to a paragraph which appeared in the *Pall Mall Gazette* on the 17th May, inspectors of markets nuisances, or weights and measures, as the local authority may appoint, are not bound to prosecute under the terms of the Adulteration Act, 1872, upon receiving a certificate from the local analyst; and, whether under such circumstances an analyst was not abusing the confidential nature of his position in sending notice of the adulteration to the seller. The paragraph to which he referred was as follows:—

"Dr. Corfield has just presented his first report as Food Analyst to the Vestry of St. George's, Hanover Square. Of fifteen samples of ground coffee only four were genuine, while nine were adulterated with chicory, caramel, etc. He had analyzed twenty samples of milk, and found five only genuine. Two or three were deteriorated, some were adulterated with water, besides having been skimmed. He proposed to send notice of the adulteration to the seller. The report was ordered to be printed."

The Attorney-General said the Act seemed clearly to lay down that when an analyst had cases of adulteration brought before him it was his duty to lay them before the magistrate, who would issue a summons, and with whom the matter would then rest. As to the other part of the question, he was sure the noble lord would see that he could give no authoritative answer. Nothing in the Act of Parliament forbade an analyst from sending notice of the adulteration to the seller; he could only say that if he were the analyst, he should not do it.

Snake Bites in India.

In reply to a question by Sir J. Hay as to the number of persons killed annually in India by snake bites, and whether any more active steps were about to be taken for the destruction of poisonous reptiles as well as for ascertaining methods of cure,—

Mr. Grant Duff said that it would appear that 14,529 persons had lost their lives by snake bites alone in the year 1869. Later returns had not distinguished deaths caused by snakes from deaths caused by other dangerous animals, but in 1871 the total deaths caused by dangerous animals amounted to 18,078. The subject of the destruction of snakes and of the medical measures to be adopted in consequence of snake bites is occupying much attention in India, and he thought Dr. Fayrer's remarkable book, of which 340 copies have been sent to India for distribution, is likely to produce excellent results.

Juries Bill.

The Committee on the Juries Bill is fixed for Thursday next, June 5, and is placed first in the orders of the day.

Trade Marks' Registration Bill.

The Second Reading of the Trade Marks' Registration Bill is deferred until Monday, June 9.

Shop Hours' Regulation Bill.

The Second Reading of the Shop Hours' Regulation Bill is fixed for Tuesday, June 24.

Weights and Measures (Metric System) Bill.

The Second Reading of the Weights and Measures (Metric System) Bill is fixed for Wednesday, July 16.

Death from an Overdose of Laudanum.

An inquest was held at Amble on Monday, May 19, to inquire respecting the death of W. E. Melrose, who had been found dead in his bed, and a bottle labelled "laudanum, poison," near him.

After evidence as to the finding of the body had been given, Mr. Thomas Brewis deposed that he was a chemist and druggist, and resided at Amble. Deceased went to his shop on the previous Thursday evening and asked for a small quantity of laudanum. Witness inquired what he was going to do with it. Deceased replied that witness need not be afraid to let him have it, as he had been in the habit of taking laudanum which he had obtained from a medical man, but that he had come away and left his bottle. To a question how much he took for a dose deceased replied "twenty drops." He also said that he took it because be could not sleep on account of pain in his leg. Witness gave him an ounce in a bottle bearing a similar label to that on the bottle produced. The laudanum was his own preparation, and was of the usual strength.

Dr. R. Wilson, who had made a *post mortem* examination of the body, stated his opinion that death had been caused by a narcotic poison like opium, and the jury returned a verdict "Died from the effects of an overdose of laudanum accidentally taken.—*From the Alnwick Mercury.*

Adulteration of Milk.

At Liverpool, Charles Edward Shakeshaft, milk-dealer, was charged before Mr. Raffles with having sold a mixture purporting to be milk, which, on being analysed, was found to be mixed with water. Mr. Atkinson, deputy borough solicitor, conducted the prosecution. William Goodier, clerk in the office of the Inspector of Nuisances, gave evidence to the effect that on the 20th ult. he had gone to the defendant's shop, where he purchased a pennyworth of milk. This milk had been handed over to the borough analyst, who certified that it contained 6 per cent. of water. The defendant stated that he did not keep cows himself, but was supplied with milk by farmers who lived at a distance. No adulteration had taken place to his knowledge. Mr. Raffles, remarking that mixture of water with milk to the extent of 6 per cent. must be apparent to anyone, fined the defendant 20*s.* and costs. When called upon to pay the fine, the defendant emphatically declared that such a penalty was worse than a highway robbery, a remark which drew from Mr. Raffles the intimation that if it was repeated the defendant would be committed to prison.—*Liverpool Albion.*

Charge of Selling Adulterated Cocoa.

At the Richmond petty sessions, Mr. Cave, a grocer, was summoned for having sold "Fry's Soluble Cocoa" as an unadulterated substance. The article had been analysed by the county analyst, who stated that it was adulterated, as it contained a mixture of sago and sugar, though nothing injurious to health. But it was shown that the label attached to each packet distinctly stated the cocoa to be "manufactured," being "combined with other perfectly pure and wholesome ingredients." It was further alleged that an Act of George IV. sanctioned such mixtures, especially with reference to cocoa, and that there was no attempt at concealment or deception, no selling of a positively hurtful commodity, and no breach of the law so far as either manufacturer or retailer understood it. The magistrate dismissed the case, with the remark, that when a customer could not read his attention should be drawn to the nature of the statement on the label.—*Daily Telegraph.*

Reviews.

Lessons in Elementary Physiology. By Thomas H. Huxley, L.L.D., F.R.S. Sixth Edition. London: Macmillan and Co. 1872.

First Principles of Human Physiology, and a few Applications of them; with Suggestions for Practical Work. By W. T. Pilter, Certificated Teacher of the Science and Art Department. London: John Kempster and Co.

The study of physiology is not only of surpassing interest, but it is of great practical importance. It teaches us how we live and how we move; it tells us the use of each part of those wondrous pieces of mechanism which we call our bodies; and it shows us the complicated arrangements by which they are all made to work harmoniously together. It is hardly possible to conceive of any pursuit more enticing than the endeavour to gain such knowledge as this, and we are inclined to wonder that everyone does not try to learn something regarding his corporeal being, even supposing that he should thereby do nothing more than gratify his curiosity. But interest is not the only recommendation which a study of physiology possesses. An acquaintance with the conditions requisite for life and health must necessarily involve more or less knowledge of those which induce disease or encourage it to spread, and its possessors are thus induced to seek for the former and avoid the latter. Such being the recommendations of physiology, it is astonishing that it has been so long neglected in schools; but it is now being very generally taught throughout the country, thanks to the exertions of Professor Huxley. Indeed, one of the great hindrances to the teaching of physiology in schools was the want of a proper text-book, as most of the treatises on the subject before the appearance of Professor Huxley's were either so meagre as to be of little service, or so technical as to be adapted rather for the use of university students than of school boys. In the present volume the author's extraordinary powers of exposition are displayed to a remarkable extent, every fact being stated with such clearness that it cannot fail to be apprehended by the meanest capacity. The admirable arrangement also assists the memory so much that the contents of the book are retained with ease, and it is only after comparison with other works that one fairly comprehends the immense amount of information it contains. Although it only bears the modest title of 'Elementary Lessons in Physiology,' it might well be called the Essentials of Physiology, for there is hardly anything of importance which has been entirely omitted. On comparing the present edition with the second, we do not observe any great alteration in the text. The absence of valves in certain veins is noticed, and a much fuller explanation is given of the nature of the pulse and of the conversion of the jerking flow of blood in the arteries into a quiet stream in the veins. Some additions are made to the account of the physiology of the liver and of digestion in the intestines. A fuller description is given of the anatomy of the eye-ball, and the necessity of some parts of it for distinct vision is more clearly explained. With the view of impressing the nature of reflex actions more strongly on the memory, an account is given of the method of showing them upon a frog. The notice of epithelium has been somewhat extended. In the preparation of this edition, as in former ones, the author has been assisted by Dr. Michael Foster. The chief alterations are in the woodcuts, which number 103 in the present edition, instead of 86 as in the second. Many of these are, of course, new, but several of those which were also found in the second edition have been enlarged and rendered more distinct. In some instances, also, representations of parts of the human body have been replaced by drawings of the same parts in the dog, rabbit, sheep, or frog. This has been done, as the author explains in the preface, with the view of aiding those who attempt to gain something more than a mere book-knowledge of the subject, by studying the organs themselves. The new woodcuts are good, and most of the old ones are still fair; but some of the blocks are beginning to show signs of wear from the numerous impressions which have been taken from them. This is especially evident in fig. 41. The type is not nearly so clear, nor the paper so good, in this edition as in the second, and the page is so much broader, that the eye cannot take in the whole of a line at a glance, as was the case in the other. We hope that in the next edition the publishers will return to the old type, size of page, and quality of paper, as they will thereby add greatly to the comfort, and, we believe, also to the profit of the readers.

Mr. Pilter's work is in the main an abstract of Professor Huxley's, and like most abstracts is rather dry. It contains, however, some notes of the methods of performing certain experiments, such as dissecting the eye, etc., which may prove useful to those who are trying to become practically acquainted with the elements of physiology.

Report on the Caoutchouc of Commerce; being Information on the Plants yielding it, their Geographical Distribution, Climatic Conditions, and the Possibility of their Cultivation and Acclimatization in India. By James Collins, F.B.S. Ed., etc. With a Memorandum on the same subject by Dr. Brandis, Inspector-General of Forests to the Government of India. Printed by order of Her Majesty's Secretary of State for India in Council. London. 1872. (Pp. xii. 55; 2 maps and 4 plates.)

A milky latex, which, when dried, possesses the peculiar elasticity of india-rubber, is a somewhat scarce production, at all events in sufficient abundance to render its collection profitable. It occurs only in the bark of certain trees and shrubs in the tropics, each great tropical region having some caoutchouc-producing species. It is very remarkable that a substance apparently identical in properties, if not in chemical composition, should be afforded by, so far as is known, a few isolated plants, all included in the three natural orders *Euphorbiaceæ*, *Apocynaceæ*, and *Artocarpaceæ*, groups the structural affinities of which are of the slightest kind.

The author of this 'Report' is well known to have paid considerable attention to both the commercial and botanical relationships of caoutchouc. In 1868 he published a useful paper in the 'Journal of Botany,' then conducted by the late Dr. Seemann, who was greatly interested in the economic value of plants, and this was extended in the next year into an elaborate account of the whole subject read before the Society of Arts. The Indian Government have therefore been well advised in their selection, and have indeed secured a very comprehensive and suggestive Report, forming, probably, the best single account of the subject yet published.

The chief, if not the only, source of the caoutchouc at present obtained from our Indian possessions is the *Ficus elastica*, Roxb. This tree grows wild in the Himalayas, especially in the rich, moist valleys of the Assam district whence it is exported: the distribution of the tree in this district is well exhibited on one of the maps accompanying the 'Report.' "Assam rubber," however, fetches but a low price in the market compared with the South American kinds yielded by various species of *Hevea*. This is largely due to the very faulty method of collecting, which allows the juice to become mingled with much bark, sand, and clay. Little or no control has been exercised over the collectors, and the result of the reckless and improvident way in which the cutting or tapping of the trees has been practised is, that they have been destroyed in thousands, and, unless artificial planting be carried out, will become exterminated in large districts. Systematic cultivation has been already recommended by Mr. Gustav Mann in the 'Report of Forest Administration in Bengal for 1868–69,' and is strongly insisted upon by the author, who also here gives various useful directions as regards the best methods of tapping the trees. To obtain a full flow of juice it is not necessary to cut deeper than into the middle layer of the bark, where the laticiferous canals ramify; deeper cutting injures the trees.

In addition to *Ficus elastica*, the introduction of as many other caoutchouc-producing trees as possible is recommended, so that it may be determined which are most suitable for cultivation in the Indian climate. As bearing upon this point, the 'Report' contains a full account of all the important sources of the substance, arranged under the three natural orders above mentioned. The botanical synonymy and the distribution of each are given, as well as details of the climate of the districts in which the best sorts are found. The distribution of the trees over the globe is clearly exhibited by a coloured map, and the 'Report' is further adorned by four plates by Mr. Blair, representing *Hevea brasiliensis*, the chief source of "Pará" caoutchouc; *Castilloa elastica*, which yields the "Guayaquil" or Ecuador sort; *Landolphia ovariensis*, whence the "West Coast" (Angola) kind is procured; and *Castilloa Markhamiana*, a new species, found by Hayes in Panama, and appropriately dedicated by the author to Mr. C. B. Markham, of the India Office. The plates have had the advantage of the supervision of Mr. Carruthers, of the British Museum. The Madagascar variety, which has taken a good position in the market, is afforded by species of *Vahea*, and the same natural family (*Apocynaceæ*) gives caoutchouc in America from *Hancornia speciosa*, etc., and in Asia from *Urceola elastica* and *Willoughbeia edulis*.

Mr. Collins's 'Report' is supplemented by a memorandum by Dr. Brandis, which thoroughly seconds all his recommendations.

The Expression of the Emotions in Man and Animals. By Charles Darwin, M.A., F.R.S., etc. London: John Murray.

In this literary age, when books are produced in shoals by a process which seems to be growing ever more mechanical and less personal, so as to require a minimum of thinking and a maximum of writing, it is very delightful to meet with a work which is based upon thirty-four years' more or less active observation and thought by a man of singular mental power. One of the most striking characteristics of Mr. Darwin's book is the wonderful wealth of data collected from the most varied sources. A catalogue of the authorities quoted would be a formidable list, as there is hardly a page which has not at its foot several references to the writings and observations of others.

Mr. Darwin's plan of study was, as stated in his introductory chapter, firstly, to observe the emotions as exhibited by infants; secondly, by the insane, because in these cases conventional restraint does not interfere; thirdly, to exhibit photographs of *artificial* expressions, obtained by acting upon the various muscles by galvanism, to a number of persons without explanation, and obtain their unbiassed opinion as to the emotions expressed; fourthly, to study pictures and sculpture; fifthly, to obtain replies to a number of queries from observers living amidst isolated races of men; and lastly, to closely watch the lower animals.

He enunciates as the result of his inquiry, three general principles of expression which he considers fundamental. These are, first, "that movements which are serviceable in gratifying some desire, or in relieving some sensation, if often repeated, become so habitual that they are performed, whether or not of any service, whenever the same desire or sensation is felt, even in a very weak degree;" second, "if certain actions have been regularly performed . . . . under a certain frame of mind, there will be a strong and involuntary tendency to the performance of directly opposite actions . . . . under the excitement of an opposite frame of mind;" third, "that certain actions, which we recognize as expressive of certain states of the mind, are the direct result of the constitution of the nervous system . . . ."

The first of these is generally admitted by psychologists and the third by physiologists. In the consideration of the second, Mr. Darwin gives some exceedingly interesting illustrations, the various moods of dogs and cats being described with a fidelity which must strike every reader.

Having given some considerable attention to these three principles, he proceeds to consider the expression of the various emotions in detail, treating of suffering, anxiety, despair, joy, reflection, ill-temper, determination, anger, disdain, helplessness, surprise, fear, blushing, etc., etc.

The chapter on suffering and weeping is illustrated by six photographs of children, which are well chosen for the purpose, although it must be admitted that they are for the most part far from handsome. Indeed, if we do not mistake, enlarged copies of the first are now to be seen for sale in London, with the title of "Ginx's Baby," perhaps bewailing his "birth and other misfortunes."

In this and the next chapter on the more passive forms of suffering, the minuteness with which the anatomy of the subject is treated is especially noteworthy, the action of each muscle concerned being carefully considered and ascertained. The author appears to have perfectly succeeded in confining his attention to one detail after another without being distracted by the general effect. The difficulty of this will be seen from the statement which he makes in his introduction—that his study of the works of painters and sculptors gave him little information, because the emotions were almost wholly expressed by skilfully given accessories; and yet everyone will admit that the absence of expression by means of the muscles in pictures and sculpture is not noticed, the attention being rivetted on these accessories.

While feeling great diffidence in differing from the opinion of one who has given so much attention to the subject as Mr. Darwin, we cannot avoid the impression that the photograph No. 1 on plate vii. does not express the emotion of pure astonishment, but rather a mixture of that with a sort of unconscious fear. It is that of a man who is astonished at something *in motion* near him, or at something which has come rapidly within sight, and the hands are raised unconsciously as a protection. The face also conveys to us the notion of fear as well as astonishment. Unmixed astonishment, we should rather say, was expressed by the whole body becoming fixed, motionless, in or nearly in the attitude in which it happened to be when the attention was first aroused. As, for example, when one is astonished at something easily within sight, but not in rapid motion, and not causing any sense of fear. Then the mouth is opened slightly, as Mr. Darwin says, for silent breathing, and the eyes widely in order to obtain a clear view; but the body and limbs remain "forgotten and neglected."

The chapter on self-attention and blushing contains an anecdote which is so good that we cannot refrain from extracting it:—"A small dinner-party was given in honour of an extremely shy man, who, when he rose to return thanks, rehearsed the speech, which he had evidently learnt by heart, in absolute silence, and did not utter a single word; but he acted as if he were speaking with much emphasis. His friends, perceiving how the case stood, loudly applauded the imaginary bursts of eloquence whenever his gestures indicated a pause; and the man never discovered that he had remained the whole time completely silent. On the contrary, he afterwards remarked to a friend, with much satisfaction, that he thought he had succeeded uncommonly well."

The same chapter is especially interesting on account of the important evidence brought forward to show the direct action of the mind upon the various organs of the body.

Taking the book as a whole, we can speak of it only in commendation as regards the department of observation; but when Mr. Darwin proceeds to draw inferences from his facts, it is at once felt that the solid foundation has been left. Much would have been clearer if distinct and accurate definitions had been given of terms such as "*instinct*," "*innate*," etc. But the prominent feeling left in the mind of the reader is, that in this book, as in the author's former one, 'On the Descent of Man,' the conclusions with reference to the evolution hypothesis are too large for the premises. Perhaps even so cautious a thinker as Mr. Darwin may have a fixed idea, and bring observation afterwards to support it. To say the least of it, many readers will probably think with the writer of this notice, that the lowest type of man is still removed from all other animals by a large space in the scale of creation, which is not lessened by this book, and is not very satisfactorily accounted for by the evolution hypothesis as at present propounded; and that the problem of the origin of man cannot be discussed with any chance of a successful solution while the lower, animal, portion of his nature is alone considered, to the exclusion of the higher and vastly more important part, his mind.

"To matter or to force
The all is not confined;
Beside the law of things
Is set the law of mind."

BOOK RECEIVED.

Les Plantes Médicinales et Usuelles de nos Champs —Jardins,—Forêts. Par H. Rodin. Ordré de 117 Gravures. Paris: J. Rothschild. 1872. From the Publisher.

Obituary.

Notice has been received of the death of the following:—

On the 11th May, 1873, Mr. Gabriel French, Pharmaceutical Chemist, of Chatham. Mr. French had been a member of the Pharmaceutical Society from its foundation in 1841.

On the 10th May, 1873, Mr. John Hudson Lewis, Chemist and Druggist, of South Street, Cockermouth.

Notes and Queries.

AERATED WATERS.—After being engaged in the aerated water trade some years, *W. Chamberlin* has met with a difficulty which completely baffles him, and concerning which he would be glad to receive any suggestions. When first made the waters appear all that could be desired, but after a few days small particles of a white flocculent matter are to be seen which gradually increase, and especially in the lemon and soda appear like bread crumbs. When opened all the aroma of either lemon or ginger is entirely gone, and after standing a short time, the water becomes fetid. The machine is certified to be in perfect working order, and the water is filtered through one of the London Water Purifying Company's filters.

[Probably the water used is not free from organic contamination.—Ed. Pharm. Journ.]

DISCOLOURED PRINTS.—*G. C.* would be glad to hear of a method by which the brown tint acquired by prints and books through age can be removed.

PRESERVATION OF HYPODERMIC SOLUTIONS.—Professor C. Johnston, of Baltimore, suggests (*Amer. Journ. Pharm.* May, 1873) the use of sulphurous acid in preparing solution of morphia for hypodermic use. He states that he has carried in his pocket for a month a half-ounce vial of a solution (1 in 30), to which sulphurous acid had been added in the proportion of from three to five drops to the fluid ounce, and at the end of that time the fluid was clear and free from any fungous formation. Professor Johnston also says that in use he has found such a solution to be as little painful as the ordinary one of Magendie, and but very little more so than the simple aqueous solution.

Correspondence.

Pharmaceutical Progress.

Sir,—Sometimes those stationed at a little distance from a battle-field can tell better how the fight is going than those immediately engaged in it; those on the look-out at sea generally mark the distant breakers or a coming storm before those guiding the ship's course. It is from this point of view that I trouble you with a few remarks on the position of the Pharmaceutical Society at the present time.

On opening a recent number of the Journal I was sorry to find that "the admission of women as members of the Society" was to form a prominent subject of discussion at the approaching General Meeting. That our "potent, grave, and reverend seigniors" should have no better subject than this to talk about, or that it should occupy any considerable portion of their time, seems to me a woful pity, when there are so many urgent practical questions affecting the interests of chemists pressing for solution. Without any disrespect for the ladies, I think questions of this nature are best dealt with somewhat after the method recommended to "Little Bo-Peep" in the old nursery ditty for recovering his missing flock,—

"Let them alone, and they'll come home
And bring their tails behind them."

If, as a matter of business, "the admission of women" must be brought forward, by all means let it be disposed of as speedily as possible. Women may, doubtless, make good dispensers, but that is no reason why they should be admitted to the Society so as to hold office and rank with men, which, on the face of it, is absurd. Nominally, in order that, as in the case of widows, they may carry on businesses by the help of a qualified assistant, there is, of course, no objection to membership. As to ladies joining the Society with the view of competing with men in business —carrying on business except by proxy,—the thing is a chimera. Two or three will be sacrificed and be left as scarecrows to frighten away the rest.

The "Correspondence" columns of the Journal teem with matters of far greater interest and importance to the trade in general than that above mentioned. Besides the sale of drugs by hucksters, the cooperative store grievance, the unsatisfactory state of the patent medicine licence and stamp duties, and the oppressive operation of the excise, there is the Benevolent Fund and the general constitution of the Society, in addition to a host of minor subjects "too numerous to mention," all of which more or less demand the attention of the executive, assisted by the general expression of opinion on the part of the members. Not to trespass too much on your space, permit me to say a few words on two of the topics here alluded to, viz., the Benevolent Fund and the constitution of the Society.

The Benevolent Fund has been pressed upon the notice of the members lately (I believe with good effect), and quite rightly so. More money ought to be contributed for this object, and more also *distributed* on account of it. In the Journal for April 19, *J. B. B.* ironically congratulates the trade on the presumption that "there are only thirteen needy druggists or druggists' widows." Alas, alas! who does not know that many who never come before the Society as annuitants, are yet only dragging out a struggling existence behind the counter? The number of annuitants is no criterion of the actual "state of trade" amongst us. Many doubtless contribute to the Fund because others do, whose "small returns" barely warrant it, and who ought almost to be recipients rather than contributors. Might not some means be devised of rendering this Fund more generally available for those who, through illness or misfortune, had become so depressed as to have no hope of again rising into that commercial independence which perhaps they once enjoyed, and yet who had too much delicacy of feeling, and were not precisely in the condition, to come before the Society *in formâ pauperis?* Are there not cases in which seasonable and needed help might be thus quietly rendered without the appearance or sense of gratuity? If the annuitants are no criterion of our prosperity, certainly the number of subscribers to the Benevolent Fund is no index to our generosity. If many give who barely can, many more do not give who long to and dare not. Were the annual subscription (as I shall presently suggest) done away with, we should all have more for benevolent purposes.

The constitution of the Pharmaceutical Society is a topic of vital interest to all the members, and indeed to the trade generally. A short time since Mr. Sandford (whose remarks are always worth listening to), speaking, I believe, on this very subject,—the admission of women, —observed that our Society was a "*private* society." In saying this I think he hit unintentionally its main defect. It *is* a "private society," and as such has done good service, but it ought to be such no longer. The time is come, or at least approaches, when it should expand into a public body, a national corporation, similar to the medical faculties, the colleges of physicians, surgeons, etc. Allow me briefly to indicate one or two changes and some advantages which, presuming this transformation possible, would thereupon ensue. First, we should have a change of name. Instead of "Pharmaceutical Society of Great Britain" (Royal or British or—) "College of Pharmacists or Pharmaceutists" (not "of Pharmacy," which, with all due deference to our American cousins, is a misnomer). Then, in lieu of being a joint examining and educational body, the Society would become simply an examining and protective one, the educational part being left to private enterprise, or, if carried on by a society, officially disconnected from the examining body. The basis of membership, again, instead of resting on due payment of subscription *plus* examination, would rest on examination alone, the fees being so regulated as to cover the working, parliamentary, and other outgoings, which, with no educational expenses, would be considerably reduced. Conjointly with these changes some modification of the present legal status might seem desirable. For example, the present Major qualification (M.R. [or B.] C.Ph.) should be compulsory in cities and larger towns; the Minor qualification (A.R.C.Ph.), in order to meet the requirements of country places, being sufficient for smaller towns and villages. A higher *optional* status of "Fellow" might be created, and the present scholarships and medals retained, with such modifications as would render them consistent with a purely examining body.

I have no room left to enumerate the advantages which might result from such a change. Many disadvantages of the present state of things would, at any rate, disappear. The educational department would no longer fetter the resources of the Society, whose whole energies would then be directed solely to the registration of duly qualified pharmacists, and to the protection of their professional interests. A "College," being a national and public body, would obtain a general recognition, and possess a parliamentary influence which no "private society" ever can. Thirty or forty years ago education was a necessary part of the Society's operations, but of late the facilities for acquiring knowledge have so much increased, that this may safely be left to private enterprise, or form a distinct social one. On the other hand, the requirements of examination, protection, benevolence, and so forth, have also increased, so that these may now well form an object in themselves. The examinations would, in such case, doubtless rise in public estimation; there could be no suspicion of partiality, cramming might be better guarded against, and a somewhat higher standard introduced. With no educational duties (on the whole, I believe, rather a loss than a profit to the Society) and with compulsory examinations, probably little, if any, increase on the present scale of examination fees would be needed to meet the expenses of an examining and protective body, especially if the number of Major candidates were increased. The discontinuance of the subscription would be a boon which requires no comment, its natural influence on the Benevolent Fund is self-evident. A further advantage arising from this change in the organization of the Society, would consist in opportunities for exerting influence in Parliament. The Society has done, and is doing, much in this way. Could it not do more? Has it reached the limit, the ultimatum, of its power in this direction? Would Jacob Bell say so if he were now amongst us? Would it not be possible, under a superior organization, to exert a greatly increased pressure on the Legislature in the interests of our body and of the public thereby? There is plenty of need for this—but where are our advocates? Have we any in the great council of the nation? We have been congratulated of late in the Journal because some pharmaceutical chemists have been, here and there, elected to the office of mayor, and one (who was a P. C.) has received the honour of knighthood. Why should not chemists go a step higher, or at least get a broader footing? Is Jacob Bell to be the last of the pharmaceutical M.P.'s, as, I believe, he was the first? It might be one of the avowed objects of a representative and examining pharmaceutical body to secure the election to Parliament of wealthy and aspiring pharmacists, who might thus do good service to their community when any question arose affecting its interests. At any rate, a change of this sort would prevent our drifting into a mere *dilettante* society, which, with our dinners, balls, conversaziones, and so forth, we run some chance of doing, or at least of being "content with things as they are." After all, it is not so much for our own good as for that of those who will come after us that we are pharmaceutical chemists at all.

I have thus attempted, in a few moments snatched from many other occupations, to sketch a rough outline of pharmaceutical progress. My ideas will doubtless be generally regarded as Utopian and impracticable; but those who may think they possess any value, are welcome to the use of them.

AN ON-LOOKER.

P.S.—By the report of the Council I see twelve persons received grants from the Benevolent Fund last year, besides the annuitants. Probably many more (judging from letters in the Journal) needed help, whose cases the present regulations of the Fund would not meet. The report, in other respects, shows "something attempted, something done:" however, I send my letter (which was written before I saw it), as there is always room for improvement, even in the "best-regulated family."

Admission of Women as Members of the Pharmaceutical Society.

Sir,—Mr. Sandford was wrong in his assertions on the 21st inst., when he said, "I had been on the register because my father had been a chemist and druggist, and that I was manager or housekeeper in an asylum."

The ground upon which I based my application for membership, was the fact of my registration on the 21st December, 1868, and in compliance with clause 18 of sec. 10 of the Society's bye-laws.

I never have been manager or housekeeper in *any* establishment; for nine years and a half I have held the appointment of secretary and dispenser in a private asylum, which appointment has nothing whatever to do with my claim upon the Society; I consider that my having been in business (on my own account) upwards of nine years, before the passing of the Act of 1868, proves the legality of what I maintain.

ELIZABETH LEECH.

Effra Hall, Brixton, 28th May, 1873.

The Shop Hours' Regulation Bill.

Sir,—Having read the remarkably well-pointed letter of your correspondent "Audi Alteram Partem," I think he has expressed the opinions of a very large number of your readers in a most comprehensive manner.

The "Shop Hours' Regulation Bill," if passed, will confer an immense boon on pharmacists in general. I am sure that no druggist will object to it, as it will give a good ground for even those most obsequious to the wants of the public, to close their establishments at a proper hour. It is only reasonable that those who have examinations to pass should have time to prepare for passing them; but this consideration seems to be overlooked at present.

I was very much surprised to read in page 924 of last week's number of the Journal, that a meeting of the Pharmaceutical Society had been held in London, and after passing more stringent bye-laws in regard to the examinations, the Vice-President said, in regard to the above Bill, that it was hardly possible for such a Bill to pass the House of Commons, but that the Parliamentary Committee would give it their attention. If by this an opposition to the Bill is meant, it is surely not in concurrence with the opinions of the profession at large.

EXCELSIOR.

Colouration of Glass by the Solar Ray.

Sir,—During the memorable cyclone that visited our southern coasts during twelve or fourteen hours on the 16th December, 1869, the Longship lighthouse, Land's End, suffered considerable damage.

By the courtesy of a gentleman residing in that part of the country, I am favoured with a specimen of plate-glass (enclosed) which, although half an inch thick, was entirely smashed by the force of the waves in that terrible storm.

The remarkable change in the colour of the glass from pure white to an amethystine hue must be ascribed to the action of the actinic solar rays upon the binoxide of manganese employed in the manufacture of the glass to increase its brilliancy. The proportion of oxide used may have been larger than usual.

Wherever the glass was protected from the sun's influence—as at the edges, where covered with putty—it retains its original purity of appearance.

A change has probably been wrought in the molecules of the glass, by reason of which it reflects purple only, instead of all colours, as it would naturally do,—the colorific rays may have also had a share in producing the change.

It is observable that the windows of the Hand-in-Hand Insurance Company, Blackfriars, have been similarly affected.

Visitors to Richmond often notice the purple glass in the windows of a house situated at the Park entrance; it is said by some to have been chosen by the original possessor of the old mansion, who died long ago, but it is more likely that the exposed position of the windows to a full blaze of light and heat may have conduced to the result.

R. GOODWIN MUMBRAY.

Richmond, S.W., May 18th, 1873.

The Minor Examination Bye-Law.—We have received from Mr. Hampson a copy of a letter addressed by him to Mr. Carteighe, with a request that it should be published, but since the letter deals chiefly with personal matters, we do not think this desirable. Moreover, it contains incidentally reiterations of the opinion that the Minor Examination bye-law is illegal, and of the charge that a proper report has not been given in this Journal of the proceedings of the Council. Both have, we believe, been so fully disposed of as not to require further discussion.

H. G. R.—Only the "tincture and all vesicating liquid preparations of cantharides" are included in the poison schedule.

"*Taraxacum.*"—You were elected an "Associate" at the February meeting of the Council, and your name appears in the "Transactions of the Pharmaceutical Society," printed in the PHARMACEUTICAL JOURNAL, p. 629. No certificates of associateship are issued by the Society.

J. Houlton.—We are obliged for the expression of your opinion and will bear it in mind.

"*Analyst.*"—In all probability the use of such a preparation as you refer to would be considered within the provisions of the Act.

E. H. Storey.—Your letter has been handed to the Secretary.

E. Brown.—We are obliged to you for the information in your letter.

Mr. Ford.—The receipt of your letter was acknowledged on p. 920, but we have not hitherto been able to insert it.

J. M. Fairlie.—Your letter with inclosure has been received and shall have early attention.

"*Hypo.*"—Your question is rather legal than pharmaceutical and you would find a lawyer best able to answer it.

"*A Student.*"—The word "zoological" refers to the animals yielding substances used in medicine.

J. J. Matthias.—Your price was moderate enough. We cannot understand how less could be charged.

Errata.—On page 862, col. ii., line 50, *for* "aceti" *read* "aceta;" line 55, *for* "vini" *read* "vina;" page 925, col. i., line 12 from bottom, *for* "Mr. James Garle" *read* "Mr. John Garle."

We are requested to state that the rejected candidate for Council was not Mr. W. V. Wright of the firm of Wright, Sellers, and Layman, but Mr. G. H. Wright.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. H. Arundell, J. Askew, J. Hallawell, J. Abraham, W. Oxford, J. Leay, H. W. Breton, E. W. Jackson, Dr. Nichols (Boston, U.S.), G. C. Druce, E. S. Balchin, G. W., J. A., C. E. G.

SOME RECENT PROPOSALS RELATING TO HEATING AND LIGHTING.

Whatever may be the position of our country as regards the study of the sciences, there can be no question as to the activity of the British inventor. The philanthropist and the commercial man, the amateur and the professional, are all busily working their brains to devise new plans, and for the most part their fingers, to make their schemes known to the public. We seem, like the Athenians of old, to "spend our time in nothing else but either to tell or to hear some new thing." The inventors proceed in very various ways. One will, after much thought and many experiments, bring out his method carefully elaborated and supported by a strong mass of evidence. Another is fired by an idea, and without apparently thinking about it at all, or trying a single experiment, snatches up a pen and "writes to the *Times*" or other paper, leaving the details to be arranged by men of less genius but more practice.

We propose to examine a few of the plans which have recently been suggested as improvements in heating and lighting, with especial reference to the scientific laws affecting them.

The first was made known in a letter to the *Times* of October 18th, 1872, under the heading "Supplementary Fuel," by the Rev. Henry Moule, so well known for his labours in the sanitary field. He proposes to cover the bottom of an ordinary grate with lumps of chalk to a depth of from two to six inches, and light the fire as usual on the top. Whilst sympathizing with him in his desire to benefit his fellow-man, and not doubting for a moment his accuracy in reporting the results of his experiments, we are bound to say that he appears to have entirely misunderstood the real bearing of the question, and that his letter exhibits a lamentable want of acquaintance with elementary chemical facts. Take the following passage as an example:—"With those who have ever noticed or read of the great specific heat of chalk, or the large amount of carbonic acid contained in it, and the convertibility of that acid by means of heat into carbonic oxide (a combustible form or substance) . . . or the effect in smelting ore of a few hundred-weight of limestone or chalk, it has long been a matter of strong persuasion that the time must come when, at least for domestic purposes, chalk, if not limestone, shall be made subservient to the increase of warmth and heat and to the diminution of the consumption of coal." Now, passing over the ambiguous use of the term "specific heat," there are in these few lines two errors of the first magnitude. Taking the latter first; chalk or limestone is not used in smelting as supplementary fuel, but merely as a flux; that is to say, in order to obtain a readily fusible slag. But for its use in this capacity, the smelter would gladly dispense with the limestone, which, far from serving as fuel, actually appropriates a considerable quantity of heat. But the first error is perhaps more important. Carbonic acid is *not* convertible into carbonic oxide by means of heat. A reducing agent is also necessary, and since ordinary combustion is a process of oxidation, reduction, the reverse of this, may be called *unburning*. Taking carbon as the reducing agent, the change may be represented in chemical symbols, thus,—

$$CO_2 + C = 2CO,$$

so that every forty-four parts of carbonic acid require

twelve parts of carbon to reduce them to carbonic oxide. Mr. Moule seems to have been misled by confining his attention to the bare fact of the combustibility of the carbonic oxide thus obtained, neglecting the consideration of the quantities concerned. It is true that the carbonic oxide will burn and thus give out a large amount of heat, but this is due entirely to the carbon employed in reduction, as we have seen above. The combustion of the carbonic oxide would be represented by the symbols

$$2CO + O_2 = 2CO_2.$$

Now if these two sets of symbols be put together we have,—

$$(1)\ CO_2 + C = 2CO,$$
$$(2)\ 2CO + O_2 = 2CO_2,$$

or combining them,—

$$CO_2 + C + O_2 = 2CO_2,$$

from which it is evident that no heat is derived from the carbonic acid, or, which is the same thing, from the *chalk* employed. Indeed, heat is actually required to be expended in tearing asunder the chalk into its constituents, carbonic acid and lime, besides a considerable quantity employed in volatilizing the water always present in chalk. Mr. Moule seems to have been aware of this without really apprehending its import, for he says in a subsequent part of his letter, "the only thing to be guarded against is that of allowing the fire to sink so low that there shall not be sufficient heat in the coal to continue to extract carbonic acid from the chalk, in which case the fire becomes dull." A statement towards the end of his letter that chalk thus used "of necessity saves fourteen times its bulk of coal," is to us utterly incomprehensible and no explanation is given.

But although Mr. Moule's theory appears to be erroneous, his observed facts may be accounted for in another way, as indeed was indicated by Dr. Attfield in the *Times* of the next day. The heat evolved by burning fuel in a common grate passes off by three channels, by conduction through the walls and surroundings of the grate, by convection with the products of combustion, and by radiation. The proportion passing by the first of these cannot be materially changed except by a radical alteration of the principle of construction and fixing of the grate, and does not concern us at present. The heat taking the second course goes, or should go, wholly up the chimney, and is manifestly wasted, except that it may warm the walls through which the chimney passes, and is serviceable in maintaining ventilation. The third portion of the heat, that radiated, is principally concerned in warming our apartments, and any device which will transfer heat from the second to the third channel, will effect a corresponding economy. Mr. Moule's plan does this in two ways: by increasing the radiating surface, and also by diminishing the draught, and in consequence the quantity of heated air passing up the chimney. The lessened draught gives us a lower temperature in the grate which must be compensated by a larger mass of incandescent fuel, but the proportion of heat radiated is greatly increased, effecting a saving of fuel which may amount to 40 or 50 per cent. Of course there is a limit to the reduction which can be made in the draught, for, if too much diminished, the products of combustion would not be efficiently removed, and the fire would not be properly supplied with air. The only question we have now to ask, before quitting this part of our subject, is whether chalk is the best material for this purpose. The result of calcining chalk is lime, and this seems to be a very objectionable substance to form in a domestic grate, as it readily breaks up into a light powder which would be rapidly distributed about the room, and by its corrosive action do much mischief. Ordinary ashes are sufficiently unpleasant in that way, and lime would probably be much worse. On the other hand the same result may be attained by other means. The draught may be effectually and without trouble controlled by means of an iron plate at the bottom of the grate in place of, or upon, the usual grating, and radiating surface may be supplied by fireclay balls, etc., or by adjusting the draught so that the mass of fuel may itself be sufficiently large, without an unnecessary consumption.

The next scheme which we would consider is, like the preceding, a proposal to employ something which has already been burnt—an ash—as a source of heat, ignoring the real fuel employed. In a letter to a Manchester newspaper, a gentleman propounds a method "by which heat may be obtained at probably a cheap rate, and certainly, to an inexhaustible extent," namely, by the electrolysis of water, and subsequent combustion of the resulting oxygen and hydrogen. He is extremely candid, and says that he is "aware that the method has been in use for some time in chemical laboratories," and that his "project is purely a theoretical one, requiring, no doubt, alterations before it can become of practical value." The plan is described in considerable detail; the collection of the gases in separate receivers, their conveyance by pipes to the place to be heated, the arrangement of the jets at an acute angle, and the combination of the gases "producing a most intense heat, with a blue flame and an impalpable" (!!) "amount of steam." The flame is to heat a fireclay ball in order to facilitate radiation, and the whole is to be protected by a perforated earthenware cover. The author says that the advantages of this method over our present system of fires, "besides its cheapness," (!) are twofold—firstly, that no oxygen is removed from, or carbonic acid added to, the atmosphere; and secondly, that that desperately expensive luxury—an English fireplace and chimney—may be dispensed with. The last sentence contains a somewhat mysterious statement, namely, "that the two gases in question never explode so long as they are present in proper proportions."

Now, the author of this scheme apparently does not see that the real source of his heat is not the water decomposed and again formed, but the fuel employed in obtaining the zinc or other material used in the battery; and that the question does not turn, as he thinks, on "whether the intense heat of the oxy-hydrogen flame can be so placed as to render incandescent the whole surface of the fire-balls," but on whether his circuitous method of applying the fuel above mentioned admits of less waste of energy than other modes.

The third proposal which we will consider is primarily directed to lighting, although it is said to be also available for heating. We refer to the air gas introduced by the "Air Gas Light Company, Limited." Several schemes have at various times been brought forward for charging ordinary atmospheric air with some volatile hydrocarbon, so as to produce an inflammable mixture which shall serve as a substitute for coal gas. In the plan we are now considering, air is driven through a light hydrocarbon spirit, which has been subjected to a process (not made public) by which its proportion of carbon has been increased, as the light petroleum oil alone would hardly give sufficient illuminating power. There are four questions which at once suggest themselves in regard to this process. Can these light petroleum oils be always obtained at their present low price? The directors of the Air Gas Light Company seem to expect to obtain them at a still cheaper rate; but if their process were to come into general use it is very likely that the price would rise considerably, for its present lowness is probably due only to the absence of demand. Once find a use for large quantities of the material and the price must rise, just as did that of coal-tar and gas-liquor.

Next, is the "gasogen" a substance which can be safely stored in quantity? This may not be a matter of much difficulty if large public gasworks only are considered, where it would be kept and used under proper skilled superintendence; but the Company proposes to light private residences, churches, hospitals, etc.; and considering the class of persons in whose care it would probably be placed for such purposes, we can hardly think its use other than dangerous. We may mention that the Company apparently recommends the "generator" to be placed outside the building.

Further, can the illuminating power always be kept to the same standard? It must be remembered that the quantity of hydrocarbon taken up by the air depends on the temperature and on the time during which the air is in contact with the liquid. If it is allowed to stand for some time over the hydrocarbon, or is passed very slowly through it, it would become saturated, and the quantity of hydrocarbon volatilized would depend solely on the temperature; but if the current is too rapid the saturation would not be complete, and the amount volatilized would depend both on the temperature and on the rate of passage of the air. Therefore, to ensure a gas of constant illuminating power, the temperature and velocity must be uniform, or must vary proportionately.

Our fourth question is, can the gas be distributed through long services of pipes without deterioration, that is, without depositing the hydrocarbon with which it has been charged? The answer to this will depend on whether in its course it will at any point be reduced to a temperature below that at which the hydrocarbon which it contains would be sufficient to *saturate* the air. If this be the case, the excess of hydrocarbon must of course be deposited at that point, and the practical result would be a more or less rapid transfer of the "gasogen" from the "generator" to the cold region by a process of distillation. This is precisely the way in which it happens that we are so often troubled with "jumping" gas-lights, due to "water in the pipes;" and we need hardly point out that "*petroleum* in the pipes" would be far more objectionable, and, indeed, dangerous. This can be prevented, either by giving the air a charge of hydrocarbon so small that it would not be sufficient to saturate it at the lowest temperature to which it will be subjected, or by keeping the temperature of the generator below such a point. In fact, this latter would probably happen in any case, for the volatilization of the hydrocarbon renders latent a large amount of heat; and we are informed that the temperature of the generator is so reduced, that its exterior becomes covered with ice from the condensation and freezing of moisture from the surrounding air.

The last process to be mentioned is patented by Mr. Ruck, and is to be worked by "The New Gas Company, Limited." Superheated steam is passed over a mixture of coke and metallic iron at a high temperature. A mixture of hydrogen, carbonic oxide, and carbonic anhydride is thus obtained, which is called "heating gas," and is intended to be used for heating purposes without further treatment, except passing over oxide of iron to remove traces of sulphuretted hydrogen. In this state it is said to consist of about 58 per cent. of hydrogen, 30 per cent. of carbonic oxide, and 12 per cent. of carbonic anhydride. To convert it into illuminating gas it is made to bubble through light petroleum spirit of a specific gravity of about 0·680, in a similar manner to the "air gas."

This process has been advocated by some persons as utilizing what is called "the exhaustless store of heating power that lies ready to hand in water." But it will be clearly seen that this involves the same mistake as that in the first two processes which we have considered. For, although the hydrogen in the gas does come from the water introduced into the retort as steam, yet it is obtained at the expense of the coke and iron over which it passes. So that the heat is not derived from the water, but from the coke or iron; and the real question at issue is again, whether this is an economical method of obtaining heat from coal or coke.

It has been stated that the combustion of one ton of coke in the retorts, and of two tons externally in the furnace, will yield 133,000 cubic feet of gas, and that this will be increased in volume to 165,000 cubic feet by passing through the petroleum; the cost of the heating gas being estimated at 7*d.* per 1000 cubic feet, and of the illuminating variety 1*s.* 8*d.* In this estimate there is apparently no account taken of the cost of the iron oxidized (*i. e. consumed*) in the retorts, although this must be a point of some importance, especially as scrap iron is used, which is rather costly.

The four questions as to cost and storage of petroleum, uniformity of illuminating power, and practicability of distribution through pipes, all apply again here. It is true that certain advantages are claimed for this gas in regard to the last particular, but we fear these will not, for the most part, bear investigation. It is said that this product is a *true gas*, and that therefore it forms a more intimate union with the petroleum than air does. But it is evident that this is using the word "gas" ambiguously; for although air is not in the ordinary sense a *combustible* gas, yet it is quite as truly *a gas* as the mixture of hydrogen, carbonic oxide, and carbonic anhydride in question. The petroleum vapour forms precisely similar mixtures in both cases; and although the mixture would become homogeneous rather more rapidly in the "new gas" process than in the "air gas," yet the difference of time would be very slight, and, the mixture once made, the result would be as permanent in the one case as in the other. A real advantage in favour of the new gas is its low specific gravity—little more than half that of air—so that its passage through pipes would be effected with less mechanical difficulty.

On the other hand, we must point out two disadvantages. The first of these seems to be inseparable from the process, namely, the large percentage of carbonic oxide which the gas contains. It is a very serious matter to introduce into our dwelling-houses a gas containing 30 per cent. of so active and well known a poison as carbonic oxide. Of course, if we could be sure that it would all be burnt, no objection could be raised, but gas fittings are by no means always perfect, and serious escapes frequently occur. As this gas has decidedly less odour than common coal gas, the facility for detection in such cases would be proportionally diminished. The other disadvantage is the presence of so much as 12 per cent. of carbonic anhydride As this could be removed with little difficulty, we are rather surprised to see that the directors do not propose to do so; for it has a powerfully deteriorating effect upon the illuminating power. Mr. Barlow found that 1 per cent. of it in common coal gas caused a loss of 7 per cent. of light, and even if the New Gas Company is able by an increased quantity of petroleum to overcome this, it is likely that the removal of the carbonic anhydride would be much cheaper, and the purified gas would be less injurious to the atmosphere of the rooms in which it was burnt.

CHERRY-LAUREL WATER.*

BY M. LEGER.

The leaves of the cherry-laurel yield to distillation a volatile oil and prussic acid in variable proportions, dependent upon the time of year at which they are gathered. According to Brugnatelli, the most is obtained in the spring-time. Soubeiran, on the other hand, affirms that in the neighbourhood of Paris the leaves afford the richest yield in July and August. Garot states that in the month of April the leaves give, upon boiling them with water, a large quantity of vegetable wax and no volatile oil, whilst in August the contrary is the case. This observation the author has found to be completely erroneous, as he has obtained both products simultaneously at all seasons of the year. There being therefore considerable discrepancy between various authorities upon this subject, the author, in an investigation lasting more than a year, has sought to elucidate it, by ascertaining what period of the year corresponded with the largest quantity of hydrocyanic acid, leaving for future inquiry the estimation of the volatile oil. The method employed was that of Buignet.

The essence and the prussic acid, as has been shown by Lepage, preexist in the leaves of the cherry-laurel, being developed there during vegetation by the action of synaptase upon amygdalin, two substances which Robiquet had already found in almonds, and of which Wicke and Lepage had demonstrated the existence in the cherry-laurel. When, therefore, the leaves are distilled with water there is no chemical action produced, as in the case of almonds; the object of the distillation is simply to separate the products already elaborated by Nature. The author distilled each month 1 kilogram of leaves with sufficient water to obtain 1500 grams of product ('Codex'); the various distillates, containing all the essence and acid, were immediately titrated, and the following table indicates the results obtained during one year:—

January	76 milligrams.
February	96 „
March...	100 „

* Abstracted from the 'Répertoire de Pharmacie,' vol. i. new series, p. 369.

April	Old leaves	76 milligrams.
	Buds	100 „
May	Old leaves	44 „
	New leaves	110 „
June, Old and new leaves		84 „
July		125 „
August		116 „
September		110 „
October		106 „
November		100 „
December		66 „

The leaves were collected at the same period in every month from the same bushes, which were very vigorous, and had been grown near Paris under the best possible conditions, so that the numbers obtained are comparable with each other. The experiments being made at the end of each month, the figures indicate the maximum quantity of prussic acid produced during that lapse of time.

Examining attentively the preceding table, it will be remarked that the richness of the yield, instead of progressively increasing until the month of July, when it attains its maximum, presents in April and May a remarkable irregularity. In fact, the figures fall from 100 to 76; but, on the other hand, having gathered the buds which appear just then and distilled them, a distillate was obtained containing 100 milligrams of acid. The question arises, What is the origin of so enormous a quantity of acid in organs which have only been a fortnight in existence? It is not probable that the roots alone have contributed to its production: might it not be that the old leaves part with a portion of their elements to the new ones?

In May we see the same peculiarity renewed; the proportion of acid is lower in the old leaves and higher in the new ones, which are then half developed. In June a fresh anomaly presents itself; the proportion of 84 milligrams appears at first surprising, but this is explained if it be remembered that this product is obtained by distilling a mixture of equal parts of new and old leaves, and that the 84 milligrams expresses nearly the mean between the numbers 110 and 44 obtained in the preceding month. In July the hydrocyanic acid amounts to 125; from that time the proportion decreases, until at the end of December, after a cold of 20° C., it falls to 66.

These experiments show the extreme variability of cherry-laurel water, according as it is prepared at different periods of the year; they also explain the different results obtained with the similar doses, to remedy which inconvenience the 'Codex' prescribes a strength of 50 milligrams.

Cherry-laurel water, however, contains not only prussic acid in varying proportions, but also a volatile oil, which is a powerful poison, and of which the 'Codex' takes no account.

The titrated water does not remain long unaltered; it is known that it loses gradually part of its acid. To ascertain the rate and proportion of this loss, a portion of each monthly distillation was put into a well-filled glass-stoppered bottle, and examined after keeping for six months, with the following results:—

First titration. Immediately after distillation.	millig.	Second titration. After six months.	millig.
28 January, 1871	76	28 July, 1871	68
28 February	96	28 August	80
28 March	100	28 September	86
28 April (old leaves)	76	28 October	68
28 May (new leaves)	110	28 November	108
28 June	84	28 December	82
28 July	125	28 January, 1872	118
28 August	116	28 February	110
28 September	110	28 March	110
28 October	106	28 April	98
28 November	100	28 May	92
28 December	66	28 June	50

The loss of acid is much more considerable when the distilled water is kept in bottles stopped with cork and not full. In order to ascertain these alterations, water distilled in February, 1871, and then containing 96 milligrams of acid, was examined during fifteen consecutive months, with the following results:—

	millig.		millig.
March 28, 1871	86	November 28	74
April 28	84	December 28	72
May 28	80	January 28, 1872	72
June	80	February 28	72
July	80	March 28	72
August	76	April 28	72
September	74	May 28	72
October	74		

These figures show that from water kept in corked and only partially-filled bottles the loss of acid was at first very rapid, and afterwards became very slow, the strength remaining at 72 milligrams during six months.

NOTES ON THE CULTIVATION AND PREPARATION OF LACTUCARIUM.*

BY THOMAS FAIRGRIEVE.

Lactucarium—a substance allied to opium in appearance and in physical and physiological properties—is prepared from the milky juice of various species of *Lactuca*. It was introduced into the pharmacy of this country by Dr. Duncan, Professor of Materia Medica, Edinburgh, in the early part of this century; but it had been in use for some time previously in America, on the recommendation of Dr. Coxe, of Philadelphia. Professor Duncan employed the garden lettuce as his source of lactucarium, and his process of preparation was as follows:—When the plant reached the flowering period, a portion of the stalk was cut off, and the milky juice which exuded was permitted to harden in the sun. On the following day this hardened juice was secured by cutting a thin slice off the stalk, and to this fresh wound a further quantity of juice flowed and again hardened, and so the process continued from day to day till the plant was exhausted. The thin slices which bore the thickened juice were digested in spirit of wine till a solution of a certain degree of concentration was obtained, which was then evaporated to a thick extract.

Among later local cultivators were the late Dr. Young of Canonmills, and Mr. John Duncan, of Duncan, Flockhart, and Co., who used the wild lettuce, *Lactuca virosa*, as the source from which they drew lactucarium. This plant is still found sparingly on Arthur's Seat, near Duddingston, and is abundant on the rocks of Stirling castle and elsewhere.

For the last sixteen years I have had from one to two acres under cultivation for the preparation of lactucarium. The plant employed is *Lactuca virosa*, var. *montana*, the seeds being sown in autumn, and the young plants planted out early in the following spring. The plant, under favourable circumstances, grows to a height of from 10

* 'Transactions and Proceedings of the Botanical Society of Edinburgh,' vol. xi. part 2.

to 12 feet, with a stalk of from 1 to $1\frac{1}{2}$ inch in diameter. The flowers appear about the end of July and continue throughout August. The capitulum only expands during sunshine, and as when in fruit the least breath of air wafts away the pappose achenes, the collection of seed is a matter of constant anxiety and attention. In one wet and sunless autumn I was unable to secure a single seed, none having ripened.

In favourable seasons the collection of the juice may commence about the middle of July, but it more commonly is the beginning of August before anything is done. The plants are then 3 to 5 feet high, with thick succulent stalks, and the flower-buds just appearing. The collectors proceed over the field, cutting the head of each stalk, and scraping the flow of juice into their vessels—one person cutting being followed by two collecting the juice. This process they repeat six or seven times a day, each time a new cut being made a little lower down the stalk. The period of collection generally lasts from six weeks to two months, closing usually about the third week in September; but for the last two years I collected up to the end of September. Towards the close of the season the plants become so woody and hard that it is with great difficulty new cuts can be made for the flow of the juice. About this time the frosty nights seriously influence the flow of the juice, and determine the cessation of the year's collection. The juice after frost usually becomes of a watery consistence, and when it remains thick, as it sometimes does, it is so deteriorated in quality as to be worthless.

The amount collected during the day is by the evening changed into a thick viscous mass. It is then turned out of the vessels, divided into pieces suitable for drying, and spread out to the influence of a fire, as the sun heat in our climate is not sufficiently strong for the drying process. The time occupied in drying varies according to the heat applied, but I obtain the best results in about five days.

As regards the yield of lactucarium much depends upon the season. In rainy weather no collection can be made; moist warm weather causes the greatest flow of juice, while in dry, hot seasons the stalks are slender, the yield of juice small, but usually of very superior quality. So much does the yield vary that in some seasons the collecting vessel of 8 or 9 oz. capacity is not more than half filled daily, and in other years three such measures-full are gathered each day. Generally six such measures, equal to a little more than 4 lb. of thickened juice, yield 1 lb. of solid lactucarium. On an average I calculate each plant yields 40 or 50 grains of lactucarium, but this estimate includes plants of all descriptions. Were the really healthy and productive plants only taken into account, the average yield would be much greater.

A very small quantity of lactucarium is now used in the medical practice of this country, and I do not know the source of the demand which I am annually called on to supply.

For many reasons lactucarium cultivation is a precarious industry. Besides its dependence on rainy or dry weather, wind is fatal to the plants in all stages after the stems have shot up. From their first appearance, the plants are also peculiarly liable to be attacked at the root by a species of grub, which causes great havoc.

GUM ARABIC.*

BY DR. GRAEGER.

Formerly gum arabic was generally considered to be a vegetable principle, similar to sugar and starch, and it is not many years since Fremy for the first time called the attention of chemists to the special relations which existed between the organic substance of the gum and the mineral elements or residues of its ash. The researches of Fremy relative to this question not being generally known, a brief *résumé* of them may be given here.

Just as the part played by its inorganic elements is not yet exactly defined, so there exists little precise information respecting the physiological phenomena attending the formation of the gum itself. It is known that the abnormal formation of gum in certain trees takes place at certain periods, at the same time as that of the ligneous parts and at their expense; but it is not known to the transformation of what matter the production of gum is due. One thing is surprising that a neutral substance like it should proceed from an acid fruit.

It had previously been remarked that under certain circumstances, gum submitted to the action of concentrated sulphuric acid was changed into a new body entirely insoluble in water. This takes place when an aqueous solution of gum, so concentrated that it will scarcely run, is poured into a suitable vessel containing strong sulphuric acid,—care being taken not to mix the two liquids,—and left in contact for several hours. The gum is changed into a kind of membrane that is insoluble even in boiling water. If water and a slight quantity of some alkali be added, and the mixture slightly heated, this substance dissolves into a clear liquid, from which it is not precipitated by an acid, showing that it has undergone a new modification by which it has again become soluble. The insoluble membranous substance was named by Fremy metagummic acid; the soluble modification of it as changed by alkalies has received the name of gummic acid. Ordinary gum arabic then contains a substance insoluble in water,—metagummic acid,—which like œnanthic and lactic acids loses its insolubility by the action of alkalies, and is transformed into gummic acid, combining like them with the alkali to form a true salt.

These data of Fremy have to the present time neither been contradicted nor confirmed; they have been little noticed, although there can be no doubt that they would be of great importance to vegetable physiology.

In taking up the investigation the author proposed first to determine with precision the bases combined with the gummic acid, and also to find a method of preparing pure metagummic acid, that employed by Fremy not appearing to be sufficiently practical, since it is always difficult to free the viscous mass from the last traces of sulphate of lime and sulphuric acid.

Analysis was made of some picked gum, clear and free from powder. Gum dried in the air was found to contain 11·6 per cent. of water, the composition being—

Organic matter	85·25
Ash	3·15
Water	11·60

The composition of anhydrous gum was—

Ash	3·563
Organic matter	96·437

The ash was analysed, with the following result:—

	I.	II.	III.
Lime	46·70	54·63	44·53
Magnesia	12·61	14·38	26·18
Potash	40·69	30·99	29·29

These constituents, calculated as potash, are equal to the following amounts of that base—

I.	II.	III.
128·27	134·10	122·91

Adopting 3·563 per cent. as the average quantity of ash contained in dried gum, it appears that 96·437 parts of organic matter were combined with an average of 4·45 parts of potash or 2·644 parts of lime.

It is not surprising, says Fremy, that gum, which is a salt of lime, contains only 3 per cent. of that base. Gummic acid has a very feeble capacity of saturation, which is generally the case with all the gelatinous acids in proportion as they approach organic vegetable products; their capacity of saturation augmenting in proportion as, transformed by chemical means, they depart from their primitive organic form.

The numbers given above coincide with the results of a great number of experiments, showing that the propor-

* 'Neues Jahrbuch für Pharmacie,' xxxviii. 129.

tions between the bases of the gum and the organic matter are constant, and are not dependent upon circumstances by which the quantity of lime might be augmented or decreased.

Preparation and Properties of Metagummic Acid.—One principal reason why metagummic acid so long remained unknown was, that it is not produced except under special circumstances. Gélis had, it is true, shown that gum became insoluble in water after exposure during several hours to a temperature of 125° C., and that it again became soluble if it were boiled in water a sufficiently long time. It was also known that in heating a concentrated solution of gum with strong sulphuric acid, besides sulphate of lime, an insoluble viscous body was precipitated. But the examination of the bodies so obtained could not be carried further, since through the quantity of lime present in the first it became too soluble when experimented on, and the second could not be freed from the sulphate of lime and the sulphuric acid. The plan adopted by the author is to pour a cooled mixture of 50 c. c. of 92° alcohol, 10 c. c. of water, and 5 c. c. of strong sulphuric acid, upon 25 grams of perfectly pure gum, and allow them to remain together for twenty-four hours, stirring frequently. The whole is then thrown upon a filter in connection with an air-pump, and the undissolved portion is washed several times with alcohol. It is then placed in a vessel nearly full of distilled water, shaken and washed by decantation until it gives no reaction either of lime or of sulphuric acid. The metagummic acid has then the appearance of a slightly opaline, colourless, translucent jelly, of which the volume is ten or twelve times that of the gum employed to produce it. In order to dry it, it is shaken in a linen bag to remove moisture; then placed in a vessel and alcohol poured upon it. This causes it to contract a little; the supernatant liquor is removed, and fresh alcohol poured on. It becomes pulverulent, is thrown on a filter, and, when drained, the powder is pressed between linen and left to dry in the air, which it does in a few minutes.

Metagummic acid so dried resembles exactly white gum arabic, with a slight yellow tint; reduced to a fine powder it is perfectly white. It has neither odour nor taste, but it exercises a decided acid reaction upon blue litmus paper. It will absorb 15 per cent. of water from the air, but without becoming humid. It is not soluble in cold water,—which causes it to swell into a voluminous gelatine,—or in boiling water. It dissolves, however, in dilute alkaline solutions, when the alkali does not exceed the quantity necessary to dissolve it. When there is excess of alkali the solution acquires a colour varying from yellow to dark brown, in consequence of the decomposition that takes place; metagummic acid is thereby changed into gummic acid, and in this manner salts of potash, soda, magnesia, baryta, etc., may be obtained, which all form colourless and mucilaginous solutions like gum. Acids do not precipitate metagummic acid from these solutions, but if they are evaporated to dryness and treated as before with alcohol and sulphuric acid, metagummic acid is reproduced.

The author also obtained the metagummic salts of copper and of zinc: the first is insoluble and forms a pale blue precipitate; the zinc salt is slightly soluble.

Fremy found the elementary composition of metagummic acid to be—

	I.	II.	III.
Carbon	41·10	40·82	40·96
Hydrogen	5·93	6·16	6·01
Oxygen	52·97	53·08	53·03

According to this its formula would be $C_7H_6O_7$, approaching the formula of metapectic acid, $C_8H_5O_7$. Hence it would appear to resemble the pectic or gelatinous bodies, rendering the hypothesis probable that gum is due to phenomena analogous to those which give rise to the pectic bodies. The resemblance would be still more complete if future research should discover in plants a substance analogous to the pectones, of which gum would be a product of transformation.

It will be seen from the foregoing that gum arabic cannot be considered an immediate vegetable principle, but rather a mixture of the metagummates of potash, lime, and magnesia. Experiment has not yet shown whether the proportions of these salts in gums are always the same; but it is probable that they are very variable, for there is no reason why these several bases should not substitute one another, according to the nature of the soil. The substitution would have no effect upon the appearance of the gum or its properties; the various metagummates all forming colourless solutions of the same consistence, except the ammoniacal salt, its solution being more liquid than the others. All these bases are chemically combined with the gummic acid.

Preparation of Gummic Acid.—For this purpose pure metagummic acid was dissolved in an exactly-measured quantity of lime or baryta water. A sufficient quantity of oxalic or sulphuric acid—according as lime or baryta was used—was added to neutralize the alkali. As the milky liquid so produced could not be cleared by filtration, it was allowed to stand some time. In this manner a solution of gummic acid was obtained, still a little opaline, but perfectly colourless. Evaporated to dryness it yielded a transparent, hard, brittle substance, an aqueous solution of which was strongly acid, and less viscous than a solution of an equal quantity of ordinary gum. Its reactions with alkalies and their salts were the same as those of metagummic acid.

NOTE ON ACONITE ROOT.*

BY EDWARD R. SQUIBB, M.D.

There is good reason to believe that the appreciation of the value of preparations of aconite root in therapeutics, and the increasing use of these medicines, are hindered by the want of uniformity in quality of the root as met with in the markets, and the custom of pharmacists generally of buying by appearance, or what is still worse, buying in powder. The writer has been for some years past almost constantly in search of this drug of proper quality for medicinal use, and has been frequently out of it and its preparations through inability to find it in the markets of the seaport cities of this country, and has even failed to get it in London. Yet if quality be not considered or not tested, there are few drugs more easily or more cheaply attainable at all times. From the large brown root, which rarely is, though often is called, "English," to the small black root commonly known as "German," the markets are always abundantly supplied with root of various sizes and shades of colour. The general appearance is almost always good, and the root clean and sound, and even on fracture, the substance of the root appears to be of fair quality. Upon testing, however, it will often be found that not more than four or five roots in ten have any medicinal activity, and these only in feeble degree. Occasionally parcels will be met with in which every root possesses the desired activity, at least in some notable degree. Thus it becomes necessary to decide upon some arbitrary standard of strength to govern the selection, and in the present state of the markets this must not be set too high, if anything like a uniform supply of fresh preparations is to be kept up. The arbitrary rule adopted by the writer many years ago was not to buy any parcel from which six roots out of ten did not yield a fair degree of medicinal activity, and to get as much above this as possible. Within the past two years the quality in the United States market has improved, and now the arbitrary rule has been changed, and eight roots out of ten from an ordinary handful sample is the

* From the 'Proceedings of the American Pharmaceutical Association,' 1872.

standard. If pharmacists generally would apply some such rule, we would soon have a market supplied with a much better and more uniform quality; and it is the first object of this note to urge pharmacists to a more careful discrimination, since upon this all uniformity and efficiency in medicinal use of the drug must be based. The root should never be bought in powder, because in the present state of pharmacy quantitative testing would not be applied, and because a proportion of even three or four good roots in ten gives to the powder an apparent activity which is deceptive when judged by qualitative testing.

The causes of this general bad quality of aconite root are, so far as this writer is concerned, unknown; yet two or three prominent causes may be reasonably inferred, and perhaps should be mentioned, in order that the reader may judge of their value.

One of the most probable causes of this condition of the market is that terrible screw of price from which it seems almost impossible to escape. The present ruling price of aconite root by the bale in this market varies between fourteen and twenty cents per pound, according to the appearance. Now when it is remembered that this includes two or three profits or commissions, the freight and charges inseparable from a three thousand miles' transit, to say nothing of the time, capital, and risk involved, it will be seen that the price realized by those who collect and dry the drug for the market must be very small indeed, and totally insufficient to pay for the requisite knowledge, care, and skill, since two pounds or more of fresh root are required to yield one pound of dry. Hence, in order to be sold at so low a price, it may be and probably is, collected by ignorant women and children, who take it at any season of the year in which they can find it, leave as much of the stalk on the root as they can, dry it in the easiest and most rapid way possible, and then hurry it into the market. Occasionally parcels will be found within this range of prices which are of good quality, but for anything like uniformity in good quality, the common drug market and its prices must be abandoned for special importations to order, at two or three times the common price, and under strict conditions as to quality.

From all this it would follow that if buyers would look carefully to quality so as to recognize it when they get it, and then be willing to pay for it in proportion to its intrinsic value, the markets would respond to their knowledge and true interests in the character of supplies. It is the aggregate buyer who makes the aggregate market, and if so, the pharmacist has but himself to blame for the condition of his market. No reasonable probability should escape his thoughtful consideration, and his knowledge and skill should keep pace with the artistic refinements in cunning and deception.

Many parcels of aconite root seen within the past few years, by their partial or entire tastelessness, lead directly to the suspicion that they have been partially or entirely exhausted, and afterwards dried and put into the market. There is no doubting the identity of the root, and yet there is no season of the year, age of the plant, nor probable mode of drying, which would yield it totally insipid and devoid of activity, as more than half the roots of some parcels prove to be.

It is now generally believed that the growth of microscopic plants and animals destroys the active principles of many substances, and the published results with solutions of salts of atropia seem to establish the fact for belladonna. If this be true of aconite, then mouldiness would be a cause of inertness, as it is frequently seen mouldy on arriving here, though the appearance of mould soon disappears under the skilful hands of an energetic salesman.

Aconite is a prominent illustration of the general practical fact, that when the drug can be had of good uniform quality, and the preparations from it are made with care and skill, the alkaloid from it is not only a useless but a dangerous refinement, and becomes, through variation of species or variation of process of manufacture, as deficient in uniformity as the root itself is in commerce.

Aconite leaf and its preparations are comparatively feeble, and the natural and accidental causes of want of uniformity of strength are more numerous, and less susceptible of useful control. The leaf might therefore with advantage be omitted from the materia medica.

It now only remains to be shown that there is a simple, practical, easy, and effectual way of testing aconite root by tasting it.

If a root be broken across, near the middle, and a piece the size of half a pin's head be bitten off from the edge of one of the fragments at the place of fracture; and if this piece be chewed between the front incisor teeth, in contact with the tip of the tongue, until it is converted into a pasty or liquid mass, and be then discharged from the mouth, and the parts with which it has been in contact be cleansed as thoroughly as possible by the natural flow of saliva which is produced, the testing process for the particular root in question is finished. If the root be inert, the fragment is nearly or quite tasteless, and no impression remains upon the tongue or lips after the parts are cleansed by the saliva. But if the root be a thoroughly good one, the taste is at once moderately bitter, the bitterness being in a great degree proportionate to the activity of the root.

The bitterness is, however, to a great extent lost when the mouth is cleansed, and there is then an interval of a minute or more of tastelessness. Soon, however, the peculiar and perfectly characteristic aconite impression comes gradually on, beginning with a sense of tingling, which soon becomes a pricking sensation, which passes into a local numbness, which, once felt, cannot be mistaken. This is not taste, but rather a paralysis of all sensation in the parts, and it is quite persistent, continuing from one to three hours, in proportion to the strength of the root and the quantity taken for the trial. It is not painful nor even annoying, nor is it hurtful when properly managed, but in using the test the virulently poisonous character of the drug should never be forgotten.

Both the taste and the aconite impression or effect will vary in intensity or degree in various roots, but no parcel of the root should be accepted, or be considered as officinal, in which more than two or three roots in ten fail to give the aconite impression or numbness.

If a tasted root fails to give the impression within ten or fifteen minutes, its parts should be laid off by themselves upon the sample paper, and another root may be at once taken. But if the aconite impression be obtained, this must be allowed to disappear entirely before another root is tasted, and the fragments of the good root must be laid together on another part of the sample paper. Thus in testing a good sample of the root, not more than three or four pieces can be tried in any one day, and about three days will be required to determine the quality of a sample of good root. But the testing, of course, is not incompatible with the ordinary duties of the pharmacist, and therefore involves no loss of time. In practice, the time mentioned as requisite to test a given sample is almost always exceeded, because in the routine of a busy day the subject is often forgotten for a time, so that but one or two pieces are tried in a day.

THE ROYAL GARDENS AT KEW.*

During the year 1872 the Royal Gardens at Kew were visited by 553,249 persons, an increase of a little more than 6000 over the numbers in 1871. Of this number

* From the 'Report on the Progress and Condition of the Royal Gardens at Kew, during the year 1872,' addressed to the First Commissioner of Works by the Director, Dr. J. D. Hooker.

274,250 persons visited the Gardens on Sundays, and 278,999 on week-days. The greatest monthly attendance (106,236) was in May; the greatest week-day attendance (37,795) was on Whit-Monday, May 20; the greatest Sunday attendance (18,791) was on August 18. On two occasions the daily attendance was only 7. The numbers of each class of visitors were much the same as in last year, except that there was a greater attendance of professional gardeners, an increase attributable chiefly to the greater facilities for naming the ferns and ornamental herbaceous plants. Increased interest has also been shown in the Arboretum as it progresses towards completion, and especially in the collections of deciduous trees, the planting of which has in this country, during the last quarter of a century, been to a very great extent superseded by that of conifers.

The degree to which the displacement of deciduous trees and shrubs by conifers has extended in England is best illustrated by a comparison of both public and private parks planted during the last century and the beginning of this, with those more recently laid out, and an examination of nurserymen's catalogues gives the same result.

Thus, in the Kew grounds, as at those of Sion House, Bicton, etc., very many kinds of South European, Western Asiatic, and American timber trees, besides numbers of shrubs, still survive, few or none of which are now planted, or are to be had in English nurseries; and even twenty-five years ago, when the Kew Arboretum was commenced, various American maples, oaks, poplars, limes, etc., were procured in England, for which resort must now be had to continental nurserymen or to America.

The demand for deciduous trees and shrubs is rapidly reviving, and over and above the interest of this department to botanists, Dr. Hooker states that he has every reason to believe that the named collection in the Kew Arboretum will soon be as much frequented by planters and landscape gardeners as the Botanic Garden and plant-houses now are by amateurs and professional gardeners.

The interest taken by the principal nurserymen, both at home and abroad, in this, which was once an eminently national branch of gardening, is best evidenced by the liberality with which the most celebrated firms have for some years past presented to the Kew Arboretum many rare shrubs and trees; amongst whom the foremost have been Messrs. Booth of Hamburgh, Van Volxem of Brussels, Veitch, Lucombe and Pince, Lee, Dickson and Turnbull, Paul of Waltham Cross, and Smith of Worcester.

Botanic Gardens.—No change of importance has been introduced into this department. The demand for tropical economic plants from various Governmental establishments increases so fast, that more accommodation for propagating them will soon be required.

Named ornamental plants selected from the herbaceous grounds have been introduced along the shrubberies. The American garden at the back of the Palm House has been in great part renovated. A named collection of ivies has been placed along the Rose walk, the species being trained up tree stumps eight feet high, which alternate with the pillar-roses.

Large beds of mixed shrubs have been introduced opposite the Museum of Woods, and along both sides of the Pagoda vista, within the garden fence.

A great improvement has been effected by the Works department in the painting of the plant-houses, both as regards the durability of the composition and the colours used. The introduction of a little blue on the girders of the long Succulent House (200 ft. long), and the Temperate House in the pleasure grounds, has been much approved. The dark green glass with which the fern-houses have been glazed has answered well, and very numerous inquiries have been made respecting its use in this establishment. Dr. Hooker has no reason to suppose that it has any specific effect whatever on the plants grown under it, beyond that, by partially intercepting the sun's heat-rays, it prevents scorching of the plants and drying up of the houses, whence its use in doing away with the necessity for expensive shading during a great part of the year, and in days of alternate sun and cloud, is very manifest, as also in maintaining a more uniform temperature and humidity. The cultivation of ferns and orchids in houses large enough to accommodate a stream of several thousand visitors in the afternoons of summer and autumn must always be a difficult problem, owing to the inevitable draughts and consequent drought that attend their transit, and there is no question that green glass, under such circumstances, is, whether in a horticultural or economic point of view, decidedly advantageous. In small lean-to fern-houses, built against a north wall (the best of all arrangements for growth), and in which the doors are habitually kept closed, there is probably no advantage in using green glass. The Director is, however, inclined to think that certain insect pests are much less troublesome in houses thus glazed.

The Arboretum.—Throughout the winter and spring months nearly the whole staff of the establishment has been employed in these grounds, in the formation of new walks, the rearrangement of the collections, and replanting. A new entrance has been made at the further extremity of the grounds for the accommodation of visitors arriving from Isleworth and Spring Grove by the Isleworth ferry (half a mile further up the river than the Brentford entrance), consisting of a drawbridge over the moat by the river.

The acacias, robinias, gleditschias, etc., which were scattered over about five acres of ground, have been arranged in a broad avenue, 250 yards long, leading from the old Arch to the Pagoda, the trees of the Old World being planted on one side, and those of the New World on the other.

The remaining *Leguminosæ*, which occupy beds in this ground, are, owing to the excessive poverty of the soil, almost worn out. These will be in part renewed, and the rest be classified and replanted. The named collection of alders and willows has been taken to the banks of the lake. The named collection of ashes has been planted along the Stafford walk (skirting the Botanic Garden from the Sion vista to the Cedar vista), and extends for 250 yards: here also the European and American trees are planted on opposite sides of the path, to facilitate reference.

The rose garden on the slope of the mound on which the King William Temple stands is completed, and filled with a collection of 500 of the best kinds, presented by Mr. William Paul, of Waltham Cross; to whose liberality this establishment is indebted for various other gifts.

A great deal remains to be done before the Arboretum is completed. The rearrangement of the collection of oaks will be begun forthwith, and will be followed by that of the beeches, chesnuts, hornbeams, ostryas, planes, etc., which will occupy a belt parallel to the Sion vista on the side opposite to the lake.

The birches will be planted along the path leading from the Brentford ferry gate to the Botanic Garden, the elms by that running from the Brentford gate to the Sion vista, parallel to the river, and the poplars by the one leading from the Botanic Garden to the Hollow walk; celtis, morus, and their allies will border the walk skirting the Botanic Garden on the south. The limes, etc., will be planted along the path leading from the Botanic Garden to the Douglas Spar mound. The magnolias will occupy the S.E. angle of the grounds near the unfinished garden of berberis, clematis, etc., in the gravel pit, to the north of the Douglas Spar mound.

The *Pinetum*, which is by far the most important and extensive collection in the grounds, is now all but comcompleted. The genera abies, picea, and a few others, which had previously been planted along the new walk on the south side of the lake, and extended for 160 yards on both sides of the path, are now succeeded by the collection of pinus proper, which extends from the termination of abies to the Isleworth entrance (340 yards), and thence along the lined out path (100 yards), that leads to the Sion vista. The collection of pinus proper also extends a little way up the Pagoda avenue, and 100 yards up the new path skirting the Queen's Cottage grounds, where it is succeeded by the collection of yews, cypresses, retinosporas, taxodiums, thujas, and smaller American and Japanese genera. The juniper collection is planted on either side of an avenue leading through the woods from the lake to the King William Temple, and extends for 200 yards.

The classified and named pinetum thus extends along nearly 2000 yards of path and avenue, representing double that length, or two and a quarter miles of made soil, beds, and plantations, except where interrupted by old trees. The plants are throughout so arranged that the Old World species are as far as possible placed opposite to the American species of the same genera, and there are on the average 3–12 specimens of each species or conspicuous varity, placed in groups. The number of specimens is about 1200, all correctly named, with the exception of some doubtful ones. Almost every species that can be grown in the open air in this country is represented. Very few have been bought, the majority being plants procured by exchange and correspondence with different parts of the world, and through the liberality of the various eminent nurserymen whose donations are mentioned in last year's report.

Whenever possible, the specimens in the old pinetum of the Pleasure Grounds have been transplanted to this, in most cases with apparent success, but of this there is no assurance till the spring is over. The specimen pines in the Botanic Garden have not been removed.

Method of Ticketing in the Arboretum.—The labour and expense involved in procuring ground tallies for such a large collection are great, and the subject is full of difficulties. The tallies should be so firmly planted in the ground as not to be easily removed—so strong as to resist the blow of the butt end of a scythe,—so legible as to be clearly read, and, indeed, to attract attention at five paces' distance, and should last many years without repainting. Maw's Parian tallies are imperishable, and by far the neatest, but they are shipped by a scythe blow. Cast-iron tallies, well smoothed, and painted black on a white ground, if well done, should last from eight to ten years at least; a great number of these are in use in the arboretum; the best have an oblong top or face of 5 × 4 inches, and a leg 10 inches long. The face is perpendicular (not slanting backwards from the leg), and the top edge is sharp, to prevent birds sitting on it and defiling the writing. Experiments are being made of coating the paint with paraffin, the results of which will be reported hereafter. A trial is being made of slate, teak, and Australian gum-tree wood tallies. Hanging wooden tallies are very durable, but are not always easily discovered on the trees, and from hanging obliquely are pulled aside to be read, and hence detached by visitors, who afterwards simply fling them on the ground. They should be of a light wood (good deal answers well), hung with well tarred twine or strips of oiled hide. Iron hanging labels, fixed with wire, are very objectionable, their weight and motion in the wind soon breaking the wire.

The writing on the tallies is confined to the vernacular name (given only when in common use), the Latin name with its author's initials, and the native country. Synonyms are added only when the plant is equally well or better known under such. English names not in general use, and especially such as are formed by translating the Latin one, are useless and pedantic. In the case of varieties, the varietal name follows the specific.

Interchange of Living Plants and Seeds.—The receipts during the year have been 2700 seed packets, and 11,240 plants of all kinds. This includes a very large number of young trees, shrubs, and evergreens, procured by exchange or purchase, upwards of 4000 presented by Messrs. Lucombe and Pince of Exeter, and 1000 presented by Messrs. Dickson and Turnbull of Perth. Mr. Booth of Hamburgh has again presented to the arboretum no less than 800 named species and varieties, and Messrs. Makoy of Liége upwards of 100 selected species. A very valuable selection of authentically named East Siberian, Japanese, and Amoor River trees and shrubs has been presented by the Imperial Garden of St. Petersburgh under Dr. Regel's direction. Besides the above, the following donations require especial acknowledgments:—A set of British willows from the Rev. J. E. Leefe, M.A., an eminent authority on this genus; magnificent trunks (12 feet high) of cycas and tree-ferns from Australia by Baron von Müller of Melbourne; a very fine collection of Brazilian tree-ferns and other plants, collected by himself, from the Rev. T. Preston, M.A., of Marlborough College; a set of rare palms from the Royal Botanic Garden of Herrenhausen (Hanover), under the direction of Herr Wendland; and a fine set of the larger ferns of South Africa from Mr. McGibbon, Superintendent of the Cape Town Botanic Garden.

During the autumn the Curator visited Belgium for the purpose of inspecting the magnificent collections of tropical plants cultivated there, and especially that of M. Linden of Brussels, who presented on the occasion to the Botanic Gardens of Kew a collection of 400 interesting species, many of them not previously in cultivation in England; and that of Messrs. Van Houtte of Ghent, to whose liberality on the same occasion the Royal Gardens are also greatly indebted.

Of seed packets and living plants sent out from Kew, there have been during the year 7000 of the former, and 9000 of the latter; Jamaica still claiming the largest share of contributions.

A further selection of plants has been sent to the Jardin des Plantes, Paris, to replace the losses occasioned by the siege; and large collections have been sent to the Governments of Bermuda, Gibraltar, Hong Kong, Trinidad, Barbados, Natal, India, and all the Australian colonies.

Instructions have been received to introduce the teak into Jamaica, and the West African (Liberian) Coffee into Ceylon, where the ravages of the coffee blight, a minute fungus (*Hemileia vastatrix*), are still very serious.

The cultivation of tea in Ceylon (upon which a report was called for from Kew a few years ago) is successfully established, and the quality pronounced satisfactory. The cinchona continues to flourish in the island, and the bark has been pronounced of the best quality. The Director of the Botanic Garden there is actively promoting the cultivation of chocolate, for which the climate of the island is admirably suited.

A skilful superintendent (trained at the Glasnevin Botanic Garden) has been sent out from Kew to the Botanic Garden of Natal, and has taken with him a large collection of economic plants. A gardener has been sent to the Embassy Garden at Constantinople, and another as Superintendent of the Agri-horticultural Society's Garden at Calcutta.

Under instructions from the Secretary of State for the Colonies a skilled propagator has been sent to superintend the extension of forest plantations in the Island of Mauritius. Others have been selected for the tea and cotton plantations in India.

Dr. Henderson, of the Indian Medical Service, after devoting a year to the study of his Turkestan collections at Kew, has been appointed *locum tenens* at the Royal Botanic Gardens, Calcutta, during the absence in Europe on sick leave of Dr. King, the present superintendent.

The yield of cinchona in the Indian plantations is already very large, and the bark has fetched good prices in the English market; the manufacture of quinine has been established in the Nilghiri plantations, and will shortly be commenced in the Sikkim Himalaya.

The papers respecting the opium poppy disease in India have been transmitted to Kew from the local government to be reported on, as have those on the ravages of the vine pest, *Phylloxera vastatrix*, from various continental states, by the Secretary of State for Foreign Affairs. This is a subject of very grave import, even to this country, the disease being reported as existing in various parts of England, and quite lately in the neighbourhood of London.

Samples of excellent cigars have been sent from Jamaica by Sir J. P. Grant, which prove that this island ought to rival Cuba in respect of this produce. It cannot be too often and too persistently repeated, that notwithstanding the immense possessions of Great Britain in the East and West Indies, no tobacco of any consequence is imported from either country, except from the comparatively small Spanish territories of Manila in the Old World and Havannah in the New.

Museums.—The principal acquisitions have been magnificent slabs of Deodar and Himalayan cypress (*Cupressus torulosa*) from the largest trees in the North-western Himalaya, from Major Pearson.

From the Royal Horticultural Society a valuable collection of Mexican pine-cones, models of Indian fruits and of fungi, a large slab of *Pinus lambertiana*, etc. A collection of 500 Java woods, from Dr. Scheffer of the Botanic Garden at Batavia; and a very fine collection of Central African vegetable products, from Dr. Schweinfurth, the celebrated traveller.

Amongst the other donations to the museum may be mentioned specimens of coorongite from South Australia (C. Drury, Fortnum); portion of stem of *Fraxinus Ornus*, with incisions made for the exudation of the manna; also joint of *Opuntia*, used for receiving the manna as it flows from the trunk; also a specimen of pachyma (D. Hanbury); portions of plant of *Euphorbia resinifera*, yielding gum euphorbium; also portions of plants of the true gum arabic yielding acacia, from Ait Aatab; and specimens and trunk of arar (*Callitris quadrivalvis*) (G. P. Hunot, Vice-Consul at Mogadore); series of leaf skeletons, prepared to show the ready separation of the wood and bast elements of the vascular bundles (Herr H. Lindemuth); specimens of lichen brandy manufactured in Sweden from *Cladonia rangiferina*; also specimens of cudbear, and woollen articles dyed with lichen dyes (Dr. Lauder Lindsay); samples of varieties of peppermint grown at Mitcham (Dr. Piesse).

Herbarium.—The accessions to the herbarium are of exceptional importance as regards novelties. The number of specimens acquired during 1872 has been about 17,500, of which 1500 were purchased, and the rest procured by gift or exchange. Among the most valuable presentations are the Rev. C. New's plants, collected on the Alpine zone of Kilima-njaro, the only hitherto visited snow-clad mountain in equatorial Africa, which possesses a remarkable interest, as the Flora of the Alpine zone of Africa was previously wholly unknown. A notice of it is being prepared for immediate publication. A fine collection of 2000 Brazilian plants from Mr. Glaziou, director of public parks, etc., at Rio de Janeiro. A beautiful collection of Appalachian mosses has been received with many other plants from Dr. Gray, of Cambridge, U.S., and of Mexican and New Caledonian plants from the museum of the Jardin des Plantes, Paris. The very valuable herbarium of Dr. Rottler, made by himself and the early missionaries in India, has been presented by the authorities of King's College;—as containing the types of many species imperfectly described by the first Indian botanists, and representing the state of the botany of the Peninsula at the beginning of the century, it is of great interest and importance both in a scientific and historical point of view.

A beautiful collection of Burmese orchids has been presented by the Rev. C. Parish. Dr. Brandis, F.L.S., Conservator of Forests for India, has placed his herbarium, formed in many parts of India, at the disposal of this establishment, to be selected from; together with a collection of Tibetan plants, made by the Rev. Mr. Heyde. Mr. Kurz, Curator of the Herbarium of the Calcutta Botanic Gardens, has transmitted large Burmese collections made during a late mission to that country.

For novelty as well as interest no contributions are of greater value than Beccari's Bornean plants, amounting to 1850 species, communicated by Professor Parlatore, of Florence; M. Maximowicz's Japan plants, a splendid series; Dr. Henderson's collections, made during Forsyth's mission to Yarkand; and Dr. J. Anderson's, made during the expedition to Yunan, the botany of the two latter countries having previously been wholly unknown to science.

Library.—By order of His Grace the Secretary of State for India, a complete set of the Trigonometric Survey, Revenue, and other maps of India, consisting of 174 sheets, mounted and enclosed in lettered cases, has been presented to this establishment. This is of the utmost value in reference not only to the vast Indian herbarium now collected at Kew, but to the agricultural statistics, and distribution of Indian forests, and many other matters which engage the attention of the Indian botanists habitually working here, whether in the preparation of floras, or of reports on botanical, agricultural, and forest subjects, for the supreme and local governments of India.

The classified collection of drawings of plants has been largely increased by donations, including a valuable set of drawings of Burmese orchids from the Rev. C. Parish. The collection is of great value for facilitating the naming of the living plants in the garden, and those sent by horticulturists, which arrive in large numbers, throughout the summer months especially.

Publications.—This portion of the work done at Kew is liable to be lost sight of by the general public in view of the more apparent value of the ornamental and economic uses of the gardens. But the list of works issued more or less officially during the past year is a considerable one.

The sixth volume of the 'Flora Australiensis,' prepared by Mr. Bentham and Baron von Müller, has been published under the authority of the Australian Government.

The first part of the 'Flora of British India' has been published under the authority of the Secretary of State for India in Council, and the second part is being printed.

The 'Forest Flora of North-West India,' by Drs. Brandis and J. L. Stewart, to be published under the authority of the Secretary of State for India, is nearly completed.

The 'Flora of the South African Colonies,' in continuation of the unfinished 'Cape Flora' of the late Dr Harvey and Dr. Sonder, has been authorized by the Government of those colonies, and is in preparation by Professor Thiselton Dyer.

The continuation of Von Martius' 'Flora of Brazil,' published under the auspices of the Emperor of Brazil, is being in part executed at the Kew Herbarium, by Mr. Bentham, Dr. Masters, Dr. Kanitz, Mr. Baker, Mr. A. W. Bennett, and others.

Mr. Hobkirk has been preparing a 'Synopsis of the British Mosses,' which is now published.

Col. Grant is now continuing his account of the plants collected by Captain Speke and himself in Central Africa and deposited at Kew; the first part of which has been published in the 'Linnean Transactions.'

Mr. W. B. Hemsley has published his manual of hardy garden plants.

The fifth part of the 'Icones Plantarum' (devoted to the illustration of new and little-known plants contributed to the Herbarium) has been published, together with the 98th vol. of the 'Botanical Magazine,' with plates of rare plants that have flowered, chiefly in the Royal Gardens.

Dr. Henderson's 'Report on the Botany of the Yarkand Expedition' is in the press.

Mr. Ball is still engaged in studying the Morocco collections formed by himself, Mr. Maw, and the Director in 1871, which amount to nearly 3000 species.

The Pharmaceutical Journal.

SATURDAY, JUNE 7, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ADULTERATION ACT.

THE Adulteration Act has now been long enough in force to justify the expectation that by this time there would have existed some decisive evidence as to its operation throughout the country. This is especially the case since the 7th clause provided that a quarterly report as to the number of articles analysed and the nature of the adulterations detected should be furnished to local authorities by the analysts appointed under the Act. As yet, however, but little of such evidence appears to exist, and in one case a chief constable candidly reports that nothing has been done beyond the appointment of an analyst. There are, however, some exceptions. In Glasgow Professor THORPE reports that between the 12th March and the 24th April he received 30 samples—viz. flour, 5; milk, 8; butter, 4; tea, 11; bread, 1; and one of a green paper used in covering confections. The flour he found to be unadulterated; 6 out of the 8 samples of milk, he states, contained water varying from 5 to 30 per cent.; all the butter was inferior, containing from 12 to 26 per cent. of starchy and curdy matter, and from a trace up to 16·4 per cent. of water; the samples of tea were, with one exception, genuine; the bread was free from alum; and the green colour of the paper was found to be due to a compound of copper and arsenic. In Clerkenwell, Dr. STEVENSON has reported the results of the analysis of 47 samples,—34 of bread and 13 of tea. Of the tea samples 4 were in his opinion adulterated, but he did not advise a prosecution, since he did not feel sure that the adulterations were effected in this country, and because they were not injurious to health. Of the bread 8 samples contained alum, but some duplicate samples obtained from the same shops showed a marked improvement.

Professor THORPE points out that one of the chief difficulties in working the present Act consists in the fact that the prosecutor is under the necessity of proving that the vendor of the article adulterated is aware that it is so, a difficulty which is increased by the fact that few simple and, in the hands of dealers, easily applicable tests are known, whereby the dealer can satisfy himself as to the purity of the article he retails. Such tests, he thinks, might be devised, if analysts would give their attention to the matter. Unfortunately, however, he illustrates the difficulty of the subject by himself suggesting the use of a test for butter which might sometimes lead to very erroneous conclusions.

Dr. CORFIELD and Mr. WHITMORE have also presented reports in reference to their respective districts; but neither have furnished much reason for satisfaction. Mr. WHITMORE, as analyst for the parish of Marylebone, has in his report confined his attention chiefly to milk, and has elicited a vigorous criticism from the *British Medical Journal.* Starting with the assertion that the report is weak and abortive, our contemporary proceeds to justify these comments by showing the absence of any useful purpose the report can serve. The general prevalence of the practices of skimming and watering milk have long been sufficiently well known not to require further evidence, and there was no reason to suppose Marylebone is any exception to the rule. The only useful information that could be furnished in connection with these practices has not been made public, viz., the names of the offenders. Consequently the effect of the Act, so far as the inhabitants of Marylebone are concerned, is merely the raising a vague impression that an every day article of food is systematically debased. We doubt the deterrent influence of such a course, and in the interest of the honest tradesman, would much prefer more decided measures.

But the Marylebone analyst appears to be most of all unhappy in the chemical evidence he brings forward as indicating the existence of gross adulteration of milk. He reports determinations as to specific gravity and amount of cream, together with admissions that both these data are utterly valueless for indicating the quality of milk. His attempts to obtain other data more adequate as a measure of quality in milk seem to have been frustrated by insufficient familiarity with the details of analytical work; and this is an instance in support of the opinion we expressed long since, that medical analysts would generally fail in this particular. It is here indeed possible to refer to the criticisms of a medical journal in confirmation of this view, for our contemporary mentioned above speaks of the Marylebone analyst's determinations as being "absurd" and confused.

Dr. CORFIELD's report to the Vestry of St. George's appears to have raised some difficulties, as reported in this Journal at page 963. These seem to have arisen from his misinterpretation of the proper functions of an analyst under the Act, and from a too zealous desire to deal effectively with the evil of adulteration. Such misunderstanding is made too possible by the terms of the Act as it stands, and its occurrence shows the need of further definition of duties and modes of procedure.

While dealing with this subject it is impossible to avoid referring to the general absence of anything like satisfactory results from the operation of the Adulteration Act. A large number of appointments have been made and confirmed in various parts of the country, but we are still waiting to see what benefit may accrue to the public in consequence. And if we may judge from what is publicly stated on the subject, there does not seem to be much hope of any advance. Thus, for instance, our contemporary, *Food, Water, and Air*, offers the following explanation of the present stagnation in respect of the Act:—

"It is notorious that a large number of these appointments have fallen into the hands of persons who are totally unacquainted with analytical chemistry, and who are therefore entirely incompetent for the responsible and difficult duties which, in some cases, have been thrust upon them through the interested but short-sighted policy of many of the Local Authorities, and which in others they have foolishly or greedily undertaken. Again, it is also notorious that the remuneration attached to very many of these appointments is of the meanest and most paltry description, and utterly inadequate to insure the efficient performance of the duties of the office."

Quite consistent with these remarks are the expressions of opinions heard on all sides from those competent to judge, and if further evidence were needed, it may be gathered from the fact that persons recommended and actually appointed as chemical experts under the Adulteration Act are endeavouring to learn the art of which they ought to have been thorough masters previously to their appointment. It is by no means encouraging to find that in regard to this point and in answer to the inquiry, what our Food Analysts are about? such statements as the following can be put forward with good reason.

"We can certify that many of them are engaged in the endeavour, vain and futile in some cases, to obtain a smattering of the knowledge requisite to enable them to even attempt to fulfil their duties; others, again, are endeavouring to find persons who, knowing something of analytical proceedings, are willing to act as their unacknowledged deputies, and to make the requisite analyses for them, upon which their official reports can be founded. It is in this way, therefore, that the inaction of our analysts and the consequent present failure of the Adulteration Act are to be explained."

If this statement be a true one, and we know of no reason for doubting it, what has become of the careful consideration of fitness before sanctioning an appointment promised by the Local Government Board?

THE NEW OFFICERS OF THE SOCIETY.

If the Council election this year has been wanting in that strong interest which prevailed on some previous occasions, there can be no doubt that the first proceedings of the new Council will excite a lively feeling of satisfaction throughout the whole trade. First, as regards the election of Mr. Thomas Hyde Hills to the office of President, we are sure the unanimity with which it was carried in the Council will be similarly responded to on all sides. The fact that he has been for three successive years returned at the head of the poll, as a member of Council, might alone be regarded as constituting a solid claim to the Presidential chair without reference to other considerations, and we doubt not it will be generally thought that, in electing Mr. Hills the President, his colleagues have manifested a graceful and well earned recognition of the high esteem in which he is universally held.

The election of Mr. Bottle as Vice-President will also, we believe, be received with unqualified satisfaction, by reason of his long connection with the Society and his zealous labour as a member of Council for so many years.

And if any regret were felt that Mr. Hills no longer holds the important office of Treasurer, it perhaps could not have been mitigated more thoroughly than by the appointment of Mr. Williams as his successor, for there is no member of the Council who excels him either in ability as a man of business, in earnest interest for the welfare of the Society, or in the desire to encourage all that tends to promote the advancement of pharmacy.

THE STATUE TO BARON LIEBIG.

At a meeting of the German Chemical Society recently held in Berlin, it was resolved to erect a statue at Munich in honour of the late illustrious chemist, Baron Liebig, and to invite his pupils and friends, as well as chemists of all nations, to contribute towards the funds necessary for that object. In order to carry out this resolution a committee was named; and the English members of the Committee, Messrs. Warren De la Rue, E. Frankland, J. H. Gilbert, W. Odling, John Stenhouse, and A. Williamson, have issued a circular inviting contributions. It is requested that communications on the subject be sent to Dr. Hugo Müller, 110, Bunhill Row, E.C.

EARLY CLOSING IN HULL.

The principal pharmaceutical chemists and chemists and druggists of Hull, at the request of their assistants and apprentices, have agreed to close their establishments at 7 P.M. (Saturdays excepted) on and after Monday, June 2nd, 1873.

THE BOARD OF EXAMINERS.

It will be observed by the report of the meeting of the Council that Mr. George Edwards, of Dartford, has not been reappointed as a member of the Board of Examiners. We understand that much regret was expressed by the members of the Council that through the operation of the bye-law limiting the age at which an examiner can be appointed, the Board will lose the services of a gentleman who has for so many years held an official position in the Pharmaceutical Society as member of the Board of Examiners, member of the Council, and Vice-President of the Society. At the same time we cannot but congratulate the Board that the vacancies have been filled by the appointment of Messrs. Haselden, Schweitzer, and Umney.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

June 4th, 1873.

Present—Messrs. Atherton, Baynes, Betty, Bottle, Brown, Greenish, Hampson, Hills, Owen, Radley, Robbins, Sandford, Savage, Schacht, Shaw, Stoddart, Sutton, Urwick, and Williams.

Mr. W. Scott Brown having been elected Chairman until a President should be chosen, the minutes of the previous meeting were read and confirmed.

Election of President.

A vote by ballot having been taken in the usual manner, Mr. Thomas Hyde Hills was declared unanimously elected.

The President having taken the chair expressed his appreciation of the kind feelings which had prompted his colleagues to confer this mark of honour upon him, and his intention to do all he could, relying on the hearty co-operation of every gentleman at the Council Board, to support all measures having for their object the advancement of pharmaceutical science and the improvement of the position of those engaged in pharmacy.

Vice-President.

Mr. Bottle was then elected Vice-President, and in thanking the Council for the honour they had done him, remarked that he felt he should be following in the steps of a very able man of business, who had rendered valuable services to the Society. It would be his province to endeavour to imitate his predecessor's good example, to support the President as an independent member of the Council, and to encourage everything which tended to promote the science of pharmacy and the success of pharmacists.

Treasurer.

Mr. Williams was elected Treasurer for the ensuing year and briefly returned thanks.

The President then moved a cordial vote of thanks to the late President and Vice-President for their valuable services.

The vote was immediately carried, and Mr. W. Scott Brown, in the absence of Mr. Haselden, which he regretted, acknowledged the compliment. He paid a hearty tribute to the zeal and ability displayed by the late President in his official capacity, and for his own part begged to say that he thanked the members of Council for the kindness which he had always received at their hands, more especially since they had adopted in his own case what he believed to be a right principle, in electing a provincial member as Vice-President. In discharging the duties of that office he had acquired a more thorough knowledge of the practical business of the Society than he before possessed. Living at such a distance from London he was glad to be relieved of so many calls upon his time, especially as he was succeeded by the gentleman whom—if he had had the selection—he should have chosen for the office.

Secretary and Assistant Secretary.

Mr. Elias Bremridge was reappointed Secretary and Registrar, and Mr. Richard Bremridge Assistant Secretary and Deputy Registrar.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Bascombe, Frederick ....Weymouth.
Ellis, Robert ....Aberystwith.
Greenish, Thomas Edward ......London.
Marshall, Eli..........................London.
Wheeler, Albert ....Southsea.

Elections.

MEMBERS.

Pharmaceutical Chemists.

Bascombe, Frederick ....Weymouth.
Ellis, Robert ....Aberystwith.
Greenish, Thomas Edward ......London.

Chemists and Druggists.

Bird, Frederick....................Coventry.
Lear, George Hill.................Birmingham.
Manley, William Frederick......Peckham.

ASSOCIATES.

The following, having passed their respective examinations and being in business, were elected "Associates in Business" of the Society:—

Minor.

Appleton, Arthur James ....Sheffield.
Burbidge, Edwin ....Oxford.
Emms, William Robert ....Strood.
Frowd, Edward Francis ....Blackheath.
Harrington, Arthur Lewis ......Rochford.
Southerst, Marshall ....London.

Modified.

Howe, Henry Albert ....Eynsham.
Smith, William......................Bermondsey.
Watts, Walter ....Kington.
Womack, Thomas.................Leeds.

The following, having passed the Minor examination, were elected "Associates" of the Society:—

Archer, Albert ....Newport, Mon.
Blackmore, James ....Doncaster.
Blackmore, Peter Ludgate ......London.
Bracher, Walter Phipps ....Grantham.
Brouard, Ernest James ....Guernsey.
Cadoux, Samuel Henry ....Colchester.
Clare, Thomas ....Cheltenham.
Davies, George Edward ....Notting Hill.
Dawson, Francis Robert ....Bolton.
Hart, Philip ....Bolton.
Herd, Henry Wilson.........Bowness-on-Windermere.
Hine, Alfred Leonard ....Cheltenham.
Holmes, Samuel ....Hampstead.
Lomas, Charles Benjamin ......Towcester.
Mager, William Kelk ....Doncaster.
Moore, George Brass ....Barnard Castle.
Moorhouse, Walter ....Wakefield.
Pickard, Henry......................Barnstaple.
Strawson, George ....Louth.
Summers, Frank ....Durham.
Sutton, William ....Chatteris.
Towler, George Bland .... Bishop Stortford.
Wilson, Richard Edward.........Newport, Mon.
Wrigglesworth, George ....Hull.
Yeats, Thomas Flasby............Manchester.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination, were elected "Apprentices or Students" of the Society:—

Biddiscombe, Charles ....London.
Boyden, John Augustus Charles.Wisbeach.
Collingwood, John Henry ......Little Gonerby.
Cumber, Henry......................Guernsey.
Hart, James Connorton ....Horselydown.
Hubbard, Alfred Coath ....Walsall.
Knowles, James ....Burslem.
McGibbon, George Laidlaw ...Edinburgh.
Mays, Robert Man ....South Shields.
Raynor, Charles Thomas ....Leicester.

Rickinson, Valentine, jun. ......West Hartlepool.
Tompsett, Leighton ....Strood.
Walker, Alexander ....Cullen.
Wright, Edwin ....Ipswich.

CONVERSAZIONE.

Votes of thanks were passed to the Committee of Council for Education for the use of the South Kensington Museum at the late Conversazione, and also to the official staff of the Museum for their services on the same occasion.

FINANCE.

The report of certain members of Council acting as a Finance Committee was received and adopted, and sundry payments ordered to be made.

BENEVOLENT FUND.

Several applications for relief from this Fund had been received, and had been considered by members of the Council acting as a Committee.

The SECRETARY read a short abstract of the various cases in which the Committee recommended that relief should be given, and grants were made as follows:—

The Widow of a late Annuitant in Jersey, having two daughters dependent upon her £10
A Registered Chemist and Druggist, residing at Hamilton, N.B., disabled by illness from following his business 10
The Widow of a Registered Chemist and Druggist at Brandon, having four children dependent on her 10
A Registered Chemist and Druggist aged 73, residing at Daventry 10
A Chemist and Druggist, aged 66, formerly in business, but at present only in occasional employment 10
A Registered Chemist and Druggist, aged 54, formerly in business, which he was obliged to give up through severe illness 10
A Registered Chemist and Druggist, who met with a severe accident, and has since been afflicted by illness 10

The consideration of the cases of other applicants for aid from the Fund was deferred for further inquiry.

The names of the following persons were placed on the list of approved candidates for annuities:—

Thomas Potts, of Daventry; and
Bine Linging, of Lower Norwood.

PARLIAMENTARY.

Several matters had been discussed by the late members of this Committee, who presented a report stating that certain cases were still under consideration, and recommending that the name of a person alleged to have been improperly placed upon the Register should be struck off. A communication had been received from a provincial association with reference to the illegal sale of poisons, asking if the Council were prepared to take action in the matter. The Committee recommended that an answer be sent to the effect that the Council would give their best consideration to any case brought under their notice. In the case of a firm using the style Pharmaceutical Chemists, only one member of it being on the register of Pharmaceutical Chemists, an assurance had been received that a change of the style should be made so as to avoid any cause of complaint. With regard to the Shop Hours' Regulation Bill, the Committee referred the matter to the Council with a recommendation that the Bill should be opposed.

The report and recommendations of the Committee were received and adopted, and the name of Gustavus Jordan, of Luton, was ordered to be erased from the Register.

The question of the supply of medicines, etc., by Co-operative associations, also came before the Committee *à propos* of some prescriptions which had been made up at one of these establishments in London, and the Committee referred the matter to the Council.

The PRESIDENT suggested that it should be referred again to the Parliamentary Committee when appointed, with a recommendation that a special sub-committee should be appointed to deal with it with such legal assistance as might be necessary.

After some discussion the following resolution was carried unanimously,—

"That the question of the illegal sale of poisons and dispensing prescriptions by so-called associations be referred to the Parliamentary Committee for full consideration, and that the Committee be authorized to take legal advice to any extent required."

Mr. SUTTON remarked, with reference to the Shop Hours' Regulation Bill, he had no doubt Sir John Lubbock would modify its provisions if the hardships it would inflict upon them as a trade were properly represented to him.

The PRESIDENT thought the Bill should be opposed *in toto.*

Mr. BAYNES regarded it as a mischievous piece of over legislation which would, if it were possible to conceive of its being carried, lead to innumerable practical difficulties in the carrying on of business by any one who employed persons under twenty-one years of age.

On the motion of Mr. BROWN a resolution was passed that the Bill be opposed, and that the President, Vice-President, and Mr. Sandford be requested to watch the progress of the Bill, and take such action as might be deemed needful.

APPOINTMENT OF COMMITTEES.

Mr. SCHACHT begged leave to suggest, before the Committees were appointed, that it would add much to the efficiency of the Committees, and tend to prevent the needless discussion of matters of detail at the Council, if it could be so arranged that no member should be appointed on more than one, or at the most two, Committees. He believed this desirable end could be accomplished by a redistribution of the members amongst the different Committees, placing as far as possible each gentleman upon such Committees only as it would be possible for him to attend. It was much to be desired that the business should not be hurried. Committees followed each other so closely, that the business brought before them could not be fully discussed. In addition to the Secretary they had now a very efficient Assistant Secretary, and he saw no reason why two Commitees should not sit at the same time; by this means he believed the business would be got through in a more satisfactory manner than at present. It was very desirable also that provincial members should not be appointed to serve on Committees which they were not able to attend, as had happened to himself.

Mr. STODDART desired to endorse what had fallen from Mr. Schacht; especially with regard to the attendance of provincial members.

Mr. SHAW also remarked on the difficulty experienced by gentlemen at a distance in reaching town in time to attend some of the Committees.

The PRESIDENT agreed that it would be a great advantage in many cases to have two Committees sitting at once.

After some remarks in the same direction by Messrs. BROWN, SUTTON, SAVAGE, URWICK, SANDFORD, and WILLIAMS, the Committees were appointed as follows:—

General Purposes.—The whole of the Council; to meet as occasion may require.

Finance.—Messrs. Greenish, Hampson, Owen, Robbins, and Urwick.

Benevolent Fund.—The same as the above.

Library, Museum, and Laboratory.—Messrs. Betty, Greenish, Hampson, Sandford, Robbins, and Williams.

House Committee.—The same as the above.

Parliamentary. — Messrs. Atherton, Baynes, Betty, Brown, Mackay, Owen, Sandford, Savage, Shaw, Sutton, Urwick, and Williams, with power to add to their number.

Provincial Education.—Messrs. Atherton, Baynes, Betty, Brown, Frazer, Mackay, Radley, Schacht, Shaw, Stoddart, Sutton, and Urwick.

Election of Examiners.

A ballot was taken for the appointment of Examiners in the usual way. In addition to the two vacancies reported last month, there was a third, occasioned by Mr. George Edwards, of Dartford being over the prescribed age for re-election. The following gentlemen were elected to serve until the end of the present year :—

England and Wales.

Messrs. Allchin, Barnes, Carteighe, Cracknell, Davenport, Gale, Haselden, Linford, Martindale, Schweitzer, Southall, and Umney.

Scotland.

Messrs. Ainslie, Buchanan, Gilmour, Kemp, Kinninmont, Noble, Tait, and Young.

Appointment of Editor, etc.

Dr. Paul was re-appointed Editor of the Journal, and Mr. F. Passmore Sub-editor.

Local Secretaries.

The Secretary reported that out of more than 2000 voting papers which he had sent out, only 489 had been returned. He suggested that where no nomination had been made, no local secretary should be appointed.

Mr. Sutton said he thought local secretaries might be dispensed with altogether, but certainly he should not appoint them where no trouble had been taken to make a nomination.

Mr. Savage thought the absence of fresh nominations merely showed the satisfaction which was felt at the present appointments, and did not approve of the suggestion that the appointments should not be made.

It was then resolved —

> "That the report of the scrutineers in reference to the nomination of local secretaries be referred to the Parliamentary Committee ; the Committee to be authorized to nominate, if they deemed it desirable, local secretaries in those districts from which no return had been received."

The Sessional Lectures.

A letter from Professors Redwood and Bentley was read suggesting that the lectures would be more beneficial to the students if the course of instruction were somewhat altered, being given twice during the session instead of once, and that the fees might be raised with advantage, etc.

Mr. Scott Brown moved that the letter be referred to the Library, Museum, and Laboratory Committee, to report thereon to the next meeting.

Mr. Williams seconded the resolution, and suggested that the Committee should take into consideration the whole question of the educational action of the Society.

Mr. Hampson thought they could not do better than seize the opportunity afforded by the Professors' letter to reconsider the whole matter. Everyone seemed to agree that there was something not quite right in the present arrangements, and he hoped some decision would be arrived at.

Mr. W. Scott Brown thought the letter only should be referred to the Committee, leaving them of course to adopt any hints that might be offered them.

Mr. Schacht thought the whole matter had better be included, and that the Committee should also take into consideration the instruction given in the laboratory. The chief point which had weighed upon his mind of late was that they kept up the educational establishment at considerable cost, and yet they scarcely seemed to have what struck him as a perfect system of education. Great differences were attempted to be drawn between the instruction given there and that which young men received at other educational places, the latter of which had been called a cramming process, whilst that afforded there was said to be quite the reverse, though what the reverse was he did not exactly know, particularly as he knew that in the laboratory part of the system a man might enter for a week only, and do the best he could to grind up any particular subject in that time. This certainly looked something like cramming. He was perfectly willing that their educational system should cost them a good round sum, but at the same time he should like everything to be complete and thorough, so that a student might really go through the educational course steadily, honestly, and well.

The President reminded the members that the Professors must be appointed next month, and if the whole subject were taken up he feared it would be too large for the Committee to deal with in so short a time.

Mr. Williams said it was not absolutely necessary to appoint the Professors next month, as the Session did not begin till next October. The Committee might propose adding other names, or a totally different system. He should like to know from the Council whether the Committee were to go into the whole question. It was admitted even by the Professors themselves that many who attended their lectures simply went there for the purpose of passing their examination, and this was what they all wished to discourage as much as possible.

Mr. Greenish thought the Professors' letter was one of the most important matters that had come before them for some time. If they commenced an inquiry they should go through the whole, and deal, not only with the lectures, but the laboratory also.

Mr. Sandford said they might send the letter to the Committee without any instructions to go further, as they would naturally consider any point bearing upon it.

Mr. Baynes said the matter was of the greatest importance. In his opinion they ought not to stand second to any institute in Europe. But he was quite sure at present that the position of the Society in relation to education was very imperfectly understood in many parts of the country. Some of the arrangements might perhaps be somewhat antiquated, but all these matters of detail had better be referred to the Committee.

Mr. Urwick suggested that a Special Committee should be appointed to deal with this matter, as it was one of great importance, and ought to be considered in all its bearings.

Mr. Sandford said it had been stated repeatedly that the time was coming, and he hoped it would come very soon, when the Society would give up educating. Education, in his opinion, should be separated entirely from examination, but here they both educated and examined, which was wrong in principle ; and he thought if they could get rid of the laboratory altogether it would be a very good thing. With regard to the fees, it must be remembered that when they were established and the lecturers were engaged the object was simply to tempt young men to come here to be educated, and everything was done to induce them to attend. Thus, a young man could attend the whole course from October to the end of July, if he were connected with the Society, on payment of one guinea, whereas in the medical school eight guineas was the fee charged for a course from October to the end of March. The lectures were at present simply given away. He thought, however, it would be better to consider the letter of the Professors first, for if they went into the whole question they would not get through it in a month, or perhaps a year.

The President said it must be remembered that the Council, not the professors, fixed the fees. They must bear in mind, when it was suggested that the lectures should be abolished, that these gentlemen had been engaged for thirty years and upwards, and therefore their past services must be considered. If two guineas each course were charged instead of one, there would perhaps be a deficiency of £200 instead of £400; and if three guineas were charged probably there would be no deficiency at all. He believed that it would be better at first to deal with the letter only.

Mr. GREENISH thought the letter should be dealt with, but still the Committee ought to have a wider scope for their investigation.

Mr. BROWN said he would alter the motion to this form:—

> "That the letter from Professors Redwood and Bentley be referred to the Library, Museum, and Laboratory Committee to report thereon, and also as to the other educational arrangements, and to report thereon to the Council at an early meeting."

That would leave the Committee at liberty to take up the letter first, and to report thereon, and also subsequently, or simultaneously if they thought fit, to take into consideration any other matters bearing on the educational arrangement.

The resolution was then carried unanimously.

INAUGURAL ADDRESS.

It was unanimously resolved that Mr. R. Reynolds, of Leeds, be invited to deliver the Inaugural Address in October next.

ANNUITANT ON THE BENEVOLENT FUND.

The SECRETARY said it was necessary to decide whether they should elect one or two annuitants in October next. According to their rules, annuities were only granted from the income of the invested property, and the state of the funds at present would not allow of the election of two annuitants.

Mr. ROBBINS thought it would be a pity to confine the annuities to the interest on funded property.

Mr. SANDFORD said they could not touch the invested capital according to the bye-laws.

Mr. W. SCOTT BROWN said it was impossible to settle an annuity on a person unless capital was invested to produce the requisite income.

Mr. ROBBINS said he thought if people were properly encouraged they would support the Benevolent Fund much more largely than they did at present. He should like to see the same encouragement given as was done in many other societies by conferring the rank of Vice-President, or giving a certain number of votes to those who subscribed a certain amount. There were also persons who, being members of the Society, had votes, but never subscribed at all, which was a principle he did not understand.

Mr. SANDFORD said that arose from the fact that a portion of the money from the "General Fund" of the Society was from time to time transferred to the Benevolent Fund.

The SECRETARY thought if the Council would pass a resolution to elect two annuitants in October they might try in the meantime to raise the requisite funds. He thought he could see his way to raising the necessary amount for investment.

Mr. W. SCOTT BROWN said he believed there was a great deal of misapprehension throughout the country with regard to the position of the Fund.

It was then resolved that one annuitant should be elected in October next, the annuity to be of the value of £30 per annum.

LIBRARY, MUSEUM, AND LABORATORY COMMITTEE.

The Report of this Committee was received and adopted, but it contained nothing requiring special notice.

A letter was read from Professor Attfield, reporting that Mr. Shenstone, who had been acting as Assistant-Demonstrator in the Laboratory, had accepted an engagement in another establishment, and asking that the office might be announced as vacant, to be filled up by October next. The subject was referred to the Library, Museum, and Laboratory Committee.

EXAMINATIONS IN LONDON.

May 28th, 29th, and 30th, 1873.

Present on the 28th—Messrs. Allchin, Barnes, Carteighe, Cracknell, Davenport, Edwards, Gale, Haselden, Linford, Martindale, and Southall.

Present on the 29th and 30th—Messrs. Allchin, Barnes, Brown, Carteighe, Cracknell, Davenport, Edwards, Gale, Haselden, Linford, Martindale, and Southall.

Dr. Greenhow was present on the 28th, on behalf of the Privy Council.

MAJOR EXAMINATION.

Seven candidates were examined. *Two* failed. The following *five* passed, and were declared duly qualified to be registered as "Pharmaceutical Chemists:"—

*Greenish, Thomas Edward	London.
*Bascombe, Frederick	Weymouth.
*Marshall, Eli	London.
Wheeler, Albert	Southsea.
Ellis, Robert	Aberystwith.

The above names are arranged in order of merit.

MINOR EXAMINATION.

Eighty-one candidates were examined. *Twenty-four* failed. The following *fifty-seven* passed, and were declared duly qualified to be registered as "Chemists and Druggists:"—

	*Wells, Ernest William	East Dereham.
	*Archer, Albert	Newport, Mon.
	Clare, Thomas	Cheltenham.
Equal.	Fairman, George Peters	London.
Equal.	Hine, Alfred Leonard	Cheltenham.
	Willis, Blankley William	Kidderminster.
	Emms, William Robert	Tetbury.
	Moore, George Brass	Barnard Castle.
	Davies, George Edward	Notting Hill.
	Wheatly, Arthur William	Thame.
Equal.	Bluett, Reginald	Tetbury.
Equal.	Yeats, Thomas Flasby	Manchester.
	Slater, Elias	Fallowfield.
Equal.	Hart, Philip	Bolton.
Equal.	Mason, Michael	Salisbury.
	Bales, William	Ipswich.
Equal.	Ashby, Thomas Lacey	Leicester.
Equal.	Herd, Henry Wilson	Bowness on Windermere.
Equal.	Rees, Samuel Lawrence	Hayle.
	Towler, George Bland	Bishop Stortford.
	Longley, Joseph	Barnsley.
	Wrigglesworth, George	Hull.
Equal.	Damon, Alfred Ferris	Bristol.
Equal.	Lister, Robert	Leeds.
Equal.	Mills, John Perry	Taunton.
	Betty, Robert	London.
Equal.	Strawson, George	Louth.
Equal.	Taplin, Joseph Whelan	Bristol.
Equal.	Wilson, Richard Edward	Newport, Mon.
	Monti, Peter	London.
Equal.	Anderson, Henry Dingle	Guernsey.
Equal.	Dawson, Francis Robert	Bolton.
Equal.	Barry, Frederick	Bath.
Equal.	Gould, William Robert	Southsea.
	Piquet, Frederick George	Jersey.
	Matcham, Edward	Norwich.
Equal.	Hutton, Robert Henry	Wisbeach.
Equal.	Matthews, Thomas Averill	Worcester.

* Passed with Honours.

	Blackmore, Peter Ludgate	London.
	Tucker, William Charles	London.
	Otley, John	Sheffield.
Equal.	Askew, Hugh de Bosco	Workington.
Equal.	Brouard, Ernest James	Guernsey.
Equal.	Greenwood, Dennis	Cambridge.
	Pike, John	Yarmouth.
	Summers, Frank	Durham.
	Sutton, William	Chatteris.
Equal.	Moorhouse, Walter	Wakefield.
Equal.	Nicholls, Alfred	Penzance.
Equal.	Smith, Alfred Lambert	Birmingham.
	Lomas, Charles Benjamin	Towcester.
	Boon, Nathaniel	Oakham.
	Evans, Richard	London.
	Morgan, George Henry	London.
	Mager, William Kelk	Doncaster.
	Holmes, Samuel	Hampstead.
	Turner, Charles	Buxton.

The above names are arranged in order of merit.

PRELIMINARY EXAMINATION.

The undermentioned Certificates were received in lieu of this Examination :—

Certificates of the College of Preceptors.

Brick, John	Welchpool.
Hargraves, James W.	Liverpool.
Mayne, James	Chertsey.

Certificates of the University of Cambridge.

Robinson, Charles Bradshaw	Great Bridge.
Watson, Robert John	Market Rasen.

Certificates of the University of Oxford.

Ballard, William	Hammersmith.
Fletcher, Howard Bennett	Leicester.
Hart, James Connorton	Horselydown.

Provincial Transactions.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

The half-yearly meeting of the above Association was held on Friday, May 23rd, in the College Street Room. J. Barry, Esq., J.P., Local Secretary, occupied the chair.

Mr. C. Hester, President, opened the meeting by expressing his pleasure at seeing those principals who had attended, and trusted that the little relaxation the members were going to enjoy on the following Tuesday would induce them to pursue their studies with redoubled vigour, so that the summer session might be as successful as the winter had been. He heartily thanked the examiners for the service they had rendered, and then referred to the obligation the Association was under to its late president, whose tact and zeal had so much helped it in its early life.

The Secretary (Mr. Druce) then read the following statement of receipts and expenditure and the report :—

RECEIPTS.	£	s.	d.
26 Members' Subscriptions, at 5s.	6	10	0
7 „ „ to Chemistry Class	0	14	0
1 Member's Donation	0	2	0
Balance	3	9	7½
	£10	15	7½

EXPENSES.			
Reports, etc.	1	3	0
Cupboard	1	0	0
Herbarium and Chemicals	2	14	5
Gas, 3 quarters	0	10	6
Sundries	0	8	1
	5	16	0
Balance	4	19	7½
	£10	15	7½

The Report stated that the hope expressed by the Council at the beginning of the winter session that the good attendance of the classes in 1872 might be continued or, if possible, increased, had been responded to by larger classes. Forty-two meetings had in all been held, at which structural botany had been taught, questions on two-thirds of the Pharmacopœia asked, all the official materia medica considered, and the analytical reactions of the basylous radicals practically performed, several lessons also being occupied by descriptions and explanations of the principal laws regulating the science of chemistry. During a portion of the session also a class was conducted in dispensing and reading prescriptions. The knowledge of materia medica had been much increased by the possession of Lescher's cabinet and Siebold's herbarium, and the Council suggested to the members the great service a herbarium of indigenous plants would be to the Association. The prescription book now contained a very fair collection, and a little more exertion would complete it. The Council thanked most warmly the class conductors for the diligence they had displayed in fulfilling their duties, and hoped that the members would reward them by forming as large and attentive classes as possible. The examinations had been conducted in a very able manner. From various causes, however, the competitors among assistants had not been so numerous as had been expected; but the apprentices had been very eager in the contest, and on the whole the experiment had been so successful that the Council recommended it be repeated at least yearly. The Council took the opportunity of tendering to the late president, Mr. H. J. Masters, their sincere thanks for the services he had rendered to the Association.

Several special meetings had been held and papers of an interesting nature read, but a difficulty in getting a supply of original papers had been felt. It would afford the Council great satisfaction if their principals would occasionally favour them with a paper on some subject appertaining to pharmacy. After thanking Mr. Leyes for the continued use of the room, Messrs. Maxwell and Sandall for their services as examiners, and the various donors who had so kindly rendered assistance, the report stated that during the session four members had passed the Minor examination (one in honours and the others all in good positions) and three the Preliminary, being 30 per cent. of their members who had been successful in the examination ordeal.

The report having been adopted Mr. W. Sandall read a report of the examinations which he had conducted in Botany and Materia Medica. He said the first examination was on Botany in which 3 assistants and 6 apprentices competed. In the Materia Medica examination, 4 apprentices, but no assistants competed. He confessed himself a little disappointed at the result; as he expected a larger proportion of marks in this subject, it being more generally popular. On the whole the result obtained was satisfactory considering that it was the first examination held by the Association. He suggested that in future they should be held at stated times and as frequently as possible.

Mr. G. N. Maxwell being unable to attend, sent a report of the Pharmacy examination. He said that the answers in this department of study were not so satisfactory as could have been desired, more attention was required to the various strengths and proportions of ingredients. In the more important preparations, however, the answers were good. Four apprentices competed.

The President's prize was awarded to Mr. O. Wallis.

The Secretary's prizes for the greatest aggregate number of marks in the three subjects, competition limited to apprentices, were awarded as follows :—

First . . . Mr. J. Cross, 450.
Second . . . Mr. L. Bird, 420.

Mr. James Barry then addressed the class, cautioning the members against trusting to superficial knowledge of a subject. The examination had, he trusted, evoked a healthy spirit of competition, but the examination would be altogether insufficient by itself if home study were neglected. Examinations were not the end, but a means of taking stock of the quantity and quality of knowledge obtained, and it was not only the successful men who benefited, but each and all, if proper attention were paid to improving and increasing the store of knowledge. He should have great pleasure in helping to carry out the suggestion of the Council that the examinations should be repeated, and accordingly offered two prizes, one for assistants, the other for apprentices, to be competed for, leaving the arrangement for the Secretary and Council to decide. He then presented the prizes to the successful candidates.

The Secretary read a letter from Mr. Tutton, resigning his post as Vice-President, on account of his leaving the town, and said that the prize Mr. Tutton had offered would be competed for in August.

Mr. Sandall said Mr. Druce in the report mentioned the slight attention indigenous botany received; he should be much pleased to assist the Council by offering a prize for the best herbarium, leaving the arrangement to the Council, but would suggest that rules similar to those adopted by the Pharmaceutical Society should be chosen.

Mr. Armitt said that perhaps an arrangement might be made to let the members remain out till a later hour on one morning in the week, so that an opportunity might be given to revive the botanical rambles under more auspicious circumstances.

The President having thanked the principals for their very kind offers of assistance, mentioned the proposed route for the following Tuesday's botanical ramble, and after the votes of thanks to the chairman and donors of prizes, the meeting terminated.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Juries Bill.

On Thursday, June 5, the House went into Committee on the Juries Bill. Clause 5, which relates to exemptions from the obligation to serve on Juries, was discussed at great length, and several additions were made to the list. Mr. Gathorne Hardy carried, on a division, by 70 to 55, the exemption of Schoolmasters of Public Schools, Professors and College Tutors resident in the Universities to which they belong ; and Mr. H. Palmer, with the assent of the Attorney-General, added to the list Officers of both Houses of Parliament during the Session of Parliament. At the Instance of Colonel Barttelot, Members of the Royal College of Veterinary Surgeons actually in practice were exempted, as also were the Governor and Deputy-Governor of the Bank of England. This last provision was carried by Mr. Crawford with the support of the Government, against the opposition of Mr. Anderson, by 88 to 57. On the other hand, Mr. West was beaten by 126 to 42 in an attempt to free Borough Justices, Councillors, Town Clerks, and Treasurers from service within the Borough and County. Mr. Alderman Lawrence failed by 81 to 17 to obtain an exemption for the Aldermen of London, and Mr. R. Fowler, who wished to reduce the age of exemption from seventy to sixty, was defeated by 54 to 18. Registrars of Births, etc., Members of the Mersey Docks Board, and Commissioners of Income Tax were also proposed for exemption by Mr. Monk, Mr. Rathbone, and Mr. Alderman Lawrence ; but in each case the Committee negatived the suggestion.

On clause 45 a proposal was made by Mr. Magniac which incidentally raised the question of local taxation. After a sharp debate, in order to avoid a division, it was agreed to report progress. In reply to a question, Mr. Gladstone said that he was afraid the measure must now stand over until more urgent business had been disposed of.

Reviews.

Botanical Companion to the British Pharmacopœia. By Hyman Marks, L.R.C.S.I. Dublin: Fannin and Co. 1873.

Of all the branches of medical education, botany is perhaps considered by students generally to be the most dry and uninteresting. The majority of botanical works are of necessity so condensed that there is but little room in them for those explanatory remarks which, in a botanical lecture, render the subject so much more lucid and interesting. This condensation is nowhere more apparent than in the descriptions of the Natural Orders of plants. The student may read over many times these scientific descriptions, and after poring over them until he is tired, frequently fail to grasp the real distinctions between one Order and another—distinctions which a botanist who has become practically acquainted with them would not fail to point out in a very few words. The natural consequence is that the whole of the descriptions given are often learnt by rote, and forgotten soon after the necessary examination is passed.

The idea of "supplying to students of medicine a ready means of acquiring the special information which heretofore they had much trouble and attendant loss of time in searching for through cumbrous works on the subject" is an excellent one, and we gladly welcome any attempt to render botany, more especially systematic botany, less irksome to students.

The little work before us has the advantages of being in a portable form, and of presenting a large amount of information in an easily accessible manner. A little alteration in the arrangement would, however, render it much more easy of reference. Thus the descriptions of the Natural Orders are given in paragraphs which require to be read through when searching for any particular character. If printed in a tabular form, the character sought would be seen at a glance.

The pamphlet is divided into three sections, the first giving short descriptions of the characters of the classes and subclasses of the vegetable kingdom, and a tabulated list of those Natural Orders comprised in each subclass which contain official plants ; the second section gives descriptions of the characters of all the Natural Orders which contains official plants ; and the third section gives an alphabetical arrangement, in a tabular form, of all the official plants, with the Linnean class and order of each, the Natural Order to which it belongs, and the part of the plant which is official.

What may be the object in giving full definitions of such orders as Menispermaceæ, Guttiferæ, Zygophyllaceæ, etc., is not very evident. Few students have the opportunities of studying these orders practically, and indeed a practical acquaintance with them is not required from medical students at the universities. If the space occupied by the descriptions of these exotic orders were used in giving a few remarks upon the best practical means of distinguishing one order from others to which it is nearly allied, the work would be rendered exceedingly useful, and a tabular comparison of the Linnean and Natural Systems would enable the student to refer any plant to its proper position in either. As the list stands at present, however, it must be entirely a matter of memory.

Explanatory notes are wanting thoughout. The student might well be puzzled on finding Gymnospermæ included under Monochlamydeæ, when, on referring to many botanical works, he will find they form a section of Exogenæ. Upon finding reticulated leaves given as a character of exogens, he might be pardoned for supposing that Dictyogenæ belonged to that class, instead of to Endogenæ, and that there must be an error somewhere. A few words in explanation of apparently contradictory statements would have entirely done away with these difficulties. It is to be hoped, therefore, that the next edition will form a really useful pocket companion for the student of botany in connection with the British Pharmacopœia, for such a work is still a desideratum.

NOTES ON THE PHARMACOPŒIAL PREPARATIONS (B. P. 1867): Specially arranged for the Use of Students preparing for Examination. By W. HANDSEL GRIFFITHS, Ph.D., L.R.C.P.E., etc. London: Baillière, Tindal, and Cox. 1873.

Dr. Handsel Griffiths is well known as an able and accomplished lecturer on the materia medica in the Dublin School of Medicine. He has already placed the student under considerable obligations by his system of 'Botanical Analysis applied to the Diagnosis of British Natural Orders,'—a work on which a deservedly favourable opinion has been expressed in our own columns. His 'Posological Tables' made a welcome addition to the resources of candidates for examination and served still more to commend its author to the pharmaceutical and medical student as a judicious and well-informed compiler of "handy-books" for qualifying boards. His 'Notes on the Pharmacopœia' will prove useful to all who find the volume issued under the authority of the Medical Council in need of supplement.

The student has only to turn to the section on the "Tinctures" to appreciate the succinctness and accuracy with which Dr. Handsel Griffiths has condensed into brief compass the chief points that he needs know about them. The section "Pilulæ" is also a favourable specimen of neat and correct condensation. Though we regard with no great partiality publications which may be abused by the indolent as substitutes for thorough and independent work, we do not otherwise object to such specimens of the class as this.

Our commendation, however, must not be unqualified. The carelessness with which Dr. Handsel Griffiths has revised the press is discreditable. We hope that in the next edition such blunders as "Tarax*i*ci" and "Hyosc*i*ami" (p. 26); "Liquor Sod*a*" (p. 45); "Pilula Rhei Composit*us*" (p. 56); "Syrupus Rhæad*dos*" (p. 70), etc., will be removed. They are apt to cause misgivings as to the compiler's scholarship, and to mislead the confiding candidate.

BOOKS RECEIVED.

PHARMACOPŒIA OF THE UNIVERSITY COLLEGE HOSPITAL. Published by Authority of the Medical Committee, 1873. Edited by WILLIAM MARTINDALE. London. 1873. From the Editor.

NATURAL PHILOSOPHY FOR GENERAL READERS AND YOUNG PERSONS. Translated and Edited from Ganot's 'Cours Élémentaire de Physique,' by E. ATKINSON, Ph.D., F.C.S. London: Longmans, Green, and Co. 1872. From the Publishers.

Obituary.

Notice has been received of the death of the following:—

On the 15th May, 1873, Mr. Robert Forster, Pharmaceutical Chemist, of Dover, aged 64. Mr. Forster had been a member of the Pharmaceutical Society since 1845.

On the 8th May, 1873, Mr. Edward Coward, Chemist and Druggist, of Western Hill, Durham.

On the 10th May, 1873, Mr. John Hudson Lewis, Chemist and Druggist, of South Street, Cockermouth.

Notes and Queries.

[338.]—DISCOLOURED PRINTS.—In reference to the subject of the query of *G. C.*, the *Boston Journal of Chemistry* states that all kinds of printed matter that has turned yellow may be completely restored by immersion, for one minute, in Javalle water, without the least injury to the paper, if the precaution be taken to thoroughly wash the article in water containing a little hyposulphite of soda. For the preparation of Javalle water, take four pounds of bicarbonate of soda and one pound of chloride of lime; put the soda in a kettle over the fire, add a gallon of boiling water, and boil for ten or fiteen minutes; then stir in the chloride of lime, avoiding lumps.

[339.]—MARKING INK.—For the information of *C. E. G.*, we reproduce the formula introduced by Professor Redwood (PHARM. JOURN. 1st Ser., Vol. VI., p. 420) of a marking ink which flows freely from the pen, without running or blotting, becomes perfectly black upon application of a moderate heat, and will not destroy the texture of the finest cambric.

℞	Nitrate of Silver	℥j
	Carbonate of Soda, crystallized .	℥iss
	Tartaric Acid	℥ij ℈ij
	Strong Liquor Ammoniæ . . .	f℥ij or *q. s.*
	Archil	f℥ss
	White Sugar	℥iv
	Powdered Gum Arabic. . . .	℥xij
	Distilled Water	*q. s.*

Dissolve the nitrate of silver and carbonate of soda separately in distilled water; mix the solutions; collect and wash the precipitate on a filter; introduce the precipitate, still moist, into a Wedgwood's-ware mortar, and add to it the tartaric acid, rubbing them together until effervescence has ceased; add liquor ammoniæ in sufficient quantity to dissolve the tartrate of silver; then mix in the archil, white sugar, and powdered gum arabic, and add as much distilled water, if required, as will make f℥vj of the mixture.

APPOINTMENTS.

BARCLAY, A. W., M.D., has been appointed (provisionally) Public Analyst for Chelsea.

BLUNT, Mr. T. P., has been appointed a Public Analyst for Shropshire: 13*s.* 4*d.* for each analysis.

BROWN, Dr. J. C., has been appointed Public Analyst for Cheshire: £100 per annum, and 6*s.* for each analysis. Also Public Analyst for Carnarvonshire: £5 per annum, and £1 1*s.* for each analysis.

COLLINS, Mr. J., has been appointed Public Analyst for Bolton: £30 per annum.

HORSLEY, J., F.C.S., has been appointed Public Analyst for Gloucestershire: £115 per annum, with offices, etc.

JOHNSON, H., M.D., has been appointed a Public Analyst for Shropshire: 13*s.* 4*d.* for each analysis.

LETHEBY, Dr. H., has been appointed a Public Analyst for Hertfordshire and for East Sussex.

MUTER, Dr., has been appointed Public Analyst for Streatham, Tooting, and Balham.

TURNER, G., M.R.C.S., has been appointed Public Analyst for the borough of Portsmouth: £50 per annum.

Correspondence.

The Minor Examination Bye-law.

Sir,—I had hoped that the bye-law controversy would have expired with the Special General Meeting. Any desire on my part to re-open the discussion terminated when the meeting gave its sanction to the bye-law. I must, however, claim from you—and I feel that I am fully entitled to what I ask—another opportunity of saying a few more words on this most vexed question, since you have done me the honour of applying your editorial and "quasi" legal calipers to my reasoning and opinions in respect to the particular bye-law in question.

It is not needful—although much may be said on this phase of the subject—to enter fully into the general question of the advisability of making a compulsory and fixed term of practical experience, and a fixed interval of three years, before candidates are allowed to submit themselves to the ordeal of examination.

The question strictly is, Is the *new interpretation* of the statutes a *legal or illegal* interpretation?

The absolute and obligatory duties of the examiners to examine *all persons* who present themselves for examination, are clearly expressed in the following clause, to which I have so often reverted (6th section of the Pharmacy Act of 1868):—The "Examiners for the purposes of this Act" "are hereby empowered and *required* to examine all such persons as shall tender themselves for examination under the provisions of this Act."

There are no discretionary or conditional powers here enunciated. The Society is bound in this section by the clearest legal phrase; and I still maintain that a fixing of conditions *antecedent* to the examination is beyond the legal scope of any part of this or any other section of the statutes.

The examiners have only to do with the practical and technical knowledge to be displayed and educed to their satisfaction *by means of examination.* This latter word being used in the ordinary sense.

The further provision of the 6th clause has not, as you suppose, escaped my attention. The words by which you contend the antecedent conditions of three years' services, or three years' practical experience, as well as a three years' interval between the Preliminary and Minor examinations, may be enforced—for all the three conditions are included in the bye-law—are as follows: "The examination aforesaid shall be such as is provided under the Pharmacy Act (1852) for the purposes of a qualification to be registered as assistant under that Act, or as the same may be varied from time to time by any bye-law to be made in accordance with the Pharmacy Act as amended by this Act" (1868).

By this provision the Society is empowered to vary the examination by the addition of "such *other subjects* as may be determined by any bye-law." These latter words are quoted from the 8th clause of the Act of 1852, and are referred to in that portion of the Act of 1868 (6th clause) to which you direct my particular attention.

Upon this very definite provision, by which new subjects may be introduced, you build up, *without license*, something *clearly outside the provisions of the statute.*

The *only power* granted by this provision is that in reference to *new subjects* upon which candidates may be examined, and there is not the remotest reference to any conditions to be exacted from candidates, *antecedent* to the examination. This opinion is not simply my own but it is the carefully considered opinion of more than one professional gentleman of high standing in the law.

The next important point about which you suppose I labour under a misconception, and to which I must again refer, is the legal difference and distinction between the bye-law as first proposed, and objected to by Mr. Flux (section x., clause 16), and the one sanctioned by Mr. Flux and accepted by the Special General Meeting.

The *only difference* I am as yet able to discover between the two formulæ is, that the one accepted being more onerous, exacting, and more difficult to conform to, is in consequence *more illegal* than the one signalized as contrary to "the intention of the Act," on the following plea, "that the examinations should be freely open to all the world."

The result of this new bye-law will be that the examinations will *no longer* "be freely open to all the world." It will no longer be free to a person, however competent he may be, if by the quickness of his understanding and the severity of his application, he has obtained his knowledge in less time than three years, and not according to the special mode indicated in the bye-law.

And another consequence operating as a fetter, rather than something free, will be, that however anxious a person may be to pass his Minor or Major examinations within a less interval than that of three years after passing the Preliminary examination, and however important it may be to him to pass either the one or the other examination within a less interval, he will be compelled to wait until the three years have terminated and until he is twenty-one years of age.

There is nothing free in these conditions, and notwithstanding my sincere desire to discover proof that I am an innocent victim of misconceived opinions, and that I ought to be in accord with the majority of my esteemed colleagues in this matter, I am reluctantly obliged still to adhere to my previously-expressed opinions.

I am, dear Sir,
Yours faithfully,
Robt. Hampson.

205, *St. John Street Road, E.C.,*
June 3rd, 1873.

Mr. J. Askew.—Our remarks, to which you refer, were entirely impersonal, and were written in reply to the inquiry of a correspondent. We cannot, therefore, recognize the existence of any reason for reclamation on personal grounds.

"Burry Port."—Cooke's 'Manual of Structural Botany' (Hardwick) or Oliver's 'Lessons in Elementary Botany' (Macmillan).

Payment of Assistants.—We have received a letter from *"An Underpaid Assistant"* upon the above subject, in which he speaks of the payment of masons and carpenters as contrasting favourably with that of chemists and druggists' assistants. In consideration of the increasing stringency of the examinations, he thinks there ought to be a general advance in the rate at which assistants are remunerated, and a decrease in the number of business hours. He believes that "strikes are not the first move, but the result of neglected appeals," and that chemists' assistants will form no exception to the rule.

Mr. G. H. Wright desires it to be known that it was at his request we stated that he was the rejected candidate for Council and not Mr. W. V. Wright. As regards his other complaint, we imagined that it was sufficiently well known who Mr. G. H. Wright is, and it would not have been possible to publish his letter elsewhere than in our advertisement columns.

"Vive, Vale."—(1.) Inquire of the Secretary of the Apothecaries' Company. (2.) Yes.

M. Rennaud (Torrington).—We are not aware of the existence of any laws regulating the practice of pharmacy in the countries mentioned.

Erratum.—In p. 968, col. ii. line 21, *for* "colorific rays" *read* "calorific rays."

Communications, Letters, etc., have been received from Messrs. J. R. Jackson, Fairlie, Stoakes, C. S. Davies, Macdowall, "One of the Bitten," "Roy," W. A. M., B. W. L.

The following journals have been received:—The 'British Medical Journal,' May 31; the 'Medical Times and Gazette,' May 31; the 'Lancet,' May 31; the 'London Medical Record,' May 28; 'Medical Press and Circular,' May 30; 'Nature,' May 31; 'Chemical News,' May 31; 'Gardener's Chronicle,' May 31; the 'Grocer,' May 31; 'Journal of the Society of Arts,' May 31; 'American Chemist' for May; 'Doctor' for June; 'Pharmacist,' January to April; 'British Journal of Dental Science' for June; 'L'Union Pharmaceutique' for May; 'Florist and Pomologist' for June; 'Archiv der Pharmacie' for April; 'Zeitschrift des allg. österr. Apotheker-Vereines' for May and June.

THE PHARMACY OF THE UNITED STATES' PHARMACOPŒIA.

BY WILLIAM MARTINDALE, F.C.S.,

Dispenser, and Teacher of Pharmacy to the University College Hospital.

(*Continued from page* 902.)

Extracta.—There are thirty-four formulæ for these, and the following instructions are prefixed to this class of preparations:*—Unless otherwise directed, they are to be evaporated "as quickly as possible in a broad, shallow vessel, by means of a water-bath, until they have acquired the consistence proper for forming pills; and towards the end of the process stir them constantly with a spatula. Sprinkle upon the softer extracts a small quantity of alcohol."

In all except six cases the process of percolation is adopted for exhausting the crude drugs in making these extracts. The exceptions are the extracts of fresh parts of plants,—the leaves of belladonna, conium and hyoscyamus, and taraxacum root;—extract of opium is made like B. P.—three cold macerations in water and evaporation of the clear liquors; extract of logwood is also made like B. P. from a decoction with water, and the subsequent evaporation of this.

The official extracts may be divided into five classes, viz.:—

Pure alcoholic.—The extracts of ignatia, nux vomica, cannabis americana, cannabis indica, and physostigma. The drugs are taken in powder, of various degrees of fineness, and percolated with alcohol (sp. gr. ·835), a sufficient quantity. The spirit is distilled from the tincture so obtained, and the residue evaporated by a water-bath to a soft extract. The last three drugs are macerated for four days with a portion of the spirit before proceeding to percolate.

Semi-alcoholic.—Of these there are—

a. Extracts in which diluted alcohol only is used as a solvent—*Extractum dulcamaræ, extractum senegæ, extractum stramonii seminis,* and *extractum colocynthidis.* The spirit is directed to be recovered from all, except senega, by distillation. In extract of colocynth, the colocynth pulp is first macerated with a portion of the spirit and pressed, the marc percolated with more spirit, the mixed liquors are then distilled to collect the alcohol, the residue being afterwards dried and powdered. About seven ounces of extract, it is stated, are obtained from forty-eight ounces of colocynth fruit (with seeds). *Extractum colocynthidis compositum* is a mixture of this simple extract with purified aloes, resin of scammony, cardamom, and soap, all in the state of fine powder.

b. Extracts in which the powdered drugs are percolated, first with alcohol (sp. gr. ·835) and then with diluted alcohol; the two percolates are partially evaporated separately, and then mixed and evaporated to a proper consistence. The following are so prepared:—*Extractum aconiti, extractum conii alcoholicum* (leaves), *extractum digitalis, extractum hellebori, extractum podophylli, extractum rhei, extractum stramonii foliorum, extractum valerianæ.*

c. Extracts in which the powdered drugs are treated by percolation, first, with a mixture of two volumes of alcohol (sp. gr. ·835) and one of water, and afterwards with diluted alcohol, and the mixed percolates evaporated to an extract. The following are so made:—*Extractum arnicæ* (flowers), *extractum belladonnæ alcoholicum* (leaves), and *extractum hyoscyami alcoholicum* (leaves).

d. Extracts in which the powdered drugs are treated by maceration and percolation, first with alcohol (sp. gr. ·835) and then with *common* water. The first portion of percolate is distilled to recover the spirit, and the two products are separately evaporated until syrupy, mixed and concentrated to an extract. These are *extractum cinchonæ* (yellow bark),* and *extractum jalapæ.*

Aqueous.—Extracts prepared by percolation of the powdered drugs with cold water, and the subsequent evaporation of the percolate to a proper consistence. These are *extractum gentianæ, extractum juglandis* (butternut bark), *extractum krameriæ*, and *extractum quassiæ.* The evaporation of the percolate from rhatany, after heating to the boiling point and straining, is to be continued at a temperature not exceeding 160°, to form an extract. *Extractum opii* and *extractum hæmatoxyli*, before mentioned, are also aqueous extracts.

Acetous.—*Extractum colchici aceticum.* This is prepared by diluting acetic acid with four volumes of water, percolating the powdered dried "root" (*sic*) with this solvent, adding more water until the drug is exhausted, and evaporating the percolates in a water bath to a proper consistence.

Extracts of fresh parts of plants.—There are four of these preparations; three of them are prepared from the fresh leaves separated from the branches entirely (not like the B. P., or Mr. P. Squire, in this respect)—these are the extracts of belladonna, conium, and hyoscyamus. The leaves are bruised in a stone mortar, sprinkled with a little water, and the juice expressed; then having heated this to the boiling point, the liquor is strained and evaporated to a proper consistence. The chlorophyll is thus separated from these extracts. They will therefore not be *green* extracts in the sense in which we understand the corresponding preparations of the British Pharmacopœia. When the chlorophyll is separated from these extracts, they are very hygroscopic in their nature, and troublesome to manage pharmaceutically, especially when prescribed in the form of pills, else the separation of the chlorophyll is an advantage therapeutically, as it is merely an inert substance which increases the bulk

---

* Dividing the preparations into classes allows the editors of a national pharmacopœia the opportunity of giving general instructions for preparing each class, which, in the compilation of the British Pharmacopœia, was not embraced—the strict alphabetical arrangement of the whole being adhered to. The alphabetical and class arrangements might, I think, with advantage be blended together so as to permit some instructions to be given under the head of each class. Many pages of space might have been saved by such means by condensing and omitting the repetition of the process for making tinctures by maceration and percolation under each separate formula in the British Pharmacopœia. In the London Pharmacopœia short heads of this kind were appended to some classes, which were often useful. As an example of the effect of such omission, none of the infusions in any of the three Pharmacopœias under notice are directed to be agitated, as they ought to be, during their maceration, and the consequence is that, in perhaps seven cases out of ten, when negligently prepared according to the Pharmacopœia, they are never agitated at all until they are strained off.—W. M.

* I have previously mentioned that *common water* is ordered in the preparation of *extractum cinchonæ* and *extractum cinchonæ fluidum.* This appears to be a great oversight.—W. M.

of these preparations. Extra care is directed to be used in the preparation of *extractum conii* to prevent the volatilization of the alkaloid this ought to contain. After heating the juice up to the boiling point and filtering, the liquor is evaporated to the proper consistence, either in a vacuum with the aid of heat, or in shallow vessels, at the ordinary temperature, by means of a current of air directed over the surface of the liquid. *Extractum taraxaci*, the other fresh extract, is prepared by slicing the root, sprinkling it with water and bruising, until reduced to a pulp. The juice is then expressed, strained, and evaporated in a vacuum, or in a shallow dish over a water bath, to the proper consistence,—it is never heated to the boiling point; it will thus contain all the albuminoid matter the fresh juice contains, if carefully prepared.

Great care has been taken to give very minute instructions about the preparation of each separate extract, but a point that strikes one very forcibly is the liberal use of spirit ordered in making this class of preparations, and in many cases the spontaneous evaporation of it from the percolates in such a way as to materially increase the cost of the extracts so obtained. I am not aware whether, in the United States, pharmacists are liable to such a heavy duty upon alcohol as we are in this country, but I think our American cousins are wide enough awake to their own interests, not to permit of the "spontaneous evaporation" of alcohol, although the Pharmacopœia may order it.

(*To be continued.*)

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from p.* 825).

Eucalyptus Globulus.*—A remarkably beautiful and striking group of the Myrtaceæ is represented by the extensive genus *Eucalyptus* which predominates to such a degree in a great part of New Holland that it principally determines the character of the vegetation of the country. The Eucalypti, which belong exclusively to New Holland and Van Dieman's Land, sometimes reach an enormous circumference, for *E. globulus* (Labill.) not unfrequently attains a height of 150 feet, while the trunk near the ground is from 25 to 40 feet in circumference. The foliage of the Eucalypti is very remarkable, and the sabre-like form of the leaves, the edges of which are turned toward the trunk, together with their bluish green colour, gives them a sombre appearance.

In the maritime zone of Corsica, according to a pamphlet published by Messrs. Savory and Moore, the *E. globulus* vegetates throughout the year, and if the soil be suitable its growth is more rapid than that of any other ligneous plant.

"Every year, in the spring, the trunk strips itself of a portion of its outer bark, and this bark as well as that which adheres to the sapwood, and even the leaves, when dried, preserve the characteristic odour, and when chewed, have a decided bitter taste, with an after taste of resin. The wood is hard, close, compact, and suited for building purposes and ship timber." The bark and leaves only are used in pharmacy.

* Meyen, 'Geography of Plants.'

The bark is remarkable for the ease with which it separates into thin layers, whence one of its vernacular names of stringy bark, and is on this account not particularly easy of microscopical examination. A few hours' maceration in cold water, and a final gentle boiling for five minutes will generally render the ligneous fibres sufficiently soft to permit the cutting of a thin section without tearing the softer tissues. Sections cut transversely radially are the most useful and must be very thin.

The outer layers of the bark are corrugated layers of loose cork cells covered by compressed epidermal cells, and in no wise remarkable. The warty elevations are produced by semi-sub-epidermal receptacula, large very minutely porous cells, containing a mixed substance of great complexity, in large part proteinaceous, the exudation of which appears to be concerned in the stripping off of the epidermis just referred to; and in part consisting of an essential oil to which the characteristic odour is due, and which is also found in similar receptacula in the leaves. The receptacula of the bark are best seen in transverse sections, treated a short time with carbon bisulphide, and then with iodine solution. Their size and form are only to be ascertained by carefully cutting thin slices off the epidermis, and thus exposing the receptacula beneath. Ether, alcohol, and carbon bisulphide remove the essential oil, as also alcohol, and leave the proteinaceous constituents which may then be examined by the usual reagents. Nitric acid dissolves these and leaves a small residuum of doubtful character. Within these receptacula and the loose layer of parenchymatous cells immediately beneath the epidermis, are the several tissues forming the stringy bark. The stringiness is due to the long cord-like liber-tubes which are pretty evenly distributed amongst thin-walled, tender, parenchyma cells, medullary rays, and resin or oil receptacula. The liber-cells are tough and in bundles of six or more, adhere closely to each other with very slight adhesion to the other cells of the bark, so that very slight force suffices to strip the bark into layers and finally into fibres, whence it occurs to me, that were the bark cheaply obtained it might be of economic value, after being exhausted of its tanning and febrifuge qualities, for the purpose of making paper of great strength.

The liber-tubes are very long and tough, porous, with a small central cavity containing tannic acid, a proteinaceus substance that intensely stains with solution of logwood, and also the essential oil, to which probably the camphoraceous smell of the bark is in part due, though the oil is chiefly contained in large special receptacula and in the large subcutaneous cells just described. The liber-cells are best studied in a radial section stained with magenta, as much of the dye as possible being removed with hot alcohol, and their pores are best examined in transverse logwood-stained sections. Careful use of sulphochromic acid is needful to demonstrate the successive ligneous deposits of the cells.

In the cells adjoining the liber-tubes are considerable quantities of the crystal prisms of Professor Gulliver, very variously shaped, and resembling those found in the Portugal onion. They and the liber-tubes are intensely doubly refractive, and, being of various size and shape, polarize very beautifully. So that a carefully-executed section from the middle of the bark forms an exquisitely lovely polariscope object, but is very difficult to mount successfully.

The play of colour when the prisms are crossed without the intervention of a selenite filter is very fine.

The cells of the parenchyma are thin-walled, subglobose in shape, and contain, besides the crystal prisms and the ordinary albuminous contents, tannic acid and a saccharine substance that very rapidly reduces Fehling's test. The tannin is most largely present in the middle portion of the bark, in the medullary rays, and in the oil receptacula distributed through the bark, and in small quantities only in the sub-epidermic receptacula. The crystals are not imbedded in the cell-contents, and are evidently an oxalate of lime, and perhaps, some of them, of some other salt. Starch very doubtfully present in any of the specimens I have examined.

The medullary rays are narrow, and composed of nearly square cells containing a yellow, red-brown substance consisting of tannin, an oil, and protein substance. The cell walls at right angles to the direction of the rays are much more delicate than the other walls, and easily give way under tension, much facilitating the "stripping" of the bark.

Two forms of oil and resin vessels are common in the inner portion of the bark. One very long and thin-walled kind lies alongside the liber-tubes, and is not to be distinguished from them until the section has been deprived of all its colouring-matter and is either slightly stained or is examined by polarized light. The other form consists of irregularly-shaped cells, thick-walled and consolidated, and very minutely porous, of very various shapes, and chiefly aggregated in the middle portion of the bark. These cells can only be studied after the careful application of ether and alcohol to remove resin, and sulphuric acid and chlorate of potash to remove albuminous and gummy matters and to bleach the specimen. Large receptacula in the form of intercellular spaces, bounded by small cells and very similar to those found in the rind of the orange, occur near the exterior, and also, but rarely, in the inner portions of the bark, and are easily seen if the section containing them be partially exhausted with alcohol and then stained with iodine solution. The contents of these receptacula apparently do not include tannic acid, at any rate not in a state sufficiently free to give the usual reaction with iron salts. (A section stained with proto-sulphate of iron is very interesting, and shows the distribution of the astringent principle very clearly.)

To conclude, it is doubtful whether any bark requires more careful examination, or is worthy of more careful study, than the one that has occupied us so long. The leaves may now perhaps be noticed, as the substances present in them bear some relation to the oils and resins in the bark. As has already been said, the leaves are more or less sabre-shaped, and bear a white bloom, due to depauperation of the epidermis, here as in all the Australian Myrtaceæ of abnormal development. The longer leaves have great numbers of semi-lunar stomates on each surface, and the two surfaces agree more closely than is usually the case. This might be expected, from the fact that these leaves grow edgeways, and not, as our English and most other leaves, with their flat sides to the sky and sun. The structure of the petiole should first engage our attention on commencing the histology of the leaf. The first thing that we notice on examining a transverse section is the presence of receptacula a little within the epidermis, not immediately beneath it, as in the bark and in the rind of orange, containing a yellow essential oil, similar to the oil of the bark but lighter in colour, probably from the absence of one of the tannic compounds, to which a portion of the darker colour of the bark oil is due. These receptacula are precisely similar in construction to the other one, and do not on this account require further notice here.

The cells of the epidermis are thickened, not so compressed as usual, and much longer than broad (differing, however, much in this respect in different specimens). The subepidermal layer is chiefly composed of globose cells, many of which contain a rose or rose-purple chromule,* often present in sufficient quantity to give a decided purple colour to the petiole and midrib. The parenchyma cells are much thicker-walled than in the bark, and contain chlorophyll, and a few starch granules. Crystals are not usually abundant. The central woody tissue is by no means in the circular bundle commonly found in the petioles of the leaves of ligneous plants, but resembles a section through an involute vernation, the opening of the "scroll" is occupied by wood cells nearly filled with ligneous deposits, and the small central cavity containing only protein matter. Within the scroll are ordinary parenchyma cells containing granular substances, starch and small crystals. The liber-cells bounding the "scroll" are larger than the inner and have larger central cavities. Their resemblance to the cord-like liber-cells of the bark is very close, and their contents are very similar.

The structure of the "scroll" itself is somewhat complex and consists chiefly of wood fibres, pitted and dotted, fibrous and annular vessels, all interesting, but requiring more space than can be devoted to them here.

The leaves are easily sectionized if they be placed in a soft split cork, and the usual section-cutting instrument be made use of. The epidermis is composed of irregular cells, little compressed and nearly equally thickened on each cell wall. The stomates are very numerous, and consist of two equally-sized semilunar cells, the whole stomate being of course circular, the semilunar cells containing no chlorophyll, but an amorphous semigranular substance, of which I have not been able to ascertain the nature. Exudations of a yellow resinoid substance, an oxidation product probably of one of the oils of the leaf, is found on the surface of the older leaves, as tear-shaped masses immediately above pear-shaped receptacula situate below the epidermal and subepidermal layers. The receptacula within the leaf are of two forms, one circular in cross-sections, and not communicating with the exterior, the other pear-shaped, and frequently opening at the surface by a small circular orifice, not due merely to disruption of the outer cell wall, but often perfectly formed as a pseudo-stomate. The contents of the two receptacula are slightly different, the latter containing the more camphoraceous oil, not, however, unlikely an oxidation product of the other. The middle layers of the leaf do not require special notice. The margin, where the submarginal vein characteristic of Myrtaceæ is found, requires brief notice only in one particular. Within the wood cells, of which the hard margin is chiefly composed, lie small aggregations of porous cells, apparently connected with, or the terminals of, the vessels, with little or no contents and performing no appa-

* A product, as we shall see presently, of one of the chlorophylls or chlorophyll compounds of the leaves.

rent functions. Similar congeries of cells occur in a few other leaves, but are more easily seen here than in any other leaf that I have examined, excepting, perhaps, the leaf of *Tropæolum magus.*

A somewhat complete examination that I have made of the colouring-matters of the bark and leaves must stand over for the next chapter.

(*To be continued.*)

CHEMICAL EXAMINATION OF THE BARK OF THE AZADIRACHTA INDICA.*

BY J. BROUGHTON,

Government Quinologist.

The use of the bark of this well-known tree, the *Azadirachta Indica,* generally called the Nim tree, is quite general throughout the whole of India as a tonic and febrifuge. It is generally employed in the form of a decoction, though sometimes as powder, and has been stated by certain English authorities to have the same febrifuge qualities as cinchona bark. The taste of the bark is intensely bitter; the inner layer, or liber, is however by far the bitterest. The tree being very handsome, and the wood of value, it is well known in avenues; the plants generally bearing marks of having been robbed of their bark for medicinal use. The pinnate leaves have also an intensely bitter taste, and are employed in native medicine, though not as a febrifuge, being used as a poultice externally, and are said to have a powerful effect in preventing glandular tumours from coming to maturity. They are also employed by natives in their fresh, green state to cover the bodies of patients suffering from small-pox, though I believe this is done rather from a religious than a medicinal motive. The seeds yield a considerable amount of oil, which has also a strong, bitter taste, is used for lamps and in medicine. The roots are said to have vermifuge properties, but I have not examined them. The main virtues of the tree reside in the bark.

The investigation has been a matter of much labour and difficulty, from the circumstance of the bitter principle having scarcely any definite qualities, it being a neutral resin. It is slightly soluble in water, and hence the decoctions of the bark are intensely bitter, though water will not extract the whole present. To obtain it in purity the bark is exhausted with spirit of about 60 per cent., the filtered tincture precipitated with water, the dried precipitate again exhausted with benzol, again evaporated, again exhausted with carbonic disulphide, then by dry ether, and finally by absolute alcohol. The last exhaustion causes the separation of a small amount of a white transparent substance, crystallizing in fine needles, which is quite insoluble in water, has no taste, and consists of carbon, hydrogen, and oxygen. Obtainable in but small quantities, it has not been satisfactorily analysed, and has the general characters of a crystalline fat, though fusing at 175° C. It is certainly not the effective principle of the bark nor an alkaloid.

The resin purified by the successive solvents is a dark brown, somewhat soft resin, of agreeable smell, resembling that of the bark. It is slightly soluble in water, and entirely in all the foregoing solvents, but not in fixed oils. In any dilute solution its bitter taste is strong, but not disagreeable. It is soluble in strong boiling solutions of the fixed alkalies, from which acids again precipitate it apparently altered, likewise in strong sulphuric acid, by which it is also altered. It fuses at 92° C.

The determination of its true chemical formula has been a matter of great difficulty and labour, from the circumstance of its refusal to combine with other substances in a definite manner. It was finally determined by the discovery of a nitro-compound which yielded a silver salt, not, however, crystalline. From the analyses of these I ascribe to the resin the formula $C_{36}H_{50}O_{11}$. Its nitro-compound is formed in the usual manner by nitric acid and precipitation with water, is yellow, uncrystallizable, somewhat soluble in water, more readily in alkalies, and having the formula $C_{36}H_{46}(NO)_4O_{11}$.

The resin is, therefore, not in any respect an alkaloid, as it contains no nitrogen. Its chemical constitution appears to me scarcely to confirm the ascribed antiperiodic febrifuge qualities of the bark, though doubtless the bitter solution of the resin may be a good tonic. If required for medicinal purposes, it will be most conveniently employed in alcoholic solution. As the bark varies very considerably in its content of the bitter resin, a direct tincture would be unsuitable, but the impure resin, after the application of benzol in the foregoing process of preparation, would be fit for solution in alcohol and employment in medicine.

It is singular that native physicians never appear to have employed a tincture of the bark instead of an aqueous decoction. From some conversation I had with a native physician in Bengal, I believe it is the native religious dislike in that country to the use of alcohol which has prevented its use for this purpose.

The leaves contain a small amount of bitter substance of a similar nature, but which is far more soluble in water. The same substance is also contained in the bark in addition to the one described. It has very similar properties to the resin, of which it is a hydrate. No peculiar alkaloid is contained in the leaves. The oil contains a small amount of the bitter substance of the leaves, not the resin of the bark. The powerful smell of the tree is well known, but it is not due to the presence of a sulphuretted oil, as has been surmised; indeed, I have not succeeded in obtaining an essential oil from the tree. If the bark is distilled with water, the distillate has the perfume of the tree, but no oil is perceptible, though it has the power of decolorizing potassic permanganate.

A condensed account of our present knowledge of the therapeutics and chemistry of *Azadirachta Indica* is to be found in the Indian Pharmacopœia, pp. 53 and 443, from which, however, I differ in some points.

* From the *Madras Monthly Journal of Medical Science.*

WHAT IS THE TRUE COLOUR OF PULVIS CRETÆ AROMATICUS?

BY ARCHIBALD PATERSON.

With an article of such importance as Pulvis Cretæ Aromaticus, one which is so frequently prescribed, and which forms the basis of that useful remedy, aromatic powder of chalk and opium; one would very naturally suppose, that a question such as the heading of this paper asks, would be altogether uncalled for.

The ingredients of its composition only require to be in fine powder and mixed carefully.

Such being the conditions of its preparation, we should expect that it would at all times present a uniform colour. Such, however, is not the case.

This preparation finds its way into the drug market, a variety of shades, from a bright ochre yellow to a colour very much resembling Dover's Powder, which Mr. Squire, in his 'Companion to the British Pharmacopœia of 1867,' describes as a "dark fawn colour."

Now, if the dispenser gets supplied at one time with an article bearing this name, of a bright ochre colour, and next time he requires it, having asked for the same preparation, he is supplied with a powder bearing the same name, but of a colour perfectly different; it becomes a matter of doubt in his mind; and he asks himself which is the correct one?

He knows the formula prescribes a quantity of saffron in powder, and is aware that saffron gives a most brilliant colour with spirit.

He, without trying to prepare a few ounces for himself, very naturally expects that saffron should also impart the same beautiful colour to a mixture of chalk, sugar, etc., etc., and at once decides in favour of the high coloured preparation; while he attributes the want of colour in the other specimen to a deficiency of saffron.

The result of this is, that he loses confidence in the house which supplied the pale coloured article, while the establishment which sent him the powder of a high colour rises in his estimation.

Now, the strange part of the matter is this: these specimens may be both equally genuine.

It is not necessary that the rich coloured preparation should contain a grain more of saffron than its pale-faced brother; neither is it imperative that pale face should be a cheat because he does not exhibit all his colour in his countenance. The difference in appearance is simply a matter of manipulation during the preparation, which I will endeavour to show.

If the ingredients are simply in fine powder, and mixed, as the 'British Pharmacopœia' directs, and as any dispensing chemist making the powder himself would do, without any mechanical aids except his mortar and pestle, and a sieve, then the resulting product will be the pale coloured preparation. Again, if the ingredients are ground in a mill, as is done by most wholesale houses, and during the pulverising of the saffron, a few drops of rectified spirit is introduced, the result is, that the colour of the saffron (which is not intended to be displayed in the dry state) is diffused through the mixture, and the product is the high coloured powder referred to.

There is no doubt the latter preparation is the most pleasing to the eye; but I question if the production of this bright colour in the powder is quite justifiable, it gives it a richness of colour, which, although it may not be false, is certainly premature.

At the same time it causes the dispenser to expect more than he is entitled to, and to find fault with firms which do not supply the high coloured preparation. If any gentlemen suspects that the full quantity of saffron is not present in any given specimen, I would advise him to prepare a few ounces of the powder himself, to be kept as a standard test specimen. Let him now take, say ten grains of the suspected article, and an equal quantity of his own standard specimen, and macerate each in an equal quantity, say four drachms, of rectified spirit for a few hours, the shade of colour produced will give a pretty accurate estimation of the saffron value of the suspected specimen.

By adopting some such simple test, and discontinuing to ask for the high coloured article, this powder would soon become a uniform colour, resembling the old pulv. confect. aromat. which it was intended to supersede.

ADULTERATION OF PEPPER.*

BY M. BOUCHARDAT.

During the examination of a large number of specimens of ground pepper the author met with various inert powders, and among those which he detected the most often was one prepared by drying and finely pulverizing the parenchyma of potatoes which is left as a residue in the manufacture of starch. Pepper mixed with this adulterant has a more feeble odour; its taste is at first sweetish, and afterwards pungent, but less intensely so than in normal pepper. The mixed powder is uniformly grey, whilst the powder of pepper presents some blackish particles and some of a yellowish grey colour. Comparison should therefore be made between a suspected powder and one prepared by grinding pepper to the same degree of fineness. Ground pepper mixed with this potato powder floats longer on the surface of water than that which is pure, and the coloration of the water is different. Liquor iodi, added drop by drop, gives a more intense blue with the potato mixture than with normal pepper. Too much importance, however, must not be attached to this test, as M. Léon Soubeiran has shown that pepper contains a considerable quantity of a peculiar fecula.

The other substances found mixed with ground pepper were (1) lentil flour mixed with earth, which can be detected by the microscope and calcination; (2) chalk; and (3) linseed cake, ground to a degree of fineness comparable to that of ground pepper. By the aid of a good glass the fragments of linseed could easily be seen. In some specimens seized at the custom-house the powder of sesame seeds was detected; and it appeared probable that in this case, in order to obtain the proper shade for the powder, the adulterator, who had sent from Marseilles several hundred bags of this product, had mixed many sorts of seeds.

White pepper, obtained, as is known, by the decortication of black pepper, is often adulterated with talc, chalk, and starch in considerable proportions. The introduction of these three inert matters may have for its object either the direct increase of bulk or the masking of an imperfect decortication. After the examination of numerous specimens, M. Bouchardat came to the conclusion that many manufacturers supplied two products: one, known as *poivre léger*, consisting principally of the cortical part of the pepper, black fragments forming the greater portion of it; the other, known as *poivre blanc*, being mixed with talc or starch, to imitate the shade of white pepper. Although the *poivre léger* contains nothing foreign to pepper, yet as the useful part is eliminated, the sale of such an article must be looked upon as a fraud on the part of the dealer. It is also sometimes adulterated with ground grains of paradise, which is easily detected by means of a magnifying glass. In France, to avoid prosecution, the wholesale dealer is said often to sell the ground pepper pure and the mixture intended for its adulteration separately.

The usual adulterants of pepper may be clearly identified by means of a microscopic examination, with an instrument of 300 to 400 magnifying power, in the hands of a skilled person. The powder of pepper is characterized principally by its starch. This appears in compound grains retaining the form of the cells in which they were contained, and which they entirely filled. They are of variable forms and dimensions; M. Mussat has measured them from 0·030 mm. to 0·20 mm. in diameter. The simple grains of which they are formed are, from their juxtaposition, irregularly rounded, and are from 0·001 mm. to 0·0056 mm. in diameter. Under the action of iodine they assume a rather dull violet-blue colour. Solution of caustic potash attacks them but slowly. This fecula is accompanied by the *débris* of the pericarp, which presents two very distinct forms of cells. In one case they are nearly cubical, with rather thin walls, containing a blackish granular matter, which is the fleshy portion of the

* 'L'Union Pharmaceutique,' vol. xiv., p. 145.

pericarp; in the other, the cells forming the endocarp, they are cuneiform, often slightly curved, and their very thick walls are canaliculate. The author found their mean size to be 0·025 mm. wide by 0·062 mm. long. Potato starch is easily distinguished from that of pepper by its simple, more or less rounded or ovoid or irregularly trigonal, strongly refractive grains. The largest measure 0·180 m.m. All, except the smallest (which measure about 0·010 m.m.), have a conspicuous, often stellate hilum, and their concentric zones are clearly visible. Dilute solution of caustic potash attacks them very rapidly. A yellow tissue contained in several of the specimens examined was distinguished easily by its elongated polygonal cells, with thin, clear, yellow walls, enclosing a slightly darker granular substance. It probably belonged to some oleaginous cruciferous seed, or to linseed.

In consideration of the great skill with which pepper is now adulterated, M. Bouchardat recommends that dealers should, as far as possible, buy their pepper whole and grind it themselves.

NOTES ON ALOES.*

BY EDWARD R. SQUIBB, M.D.

A pretty close examination and cross-examination of the aloes of the commercial market, during the past few years, has led the writer to the inference that the differences in it are due quite as much to difference in mode of preparation as to difference in species, climate, etc. Comparing the varieties of the market with the uses and effects of the drug, without too much dependence upon the books, it will be found that there are two distinct classes.

Between these classes there seems to be a pretty sharp line of difference, while the individuals of each class shade off into each other without any well-marked boundary line. The prominent, and perhaps characteristic difference between the two classes of the drug is, that in their therapeutic effect one is comparatively mild and gentle, and unirritating, with tonic and aromatic qualities, while the other is more harsh and drastic, producing more irritation, and much more liable to overaction. This difference adapts the individuals of the first class better to use in human beings, and renders a selection for the mildest among the individuals very desirable, if not necessary, in the delicate organization of women, in the treatment of whose diseases this drug is so important and so valuable. The individuals of the second class are better adapted to the medication of animals, and by right should not be used for mankind.

Carrying this therapeutic distinction into the drug market, and applying it closely, the two classes will be easily made out by a marked difference in the sensible properties. The one class is of a lighter colour, generally soft, and often semi-fluid in consistence, and varying in both colour and consistence with length of exposure to the air, and with temperature. The odour is entirely different, both in quality and degree, being aromatic in quality and feeble in degree. When strong, and approaching to the character of a stench, as it not unfrequently does, this may arise from decomposing animal matter, such as goat-skin, fragments of which are often found in the aloes. From the appearance of these fragments of skin, and fragments of the aloe plants, and from the presence of uncoagulated albumen, it seems almost certain that the individuals of this class have not been subjected to artificial heating, but that the exuded juice is dried in the sun,—perhaps in goat-skins, which line a shallow excavation made in the sand at the stump of the plant, whose leaves may have been cut off near the ground and laid with their exuding, cut ends over the goat-skin.

The second or more drastic class affords equal evidence of being prepared by artificial heat, and the depth of colour, to some extent, indicates the amount and quality of the heat used. Most, but not all, the varieties of this class give evidence of being made by decoction of the plant, rather than by evaporation of juices obtained by exudation from the fresh plant.

All the individuals of the first class are known in the market as Socotrine aloes, or occasionally as East India aloes; while the second class has no generic or class name, but embraces the individual varieties which come from the West India Islands, and from Eastern and Southern Africa. This group is well represented by the commercial titles Barbadoes aloes, Cape aloes, etc. And each of the two names mentioned covers, in the market, sub-varieties, produced neither in Barbadoes nor in the Cape of Good Hope.

While some of the finer varities of this class are occasionally met with which are very aromatic and very nice, giving evidence of careful preparation, this is so rare an exception that it does not modify the judgment of the writer to the effect that the whole class should be excluded from the materia medica and pharmacy which is specially applicable to mankind, and be confined to the larger uses of veterinary practice, where it has special and very important advantages over the other class.

The so-called Socotrine aloes varies quite as much, though all under one name, as the other class with its various names, but of late years there is a growing tendency in the market to separate it into two sub-varieties by difference in colour, so that it is now not uncommon to hear of red Socotrine aloes, and yellow Socotrine aloes, the red variety being justly held in the highest estimation. A curious observation, often verified by the writer, is that the red variety is always yellow at first, and gradually changes to red through intermediate shades, by age and exposure to the air: and that continued exposure tends constantly to deepen the red colour into garnet at first, and finally into reddish-black, when the edges are no longer translucent. The yellow sub-variety, however, does not become red by age and air contact, but only deepens, as it dries and becomes brittle, into a yellowish liver colour, or yellowish-brown, with very little of the red tinge, or none at all. This yellow subvariety it is in which the fetid, stinking odour is occasionally met with, and as both subvarieties are of the same yellow colour at one early stage, even of their drug market career, and at this stage distinguishable chiefly by odour and visible impurities, the question arises as to whether both are not from the same source, and the same process of preparation, the parcels which become red being well and carefully prepared, while the parcels which do not become red, may, from containing putrescible matter, undergo a fermentation which may destroy the elements upon which the red colour depends, and other more valuable qualities, as the aroma, etc.

The fetid odour of this subvariety is always diminished by age, and is altogether lost in the powder made from it.

As a general rule this Socotrine aloes is much higher in price than any of the grades of aloes by decoction, and loses much more largely by drying. All except the finer parcels of the red variety require to be melted, diluted, and strained before they are fit for medical use, and the loss by straining varies very much, say from 5 to 10 per cent. It is curious to notice how small a proportion of these impurities is visible by inspection of the aloes beforehand. The average loss from straining and drying is perhaps 15 to 18 per cent., but has, in the writer's experience, once reached 27 per cent. upon a large lot. The substances separated by straining through a sieve of sixty meshes to the linear inch are chiefly pieces of goat-skin, shreds of the aloe plant, sticks, small stones, and hair. Exceptionally entire goat-skins are found in the parcels, and one was met with tied up at the openings, showing how the juice is transported to the packing places. One outlet—the neck—appeared to have been left open, as in the transportation of grape-juice from the wine-presses, through which to pour out the contents. After being emptied—for it was found empty—this skin appears t

* From the 'Proceedings of the American Pharmaceutical Association.'

have been dropped into the package of aloes, possibly by some child, as the skin is smaller than others which have been met with. From another parcel a rude knife of very peculiar shape and construction was strained. This knife, as shown, was probably used to cut off or incise the leaves of the plant, though it does not appear to be particularly well adapted to such purpose for civilized hands. The above figures are given from an experience of straining, drying, and powdering more than twenty-two thousand pounds of Socotrine aloes.

The melting, straining, and drying of the aloes by artificial heat is very injurious to it, of course, as in proportion to the want of skill and care with which this is done it degrades the aloes to the character of the lower grades made by decoction. But when the question is reduced down to a choice between this injury done and the common practice of drying on steam tables without straining, and thus powdering up goat-skin, stones, sticks, etc., there can be no doubt as to which course is best for the interests of medicine. The finer packages of red Socotrine aloes, which always command a high price but are slow sale, contain so little of impurity which can be separated by a No. 60 sieve, that as a rule it is better to use it without this hurtful process. Spread thinly out upon shallow trays of tinned iron, the advisability of straining can be approximately and usefully judged. And if this be done in cold weather when the aloes does not run, and when the air is comparatively dry, a couple of months' exposure, at ordinary temperatures, is sufficient to dry the aloes well, retaining its natural aroma to a highly desirable and useful extent. It is very much to be feared that the use of such aloes in the officinal formulas is very much undervalued, since the Socotrine aloes which has passed through the writer's hands within the past ten years has been very nearly all used by successive crops of quack pill men, who must have good drugs while getting up the reputation of their nostrums, though this may not be the time when the money is made. Pharmacists, as a class, use very few such drugs, because not knowing their value they will not pay the price.

A case of very good red Socotrine aloes, imported by the writer from Messrs. Arthur S. Hill and Son, of London, is shown herewith, and will be found in the exhibition-room of the Association during the meeting. The members are invited to make a critical examination of it. This case cost £19 10s. per cwt. of 112 lbs. in London. That is to say, about 83 cents gold without freight, duty, or any other element of cost. The currency cost price to the writer cannot be far from 1 dol. 20 cents per pound. It is drier than usual, though not cleaner than the best of its kind, and will not lose in drying more than about 10 per cent., while it does not need straining. Add 10 per cent. to 1 dol. 20 cents and the cost will stand about 1 dol. 32 cents currency. A very high price, but the cost well represented in intrinsic value.

This case, however, is exceptionably costly, since five cases had by the writer from Messrs. Dix and Morris, of New York, next previous to this shipment, were of nearly as good quality, and quite as clean, though not quite so dry, at 75 cents per pound currency.

ANIMAL NUTRITION.

BY HERR STOHMANN.

The author, who has studied the subject of animal nutrition by the aid of a series of experiments upon goats, has published the results in *Der Naturförscher* for April. The following abstract of the memoir is taken from the *London Medical Record* (June 4):—

With regard to the proportion of food-stuffs utilized in nutrition, as deduced from a comparison of excrement with food consumed, Herr Stohmann finds that "there is no essential difference in the utilization (*Ausnützung*) of meadow-hay in different kinds of ruminating animals—the ox, the cow, the sheep, the goat." The same thing, indeed, has been previously expressed by other observers; it is a result of some methodological importance, as establishing the possibility of comparing experiments made on different species of animals, and drawing general conclusions from these.

"The addition of greater quantities of easily digested non-nitrogenous matters to hay causes considerably less absorption of albuminous substances and of raw fibres (*Rohfaser*—a somewhat impure cellulose, obtainable by a simple analysis)." As proof of this is given the following. The absorption of albumen in meadow-hay, in one of the animals, was 58·4 per cent.; on addition of 200 grs. starch-flour and 200 grs. gum, the absorption sank to 32·6 per cent. So also with the raw fibres, though in greater degree. In the fodder consumed there were 110 grs. of raw fibres furnished daily. Supposing a digestibility in these equal to that in meadow-hay for fodder, 49 grs. ought to be digested daily, whereas only 11 grs. were digested. The digestibility of raw fibres is therefore diminished in the proportion of these numbers.

"The addition of carbohydrates seems to have no influence on the digestibility of fat." The percentage absorption-numbers were the same as for unmixed hay.

"The absorption of substances of the albuminoid group is dependent on the proportion of nitrogenous to non-nitrogenous matter in the fodder." In this statement, partly the same thing is expressed as in the former, but it has special reference to protein-stuffs, and to the addition of any other food-stuffs, not merely the easily digestible non-nitrogenous materials. This relation Herr Stohmann has endeavoured to express by way of mathematical formula, as follows:—

$$p' = \frac{p}{1 + \frac{1}{9} \cdot \frac{S}{p}}$$

where p denotes the quantity of protein-stuffs consumed, p', the digested portion of these, and S, the weight of the non-nitrogenous constituents of the fodder." It will be seen that p increases with the decrease of S; so that the protein-stuffs are the more digestible the more they preponderate in the food.

There can be no doubt that a formula of this kind will never be absolutely accurate. Apart from the various digestibility of protein-stuffs of different origin, there would, in the case where $S = 0$, be a perfect absorption of the protein-stuffs; *i. e.*, the fæces would be free from nitrogen; whereas Herr Stohmann himself takes cognizance of the fact, that the solid excrements are richer in nitrogen, the more protein-stuffs have been consumed as food. But this is not the meaning of the formula; it claims only a relative validity, and that only within the limits of variation of ordinary fodder mixtures (or a little beyond these). To this must be added that it agrees very fully with the numbers obtained in experiments; and so, with the proviso mentioned, it may be accepted as a means of estimating beforehand the digestion of protein matter, in a healthy ruminant, for a given amount of fodder. Herr Stohmann does not attempt a theoretical explanation of the phenomenon in question, and probably the data are insufficient for this; it is, however, a decided advance, to succeed in constructing a valid formula like that just given.

"Easily-digested carbohydrates diminish the absorption of fat." Under the influence of starch-flour and gum, the absorption of the fat of meadow-hay is reduced from 35 to 23 or 24 per cent.; through sugar, even to 7 per cent. We here see again the similar influence of starch-flour and gum, whence it appears that both substances are closely allied in the process of digestion.

In addition to the foregoing propositions, there are others which are of a more secondary and methodological interest.

"The sum of the digested non-nitrogenous constituents of meadow-hay is approximately equal to the quantity of non-nitrogenous extractive matter and fat contained in it; it is, however, influenced by the various digestibility of the raw fibres. Fodder materials of the same kind, but of different origin, are digestible in very various degrees. The digestive power of one and the same animal for the same fodder varies little, and may, under normal conditions, be regarded as almost constant. The digestive powers of different individuals of the same species are slightly but not essentially different."

Herr Stohmann further extended his researches to the connection of milk-production, and other phenomena of metamorphosis, with nutrition.

The amount of milk.production is dependent on the individuality of the animal, on the duration of the lactation period, on the fodder, and especially on the albumen contained in this,—as appeared from experiment, by increasing and diminishing the amount of albumen. A fodder which, reckoning for a constant animal weight, is sufficient for abundant production of milk in a large animal, does not meet the requirements of a small animal; whence it follows that a small amount of animal weight of a goat is more expensive to maintain than a corresponding quantity of a cow. The goat is, during its comparatively short lactation period, a more liberal milk-producer than the cow; since, for the same weight of animal, an equal supply of milk is never obtained from the cow. The milk-production is influenced by the quantity of water consumed and distributed through the body. Cows fed with watery fodder, green fodder, turnips, and the like, give considerably more milk; we also find nursing women drink large quantities (proportionally) of liquid. This shows that the production of milk is an essentially different process from fattening. Greater consumption of water, while it furthers milk-production, hinders fattening; milk-production demands a large exchange of albumen, while everything that promotes this exchange opposes fattening. The fat contents of fodder have, according to Herr Stohmann, no special influence on the secretion of milk. Protein-stuffs, also, do not operate immediately, but after some time; and it would appear that the lacteal glands are slowly "built up" at the expense of the albuminous blood, and afterwards, on falling asunder, they give forth the milk.

Lastly, with reference to the influence of nature of food on change of material (*Stoffumsatz*), Herr Stohmann has some propositions which closely correspond with those advanced by Voit with reference to carnivora.

"Increase of albumen in food causes increased change of albumen in the body;" a statement, which, *e.g.*, is proved by the following numbers from experiment:—

Fodder.		Nitrogen Absorbed by the Goat.	Nitrogen Excreted in Urine.
Hay.	Linseed Meal.		
1500 grammes	100 grammes	17·9 grammes	10·7 grammes
1400 ,,	200 ,,	21·1 ,,	14·5 ,,
1100 ,,	500 ,,	31·0 ,,	18·9 ,,
800 ,,	800 ,,	41·1 ,,	27·8 ,,

The quantity of nitrogen employed for the production of constituents of the body rises and falls with the increase and diminution of albumen in the food; a fact which is readily explained if one considers that the albumen-change increases almost proportionally to the nitrogen received, but not quite; so that there is an ever-increasing remainder for incorporation of protein in the tissues, and for the production of milk.

Increase of albumen in the food acts, in the first instance, on the production of milk-albumen, and in much smaller degree on incorporation of albumen. The incorporation and expenditure of albumen are dependent on the state of the body; a fact which is especially apparent in changing from one fodder to another, when the albumen-change corresponding to the new food does not at once come into play. The albumen-change in the body increases with increased water consumption.

An incorporation of fat takes place, when with great quantities of albumen there are given great quantities of easily digestible non-nitrogenous matters.

SAND EROSION.

The novel method of engraving and boring glass, stone, etc., by causing jets of fine siliceous sand to impinge with great velocity upon the portion intended to be removed is illustrated in the International Exhibition at South Kensington by a machine invented by Mr. Tilghman, of Philadelphia. The machine is thus described in a Report on Machinery and the Processes connected therewith, furnished to the *Journal of the Society of Arts* by the Rev. Arthur Rigg, M.A.

"There are two machines now in operation upon glass, and one at work on stone. The small machine is to appearance a very plain painted box or stand—nothing of machinery visible. In the top of this box are two holes, about an inch and a half in diameter. If the wooden casings were removed, there might be seen below these holes a pipe, which descends, and is formed somewhat trumpet-mouthed on the outside of the bottom of the box. Below this mouth is a turned wooden basin. From the upper part of the box, on the spectator's left hand, a pipe passes underneath the floor to the centre of a rotating fan, near the wall of the room, and therefore by this a vacuum can be formed in the box. As the only inlet of air is past the trumpet-mouthed opening, a rapid current ascends the pipe connected with it whenever the exhaust-fan is at work. From large hoppers (funnel-shaped) containing sand, a regulated quantity falls towards the turned wooden basin; in falling on the basin it is influenced by the entering air, is jetted from the pipe, and so strikes upon, say, glass covering the holes; the exposed glass is rapidly depolished. Where, however, an elastic substance, as paper, india-rubber, etc., covers the glass, no action of the sand takes place.

"If interstices or openings be formed in this elastic substance, as a pattern, then the surface of the glass is removed in accordance with such pattern, and to a depth dependent upon the time of exposure, and the intensity of the current of air, and quality of the sand.

"Next to this small "vacuum" machine is a large compressed air-blast one, capable of acting upon a sheet of glass three feet broad. A design in paper or lace being pasted on the glass, it is laid upon endless bands, by the motion of which it may be carried forward. In the middle of the compartment (which is glazed upon one side so that spectators may see the operation) provision is made, by a suitably-formed transverse opening, for a blast of air with sand. When the ordinary machinery is set in motion this blast commences, the glass is travelled at a prearranged velocity, and in as little time as one may require to read this account, the ornamented glass is delivered at the side of the box opposite to that at which it entered.

"So slightly an elastic surface as the changed character of some of the materials used in photography suffices to resist the action of the sand; hence the photographic design may be etched by sand on glass. Examples of various works done by this process are on a table near to the machine. The third machine is in a separate building. It consists of a wooden table, on which the stone is laid. This table can be traversed impulsively in one direction, by the action of a Clement's driver, on a spur wheel, and so motion is given to a rack.

"Above the table, provision is made for traversing the combined steam and sand jet. This is accomplished by a mangle-wheel motion, variable according to the breadth of the stone to be operated upon. By these two motions, transverse to each other, every portion of the stone may be reached. The steam and sand jet is arranged upon the plan adopted by Mr. Siemens, for exhausting the telegraph despatch tubes—the sand being admitted by an inner small tube, surrounded by jets of steam, as from concentric rays of an argand burner. Whilst your reporter was present, a delicate and somewhat intricate cast-iron pattern was laid upon a piece of marble. The steam in the boiler was at 55 lbs. pressure. In five minutes the marble, measuring 13 inches by 6, was penetrated to a depth of about 3-16ths of an inch, leaving the surface as originally polished, and with the beautiful tracery design in high relief. The sand is ordinary silver sand, and was used at the rate of one pint per minute; the slab of marble was three-quarters of an inch in thickness, and was rapidly cut by the sand blast, and so separated from a larger piece.

"This eroding action of sand mixed with water has formed many of the ravines and glens in our island. If the following statement, made to the writer of this report about ten years ago, be true in fact, there is a property in water which has not yet been utilized. Whilst standing near a new steam-boiler which was being tested under water pressure, and when the load was near its maximum, a small and (except that the sun shone upon it so that the light was decomposed) imperceptible jet appeared; the writer was about to pass his finger across it, when a workman said, 'Don't do that, sir; a boy had his finger cut off with one of those jets.' Might not a jet of water be used as a saw?"

With reference to the remark in the last paragraph as to the part this eroding action of sand mixed with water has played in affecting the physical features of this country, it will be interesting to quote from the lecture "On Niagara," recently delivered at the Royal Institution, by Professor Tyndall, some remarks as to the genesis and proximate destiny of those falls:—

"Time and intensity are the main factors of geologic change, and they are in a certain sense convertible. A feeble force acting through long periods, and an intense force acting through short ones, may produce approximately the same results. To Dr. Hooker I have been indebted for some samples of stones, the first examples of which were picked up by Mr. Hackworth on the shores of Lyell's Bay, near Wellington, in New Zealand, and described by Mr. Travers in the 'Transactions of the New Zealand Institute.' Unacquainted with their origin, you would certainly ascribe their forms to human workmanship. They resemble flint knives and spear-heads, being apparently chiselled off into facets with as much attention to symmetry as if a tool guided by human intelligence had passed over them. But no human instrument has been brought to bear upon these stones. They have been wrought into their present shape by the windblown sand of Lyell's Bay. Two winds are dominant here, and they in succession urged the sand against opposite sides of the stone; every little particle of sand chipped away its infinitesimal bit of stone, and in the end sculptured these singular forms.

"The Sphynx of Egypt is nearly covered up by the sand of the desert. The neck of the Sphynx is partly cut across, not, as I am assured by Mr. Huxley, by ordinary weathering, but by the eroding action of the fine sand blown against it. In these cases nature furnishes us with hints which may be taken advantage of in art; and this action of sand has been recently turned to extraordinary account in the United States. When in Boston, I was taken to see the action of the *sand-blast*. A kind of hopper, containing fine siliceous sand, was connected with a reservoir of compressed air, the pressure being variable at pleasure. The hopper ended in a long slit, from which the sand was blown. A plate of glass was placed beneath this slit, and caused to pass slowly under it; it came out perfectly depolished, with a bright opalescent glimmer, such as could only be produced by the most careful grinding. Every little particle of sand urged against the glass, having all its energy concentrated on the point of impact, formed there a little pit, the depolished surface consisting of innumerable hollows of this description. But this was not all. By protecting certain portions of the surface and exposing others, figures and tracery of any required form could be etched upon the glass. The figures of open ironwork could be thus copied; while wire gauze placed over the glass produced a reticulated pattern. But it required no such resisting substance as iron to shelter the glass. The patterns of the finest lace could be thus reproduced; the delicate filaments of the lace itself offering a sufficient protection. A fraction of a minute suffices to etch upon glass a rich and beautiful lace pattern. Any yielding substance may be employed to protect the glass. By immediately diffusing the shock of the particle, such substances practically destroy the local erosive power. The hand can bear without inconvenience a sand-shower which would pulverize glass. Etchings executed on glass with suitable kinds of ink are accurately worked out by the sand-blast. In fact, within certain limits, the harder the surface, the greater is the concentration of the shock, and the more effectual is the erosion. It is not necessary that the sand should be the harder substance of the two; corundum, for example, is much harder than quartz; still, quartz-sand can not only depolish, but actually blow a hole through a plate of corundum. Nay, glass may be depolished by the impact of fine shot; the grains in this case bruising the glass before they have time to flatten and turn their energy into heat.

"And here, in passing, we may tie together one or two apparently unrelated facts. Supposing you turn on, at the lower part of a house, a cock which is fed by a pipe from a cistern at the top of the house, the column of water, from the cistern downwards, is set in motion. By turning off the cock, this motion is stopped; and when the turning off is very sudden, the pipe, if not strong, may be burst by the internal impact of the water. By distributing the turning of the cock over half a second of time, the shock and danger of rupture may be entirely avoided. We have here an example of the concentration of energy in *time*. The sand-blast illustrates the concentration of energy in *space*. The action of flint and steel is an illustration of the same principle. The heat required to generate the spark is intense, and the mechanical action being moderate, must, to produce fire, be in the highest degree concentrated. This concentration is secured by the collision of hard substances. Calc-spar will not supply the place of flint, nor lead the place of steel in the production of fire by collision. With the softer substances, the *total* heat produced may be greater than with the hard ones, but to produce the spark, the heat must be intensely *localized*.

"This power of erosion, so strikingly displayed when sand is urged by air, renders us better able to conceive its action when urged by water. The erosive power of a river is vastly augmented by the solid matter carried along with it. Sand or pebbles caught in a river vortex can wear away the hardest rock; 'potholes' and deep cylindrical shafts being thus produced. An extraordinary instance of this kind of erosion is to be seen in the Val Tournanche, above the village of this name. The gorge at Handeck has been thus cut out. Such waterfalls were once frequent in the valleys of Switzerland; for hardly any valley is without one or more transverse barriers of resisting material, over which the river flowing through the valley once fell as a cataract. Near Pontresina, in the Engadin, there is such a case; the hard gneiss being now worn away to form a gorge through which the river from the Morteratsch glacier rushes. The barrier of the Kirchet above Meyringen is also a case in point. Behind it was a lake derived from the glacier of the Aar, and over the barrier the lake poured its excess of water. Here the rock, being limestone, was in great part dissolved; but added to this, we had the action of the sand particles carried along by the water, each of which, as it struck the rock, chipped it away like the particles of the sand-blast. Thus by solution and mechanical erosion the great chasm of the Fensteraarschlucht was formed. It is demonstrable that the water which flows at the bottoms of such deep fissures once flowed at the level of what is now their edges, and tum-bled down the lower faces of the barriers. Almost every valley in Switzerland furnishes examples of this kind; the untenable hypothesis of earthquakes, once so readily resorted to in accounting for these gorges, being now for the most part abandoned.

"And now we come to Niagara. Soon after Europeans had taken possession of the country, the conviction appears to have arisen that the deep channel of the river Niagara below the falls had been excavated by the cataract. In Mr. Bakewell's 'Introduction to Geology,' the prevalence of this belief has been referred to: it is expressed thus by Professor Joseph Henry in the 'Transactions of the Albany Institute:'—'In viewing the position of the falls, and the features of the country round, it is impossible not to be impressed with the idea that this great natural raceway has been formed by the continued action of the irresistible Niagara, and that the falls, beginning at Lewiston have, in the course of ages, worn back the rocky strata to their present site.'

"A connected image of the origin and progress of the cataract is easily obtained. Walking northward from the village of Niagara Falls by the side of the river, we have to our left the deep and comparatively narrow gorge through which the Niagara flows. The bounding cliffs of this gorge are from 300 to 350 feet high. We reach the whirlpool, trend to the north-east, and after a little time gradually resume our northward course. Finally, at about seven miles from the present falls, we come to the edge of a declivity which informs us that we have been hitherto walking on table land. At some hundreds of feet below us is a comparatively level plain, which stretches to Lake Ontario. The declivity marks the end of the precipitous gorge of the Niagara. Here the river escapes from its steep mural boundaries, and in a widened bed pursues its way to the lake which finally receives its waters.

"The fact that in historic times, even within the memory of man, the fall has sensibly receded, prompts the question, how far has this recession gone? At what point did the ledge which thus continually creeps backwards begin its retrograde course? To minds disciplined in such researches the answer has been and will be, at the precipitous declivity which crossed the Niagara from Lewiston on the American to Queenston on the Canadian side. Over this transverse barrier the united affluents of all the upper lakes once poured their waters, and here the work of erosion began. The dam, moreover, was demonstrably of sufficient height to cause the river above it to submerge Goat Island; and this would perfectly account for the finding by Sir Charles Lyell, Mr. Hall, and others, in the sand and gravel of the island, the same fluviatile shells as are now found in the Niagara River higher up. It would also account for those deposits along the sides of the river, the discovery of which enabled Lyell, Hall, and Ramsay, to reduce to demonstration the popular belief that the Niagara once flowed through a shallow valley.

"The physics of the problem of excavation, which I made clear to my mind before quitting Niagara, are revealed by a close inspection of the present Horseshoe Fall. Here we see evidently that the greatest weight of water bends over the very apex of the Horseshoe. In a passage in his excellent chapter on Niagara Falls, Mr. Hall alludes to this fact. Here we have the most copious and the most violent whirling of the shattered liquid; here the most powerful eddies recoil against the shale. From this portion of the fall, indeed, the spray sometimes rises without solution of continuity to the region of clouds, becoming gradually more attenuated, and passing finally through the condition of true cloud into invisible vapour, which is sometimes reprecipitated higher up. All the phenomena point distinctly to the centre of the river as the place of greatest mechanical energy, and from the centre the vigour of the fall gradually dies away towards the sides. The horseshoe form, with the concavity facing downwards, is an obvious and necessary consequence of this action. Right along the middle of the river the apex of the curve pushes its way backwards, cutting along the centre a deep and comparatively narrow groove, and draining the sides as it passes them. Hence the remarkable discrepancy between the widths of the Niagara above and below the Horseshoe. All along its course, from Lewiston Heights to its present position, the form of the fall was probably that of a horseshoe; for this is merely the expression of the greater depth, and consequently greater excavating power, of the centre of the river. The gorge, moreover, varies in width as the depth of the centre of the ancient river varied, being narrowest where that depth was greatest.

"The vast comparative erosive energy of the Horseshoe Fall comes strikingly into view when it and the American Fall are compared together. The American branch of the upper river is cut at a right angle by the gorge of the Niagara. Here the Horseshoe Fall was the real excavator. It cut the rock and formed the precipice over which the American Fall tumbles. But since its formation, the erosive action of the American Fall has been almost nil, while the Horseshoe has cut its way for 500 yards across the end of Goat Island, and is now doubling back to excavate its channel parallel to the length of the island. This point, I have just learned, has not escaped the acute observation of Professor Ramsay. The river bends; the Horseshoe immediately accommodates itself to the bending, and will follow implicitly the direction of the deepest water in the upper stream. The flexibility of the gorge, if I may use the term, is determined by the flexibility of the river channel above it. Were the Niagara above the fall sinuous, the gorge would obediently follow its sinuosities. Once suggested, no doubt geographers will be able to point out many examples of this action. The Zambesi is thought to present a great difficulty to the erosion theory, because of the sinuosity of the chasm below the Victoria Falls. But, assuming the basalt to be of tolerably uniform texture, had the river been examined before the formation of this sinuous channel, the present zigzag course of the gorge below the fall could, I am persuaded, have been predicted, while the sounding of the present river would enable us to predict the course to be pursued by the erosion in the future.

"But not only has the Niagara River cut the gorge, it has carried away the chips of its own workshop. The shale being probably crumbled is easily carried away. But at the base of the fall we find the huge boulders already described, and by some means or other these are removed down the river. The ice which fills the gorge in winter, and which grapples with the boulders, has been regarded as the transporting agent. Probably it is so to some extent. But erosion acts without ceasing on the abutting points of the boulders, thus withdrawing their support and urging them gradually down the river. Solution also does its portion of the work. That solid matter is carried down is proved by the difference of depth between the Niagara River and Lake Ontario, where the river enters it. The depth falls from 72 feet to 20 feet, in consequence of the deposition of solid matter caused by the diminished motion of the river.

"In conclusion, we may say a word regarding the proximate future of Niagara. At the rate of excavation assigned to it by Sir Charles Lyell, namely, a foot a year, five thousand years or so will carry the Horseshoe Fall far higher than Goat Island. As the gorge recedes it will drain, as it has hitherto done, the banks right and left of it, thus leaving a nearly level terrace between Goat Island and the end of the gorge. Higher up it will totally drain the American branch of the river, the channel of which in due time will become cultivable land. The American Fall will then be transformed into a dry precipice, forming a simple continuation of the cliffy boundary of the Niagara. At the place occupied by the fall at this moment we shall have the gorge enclosing a right angle, a second whirlpool being the consequence of this. To those who visit Niagara a few millenniums hence I leave the verification of this prediction. All that can be said is, that if the causes now in action continue to act, it will prove itself literally true."

The Pharmaceutical Journal.

SATURDAY, JUNE 14, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE SOCIETY'S SCHOOL OF PHARMACY.

THE appointment of a Committee to consider the suggestions submitted to the Council by Professors REDWOOD and BENTLEY, in regard to alteration of lecture courses and the fees for attending them, may be accepted as an earnest that some steps will now be taken towards the realization of that severance of the School from the Society which has so often been pointed to as an event not only necessary but also in some respects desirable under present conditions. The resolution by which the Committee was appointed had indeed a wider scope than the suggestion of the above-named Professors, taking in not only the lectures but also the laboratory; but it is mainly in regard to the lectures that there seems to be most urgent need for some modification of the practice hitherto followed.

The extremely low fees charged for attendance at these courses of lectures are quite anomalous, and though it was no doubt sound policy for the Society to continue for a time the fees adopted when the School was in its infancy, it must be evident to all that when the work of establishing recognition of the necessity for special education had been achieved, there was no longer any reason for maintaining the lecture fees at so low a rate. At the outset it was necessary to attract students, and almost to give them the means of improving themselves, since it was wholly optional whether they did so or not. Under such circumstances the funds of the Society were well applied in defraying the cost of lectures; but now, when the technical education of pharmacists has become a necessity, it is time to stop such a course, since the various means by which that necessity is provided for have acquired a value which should make them remunerative, or at least self-supporting.

These views in regard to the Society's lectures, which have long been entertained by a few, were broached in the Council some years ago, and a distinct proposition was made, more than once we believe, to raise the lecture fees. It is to be regretted that this was not done long ago; for in place of a single difficulty there are now two which present themselves in connection with the subject. On the one hand we have complaints that so large a sum is absorbed in meeting the difference between the cost of lectures at Bloomsbury Square and the fees paid for attending them; while, on the other hand, any endeavour to place the Society's School upon an independent footing would seem to be rendered impossible until such time as the attendance fees shall have been raised to a standard that would make the lectures remunerative to the professors.

The opinions expressed at the late Council Meeting and at the General Meeting, as well as on various previous occasions, sufficiently justify us in speaking of the financial dissociation of the metropolitan School from the Society as being both necessary and desirable. It is therefore now especially important that this School should be made—what every such school should be—self-supporting; and our readers will doubtlessly look forward with considerable interest to the result of the Committee's deliberations.

THE CONFERENCE OF 1874.

AT page 1001 of the present number will be found a discussion which seems to indicate the prospect of a break in the periodical recurrence of a gathering at once useful and pleasant to all connected with pharmacy; unless, indeed, ingenuity is exercised meanwhile to devise a remedy for the state of things which is said to preclude the Conference from meeting in Ireland. Failing this, we may, next September, have the President and officers of that body asking each other when they shall meet again, like the witches in 'Macbeth,' and with as little idea of the precise locality as those erratic females.

Certainly the representations of the gentlemen who lately came over from Ireland as a deputation to the Executive Committee of the Conference are such as to justify the opinion that it is not expedient for the Conference to meet in Belfast, or, indeed, at all in Ireland, until the pharmaceutical difficulties prevailing in the sister island have been removed. We shall probably yet hear more on this subject before it is definitely settled. But it will not be out of place to express the opinion that it would be eminently inconsistent with the objects and principles of the Conference to find itself in the position of a bone of contention between two antagonistic parties, and compelled to share the regrets of Captain MACHEATH under similar perplexity.

EARLY CLOSING AT PETERBOROUGH.

IN reference to the subject of a paragraph in last week's Journal, stating that the Chemists and Druggists of Hull had determined to close their establishments at 7 P.M. (Saturdays excepted), we are informed that the Chemists and Druggists of Peterborough have unanimously adopted the same practice during the last fifteen months, and that the arrangement works well, giving general satisfaction. The Bank Holidays also are observed in that city by all classes of tradesmen.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, 5th June, 1873; Dr. Odling, F.R.S., President, in the chair.

After the customary business was completed, six communications were read before the Society, the first being "On the Dioxides of Calcium and Strontium," by Sir John Conroy, Bart., M.A., in which the author gave the method of preparation and properties of these substances. Mr. T. Wells then described a new form of ozone generator, which gives abundance of ozone, and has the advantage of being easily constructed and not liable to be broken. The other papers, which contained but little of general interest, were entitled "On the Behaviour of Acetamide with Sodium Alcohol," by W. N. Hartley, "On Iodine Monochloride," by J. B. Hannay, "On Triferrous Phosphide," by Dr. R. Schenk, and "On Sulphur Bromide," by J. B. Hannay.

The meeting finally adjourned until Thursday, the 19th June, for which the following memoirs are announced:—1. "On the Influence of Pressure upon Fermentation, Part II.," by Horace Brown. 2. "Researches on the Action of the Copper-Zinc Couple on Organic Bodies, Part III," and "On Normal and Iso-Propyl Iodides," by Dr. J. H. Gladstone and A. Tribe. 3. "On Cymenes from different Sources, optically considered," by Dr. J. H. Gladstone. 4. "On the Action of Bromine on Alizarine," by W. H. Perkin. 5. "On some Decompositions and Oxidation Products of Morphine and Codeine Derivatives," by E. L. Mayer and Dr. C. R. A. Wright. 6. "On the Decomposition of Tricalcic Phosphate by Water," by R. Warington. 7. "On a New Tellurium Mineral, with Notes on a Systematic Mineralogical Nomenclature," by J. B. Hannay. 8. "Communications from the Laboratory of the London Institution, No. XII., on New Derivatives of Cresol," by Dr. H. E. Armstrong and C. L. Field.

BRITISH PHARMACEUTICAL CONFERENCE.

Meeting of Executive Committee

At 17, Bloomsbury Square, London, on Wednesday, May 21st, 1873.

Present—Messrs. Schacht (in the chair), Carteighe, Clayton, Greenish, Rimmington, Savage, Attfield, and Moss.

The minutes of the previous meeting were read and confirmed.

Bell and Hills Fund.—Professor Attfield reported that, in accordance with a resolution passed at the last meeting of Committee, he had caused to be printed a circular setting forth the origin of the Fund, the action taken at the last annual meeting respecting Mr. Hills's gift of £200 for the encouragement of pharmaceutical research, and the proposal of the Committee to appropriate this sum by a method similar to that adopted under like circumstances by the British Association, including a set of rules for guidance in making grants. A copy of the circular had been sent to the respective editors of the Pharmaceutical Journal and the *Chemist and Druggist*, who had kindly given considerable prominence to the matter. A copy, together with a private letter on the subject, had also been sent to each member of the Executive Committee and to every member who had contributed an original paper to the Conference. In all, about seventy copies had been distributed. In answer, no actual applications for grants had been made, but several suggestions of subjects for investigation had been offered. Mr. Martindale suggested a thorough investigation of the plasters of the Pharmacopœia. Dr. Wright suggested that sums might be offered to members who would aid in clearing up questions about doubtful alkaloids. Mr. A. H. Allen would give a grant to any member who would further work at methods for detecting adulterations or admixtures of fixed oils; and there were the suggestions by Mr. Tichborne respecting researches having for their object the improvement of many of the official formulæ and the exclusion of others, contributions to the natural history of drugs, modes of economizing alcohol in making spirituous preparations, investigations on disinfectants, and papers on the application of physical instruments in pharmacy. Mr. Savage would encourage gentlemen having mechanical skill to produce an improved pill-machine for dispensing purposes, and machines for rapidly and perfectly commingling ingredients for large and small pill-masses. Mr. Greenish would urge the production of a model compact pharmaceutical laboratory. Professor Attfield said he had also received letters respecting the circular from Messrs. Proctor, Rogerson, Keyworth, D. B. Sharpe, Braithwaite, R. H. Davies, S. R. Atkins, and E. C. C. Stanford, and reminded members that some two hundred subjects for research were given in the "blue" list, a copy of which had recently been sent to every member of the Conference. If the cost of working out any of these subjects deterred members from accepting them, such members should at once apply to the Committee for grants.

The Chairman said the issue of the Bell and Hills Fund circular had produced some valuable suggestions, which would probably be further entertained by members when the minutes of the Committee came to be published.

Increase in the Annual Subscription to the Conference.—Professor Attfield said that when the Conference was established the founders did not entertain any idea of publishing that large, handsome, and important volume, the 'Year-Book of Pharmacy.' Indeed, when such an enterprise was mooted, it was accompanied by a proposal to charge members cost price for the work; but finding that their small annual subscription left them year after year with an increased balance in hand, a decision was arrived at to use up the accumulated funds before making any charge whatever for the book. These funds had now been exhausted, and indeed the Conference was slightly in debt; the cost of printing and binding the 'Year-Book' had moreover recently increased, in consequence of the advanced price of materials and labour. In short, the expenditure of the Conference now exceeded its income, and any increase in the numbers of members beyond the present roll of 2000 would not only add to the labours of the already overworked secretarial staff, but also actually tend to increase instead of diminish debt. Under these circumstances it became necessary for the Committee to devise and recommend a scheme which would again place the Conference on a sound financial basis.

Mr. Clayton said the 'Year-Book' was a volume for which a publisher would charge 12*s.* 6*d.* or 15*s.* Indeed with regard to its money value he had heard only one opinion—that the book was worth far more than the annual subscription and postage (5*s.* 6*d.*). Probably not five per cent. of the members would object to pay more for the book than the present subscription to the Conference.

Mr. Hanbury, Mr. Brady, and Mr. Reynolds had written letters to the Secretary supporting a proposition to raise the annual subscription to 7*s.* 6*d.*, and in return for this sum to present every member of the Conference with the 'Year-Book,' post-free.

Mr. Rimmington and Mr. Greenish supported the adoption of this course, and Professor Attfield said it would remove all financial difficulties, probably without alienating any important number of their supporters.

Mr. Carteighe proposed, and Mr. Savage seconded the following resolution:—"That the annual subscription to the Conference be in future 7*s.* 6*d.* per annum." Carried unanimously.

Place of Meeting for 1874.—Professor Attfield said that on the 7th of December last he had ventured to ask two prominent members of the Conference resident in Ireland for some general information respecting pharmacy in Ireland, where the Conference might possibly meet (in Belfast) in the autumn of 1874, in accordance with the custom hitherto obtaining of assembling at the time and place of meeting of the "British Association for the Advancement of Science." One of these gentlemen wrote:—"After careful consideration I cannot advise that the Conference should meet in Belfast. I fear that scientific pharmacy is not very well represented here in Ireland. Moreover, Belfast is a long way from London, and unless the collateral attractions of the 'Giant's Causeway' might be an incentive, the local inducements are but small." The other gentleman wrote:—"After viewing the matter in every light, I cannot recommend the Conference to go to Belfast. You would get very few Irish papers at the meeting." In April also Professor Attfield, as secretary, had at the suggestion of Mr. Schacht, written to Mr. Pring (Messrs. Grattan and Co.), Belfast, explaining the objects of the Conference, and its custom respecting the place of meeting, and had forwarded to him a 'Year-Book' and various papers relating to the Conference. Mr. Pring said in answer that he feared a sufficient number of members to make the meeting a success would not attend. In answer to a fuller and more explanatory letter which the Secretary read to the Committee, Mr. Pring gave reasons (which he afterwards personally repeated to the Committee at greater length) why it would be inexpedient in his opinion for the Conference to meet at Belfast.

Mr. Greenish said that notwithstanding the opinions of Mr. Pring, and those whom Mr. Pring represented, he hoped the Conference would keep up the practice of meeting in the town in which the British Association assembled.

Mr. Carteighe would like to hear more about Belfast and the pharmacists there, before finally deciding the question under consideration.

Mr. Clayton, who had just visited Belfast, gave valuable information regarding the relative positions there of the dispensing apothecaries and the so-called druggists.

Professor Attfield had also made extensive inquiry in the same direction, and placed the result before the Committee for its guidance.

Mr. Schacht thought that the further consideration of the subject had better be adjourned. The Committee consequently postponed the discussion.

Editorship of Year-Book.—The Secretary reported that Mr. C. H. Wood had intimated that in consequence of his appointment as Quinologist to the Government in India, he would have to leave England about next October. But this would not prevent him from editing the next issue of the 'Year-Book,' and he proposed, therefore, to hold his present office of Editor until September next when he would place his resignation in the hands of the Committee.

The Secretary was instructed to issue an advertisement announcing that the Editorship of the 'Year-Book for 1874' would be vacant, and inviting applications from candidates for the appointment.

The following gentlemen were duly elected members of the Conference:—A. S. Amoore, F. J. Barrett. G. H. Bayley, G. F. Bindloss, W. H. Booth, J. Bordass, F. W. Branson, W. Brewster, W. L. Bridgman, J. B. Brierley, T. H. Clifford, A. G. Cole, Cooke, M. P. Davies, T. Dobinson, Edwards, J. Elgey, A. W. Field, J. Finlay, R. Fortune, Grimwade, A. Harrington, H. G. Harradine, J. Hart, J. Hayes, E. Histed, W. H. Horril, J. C. Hunter, J. Jackson, W. King, J. MacCreath, H. J. Masters, H. Mathews, A. Mercer, A. T. Monkhouse, W. Pitchford R. M. Pratt, R. W. Pring, A. J. Rayson, J. Robson, C. Shapley, J. Spencer, J. Simpson, N. Spyer, J. Swaine, T. C. Taylor, G. P. Tennent, J. D. D. Thomas, W. Thorp, jun., J. Tirrell, W. W. Urwick, M. F. Walton J. S. Ward, W. A. Watts, J. Westlake, E. Wildsmith, J. L. Wills, J. H. Wilson, B. Wood, R. Wood, A. Wrigh.

Meeting of Executive Committee at 17, Bloomsbury quare, London, on the 29th May, 1873. Present—Messrs. Deane (in the chair), Hanbury, Greenish, Carteighe, Hills, Williams, Umney, Attfield, and Moss.

The minutes of the previous meeting were read and confirmed.

Place of Meeting for 1874.—Professor Attfield reported that on the day after the last meeting of the Committee he received the following letter:—

"9, *Trinity Street, Belfast,*
"*20th May*, 1873.

"To Professor Attfield,

"Sir,—At a meeting of the Protective Association of Licentiate Apothecaries of Ireland, held in this town on the evening of the 15th inst., Mr. Pring stated that he had been in correspondence with the London Secretary of the British Pharmaceutical Conference respecting the advisability or otherwise of the Conference assembling in Belfast at the same time as the British Association in 1874. The unanimous opinion of the members present was that it would give them very great pleasure to welcome the Pharmaceutical Conference, and to co-operate in furthering its objects, if the present movement of druggists in Ireland against the interests of the apothecaries did not present an obstacle. To fully explain the matter and the difficulties of the situation, it was agreed that a deputation of two or more of the members should proceed to London some time next week to meet the Committee of the Conference, if the Committee was willing to receive them. I would feel obliged if you would kindly inform me at your earliest convenience of the time and place of meeting.

"I am, dear Sir, faithfully yours,
"REUBEN BOLTON, L.A.H., *Hon. Sec.*"

Professor Attfield said that he at once acknowledged Dr. Bolton's letter, assuring him that the executive of the Conference would gladly hold a special meeting on any day that would best suit the deputation, explaining also that the Conference was a non-political body, that membership of it conferred no guarantee whatever of professional competency, and giving other information respecting the Conference. In answer, Dr. Bolton fixed Thursday, May 29th, as the day of meeting, and stated that the deputation would consist of Dr. Whitaker, Mr. Pring, and Dr. Cantrell. Professor Attfield at once telegraphed to Dr. Bolton that the executive would meet the deputation at 17, Bloomsbury Square, on the day mentioned at eleven o'clock in the forenoon, and two of the three gentlemen were now waiting to meet the Committee.

Dr. Whitaker and Mr. Pring were then introduced to the Chairman and other members of the Committee. Dr. Cantrell was unable to be present.

Mr. Pring, after making some remarks complimentary to the Conference, and acknowledging the welcome given to the deputation by the Chairman, went on to say that the compounders of medicine in Belfast, who, before they could legally dispense prescriptions had been obliged to pass a classical examination, to serve a long apprenticeship to pharmacy, and to face the ordeal of examination in chemistry, botany, and materia medica, were disinclined, in the interests of pharmacy as well as in self-interest, to recognize on any such common footing as that afforded by the Conference the so-called druggists of Ireland, men who might be of good social position, and who often traded largely in other articles, but who had given no guarantees of educated fitness for pharmacy such as those just mentioned. They had never dispensed prescriptions, and had been by law prevented from so doing for the last hundred years.

Dr. Whitaker adverted to the honour conferred on him by his appointment as a representative of Irish compounders of medicine to a body like the British Pharmaceutical Conference, which had such excellent aims as encouragement of research, and the promotion by non-political means of friendly feelings amongst pharmacists. He was glad, too, because the occasion gave him an opportunity of explaining that, although he and Mr. Pring, and those whom they represented, were termed apothecaries, they were not apothecaries in the English meaning of the word, and still more, their position was identical with that of English pharmacists, who merely sold poisons and dispensed prescriptions. It was true that the state of the law was such that they—the apothecaries of Ireland—were legally recognized as medical practitioners, and had had to pass a medical as well as a pharmaceutical examination, but this accomplished, many of them, who obtained the qualification merely for the purpose of keeping shop and dispensing medicines, ceased to keep up their medical knowledge, and practised pharmacy only. Pharmacy in many respects was more advanced in Ireland than in England, for only those could legally practise it who had spent a certain number of years in preparing medicines, then in attending the classes of the Professors, and lastly, in passing a much more severe examination than the English "Minor," and he thought pharmacy would be degraded instead of elevated if an Act came into force admitting into the ranks of Irish pharmacists the grocers and sundriesmen, who, as a rule, knew nothing of pharmacy beyond the art of buying and selling, among other things, drugs; who on the strength thereof called themselves "druggists," and latterly added thereto the title of "chemists." Such men would no doubt gladly fill the meeting-room of the Conference, but the apothecaries, who were the real pharmacists, the sole preparers of prescriptions, would rather not meet gentlemen who would know little or nothing of the subjects likely to be considered there. Doubtless the so-called druggists might even now become members, without waiting for a visit from the Conference, but that was a very different thing from the Conference being brought to their doors, thereby giving them a certain kind and amount of status to which they were not fairly entitled.

Some conversation then ensued on the general position of parties in Irish pharmacy. Nearly all present took part in the discussion, the object of which was to enable the Committee to come to a satisfactory decision respecting the question of holding a meeting in Belfast in 1874. In the end it appeared that in Ireland there were apothecaries practising medicine and pharmacy, apothecaries practising pharmacy but not medicine, and druggists practising neither medicine nor pharmacy. The second of these three classes was the most numerous of the avowed dispensers of medicine, and provided anatomy and physiology could be removed from their examinations, would be content to let matters remain as at present; they would, however, gladly aid in establishing a new society like the Pharmaceutical Society of Great Britain, or perhaps better, in founding an Irish Branch of the latter Society. They would not, however, admit any qualification for dispensing inferior to the English Major examination.

The deputation then retired. The following resolution was proposed with the view of deciding the question as to whether or not it would be desirable in 1874, to continue the custom of the Conference assembling in the town and just before the time of the meeting of the British Association.

Moved by Mr. Daniel Hanbury,—

Seconded by Mr. Thomas Hyde Hills,—

"That the Committee, having heard the statements of Dr. Whitaker and Mr. Pring, apothecaries of Belfast, regarding the present unsettled condition of pharmacy in Ireland, are of opinion that it would not be expedient for the Conference to meet in Belfast in 1874."

Carried unanimously.

Some discussion ensued respecting the class of town at which to meet in 1874, and a very general opinion was expressed in favour of London. A letter from the President was read, in which, while agreeing to London, Mr. Brady questioned whether or not some attractive watering-place, not likely to be visited by the British Association, and where high-class pharmacy was in the ascendant, might be chosen for the gathering in 1874. No decision followed, but it was remarked that if London were selected, the time of meeting should be quite early in August or even during the last week in July.

PARIS SOCIÉTÉ DE PHARMACIE.

This society met on Wednesday, May 7, under the presidency of M. Grassi. After the preliminary business had been disposed of, M. Boudet and M. Buignet referred to a paper presented to the Academy of Medicine by M. Chantard, on the "Spectrum of Chlorophyll." (A translation of this paper will be given in an early number.)

Syrup of Iodized Tar.

M. Latour read a report of a commission upon an iodized preparation of tar which had been presented to the Society by M. Bretet, a pharmacien at Cusset. This gentleman had attempted to utilize an observation made by M. Lefort, that cold tar water, prepared according to his method, possesses the property of dissolving a limited quantity of iodine, and that in consequence of its combination or association with the fixed or volatile principles contained in the tar water the presence of the iodine is obscured, and is no longer detected by starch and nitrate of silver. M. Bretet proposes to use such an iodized tar water in the preparation of a syrup. For this purpose the tar water is prepared by the process of Lefort, with 100 grams of liquid tar to each litre of water at 75° C. The liquor being cooled and filtered, 1800 grams of sugar are added to each litre, left to dissolve in the cold, and the whole passed through canvas. The liquor is then of a full brown colour, but it gradually loses colour, and after a few hours its tint is not much darker than the ordinary syrup of tar; it is then filtered into a closed vessel. This syrup is slightly opaline, does not colour starch, does not taste of iodine, has a good appearance, and is easily preserved.

The reporters found that in this process the iodine dissolved slowly, and they proposed instead to divide 1 gram of iodine carefully and rapidly with 600 grams of powdered sugar, incorporate with this mixture 33 grams of Norwegian tar previously washed, place the whole in a wide-mouthed glass-stoppered bottle, pour on it 400 grams of distilled water at 80° C., shake frequently until cold, pour the product upon a moistened strainer, and filter through paper. The filtration is slow, but it can be made in the open air without fear of any loss of iodine. So prepared, the syrup is transparent, very aromatic, and faintly amber-coloured; it does not give off any iodine vapour. The proportion of iodine may be increased, but the syrup is very acid, and the reporters doubt its tolerance by the patient.

The report referred to certain physiological and chemical points which require further investigation.

M. Grassi exhibited some specimens of ceresin, a substance obtained from ozokerite. He also gave some information respecting it the substance of which has already appeared in this Journal at page 513.

M. Guichard described some large crystals of benzoic acid that had been produced by the prolonged action of bisulphide of carbon upon benzoin.

M. Latour presented specimens of nitrate of zinc and caustic pencils made from that salt. (See Pharm. Journ., *ante*, p. 903.)

M. Roucher read a short communication on the use of glycerine in plasters. He stated that by the addition of a small quantity of glycerine to diachylon plaster, or even to pitch plaster, they were preserved better and a much less friable product was obtained.

SOCIETY OF ARTS.

Recent Processes for the Manufacture of Gas for Illuminating Purposes.*

BY T. WILLS, F.C.S.

During the last two years various causes have combined to make the time a very favourable one for the introduction of new schemes for the manufacture of gas. Amongst these causes the following may be mentioned:—First, the fear (although to a great extent perhaps groundless, yet, nevertheless, frequently expressed) that our supply of coal will be gradually lessening, and that, at no very distant date, it will become so curtailed as to increase its value to a formidable extent; second, the tendency of the coal market to push the price of coal up, to an extent out of all proportion to the necessity, has also created uneasiness; and third, partly in consequence of this, although it must also be said, partly on account of a widespread suspicion of mismanagement, gas companies have avowedly been occupying lately an exceedingly difficult position (a position immediately recognised and very soon taken advantage of by their *employés*), with no great prospect which could inspire hope for the future. Again, the great prosperity of the country, and the free circulation of money, coupled with a comparatively small number of safe and lucrative investments, have to a great degree been the motive power of many schemes, which, without their aid, would have had considerable difficulty in fighting their way into public notice. There is one other cause lending its tendency in this direction, which, though perhaps only entertained by a few, is yet continually growing in importance, and that is the belief that the present mode of gas manufacture is wasteful and unscientific, and only at the best a poor method of obtaining the desired result. To those who have not realized this fact, it is only necessary to point to the very small amount of the hydrogen and carbon contained in the coal which find their way into the gas; to the large number of bye-products obtained in the process—bye-products which, it must be remembered, although themselves valuable, and daily increasing in value, are produced and disposed of only because at present it is impossible to prevent their formation, and which should consequently occupy quite a secondary position; and to the existing imperfections in the apparatus used in the purification, storage, and distribution of the principal product.

The present paper takes into consideration two or three of the most important of these new processes. It is intended to examine them by the light of scientific facts, and to say very little about the commercial merits or demerits of any particular scheme or schemes, although it cannot be overlooked that the one has a very important bearing upon the other. To do even this satisfactorily, it will be necessary to review briefly the chemical and physical laws which are called into operation in the manufacture of gas, and also to give a short description of the apparatus at present employed for this purpose.

The organic origin of coal is, at this time, an undisputed fact; and we recognize, in the black carbonaceous mineral, the decayed and partially decomposed remains of a luxurious tropical vegetation, a vegetation as far excelling, in extent and rapidity of growth, the present growth of the tropics, as that does the more moderate growth of the temperate regions. This being so, in order to arrive at a correct knowledge of the nature and constitution of coal, we must go back to the stems, tissues, and foliage of the plants and trees, the growth and death of which has given us our coal measures.

The number of elements entering into the constitution of such vegetation is exceedingly limited—at the most four—yet the arrangement of these four is so complex that it is at times impossible to perceive in what manner they are united. This complexity of arrangement is peculiar to organic compounds, and as a rule stamps them as being the product of some vital energy or force.

Woody fibre, viz., that part of the plant or tree which gives to it its form and shape, we know contains the elements carbon, hydrogen, and oxygen, and we also know the amount of each which enters into its constitution, but the exact manner in which the three are united to each other is unknown. Now, when any complex organic body is left to itself to decay, in other words, to become oxidized, the tendency is for it to resolve itself into simpler compounds; and if the decomposition goes on to completion, the carbon and hydrogen will each unite with oxygen, to form the most stable compound which they possibly can with that body, viz., in the case of carbon, carbonic acid ($C\,O_2$), and of hydrogen, water ($H_2\,O$). If the fermentation or decay be arrested at some intermediate stage, then compounds will be formed less complicated than the original woody fibre, but still more or less removed from the final result, according to the stage at which the action was stopped. The decomposition of this woody fibre has proceeded to a considerable extent in coal, a portion of the carbon and a large portion of the hydrogen having gone off in the form of marsh gas (fire-damp), and a further portion of carbon, together with the oxygen, as carbonic acid, while a third portion of carbon has been separated in its elementary state. We are able to trace this action through several stages, which will be more distinctly seen from the following table, in which the amount of carbon is kept up to 100 in the several carbonaceous materials:—

	Carbon.	Hydrogen.	Oxygen.
Wood	100	12·18	83·07
Peat	100	9·85	55·67
Lignite	100	8·37	42·42
Bituminous coal .	100	6·12	21·23
Anthracite. . .	100	2·84	1·74

Here, not only are we able clearly to trace, by the analysis of these substances, the changes through which they have passed and are passing, but their physical appearance and structure fully confirms this evidence. Thus, in peat, the structure of woody fibre is recognisable at a glance; in lignite and bituminous coals this structure is not so clear, but still unmistakable; while in anthracite or stone coal nearly all trace of it is gone. This slow decomposition or fermentation may be regarded as a slow burning or combustion, viz., a union of the matter of the wood or coal with oxygen, and it is attended with the same result.

If, instead of slow fermentation and decay of the wood into coal taking place, the wood had been burned at once, practically the same result would have been obtained; the elements of the wood would seek to place themselves in a much simpler relationship to each other; the various changes would have been gone through more rapidly, but the final result would be identical with that of the previous case, viz., the production of water and carbonic acid. Here also there are many intermediate stages. Combustible gases are formed in abundance, together with tarry and oily matters, composed of carbon and hydrogen, and it is only by the further burning of these that the complete decomposition is obtained. What is true here of wood is also true of coal itself, if it be taken as the starting point, more particularly, however, of those coals which still contain a fair proportion of hydrogen and oxygen.

In each case the more intense the heat, the more rapidly does the decomposition proceed, or, in other words, the quicker does the combustion take place. Further, the more complicated the structure of any particular substance, the more readily will it be split up by the action of heat, provided that its constituents can exist in a number of simpler states, which in carbon compounds and organic substances is invariably the case. In the above instances

* Read Wednesday, May 21, 1873.

it is supposed that the wood or coal is heated in air, but it is evident that we may prevent the access of air to the heated material, and by so doing we can arrest the decomposition of such material before the final stage of decomposition, as the only oxygen present will be that given off from the substance, which will in either case be insufficient for the complete combustion of the carbon and hydrogen. If the substances be heated under such circumstances, a number of compounds of carbon and hydrogen will be formed, simpler than the original wood or coal, but still having a considerable complexity of constitution.

This resolution of complex bodies to simple forms, under the influence of heat, out of contact with air, is termed destructive distillation, and is the process invariably employed in the manufacture of gas directly from coal. Thus it will be seen that the possibility of making such gas depends in the first place upon two things:—

1st. The great complexity of organic bodies, especially vegetable matter, and consequently coal.

2nd. The power which the elements constituting such substances possess, of forming a number of simpler bodies (some of them gaseous) when heated out of contact with air.

Although it is perfectly true that we cannot, in the process of destructive distillation, burn up our carbon and hydrogen into carbonic acid and water, for the want of the necessary oxygen, yet we may even go further than this, and reduce the carbon and hydrogen to their elementary condition, if the heat be only sufficiently intense, and it may be mentioned here that the reason why the experience of gas-engineers has always shown that a higher temperature gives a greater yield of gas per ton of coal, but gas of lower illuminating value, is to be found in this tendency of the carbon and hydrogen gradually to resolve themselves, under the influence of heat, into simpler and yet simpler products, until eventually a temperature is reached at which the greater portion of the carbon is deposited, and the hydrogen goes off in its elementary gaseous state.

The following Table, in which the proportion of hydrogen is maintained at 100, illustrates this point.

Table, showing the Proportion of Hydrogen and Carbon in Coal Gas distilled at different Temperatures.

Temperature.	Hydrogen.	Carbon.	Name of Gas.
Dull red heat..	100	614	Principally olefiant gas (C_2H_4).
Red heat	100	580	
Bright red heat.........	100	472	Olefiant gas (C_2H_4) mixed with marsh gas (CH_4).
White heat.....	100	325	Marsh gas (CH_4).
Continued white heat.	100	7	Nearly pure hydrogen, carbon deposited.

The number of well-known intermediate products obtained during the destructive distillation of coal is very large, and it is extremely probable that there are many that have as yet escaped observation. The subjoined table enumerates the principal of these products, as well as the physical condition in which they exist at ordinary temperatures. It seems scarcely necessary to say here, that these are true products, and in no wise educts, that is to say, they had no previous existence in the coal.

Gaseous.

Hydrogen	Butylene
Marsh gas	Carbonic oxide
Acetylene	Carbonic acid
Olefiant gas	Nitrogen
Propylene	Ammonia

Liquid.

Water	Cymol
Benzole	Aniline
Toluole	Picoline
Cumol	Bisulphide of carbon

Solid.

Paraffin	Pyrene
Naphthalin	Chrysene
Paranaphthalin	

These products are here represented as isolated and existing by themselves, but, in reality, they are found mechanically mixed in the rough materials obtained during gas distillation; practically, the result of this distillation consists of only four products:—1st. The coke which remains upon the bed of the retort in which the coal is carbonized; 2nd. A light, watery fluid, which contains some of the more soluble gaseous substances dissolved in water; 3rd. A pitchy or tarry substance formed of the liquid and solid products, the lighter portion of which contains the liquid oils and naphtha; and finally, the gaseous bodies, together with which is always found more or less of the vapours of the more volatile liquids.

As the hydrocarbons become richer in carbon, and proportionately poorer in hydrogen, the tendency is for the substance to assume the liquid state; and if this excess continues to increase, eventually to become solid. Thus, olefiant gas is C_2H_4; benzole (a liquid), C_6H_6; while naphthalin (solid) is $C_{10}H_8$.

It is advisable here that we should look a little more closely into the physical condition of some of these bodies, as upon this depends the success, or want of success, which attends many of the new schemes.

The solid, liquid and gaseous states of matter are not divided from each other by any sharp line of division, but gradually pass from one to the other by insensible gradations; this is evident to us in the case of solids and liquids, for we are acquainted with many bodies which cannot fairly be placed in either class, and to which the term viscous may appropriately be applied; not so evident, but still observable, is a state of matter bearing a relation to the liquid and gaseous states, such as viscous bodies do to liquids and solids; and, from such and other evidence, we regard gases as being the vapours of liquid bodies, more or less removed from the boiling points of such bodies.

A perfect gas would be defined as possessing the condition of perfect fluid elasticity, and presenting under a constant pressure a uniform rate of expansion for equal increments of heat, but it seems probable that this theoretical definition is never absolutely realized, for although we still speak of a few gases as perfect, and represent them therefore as fulfilling the above law, yet all analogy and previous experience would indicate that eventually even this statement will have to be modified. The term vapour was for a long period a term for a distinct class of gaseous substances, viz. those which could be made to assume the liquid condition; but, by the investigation of many experimenters, led by Faraday, this point is at present only a question of the adequateness of the means employed, and hence this term may now be used in a much wider sense, and may include all gases whatsoever, for that these are but the vapours of liquids possessing exceedingly low boiling points appears to be distinctly proved. All liquids whatever, at all temperatures, give off certain quantities of vapour from their surfaces; the amount thus given off differing for different bodies and for different temperatures; if the liquid be enclosed in any vessel, the vapour will exert a certain pressure upon the sides of such vessel, and this pressure will vary with the temperature, being higher for higher temperatures, and lower for lower ones. This pressure is termed the tension of the vapour of that particular substance. This may be readily illustrated in the following manner:—If a small quantity of water be passed up into the vacuum existing at the top of an ordinary barometer, the mercurial column will immediately be depressed to a certain extent, which depression will be due to the vapour given off from the water at the particular temperature at which the observation is made, and its amount will represent the vapour tension of water. Now, if alcohol be used in a similar experiment, the depression will be much greater, and hence the vapour tension of alcohol is said to be greater than that of water, and so on, every liquid giving a different result.

Now, if we take a case in which the amount of liquid passed to the top of the mercurial column is insufficient for the formation of that amount of vapour which the given space can take up, the whole of the liquid will then disappear, and the depression will appear to be due to the presence of a quantity of true gas, and this is borne out by the fact that a vapour in this state—unsaturated, as it is called—follows all the laws that the more permanent gases do. It will be found, for example, to vary in volume directly as the pressure, and further to increase or decrease in volume at a uniform rate on an increase or decrease of temperature. But now, on the other hand, let more of the liquid be passed up into the vacuous space than can possibly be required to fill it with vapour; in this case a quantity of the liquid will remain upon the surface of the mercury, and the superincumbent vapour is then said to be saturated, which indicates that as much vapour as can exist at that particular temperature will be found so existing in the given space; if, therefore, the temperature be now raised, a further quantity of the liquid will be converted into the gaseous condition; if lowered, a portion of the liquid already existing as gas will return to the liquid state; in the same way, if the pressure be lowered or raised, the same result will be observable. Thus it is seen that the vapour proceeding from every liquid substance possesses a fixed maximum tension for every particular temperature or pressure, which it cannot exceed under any circumstances.

It follows, also, that if we take the case of an unsaturated vapour, by either increasing the pressure or reducing the temperature, we shall eventually reach this point of maximum tension or saturation, after which any further increase of pressure, or decrease of temperature, will be attended with a condensation of the vapour into the liquid state; and, in fact, it has been by using either one of these processes, or both combined, that nearly the whole of the bodies existing as gases have been liquefied. Another point must be mentioned here. In the above illustrations the various liquids were supposed to be passed up into a vacuum, the vacuum existing above the mercury, in an ordinary barometer. Now, precisely the same results would have been obtained if this vacuous space had been filled by any gaseous body; the quantity of vapour given off by a liquid is absolutely independent of the medium into which it is so given off.

The importance of some of these facts, as regards the manufacture of gas for illuminating purposes, will be seen when it is considered that coal gas not only contains certain permanent gases, but also a large quantity of the vapours of volatile hydrocarbons, which contribute in no small degree to its luminosity; and these points will be referred to again, more particularly when speaking of carburetting air or gas.

A few words are necessary here to state a few facts regarding the luminosity of the flame of gaseous hydrocarbons.

It is still generally accepted that the luminosity of flame is due to the presence of intensely heated solid particles (although some powerful objections have been urged against such a belief). In the case of the combustion of all hydrocarbons, these solid particles are particles of carbon.

Now, a flame will be more or less luminous according to the greater or less number of such particles present, and to the temperature to which they are raised. The denser the hydrocarbon, the greater number of carbon particles will exist in a given space, and when its vapour is burned there will be a correspondingly greater number precipitated into the interior of a flame. Now, bearing these two points in mind, it will be manifestly advantageous to obtain for combustion such compounds of carbon and hydrogen in that proportion of the two which shall give us the greatest quantity of carbon to the smallest quantity of hydrogen, provided that the heat of the flame is maintained sufficiently high to raise the carbon particles to whiteness. This latter condition is quite as important as the former, for it is quite possible that a gas containing a considerable amount of the denser hydrocarbons shall, by reason of the comparatively low temperature of its flame, possess less illuminating power than a gas possessing a smaller quantity of such hydrocarbons, the temperature of the flame of which, however, is somewhat higher. It would appear to follow from this, that every effort ought to be made by the gasmaker to obtain a gas containing as large a proportion as possible of these more luminous compounds; but a glance at the following table, containing analyses of the gas supplied by several different companies, will show that, at any rate, this effort, if made, is not very successful, the greater bulk of the gas being composed of hydrogen, the flame of which is without any light-giving properties whatever, and marsh gas, a gas possessing the least light-giving power of any hydrocarbon, as it contains the smallest proportion of carbon to the largest of hydrogen.

Composition of Coal Gas Supplied by the Following Companies:—

	Great Central.	Imperial.	Chartered.
Illuminating hydrocarbons	3·56	3·67	3·53
Marsh gas	35·28	40·66	35·26
Hydrogen	51·24	41·15	51·80
Carbonic oxide	7·40	8·02	8·95
Carbonic acid.	0·28	0·29	—
Nitrogen	1·80	5·01	0·38
Oxygen	0·44	1·20	0·08
	100·00	100·00	100·00

The result, as stated here, is even more unfavourable than it at first appears, for the above figures, representing the quantity of illuminating hydrocarbons, express not only those that are really gaseous bodies, but also the vapours of liquids held dissolved in the gas. There can be no question that a great advance in the manufacture of coal-gas would be made, if by any means, applied either to the primary distillation of the coal or to the gas after its production, whereby the amount of acetylene (C_2H_2) or of olefiant gas (C_2H_4) could be increased; for olefiant gas contains, in a given bulk, just twice as much carbon as marsh gas, and acetylene a still larger quantity. The value of this increase is not to be measured only by the increased quantity of carbon contained in a given bulk of gas, for a small portion of either of the above compounds, diffused through a non-illuminating gas, is much more than equivalent to a similar quantity of carbon combined in some less condensed compound. An illustration of this occurs in the case of marsh gas. If marsh gas, possessing, it will be remembered, only a small amount of luminosity, be decomposed, either by its passage through a heated tube, or by the electric spark, the carbon it contains will be deposited, while the amount of hydrogen set free will occupy double the volume of the original gas. Yet the flame of this nearly pure hydrogen will be found to possess a greater luminosity than the flame of the original marsh gas, although it has lost nearly the whole of its light-giving material, accounted for by the presence of a very small quantity of acetylene, produced during the decomposition. The light of a coal-gas flame is, without doubt, somewhat increased in a similar manner, for the reason that during the precipitation into the interior of the flame of the solid hydrocarbons—viz., during the decomposition, under the influence of the high temperature of the flame of the gaseous bodies—small quantities of very much more highly condensed substances are formed, substances which probably would exist in the solid state if isolated at ordinary temperatures. Further than this, coal-gas, although practically a gaseous body at all temperatures, does, as has been said, act as a vehicle for holding in suspension, and carrying a certain quantity of the vapours of such bodies as benzole, toluole, naphthalin, etc., which are to be found in the tar, with what practical success—success which is sufficiently certain as to be relied upon—we shall have to consider when speaking of the special carburation of gaseous bodies as a means of obtaining illuminating gas. It is, indeed, for this purpose that these remarks regarding the luminosity of flame have been introduced.

As there are at least three schemes, to which reference will be made, for the manufacture of gas, which deal with modifications of the existing apparatus employed, it will be desirable to give a general statement of that which is at present almost exclusively used.

The coal to be distilled is exposed, in quantities of about five hundred-weight at a time, to a comparatively high heat—a bright cherry-red heat is usually employed—in elongated tubular vessels of earthenware or iron, called "retorts," the shape of which varies slightly, some being that of a capital D, with its perpendicular stroke placed as a base, others circular, and others elliptical; ten feet long, twenty inches wide, and fourteen inches high, are about the proportional measurements. A number of such retorts are usually set in a furnace, and heated by one fire; in most large works double retorts are used, which are worked from both ends, as if they were two single ones. At the mouth, or mouths, is a flange, upon which a plate of metal—the lid—is capable of being secured strongly, and made tight with luting, if necessary; through these mouths the coal is introduced by means of long scoops or gutters, and the coke at the close of the operation withdrawn by the aid of rakes. Immediately upon the introduction of a charge of coal into a heated retort, carbonization commences, and gas is evolved. This carbonization occurs first with that portion of the coal which lies in contact with the sides and bed of the retort, and hence is more complete than that of the interior, which, however, undergoes destructive distillation, and furnishes gases and vapours of higher hydrocarbons. These coming into contact with the heated mass on the exterior, split up into simpler bodies, the great desideratum being to heat the coal to an equal extent all through at the same time. The gas is conducted from the retorts by perpendicular pipes, about five inches in diameter, which rise near the mouth, called stand-pipes; these pipes, which taper towards their upper extremities, are, above the furnace, bent twice at a right angle, and enter a larger pipe running horizontally over the centre of the retorts. This tube, which is called the "hydraulic main," is at all times half full of tar and oil, and the ends of the bent tubes are allowed to dip into this tar to the depth of two or three inches, for the purpose of cutting off all communication between the retort and the gas which has left it. This hydraulic main is fixed horizontally, the tar being drawn off from its extremities, and as the whole length of tube is kept at a fair heat—which heat should not be too strong—by reason of its contiguity to the furnace, the tar is usually in a liquid condition. It becomes essential that the gas should be submitted to a process of cooling, in order that those more condensible bodies which have been vaporized by the great heat may be deposited; owing to the great mobility of gaseous matter, and its possessing a high latent heat, this process becomes one of some little difficulty, and necessitates the exposure of the gas to a very large cooling surface. This is attained either by simply passing the gas through iron tubes of sufficient length, or through hollow iron columns, having an annular closed space through which the gas circulates. The extent of surface needed is sometimes very large, as much as ten square feet of cooling surface being often necessary for every cubic foot of gas passing per minute. If it were left for the evolution of the gas in the retorts to maintain a sufficient pressure to drive it through the various apparatus, considerable loss would result from leakage; and it is found further that the gas produced under pressure is not so good in illuminating power, a considerably greater quantity of carbon being deposited under such circumstances. Hence is is customary to employ what is called an exhauster, this being usually a rotary fan, acting the part of a rough air-pump. The use of this apparatus places the pressure entirely under control, and allows it to be reduced at the retorts to about half-an-inch of water.

After the gas leaves the condenser, it has to be submitted to the various processes of purification; but as these do not in any way bear upon the present subject, it will be sufficient to state that it is first washed or *scrubbed* by passage through a coke tower, over which water is allowed to trickle, to remove any residue of tar and also the ammonia which it contains. Thence it passes into a tank of milk or cream of lime, kept in continuous motion for the removal of carbonic acid and sulphuretted hydrogen, and lastly through a series of trays filled with dry lime and oxide of iron, for the removal of the residual sulphur existing in the form of sulphuretted hydrogen or bisulphide of carbon. The gas is then stored and distributed.

It was mentioned in an earlier portion of this paper, that if coal be distilled at a high temperature, a very large yield of gas can be obtained; this increased yield, however, will be coupled with a considerable diminution of illuminating power. The reason for this was then explained—in fact, the distillation of coal may be carried on at such a low temperature that the quantity of gas obtained is practically nothing, the whole of the products appearing in the solid or liquid state (a *prolonged* exposure of gaseous hydrocarbons to a low or even moderately high heat is attended with precisely similar results, viz., the formation of more complex substances), or conversely the heat may be so high as to completely decompose the whole of the hydrocarbons into their constituent elements. It is found advisable, in ordinary working, to take a mean of these results, and thus a fair yield of gas is obtained, together with a not inconsiderable amount of tar and oily matter. These latter products increase in direct proportion to a decrease of temperature, and a consequent decrease of gas—thus:

Table of Amount of Gas and Tar obtained at Different Temperatures.

Temperature of Distillation.	Amount of Gas obtained.	Amount of Tar.
Very low red heat ...	7500	150 lbs.
1300° to 1400° F. ...	8300	120 lbs.
Bright red heat	9500	70 lbs.

There are three considerations which influence a gas engineer with regard to the temperature at which he shall distil the coal, and which sometimes compel him to use a heat higher than would otherwise be advantageous; these are, first, the time which can be afforded for the production of a given quantity of gas—a lower temperature means a more or less lengthened time of exposure for the same quantity of coal, and where, as is usual, the necessary plant is only just sufficient for the supply of the required quantity of gas, this prolongation of the process is impossible; second, the percentage of fuel (coke) used in the furnaces for the distillation, this is likely to be greater for a greater interval of time; and, thirdly, the quality of the coke produced, for the demand for coke, and consequently its value, is great, and it is therefore the principal bye-product in the gas manufacture, and its production in fair quantity and of good quality becomes an important point in the economy of gas-making.

In 1871 a patent was taken out for "Improvements in the manufacture and purification of gas, and in certain parts of the apparatus employed therein," which, while mainly dependent upon the distillation of coal and other bodies at low temperatures, proposed to fulfil all that could be desired with regard to the second and third of the above considerations, and at the same time offered in compensation for the prolonged time occupied by the distillation a very considerably increased yield of gas of a much higher than usual illuminating power. This process is carried out by distilling the coal at a much lower temperature than usual—in the original scheme from 600° to 1000° F. is mentioned, but in practice from 1300° to 1400° F. will probably be employed; at this temperature, from a ton of gas coal about 8500 cubic feet of gas are obtained, together with a greater than ordinary yield of tar and oil; this tar is condensed, by special means employed for securing a greater rapidity in the process, and collected as free from water as possible, with a view to its being re-distilled in a separate and peculiar retort. The gas produced during the carbonization of the coal is, as may be expected, a rich gas of high illuminating power, and after its production it is in all respects treated in the ordinary manner, and will therefore not require further special mention, unless it be in one particular, and that is its comparative freedom from what has been called the *residual* sulphur impurity; as this sulphur impurity consists almost entirely of the volatile bisulphide of carbon, which is recognized as a product of high temperatures, the occurrence of only a small portion of that body in gas distilled at as low a temperature as that used in this process is in no wise strange, although, doubtless, at the same time it is a favourable result. The special point of this invention consists in the submission of the oil and tar collected to separate destructive distillation at a low heat, whereby a certain quantity of those substances is vaporized, attended at the same time with the formation of another quantity of condensible products. These products are again distilled with a further partial decomposition, and this process is repeated until a given quantity of tar has been converted into vapour, and a certain amount of pitch. The means used for obtaining this result are as follows:—The tar and oil are allowed to flow into an iron pan, maintained at a temperature of about 700° or 800° F.; in this apparatus the more volatile constituents are rapidly evaporated, and are conveyed into a hollow iron tank for the purpose of retaining any of the material mechanically carried over, thence through a retort filled with charcoal in small pieces, and heated to a temperature of about 1000° F.; by the passage of the various vapours through this vessel they no doubt suffer decomposition, not brought about by any property of the ignited charcoal, but doubtless by the more thorough heating of the gas, the very large heating-surface afforded by the charcoal successfully bringing the particles of vaporous matter up to a sufficiently high temperature for decomposition; in this manner a quantity of gaseous matter is formed, notably hydrogen, carbonic acid, carbonic oxide (the oxygen being obtained by the splitting up of what water there is present), marsh gas, and a small quantity of illuminating hydrocarbons; the condensible products are treated again in the same manner as before mentioned. The gas obtained from the oil and tar is treated in the ordinary manner as regards purification, and is ultimately mixed with the gas originally obtained from the coal. The aggregate quantity thus produced is declared to be in excess of that usually obtainable from an equal quantity of coal, and possesses a considerably greater illuminating value.

This is the most recent of many processes for the distillation of coal tar and oil. Hitherto it has been found most economical to distil the substance from which gas is to be manufactured at once, that is, having only one stage in the process, for previous experience has shown that the production of a quantity of intermediate products, and their after distillation, has always been a wasteful mode of working, both as regards the result obtained and the expenditure of power and material in order to obtain it.

HOUSE OF COMMONS.

Juries Bill.

The adjourned Committee on this Bill will be resumed on Thursday, June 12.

Trade Marks' Registration Bill.

The second reading of this Bill was adjourned from Monday to Thursday, June 12.

The Adulteration Act.—Decision of the Court of Queen's Bench.

Court of Queen's Bench, Westminster, June 4. Sittings in Banco, before Mr. Justice Blackburn, Mr. Justice Quain, and Mr. Justice Archibald.

Fitzpatrick *v.* Kelly.

This case raised an important question under the Adulteration of Food Act of 1872. The respondent, a butterman of Liverpool had been proceeded against for selling adulterated butter. It appeared that the butter, which was sold for 7*d.* a pound, was mixed with lard, dripping, tallow, palm oil, and the fat from certain seeds. By the 2nd section of the Act it is provided that whoever shall sell any articles of food as unadulterated which are adulterated shall be liable, etc. The stipendiary magistrate of Liverpool dismissed the summons, on the ground that the respondent could not be brought within the section unless he represented that the butter was unadulterated, or unless it was shown that he knew the butter was adulterated.

Mr. Justice Blackburn thought the construction which the magistrate had put upon the Act was wrong. His Lordship was of opinion that, unless the seller said that the butter was adulterated, he represented that it was butter, and not anything else, and he thought that this construction imposed no hardship upon the seller, for before selling he could easily ascertain whether the article was pure or not. The 3rd section was so drawn that it was difficult to say what it meant, but his Lordship was clearly of opinion that it was not necessary to prove a guilty knowledge on the part of the seller.

Mr. Justice Quain thought when, on being asked for butter, a tradesman handed an article across the counter, he thereby represented that that article was butter, and not a mixture of the horrible ingredients mentioned in the case, and that the magistrate was wrong in holding that an express representation was necessary.

Mr. Justice Archibald thought that this was an important and valuable enactment, and that the construction which the magistrate proposed to put upon it would considerably curtail its provisions.

The case was, accordingly, sent back to the magistrate.

Mr. Milward, Q.C., and Mr. Bigham (with whom was Mr. R. G. Williams) were counsel for the appellant; Mr. Segar argued for the respondent.

During the argument, Mr. Justice Blackburn pointed out that any tradesmen who might be desirous of selling mixed or adulterated articles without rendering themselves liable to be proceeded against under the Act, could do so if they announced that the articles which they sold were mixed and adulterated.—*Times.*

Obituary.

Notice has been received of the death of the following:—

On the 9th May, 1873, Mr. Charles Palmer Gibson, Chemist and Druggist, of Whitefriargate, Hull. Aged 32. Mr. Gibson had been a Member of the Pharmaceutical Society since 1869.

On the 25th May, 1873, Mr. Henry Savage, Chemist and Druggist, of Brechin.

On the 2nd June, 1873, Mr. George William Pickles, Chemist and Druggist, of Leeds.

On the 4th of June, 1873, Mr. James Orissa Peggs, Chemist and Druggist, of Norwich.

Notes and Queries.

[340.]—TINCTURA LARICIS.—"*Isca*" asks for information respecting the proportions for making Tinctura Laricis.

[In 1858, Dr. Moore read a paper before the College of Physicians, Dublin, on the "Therapeutical Properties of Larch Bark" (PHARM. JOURN. 1st Ser., Vol. XVIII., p. 35), in which reference was made to an extract of larch, prepared and made from the watery infusion, and a tincture, made with proof spirit in the proportion of one pint to two ounces of larch bark. This tincture is of a "dark carmine colour, has an agreeable 'pinic' smell; in taste it partakes of the oleo-resins, is styptic and carminative."—ED. PH. J.]

[341.]—CAPSULÆ PAPAVERIS.—Will any correspondent furnish a few hints for the cultivation of papav. alb. so as to produce good marketable capsules (or give a reference to a work on the subject), and oblige an INQUIRER?

[The poppy likes a strong, rich soil, not too dry. The cultivation is, we believe, of the simplest character. The seed is sown in the spring in rows, the plants being in due time thinned out, so as to allow each proper space.—ED. PH. J.]

ARTIFICIAL FIBRIN.—Dr. Goodman of Southport describes (*British Medical Journal*, May 17th) the preparation of an "artificial fibrin," which he believes will prove a valuable dietetic substance in cases of feeble alimentation and deficient nutrition, especially where rejection of food constitutes a prominent feature. It is formed by exposing albuminous material, such as the ordinary hen's egg, to the action of cold water for a given period. He states that if the shell be broken and removed, and the contents immersed in cold water for about twelve hours, they are found to undergo a chemico-molecular change, and to become solid and insoluble. This change is indicated by the transparent white of the egg assuming an opaque and snowy white appearance, far surpassing that of an ordinary boiled egg. The product and the fluid in which it is immersed must now be heated to the boiling point, and the fibrin will then be ready for use.

[The application of the term "fibrin" to this prepared albumen is quite arbitrary, and does not represent any real chemical resemblance.—Ed. PH. JOURN.]

A POTENTIAL CHARM IN DRUGS (?)

Sir,—The following incident occurred a few weeks since in a market town in Lincolnshire, and will serve to illustrate one of the popular beliefs in that locality as to the nature and qualities of certain drugs in subduing the otherwise unruly and naughty propensities of a certain class of wives and husbands.

A man, by occupation a pedlar, entered a druggist's shop and, in a serious and dejected tone, asked to be supplied with a pennyworth of devil's dung and a pennyworth of dragon's blood. The curiosity of the druggist being aroused as to the purpose for which they were required, he thereupon asked his customer what on earth he was going to do with them. After a little hesitation he replied, "Why? I've a purpus for 'em,—I don't mind telling you,—my wife has run away from me, and I've been told by a woman that if I burnt the devil's dung and buried the dragon's blood, it will fetch her back—she can't help herself." "Well," replied the druggist, "I have never known them used for that purpose before, but you can try them." A few days afterwards, the pedlar, on being asked how he got on with the devil's dung and dragon's blood, said, "O, it's all right, she came back next day."

Dragon's blood is believed to be very efficacious, and is frequently sold to village girls, or to old crones who procure it for them (generally in ounce packets) as a means of ascertaining who are to be their future husbands. The method of using it is, so I have been informed, to put the packet of dragon's blood under the pillow on going to bed, and the damsel will see in a sweet vision, about the hour of 12 P.M., the village swain she is to marry.

I may say that at least three-fourths of the dragon's blood sold in these parts is used for this purpose. It is invariably sold in the powdered state, and it is to be hoped that the packet does not get burst during the visionary excitement. G. W.

May 21st, 1873.

A BOTANICAL EXCURSION.

Sir,—By all means have dinner, conversazione, ball, etc., *quantum velis*; but besides all these for the *élite*, can nothing be done for or by those whose tastes lie out of the sphere of a white cravat and a dresscoat?

Were I to suggest an object for a free and easy gathering, it would be a botanical excursion. The summer is before us, what better use could be made of a bank holiday? The general public set us druggists an example by going to Bushy Park to see the horse-chestnuts (Whit Monday to wit); or again, the May-blossoms in the Pagoda vista at Kew. Wishing to see a revival of the old "simpler's" spirit, I am, etc., GERARDE'S GHOST.

H. Proctor.—We regret the inconvenience you have experienced through the late receipt of your journal. Your letter has been handed to the Secretary, who will, no doubt, make inquiries respecting your complaint.

W. Ganderton.—Your advertisement, and the stamps enclosed have been handed to the publishers.

W. A. M.—Having made inquiries respecting the occurrence mentioned by you, we are informed that it was quite by an accident the list in question was put upon the table of the reading-room. The librarian has found out where it came from, and will take care that it does not appear in the room again. We think you were quite right in calling attention to the circumstance.

J. C.—(1) We do not know. (2) We think it quite possible.

J. A.—Probably the name is the result of an arrangement between the prescriber and a particular dispenser, or it may refer to a special Pharmacopœia.

W. Fingland.—We purpose publishing shortly an article descriptive of the apparatus you refer to.

C. Davies.—We do not know of any such preparation.

Mr. Baynes (Hull).—We are obliged for your communication.

MATERIA MEDICA OF THE UNITED STATES' PHARMACOPŒIA.

BY E. M. HOLMES,

Curator of the Museum of the Pharmaceutical Society.

The new Pharmacopœia of the United States, representing as it does the medical progress of a country so closely allied to our own in many respects, cannot fail to attract the attention of all who are interested in medicine in this country. It will doubtless be eagerly scanned, to see what new medicines have been introduced and what improvements adopted by the medical authorities; and the results of the last ten years' experience, as embodied in the present issue, will doubtless influence to a certain extent the proposed additions to our own Pharmacopœia. The general features of the work have already been fully described in a previous number of this Journal, and remarks have also been made upon many of the preparations.

A comparison of the materia medica of the present edition with that of the last Pharmacopœia, as well as with that of the British Pharmacopœia, may perhaps reveal a few points of interest.

The materia medica is subdivided into a primary and a secondary list. The primary list contains chiefly medicines of acknowledged value, with a few others, which, although they appear as ingredients in some of the more important preparations, cannot be regarded as possessed of remedial properties; to this class belong cochineal, red sanders, marble, etc. The secondary list includes medicines which were at one time much employed, but are now gradually falling into disuse, without being entirely discarded, as well as others which have been lately introduced to the notice of the medical profession, and are undergoing trial, but which are not generally accepted as possessed of decided remedial properties.

This arrangement doubtless presents certain advantages. Medicine is not entirely free from the sway of fashion, and although "pandering to fashion, or to doubtful novelties in pharmaceutical science," is reprobated in the preface to the Pharmacopœia, it cannot be denied that practically it is difficult to avoid doing so; thus the great demand for palatable medicines in America has probably led to the introduction of the large number of fluid extracts sweetened by glycerine, and these would probably have found a more fitting place in the secondary list, had doubtful preparations been allowed in it. Some really valuable medicines are occasionally allowed to fall into disuse, while newer and less useful drugs usurp their place. Many medicines which are frequently ordered in the prescriptions of older physicians rarely occur in those of a later school, but should not on that account be expunged from the Pharmacopœia. In such cases the secondary list is of great service in preventing really useful remedies from being entirely lost sight of. It also provides a place for those medicines which are used to some extent in particular localities only, but which are almost unknown in others.

It is very doubtful, however, if the secondary list is of much practical use as a half-way house for the introduction of new remedies, especially as it only appears once in ten years. During that period the medical public has made up its mind as to what medicines are of real value, and such are accordingly placed at once in the primary list. Within the last twenty years only seven remedies have been adopted into the primary list from the secondary one, viz.: brominium, chondrus, statice, stillingia, gelsemium, hydrastis, and ruta. Of these brominium and gelsemium alone can be said to possess powerful properties. Chloral, conii fructus, cerii oxalas, physostigma, and the other valuable introductions into the new Pharmacopœia, have never appeared in the secondary list. This list must therefore be regarded rather as a resting place for remedies which are doubtfully received from the first, and for those which, like saffron, although much used in domestic practice, have no decided properties to recommend their use. It is rather singular that there should be no similar purgatory for doubtful preparations. It may reasonably be hoped that the proposed Appendix to the British Pharmacopœia, while it retains the useful characters of the secondary list, will admit doubtful preparations into its catalogue.

The primary list of materia medica might perhaps be found more easy for reference if united with the preparations, the whole being arranged alphabetically as in the British Pharmacopœia.

Since the last decennial revision, 24 additions have been made to the primary, and 3 to the secondary list.

(*In the P.B.*)	(*Not in the P.B.*)
Acidum carbolicum.	Acidum carbolicum impurum.
Acidum oxalicum.	Ammonii nitras.
Cannabis indica.	Calcii hypophosphis.
Cerii oxalas.	Cannabis americana.
Conii fructus.	Chloral.
Cuprum.	Cinchona.
Physostigma.	Ferri hypophosphis.
Sodii nitras.	Gossypii radicis cortex.
	Iodoformum.
	Origanum.
	Potassii hypophosphis.
	Potassii sulphis.
	Sodii bicarbonas venalis.
	Sodii hypophosphis.
	Sodii hyposulphis.
	Zinci oxidum venale.

Of these conii fructus and origanum were dismissed from the U. S. Pharmacopœia of 1864. The rejection of conii fructus was certainly a blunder, the weight of evidence being greatly in its favour as compared with conii folia. The progress of science during the last ten years not having shown any good reasons why origanum should be regarded as possessing any very remarkable properties, its reintroduction seems to have been a mistake in the other direction. The reason for the readmission of cinchona—a term denoting any variety indifferently, provided it contain 2 per cent. of alkaloids—is not very evident; the kind of bark to be used being specified in each of the preparations containing cinchona. As different varieties contain different alkaloids, or a variable proportion of alkaloids, and as some of the alkaloids are said to be more efficacious than others, the license allowed must produce different results in the hands of different dispensers. It is difficult to understand why *Cannabis americana*, a plant but little used in America, should occupy a place in the primary list, while its more powerful congener, *C. indica* is also official. Gossypii radicis cortex is said to possess emmenagogue and parturient properties, but its action appears to be very uncertain, so that it is doubtful whether it deserves a place in this list. Iodoform was recommended some time ago in this country for glandular diseases, on account of the large proportion of iodine which it contains, but did not meet with much favour. Whether it deserves the position it has obtained has yet to be proved. The rest of the new remedies are well known in this country, and it is to be hoped that the more important of them, physostigma, chloral, ammonii nitras, and acidum carbolicum impurum will be included in the proposed Appendix to the P. B. About the importance and extensive use of chloral there can be no question; a syrup or solution of which one fluidounce should represent one ounce or half an ounce of chloral, would have been an exceedingly useful and convenient preparation, especially if combined with some really efficient flavouring agent to disguise its very disagreeable taste. It is much to be regretted that such a solution was not introduced among the preparations. Acidum carbolicum impurum is frequently ordered by medical men as a disinfectant, and varies greatly in appearance and in quality, some specimens being more offensive than the impurities they are intended to remove. Two medicines, however, which are in constant use, and which might be supposed to have at least an equal claim with such substances as iodoform and oxalate of cerium, appear to have been overlooked. These two are pepsine and a preparation to represent chlorodyne.* An official recognition of the former with appropriate tests for ascertaining its purity and strength, is certainly a desideratum. With regard to the latter, it is, I believe, as largely prescribed in America as it is in this country, and is quoted in most wholesale drug-lists. Several formulæ have been published, and each manufacturer probably uses the formula he finds most advantageous, or such a modification of it as his experience may suggest. Many retail chemists also make their own chlorodyne. Hence it is most desirable that so powerful and useful a remedy should have a recognized standard of strength and composition.

Many of the most useful remedies in the Pharmacopœia are imitations of secret preparations formerly introduced by enterprising and clever men. Charta sinapis, ext. cinchon. fluid. liq. potass. arsen., liq. potass. permang., mist. ferri co., pil. antim. co., pulv. ipecac. co., tinct. cinchon. co., etc., owe their origin to patent medicines or secret preparations. Indeed, it is very probable that if a little trouble were taken to trace the history of Pharmacopœia preparations, at least one-half would be found to have originated in a similar manner. There could therefore be no objection, on the ground of countenancing secret remedies, to the introduction of an equivalent for this excellent preparation.

Two of the preparations, valerianic acid and valerianate of zinc, have been removed to the primary list. This small number might perhaps have been considerably increased, as there are many preparations which it is impossible for the majority of chemists to manufacture with convenience or profit on their own premises, and these would find a more fitting position in the materia medica, provided that the descriptions and tests appended to each were thoroughly practical and easily applicable.

Three of the articles in the secondary list of the last edition, have been removed to the primary list in the present one. These are—gelsemium, hydrastis, and ruta.

* Although scarcely within the province of materia medica, but belonging rather to the preparations, the importance of chlorodyne may excuse a reference to it here.

Gelsemium.—This is certainly a powerful remedy, and worthy of the attention of therapeutists in this country. According to King's 'Dispensatory' it removes nervous irritability more completely than any other known agent. It is much used in America as a febrifuge. The peculiarity of its action seems to be that it causes a most complete relaxation of the muscular system, so that the patient is unable even to raise the eyelids. This effect, however, passes off in a few hours, and leaves the patient refreshed. On account of this action it has been recommended in the treatment of tetanus, and spasm of the glottis, etc. Instances of death resulting from large doses being taken are on record. It has been stated, however, but the statement seems to require further investigation, that these fatal results have been owing to the admixture of the root of a plant very similar to it in appearance, which is known as the white jessamine, or white poison vine, *Gelsemium sempervirens* being called the yellow jessamine in America. In this country it is known as the Carolina jessamine.

Hydrastis canadensis, or golden seal.—A full account of the properties and uses of this plant have been given in a former volume of the PHARMACEUTICAL JOURNAL, by Professor Bentley, and therefore it need not be alluded to here.*

Ruta graveolens.—Rue appears to be one of those drugs, the use of which is more or less influenced by fashion. Long used as a domestic remedy, and possessing some powerful properties, it occasionally finds its way into Pharmacopœias. It is rather surprising, however, to find it in the primary list, since there are other remedies for the complaints for which it is used, which are more pleasant and safer to administer.

The other changes which have taken place in the primary list consist in the transference of extractum cannabis to the preparations under the name of extractum cannabis indicæ, and in the dismissal of oleum bubulum or neat's foot oil.

With regard to the secondary list, three new articles have been introduced—

Asclepias incarnata.
Asclepias syriaca.
Castanea.

Asclepias incarnata and *syriaca* were dismissed from the U. S. Pharmacopœia of 1864. It has been stated that this was done on insufficient grounds. They possess alterative properties, and are used in the United States in scrofula, etc. For this purpose *A. syriaca* is more particularly used. It appears somewhat doubtful, however, whether the root which gives the best results is yielded by either of the above-mentioned species.

Castanea.—This must not be confounded with the *Castanea pumila* or chinquapin, which was formerly officinal. The present *Castanea* is the *C. vesca*, or Spanish chestnut, as it is called in this country. The leaves of this plant have been strongly recommended of late years as a specific for whooping-cough. In the only case which has come under my observation, the decoction of these leaves effected a speedy cure. As we have no specific for this distressing malady, the remedy is well worthy of a trial in this country.

One article only has been transferred from the primary to the secondary list, and this fact appears to have escaped the notice of the compilers of the Pharmacopœia. The article alluded to is gillenia. It includes the root of two species, *G. stipulacea* and

* PHARMACEUTICAL JOURNAL, 2nd Ser., Vol. III. p. 540.

G. trifoliata. These roots possess emetic and cathartic properties. As an emetic they are in no way superior to ipecacuanha, although in case of a scarcity of the latter drug, they might in some measure replace it.

Four articles have been dismissed from the secondary list—aletris, angelica, arum, gossypii radix. Aletris is the *Aletris farinosa,* which has been used as an uterine tonic. Angelica is the same species that was formerly officinal in this country. Arum is the *A. triphyllum,* known in America as dragon-root or Indian turnip. Like most of the *Araceæ*, it is very acrid when fresh, and loses its properties when heated or dried. It was one of those unstable remedies which are well weeded out of a Pharmacopœia. Gossypii radix has been replaced by gossypii radicis cortex, which now figures in the primary list.

NEW METHOD OF ESTIMATING NITRIC, CHLORIC, AND IODIC ACIDS.

In the current number of the *Journal of the Chemical Society*, page 541, appears a paper on a new method of estimating nitric, chloric, and iodic acids, by T. E. Thorpe, Esq., F.R.S.E. The method devised by Professor Thorpe is based on a reaction noticed by Messrs. Gladstone and Tribe, an account of which appeared in a recent number of this journal. When zinc-foil is placed in a solution of copper sulphate, its surface, after a time, becomes coated with a spongy deposit of copper. The zinc thus coated causes rapid evolution of small quantities of hydrogen when placed in pure distilled water, especially if gently heated. Professor Thorpe has found that if nitre be placed in the water surrounding the two metals no hydrogen is evolved, but a distinct smell of ammonia is perceived, the water acquiring a permanent alkaline reaction from the formation of potassium hydroxide. This reaction is represented in the following equation—

$$8H_2+2KNO_3=2NH_3+2KHO+4H_2O$$

The ammonia evolved from a given quantity of pure nitre was estimated by leading it into dilute hydrochloric acid, precipitating as platinum-ammonium chloride, drying and weighing. The following results show that the conversion of the nitrogen into ammonia is complete—

(1) 0·5090 grm. KNO_3 gave
1·0498 grm. $PtCl_4\,2NH_4Cl$, and 0·0301 gram. Pt, equivalent to 0·50908 grm. KNO_3

(2) 0·4183 grm. KNO_3 gave
0·9208 grm. $PtCl_4\,2NH_4Cl$, and 0·0013 grm. Pt, equivalent to 0·4188 grm. KNO_3

In other experiments the following numbers were obtained—

KNO_3 used.	KNO_3 found.
0·0474 gram.	(1) 0·0476 gram.
——	(2) 0·0473 „
——	(3) 0·0487 „
——	(4) 0·0469 „

The presence of alkaline chlorides and sulphates is without influence on the result. *Calcium nitrate, lead nitrate,* and therefore in all probability the nitrates of *silver, mercury, copper, thallium,* and in fact of all metals precipitated by zinc, are similarly decomposed, the zinc nitrate which is formed being afterwards reduced. Of all the nitrates experimented upon, the most difficult of reduction appears to be *ammonium nitrate.* The discordances appear to depend upon differences in the strength of the solution and the amounts of zinc and copper taken. If the solution is too strong, nitrogen dioxide is evolved, and if the amount of zinc and copper be insufficient the reduction is incomplete. With precautions ascertained by experiment, however, the conversion of the nitric acid into ammonia is complete in the case of ammonium nitrate.

The mixture of zinc and copper appears to have very slight action upon *urea.* A minute quantity of ammonia found was referred to a trace of ammonium salt present in the urea, arising from the mode of its formation, or more probably being produced by decomposition of the urea from long-continued boiling with water.

Professor Thorpe believes that this reaction might be usefully applied to the determination of nitrates when present in drinking waters, and suggests a *modus operandi*, which, omitting certain details, is as follows. The weighed residue in the platinum dish obtained in the determination of the total soluble matter in the water is treated with 10 or 12 c. c. of water, to which a small piece of previously ignited lime about the size of a hemp-seed is added, and the liquid is gently boiled until about 4 or 5 c. c. only remain. The primary object in adding the lime is to facilitate the evolution of the ammonia. Three or four grams of thin sheet zinc previously cleaned by a little dilute acid, and cut into small pieces, are placed in a flask, which has a capacity of 100 c. c. The zinc is covered with a moderately concentrated solution of copper sulphate, which is allowed to act until a thick dark brown spongy covering of copper is precipitated. The metals are repeatedly washed by decantation with cold water, care being taken to detach the copper particles as slightly as possible from the zinc, and lastly drained. The nitrate solution and the rinsings from the platinum dish are transferred to the flask until the liquid therein amounts to 25 or 30 c. c. A caoutchouc stopper pierced with two holes and carrying a funnel-tube provided with a well-fitting glass stopcock, and a delivery-tube bent twice at right angles, is then inserted. The delivery-tube terminates in a test-tube, also provided with a caoutchouc stopper, into which is fitted an exit-tube containing fragments of glass moistened with very dilute hydrochloric acid. One drop of pure dilute hydrochloric acid is placed in the test-tube, which is cooled by immersion in distilled water, and the distillation is commenced. The liquid in the flask is boiled away, nearly to dryness; boiling distilled water is added by means of the funnel, and the distillation continued. This process is repeated till the test-tube contains about 40 c. c. of water, the contents of the exit-tube are rinsed into the test-tube, and the latter replaced by a second tube of precisely the same size. Another distillate of 40 c. c. is collected, the glass fragments again rinsed and a third tube substituted. The contents of the three tubes are diluted till they measure 50 c. c., and the amounts of ammonia contained in each are then estimated in the usual way by Nessler's solution.

Direct experiments made with the view of testing this method of determining nitrates in water show that it is thoroughly trustworthy. In each case all the ammonia was contained in the first 40 c. c. of distillate.

The chief advantage claimed for this process over the aluminium, or the zinc and iron process, is that it does away with the use of strong alkali, which is not only difficult to distil on account of bumping, but unless great care is taken frequently introduces more nitrates than are originally present in the water.

Alkaline chlorates and *iodates* are reduced by zinc and copper to chlorides and iodides, which are afterwards estimated by the usual volumetric or gravimetric methods.

ACTION OF GASEOUS AMMONIA UPON NITRATE OF AMMONIA.*

BY F. M. RAOULT.

If a current of dry ammonia gas be directed upon crystals of nitrate of ammonia, the salt melts, absorbing the gas, as ice would do. This phenomenon is produced under ordinary pressure at all temperatures between $-15°$ C. and $+25°$ C. The liquid obtained is colourless. Exposed to the air, it loses at first a part of its ammonia, and deposits crystals containing one equivalent of the gas to one equivalent of the salt; these crystals in their turn lose their ammonia by a prolonged exposure to the air, and at length only pure nitrate of ammonia remains.

The composition of the liquid in question varies with the temperature. At 10° below zero 100 grams of nitrate of ammonia absorb 42·50 grams of ammonia gas; consequently the product formed at this temperature contains one equivalent of the salt combined with two equivalents of the gas, and corresponds to the formula $NH_4,NO_3 + 2NH_3$. It is not frozen by a mixture of ice and salt. Its sp. gr. is 1·05. Heated, even slightly, this ammoniacal nitrate is decomposed. It boils with loss of ammonia, and at about 28·5° C., under the ordinary pressure of 760°, it is transformed into a crystalline mass, containing 21·25 grams of the gas combined with 100 grams of the salt, and corresponding consequently with the formula $NH_4,NO_3 + NH_3$.

This new ammoniacal nitrate, which is solid, is broken up in its turn, if heat be continued, and at 80° C. there is left a residue of pure nitrate of ammonia.

The following are the exact quantities of ammonia absorbed by 100 grams of nitrate of ammonia, under a pressure of 760° and at different temperatures:—

Temperature.	Gas absorbed.	State of product.
− 10 deg.	42·50 grams.	liquid.
0 „	35·00 „	liquid.
+ 12 „	33·00 „	liquid.
18 „	31·50 „	liquid.
28 „	23·25 „	liquid.
29 „	20·90 „	solid.
30·5 „	17·50 „	solid.
40·5 „	6·00 „	solid.
79 „	0·50 „	solid.

These ammoniacal nitrates, as will be seen, are analogous to the ammoniacal chlorides, and, like them, decompose easily.

An aqueous solution of ammonia dissolves much more nitrate of ammonia than pure water does. The absorbent power of the salt for the gas is therefore not diminished by the presence of water. On the contrary, a solution of nitrate of ammonia in water absorbs a little more ammonia gas than the water and the salt it contains would do separately. At temperatures between zero and $+20°$ C. the coefficient of the solubility of the gas is the same in water and in the saline solution, and, what is no less remarkable, the heat due to the absorption of the gas is almost identical in both liquids.

The liquid and anhydrous ammoniacal nitrate of ammonia, prepared and kept as much as possible at a low temperature, constitutes a new reagent and solvent, low in price and easily manipulated. It can be used for the rapid production of pure and dry ammonia gas, for which it only requires slightly heating. It can be used also, under the guise of an ammoniacal chloride of silver, for the liquefaction of ammonia gas in a Faraday's tube; it yields in fact one-third of its volume of liquid ammonia, provided only that one of the branches of the tube be kept at 100° C. and the other at zero. Its decomposition, however, is not complete under these conditions; it still contains one equivalent of ammonia combined with one equivalent of the salt, and upon cooling forms a white crystalline mass.

* 'Comptes Rendus,' vol. lxxvi. p. 1261.

THE SILPHIUM OF THE ANCIENTS.*

BY A. S. OERSTED.

In a paper originally published in the 'Overs. over de K. Danske vid. selsk. Forh.' for 1869, of which a German abstract appeared lately in the 'Zeitschrift für Ethnologie' (1871, pp. 197–203), the author gives a history of our knowledge of the silphium plant of antiquity, and the results of modern researches directed to the determination of its nature.

In the middle of the seventh century B.C. some Greeks from the island of Thera settled on the north coast of Africa, in the district then called Cyrenaica, and now known as Barka. The state which was subsequently developed owed its great commercial prosperity very largely to its trade in silphium, and the numerous coins found in the district bear on one side the head of Jupiter Ammon, and the silphium on the reverse. This plant grew wild in the uncultivated southern part of the country, and did not succeed under cultivation. From its root when sliced a milky juice exuded, which, when dried or mixed with meal, formed that costly spice which was so highly valued by the Greek and Roman *gourmets*, and was also in high repute as a medicine. Silphium fetched its weight in silver, and was reckoned with other precious things in the Roman state treasuries. During the decline of Cyrenaica the production of silphium gradually decreased; the country first fell into the hands of the Ptolemies (322 B.C.), and afterwards became a Roman province. In 61 B.C. 30 lbs. of silphium were brought to Rome; and the Emperor Nero had a specimen of the plant sent to him as a curiosity. It was still known in the fifth century A.D.; Synesius, who, when he died in 431, was Bishop of Barka, mentions that he supplied a friend with a specimen of the rarity. The reason of its decrease is said by Strabo to have been an incursion of nomadic barbarians who laid the country waste. The farmers also let their cattle feed upon it.†

Much has been written as to the nature of this remarkable plant, which, from the description and the figures on the coins, has always been known to be an umbellifer. Modern travellers who have visited Barka (now an altogether desolate land, with numerous ruins of towns and temples), such as Della Cella, Pacho, Barth, the brothers Beechey, and more lately Rohlfs, have considered a common umbellifer which the natives call drias (*Thapsia Silphium*, Viv., *Laserpitium Derias*, Pacho; according to Cosson (Bull. Soc. Bot. Fr. 1865, p. 277) merely a form of the South European *Thapsia garganica*, L.) to be the silphium plant; but neither its appearance nor its properties bear any resemblance to those of that plant. The celebrated plant of antiquity was wholesome to cattle; the drias is poisonous and has frequently proved fatal to camels. Various other species have been suggested by authors:—*Ferula tingitana*, L., by Sprengel; *Laserpitium gummiferum*, Desf., by Link; *Ferula Assafœtida*, by the Dict. d'Hist. Nat.; and *Laserpitium Siler*, L.

Prof. L. Müller, when engaged in his work on the coins

* From the *Journal of Botany*, June, 1873.

† For an exhaustive account of all that can be read in the ancient authors on the silphium plant, reference may be made to Thrige's 'Res Cyrenensium' (Hafniæ, 1828), pp. 304–315.—[*Ed. Journ. Bot.*]

of Cyrenaica ('Numismat. de l'ancienne Afrique,' vol. i., "Les monnaies de la Cyrénaique," 1860), asked the aid of the author on the question of the silphium; and it was then discovered that a figure on the coins which had been supposed to represent a heart (Dujalais in 1850 ('Rev. Numism.' pp. 256–264) had correctly explained its nature) was the fruit of the silphium. A close examination showed that this figure presented with considerable clearness the characters of the genus *Ferula*, or a closely-allied genus.

The fœtid gum-resin called assafœtida was also known to the ancients, and considered by them as closely allied to the silphium, being called medicinal silphium. The plant yielding this drug was first ascertained by Kaempfer, who in his 'Amœnitates Exoticæ' (1712), which contains the results of his travels in Asia from 1683–1693, gives (p. 536) an account of it, which, though remarkable for its precision and accuracy, has no exact description of the fruit. This was only supplied a few years ago, when Lehmann, Bunge, and Borszczow again discovered the plant, which was described by Bunge* as the type of a new genus, under the name of *Scorodosma fœtidum*. Besides Kaempfer's plant we know now, however, a second plant yielding assafœtida, discovered in 1838 by Falconer in North Cashmere, and described by him in 1846 as a new genus, *Narthex*. This flowered in the Botanic Garden at Edinburgh, and Sir W. Hooker published an excellent figure of it in Bot. Mag., t. 5168. The plant is 7 feet high, the leaves grow in pairs close together, and the sheaths closely cover the thick, upright stem in a way very unusual in umbelliferæ. The first glance at Hooker's figure recalled to the mind of the author the silphium plant on the coins, and a closer examination confirmed him in considering *N. assafœtida*, Falc., to be very nearly allied to it.

In the determination of their affinity it is important to insist upon the accuracy with which other plants and animals (*e. g.*, the date-palm, the horse, sheep, gazelle, and jerboa) are represented on these coins; we cannot doubt that in the case of so valuable a plant equal accuracy would be employed. A minute comparison of the figures of the two plants will strengthen our belief in this.

If we reduce the picture of *Narthex* to the size of the representation of the silphium on the coins, and place the one by the other, we shall remark a surprising likeness in the appearance of the two plants. The stem, and form and arrangement of the leaves and flower-stalks, are quite the same, and a comparison of each distinct organ brings out still more clearly this resemblance. The root, or rather the root-stock, of both plants is of the same form and ramification. The erect, thick stem, longitudinally furrowed, which characterizes *Narthex*, is also found in the silphium; these furrows are very clearly depicted on the coins. There is also, particularly if one examines the best representations on the coins, a remarkable resemblance in the arrangement of the leaves; we can see that these are not truly opposite, but only approximate in pairs; the sheaths are very large, with conspicuous longitudinal nerves; the blade is divided into three to five segments, on which again subdivisions are indicated. That these notches should not be represented on the common coins in so small a space is quite natural; if, however, we compare the outline of the *Narthex* leaves with the representation of the leaf-surface of the silphium, there is a great resemblance. The form and size of the flower-stalks agree entirely in both plants. As to the fruit, we see from the coins that the silphium quite agrees with *Narthex* and *Ferula*. In these umbelliferæ the fruit is very closely compressed, and furnished with a thin membranous border, for which reason Theophrastus characterizes it as foliaceous. The small differences in the structure of the vittæ, by which these genera have been separated, we need not of course expect to find drawn on the coins. On the other hand, there may be usually observed at the bottom and top of the fruit of silphium small globular bodies, of which the first represents the base of the fruit-stalk, and the second the stylopode. On one coin the carpophore is represented between two mericarps, with their apices turned towards each other. So far as the coins go the silphium plant might be referred equally well to *Ferula* or to *Narthex*. As, however, it so entirely agrees with the only known species of *Narthex* in habit, it is in every way more probable that it should belong to that genus.* As a species it is not of course to be identified specifically with *N. Assafœtida*; not only does the obcordate form of the fruit forbid this, but the properties of the gum-resin. That obtained from the Indian plant entirely agrees with the Persian assafœtida. The author proposes to call it *N. Silphium*.

According to Pliny (Nat. Hist. xvii. 2) there were three distinct zones of vegetation to be distinguished in Cyrenaica —the wooded coast zone, an intermediate zone in which agriculture was carried on, and a hilly and desert zone where the silphium grew. This description is equally applicable at the present day. The slope of the plateaux from Barka towards the coast is still covered with a luxurious growth of wood, amongst which is especially noteworthy the occurrence of the cypress, of which Rohlfs brought with him fruiting specimens. As soon, however, as the heights are attained, the appearance of the landscape changes; only low, stunted bushes, artemisias, and thistles clothe the ground, whilst splendid ruined towns attest the density of the earlier population. Farther on towards the south the land takes a wilder character, and it was here that the silphium grew in the past. As Barka has not yet been thoroughly explored (since the collection of Della Cella, which laid the foundation for Viviani's "Floræ Libycæ Specimen," and Pacho's small collection, we have only the very considerable collection of Gerhard Rohlfs), the hope need not be given up that the silphium plants may still be found either there or farther into Africa. Other plants which have disappeared from the places in which they were known to the ancients are often refound in distant regions; for instance, the African papyrus, which was formerly very common in Egypt, is now no longer to be found there, but occurs again in the distant swampy regions of the White Nile.

* Mém. de l'Acad. Imp. des Sc. S. Petersb., 1860, 1861.

* The genera *Narthex* and *Scorodosma* are both reduced to *Ferula* by Boissier (Fl. Orient, vol. ii., p. 994) and Bentham (Gen. Plant. i., p. 918).—[*Ed. Journ. Bot.*]

EDUCATION OF DRUGGISTS' APPRENTICES.

[At the present time, when the subject of education is attracting so much attention, and the organization of a general educational system is felt to be a necessity, the following paper, taken from the *New York Druggists' Circular*, though referring especially to America, will doubtless be of interest.]

A year ago I contributed some hints upon this subject for the readers of the *Druggists' Circular*, and have till now failed to redeem my pledge of adding further thoughts upon the subject.

The points then urged were, preliminary education, study, attention to business; and nothing surely is more important than these. If there was need to direct the thoughts of the rising pharmacists then, that need is still as urgent as ever. Our colleges of pharmacy are being multiplied, but the field is vast, and colleges cannot be brought to every man's door. The public demand at our hands that we give reliable medicines, that we dispense them with care, that we know our business. The increasing classes in attendance upon the lectures of the various colleges of pharmacy during the past winter, and the large number of graduates this year, show the desire of the young men to perfect their education. But these are few, compared with the great number of young men to whom such privileges are, from various causes, denied.

They want information: how shall they obtain it? There are but two ways,—by study and by experiment. Of all the works relating to our business, none can compare with the 'U. S. Dispensatory' for such a variety of information, reliable, compact, and appropriate to the wants of the student. The employer who values his own interests and cares for the advantages which he will derive from the proper education of his young men, will seek to give them opportunities for study as well as direct the proper objects of such study.

Perhaps no better method of explaining the subject could be adopted than to sketch an outline of study; and this the writer, with some misgivings as to his own judgment, will do.

Presuming the student has a copy of the last edition of the 'U. S. Dispensatory,' the references to pages which follow will be understood as referring to the thirteenth edition of that work. The student should, however, possess a copy of the new edition of the 'U. S. Pharmacopœia,' issued this year, as there have been quite a number of changes in the formulæ of some of the preparations, and he *should always make that book his guide* when preparing any of the officinal formulæ.

The first portion of the 'U. S. Dispensatory' is devoted to materia medica; and here will be found the description, botanical characters, commercial history and varieties, properties, and medicinal uses and doses of the drugs with which he is surrounded. The second portion of the work has a most excellent introductory, covering the main points of pharmaceutical manipulation (pp. 909–947), and which should receive the careful study of every young student of pharmacy. The preparations of the pharmacopœias of the United States and Great Britain are detailed, and followed by explanations of the process, and the properties, medicinal uses, and doses of the finished preparation.

Many of the less used drugs and preparations will be found in the third portion of the 'Dispensatory,' but these may be left out of consideration for the present.

The student should read, and, under the supervision and with the assistance of his employer or an older clerk, endeavour to carry into practice some of the instructions on pages 909–947, beginning with weights and measures, and making himself master of each portion as he proceeds. Do not be in too much haste to pass to the next subject or process. If it is worth knowing or doing, let it be understood or done well. In connection with the processes and instruction on the pages alluded to, their practical application can be daily made in the various requirements of business, but it must not be done by the young student unless under the immediate oversight of his superior. Many of the operations can be done on a small scale as experiments, and no opportunity should be lost to make a practical application of the hints you obtain by reading.

Beside the manipulations of pharmacy, the young student should systematically peruse the first portion of the 'Dispensatory,' and make himself familiar with materia medica. The better plan is to take up a class of drugs and study them in their resemblances, as also in their peculiar traits. For instance, they may be grouped as gums, gum-resins, resins, oleo-resins, balsams, fixed oils, volatile-oils, leaves, barks, roots, seeds, or fruit. Crude chemicals, mineral acids, and the various chemicals which are purchased, should be classified under the metallic base or alkali which is present. Make a list of the articles you see about the store under some such arrangement as this, and when the opportunity offers read up the subject and note the main points in a blank-book kept for that purpose. Nothing will so surely help to fix it in the mind as making a written memorandum for reference,—and the writer urges this point particularly. I have before me a little book with an alphabetical index, under which I can find almost every article which is used in medicine and is mentioned in the 'Dispensatory,' giving the officinal name, the principal synonym, the ordinary name, its medicinal properties and doses, and yet the book will readily go in the pocket. It is the work of one of the best pharmacists in New England, who, after successfully conducting business for several years, thought it an honour worth seeking to graduate in a college of pharmacy.

The second hint is, to assist study by experiments to prove the truth of the statements and formulæ read. Whether it be chemical, pharmaceutical, or botanical, there are almost invariably some simple and inexpensive tests or experiments which can be easily used to affirm the reliability or correctness of the information received. Attfield's 'Chemistry' has been highly recommended as a text-book, and the experiments which are detailed in it are peculiarly adapted to the wants of the student in pharmacy. The apparatus required is but little; a majority of the reagents are in every drug-store; it needs only a little time, now and then, and *the will*, to do the work. The time thus redeemed from other less useful occupation, or which is in many instances wasted, will repay amply both the student and the employer.

The writer has alluded to but three books as subjects of study, as he knows from personal observation that too many of the drug-stores in our land have a much smaller collection of books relating to the business than they should possess; and this is one reason why many young men make less progress than they should, while employers in many cases actually progress *backward*, at least so far as scientific knowledge is concerned. In these days, it is not only *economy* in the management of business which insures success, but it requires *brains* to know the business and acquire the respect and confidence of those who patronize you. To keep up with the advances which are being constantly made in our business, we must necessarily read those periodicals which will inform us on those subjects. The employer who neglects to provide his store with these does himself an injury; and if he or his assistants think they are too busy to read them, they neglect a duty to themselves and their patrons.

Systematic study, accompanied by experiments, should be a part of the daily experience of every student in pharmacy, and attendance upon the lectures of a college of pharmacy when it is possible.

CLASSIFICATION OF THE ABSORPTION BANDS OF CHLOROPHYLL.*

BY M. J. CHAUTARD.

The author divides the various absorption bands of the spectrum of chlorophyll at present known into three distinct classes.

The first consists simply of the band in the middle of the red, comprised between the B and C Fraunhofer lines, which he calls the "specific band."

In the second category he includes all the other absorption bands, however numerous, noticed in the spectra of neutral, acid, or alkaline solutions of recent or old chlorophyll. These he designates "supernumerary bands." The most remarkable is that which results from the breaking up of the "specific" band of the red under the influence of alkalies. As to the bands recognized in the other colours, they are liable to modification by so many different causes that he considers their study would not lead to uniform results.

Finally, a third and new category will include what he calls "accidental" bands, or those not having the permanent character of the former, and produced under special conditions. There is here again a breaking up of the "specific" band of the red, due in this case, not to an alkali, but an acid. Whilst in the former case the "supernumerary" band occurs by the side of the orange, near to C., in this latter case the band occurs in the least refrangible portion, at the commencement of the red, about A.

The author mentions the following points as the most

* 'Comptes Rendus.' vol. lxxvi. p. 1273.

important, taking for a type the alcoholic solution of young and fresh nettle leaves.

The leaves, wetted with dilute alcohol, are to be bruised rapidly in a mortar, then expressed with the fingers and filtered. The green tincture which results gives the four bands, distributed from red to green, of fresh chlorophyll. The "specific" band appears at from 20° to 24°.* A drop of hydrochloric acid being added, the black band of the red is transported laterally to about 15°; at the same time the limit of the red is extended in the same proportion. The liquor becomes yellowish and slightly turbid. This band, much widened, is in reality composed of two distinct rays, which may be separated either by diluting the liquor slightly with alcohol, or, more surely, by diminishing the thickness of the solution. One of these bands appears then in the ordinary place, 20° to 22°; this is the "specific" band. The second, "accidental" (itself double sometimes), appears at about 15°, preceded and followed by a very decided red tint.† In the remainder of the spectrum the colours are slightly obscured, and it is only after an interval of time, varying from half an hour to a day, that the "supernumerary" bands of the altered chlorophyll become visible, at the same time as the "accidental" ray of the extreme red is gradually extinguished in the darkness which limits the spectrum on that side. The addition of the alcohol should be carefully made, for it may happen that a too great dilution of the solution, instead of separating the "accidental" band, prevents its appearance; this it would do by overshooting the ephemeral state of the solution to which the band owes its origin.‡

The generation of this "accidental" band presents numerous variations; thus it may be that the "specific" band in the red undergoes no modifications either in position or in extent, but the limit of the red is extended, and from it there arises a very thin, dark band, followed quickly by a second, and these finish by combining into a single thick, dark band, which acquires the same breadth and tint as the former, and soon afterwards disappears in the obscure extremity of the spectrum.

As an important detail, the author adds, that if the leaves, after being once expressed, are again treated with alcohol, a new tincture is obtained, possessing a smaller degree of sensitiveness than the first. The sensitiveness of the solution also diminishes after it has been prepared a few days. Solutions from old, but unaltered leaves, accord less readily than those from young leaves with the phenomena above indicated, which appear to belong to a particular state of the chlorophyll at the period of formation, when the stability of its elements is less complete.

If the solution be filtered just as the two bands in the red are clearly seen, there is, with the clear liquid, a disappearance of the "accidental" ray—only the "specific" band and the "supernumerary" bands of the most refrangible portion of the spectrum being produced. If the solution be allowed to clear by standing, there is the same disappearance of the "accidental" band, which can be made to reappear momentarily by agitation.

The colouring matter which accompanies the chlorophyll in certain plants,—red beetroots for example,—may sometimes mask the "supernumerary" bands of the chlorophyll, but the "specific" band of the red always appears, as well as the "accidental" band, under the conditions before mentioned.

The foregoing results are also obtained (and that naturally because of the acidity of the plant) with the leaves of the sorrel; but what is most curious is that the "accidental" band, after attaining the same intensity as the "specific," becomes increasingly stronger, whilst the latter becomes more feeble, until sometimes at the end of an hour it has completely disappeared, and there remains but one band of absorption, two or three degrees in width, having its centre at about 15°. In order to observe all the details of this phenomenon, it is often necessary, from the feeble coloration of the solution, to use it in a thickness of from eight to ten centimetres.

Many other plants, especially the red cabbage and the St. John's wort, present peculiar "accidental" or permanent bands, and to these the author proposes to call the attention of the Academy on a future occasion.

* = to 1-2 Sorby.

† This is a verbatim translation, the words in the original memoir being, "précédée et suivie d'une teinte très franche." But perhaps, "preceded and followed by a narrow well-marked red band" would better meet the facts of the case.—Ed. Ph. J.

‡ The appearance of the "accidental" is due to the unlocking of the chlorophyll compounds by the reagent, which acts upon one very rapidly and less rapidly upon another, all being differently soluble in different menstrua, such as carbon bisulphide, alcohol, ether, etc.—Ed. Ph. J.

THE DIRECT SYNTHESIS OF AMMONIA.*

BY W. F. DONKIN.

The action of induced electricity on mixtures of certain gases has been lately shown by Sir Benjamin Brodie† to yield very interesting results.

An obvious application of his method was to treat a mixture of dry hydrogen and nitrogen in a similar manner as those referred to above, with the view of effecting the synthesis of ammonia; and Sir B. Brodie kindly allowed me the use of his apparatus for the purpose of the experiment, which was conducted as follows:—

A mixture of about three volumes of hydrogen with one of nitrogen in a bell-jar over water, was passed through two tubes containing pumice moistened with alkaline pyrogallate and sulphuric acid respectively, then through a Siemens induction-tube, and into a bulb containing dilute hydrochloric acid. The whole apparatus being first filled with pure hydrogen, about half a litre of the mixed gases was sent through the apparatus, the induction-coil not being in action; the bulb containing the acid was then removed and another substituted, containing an equal volume of the same acid.

About half a litre of the mixed gases was now passed through the apparatus, submitting them to the action of the electricity. The contents of the two bulbs were next transferred to two test-tubes; and after adding excess of potash to each, Nessler's test was applied. The first solution gave a faint yellow coloration, the second a rather thick reddish-brown precipitate.

No attempt was made to estimate the quantity of ammonia formed, as it would vary with many of the conditions of the experiment.

Since writing the account of the above experiment, which was made in Dr. Odling's laboratory at Oxford on March 24, I have seen in the 'Comptes Rendus' for April 22, 1873, a note of an experiment by Messrs. Thénard of Paris, in which they observe the formation of traces of ammonia by the action of electricity on a mixture of hydrogen and nitrogen; but no details of the mode of operating are given.

LABORATORY NOTE ON THE RED AND GREEN IODIDES OF MERCURY.‡

BY F. R. WILLIAMS.

Nearly ten years ago I was frequently engaged in the manufacture of considerable quantities of red and green iodides of mercury. At first I was in the habit of washing the green iodide with alcohol to purify it from adhering red iodide, as is usually done. But on one occasion, by reason of a misunderstanding, the proportion of iodine was considerably increased, and therefore the union between it

* Read before the Royal Society, May 1, 1873 (Proceedings, vol. xxi. p. 281).

† Proceedings of Royal Society, April 3, 1873, and Pharm. Journ., 3rd series, vol, iii. pp. 136, 156.

‡ From the *Chicago Pharmacist* for May, 1873.

and the mercury was almost instantaneous and very violent, so much so that the whole material was for a moment in a complete state of fusion, the evolution of heat being sufficient to fill the spacious apartment with dense violet vapours. The proportion of the materials was then rectified by supplying the deficiency of mercury, and the mixture was now thoroughly triturated. The resulting compound did not have the deep olive green colour that this preparation usually possessed, but, on the contrary, it was of buff or yellowish green cast. Alcohol did not change its colour, and therefore I presumed that the intermediate iodide had been largely formed, or that the mixture contained an extraordinary amount of the red iodide. The washing with alcohol was then continued, and the filtrate at intervals examined by dropping it into water, the production of a precipitate indicating the presence of red iodide. The formation of turbidity remaining undiminished, I was led to believe that alcohol could not purify this lot. Very little satisfaction was obtained by referring to authorities, and at last I concluded that as the Edinburgh process for preparing red iodide of mercury consisted in part by crystallizing it from a hot solution of chloride of sodium, this might also answer for purifying the green iodide, consequently I boiled the refractory mixture with a strong solution of chloride of sodium, and succeeded admirably in removing the poisonous red compound. After this I never employed alcohol, but always washed the green iodide with a hot solution of chloride of sodium for purification. I found this to be the most economical, expeditious, convenient, and thoroughly efficient operation that could possibly be devised.

In the manner of preparing the red iodide I resorted almost at the outset to a very important modification of the ordinary way. The unnecessarily great amount of water employed is a disagreeable feature when the process is applied in the production of large quantities. Knowing that red iodide of mercury is only sparingly soluble in a strong solution of chloride of ammonium, I introduced this latter salt into the formula, so as to obtain a very concentrated solution of corrosive sublimate, and in this manner get rid of an enormous quantity of water. The strong solution of the chloride of mercury made with the aid of the ammonia salt is mixed with a similarly concentrated solution of iodide of potassium, and the heavy precipitate of the red iodide subsides rapidly. Pints of water accomplish here what formerly gallons only could effect. My process is given below :—

℞	Corrosive Sublimate	4 parts.
	Iodide of potassium	5 ,,
	Chloride of Ammonium	2 ,,
	Water, a sufficient quantity.	

If not already in powder, pulverize the ammonia salt coarsely. Then put the mercury chloride into a convenient Wedgwood mortar and crush it (this can be easily and quickly done) ; add to it the hydrochloride of ammonia, and pour on three or four parts of water, triturating until the salts have dissolved. Now dissolve the iodide of potassium in five or six parts of water, and pour it into the first solution, collect the precipitate on a strong filter, wash it thoroughly with water and dry it in the open air.

RESTORATION OF CHLOROFORM WHICH HAS BEEN INJURED BY AGE.*

BY E. B. SHUTTLEWORTH.

Although the nature of the changes induced in chloroform by the agencies of time, light, moisture, and atmospheric exposure, have never been precisely determined, I am inclined to think that by far the most general and injurious products of decomposition are chlorine and hydrochloric acid. In samples of imperfectly rectified chloroform, as that of ordinary German manufacture, these impurities are, after the lapse of some months, easily recognizable; and in the course of one or two years, an aqueous layer, containing these products in solution, may often be found floating upon the chloroform. Traces of sulphuric acid quickly induce this change. When that liquid has been employed as the purifying agent, and has not been completely removed by repeated washings and rectifications, the product will very soon give sharp indications of chlorine, or some of its acid compounds. In the process of purification, adopted in the British Pharmacopœia, the chloroform, after treatment with acid, is mixed with lime and chloride of calcium, and is at once rectified. I think the keeping qualities of the product would be much improved by agitating the chloroform, before being rectified, with a solution of carbonate of soda, followed by water.

In regard to the restoration of that which has become spoiled, I would recommend that the chloroform be well agitated with a dilute solution of hyposulphite of soda. It should then be separated by means of a glass funnel from the supernatant liquid and again washed; this time with simple water. After being separated, the chloroform should be passed through filtering paper to free it from traces of moisture, when it will be found much improved and comparatively sweet; good enough, in any case, for external use.

In the manufacture of chloroform I have found that one washing with hyposulphite of soda is more effectual than three with simple water. The quantity of hyposulphite used may be so small as to be of no injury to the succeeding charges of chloroform, to which it is customary to add former washings.

There are, of course, certain other impurities of chloroform, whether chlorinated or not I cannot say, which the hyposulphite will not remove. These are of a more stable character, and as they possess a higher boiling-point than chloroform, may be separated by distillation, or by treatment with sulphuric acid in the usual manner.

PRELIMINARY NOTICE OF A NEW SALT OF QUININE.*

QUININE MECONATE.

BY PETER TOWNSEND AUSTEN.

As a salt of quinine and meconic acid has not to my knowledge been before described, I attempted to prepare one.

If an alcoholic solution of meconic acid be added to an alcoholic solution of quinine, a white, curdy precipitate is formed. The precipitate is soluble in hot water, being deposited on cooling in beautiful crystals. The water solution gives reactions for both quinine and meconic acid. The first curdy precipitate on drying forms a mass resembling dried glue, the next precipitate forms minute scales of a silken lustre. Finally, small crystals are obtained. When filtered and dried on bibulous paper, the salt has a peculiar sheen, resembling minute fish scales.

A direct estimation of quinine was made as follows :— A weighed portion of the dried salt was dissolved in water by the aid of heat, the quinine was precipitated by ammonia and dissolved in ether. The ethereal solution was separated from the ammoniacal liquid and washed with water by means of a stopcock funnel, after which it was evaporated and weighed. Though the greatest care was observed in the washing, a loss of quinine occurred.

Salt.	Quinine.	Found.	Calculated.
·25 grm.	·137 grm.	54·8 per cent.	56·66 per cent.

The composition of the salt is then most probably

$$C_7H_2(C_{20}H_{24}N_2O_2)''O_7,$$

which corresponds to the silver salt

$$C_7H_2Ag_2O_7.$$

THE PERFUMED SPIRIT CASE.

"THE receiver is worse than the thief," was the expression used by Baron BRAMWELL in the Court of Exchequer, on Saturday last, when summing up in the case of the CROWN *v.* CARMOUCHE, and commenting upon the conduct of those wholesale perfumers who had purchased spirit of wine from the defendant considerably under the market price. The evidence of one or two of these witnesses was sufficiently damaging to themselves to leave the impression on the mind of judge, jury, and audience that as far as their business was concerned they were ready to purchase plain spirit of wine without permit or certificate, and have it designated on the receiving note "perfumed spirit," provided they could get it below the market price. The details of this interesting case may, perhaps, be more forcibly seen if the evidence given on Saturday be thrown into a narrative, and to do so it will be necessary to deviate a little from the course then pursued in calling witnesses for the prosecution.

MR. WATTS, manufacturing chemist, was induced to purchase a cask of spirit of wine from Mr. CARMOUCHE, 36, Mark Lane. The price was to be 17*s.* 6*d.* a gallon, and for the amount a three months' bill was to be given. At the time of purchase the market price of alcohol of a corresponding strength was 18*s.* 10*d.*, so Mr. WATTS at once came to the conclusion that something was wrong, and he immediately put himself in communication with the Inland Revenue officers. They tasted the spirit and found it free from essential oils, in fact, ordinary spirits of wine, and with this description of spirit a certificate should have been sent. Mr. WATTS wrote for a certificate, but Mr. CARMOUCHE declined to give one, on the ground that as it was perfumed spirit a certificate was not required. For the purpose of discovering where the stock of the so-called perfumed spirit was kept, Mr. WATTS, in compliance with a request from the Supervisor of Inland Revenue, ordered another cask, which was delivered on June 10th 1872. When this cask arrived, officers were on the premises ready to seize it if the spirit was not perfumed, and it being plain spirit only, the cask, horse, cart, and man were placed under detention. The man then said where the cask of spirit had been sent from, and eventually the officers found themselves at the Albion Works, Bow Common. Here they could find proof of the place having been used as a distillery. There were large vessels for holding wort, and on the side of one of them they found what was afterwards proved to be dried yeast. A still could not be found, but the appearance of the premises indicated that a still had been fixed and afterwards carelessly removed. They went on with their investigations, and learned that a person named REYNOLDS was a partner with CARMOUCHE. This man entered into particulars respecting his firm, and threw much light on what had been done at the Albion Works. Almost by accident these persons came together. CARMOUCHE, after a little time, introduced to REYNOLDS' notice the manufacture of eau de Cologne, and the large profits to be made in this business, and if REYNOLDS is to be believed, he was informed that spirit of wine was not exciseable if a small quantity of essential oil was added to it. On the faith of these statements the works were taken in the name of a man called COPELAND. Mr. CARMOUCHE purchased a second-hand still in Brussels, which was afterwards set up at the Albion Works, and in November, 1871, the manufacture of illicit spirit commenced. From the large number of puncheons of molasses used the quantity of alcohol actually manufactured must have been very great, and as only a comparatively small quantity of alcohol was seized, much of what was made must have gone into consumption. REYNOLDS at once said, when asked, that essential oils were added to only a small quantity of spirit made, the other was sent out in the state in which it ran from the still.

So matters went on at the Albion Works till about May, 1872. The owner of these works had been told that essential oils were made there by his tenant, and as the place was not insured he was anxious that it should be, and made a proposal to the insurance office. A surveyor was sent but was refused admission, on the ground that such very valuable processes were being carried on that no stranger could be admitted, for fear the secret of the manufacture should be made known. This visit frightened the firm. They removed the still at once, and thus it was that the place was in confusion when visited by the Inland Revenue officials. CARMOUCHE managed to get all the profits into his own pocket, if REYNOLDS is to be believed. In fact, all about the place seem to have been made his tools. Being a foreigner, it has been no inconvenience to him to leave the country, and whilst REYNOLDS has found his way to the Prison at Holloway, CARMOUCHE is supposed to be in Belgium, enjoying the proceeds of his frauds on the firm and the Revenue. A penalty of £13,687 5*s.* was imposed upon him on Saturday, but if it had been as many millions it would have been the same both to the CROWN and the defendant, for we may be sure he will never pay a penny of the fine now he has fled the country.

From what Mr. WATTS did it will be seen there were some slight difficulties in getting rid of the spirit, and some of the reasons given by Mr. CARMOUCHE for being able to sell it so cheaply were certainly plausible, but not such as to satisfy any person desiring to buy in a legitimate way. To one person he said the cheapness of his spirit was due to the fact that although the duty on perfumed spirit imported had been recently raised from 14*s.* to 16*s.* 6*d.* a gallon, yet in Harwich and some other small ports it could still be imported at 14*s.* a gallon. This lame tale passed muster, and the person referred to at once gave an order for the so-called perfumed spirit, which was admitted to be only very slightly altered in character by the addition of a small quantity of essential oil, and not such spirit as could be denominated perfumed spirit.

Other spirit manufactured at the Albion distillery was sent by rail to Edinburgh to be converted by Messrs. SMITH into "sweet spirit of nitre." The Messrs. SMITH, like Mr. WATTS, had their suspicion aroused by the fact that the spirit was always sent by rail and not by water. If it had been sent by water the cost of carriage would have been reduced to about one-fourth of the cost by rail, and from this fact, coupled with the further fact that the spirit was called perfumed, and sent without certificate, when it was plain spirit, they also put themselves in communication with the Inland Revenue department, and six casks were seized in consequence. When all the circumstances of this case were known, there was no difficulty in finding a reason for the casks being sent by railway. If they had been forwarded by water the Customs authorities at Leith might have examined the contents of the casks and seized them, but when forwarded by rail there was no risk run, as the spirit would be delivered at its destination without question, being sent only from one inland town to another.

We can see from the transactions thus rapidly passed under review how easy it would have been for any person understanding his business, who had made purchases such as we have described, to have concluded that Mr. CARMOUCHE was either defrauding the revenue or not acting honestly to those from whom he bought the spirit. The difference between the market price and the selling price of the spirit purchased by Mr. WATTS may at first sight appear trifling; but if we look a little more closely into the matter, the difference will be seen to be extraordinary. The strength of this spirit was 57·0 overproof, and the Customs' duty would have been 16*s.* 4*d.* a gallon, leaving 1*s.* 2*d.* for the short price of the spirit, a price which any man in the spirit trade must know was simply absurd for the article in question. The difference therefore between the selling and market price was 2*d.* per gallon more (viz. 1*s.* 4*d.*) than the short price of the spirit offered to and purchased by Mr. WATTS, a difference which when compared with the short price of spirit is by no means contemptible, and such a margin of profit to a distiller would prove a fortune to him in a very short time.

We must say a word more about perfumed spirit as defined in the Customs laws. It is that spirit which can be used for perfumery only; and evidently this definition refers to eau de Cologne, lavender water, and such like perfumed spirit, which is so defiled by the addition of essential oils as to be rendered unfit for use as a beverage. This is the reason that such perfumed spirit is sent from the Custom House without permit or certificate, because it was never contemplated that such spirit could be used for anything but perfumery. The spirit sent out by CARMOUCHE could be used for almost any purpose, and as this fact was so palpable to Baron BRAMWELL, he placed on the same footing the seller and purchaser of spirit which was sold as perfumed spirit, but which although containing little or no essential oil, was not accompanied by certificate, and was sold much below market price.

PHARMACY IN THE FLOWERY LAND.

WHATEVER may be the truth of the Chinese assertion that gunpowder, the mariner's compass, and the art of printing were known to that people millenniums before they were invented in Europe, there is no doubt that of certain therapeutic agents they possessed a knowledge antecedent to our own. The dietetic value of animal juices they early recognized. From an interesting paper read before the North China Branch of the Royal Asiatic Society at Shanghai by Dr. D. J. MACGOWAN, we learn that they had a preparation somewhat similar to Liebig's extractum carnis, called "mutton wine," which they credited with a host of therapeutic virtues, and particularly with a restorative and invigorating action on the stomach, the kidneys, and the testes. Dr. MACGOWAN, after describing its mode of preparation, forms an estimate of its medicinal properties, and records a case in which its efficacy was proved beyond a doubt. He further informs us that the Chinese recognize no distinction between medicine and food—between the materia medica and what he calls the materia alimentaria. They hold all portions of animals, brute as well as human, to possess therapeutic value in medical treatment; while in preparation these portions are made to undergo simply a culinary manipulation.

From another interesting paper read by the same physician before the same learned body, we gather that the Chinese had some inkling of the virtues of fish-liver oil in phthisical ailments. To the oleaginous secretion of the shad—nay, even to the flesh of the shad itself—they ascribed virtues similar to those which have gained for the *oleum morrhuæ* so much repute as a counteragent or even cure in tuberculosis. These are of an alterative and stimulating kind, and in the hands of Chinese practitioners have proved efficacious in precisely the same circumstances in which cod-liver oil is indicated among ourselves. Dr. MACGOWAN tells us that the shad is almost identical with the *Clupea* as caught on the American seaboard. In Shanghai it has a name which in English means "periodical" fish, from the fact that it enters the Yangtze and tributary waters in May, and remains "in season" for about four months. The earlier the week in which it is caught, the higher the price obtainable for it. It is an article of tribute to the Emperor, and, after him, the principal officers of the state have the next claim.

Dr. MACGOWAN has other and interesting facts and coincidences to give us with respect to the pharmacy of the Flowery Land. We hope he will prosecute the researches he has so ably begun, and furnish materials for a work on Chinese therapeutic agents which will not only be instructive and attractive in itself, but prove of signal assistance to the medical missionary in the fulfilment of his twofold function.

THE GUACO PLANT.

IN the progress report of Dr. SCHOMBURGK, the colonial botanist of South Australia, for 1872, just received, he mentions the introduction of the *Mikania Guaco*, Humb. and Bonpl., so highly spoken of by Baron HUMBOLDT as a sure cure for snake bites from the most poisonous kinds. "During my travels" (observes Dr. SCHOMBURGK) "in South America, this plant was spoken of everywhere as an infallible remedy. I myself had no opportunity of testing its effects, although we were so unfortunate as to lose two of our men from snake bites, not having the herb with us, which is only found growing on the banks of rivers. "For a long time the knowledge of the antidotal qualities of the guaco remained a great mystery and was confined to a few inhabitants of South America. However, the medical qualities of the guaco are now generally known in all countries where it is found. The part of the plant which is used for the snake bite is the sap or a tea distilled from its leaves.

"The frequent accidents and loss of life occurring from snake bites in Australia, especially during the last few years, induced me to introduce this valuable plant. Notwithstanding that Professor HALFORD'S method (injecting ammonia into the wound) is highly spoken of, and has indeed already saved many lives, we should try also the Mikania. When the young plants are strong enough I will send some to Professor HALFORD in Melbourne to test the nature of the plants."

IN the course of a case which came before Vice-Chancellor Sir JAMES BACON last week it was incidentally mentioned that two ladies had amassed a fortune of £100,000, out of profits derived from the manufacture and sale of a secret preparation named "black drop."

Transactions of the Pharmaceutical Society.

EXAMINATION IN LONDON.

June 13th, 1873.

Present—Messrs. Allchin, Barnes, Carteighe, Cracknell, Gale, Haselden, Hills, Linford, Martindale, Schweitzer, and Umney.

Dr. Greenhow was present on behalf of the Privy Council.

MODIFIED EXAMINATION.

Thirty-four candidates were examined. *Eight* failed. The following *twenty-six* passed, and were declared qualified to be registered as "Chemists and Druggists:—

Althorp, Henry	Chester.
Butler, Edwin	London.
Edkins, John	Walworth.
Gill, William Henry	Bromley, Kent.
Hall, Joseph	Wellington, Salop.
Henderson, Robert Hood	Maidstone.
Hewson, Joseph Frankish	Islington.
Holttum, Richard	Maidstone.
Jenkins, Alexander	London.
Kershaw, William	Halifax.
Laurence, Henry French	Pimlico.
Matthews, Frederick William	Birkenhead.
Miller, Samuel	Pateley Bridge.
Morris, Morris Davies	Wrexham.
Pascall, Frederic George	Limehouse.
Phillips, Charles	Birmingham.
Shaw, John	Ashton-under-Lyne.
Simon, Richard	Liverpool.
Storm, Elliott Baxter	Stockton-on-Tees.
Taubman, Robert	London.
Tice, Richard	Islington.
Tily, Charles Alfred	Kentish Town.
Tyler, George	Southwark.
Webster, John Henry	London.
Williams, William Frederick	Stepney.
Wilson, Franklin	Hull.

ERRATUM.

SOCIETY OF ARTS.

RECENT PROCESSES FOR THE MANUFACTURE OF GAS FOR ILLUMINATING PURPOSES.*

BY T. WILLS, F.C.S.

(*Continued from p.* 1007.)

This last-mentioned process has been submitted to the investigation of two eminent independent scientific men, both having a large acquaintance with the processes of gas manufacture. The value of such investigation cannot well be over-estimated, and it would appear desirable that in all such cases similar investigations should be resorted to, for it rarely happens that an inventor is able to perceive the weak points of his own invention, and still more rarely is he able to grapple with and surmount them by the use of his own scientific knowledge, while at the same time it is not too much to say that many processes and schemes have been allowed to dwindle and die because the good and useful points which they contained have not been perceived amongst so many erroneous views and ideas. A searching

* Read Wednesday, May 21, 1873.

and clear examination of any particular invention ought to be regarded as exceedingly valuable testimony.

The following are some of the more important points brought out by the examination of the above described process by Messrs. Keates and Odling. The experiments conducted by these gentlemen were made upon two scales, the first a manufacturing one, in which the process was in use for the manufacture of gas for the public consumption; and the second upon a much smaller one, in which, however, the various apparatus was necessarily under more perfect control, and hence some points were capable of clearer elucidation. The highest yield of gas obtained directly from the coal was 9775 cubic feet, the temperature of distillation being between 1300° and 1400° F. The quantity of oil and tar obtained from one ton of coal varied considerably with the nature of the coal used; thus, Silkstone coal gave 16·4 gallons of tar and oil per ton, Clay Cross Main 11·9 gallons, and Pelaw Main 13·9 gallons, or a mean of 14 gallons. The highest yield of gas which was obtained by the continued distillation and redistillation of the oily tar was 29 cubic feet per gallon. The mean lighting power of the gas produced from coal was 23·0 candles, and of that obtained from the tar 25·0 candles. The quantity of coke used to maintain the heat in the various parts of the apparatus was about 33 per cent. of that produced, and in the event of the distillation being repeated until complete separation into pitch and vaporizable matters takes place, this amount would be much exceeded. It must also be remembered that the time occupied in the distillation of the coal is just double that allowed when ordinary high heats are employed. The most successful experiment as yet made with this process has shown that from one ton of coal it is possible to produce 9500 cubic feet of 23-candle gas by a careful regulation of the temperature, and from 14 gallons of oil (the mean produce of one ton of coal) 600 cubic feet of gas of an illuminating power equal to 25 candles. Against this result must be placed the considerably increased time occupied for the distillation, and the increased consumption of fuel. It would appear, therefore, from these figures that the second process of distilling the oil is of very little practical utility. The expense attending the production of an equal quantity of gas of a scarcely less illuminating power from coal being far less than that attending the distillation of the oil or tar. Indeed the experimenters themselves consider that the oil would be more valuable as a marketable article than as a material for the manufacture of gas. That this process is capable of yielding a larger amount of gas of high-illuminating power, and of a character as permanent as that of gas ordinarily produced from cannel coal, is, without doubt, satisfactorily proved; and the one point for the entertainment of gas engineers seems to be the relative simplicity and economy of producing coal-gas of a high illuminating power in the ordinary way by the distillation of a rich, and consequently more expensive coal, or of the adoption of this process of distilling an ordinary gas-coal at a low heat, with a correspondingly longer exposure.

Another arrangement has been patented which, to some extent, embodies the above idea, although with some considerable modifications; thus the processes of distillation and re-distillation are carried on simultaneously. The two heated tanks for the heating of the tar and oil of the previous invention are dispensed with, and heated iron pipes, in reality continuations of the retorts, placed parallel with them, and heated by the same fire, filled with some porous material, such as pumice or coke, are substituted. The tar formed, which is not so large in amount as that obtained in the ordinary manner, is thus further decomposed by its passage over the large heated surface, and the gas so produced helps to increase the ordinary yield. If coke be used for the porous material, it speedily becomes converted into a pitchy cinder in appearance, almost identical with the charcoal after its exposure in the previous process, and forms a very fair fuel for the heating fires. There is, however, a difference in this invention, which, although not claimed as part of the patent, yet forms an important point in it, and this is that a jet of super-heated steam is driven into the retort, and brought into contact with the heated coal. During the carbonization a portion of this steam undergoes decomposition in the presence of the red-hot coal; its oxygen uniting with the carbon to form carbonic oxide, and its hydrogen being liberated as gas, it was expected that this hydrogen would also unite with a portion of carbon to form some gaseous hydrocarbon, but this is not possible, as the highest temperature attainable in a retort of this description would be far too low to bring about such a direct union, but an indirect benefit may arise from this injection of steam, and that is, that the gases formed from the coal may be more quickly removed from the heated mass, and being at the same time somewhat diluted, the tendency to form more complex bodies will be partially destroyed, and, consequently, the production of the tar and oil will proportionately cease. The previous heating of the steam is no doubt necessary in order to prevent undue condensation, but its being heated to redness, as mentioned in the specification, would prove a difficult and probably unprofitable operation, and would certainly be impossible to accomplish by merely bringing it into contact with the heated sides of the retort. The result of introducing a jet of steam into the retort during the making of gas may be said to have been successful to the extent to which it has been tried, but the amount so introduced requires very careful regulation. A very full and complete trial was made by a number of eminent men some years ago upon a plan very nearly allied to this—viz., that which was known by the name of "White's hydrocarbon process," in which steam was introduced into the retort with the heated coal, and the following points appear to have been satisfactorily proved:—

1. An increase in the produce of gas from a given weight of coal was obtained.
2. An increase in the illuminating power of the gas afforded by a given weight of coal.
3. The amount of tar and other oily products was considerably diminished.

It is a generally accepted fact that the quicker coal be carbonized in gas-making, provided it be done effectually, the more successful will be the operation. In the ordinary process this end is far from being reached, the carbonization gradually proceeding from the exterior layer of coal directly in contact with the heated bed and sides of the retort towards the centre and more protected portions; and as a consequence of this, the heavier and more condensed, and in some respects more valuable gases, coming from the interior part of the fuel, have to pass over the more thoroughly carbonized and hotter outer portion, and will thus suffer a further decomposition before leaving the retort. Many plans have at various times been adopted to obviate this evil, such as exposing the coal in exceedingly thin layers, or forming the bed of the retort of a constantly moving stage, upon which a thin layer of coal in small pieces is constantly exposed to a uniform heat. Some of these methods have been successful, but have had in most cases to be abandoned on account of greater complication of machinery, and hence greater difficulty in continuous working. A plan—probably the simplest that has yet been introduced—has recently been brought forward, the principle of which is as follows:—The retort in this case is set in a vertical position, and through its centre revolves a broad and somewhat deep screw, put together in sections, the thread of which is placed at an angle of 45°, and which comes nearly into contact with the sides of the retort. Through a hopper at the top, coal is supplied, in pieces of small but regular size; the inclination of the thread of the screw impels these pieces against the heated sides, where comparatively rapid carbonization takes place, and the rate of revolution of the screw is so regulated, that by the time the fuel has arrived at the bottom of the retort the process is complete, and coke of a somewhat inferior quality is discharged into a suitable receptacle. The yield of gas is greater by this means, and of higher illuminating power, the amount of tar being correspondingly less; the difficulties encountered appear, as in previous methods, to be chiefly mechanical, the great friction to be overcome by the working of the screw requiring considerable power, the wear and tear thus becoming also greater. Further, the exposure of the iron to such a continuous high temperature renders it extremely brittle, a quality enhanced no doubt by the presence of sulphur, which causes a superficial conversion of the iron into sulphide. That the process itself is to a great degree successful, will be seen from the following results:—

Coal Carbonized.	Quantity of Gas obtained.	Illuminating Power of Gas.	Amount of Tar.
1 ton	11,040	16 candles	8·5 gallons.
1 ton	10,160	17 candles	—
1 ton	12,000	16 candles	—

The fact of the existence of a large number of hydrocarbons of great volatility, the vapours of which, when ignited, burn with exceedingly luminous flames, has been a very great incentive with inventors to produce some scheme whereby these vapours might be used to confer luminosity upon a combustible non-luminous gas, or further, inflammability, coupled with luminosity, upon a non-combustible and negative gas. The Patent Office contains the record of many such schemes, which, for some reason or other, have failed to fulfil their originators' hopes and desires. Much misapprehension has arisen upon this matter. Too much has often been expected from such schemes; but, on the other hand, a large amount of unreasonable contempt has been poured out upon all projects of the kind, both extremes being avoidable by a short consideration of certain well-known physical laws. It should be remembered by the opposers of the possibility of there being any good in such ideas, that to a great extent, larger than is generally thought, the luminosity of coal gas itself is dependent upon the presence of the vapours of such volatile substances, which are held in a state of solution in the gas, but which still remain condensible bodies; and we shall see presently that the loss in illuminating power which coal gas undergoes on exposure to a low temperature, is really due to the condensation of such substances. These remarks apply to the principle of carburation, and not to any special means of applying that principle.

This idea of carburation is not by any means new, having been started almost at the same period that lighting by coal gas in the ordinary way was introduced; but it was not until the opening up and working of the American oil wells, by which a supply of very light petroleum oil or spirit was obtainable, that any scheme in this direction was found to have any chance of success. In 1862 a patent was taken out in France by a M. Mongruel, which proposed to pass air through an exceedingly light and inflammable spirit, the air thus becoming charged with a certain amount of a highly luminous hydrocarbon vapour, in such a quantity as to render the mixture inflammable, and to allow of its being burned as an ordinary combustible gas. This idea was introduced into England by a company known as the Photogenic Gas Company, which received some amount of support at the time, but, from some cause or other, did not prove a success.

The various inventions brought into notice since that time for the purpose of carburetting air and other gases have been based upon precisely the same principle, but have differed considerably in the apparatus employed. A general distinction may be made here—more for the sake of separate examination than from there being any fundamental difference between them—between those processes which propose to use air as the vehicle or medium for holding in solution the hydrocarbon vapour, and those in which a combustible but non-luminous gas acts in such a manner; in either case any remarks upon the quantity of vapour taken up, and its character, when held in solution, will apply to both. Many erroneous statements have been made on this matter for the want of a little scientific knowledge; for instance, in some cases patentees themselves have declared that a union takes place, other than mechanical, between the gases of the air and the vapours of certain hydrocarbons, which results in the production of such gases as olefiant gas, or acetylene, an utter absurdity and impossibility which would be evident to any who would consider under what circumstances, and under what circumstances only, such gases are produced. A vapour of any hydrocarbon whatever will, whether it exist by itself or whether it be diffused through another gas or gases, always be such a vapour, and will invariably exhibit the properties characteristic of it; and, moreover, if diffused through a gas, will be found condensible once more to the liquid from which it was formed, if proper means be applied. An illustration occurs in the case of aqueous vapour, which always exists in greater or less quantity diffused through the air; but this vapour is still the vapour of water, exhibiting all its properties, and capable once more of assuming the liquid state on a sufficient reduction of temperature. Another view equally erroneous is, that a given bulk of air or gas will take up and hold in solution an almost indefinite quantity of vapour, and some extraordinary statements have been made as to the large amount of this quantity. Now, from what has been said in the earlier portion of this paper, it will be readily understood that this point is capable of experimental proof, and is not determined either by chance or accident. Every liquid body has a maximum tension of its vapour, and this point is as fixed for any particular substance as its specific gravity or its boiling point. If, therefore, a given space, filled either with air or other gas, contain a quantity of vapour at its maximum tension, that space will be saturated with such vapour, and it will be found impossible to cause it to hold ever so slight a quantity in excess of that already existing; as, however, this tension is lower for lower temperatures, a space that is saturated at a higher temperature will become over, or supersaturated as the temperature falls, and hence must deposit a quantity of vapour in the liquid state. When experiments are made with a view to test this result, the temperature of the *gas* should be the observed temperature and not the temperature of the vessel containing it, as the conducting power of a gas for heat is so bad that it takes a considerable time for any quantity of it to fall from a higher to a lower temperature. It will be seen, then, that the fixing of the maximum tension of the vapour from a liquid for different temperatures will give us an exceedingly good indication of the quantity of the vapour which may exist diffused through any space of air or other gas. A statement was made at the outset, which, for the sake of clearness, is repeated here, viz., that the medium in which the vapour is diffused has no effect whatever upon the quantity so diffused, a vacuum, or equal volumes of all gases, taking up the same quantity of the vapour of any liquid. The boiling-point of a liquid is far more intimately connected with its vapour tension than its specific gravity; indeed the boiling-point depends upon the vapour tension, for when this tension equals in amount the pressure of the atmosphere, a body is said to boil, and does at that point enter into ebullition. A great tendency has been shown by inventors to reduce the specific gravity of the hydrocarbons which they use, with a view to obtain bodies of very great volatility, and to some extent the boiling-points of such bodies have been disregarded; probably this has not led them much astray, because, as it happens, the substances mostly used for these purposes, the light petroleum spirits, have low specific gravities and low boiling-points, the two being reduced at the same time, but if almost any other class of hydrocarbons had been dealt with, the specific gravity would have proved no guide to the volatility of the compound; thus, in the case of the following bodies, alcohol, benzole, and bisulphide of carbon, which have respectively the specific gravities 0·719, 0·85, and 1·272, the vapour tensions, and consequently the boiling-points, follow just the contrary order, and the body possessing the greatest density is really the most volatile. The vapour tension of alcohol, at ordinary temperatures, viz., about 15° C., is equal to the depression of the mercurial column to the extent of 30 mm., the boiling-point of alcohol, being 79° C.; the vapour tension of benzole, in the same manner, is 55, and the boiling-point of the liquid 78° C., and of bisulphide of carbon as high as 250, with a boiling-point of 48° C.; low specific gravity is, therefore, not always coupled with low boiling-point and great volatility.

A law was enunciated by Dalton, which, though since proved to be only approximately true, nevertheless enables us to obtain a rough idea of the vapour tension of any liquid if we know its boiling-point, which was this:—"The vapours of different liquids have equal tensions at temperatures equally removed from their boiling-points." Thus, the boiling-point of alcohol being 79°, the vapour tension of alcohol at 50° ought to be equal to the vapour tension of water (with a boiling-point of 100° C.) at 71°, which is approximately correct. Now, the boiling-points of the light petroleum spirits used in the carburation of air are pretty well known, and some of them are expressed in the following table, together with the specific gravity of the spirit:—

Boiling-Points of Light Petroleum Spirit of Different Specific Gravity.

Specific gravity.	Boiling-point.
0·600	4° C.
0·628	30 „
0·669	68 „
0·699	92 „
0·726	118 „
0·741	136 „
0·757	160 „

The spirit more commonly employed has a specific gravity of about 0·650, having a boiling-point of 58° C. In the following short table the vapour tension of this spirit has been calculated, by the above approximate law, for several different but often experienced temperatures.

Table of Maximum Vapour Tension of Petroleum Spirit of a Sp. Gr. ·650 at different Temperatures.

Temperature.		Vapour tension.
−10° C.	(14° F.)	43·5 m.m.
0 „	(32 „)	81·0 „
+10 „	(50 „)	132·0 „
15 „	(60 „)	167·9 „
20 „	(68 „)	203·0 „
40 „	(104 „)	301·8 „

These vapour tensions, therefore, express the maximum proportionate quantities of the spirit which can exist dissolved in air, or other medium at those temperatures; thus the quantity of vapour dissolved at 15° C. (60° F.) or the temperature of a tolerably warm day, is just about double that which will be dissolved at 0° C. (32° F.) or the freezing point of water; the reduction of the temperature from 15° to 10° C. (60° to 50° F.) is coupled with a loss of about one quarter of the amount of hydrocarbon vapour. These points are capable of direct experimental proof, and all claims and statements made by inventors may be brought with perfect justness to such results. We may perhaps state the above table in a still clearer way, by converting the figures representing the vapour tensions into the percentage of vapour present in any bulk of gas at any particular temperature. It will then stand thus:—

Table of Percentage of Vapour of Petroleum Spirit of a Sp. Gr. ·650, present in Air or other Medium at different Temperatures.

Temperature.		Percentage.
−10° C.	(14° F.)	5·7
0 „	(32 „)	10·7
+10 „	(50° F.)	17·5
15 „	(60 „)	22·0
20 „	(68 „)	27·0
40 „	(104 „)	39·0

Now, for an "air gas" scheme to be successful, the air must hold in solution a sufficient quantity of vapour at the lowest temperature to which it may possibly be exposed as shall confer upon it both inflammability and an adequate luminosity, and this really means that at a higher temperature it will hold in solution a much greater quantity than is necessary in order to obtain such a result. In many cases, doubtless, this is the case.

The quantity of vapour held in solution at any one time, no matter at what temperature the observation be made, will be found to be just that quantity which would be found sufficient to saturate the air or gas at the lowest temperature to which it has been exposed; hence any lowering of the temperature after carburation should be carefully avoided, as a loss would thereby be incurred of a quantity of vapour which would not be restored on the temperature becoming again higher; this, of course, applies only to the gas or air after it has left the *liquid* hydrocarbon, and is not in contact with it.

The liquid hydrocarbons, which at present are almost exclusively proposed to be employed for the purposes of carburation, are the light oils and spirit which form the first distillate in the preparation of paraffin oil from the crude American mineral oil. As this light spirit is too volatile and inflammable to be burned in any sort of lamp at present in use, and no other commercial application has been discovered, very large quantities of it are disposed of as an entirely waste product, obtainable at a merely nominal cost. Whether the difficulties of importation, or its taking its position as a marketable product, will materially affect the estimates at present put forward for the continuous acquirement of large quantities, will remain hereafter to be seen.

(*To be continued.*)

Parliamentary and Law Proceedings.

"PERFUMED SPIRIT."

Court of Exchequer, June 14. *Sittings at Nisi Prius, at Westminster, after Term, before Baron Bramwell and a Special Jury.)*

THE ATTORNEY-GENERAL *v.* CARMOUCHE.

The Attorney-General, the Solicitor-General, Mr. Locke, Q.C., and Mr. Pinder were counsel for the Crown. The defendant did not appear.

This was an information filed by Her Majesty's Attorney-General to recover from the defendant certain penalties for breaches of the Excise Laws. The information contained forty-six counts, and treble penalties were sought to be enforced on each count. The defendant was a Belgian, carrying on business at the Albion Works, Bow Common, and at Mark Lane, and at the former place was engaged in the business of an ordinary distiller, without having a licence to carry on that business. His advice notes described the spirit as "perfumed spirit," and his labels on his casks also described the spirit to be such. Several witnesses who had dealt with the defendant, and were now called as witnesses for the Crown, proved that there had been in some instances a perfume placed in the spirit, but they would not swear that it was what is known in the trade as "perfumed spirit to be used for perfumery." It appeared that a Mr. Watts, of the firm of Batley and Watts, carrying on business in Whitecross Street, purchased a quantity of "perfumed" spirit from the defendant, and, suspecting from the price of it that all was not fair and above board, instituted inquiries, and communicated with the Excise, and so brought about the exposure of the defendant's frauds upon the Excise. Mr.

R. Bannister, of the Inland Revenue laboratory, produced four samples of spirit which had been seized, and declared them to be plain spirit of wine, and he also examined six samples taken from spirits supplied by the defendant to a firm in Scotland, and found them to be spirits of wine, containing no essential oil, and neither perfumed nor medicated. Nearly the whole of the spirit sold by the defendant was about 58 over proof. He sent several casks of spirit labelled "perfumed spirit" to a firm in Scotland to be converted into sweet spirit of nitre, and this spirit, upon information supplied by the firm, was seized by an Excise officer, and was declared to be ordinary spirit of wine. At the request of the Excise the firm gave an order for some spirit to the defendant, and the officers, upon its delivery, succeeded in tracing the defendant's illicit still.

At the conclusion of the case for the Crown his lordship shortly summed up, saying that the jury were no doubt satisfied upon the evidence adduced on behalf of the Crown that the defendant had carried on the business of a distiller without a licence to do so, and had been selling illicit spirit. The defendant was not present to defend himself, and if he had been, what could he have said? There was ample evidence to show that he had an illicit still and worked it. In some cases the jury would, perhaps, be satisfied that the spirit was disguised to evade the duty. It perhaps would not be very agreeable for some of the persons who had had dealings with the defendant to hear him (the learned judge) remark that there was much truth in the old adage that the receiver was worse than the thief. If no persons had purchased spirit of the defendant he could not have carried on his business. Mr. Watts was to be greatly commended, but he had done no more than his duty as an honest man. The amounts sought to be recovered were large—large enough, it was to be hoped, to keep the defendant out of this country for the remainder of his days.

The jury being of opinion that the Crown was entitled to the verdict generally, a verdict was entered accordingly upon each count for duty and treble penalties, which amounted in the aggregate to a sum of £13,687 5*s*.

Prosecutions under the Adulteration Act.

COCOA.—MUSTARD.—PEPPER.

Several cases of prosecution under the Adulteration Act, which have taken place recently, offer points of special interest, as tending to show what will be held to be an adulteration, the extent to which a dealer is responsible for a knowledge of the purity of the articles which he sells, and the formalities necessary to be observed in procuring samples for analysis. The following are reported in the *Grocer* for June 14:—

At the Kingston County Police-court, three tradesmen of Walton-on-Thames appeared before the bench on summonses which had been issued against them for alleged infringements of the Food Adulteration Act. Mr. Humphries and Mr. John Coldwell, grocers, were charged with having sold adulterated packets of cocoa; and the charge against Mr. Robert Ridges was that he had sold two ounces of adulterated mustard. The charges were preferred by Inspector Bunyard. In the course of the forenoon, whilst the general cases were being heard, and before the above-named summonses came before the Court, Mr. Humphries applied for the postponement of his case until the following week, on the ground that Mr. Wontner, solicitor, who had been engaged to defend him by Messrs. Dunn, Hewett, and Co., the manufacturers of the cocoa which he was charged with having adulterated, was unable to attend that day. The magistrates consented to the application.

The case against Mr. John Coldwell was then proceeded with. Mr. Haynes, solicitor, appeared on his behalf. The charge against the defendant was that he had sold a packet of Taylor's cocoa which was labelled "soluble cocoa," and on which was also the following:—"This admixture contains no injurious ingredient." Inspector Bunyard, in support of the charge, stated that on May 19 he purchased a packet of cocoa at the defendant's shop, for which he paid 2*d*. After purchasing it he took it to Dr. Stevenson, the analyst for the district, and directed him to analyse it. He subsequently obtained Dr. Stevenson's certificate. The witness produced the packet he had purchased, which was labelled "Taylor's Soluble Cocoa."

Mr. Haynes: When you purchased the cocoa you knew it was soluble cocoa?

Witness: It was so stated on the label.

Mr. Haynes: Well, then, you were well aware that it was not pure cocoa, for pure cocoa is not soluble?

Witness: Yes, I suppose I was.

Mr. Haynes: Of course you were.

Mr. Bell (clerk to the magistrates): It did not state on the label that it was pure cocoa?

Witness: No.

The analyst's certificate was here put in, which stated that the cocoa submitted for analysis contained a mixture of cane sugar and sago, but that it was not injurious to the health of persons eating or drinking it.

Mr. Haynes, on behalf of the defendant, contended that the charge against him could not be sustained for several reasons. In addition to the fact that the analyst had certified that the article sold was not injurious to health, which under the Act of Parliament he was required to do before a conviction could take place, there was the further fact that on the face of the statement on the label on the packet there was no intention whatever to pass the article off as pure cocoa, and of that fact the inspector was perfectly aware at the time he made the purchase and took the article to the analyst.

Colonel Terry, in giving the decision of the bench, said it was perfectly manifest that the cocoa was not sold as pure cocoa, and there was a difficulty in arriving at the conclusion that it was deceptively sold as an adulterated article, inasmuch as the label on the packet bore evidence that it contained other ingredients beyond that of pure cocoa. In the case of a person named Kelly, at Liverpool, who was acquitted the other day by the magistrates on the charge of having sold adulterated butter, the Court of Queen's Bench had decided that the magistrates were wrong, and that the defendant ought to have been convicted on the ground that the butter was adulterated, whereas the defendant represented it as butter only, and in that case Mr. Justice Blackburn remarked that an acquittal would have been justifiable had he stated that it was not pure butter, or that there was a mixture with it of other ingredients, thereby inferring that, although an article might be adulterated, a fine for selling it ought not to be imposed if a representation to that effect were made at the time of the sale. In this case it was clearly represented on the label of the packet that the article was not sold as pure cocoa, but that it contained a mixture of other ingredients. Under these circumstances the charge must be dismissed.

Mr. Bell, clerk to the magistrates, after the decision in the first-named case, called the attention of the bench to the charge preferred against Mr. Humphries, which in the course of the forenoon it had been agreed should be postponed until next week. He suggested that, after the decision which they had just given, it might be desirable to dispose of it at once. He submitted to the bench, for their inspection, the packet for the sale of which Mr. Humphries had been summoned, which was labelled "Dunn's Digestive Cocoa," and on which it was also stated "this article contains nothing but fecula and sugar." Looking at that label, it appeared to him that the prosecution had not a leg to stand upon.

The Chairman, having inspected the packet, said it appeared to him that the evidence on the face of the packet was even stronger against the probabilities of a conviction than in the last case. The label on the packet not only said that it contained nothing injurious to health, but it also stated what articles it did contain. However, the hearing of the case had been postponed, and he would ask Mr. Humphries whether he wished that the arrangement should stand and the case be gone into next week.

Mr. Humphries said he certainly had no desire whatever to be compelled to attend the court again if the bench then wished to dispose of the case. The bench having consulted with the clerk, the Chairman said it appeared to the magistrates that it would be useless to go further into the case, as a conviction was highly improbable. The summons was accordingly withdrawn and the charge dismissed.

[We understand that Messrs. Dunn, Hewett, and Co., the manufacturers of the cocoa, for selling which Mr. Humphries had been summoned, were prepared to have offered a strenuous defence had the case proceeded, and that in the event of a conviction they would have appealed to a higher court.]

Mr. Robert Ridges was charged with having sold two ounces of adulterated mustard. Inspector Bunyard stated that he went to the shop of the defendant, and asked the price of mustard, when the defendant replied that it was 1*s.* 8*d.* and 1*s.* per lb. Witness asked for two ounces of that at 1*s.* per lb., and he was served with two ounces, for which he paid 2*d.* There was no label upon it. When he bought it he told the defendant he was going to have it analysed. He took it to Dr. Stevenson, who analysed it, and gave him a certificate, which stated that the mustard contained a mixture of flour and turmeric, but that these substances were not injurious to the health of persons partaking of them. [The certificate and the packet of mustard were here put in.]

The defendant, in reply to the charge, said that he did not sell it as the best or as pure mustard. It was sold in the same state as that in which he received it. He did not sell it as unadulterated mustard.

The Chairman said the bench acquitted him of any fraudulent intention, but they were of opinion that there had been an infringement of the Act. They advised him in future to label all the mustard he sold which was mixed with other ingredients. The bench were not disposed to inflict a heavy fine, but he must pay the costs of the summons and the expenses.

It was stated that these amounted to about £1.

At the Dorking Public Hall, Mr. Arthur John Wyld, grocer, of Dorking, was summoned under the Adulteration Act for selling two ounces of pepper which were alleged to be adulterated. Mr. White appeared for the defendant. From the evidence of a police-constable it appeared that on the 29th of April the officer went to the shop in private clothes and purchased two ounces of pepper, not saying for what purpose he wanted it. The constable handed it to Superintendent Page, who sent a portion of it to Dr. Stephenson, of Guy's Hospital, for analysis. Dr. Stephenson's certificate was now handed in to the chairman of the bench, stating that the sample was adulterated by an admixture of refuse, or husks of linseed and rice flour, but that the same adulteration was not injurious to health.

Mr. White, on behalf of the defendant, said although he had some technical objections to take, his client did not wish to get off by a side-wind, as he conscientiously believed the pepper was not adulterated. He only kept two kinds of pepper, which were supplied by Messrs. Borwick, of London. He had taken a sample of the same pepper as was sold to the constable to Dr. Hassall, the eminent analyst, whose certificate he now produced, stating that the pepper was not adulterated, and he contended that that was an answer to the case on its merits. Independently of that, he had three points to raise. The first was that under the Act of 1868, 23 & 24 Vict., cap. 68, which is incorporated with the new Act of Parliament, the purchaser was bound to inform the seller of his intention to have it analysed, and to afford him reasonable opportunity of seeing the article handed over to the analyst, so as to guard against the article being tampered with between the time it was purchased and the time it was analysed. That was a very necessary provision, as otherwise no tradesman would be safe. In this case the article was purchased on April 29, and it was not until just a month afterwards that his client had any information of its having been analysed. His next point was that Superintendent Page, under the 6th section of the Act, ought to have purchased the article himself, and that it was a stretch of power for him to send a deputy in private clothes. It was never intended that there should be any sly or underhand way of executing the Act, and the inspector, who was the person specially appointed by the Act, should himself go into the shop openly to make his purchase, just as he would go in to inspect the weights and measures. Finally, he contended that there was no proof of guilty knowledge on the part of his client, who sold the pepper as he received it from the manufacturer, and certainly believed it to be pure.

The Chairman remarked that Justice Blackburn had decided that the guilty knowledge might be inferred.

Mr. White said that Justice Blackburn made that remark only in reference to the case immediately before him. Whatever Justice Blackburn might have said, they were bound to go by the Act of Parliament. There were some cases where, from the low price of the article, the seller must know it to be adulterated; but it was very different in cases of tea and pepper which were bought at the regular prices from respectable firms, and which the seller had a right to suppose were pure; at any rate, he would not know to the contrary without paying £2 2*s.* to have every article analysed.

The magistrates retired, and after a few minutes' consultation the chairman said that the magistrates had decided on dismissing the case, on the ground that no intimation had been given to the seller of the intention to have the article analysed, as was required by the 3rd section of the 23 & 24 Vict., which was certainly incorporated with the new Act. The case against Mr. Wyld was dismissed accordingly.

Review.

Du Corps des Pharmaciens Militaires, son Rôle dans les Etablissements Hospitaliers aux Armées Actives et près de l'Administration Supérieure de la Guerre. Par le Dr. C. Roucher, Pharmacien Principal de l'Armée. Paris: Baillière. 1873.

To hear of a class of men who are "satisfied with their present position," and "do not seek any new personal advantage," is quite refreshing in the present stage of the struggle for existence. When, however, we find these words used by the spokesman of a body of pharmacists, the pleasantness of the surprise is increased, and only it is tempered by regret at the certainty that evidently he is not speaking on behalf of English pharmacists. In fact the words are used in reference to a class of men who unfortunately have no representatives in this country, the French corps of *pharmaciens militaires*. At present, although there are certain regulations in existence requiring that navy dispensers shall possess the "Major" or "Minor" qualification of the Pharmaceutical Society, and some attempt has been made to induce properly qualified men to enter that service, there exists no similar provision as to the army. We believe we are right in saying that there is no way by which a pharmaceutist with military tastes, who wishes to place his special acquirements at the service of the State, may do so without entering as a private, in the hope that *when* he reaches a certain rank a vacancy *may* occur in the office of compounder of medicines, to which he *may* be appointed. But in France it is not so, and it is to be hoped that in Great Britain the time will come when the benefits of skilled dispensers, which are at last being gradually provided for the pauper in the workhouse infirmary, may be extended to the British soldier when in hospital.

The general projected reorganization of the French army, including, among other departments, those relating to the health of the soldier, appears to have brought with it some danger that the pharmaceutical service would be subordinated to the medical. This has induced Dr. Roucher to issue the *brochure* bearing the title at the head of this notice, in which he seeks to maintain the acquired rights of the body as being identical with the interests of the army, stating that if it were otherwise he would not hesitate to sacrifice persons to things, for that servants are made for the service and not the service for the servants. One introductory remark is worthy of quotation as having a general application in matters of this kind, that while on the one hand it is useless to pretend personal interests entirely disappear before the general interest, on the other it is not sufficient for the State to appeal to the spirit of generosity and sacrifice, without recompensing worthily those from whom it accepts service.

As a contribution towards the spread of information necessary for the proper appreciation of the important service which can be rendered to the State by a body of men like the French military pharmaciens, we quote from Dr. Roucher's pamphlet an account of some of the principal duties which they perform. The military pharmaceutical service embraces, besides that relating to the regiment, the veterinary service of the army, prisons, penitentiaries, etc., the colonial service, and investigations connected with the war administration relative to food, dress, and encampment. The military pharmacien is required to see to the supply of medicines wherever there is a soldier ill or a military physician has a remedy to prescribe. He has to guarantee the quantity, and especially the quality of the medical supplies; to verify the genuineness of substances used for food, and to assist in the solution of problems which lie within the domain of the physical sciences. He has to study economy in the purchase of medical substances, to superintend their preparation and preservation, and to render an exact account of all the material confided to his care by the State. In the hospital his daily duty is to examine all the medical prescriptions to see that they conform to the formularies laid down by the Council of Health; also that the mixtures or compounds prescribed in them follow the rules of the pharmaceutical art, and that they do not through momentary inattention, ignorance, or negligence, contain dangerous doses. The pharmacien is expected to reply to questions of the medical men respecting the quality or properties of new or little known medicines; to suggest means of preparing new remedies suggested by extraordinary cases or the progress of the healing art; to be able to demonstrate to them the purity and good quality of the substances used, and to indicate possible substitutions. He is also consulted respecting the food and drinks by which the patients are nourished. Finally, he must be able to analyse morbid products interesting in the history of disease, and a knowledge of which is of importance to the physician. All this work requires an acquaintance with not only the substances which are comprised in the official list of the military hospitals, but the whole field of natural history, materia medica, physics, and chemistry. Some objection appears to have been taken to the necessity for the presence of the pharmacien with the army in the field, on the ground that after a battle the medicines used are of the simplest description, requiring but little skill to prepare them. But as the author forcibly remarks, even these require supervision, and the presence of a skilled pharmacist leaves the medical man at liberty to attend to duties more in accordance with his calling. But besides this duty the pharmacien of the divisional ambulance has to renew the stock of the medical and surgical canteens, and to provide supplies on the march to the veterinary service, which requiries larger quantities of drugs than the medical service, and is second in importance only to it. In fact, the valuable services rendered by the French military pharmaciens were gratefully recorded at the time of the Crimean war, and during the more recent campaign against Germany.

Dr. Roucher, however, does more than national service in claiming for the pharmaceutist a position in relation to medical men considerably beyond that generally conceded to him. Although English pharmaceutists as a whole have not yet acquired the same *locus standi* as scientific men as their continental brethren, it is incontestable that skilled pharmacists, educated as highly and with a knowledge as wide as that possessed by medical men, are becoming yearly less exceptional. And to quote the words of our author, "Either medical men will have to renounce the support of the pharmaceutical chemist in their forward march, or they will have to share with that powerful auxiliary the honour of progress in this domain of the medical sciences, where they can never venture alone. Comprehended or not, this sentence is absolute." Three years ago, Professor Huxley questioned the propriety of burdening the mind of the medical student with a knowledge of materia medica, except so far as it related to therapeutics, and threw a doubt upon the permanence of its retention in the memory. The opinion of M. l'Inspecteur Jeannel, quoted in this pamphlet, is quite in accord with this. He says that after being at the same time doctor of medicine and pharmacien militaire, teaching during sixteen years materia medica to both medical and pharmaceutical students, and well acquainted with the too feeble stock of chemical and pharmaceutical knowledge possessed by a doctor of medicine, he is persuaded that the incompetence of medical men as to pharmaceutical compatibilities and the preparation of medicines is nearly absolute. And the author, who, after several years of professional duties and special persevering study, laments that he is not so good a pharmacist as he would be, adds his testimony that, had he to retrace his steps, if he wished to be a doctor he would study medicine, and if a pharmacist he would devote himself exclusively to the pharmaceutical sciences.

But *revenons à nos moutons*. It is interesting, with the memory of recent events fresh in our minds, to note that the man aspiring to be a *pharmacien militaire* cannot enter the service until he has spent three years at practical pharmacy, passed through a full course of three years at the schools, and taken his degree as *bachelier ès sciences*. The service has always attracted a high class of men, and some of them have borne names of which not only France but the scientific world is proud. Without neglecting their more modest functions, they have always been associated with scientific progress, they have been represented at the Institute, at the Academy of Medicine, in the chairs of the Faculty, and everywhere where science hás shone. We shall conclude our notice with a list of a few of the principal, expressing the hope that the time will come when the pharmacist in this country also will receive more general recognition as a man who can render valuable services to the State.

The *Corps des Pharmaciens Militaires* has counted among its members:—

Guéret, known by his labours in reference to *Cruciferæ*, for which he received several academical prizes.

Bayen (1725–1798), an original investigator who examined by chemical analysis substances hitherto unknown. His valuable researches upon the calcination of metals overthrew the famous theory of phlogiston, and prepared the way for Lavoisier.

Deyeux, the colleague of Parmentier, who made improvements in the manufacture of cheese, and with Vauquelin and Thénard performed numerous analyses of mineral waters.

Parmentier (1737–1813). Some of the services of Parmentier to science have recently been recorded in this Journal (*ante*, p. 537). It is worthy of note that his profound study of the food question in connection with his duties prepared the way for the introduction of the potato, with which tuber his name is in France indissolubly connected.

Alyon (1758–1816), the author of many works on botany and chemistry.

Chaumeton (1775–1819), who produced several works on natural history.

Bertrand, who died in 1826, leaving several valuable works on pharmacy.

Sérullas (1774–1831), a bold and indefatigable investigator of the secrets of analysis, whose numerous discoveries gained for him the chair of chemistry at the Jardin des Plantes, left vacant by the death of Langier.

Laubert (1762–1834), the friend of Joubert and Championnet, whose labours on the cinchonas prepared the way for the discovery of quinine.

Lodibert, who investigated the gaseous products applicable to medicine. He obtained caryophyllin from the clove at a time when the active principles of plants were little understood, and thereby gave a new impulse to the study of the alkaloids.

Besides the above might be mentioned Alexander Brogniart, Bruloy, Brault, André, Tripier, and many others belonging to the past history of the body, whilst the names of many of its living members are familiar as household words to the readers of this Journal.

BOOKS RECEIVED.

NOTES OF A COURSE OF NINETEEN LECTURES ON NATURAL PHILOSOPHY, delivered at Guy's Hospital during the Session 1872–73. By G. F. RODWELL, F.R.A.S., F.C.S., etc. London: J. and A. Churchill. 1873. From the Publishers.

THE PHILOSOPHY OF EVOLUTION. (An Actonian Prize Essay.) By B. THOMPSON LOWNE, M.R.C.S., F.L.S., etc. London: Van Voorst. 1873. From the Publisher.

Obituary.

Notice has been received of the death of the following:—

On the 2nd April, 1873, Mr. William Clark Miller, Chemist and Druggist, of Stirling Road, Glasgow.

On the 10th of June, 1873, Mr. David Aymer, Chemist and Druggist, of Tutbury, Staffordshire.

We are requested to state that the death of Mr. Gibson, of Hull, took place on the 9th June, instead of 9th May, as stated on p. 1008.

Notes and Queries.

[342].—SPICED CONDIMENT FOR CATTLE.—Can any correspondent favour me with a formula for spiced condiment for cattle?—R. R.

[343].—PRESERVED VEGETABLES.—*C. Marshall* wishes for information respecting the different processes and ingredients used for keeping the bright colour in pickles, fruit, jams, and jellies, and also in vegetables, when preserved in hermetically-sealed cans.

[344].—CALICO WATERPROOFING.—"*Wales*" would be obliged for a good recipe for rendering calico waterproof without staining and at little cost.

ALKALIES IN BURNS.—In a letter to the *Medical Times and Gazette* (May 17th), Dr. Dalzell states that in looking over the papers of a deceased friend (an analytical chemist) he has found a memorandum to the effect that liquor potassæ applied to a burned or scalded skin never fails to remove pain in a few minutes. The lotion is to be applied with a feather, and the injured part left uncovered. The *rationale* of the cure is stated to be as follows:—"Scalds, burns, and bruises occasion decomposition of the blood of the injured part. In all animal decomposition (especially in that of blood and coagulable lymph) nitrogen is given off, and combines with the oxygen, forming, perhaps, hyponitrous acid, which occasions much of the pain felt. If an alkali such as liquor potassæ be applied, it aids the formation of nitric acid and combines with it. Nitrate of potash (a cooling salt) is thus formed, which aids in abstracting the heat, and by this and the antiseptic constringing action of the alkali on the animal textures, the decomposition is speedily arrested, and nature is left at liberty to repair the injury." When a large surface is denuded of cuticle, or a very capillary part is injured, Dr. Dalzell considers it necessary to dilute the alkali, or apply it in the form of a soap, by mixing about two parts of liquor potassæ with two parts of olive oil. In some cases he has been obliged to dilute it still further.

HYDROCHLORATE OF TRIMETHYLAMINE.—The following formulæ for the administration of hydrochlorate of trimethylamine are given in *L'Union Pharmaceutique* (vol. xiv. p. 129). It is stated that as much as one gram of the hydrochlorate may be given daily, so that the doses appended to each formula may be varied by the medical man according to the case he has to treat:—

Mixture.

Hydrochlorate of Trimethylamine .	0·50 grams.
Eau de Tilleul*	100·00 „
Syrup of Bitter Orange Peel . . .	30·00 „

Dose, a tablespoonful daily. Each spoonful will contain 75 milligrams of the hydrochlorate.

Solution.

Hydrochlorate of Trimethylamine .	5 grams.
Distilled Water	195 „

Dose, a tablespoonful in a litre of decoction of couch-grass daily. Each spoonful will contain 50 centigrams of the salt.

Syrup.

Hydrochlorate of Trimethylamine .	20 grams.
Syrup of Bitter Orange Peel . . .	990 „

Dose, a tablespoonful in a litre of decoction daily. Each spoonful will contain 50 centigrams of the salt.

Pills.

Hydrochlorate of Trimethylamine .	2·50 grams.
Guimauve Powder (root of *Althæa officinalis*)	7·00 „
Honey	*q. s.*

Divide into one hundred pills, and as the salt is very hygroscopic, coat with balsam of tolu. Each pill, weighing 10 centigrams, will contain 25 milligrams of the hydrochlorate. Dose, two pills every two hours.

Appointments.

GERRARD, A. W., Pharmaceutical Chemist, late of Guy's Hospital, has been appointed Dispenser and Teacher of Pharmacy at University College Hospital.

WHARTON, W., late of St. Bartholomew's Hospital, has been appointed Surgical Dispenser to Guy's Hospital.

* *Eau de Tilleul* (Codex).—Prepared by distilling 1000 grams of dried lime (*Tilia europæa*) flowers with a sufficiency of water until 4000 grams of product are obtained.

Correspondence.

British Pharmaceutical Conference.—Meeting of 1874.

Sir,—I write to express a hope that no action will be taken on the resolution of the Executive Committee of the Conference respecting the place of meeting for 1874, until the subject has been more fully considered.

It follows from the language of that resolution that the whole of Ireland should be closed against the meetings of the *British* Pharmaceutical Conference, which is a serious conclusion to arrive at in committee, if, indeed, it is not a breach of geographical propriety.

I have no wish to argue the point upon the scanty information now before us, and will only say that for all that we yet know, the reasons for departing from a good precedent appear exceedingly unsubstantial.

Richard W. Giles.

Clifton, June 16th, 1873.

Pharmaceutical Education.

Sir,—I have observed with considerable interest the appointment by the Council of a Committee to inquire into the condition and necessity of continuing the School of Pharmacy in Bloomsbury Square. As an old student of the school permit me to say that, for a man who has thoroughly qualified himself in shop routine and dispensing, the attendance at the lectures delivered by our learned professors (and I speak from experience) is the most complete finish a pharmaceutist can possibly desire. That the fees should be raised I am perfectly sure, for I have it on the testimony of several students who have attended the courses of lectures during the last few years, that the classes (very unlike the old ones) are very noisy, and men who go there to study are often so interrupted that on two occasions students have complained to me that if matters got much worse it would be scarcely worth their while to attend at all. Now higher lecture fees and an absolute power vested in those excellent lecturers to cancel the permission to attend of any student misconducting himself in any way would, I believe, give the classes greater popularity than they now possess.

The word "cram" has been used pretty freely lately, evidently with a very different meaning. To teach chemistry and botany by a system of cram may deprive students of the very many advantages arising from regular attendance and attention to the professors' lectures. But what I object to is, that the examiners in practical dispensing and pharmacy cannot tell a well-taught and experienced dispenser from a man who has scarcely ever prepared medicine in his life, but who has gained the cue necessary to meet the questions of the examiners, by making a few emulsions, etc., whose destiny is the sink, and pills divided and silvered, only to decorate the dust-heap. I know that fifteen years ago students dreaded the dispensing counter of the examination room more than any other, and I believe that twenty years ago practical dispensing was not enforced at all. How is it now?

For the diploma of the Society to possess any "money value" at all, it must ensure that the man who holds it is competent to be left in full charge of a dispensing establishment, without *risk* or *inconvenience*. It is in this practical point that cram is so utterly reprehensible. For when is a man asked in his business the Natural Order of a medicinal plant? or whether medicines are cells or contents of cells? or the composition of a chemical? *True, he ought to know them all;* but to do so a student of ten years' standing (for we must always be students) would have to turn to a recent class-book or his recent knowledge to answer correctly and according to the last turn of the scientific votaries' kaleidoscope. Carbonate of ammonia or ammonium may contain carbamate too. But a man who puts one dram of that salt into a three-ounce bottle with one dram and a half of citric acid, and deliberately fills it with water, when in a hurry for the medicine, exhibits a want of training and experience more to be deplored than the profoundest knowledge of chemical memory can make amends. And during the last six years in a shop in a large provincial town, where several assistants were buzzing behind the counter, I have had to beg for and obtained a mortar, and have mixed the medicine myself on the customers' side of the counter. A medical man not long ago asked me what was the best thing to make three grains of reduced iron and two grains of powdered rhubarb into a moderately-sized pill, for he assured me he had it made of all sizes, in London too. I have heard it solemnly stated, even at Bloomsbury Square, that glycerine and fats will mix on no conditions whatever. These are of the genus of facts that damn chemists in the eyes of medical men, and furnish the mould on which flourish the moss that grows on dead men's skulls, who in life were distinguished by a thorough knowledge of their business, and above all, by a high moral rectitude; and the Pharmaceutical Society will fail in its function if, by its influence and teaching, it does not extend among its members that confidence so well deserved, but centred in comparatively few, by physicians, medical men, and the public.

George Mee.

79, *Grosvenor Road, Highbury New Park, June 13th*, 1873.

"Hospital Sunday."

Sir,—The 15th of June, 1873, has come and gone. "Hospital Sunday" has been weighed in the balance and, happily, has not been found wanting. The great experiment of appealing to the pocket from the pulpit for aid in ministering to the suffering and the sick, who, at the same time, in the hard battle of life, take their rank with the needy and the poor (in addition to other means to the same end, though on widely different grounds), has been attended with a most encouraging success. The idea, transferred from the provinces, has been readily adopted by the great metropolis, and "Hospital Sunday" will now become a permanent institution amongst us. For replenishing, in great part, the funds of our large hospitals and infirmaries, "annual festivals" are held in which the stomach is appealed to, and after-dinner speeches are made which rarely fail to elicit a most praiseworthy and successful endeavour to supply the "urgently needed" assistance. But in the scheme of "Hospital Sunday" not a single stomach is involved or asked to take a part. Should that capricious member rebel on the morrow, the festival, so to speak, of the preceding day will be entirely innocent of the cause. Upon far higher grounds than this did the religious community of London on Sunday last pour their treasures of silver and gold into the official plate as politely handed from pew to pew. The one sentiment sought to be inculcated throughout—putting aside for the moment all points of doctrine which unhappily divide and split up the various phases of faith, until the truth ever lies "deeper and deeper still"—was involved in the aphorism or text, "Inasmuch as ye have done it unto one of the least of these my brethren, ye have done it unto me." The heart and the affections formed the channel through and by which the lesson was to be learnt and the grand effort made. "By all your hopes of happiness hereafter," said, in effect, one eloquent preacher—"by all that you hold dear in your moral and religious life—by the example and the acts of the Saviour himself—by the sympathy and Christian love you owe one to another, I call upon you this day to do your duty." How nobly the response came to this and similar appeals is now well known.

But the question has a scientific not less than a religious aspect. There are many ways of healing the sick, and some of them very curious, not to say novel or remarkable. Theories are plentiful but results are few. It was not long since that an enthusiastic *savant*, presumably of a materialistic turn of mind, proposed to test the efficacy of *prayer* by isolating a hospital ward for the purpose, and then subjecting the results to a careful analysis. If this is to be the direction of our scientific and medical studies, surely other institutions than hospitals, equally significant, will flourish amongst us. Far better acknowledge our utter inability to comprehend the phenomena of health and disease, and commend, in all humility and with suitable aspirations, our sick and suffering poor to the great Parent of Good. Accompanying this with as large an amount of material aid as we can afford, and thus encouraging the application of such scientific and truly valuable knowledge as the study of medicine may impart, we shall be reducing to practice one of the noblest duties we can be called upon to perform. This is not the moment to criticize the working of our many hospitals and infirmaries, but certain it is that (like all matters wherein human agency is concerned) they are not an unmixed good. We scarcely know the harm they do with their sharp-bladed and highly polished instruments, their youthful tyros, and their hundreds of gallons of nauseous physic. "Two tablespoonfuls three times a day" by the pint and the quart is still the *sine quâ non* of the hospital consulting-room and the hospital ward. There is an old saying, too, which perhaps may be commended to many of these institutions, namely, "Waste not, want not." Again, are not hospitals antagonistic to the pecuniary interests of prescribers and dispensers of medicine who are unconnected with them, and who require, in the ordinary course of things, to be remunerated for their talent and their labour? All this and much more may reasonably be set down on the "off" side. Nevertheless, making these and all necessary deductions, if need be, a large balance for good resides in the fact that the best efforts of our ablest men are directed to bringing back the sufferer stricken down by a cruel fate into the arena of life, able therein to battle successfully with the stern realities around him. Here, then, is a great truth which, if we are not reached by the *preacher's* appeal, ought, without doubt, to command our sympathy and secure our material support. That the chemists of London, notwithstanding the apparent rivalry of hospitals, have helped liberally and cheerfully in this good work, there cannot be a question; and whilst the hospital ward with its trained supervision is an institution in our midst, ever ready to do battle with sickness and disease, we say unhesitatingly let the duty remain alike to all, for even so shall the good cause progress, and a sympathetic voice be heard far and near, wishing God-speed to "Hospital Sunday."

"How far that little candle throws its beams!
So shines a good deed in a naughty world."

June 17*th*, 1873. W. W.

A Potential Charm in Drugs.

Sir,—From the letter of "G. W." it appears the age of superstition is not past.

During my apprenticeship, in the West Riding of Yorkshire, now more than forty years ago, I acted for some time as amanuensis to a local astrologer, or "wise man," as he was called, and who was celebrated for removing "spells" from cattle and evil wishes from human beings; he was also much consulted in love affairs. Many of his customers were of a respectable class.

"For removing the spell from cattle, take sulphur 2 oz., nitre 1 oz., aqua fortis 1 oz., spirit of salts 1 oz., devil's dung ¼ oz., cold spring water 1 quart; put all into an iron pan over hot ashes for half an hour; dig a hole in the ground two feet deep, pour in the contents of the pan and fill up the hole." If the case was a very bad one, a sheep's heart was also to be buried.

For taking off an evil wish, use the same articles, adding 1 oz. of powdered hell coke (pumice stone) and ½ oz. dragon's blood, also (wrapped in paper) 9 new pins, 9 new needles, and 9 thorn pricks; read a chapter in the Bible and repeat the Lord's Prayer; the whole to be completed between eleven and twelve o'clock at night. First thing the following morning a powder was to be taken, and repeated in nine days if the person was not cured. The powder consisted of jalap ½ dram, calomel 5 grains. If the incantation sometimes failed to operate, the powder never did! My master used to caution the "doctor" that the powder was much too strong for females, but his reply was that the d—l took as much driving out of a woman as a man.

Love charms, for bringing back faithless swains, were packets containing a small square of parchment marked with cabalistic figures, worn next the heart for one moon, and repeated for three moons, if necessary. These amulets were said to be very successful, but whether from the potency of the "charm" or that "the quarrels of lovers lead to the renewing of love" I leave your readers to decide.

Jas. Baynes.

Hull, June 17*th*, 1873.

G. H. Jones.—To be frightened by the external appearance of a book is but a poor preparation for the study of its contents. If not able or willing to work systematically and thoroughly at the book in question, the index at the end would point out the portions of the work treating of the subjects mentioned in the syllabus of the examination.

W. L.—Apply to the Secretary at the College of Surgeons.

H. Campbell.—We answer your present question in the hope that after a few lessons on numeration you will be able to decide similarly difficult questions yourself. If A, B, and C, and no other, preceded D in a list, D would be the fourth on such list.

C. X.—A candidate who obtains a certain percentage of the marks allotted to the questions would be passed.

W. R. F.—It would not be practicable to do what you speak of, but an emulsion may be prepared by suspending the oils in a strong solution of soap.

R. Sturton.—Microscopically, dextrin can be detected in sugar by moistening a portion of it with ordinary spirits of wine, and then looking for the starch granules under the field of the microscope. Chemically, its presence can be discovered by taking 100 grains of the powdered sugar, dissolving it in the smallest quantity possible of lukewarm water, then adding to the sugar solution one ounce of concentrated hydrochloric acid, and afterwards 8 oz. of methylated spirit. If dextrin be present there will be a flocculent precipitate almost at once; if absent, the solution will remain clear. To prove the presence of the dextrin the precipitate can be washed with methylated spirit till free from sugar, then redissolved in water and again precipitated, washed, and boiled with a few drops of sulphuric acid to convert the dextrin into sugar, and then tested for sugar with the ordinary copper test. Alcohol is better than methylated spirits, but it is more expensive. The reason why alcohol must be used for the microscope is, that in commercial dextrin the starch cells remain intact. These cells are immediately soluble in water, but insoluble in alcohol. The starch granules can easily be distinguished from the bold sugar crystals, as the former are nearly all round or oval, with the exception of rice, maize, and oats.

R. E. S.—Marking Ink.—We cannot give a reason for the brown colour. Perhaps a better result would be obtained with the following:—

Nitrate of Silver,	
Bitartrate of Potash, ana	℥j
Solution of Ammonia	℥iv
Archil	℥ss
White Sugar	ʒvj
Powdered Gum Arabic	ʒx

Rub the nitrate of silver and bitartrate of potash together, then add the ammonia, the archil, and the other ingredients. Linen marked with this ink will require to have a hot iron passed over it, or the part marked must be held to the fire until the marks have assumed a jet-black colour.

"*Corolla.*"—M. C. Cooke's 'Manual of Botanic Terms,' published by Hardwick.

"*Lavender.*"—It would not be possible to hold the colouring-matter of the Sp. Lavand. Co. in solution in water without making the mixture alkaline, in which case the quinine would be precipitated.

"*An Apprentice of the Society.*"—Details of the preparation of artificial alizarine from anthracene may be found in the *Journal of the Chemical Society* and in the specifications of the patents for the various processes relating to the subject.

D. Amos.—From what you state about "water on the brain" it is probable that the disease referred to is what is commonly called "gid" or "sturdy," and is due to the presence of *hyatids* on the brain, the result of sheep or cattle swallowing the ova from the tapeworms passed by dogs and deposited on the grass. See an article on the subject in the 'Edinburgh Veterinary Review,' vol. i. p. 301.

"*Indignans.*"—Inquiries are being made respecting the subject of your letter.

Army Hospital Corps.—We are indebted to an anonymous correspondent for a copy of the regulations respecting enlistment in the above corps.

Communications, Letters, etc., have been received from Messrs. Fannin, Pocklington, Garside, Duguid, P. Kelly, Lomas, Marshall, Macdonald, "Lamium," "Botanist."

MATERIA MEDICA OF THE UNITED STATES' PHARMACOPŒIA.

BY E. M. HOLMES,

Curator of the Museum of the Pharmaceutical Society.

(*Continued from page* 1011.)

Nomenclature.—A list of the alterations in the names of chemical compounds has been given on a former page. There is, however, one change in the signification of a name which may be noticed here. Alum has hitherto been understood to mean sulphate of aluminium and potassium, and the corresponding salt of aluminium and ammonium has been known as ammonia alum. This is now reversed in the U. S. Pharmacopœia. When alum is ordered in a prescription, the dispenser is required to use ammonia alum, and to dispense potash alum only when prescribed under the name of aluminii et potassii sulphas. This change probably arises from the fact that a large proportion of the alum now met with in commerce consists of ammonia alum. Fortunately the medical properties of the two are sufficiently alike to render the change of little moment.

The term "folium" as applied to *Aconitum*, *Belladonna*, *Hyoscyamus*, and *Strammonium*, has been changed to folia. The word semen however is not altered in those cases in which it occurs, viz., *Colchicum*, *Hyoscyamus*, and *Strammonium*. This want of uniformity is very arbitrary—the one has certainly as much claim to be placed in the plural number as the other. In some cases, the specific names have been altered in consequence of the introduction of others bearing the same generic name; thus *Asclepias* has now become *A. tuberosa*, in consequence of the introduction of two new species of *Asclepias* unto the secondary list. *Conium* is now altered to *Conii folia*, a change which has been made necessary by the addition of *Conii fructus* to the primary list. *Extractum cannabis* is now called *Ext. Cannabis indicæ*, an extract of *Cannabis americana* having been introduced into the preparations. It is unfortunate that this rule of distinguishing between two articles of the same generic name has not been followed in every case. A contrary procedure has taken place with regard to the following, the descriptive terms being omitted:—

1864.	1873.
Ulmus fulva	Ulmus.
Sesami folium, Benne leaf	Sesamum, Benne.
Sassafras radicis cortex	Sassafras.
Blackberry root	Blackberry.
Black oak bark	Black oak.
White oak bark	White oak.
Wild cherry bark	Wild cherry.

The compilers of the Pharmacopœia have carried this pruning process to a considerable extent; thus it will be observed that abbreviations have been made wherever possible, with the result, in several cases, of rendering the meaning somewhat doubtful. This may be complimentary to the common sense of the American people, but it makes no allowance for the fact that American prescriptions are sometimes prepared in other countries, where the abbreviated descriptions might possibly be misconstrued, and that therefore the terms used should be as explicit as possible. Thus *Prunum* is described as the fruit, and therefore either fresh or dried fruit might be used, although it is evident from the preparations that dried fruit is intended, and *Piper*, *Cubeba*, and *Pimenta* are described as unripe fruits, although no one would think that the green fruits were intended to be used.

But sassafras in this country would mean the whole of the root and not the root-bark; and *Ulmus* would mean *Ulmus campestris*, which is not nearly so mucilaginous as *U. fulva*. If syrup of blackberry were asked for by an American resident in a provincial town in England, the probability is that syrup of blackberry fruit would be unhesitatingly supplied, that being a favourite domestic medicine for aphthæ, etc., but it does not possess the tonic and astringent properties of the American preparation. These useless abbreviations have been carried to their utmost extent in the case of *Coptis*, the only description appended to which, if description it can be called, is *Coptis trifolia*. The root of this plant was officinal in the last edition, but whether the same part of the plant or the whole herb is to be used now is not at all clear.

The instances above given are perhaps not of any great importance, but the principle of curtailed description is a bad one. This is more especially evident when the same name is common to two or more plants, as in *Castanea*; or when different parts of the same plants are officinal in other pharmacopœias. If a description is necessary it is well that it should be accurate and lucid. While it cannot be expected that a pharmacopœia should take the place of a work on materia medica, and give a full description of the history and properties of each drug, it is only reasonable to expect that the same facilities should be afforded for attaining excellence of quality and freedom from adulteration in the organic as in the inorganic part of the materia medica. A short but practically useful description of what the roots, leaves, and barks should be, and of the means by which their quality and freedom from adulteration or admixture could be readily estimated, is in some measure necessary to ensure uniformity in dispensing.

The following names have been altered thus:—

1864.	1873.
Cranesbill	Geranium.
Fleabane	Erigeron.
Canada Fleabane	Canada Erigeron.
Hemlock	Conium leaves.
Henbane seed	Hyoscyamus seed.

This is a slight improvement in accuracy. The name of fleabane is applied to several different plants. Hemlock is a name applied also to the hemlock spruce. There is not, however, that I am aware of, any similar reason for changing the well-known name of henbane seed to hyoscyamus seed. The change of cranesbill to geranium can scarcely be called an improvement, for the one name is not more distinctive than the other; one of the other names in common use, such as spotted geranium, would have been better. A few names have been altered in deference to the progress of science, thus:—

1864.	1873.
Cytisus scoparius.	Sarothamnus scoparius.
Artemisia contra	Artemisia Cina
Cocculus palmatus, *DC.*	Jateorrhiza palmata, *Miers.*
Cinchona, an undetermined species	Cinchona succirubra

It may here be noticed that calumba root is attributed to two species, *Jateorrhiza palmata*, Miers, which is the same as *Cocculus palmatus*, De Candolle, and *Jateorrhiza calumba, Miers,* which is the *Cocculus palmatus* of Wallich, but not of De Candolle. In the British Pharmacopœia the two species mentioned are, *Jateorrhiza calumba,* Miers, and *J. Miersii,* Oliv. Jateorrhiza Miersii is the name given by Oliver to *J. palmata,* Miers. The difference arises from the B. P. names having been taken from Oliver's work, while those of the U. S. P. were taken from that of Miers.

Changes in Description.

1864.		1873.
Acacia,	concrete juice	Gummy exudation.
Tragacanth	,, ,,	,, ,,
Ammoniacum	,, ,,	Gum resinous exudation.
Myrrha	,, ,,	,, ,, ,,
Galbanum	,, ,,	Gum resin.
Gambogia	,, ,,	,, ,,
Benzoinum	,, ,,	Solid balsam.
Scammonium	,, ,,	Resinous exudation.
Mastiche	,, ,,	Concrete resinous exudation.
Pix Burgundica,	prepared concrete juice	Prepared ,, ,,
Pix Canadensis	,, ,,	,, ,, ,,
Copaiba	juice	Oleoresin.
Terebinthina Canadensis	,,	Liquid oleoresin.
Terebinthina	,,	Concrete oleoresin.
Balsamum Tolutanum	,,	Semi-liquid balsam.
Balsamum Peruvianum,	prepared juice	Empyreumatic liquid balsam.
Styrax	,, ,,	Balsam.
Cassia Marilandica,	leaves	Leaflets.
Ergota,	diseased seed	The *sclerotium* of *Claviceps purpurea,* replacing the grain of *Secale cereale.*
Vanilla,	prepared unripe capsule	Prepared unripe fruit.
Ol. Lini,	oil	Fixed oil.
Ol. Ricini	,,	,,
Ol. Tiglii	,,	,,

The new descriptions are much more accurate than those which they replace. For instance, the term exudation does not represent the juice of a plant, but only a part of its constituents. A little more uniformity, however, would be an improvement; thus myrrh and ammoniacum are termed gum resins, while galbanum and gamboge are called gum resinous exudations. If the word exudation is necessary, there is no reason why it should not be applied equally to myrrh and ammoniacum. The same want of uniformity is shown in the B. P. with regard to these articles; mastic is called a concrete resinous exudation, but scammony, which is certainly a concrete substance, is incorrectly described simply as a resinous exudation. Scammony is, however, strictly speaking, a gum resin, since it contains about 6 per cent of gum, and is very properly so described in the B. P. Canada balsam is termed a liquid oleoresin, but copaiba simply an oleoresin, although the latter is generally much more liquid than the former. Balsam of tolu is described as a semi-liquid balsam, while styrax which has an equal claim to the title is simply called a balsam.

A few other descriptions will also require attention when a new edition is again issued. *Jalapa,* described in the last U. S. Pharmacopœia as a root, is now called a *tuber.* This is not correct; jalap is a *tubercule,* and is rightly described as such in the B. P. The term tuber should be restricted to an underground *stem* enlarged by a deposit of starchy or other matter for the nutrition of the plant, and the term tubercule applied only to *roots* which are enlarged in a similar way. The peculiar substances alluded to by Mr. Martindale, including alcohol amylicum, camphora, castoreum, cera flava, cetaceum, fermentum, guaiaci resina and moschus, have no better claim to be considered peculiar than a number of other articles of the materia medica, and there can be no reason why they should not be as well defined as they are in the B. P.

Oleum amygdalæ dulcis is now altered to *oleum amygdalæ expressum,* and is described as the fixed oil obtained from the kernel of the fruit of *A. communis.* This is an improvement on the last edition, in which it was said to be derived from *A. communis,* var. *dulcis,* the fact being, that it is chiefly obtained from the var. *amara,* which is pressed for this purpose before distilling the essential oil, on account of the comparative cheapness of the bitter almond. *Fœniculum* is now directed to be obtained from the *F. dulce,* instead of *F. vulgare* as in the last edition. The former is considerably more aromatic and pleasant to the taste than the latter. There are two varieties met with in commerce, one short and somewhat pointed, and the other longer, more obtuse at the ends, and rather thicker at one end than the other. The long variety is the best, but of this fact no notice is taken here.

Rheum.—Rhubarb is now, by the description of its geographical source, limited to the Asiatic varieties and thus the use of inferior kinds is excluded. At the time that the U. S. P. was published the true source of *Rheum* was not known and therefore it is still attributed to *R. palmatum* and other species.*

Filix mas is now more correctly described as the rhizome covered with portions of the stipes, and the following directions are now added. "When used only such part of the rhizome as has retained its green colour should be employed, and the stipes being inert should be removed." These directions would have been more intelligible if the fresh rhizome freed from the stipes had been directed to be used; if the stipes be inert, there can be no reason why it should be official.

Opium is now described as being obtained by incision and spontaneous evaporation. This is an exception to the general rule, being a longer description than that given in the last edition. Opium is also now directed to be dried before analysis. This is an improvement, for it is impossible to give a fair estimate of the percentage of morphia unless this be done. According to the P. B. six to eight grains of morphia should be yielded by 100 grains of opium, but as good opium yields from 10 to 13 per cent. the percentage mentioned in the U. S. P. (10 per cent.) is not at all too high.

In the secondary list the following alterations have been made in the descriptions given :—

1864.		1873.
Carthamus	flowers	Florets.
Geum	root.	Rhizome.
Heuchera	,,	,,
Phytolaccæ	bacca, berries	Fruit.
Rottlera,	powder and hairs	Glandular powder and hairs.
Tormentilla	root	Rhizome.

It seems rather inconsistent to change the word berries into fruit and not to change the Latin *bacca* into *fructus.*

The following changes have taken place with regard to the parts of plants that are official :—

* See *ante,* p. 301.

1864.		1873.
Lobelia.	herb	Leaves and tops.
Mentha piperita,	,,	,, ,,
,, viridis	,,	,, ,,
Marrubium	,,	,, ,,
Monarda	,,	,, ,,
Cataria	leaves	,, ,,
Dulcamara	stalks	Young branches.

The above changes make very little practical difference, but the following may be classed among the improvements in the present Pharmacopœia, as the parts now ordered contain the greater part of the active principles of the plants.

1864.		1873.
Guaiaci lignum,	wood	Heartwood.
Papaver,	ripe capsules	Nearly ripe capsules.
Quercus alba,	bark	Inner bark.
,, tinctoria	,,	,,
Rosmarinus,	tops	Leaves.
Rubus,	root	Root bark.

In the secondary list a few alterations have also taken place:—

1864.		1873.
Achillea, herb and flowers		Leaves and flowering tops.
Melissa,	herb	Leaves and tops.
Solidago,	leaves	,, ,,
Tanacetum	,,	,, ,,
Viola (pedata)	,,	Root.

THE USE OF NUT OIL IN PHARMACY,

AND ESPECIALLY IN

THE PREPARATION OF UNGUENTUM HYDRARGYRI NITRATIS.*

BY M. FALIERES.

In a brief review of former formulæ for the preparation of citrine ointment, the author calls attention to the large increase which has taken place in the relative proportion of the nitric acid to the mercury. The proportions indicated by Baumé, in 1785, were nitric acid 128 parts, mercury 96 parts, lard 1000 parts. The mercury has been gradually decreased until, in the Codex for 1866, where equal parts (500) of olive oil and lard are ordered, the nitric acid is 100 parts, and the mercury 50. Thus the proportions which originally were 4 of nitric acid (sp. gr. 1·28) and mercury 3, have become nitric acid (sp. gr. 1·42) 2, and mercury 1.† Without blaming the progressive diminution of the metal, since even with this reduction the medicament still remains very powerful, the author objects to the great excess of acid. Suggestions have been made to remove the excess of acid by washing the ointment with a large quantity of water, and then adding an equal weight of almond oil, but have been rejected in consequence of the length and difficulty of the operation, and it being far from certain that the whole of the acid excess would be thus removed.

The author having had occasion to make a comparative investigation of pure olive oil and the oil of the ground nut (*Arachis hypogœa*), found that the arachis oil possesses a great aptitude for the nitric solidification. Hence he conceived the idea of suppressing entirely the lard in the preparation of nitrate of mercury ointment. The product so obtained appeared to present such marked advantages as to induce him to make known the process.

Mercury	5 parts.
Nitric Acid (sp. gr. 1·42) ...	10 ,,
Nut Oil	100 ,,

Dissolve without heat the mercury in the acid; pour the mercurial solution into the oil, agitating from time to time with a glass or earthenware spatula. After two or three hours, according to the quantity operated upon, and at a temperature of about 20° C, the mixture begins to take a milky consistence, which lasts for about an hour, then thickens to that of a soft butter. This latter stage lasts at least two hours, during any portion of which time the ointment may be poured out. The mass spreads with perfect regularity in a paper mould; the thickness of the layer is uniform, and there is no separation between the oily and mercurial elements, showing that the combination is complete. The product does not set so rapidly as the official one; at the end of ten or twelve hours it is easily divided by a wooden knife, but this is more conveniently done after it has stood for twenty-four hours; its consistence is then similar to that of cacao butter in the summer. Two or three days afterwards it appears to attain its maximum of firmness, and some has been kept upwards of two months without showing any appreciable difference in its consistence. Compared with the Codex preparation, the author considers that the ointment made with nut oil has greater cohesion, is not friable, and appears much better adapted for friction, as it melts and spreads upon the skin with greater facility.

M. Falières is of opinion that no serious exception could be taken to the change of fat excipient which he proposes. The progress attained in the manufacture of arachis oil has provided a white, bland, tasteless article, which is, commercially speaking, neutral. Perfumers, who are not, like pharmacists, bound by a formal code, make large use of the ground nut oil in the manufacture of pomades, cold cream, etc. A perfect type of a non-drying oil, it absorbs relatively small quantities of perfume; it requires the least wax, spermaceti, or stearine for its solidification, and finally may be kept almost indefinitely without turning rancid. The author promises at some future time to show in detail the advantages that may be obtained from the use of nut oil in a large number of pharmaceutical preparations.

* 'Bull. des Travaux de la Société de Pharmacie de Bordeaux,' vol. xiii. 165.

† In the B. P., where more olive oil is used, the proportions are nitric acid 3, mercury 1.

CHRONIC POISONING BY CHLORAL HYDRATE.

BY DR. LUDWIG KIRN.

In an article in the *Allgemeine Zeitschrift für Psychiatrie*, to an abstract of which, appearing in *The Practitioner* for the present month, we are indebted for the following notes, the author calls attention to the changes which the long-continued use of chloral hydrate sometimes produces in the organism. Experience has shown that the individual tolerance of patients for this drug varies within very wide limits, and he states that although at one time he administered it for the most part daily as a hypnotic, in doses of 30 to 60 grains, or occasionally 75 to 90 grains, he would now rarely go beyond the dose of 30 grains. Its calming and hypnotic influence have proved to be exceedingly variable. Whilst upon many patients the commencing dose of 30 grains continues for a long time to produce the desired effect, and for others only a gradual increase of this quantity is required, there are cases in which but slight results are obtained, although the dose be increased to 60 grains. In many patients, same dose sometimes succeeds and sometimes fails.

But the article deals more particularly with the morbid phenomena which appear sooner or later in the course of continuous employment of this hypnotic. The most prominent of these symptoms are connected with the skin, and consist of more or less extensive erythemata and pustular or papular exanthemata. Schüle speaks of chloral producing a tendency to fluxionary hyperæmias and increased heart action, early manifested in the head by an intense erythema, occurring first in spots, but afterwards more diffusely, and which in more pronounced cases extends downwards to the trunk. This chloral-rash remains latent until set going by some stimulus to the vascular system, but then appears with an intensity proportionate to the extent of chloralization. This opinion is confirmed by the author, who states that he is acquainted with a series of patients in whom the chloral rash can be produced with the certainty of an experiment. For instance, in a paralysed patient, who took 30 grains of chloral every night, ten minutes after she had drunk her beer there occurred increased action of the heart and spots of roseola upon the forehead, nose, cheeks, and neck, which quickly coalesced into a patchy erythema, with swelling and heat of the affected parts, which symptoms disappeared in about an hour. The same symptoms appeared still more strongly in a young and previously healthy woman affected with mania, who every night took 30 to 45 grains of chloral (although she had not previously suffered from congestion of the face). As soon as she took a glass of beer there was strong pulsation of the arteries, and the whole face was swollen and of such an alarmingly deep colour that the use of wine and beer was forbidden. At present the author but rarely allows alcoholic drinks to patients who are being treated with chloral. In another young woman suffering from mania, who took 30 grains of chloral at night, four ounces of wine were sufficient to induce the chloral-rash.

The effect is not always limited to congestion and erythema of the skin, but other skin affections are occasionally produced. Female patients, who had taken 60 grains of chloral daily, first had erythema of the face, and later a papular rash on the arms, with red bases. In some nettle-rash occurred.

The swelling, accompanied or not by rash, which has been noticed in the face after continued use of chloral, may equally occur on extensive portions of the body. In several patients a swollen condition of almost the whole body was noticed, which might be ascribed to serous infiltration of the skin from stasis of blood. With these affections of the skin must be associated affections of the mucous membranes.

Reimer observed in a series of patients, especially after the use of morphia and chloral together, that after slight external pressure there was congestion in circumscribed spots with much lowered sensibility, which quickly disappeared if the pressure was soon removed. Under less favourable circumstances, the red spots swelled and assumed a darker colour; vesicles were soon developed which might even run on to sloughing.

An important symptom noted in a series of cases of the long-continued use of chloral is an interference with respiration, which may remain slight and scarcely troublesome to the patient, or may become positive dyspnœa. Schüle observed a patient who, after long use of chloral, used regularly to suffer after meals from a sense of oppression which made going up stairs extremely difficult, and even interfered with speech, although there was no chest disease to account for this. The symptoms persistently recurred in spite of all treatment till the chloral was left off, when the oppression entirely disappeared. A lady, prostrated by long sufferings, suffered from attacks of extreme dyspnœa, which had increased to asphyxia; at the same time the face was swollen, the facial muscles paralysed, and there were also all the signs of cerebral effusion. Every remedy had failed, and the patient seemed on the brink of the grave. The physician therefore recommended the discontinuance of a daily dose of 45 grains of chloral which had been given as a hypnotic; whereupon all these highly alarming symptoms vanished in an almost magical way, the cerebral disturbance ceased, and the respiration quickly resumed its normal type.

In another group of cases both the quality of the symptoms and their greater or less extension in the organism indicate a distinct change in the composition of the blood. Dr. Crichton Browne reports that a woman, aged 69, suffering from periodical mania, had 20 grains of chloral thrice daily. On the fourth day a redness was developed on the skin of the chest and shoulders, which did not vanish on pressure. On the sixth day the eruption had extended over the whole trunk and limbs, livid spots and deep red patches alternating; the lips and the mucous membrane of the mouth were excoriated, the gums spongy, the tongue blistered and ulcerated, the breath fœtid. The general state was one of great depression,—pulse 120. On the eleventh day the ulceration of the mouth had extended further; the lips were covered with crusts; the petechial eruption was diminished on the chest and abdomen—the spots were yellowish with patches of white skin between them; the spots on the arm lost their redness later. On the fifteenth day there was a sort of general desquamation; fissures of the skin over the sacrum, and in the neighbourhood of the joints. From that time convalescence proceeded, and ordinary health was restored.

A woman, aged 46, suffering from cardiac disease, hemiplegia, and dementia, took 15 grains of chloral three times a day with a calming effect. On the nineteenth day of the treatment numerous purple-red spots appeared in the neighbourhood of the left elbow; on the next day many similar spots were seen on the shoulders and forearms, which coalesced with the others. On the twenty-first day livid spots came on the face; the left arm swelled and became hard; on its reddened surface appeared a multitude of minute points of a much deeper colour, which did not diminish on pressure. Next day there were dark purple spots and discolorations—some small, round, and circumscribed, others broad and irregularly shaped—on the legs and abdomen, and in stripes on either side of the vertebral column. Simultaneously with the petechiæ there were great prostration, tendency to somnolence, weakness and excitability of the pulse, sore lips, thickly-coated tongue. On the twenty-third day the spots and discoloured patches had extended in every direction, and the previously bright red spots had assumed a deep purple colour. Finally, signs of lung-congestion appeared, with gradual failure of power, and death, after several fainting fits, on the twenty-sixth day. At the autopsy numerous ecchymoses of every shape and size were observed more or less on all parts of the skin; the right lung was congested and œdematous, the heart dilated and its valves thickened; over the right central hemisphere there was a large arachnoid cyst containing fluid blood.

Other cases are quoted by the author, and the article closes with a notice of a case which occurred before the effects of chloral hydrate were yet known, and in which the use of the medicine was continued much longer than it would be now the symptoms are recognized. It was that of a young man in whom, on the ninth day of chloral treatment, a rash of groups of red spots appeared which soon became confluent. This was followed by a rise of temperature (on the twenty-third day to 106·7°), œdematous swelling of the face, cheeks, eyelids, and ears, eczema, shedding of the hair, and falling off of the nails of hands and feet. After the sixth week abscesses formed on the shoulders and armpits. The author considers that the symptoms described must be defined as those of chronic blood poisoning. There was, however, no other external cause than the administration of chloral, which for ten weeks had been given in nightly doses of 45 to 60, or even 75 grains. After a certain saturation had been produced by accumulation the symptoms began to spread, and finally they assumed the complete picture of a chronic blood-poisoning.

FRANGULIN AND FRANGULIC ACID.*

BY A. FAUST.

The bark of the *Rhamnus frangula* is digested for three days with 90 per cent. alcohol at 25°–30°; from the extract the alcohol is partially distilled off, and then lead acetate is added to the residue as long as a precipitate falls: the filtrate from this is precipitated by basic lead acetate, and the precipitate disseminated through alcohol and decomposed by sulphuretted hydrogen; the resulting liquid yields crystals of frangulin on cooling after filtration while boiling hot.

Casselmann describes frangulin as crystallizing under the microscope in quadratic tables; the author could not discern these tables either in his own preparation or in a specimen prepared by Casselmann, the two samples melting at 226° and 225° respectively, instead of 249° as stated by Casselmann. It forms a lemon-yellow crystalline mass after recrystallization from hot alcohol, and is soluble in alkalies with a deep cherry-red colour; when boiled with hydrochloric acid it splits up into glucose and *frangulic acid:*

$$C_{20}H_{20}O_{10} = C_{14}H_8O_4 + C_6H_{12}O_6.$$

Hence the author ascribes the formula $C_{20}H_{20}O_{10}$ to frangulin, instead of the sub-polymeric formula $C_6H_6O_3$ attributed to it by Casselmann.

Frangulic acid is most conveniently prepared by boiling the bark with rain-water for an hour, then adding caustic soda equal to one-twentieth or one-thirtieth of the weight of bark taken, and boiling again for several hours; the resulting liquid extract is supersaturated with hydrochloric acid, and boiled for some hours, whereupon the frangulic acid separates and can be collected on a cloth filter; the dried and pulverized precipitate is boiled with alcohol, and the hot alcoholic solution precipitated by lead acetate (which scarcely precipitates frangulic acid); the filtrate is precipitated with basic lead acetate, and the precipitate disseminated through alcohol and decomposed by sulphuretted hydrogen; and the resulting liquid is heated to boiling and filtered hot, the acid then separating from the filtrate on cooling. This treatment with lead salts, etc., is repeated several times; and the purified acid, after being dried and boiled with benzene to separate sulphur, is finally recrystallized several times from hot alcohol. Different samples of bark differ much in the quantity of frangulic acid obtainable from them; in one case, 50 lbs. yielded only a few grams.

Frangulic acid melts at 252°–254°, and sublimes partially at lower temperatures; it is but little soluble in hot water, and is insoluble in cold water and alum-solution; alkalies dissolve it, with a red colour, removed on boiling with zinc-dust; on treating it with red-hot zinc-dust anthracene is produced in small quantities; it crystallizes with $1\frac{1}{2}$ proportions of water, the last $\frac{1}{2}H_2O$ being only removed at 180°.

THE MEANS OF DETECTING AND ESTIMATING BROMIDE IN IODIDE OF POTASSIUM.†

BY ALFRED E. TANNER.

It occurred to me that the above subject would be well worthy attention at the present time, for not only are the processes for detecting and estimating bromide in iodide few and imperfect, but it also seems to me a very probable adulterant, inasmuch as there is a great difference in price between these two salts, and the difficulties attending the detection of bromide when mixed with iodide are considerable.

Cl, Br, and I, so resemble one another in their chemical characters and reactions, that it becomes a difficulty by no means easily surmounted to distinguish them when in the presence of one another, and this is especially the case with the two latter, and as a sample of KI may contain 75 or more per cent. of KBr and yet be indistinguishable from the pure article when tried by the pharmacopœia tests, it needs little further to point out the desirability of investigating this subject; and before I go further, I must confess that I fear I have accomplished little towards doing away with the difficulties. What we require is a test presenting no great difficulties of application by the ordinary pharmacist, and one which shall indicate with a fair degree of accuracy the object sought to be attained. Of course it is well known to chemists that $PdCl_2$, when added to a neutral solution of an iodide containing bromide, will remove the whole of the I without affecting the Br, but $PdCl_2$ is a rare and most expensive reagent to use, and would scarcely pay the pharmacist who examines usually but small parcels of iodide at a time. This, although I believe to be the most accurate, we must consider out of the question. Recent chemical works tell us that a mixture of $FeSO_4$, two parts, and $CuSO_4$, one part, added to a neutral solution of an iodide, in the presence of bromide and chloride, and the mixture neutralized with NH_3, will remove the whole of the I without affecting the Br or Cl. In my hands, at least, the practice of this process has been attended with only partial success, for I have found it impossible to remove *the whole* of the I; the difficulty therefore remains as great as ever; it is probable, however, that further experiments with this test may yet prove it adequate to the purpose. I rather suspect the Cu_2I_2 to be slightly soluble in the solution from which it is precipitated; we must therefore seek some salt to add to the mixture to prevent this. The following is the reaction stated to occur:—

$$2\,KI + 2\,CuSO_4 + 2\,FeSO_4 = Cu_2I_2 + K_2SO_4 + Fe_2 3SO_4$$

A test proposed by Van Melekebeke (*Journ. Pharm. d'Anvers*, xxviii., 49, 1872) seemed to promise well, and from its great simplicity would have been a valuable one if successful. It depended on the fact that a saturated solution of one salt is capable of dissolving appreciable quantities of another salt. A saturated solution of KBr was therefore used, and to this the sample of KI, in powder, was added in small quantities at a time, when, if pure, it dissolved readily, but if KBr were present, the liquid being already saturated with this salt, it would remain undissolved. Repeated trials with this test have proved to me that it is quite useless. The author recommends you to take 10 c.c. of the saturated KBr solution, and to add to this 10 drops of distilled water; 1 gram. of the suspected salt, in powder, is then added, small portions at a time, which, if the iodide be pure, should at once dissolve; but 10 drops of distilled water is quite sufficient to dissolve 5 or more grains of KBr, and if no water be added, some KBr is very liable to be thrown out of solution by the shaking necessary. The next test I tried was one by M. Personne, published in the *Journal de Pharmacie*. It depends on the property possessed by $HgCl_2$ of precipitating a solution of iodide but not one of bromide, bromide of mercury being soluble. It is necessary to the success of this test that the iodide be free from KIO_3, KCl, and K_2Co_3.

I may mention here that KIO_3 is much more frequently present than is generally supposed, and traces of it may generally be detected in the best samples of iodide, and as this salt (KIO_3) is stated on pretty good authority to be of a poisonous nature, it behoves us to be on our guard against it; it is fortunately easy to detect by adding a little starch solution to the iodide to be tested, and then adding a small quantity of tartaric acid; a blue colour is developed more or less rapidly, by the liberated iodide acting on the starch, if the KI contains KIO_3, thus:—

$$5\,KI + KIO_3 + H_2C_4H_4O_6 = K_2C_4H_4O_6 + 5HI + HIO_3$$

and

$$5\,HI + HIO_3 = I_2 + 3H_2O.$$

* *Ann. Chem. Pharm.* clxv. 229; from the *Journal of the Chemical Society.*

† Paper read before the Liverpool Chemists' Association, May 8th, 1873.

1 gram $HgCl_2$ is dissolved to 20 c.c. with distilled water, of this solution 16 c.c. is capable of removing the whole of the I from 1 gram KI. If therefore the KI be mixed with KBr a proportionably less quantity of the mercuric solution will be required.

It is a somewhat curious fact, and one which I have nowhere seen recorded, that when exactly half the mercuric solution is added a permanent precipitate begins to form, and I consider it highly probable that the reaction which takes place is analogous to that which occurs in testing HCN by what is termed Liebig's process, in which a volumetric solution of $AgNO_3$ is added to a weighed quantity of HCN; and when exactly one-half the cyanogen is displaced, and permanent precipitate of AgCN commences to form, a soluble double salt is first formed and shown by the precipitate dissolving as fast as it appears until exactly half the solution has been used; the HCN is first made slightly alkaline with NaHO

$$AgNO_3+2\ NaCN=AgCN, NaCN+NaNO_3$$

and

$$AgCN,\ NaCN+AgNO_3=2\ AgCN+NaNO_3$$

and similarly with KI and $Hg\ Cl_2$

$$HgCl_2+4\ KI=(KI)_2HgI_2+2KCl$$

and

$$(KI)_2Hg_2I_2+HgCl_2=2\ HgI_2+2\ KCl$$

I prefer to make the formation of a permanent precipitate as the finishing point of the process; it is much more sharply defined than the point at which the precipitate ceases to form. Should it be preferred, however, to make use of this latter (and it is useful as a check on the first part of the process) the best way is to take a glass tube open at both ends, about 15 cm. in length and 5 mm. diameter, and to tie over one end a small piece of filtering paper; on moistening this and depressing the tube into the iodide solution, a few drops may be filtered off and transferred (by inverting the tube) to a porcelain slab and small test glass, and a drop of the mercuric solution added; it will then be instantly apparent whether the reaction is complete or not.

I append the result of my experiments with KI containing quantities of KBr.

Percentage of KBr in 1 gm KI	Precip. commenced.	Precip. ceased.
0	8·0 cc.	16·0 cc.
5	7·6 cc.	15·3 cc.
10	7·3 cc.	14·6 cc.
15	6·8 cc.	13·6 cc.
20	6·4 cc.	12·8 cc.
25	6·0 cc.	11·9 cc.
30	5·7 cc.	11·3 cc.

1 gram KI=81 gram $HgCl_2$

In conclusion, I would strongly recommend pharmacists to practise these volumetric processes, for they afford easy means of determining purity in many cases in a few minutes where the ordinary processes take as many hours.

CORAL ISLANDS AND THEIR ARCHITECTS.*

BY PROFESSOR ALLMAN, F.R.S.

The speaker commenced by giving an account of the structure and habits of the *Actinia*, or sea-anemone, as a type of the coral polype. He described it as a fleshy sac attached by a broad base at one end, and having at the opposite end a mouth surrounded by a wreath of tentacles or feelers. He showed that its stomach consists of a smaller sac suspended in the larger, and opening at one end by the mouth, while at the other end it opens into the surrounding cavity of the larger sac. This free opening of the stomach into the general cavity of the body is a character of great importance, and is possessed by no other group of animals than that to which the sea-anemone belongs.

The group so constituted is named *Cœlenterata*, a designation derived from the Greek, and intended to express the peculiarity of structure here referred to. This curious open stomach is kept in its place by a set of vertical fleshy plates, which radiate from it to the surrounding walls of the great cavity of the body. Now, the various parts of the sea-anemone are under the control of a definite number, by which its symmetry is regulated. This is the number six; and the radiating plates just mentioned are thus either six in number or some multiple of six, and so also the tentacles, when freely and normally developed, are either six or one of the multiples.

While the sea-anemone is immersed in the waters of the sea, and is surrounded by the conditions which promote its health and well-being, it will display its beautiful crown of tentacles and spread itself out like an expanded flower, often brilliantly and beautifully coloured. But let danger threaten, let a finger rudely touch it, and it will instantly draw in its tentacles and contract itself around them; and then, instead of the expanded flower, we may believe we have before us the same flower in the bud.

The speaker then pointed out how *Caryophyllia*, which may be found upon various parts of our own shores attached to rocks at low spring-tides, and which essentially agrees in structure with the sea-anemone, has the power of separating carbonate of lime from the sea-water, and of depositing this mineral, particle by particle, in its tissues, so as to become in great part calcified; in other words, how it has the power of forming a true skeleton of coral.

Now the *Caryophyllia*, with its skeleton of coral, instead of remaining simple and solitary, like the sea-anemone, may throw out buds like a plant, or may complicate itself by partially dividing into two or more segments, and will thus be converted into a compound colony of coral-producing polypes, each polype having its own mouth and stomach and tentacles and radiating plates; and each, while providing for its own wants, contributing at the same time to the general well-being of the colony. The form of this colony will depend on the disposition and mode of growth of the buds, or of the new polypes produced by the splitting of the old ones; for if all these remain closely impacted together, there would result such massive corals as are familiar in *Astræa* and *Meandrina*; while if they become more or less separated from one another and grow out into branches, we should then have a branched coral like a *Dendrophyllia* or a Madrepore. Now it is such animals as these Astræas and Meandrinas and Dendrophyllias and Madrepores which form the reefs and coral islands to whose history the discourse is devoted.

It must not, however, be supposed that all coral animals are reef-builders. The well-known red coral of commerce, for example, never accumulates in reefs or banks. This coral also, as well as many other non-reef-building kinds, differs in some subordinate points of structure from the true reef-builders; and instead of having its symmetry controlled by the number six, it is the number four by which the disposition of all its parts is regulated.

Having thus given an account of the nature of the coral animal and its mode of forming coral, the speaker proceeded to describe the home of the reef-builders. This region forms an irregular zone, extending for some distance at each side of the equator, but never going farther from it than about 30° of latitude. There can be no doubt that this coral zone is limited by temperature, and it has been pointed out by Dana, on what appears to be good evidence, that its northern and southern boundaries are formed by the isocrymal lines of 68°, or those lines which may be drawn through the parts of the ocean where the mean temperature of the coldest month of the year is 68° F. These isocrymal lines, however, greatly deviate

* Abstract of lecture delivered at the Royal Institution March 14, 1873.

from the parallels of latitude; for while in some places they are separated from the equator by 30° of latitude, in other places they are strongly pressed towards it by the influence of the cold currents from the poles.

The extent of the coral formations within this area has, ever since the seas began to be explored, struck the navigator with astonishment. Along the western coast of New Caledonia is a reef of 400 miles in length, and along the north-east coast of Australia is one of more than 1200 miles; while it is to the labours of the reef-building polypes that almost all the beautiful islands which stud the tropical portion of the Pacific, and many of those in the Indian Ocean, are mainly due.

The speaker then drew a picture of the aspect of the ocean, and of the most striking members of its fauna in the region of coral reefs. He directed especial attention to the most superficial zone of the tropical ocean—that zone where sea and air and heat and light combine and concentrate the conditions of intensest animality, amid which becomes developed a most beautiful and marvellous fauna; where Medusæ and Siphonophores wander at their own wild will, propelled through the clear waters by the pulsations of crystal bell or of broad, many-coloured disc, or in vast fleets are floating over the sea with sail extended to the breeze; where Pteropods flit on wings through the water like butterflies through the air; where Beroes catch the sunlight on their sides and flash it back in all the brightest hues of the rainbow; where Salpæ play in long undulating chains of crystal, and Pyrosoma, no less clear and crystal-like by day, becomes a cylinder of fire by night. What exuberance of life! What intensity of happiness! What unnumbered hosts basking beneath the tropic sky, or breaking the mirror of the sea with their gambols, or yielding to the impulse of the gentle trade-wind, or lighting up at night with phosphorescent gleam the dark waters of the deep!

Now, the coral-builders share with these bright and active hosts the prolific surface zone of the ocean. But their area is also a deeper one, and for many a fathom downwards their flower-like discs and banks of living coral may be traced by the sounding-lead and the dredge.

This extension downwards, however, is not unlimited. The ocean varies with its depth in its physical characters and in the conditions of life which it presents, and the coral-builders find the conditions suited to their welfare within a limited and definite range. This range never extends beyond a depth of from 20 to 30 fathoms, so that no living reef-building coral is ever found at a greater depth than this.

Within the upper portions of this area the coral fauna may be witnessed in all the perfection of its highest development and life; for there the sea is transparent as the purest beryl, and down fathoms deep below the boat the eye can penetrate through the liquid crystal to where the coral bank spreads around, and a scene of marvellous beauty becomes revealed. For there beneath the sea is a garden: carnations, and asters, and anemones, and gorgeous cactus-flowers seem there to expand their glowing petals; flexile shrubs root themselves in the crevices of the rocks, and envelop their branches in bright clusters of flowers, like the mezereon bush in the month of March. What profusion of forms! what richness of colouring! crimson, and golden, and purple, and emerald-green, and snowy white,—no garden of the upper air can surpass that garden of the sea in loveliness. But, stranger than all, every petal is replete with sense; every flower and every shrub is an animated being;—touch it, and it shrinks; feed it, and it digests; it rejoices in the warm sunlight, and feels happy in the caress of the ocean tide.

Now the animated flowers of that wonderful sea-garden spend no life of idleness—day after day, night after night, they are at their work! they are the builders of coral, the architects of islands, the ceaseless labourers by whose untiring energy have been rescued from the ocean thousands of miles of habitable land.

Having thus examined the workers, and become acquainted with their home, the speaker proceeded to consider the nature of their works, and this subject would be best treated under the following heads:—

1. The forms and structure of the reefs.
2. The mode of their construction.
3. Their relations to man.

The Forms and Structure of Coral Reefs.—Coral formations have been divided into three classes: the Atoll, or Lagoon Island, the Barrier Reef, and the Fringing Reef.

The Atoll is the type of the Coral Island. It presents the appearance of a circular or irregularly-formed ring of coral rising out of the bosom of the ocean, generally clothed with a rich tropical vegetation of cocoanut palms, pandanus, and pisonia, surrounded by a wreath of white foam where the sea breaks upon its outer margin, and having a lagoon or lake of still water in the interior.

The ring of coral is usually discontinuous in one or more places, and through the channels thus formed ships can generally sail into the calm central lagoon, which will then afford them, no matter how rough may be the external sea, a safe and commodious harbour.

It is scarcely possible to conceive of anything more lovely than one of these Lagoon Islands, with its graceful palm-trees and its groves of pisonia, the still, quiet lake within, the restless landless ocean without, and the glowing sky of the tropics stretching over all,—where

> "Droops the heavy blossomed bower; hangs the heavy fruited tree;
> Summer isles of Eden lying in dark purple spheres of sea."

Some of the small uninhabited Atolls especially seem almost as if they had been the work of enchantment. Even the wild creatures which dwell there appear to realize the wonders of the fairy tale, and make us almost believe that they lie under the spell of a magician. The United States' explorers assure us that in some of these islands the birds were so little alarmed at the presence of man, that they allowed themselves to be taken off the branches of the trees as if they had been their flowers.

When the Atoll is examined more minutely, it is found that the depth of the central lagoon may be about ten or twenty fathoms; a pure coral sand or fine white coral mud covers its bottom; the flexible and shrub-like species of coral root themselves in its sides, and millions of strange creatures nestle in their branches, or creep over the coral rock, or dart through the waters of the lagoon.

On the outer side of the ring of coral things are very different. The reef here usually extends outwards for some distance as a flat platform, with but a slight depth of water over it; the depth then suddenly increases, and immediately afterwards the sounding-lead sinks into the fathomless ocean where no bottom can be felt. One of the most remarkable features in an Atoll is thus the extraordinarily rapid rate at which its outer side sinks into the ocean; and this fact must especially be noted, for it will aid us in our attempts to explain the formation of the island.

When masses of the coral of which the reef is composed are brought up from various depths between the surface and twenty or thirty fathoms below it, these fragments are generally found to be alive. From much greater depths, however, the sounding-lead will continue to bring up fragments of coral which it has detached from the sides of the reef; but whatever fragments are brought up from greater depths than at most thirty fathoms are invariably found to be dead. This fact is in accordance with what has been already said regarding the limited range in depth at which the coral animal can live; and it is another very important one, which must be also kept in mind as necessary in enabling us to understand the mode of formation of the island.

If a correct idea of the nature of an Atoll be now conveyed, there will be no difficulty in understanding the two remaining classes of coral formations.

The Barrier Reef consists of a ridge of coral resembling that of an Atoll, but running parallel to the shores of a continent, or surrounding those of an ordinary island, and in either case at such a distance as to include between it and the land a deep channel of still water.

A Fringing Reef differs from a Barrier Reef only in being smaller, and scarcely including any channel between it and the land, which it thus merely fringes with a skirt of coral rock.

Mode of Formation of Reefs.—When it was first known that so many of the islands in the Pacific and Indian Oceans owed their existence to the energy of coral animals, it was believed that the coral-formers commenced their labours upon the flat bottom of the sea, at unknown and unfathomable depths, and that they thence worked continuously upwards to the surface. This hypothesis, however, is inconsistent with the now well-established fact of the limited range in depth of living coral.

The circular form of the Atoll suggested also another hypothesis, which maintained that the coral animals established themselves round the crater of some submarine volcano, and that, thence working upwards, they necessarily repeated on the surface of the sea the circular form of their foundation. Now this hypothesis would involve the highly improbable supposition that there exist throughout the region of corals innumerable volcanic craters, and that all these are nearly at the very same level, namely, that which alone is suited to the energies of the living coral; while its improbability is rendered still further apparent by the fact that there is no known volcanic crater whose diameter approaches in dimensions to that of many Atolls.

For the beautiful theory which is now universally accepted—the only one, indeed, which is consistent with all the known phenomena, and one of the most important with which the physical history of the earth has of late years been enriched—we are indebted to Mr. Darwin.

The theory of Darwin is founded on two incontestable facts,—the one purely pysiological, the other purely physical.

The physiological element in the theory of Darwin consists in the fact already insisted on, that the coral animals cannot live at unlimited depths, that they need the presence of light and of other conditions which they can obtain only near the surface, and that from twenty to thirty fathoms below the surface is the greatest depth at which the reef-building polypes can continue to live.

But we have also seen that the outer walls of the coral reef have been followed downwards into depths very much greater than this; and though the coral forming those deep portions is always found to be dead, it is plain that it must have been at one time living, and some additional fact is therefore needed in order to reconcile its occurrence at these great depths with the established limited range of living coral. Here, then, comes to our aid the physical element in the theory. It is this: That while the ocean maintains the same level from age to age all over the world, the solid land is subject to repeated oscillations of level, rising in one place and sinking in another, and this sometimes to an extent of many thousands of feet.

Having demonstrated the reality of this phenomenon by reference to numerous well-known geological facts, such as the sinking of the southern shores of Scandinavia and of the western shores of Greenland, and the rising of the northern shores of Scandinavia and of Siberia, the speaker proceeded, with the aid of diagrams, to apply, as Darwin had done, the two groups of phenomena, physiological and physical, to the explanation of coral formations.

He showed how a mountain, rising out of the sea in the form of a precipitous island, in the region of the reef-builders, will present on its shores the conditions suited to the coral-polypes, which will there attach themselves, building downwards until they arrive at depths too great for the perfect exercise of their functions, and upwards until the surface of the sea sets bounds to the further elevation of their structures. A reef of coral will thus be spread all round the shores of the island, and will constitute the formation known as a Fringing Reef.

But the island is supposed to be in a region of subsidence, and has begun to sink slowly into the sea, carrying with it the already-formed fringe of coral into depths incompatible with the well-being of the polypes. Urged, however, by an unerring instinct, the reef-builders continue their labours upwards simultaneously with the gradual depression of the land, and thus the reef is always extending itself towards the warm sunlit surface of the sea, where all the conditions of coral life exist, while the lower parts have passed downwards into depths where the formers of coral must cease to live.

The reef has thus grown larger; and as the coral is produced in greater force on the outer edge, where the reef is exposed to the open ocean, with all the conditions in which the animals forming it delight, this part is sooner brought to the surface than the inner part, where the growth of the coral is still further interfered with by the accumulation of fragments which the waves tear from the reef, break down into coral sand and coral mud, and carry inwards towards the land. A deep channel is thus formed between the outer part of the reef and the shores round which the coral has attached itself, and what was at first a Fringing Reef becomes in this way converted into a Barrier Reef.

In the meantime fragments of coral broken off by the waves are gradually piled upon the upper surface of the reef, which is thus in time raised above the sea in the form of a long stretch of dry land, separated from what still remains of the original island by the intervening channel of still water, and capable in the course of time of affording, by the decomposition of its surface, a soil in which terrestial plants may take root.

But the changes do not end with the formation of a Barrier Reef; for the work of subsidence goes on, and the ancient land continues to sink deeper and deeper into the sea, carrying the coral-polypes down with it into the dark, ungenial ocean depths, where they must inevitably perish. And now at last the highest point has disappeared, all has sunk beneath the sea, and a wide waste of landless waters rolls unbroken over its summit.

The island architects are not, however, to be baffled. As the lower parts of the reef sink into depths where they must perish, the upper parts are simultaneously extending themselves as a bank of living coral towards the surface, which at last they reach in the form of a more or less circular reef, on which the waves once more break, and which includes within it a sheltered lagoon, now free from even the last remnant of included land; and the Barrier Reef becomes thus converted into an Atoll.

Now it will be here noted that throughout the whole of the changes which have been thus traced, the thickness of the bed of living coral is a constant quantity, extending always from a little below the surface of the sea to that fixed plane beyond which if the coral be carried it ceases to live, while, on the other hand, the mass of dead coral is continually increasing with the subsidence of the land.

It is also evident from what has now been said that the Atoll points out the spot where an ordinary island had become submerged, and that the whole region of Atolls and Barrier Reefs has been gradually subsiding. A subject of great significance is thus suggested by the study of the phenomena of Coral Reefs; and the conclusion is irresistibly forced upon us that in the region where now the Pacific Ocean separates the Old World from the New there lay in former times a continent with its mountain peaks and table-lands; that all has since sunk beneath the sea, except its highest table-lands and the summits of its highest mountains; that within the region of the reef-builders the coral has gathered in its encircling reefs round these last remnants of the ancient land; while an Atoll marks the spot where a mountain peak of that old continent has totally disappeared beneath the ocean.

In those regions which lie beyond the warmer area of the coral, the land may yet have sunk and left no sign; for the reef-builders could not live in the colder waters, and there was nothing else to tell the tale.

The Coral Island in its relations to Man.—But the Atoll whose formation we have been following is not yet dry land. It is still a submerged reef over which the waves roll, for the polypes cannot extend their works into the upper air. Further changes therefore still await it. Fragments torn from its outer side by the waves are piled upon its surface, and it rises higher and higher from the sea; the decomposing coral covers the reef with a fertile soil, to which the wind and the ocean currents may bring the seeds of plants from other lands, and a graceful vegetation clothes in time its sea-girt shores.

And thus the Atoll becomes fitted for the sustenance of terrestrial animals and man. Sea-birds in multitudes find shelter there, and land-birds from distant shores see in it a country where they may dwell; while the drifted trunk of the forest tree, to which the lizard and the insect still cling, is cast upon its strand to begin the peopling of its woods with still other forms of life.

Some large fruit-eating bats too have discovered it; but no other mammal has ever formed part of the aboriginal fauna of the Coral Island.

Its latest occupant is doubtless man; but whence he came, from what original stock he migrated, we have no positive evidence to determine.

If we except the Feejee group and some of the other high coral-encircled islands which lie at the extreme west of the area, and in which the inhabitants are Negrittos, characterized by their black skins, frizzled hair, and repulsive features, we shall find a great uniformity of type to prevail over the rest of the Pacific coral region, a type with lighter skin and straight or wavy hair, and one which points towards an affinity with the Malay races of south-eastern Asia. We are not, however, on this account to suppose that the islands were necessarily peopled by direct migration from the Asiatic shores. If we suppose that the high islands, with their encircling barrier reefs, represent the last remnant of a submerged continent, it is quite possible that these islands may have retained the last remnant also of its population. But whether this be so or not, it is certain that the Atolls must have been independently peopled, either from the surrounding islands or from some more distant continent. The Atoll rose from the bosom of the ocean destitute of terrestrial life, and many a century must have passed before the presence of man broke the solitude of its shores. We may well believe that at last some savages, drifted out of their course by adverse winds, had run their canoe upon the strand and had taken possession of the land of the polype. The fish of the lagoon, the mollusca of the shore, the fruits of the wood, afford them their subsistence; they have discovered that a pit dug a few feet deep into the coral rock will reach a reservoir of fresh water accumulated from the rains which had percolated through the more superficial porous structures; the friction of two pieces of dry timber yields them fire; while their spears, fashioned by a piece of sharp stone found entangled in the roots of some drift-wood, facilitate the acquisition of food, and make the struggle for existence more easy.

And so years pass on, and the descendants of the first accidental settlers have peopled the island; but though experience may have taught them many things, though an imperfect division of labour may have been adopted and a rude state of society established, the aboriginal dwellers have rather adapted themselves to the physical conditions among which they have been thrown than raised themselves above them, and centuries pass away and leave them little changed. For, after all, the Coral Island is but ill fitted for human development; without a hill to break the uniformity of its surface, without a stream to hollow out a valley, without a single metal, without a mineral beyond the unvaried calcareous coral rock, without a mammal other than the bird-like bat, the native, cut off from all communication with other lands, will have few ideas; while his wants, few and easily satisfied by the spontaneous produce of the island, will afford little motive for exertion, and little stimulus to development; and it is later times, and other lands where civilization has already spread, where knowledge has already advanced, that must carry civilization and knowledge to the Coral Island.

And so centuries still roll on, until at last from these other shores the destined race has landed on the island—a race with higher powers, a more cultivated intellect, and an increased capacity for improvement—the bearer of a new force, of a civilization with all its good, and alas! with all its evils too: but the good is greater than the evil, and so the lower yields to the higher phase of intellect; more perfect social relations are introduced; laws are instituted; the savage rites of a degrading superstition give place to a more elevated and a purer creed; no longer with that narrow policy which does not look beyond the limits of its own strand of coral, a common interest has united island to island, and a national life has dawned upon the archipelago of the polype; deficiencies are supplemented by the products of other lands; the breadfruit, and the banana, and the yam are cultivated; the fruits of the woods, and the pearl-shell, and the trepang of the lagoons are sought after by the trader; the relations of commerce are established, and the Coral Island takes its place in the great community of Nations.

DETECTION OF THE SUBSTITUTION OF CARBOLIC ACID FOR CREASOTE.*

BY JOHN A. CLARK.

The author refers to the communication from Mr. Morson on the substitution of carbolic acid for creasote, in which he states that there is no good test for distinguishing between the two, but proposes the use of glycerine, in which carbolic acid is easily soluble, but creasote insoluble. The author thinks that a far better test is the alcoholic solution of perchloride iron (or tr. ferri perchlor. B. P.), which, when added to an alcoholic solution of creasote, produces a "dark greenish-blue" colour, but with an alcoholic solution of carbolic acid only a "light brown" colouration. By this test one part of creasote in 500 parts carbolic acid can be easily detected. The adulteration of creasote by carbolic acid is more difficult to detect, but can be ascertained in the following way: Boil a few drops of creasote with nitric acid (about 2 drs.) until red fumes are no longer evolved; this yields a solution which, when neutralized with solution of caustic potash, gives *no precipitate*, the creasote forming oxalic acid. Carbolic acid, when treated in the same manner, is very violently acted on by nitric acid and forms picric acid (trinitro-phenylic acid), which, when neutralized with solution of potash, give a "yellow crystalline" precipitate. One part of carbolic acid in fifty parts creasote can be readily detected in this way.

THE BARTON CHEMICAL MANURE WORKS.

The loss sometimes sustained by large landholders and farmers in consequence of the worthlessness or inferiority of some of the so-called artificial manures and cattle-feeding materials, that are put into the market, has led the agriculturists of North Lincolnshire and Yorkshire to form a limited liability company for the manufacture of artificial manures, and ultimately the production of oil cake for their own use. Works have been erected at Barton Waterside, near the haven and within easy access of the Manchester, Sheffield and Lincolnshire Railway Station. The property of the company is more than four acres in extent—about one half of which is at present built upon. The buildings are fitted with the most approved appliances.

* From the *Canadian Pharmaceutical Journal.*

We take from the *Eastern Morning News* a few notes of a visit made to the establishment.

On entering the building the visitor is struck by the absence of the sickening smell present in many manure works. There are plenty of endless bands in the air, working a vast number of wheels whose arrangement at first seems rather intricate, while on the floor are scattered about large heaps of a stone-like substance, something harder than granite and heavier than lead, and other mounds of what might be taken for small pebbles. The large heavy stones are known in commerce as pyrites, while the pebbles go by the name of coprolite, and from these two seemingly unprofitable objects a most rich and valuable manure—superphosphate of lime—is manufactured. From the pyrites one of the constituents of the manure—sulphuric acid—is derived. The company at present import the pyrites used from abroad. As this substance reaches the works in lumps, sometimes as large as a couple of paving stones, it has to be first subjected to a bruising process. This is effected by a Blake's patent crusher, which breaks the lumps into pieces about the size of ordinary road metal, doing in four or five seconds as much bruising work as a man could do with his hammer in half-an-hour. The pyrites thus rendered more manageable falls from the crusher into a well, whence it is raised by an elevator, similar in principle to a dock dredger. In this state it is used for charging the kilns—twenty-four in number—and the fumes of sulphurous acid resulting from the burning are conveyed into large chambers, where they are converted into sulphuric acid.

The coprolite, which has much the appearance of dusty little stones, is essentially of the same chemical composition as bone. Scientific men speak of it as the vestiges, which are ordinarily of an evanescent character, of some sort of amphibious animals belonging to a pre-adamite period. These curious remains were left on the sand at that remote age, and have come down to our own day, though the race of animals is itself extinct. The company derives its supply of coprolite from Cambridgeshire, and the yield, when ground, is about 58 per cent. of phosphate of lime. The coprolite is first passed between two rollers, by which operation it is reduced to the dimensions of very small pebbles. These are hoisted by an elevator, and thrown into ordinary hoppers, which supply different pairs of millstones. The coprolite leaves the millstones in a state of fine powder that soon finds its way into the throat, and is passed into a creep or kind of long narrow box with a spiral movement inside, by which it is forwarded to another elevator, and lifted up to the room where the final operation—that of mixing with the sulphuric acid—is performed. The quantities have to be measured to a nicety. The ground coprolite is what is known as tribasic phosphate of lime, being made up of ordinary lime and phosphoric acid, in the proportion of three to one. When the sulphuric acid is brought to act upon this phosphate, monobasic phosphate of lime and sulphate of lime are produced. These, together, form the chief chemical manure in the manufacture of which the Lincolnshire Farmers' Company are at present engaged. This product leaves the mixing machine in a liquid state, flowing into large dens underneath, capable of storing immense quantities. The manure is dry and ready for transport in a few hours after manufacture. The hydrofluoric acid accumulating in these storing dens is a most deleterious and obnoxious neighbour. It is drawn off into a chimney, where it is thrown down by water, and thence runs off in the common sewers. Any annoyance to neighbours or injury to vegetation is thus easily obviated. Should the manure set and become too hard with keeping, a disintegrator, consisting of two wheels revolving in opposite directions at the rate of 500 revolutions a minute, soon pulverizes and renders it quite ready for the farmers' use. The usual appliances for grinding half-inch bones, and manufacturing dissolved bones, etc., are also complete. The entire machinery is driven by a beam engine working up to 140-horse power, with a couple of boilers.

THE SHOP HOURS' REGULATION BILL.

MEETING AT NORWICH.

A meeting of the tradesmen of Norwich was held on Friday, June 13th, at the Guildhall, to consider Sir John Lubbock's Shop Hours' Regulation Bill, and, if thought desirable, to adopt a petition to Parliament against any objectionable clauses in that measure. The Mayor, who presided, in his opening remarks said that the spirit of the legislation of the present day was getting rather too sentimental, and was neglecting the feelings and requirements of the trading interests. The trading classes were competent, by bye-laws and mutual arrangements, to make things agreeable to themselves and their *employés*. By interposing to prevent the further progress of this Bill great public service would be done, and he was of opinion that it would be for the interest of all to continue in the old jog-trot road rather than adopt any violent changes.

It was moved by Mr. A. R. Chamberlain, seconded by Mr. Copeman, and resolved unanimously—"That this meeting, while fully sympathizing with the public feeling in favour of shortening the hours of labour in retail shops, is decidedly of opinion that Sir John Lubbock's Shop Hours' Regulation Bill will not secure that object, and should it become law will improperly interfere with the conduct of retail businesses, and press most unjustly upon those tradesmen whose trade compels them to employ persons coming under the provisions of the Act."

It was moved by Mr. Caley, seconded by Mr. Snowdon, and resolved—"That legislation suited to the factory or workshop, where work commences at the specified hour, and is continuous up to the hour for meals, and again to the end of the day, is altogether inapplicable to shops, where assistants are often for hours unemployed, or only partially employed, as the character or state of trade may permit."

It was moved by Mr. Wild, seconded by Mr. Edwards, and resolved—"That it is the opinion of this meeting that, should the Bill become law, it will very seriously injure many persons employed in shops coming under the provisions of the Act, as it will not only curtail to a very large extent the employment of female labour, as well as that of young men under twenty-one years of age, but it will also discourage the training of apprentices in the various trades to which this Bill applies."

In the course of the discussion, Mr. J. D. Smith pointed out that it was impossible for the public service that chemists' shops should be closed for one half-day in the week.

A petition embodying the foregoing resolutions was adopted, and ordered to be forwarded to Mr. J. J. Colman, with a request that he would support it in his place in Parliament.

FIRE AT NEWCASTLE.

On Friday afternoon, June 13, an alarming fire broke out on the premises of Mr. H. B. Brady, pharmaceutical chemist, Mosley Street, Newcastle. While one of the assistants was engaged on the second floor with an apparatus containing an inflammable chemical, the substance suddenly ignited, and set fire to surrounding combustibles—lint, pill boxes, oilskin, etc. In an incredibly short space of time, dense black smoke issued from the front windows, and a woman who was in the topmost room of the building engaged in cleaning, afraid to make her way down by the staircase, appeared at the small window, a height of about sixty feet, and in the presence of an excited crowd of people, crept along a narrow parapet about two yards in length to the slanting roof of the adjoining premises. Here she was laid hold of by a pair of strong arms and carefully put through an attic window, amid the cheers of the mob. The engine from the Manors Police Station was immediately upon the spot, but the flames were extinguished without its aid. The damage caused was fortunately not very great.

The Pharmaceutical Journal.

SATURDAY, JUNE 28, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE BENEVOLENT FUND.

AMONG the official notifications appearing in the advertisement columns of this week's Journal is one relating to the Benevolent Fund, to which we desire to call especial attention.

The inability of the Council to elect more than one annuitant on the Benevolent Fund this year, which was reported in the minutes of the last meeting, must have caused general regret to the readers of this Journal.

The correspondence which has appeared in our pages recently on this subject is proof, we trust, that the prosperity of the Fund is deemed a vital matter by members of the Society; but those who have constantly joined in the cry "Give! give!" *from* the Fund, must now, to render that possible, reverse their cry, and urge all to give *to* the Fund.

We know that in the opinion of some persons, annual subscriptions and donations might fairly be employed in paying annuitants, as well as in giving casual assistance to the needy. This point was indeed urged by one speaker at the General Meeting, but others speedily condemned the suggestion, and entirely endorsed the more cautious system adopted by the Council.

It seems to us that those whose kindly feeling we must honour, even while combating their imprudence, do not take into account either the existing Bye-laws regulating the Fund, or the amount of its annual income, and the increased demands on it.

On reference to Sect. xix of the Bye-laws, it will be seen in Clause 2 that "Donations in aid of the Benevolent Fund *shall* be invested in Government or real securities; *and no part of the invested capital of such Fund shall be distributed among the recipients of relief.*"

The words which we have italicized plainly show the original intention, on the one hand, of providing an inalienable Fund to give settled assistance, and on the other, of leaving only the annual subscriptions at the disposal of the Council for making casual grants, supposing the interest to be absorbed as it now is by Annuitants.

Now it must never be forgotten that when once an annuitant is elected he is morally assured of an annuity for life. The Council for the time being are Trustees in charge of his maintenance, and nothing should be allowed to shake his confidence in them. Supposing, however, that the monthly grants equalled in the year the annual subscriptions, to what source could these Trustees look for the means of meeting their liabilities?

Here we shall be told there is no fear on this point; that the more you give the more you will receive. But pounds, shillings, and pence are hard matters to deal with, and we have therefore taken the trouble to ascertain exactly how the case stands; not by looking to past years, because the applications for aid in past years afford no safe data on which to calculate the future. Naturally, as the Society grows older its members grow older also, and the number of needy men may be fairly expected to increase. Again, the field for distribution has been at least trebled by the eligibility of "*all persons who may have been, and have ceased to be, Members or Associates of the said Society, or who may be or have been duly registered as Pharmaceutical Chemists or Chemists and Druggists, and the widows and orphans of such persons.*"

The amount of subscriptions received during the first six months of the present year is £634 19*s.* 10*d.*, while the casual grants made by the Council within the same time amount to £235 15*s.* When in addition it is remembered that by far the greater part of the subscriptions are paid in the beginning of the year (with the annual subscriptions of membership), whilst the applications for relief may go on even in an increasing ratio to the end of the year, we think there seems but little prospect of a surplus which would justify the Council in electing more annuitants than the interest on capital would warrant.

We commenced by saying that the inability to grant more than one pension would be regretted by all. To us it is a lamentable circumstance. Of course no comparison can be made between the Benevolent Fund of a small special class and the greater institutions which give relief *generally*, and thus fairly claim *general* support. The former is a fund to be distributed solely among the needy of one class, and is consequently dependent almost exclusively on the members of the same class, while the latter are so universal in their benefits as to be deemed worthy of advocacy from the pulpits of the whole country. Still we cannot but think that the chemists and druggists of Great Britain, numbering about fourteen thousand, could, without much personal sacrifice, at least treble the annual subscriptions to a Benevolent Fund from which any of them might in adversity receive assistance. On a previous occasion in publishing the list of contributions to the Benevolent Fund of the Society, we pointed out the disparity between their gross amount and the numbers of the trade, and urged upon the consideration of our readers that contributions to this Fund, the benefits of which were available to the whole trade, should be very much more general than they were. GOD grant that the time of need may never come! But we know that in His inscrutable Providence adversity does fall to the lot of some; and we know, too, that although He sees good to afflict, it is acceptable to Him that we endeavour to relieve each other in the afflictions cast upon us. Can we fairly say we have done this to the utmost of our ability, or even to the extent of our duty, when we find that the Council, on investigating the cases of distress brought before them, have marked five in which it is desirable to give permanent assistance, and the funds at their disposal permit only of that assistance being given to one.

THE SHOP HOURS' REGULATION BILL.

At this advanced period of the Parliamentary session repeated postponement of the consideration of a Bill may fairly be regarded as indicative of failure or abandonment. Especially under present conditions may this be inferred, and as regards the particular measure now referred to, perhaps there could not be a more appropriate fate. In another part of the present number we print a petition presented to the House of Commons last Tuesday, praying the House to reject the Bill. This petition is signed on behalf of the Pharmaceutical Society by the President, Mr. T. H. Hills, and it sets forth in support of its prayer several grounds which appear to be unanswerable so far as the Bill affects chemists and druggists.

The report on a previous page of the meeting at Norwich serves to show what is the opinion as to this Bill on the part of the trading community, and we trust the opinions expressed in the resolutions passed at that meeting will be appreciated by the promoters of this measure so far as to prevent any repetition of similar efforts of hyper-legislation.

While thoroughly admiring the good service already rendered by Sir John Lubbock in securing for the hard-worked classes of clerks and shopmen some addition to their opportunities for relaxation and enjoyment, we cannot shut our eyes to the fact that there is a wide difference between setting apart certain days in the year as general holidays and shortening the hours of employment in shops and offices. Both objects may be highly desirable in the abstract, but they require different means for their attainment. To establish a bank holiday, independent individual action would probably be of little avail, and a legislative enactment is almost a necessity. On the contrary, individual action is in the other case precisely the influence which is most likely to be effectual. If a few persons in the drug trade resolutely persevere in closing their shops at an earlier hour than has been the custom, the result will be not only to educate public opinion into a recognition of the propriety of such a course, but also to convince those who keep late hours that they are rather losers than gainers by adhering to the old plan.

Such influences have been successful in making the Saturday half-holiday almost as much an institution as the Bank Holiday. And for some time past a similar course has been pursued in regard to the early closing of druggists' shops, as we have from time to time had occasion to point out in these columns.

In the interest of the efforts thus being made we heartily wish for the total abandonment of Sir John Lubbock's present Bill, as being the course most likely to bring about the very desirable objects which we have no doubt he had in view when he introduced the measure into Parliament.

A DISHONEST DIPSOMANIAC.

It frequently falls to the lot of pharmacists to be under the disagreeable necessity of rising from their beds to supply an urgent call for drugs for the relief of some poor sufferer, and as a rule the duty is performed with as much cheerfulness as could be expected under the circumstances. But the letters printed on page 1048 show that some circumspection is required, even in yielding to the dictates of humanity, for several pharmacists at the West End have suffered inconvenience through an impostor availing himself of their kindness to satisfy his abnormal cravings. We hope the publication of these letters will have the effect of putting the members of the trade on their guard, so that the next time he attempts to repeat the fraud he may meet the reception he merits.

ACCIDENTAL POISONING AT A HOSPITAL.

At page 1046 will be found the report of a case of accidental poisoning, in which the dispenser at the Royal Berks Hospital at Reading substituted hydrocyanic acid for hydrate of chloral.

The Birmingham *Daily Mail*, in reporting this case, says an overworked official has just misadventurously slain a patient, adding that it came out in evidence that the dispenser—a steady, well-conducted, efficient man—had to make up more than two hundred prescriptions a-day, and that to discourage such miserable economy the verdict should have been "Killed by the niggardliness of the Hospital Board."

EXPORT OF CINCHONA BARK FROM COLUMBIA.

There was a large increase in the export of cinchona in 1871 from Santa Martha over the previous year. The official returns give a total of 3,415,149 lbs. in 1871, valued at £133,791, against 1,846,643 lbs., valued at £63,770, in 1870. Shipments of this article have latterly been on a largely increasing scale for the United States. For the five years 1865–69 the average annual quantity sent to New York was below 300 serons, whilst the shipments to that port in 1870 reached over 2000 serons, and rose to 8500 in 1871. The following were the shipments to other countries,—to Great Britain 11,100 serons in 1870, and 14,400 in 1871; to France 1100 serons in 1870, and 2100 in 1871; to Germany 660 serons in 1871.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

June 18th, 19th, and 20th, 1873.

Present—Messrs. Allchin, Barnes, Carteighe, Cracknell, Gale, Hills, Linford, Martindale, Schweitzer, Southall, and Umney.

Dr. Greenhow attended on the 20th on behalf of the Privy Council.

MAJOR EXAMINATION.

Nine candidates were examined. *Three* failed. The following *six* passed, and were declared duly qualified to be registered as Pharmaceutical Chemists :—

*Cleaver, Edward Lawrance	London.
*Plowman, Sydney	Boston.
Woods, Joseph Henry	Warrington.
Kirton, Christopher Henry	Hull.
Woolldridge, George	Birmingham.
Pound, Henry William	London.

MINOR EXAMINATION.

Forty-eight candidates were examined. *Twenty-five* failed. The following *twenty-three* passed, and were declared duly qualified to be registered as Chemists and Druggists :—

	*Griffiths, Francis	Weston-super-Mare.
	*Cotterell, William Burbidge	Dover.
Equal	*Griffiths, Edwin Harpham	Hanley.
Equal	*Gwynne, David William	Swansea.
	Hitchcock, Edmund Lilley	Oxford.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The twelfth general meeting was held at the Royal Institution, May 8th, 1873, the President, Mr. E. Davies, F.C.S., in the chair.

Mr. Thomas Williams, F.C.S., called attention to the coating of paint which covers some of the canisters containing the preserved meat from South America and the colonies. The paint on one which he had purchased contained red lead, and after having been carefully opened by the vendor, he found that 50 grains of red lead had got into the meat.

In reply to an inquiry by Mr. Simpson, he said that there was no necessity to paint the tins, that they were painted after their arrival in this country, to give them a more saleable appearance. He found that only one firm used red lead, other tins being painted with silicate of iron paints, which were comparatively harmless.

Mr. Taylor suggested that it would be better to lacquer the tins.

Mr. J. Abraham then read the following paper :—

NOTES ON COMMERCIAL DILUTE HYDROCYANIC ACID.

The dilute hydrocyanic, commonly called prussic, acid of the Pharmacopœia is composed of 2 parts of hydrocyanic acid and 98 of water. It is made by distilling together a solution of ferro-cyanide of potassium and a dilute sulphuric acid. The product is of uncertain strength, because the whole of the hydrocyanic acid is not necessarily condensed. The real relative quantity obtained must be ascertained, and the liquid made to correspond to the standard. The correctness of the preparation will depend upon the accuracy with which this is done. But, however carefully it may be accomplished, the resulting acid may afterwards be found defective.

It is liable to decomposition, especially if exposed to light (though our Pharmacopœia does not mention this), and to loss of strength by exposure to the air, owing to the greater volatility of the hydrocyanic acid than of the water. Especially must this be the case when the contents of a small bottle are used up by little and little during a considerable period of time.

The strength of eight specimens procured from different sources, was ascertained by Dr. Tilden, and the result of his examination will be found in the PHARMACEUTICAL JOURNAL for July 29, 1871. His report exhibits a scale ranging in percentage of real acid from 2·183 to 0·483—four of the specimens being under 1 per cent.; the true standard, as I have mentioned before, being 2.

During the latter part of last year I obtained specimens of the acid from four wholesale houses, the percentage of real acid I found to be—

2·11
2·02
1·64
1·30

instead of 2.

Compared with the pharmaceutical standard the strengths are :—

$$\left.\begin{array}{r}105{\cdot}5\\101{\cdot}\\82{\cdot}\\65{\cdot}\end{array}\right\}\text{ per cent.}$$

This is not nearly so great a disparity as is exhibited by the table of Dr. Tilden, but it is so great that I think dispensing chemists should be put on their guard.

The Pharmacopœia says, that 100 grains of the acid precipitated with a solution of nitrate of silver will yield 10 grains of dry cyanide of silver. The application of this test requires time, for unless the precipitate be thoroughly washed and dried,—and nothing but time can ensure this,—it is delusive. Moreover you cannot safely diminish the quantity operated on, unless you employ a delicate balance. The Pharmacopœia gives a further and very beautiful volumetric test. We are told that 270 grains of the dilute acid, rendered alkaline by solution of soda, requires the addition of more than 1000 grain measures of volumetric solution of nitrate of silver, before a permanent precipitate begins to form. If the acid under examination requires only 900 grain measures, then the strength is only $\frac{9}{10}$ of the proper strength—if it requires 1100 grain measures, then the strength is $\frac{11}{10}$, and so on.

The experiment is directed to be performed by means of a burette, holding 1000 grains, divided into 100 equal parts; but such quantities as these do not suit a dispenser who perhaps only buys an ounce or two at a time, as is, I suppose, the case with many. The experiment may however be performed equally well with smaller quantities and appropriate instruments.

This 100 grain tube filled as a Mobs's burette enables me to experiment on quantities one-tenth of those named, and to obtain equally accurate results, because half a grain in this tube is as distinctly indicated as five grains in the other,—indeed rather more distinctly. Filled by suction through an elastic tube, the result is obtained more easily and quickly.

In using a large tube, one is apt to get impatient and to add the test too rapidly—at least I am—and then one has to begin again. These smaller tubes holding 100—300—500 grains, in which every grain is shown, are far more convenient because you can without any great exercise of patience watch the effect of every drop which you let fall. But those who have not these tubes have the minim tube with elastic ball, which I introduced as an improvement on Alsop's more than twenty years ago. (PHARMACEUTICAL JOURNAL, 1851-2, page 268.)

An experiment with this would be far better than none, and carefully made would give almost accurate results.

Add 27 minims* to a little solution of soda or of potash (for the latter will do equally well), and the number of minims of volumetric solution of nitrate of silver, which must be added before a permanent precipitate begins to form, indicates at once without calculation the percentage of strength compared with that of the Pharmacopœia. As a check this is perhaps sufficient, but the volatility of the substance should be remembered, and accurate experiments must be performed in flasks.

Mr. A. E. Tanner afterwards read a paper on "The Means of Detecting Bromide in Iodide of Potassium," which is printed at p. 1033).

A discussion followed, in which the President, Drs. Cooke, Symes, Messrs. Mason, Redford, Shaw, and others took part.

The President then read the following valedictory address:—

"In coming before you this evening to bid you farewell, as your president, at least so far as our general meetings are concerned, I feel a difficulty in selecting a subject which will fitly close my official connection with the Association. No event of engrossing interest has marked the present year of my presidency, and I must fall back on the familiar topics of our aims in meeting together, and the manner in which these have been carried out. Whatever views we may hold with regard to cooperation in business matters, its application to increasing the store of our knowledge must commend itself to every mind. As iron sharpeneth iron, so doth the countenance of a man his friend, is our implied motto, and the more each one will contribute his talent or mite of experience to the common fund the greater will be the treasury which we shall accumulate. In the past session we have listened to practical and theoretical papers, both the business and science side of our daily avocations have been drawn upon for subjects of discussion and thought, and now a long recess will give us opportunities for the application of the facts which have come under our notice. I trust that at least some of us will remember that the future must be provided for, that another session will soon be here, and that the Secretary will be much aided and his anxious mind greatly relieved if he can begin with a goodly list of papers promised. There can be no doubt that as years roll on the difficulty of finding new subjects increases. The obvious topics have been disposed of, and we must employ more thought and research in treating those which do not directly fall in our way. It is so in all branches of science; in chemical research much labour is now needed to arrive at novelty, as any one will be convinced who studies the chemical journals and is almost overwhelmed with the complexity and intricacy of the new compounds, of which the mere names are sufficient to terrify the student. Still, we must go on,—it will never do to despair. It is quite certain that we have not found out everything yet, and new things will always be found to be said on old topics.

"In some respects we have progressed; the library has been enriched by bound volumes of the journals, and I hope that in this more accessible form we shall make acquaintance with the current scientific literature of the day. It will be well to keep this up regularly year by year, as experience has shown that many numbers of unbound periodicals are lost. Some other additions have been made to the library, and it is now a most valuable collection of scientific literature.

"With regard to our educational appliances, the chemistry class has been carried on since December, and is still going on. The time has arrived for establishing a botany class, and I hope that the notice on the circular will not escape the notice of members. A considerable number must join to render it possible for us to ensure the services of a competent teacher, and I trust that such a delightful study, when properly undertaken, will not fail to attract many pupils. I would urge all students not to trust to books; we are not favourably situated for practical study in the fields, but yet the commonest plants should be thoroughly examined, and this practical knowledge will not only be far more valuable than merely learning crabbed terms by rote, but will also stick closer to the memory, and be available when wanted.

"My suggestion as to the adulteration of drugs when I last addressed you has been proved a word in season. Whether a substitution of one thing for another is a legal adulteration, is a question as to which I am not lawyer enough to speak, but morally, in my opinion it is even worse. Sulphate of quinidine may be a useful alkaloid, and probably is, but to sell it for sulphate of quinine is totally indefensible, and has met a justly deserved punishment. I hope that it will not be possible to meet with any other case of the kind in Liverpool, and that if any chemist has any such deceptive stuff in his shop it will at once find its way to the sewers.

"During the session science has had to deplore the loss of one of her most devoted sons, Baron Justus von Liebig. Nothing was beneath his notice to which science could give any aid, and the almost inventor of organic analysis could write an article on the best way of making coffee. Purely scientific chemistry is most deeply indebted to him, and although all his views on agricultural and physiological chemistry may not be received by every chemist, those branches of the great subject to which his life was devoted would be greatly mutilated if all which he contributed to them were removed. To the public at large his name was familiarized by his preparation for infants' food, and mostly by extractum carnis. Whatever view may be taken eventually as to the exact action of this latter substance, in my opinion there is no doubt that it is a great addition to our restoratives, and will hand Liebig's name down to posterity.

"One of our own members, and one who contributed to our transactions has also passed away. The circumstances attending Mr. Hilditch's death are painful and mysterious. We might fairly have hoped, from the promise which he already gave, that he would have been a valuable member, and can only add our tribute of respect and esteem to those which have been so freely given in the land where he was a temporary resident.

"And now I must bid you adieu; thanking you for the confidence which you have reposed in me, and that for two years I have had no unpleasant word to hear or say. Whatever may have been my failings, I trust that it will be found that the interests or honour of the Association have not suffered in my hands."

Votes of thanks to the authors of the papers, and the President for his address, and the ability with which he had occupied the chair at the meetings, etc., concluded the business of the ordinary meetings of the session.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, June 19th, Dr. Odling, F.R.S., President, in the chair.

At this meeting which was the last of the season, nine communications were read of which the following were the

* Strictly, a shade more—27·09.

titles :—1. "Researches on the Action of the Copper-Zinc Couple on Organic Bodies." 3. "On Normal and Iso-Propyl Iodides," by J. H. Gladstone, F.R.S., and A Tribe, being a continuation, in the Propyl Series, of the authors' previous researches. 2. On the Influence of Pressure on Fermentation, Part II: The Influence of Reduced Atmospheric Pressure on the Alcoholic Fermentation," by Horace T. Brown; in which he stated that, under diminished pressure, the progress of alcoholic fermentation is retarded in a remarkable way. 3. "On Cymene from different Sources optically considered," by J. H. Gladstone, F.R.S. 4. "Note on the Action of Bromine on Alizarine," by W. H. Perkin, F.R.S. This reaction gives rise to *bromalizarine*, an orange coloured crystalline substance, possessing feebler dying properties than pure alizarine, the colouring principle of madder. 5. "On some Oxidation and Decomposition Products of Morphine Derivatives," by G. L. Mayer and C. R. A. Wright, D. Sc. 6. On the Decomposition of Tricalcic Phosphate by Water," by R. Warington. 7. "Communications from the Laboratory of the London Institution, No. XII: On the Nature and on some Derivatives of Coal-tar Cresol," by Dr. H. E. Armstrong and C. L. Field. 8. "On a new Tellurium Mineral, with Notes on a Systematic Mineralogical Nomenclature," by J. B. Hannay. 9. "Note on the Relation among the Atomic Weights," by J. A. R. Newlands. The President finally adjourned the meeting until after the recess, congratulating the members on the flourishing state of the Society and on the number and importance of the papers that had been read during the session.

SOCIETY OF ARTS.

Recent Processes for the Manufacture of Gas for Illuminating Purposes.*

BY T. WILLS, F.C.S.

(*Concluded from p.* 1022.)

With regard to these "air gases," all that remains is to state wherein the various plans differ in their mode of carburetting the air. The first of these recent schemes purposes to drive minute streams of air through a layer of spirit of a specific gravity of 0·670—this is accomplished by forcing air under pressure through a small tank of the liquid, having a false bottom of wire gauze; the passage of the air through the gauze divides it into innumerable fine streams, and causes it to come into close contact with the liquid material. The air, as it issues from the top of the tank, will thus be saturated with the hydrocarbon vapour. The depth of liquid through which the air passes is maintained constant by means of a somewhat ingenious float. It is further proposed, in this patent, to dissolve in the spirit a quantity of some more highly-condensed solid hydrocarbon; but it is open to very considerable doubt whether the effect of such addition could be very perceptible.

The illuminating power of this gas is very high, as high indeed as 30 candles, although this statement requires a slight qualification, as the lighting power of the flame is not expressed by it, but only the fact that if it were possible (which it is not) to burn the gas at the rate required by the photometric test, viz., five cubic feet per hour, this illuminating power would be obtained, it being a fact that a very much smaller amount of air-gas can be burned from the ordinary "London argand" burner, or from a batswing, to obtain the same size of flame than in the case of coal-gas; this effect is no doubt due to the greater density of "air-gas." It may be mentioned here that these air-gases do not burn at all well under pressure, and hence are only suited to burners which afford exceedingly free passage to the issuing gas, such as argands, there being a tendency with burners of the batswing and fishtail class for the air and vapour to separate, possibly explainable by the more rapid transpiration of the lighter substance through a narrow opening. The gas produced by this particular scheme possesses, as might be expected, a very fair degree of permanency at ordinary temperatures, and is capable of transmission through comparatively long lengths of pipe with little deterioration in quality. As an experimental trial, one side of the nave of the Crystal Palace has been recently lighted in this manner, with what success the public journals have testified, the spirit used for this purpose having a somewhat lower specific gravity than that mentioned in the patent. It is further stated that one gallon of oil will carburet 800 cubic feet of air, and the cost of this gallon of oil to be two shillings.

A second plan for obtaining the same result is a modification of the above, the special features of which are, in the first place, the required current of air being maintained by clockwork, and, secondly, the substitution of a considerable length of cotton-wool or other absorbent substance, kept saturated with the liquid hydrocarbon, in the place of bubbling the air directly through the liquid. The spirit used and the results obtained are very much the same as in the former case. This scheme also is being illustrated upon a somewhat extended scale, the small town of Great Marlow being at present illuminated by its means.

Perhaps this latter has one slight advantage over the former, inasmuch as the bubbling of air through a volatile spirit will promote its evaporation, to such an extent that the temperature of the liquid will be reduced exceedingly low, in some cases as low as the freezing-point, and consequently the temperature of the air will be very considerably reduced at the same time. Now any unnecessary reduction of temperature, either of liquid or air, should be carefully avoided, in order to keep in solution as much vapour as possible.

Yet a third plan has received some attention which possesses at least the advantage of simplicity, and this consists in using an ordinary gas-holder, with its tank, as a gas generator, to the exclusion of other apparatus. At the crown of this gas-holder is placed a valve, opening with ease inward, but closing the moment any pressure is applied to the holder. Underneath this valve are placed trays containing a shallow layer of a spirit, if anything, of somewhat lighter specific gravity than that used in other cases. As the gas-holder is mechanically raised, the entering air passes over the surface of the volatile hydrocarbon, becoming in this manner sufficiently charged to be immediately used as an illuminating gas, which may be consumed through most ordinary fittings. The illuminating power of the flame, expressed in the same manner as before, is from thirty to thirty-three candles. The spirit —of which one gallon, it is believed, will carburet 500 cubic feet—used in this process is said to be obtainable in an almost unlimited quantity, being driven off on the first heating of the crude product in the manufacture of American kerosene oil. At present this volatile distillate is allowed principally to evaporate into the atmosphere; but it is thought that, with very little extra expense or trouble, it may readily be condensed and imported. This spirit evaporates with extreme rapidity, as might be expected from its low boiling-point; and the vapour proceeding from it, as from other petroleum spirits, is an exceedingly heavy one, almost as heavy, indeed, as the vapour of ether; hence, when mixed with air, it renders the mixture considerably heavier than an equal bulk of air, and this has been taken advantage of in the construction of what is certainly an ingenious arrangement, intended to be used as a portable gas-lamp, or, in some cases, in place of the ordinary gaselier. A small reservoir, communicating by a pipe with an ordinary gas-burner, provided with a stopcock, is filled with shavings or wool, which material is saturated with the spirit. The air and vapour descend together through the pipe to the burner, and produce a flame apparently equal in all respects to ordinary gas, the air entering through a small hole at the top of the reservoir. It is stated that half a pint of oil will be sufficient

* Read Wednesday, May 21, 1873.

to saturate an amount of material to supply a light for nine hours.

It has often been thought that of a necessity these very volatile liquids must be much more liable to explosion than those of higher boiling-points; such, however, is not the case, not but that it is possible to cause them to explode, because the vapour of any combustible hydrocarbon, when mixed with that proportion of air which contains just sufficient oxygen to burn up the hydrogen and carbon, will burn throughout at once, producing thereby sudden expansion, which is nothing more than explosion; but the conditions necessary in order to obtain this result are more difficult to bring about in the case of these heavy vapours of very volatile bodies, as, just above the explosive point, the air and vapour simply inflame and burn, while just below it inflammation will not occur at all, from the presence of too small a quantity of vapour. This is contrary to the case of hydrogen gas, which explodes with ease when mixed with air in very variable proportions. The fear has been expressed that possibly, even after the complete mixture of such a heavy vapour and air, separation other than condensation to the liquid state might occur, that is to say, that a layer of heavy vapour might lie at the bottom and a layer of the lighter air at the top; but the law of the diffusion of gases, which states that gases and vapours, whatever their differences in density, will become and remain completely mixed, invariably prevents such separation, just as in the atmosphere the heavier oxygen is not found at the bottom, and the lighter nitrogen at the top, but the two are found together in practically the same proportions from wherever a sample of air is obtained.

If comparisons be instituted between gases made in the ordinary manner and these air-gases, they should be made under the same circumstances, and if this is done it will be found that coal-gas itself suffers, either on exposure to a low temperature or by long keeping—not in any way a surprising result, since it contains the vapours of benzole, toluole, etc., which are capable of being condensed to liquids. In this respect rich gases always suffer the most; thus, on continued exposure to a temperature of 0° C., or 32° F., gas made from cannel coal loses much more of its illuminating power than gas made from ordinary coal.

The employment of a combustible gas as the vehicle for holding in solution, and carrying, vapours of volatile liquids, appears at first sight to be a more rational, and, probably, a more successful method of applying the principle of carburation, for in the former cases not only has a sufficiency of vapour to be retained to confer luminosity upon the flame, but a further quantity must be present for the production of the flame itself, or we may express this difference by saying that in the one case the combustible gas is already manufactured, and requires only to be endowed with luminous properties by the hydrocarbon vapour; in the other the combustible gas has itself to be manufactured, and then, also, to acquire luminosity from the same hydrocarbon vapour, and therefore it will be perfectly clear that a non-combustible gas will require to hold a larger quantity of vapour in solution than a combustible gas, in order to attain the same amount of lighting power. This statement does not, of course, deny the possibility of a non-combustible gas, such as air, acquiring and holding a sufficient amount of vapour, but all other things being equal, a combustible gas has a distinct advantage in this respect, and probably such a gas might be carburetted with a hydrocarbon liquid, having a lower boiling-point, and hence less volatile than an incombustible gas, such as air. This advantage is also increased when air is employed as the vehicle, from the presence in it of one-fifth of its volume of oxygen which burns up—without other effect than increasing the heat of the flame—a proportionate quantity of vapour. The nature of the combustible gas used is not of any very great importance, and hence cheapness and economy in production become the chief guides for its manufacture. The possibility, without any great amount of trouble, of obtaining a quantity of hydrogen gas from water has always been a favourite theme with inventors, and many schemes for its practical utilization have been introduced; but one hardly expected to recognize in a "new gas" our old friend this water-gas once more; such is, however, the case, and a patent has lately been obtained for the carburation of this gas with some light hydrocarbon liquid. The plan is being carried out upon a small scale, and will doubtless very soon be tried upon a more extended one. The amount of attention that has been at various times bestowed upon this subject may be gathered from the number of patents obtained for the production of this so-called water-gas. The first appears to have been granted to Michael Donovan in 1830, a second to George Lowe in 1831, a third to Gilbert Saunders in 1833, and two others to Mr. Floret and Jean Baptiste Molerat about the same time, and many others, all differing by some slight modifications, but all dependent upon the decomposition of steam by red-hot coal, coke, or metal. This decomposition takes place with very great ease whenever steam is passed over such heated material. Hydrogen, carbonic oxide, and carbonic acid being produced, probably two different actions take place, as expressed by the following equations:—

$$H_2O + C = H_2 + CO$$
$$2H_2O + C = 2H_2 + CO_2$$

The amounts of hydrogen, carbonic oxide, and carbonic acid obtained are variable under different circumstances. An analysis of the gas obtained by passing steam over red-hot charcoal for some hours gave as a mean—

Carbonic acid	20	per cent.
Carbonic oxide	20	,,
Hydrogen	60	,,
	100	

Any form of carbon is capable of effecting this decomposition. If a metal, such as iron, be present, it adds to the quantity of hydrogen obtained according to the following action:—

$$4H_2O + 3Fe = Fe_3O_4 + H_8$$

This mixture of gases is inflammable, and burns with a non-luminous but hot flame, the heat of which would be increased if the carbonic acid were previously removed, the flame of hydrogen gas having a temperature of 3776° F. This heat of the flame is an undoubted advantage when the gas is carburetted, as the particles of carbon are thereby heated to whiteness; but, on the other hand, the presence in the gas of a quantity of carbonic oxide is as great a disadvantage, on account of its injurious and exceedingly harmful character. Carbonic acid is an injurious gas, but its action upon the system is not that of an active poison, but rather that of preventing the necessary amount of oxygen from entering the lungs, and hence death from its effect will be death from suffocation. On the other hand, carbonic oxide is an active poison, and recovery from its effect is much more doubtful; indeed, it is calculated that 2 per cent. in any atmosphere would prove fatal, a result that should cause great caution in the use of a gas containing it in any quantity.

In this recent process it is proposed to use retorts of the ordinary description, set, as usual, in benches of five, seven, or nine. All, except the upper one of each set, are filled with some carbonaceous substance, usually coke, together with some scrap-iron, or iron chairs, and heated up to a comparatively high temperature; steam—under pressure, generated from an ordinary boiler, and superheated by its passage through pipes set in and heated by the same furnace as the retorts—is introduced into the back of each retort, and has to traverse its whole length, passing through the red-hot coke and issuing from the front. During this passage the above decompositions take place. The upper retort is of a larger size, and is also filled with coke, but no steam is introduced into it; the gases formed and the remaining undecomposed steam from the other retorts passing through it together, this remaining quantity of steam being thus decomposed; and from this point the gas is treated precisely in the ordinary manner and stored in holders, it being in all respects a permanent gas. It is intended to utilize this gas by itself, as a heating gas; but its chief use is for illumination, and the necessary luminosity is obtained in the same manner as with air-gas, the gas being caused to bubble through some light spirit, any reduction of temperature by the rapid evaporation being avoided by maintaining the vessel containing it at a constant temperature by means of a steam-pipe. The illuminating power of the gas so obtained is equal to about sixteen or seventeen candles; and its permanent character is declared to be, and no doubt is, quite sufficient to render it of some practical utility. Let it, however, be borne in mind that no more union has taken place between the vapour of the hydrocarbon and the permanent gaseous mixture than in the case of the carburation of air, both gases taking up precisely the same quantity of vapour at the same temperature, and both being equally liable to be affected by changes of temperature, or other changes of circumstances. The whole of these carburetted gases are, of course, to a very large extent free from those impurities which are usually found in coal gas.

A suggested application of this principle of carburation, as an adjunct to the ordinary manufacture of gas, has many favourable points; for coal gas may most certainly be as successfully carburetted as either air or hydrogen and carbonic oxide, and it is quite possible to produce an exceedingly large yield of poor illuminating gas from coal, the luminosity of which might be brought up to the ordinary standard by partially carburetting the gas with some light hydrocarbon, the presence of a less quantity of vapour being requisite in a given bulk of gas, and hence a successful result would be more easily obtained, as the vapour would only have to raise the luminosity from a lower to a higher point, and not to do the whole work of illumination itself. A very large yield of gas from coal may be obtained by working at a high temperature, or at the ordinary temperature if a jet of steam be introduced into the retorts during the carbonization, it having been found possible to obtain by this latter method as much as 52,000 cubic feet from a ton of coal of an illuminating power equal to four candles.

In the preceding remarks an endeavour has been made to state and examine the claims of each of the processes brought forward in a clear and impartial manner. The extravagant statements and impossible theories sometimes put forward often obtain credence and support because those hearing them have seldom the necessary knowledge of the rudiments of chemistry or physical science to combat or disprove them; and very often such statements themselves are made in ignorance, and not with intent to wilfully mislead, by those who would be glad to state the truth if it were presented to them in a clear and succinct manner. Most schemes of this nature are open to conclusive proof with regard to their value and practicability, and in some cases this proof will be entirely to their advantage, and should not be shunned by their promoters. The introduction of so many new inventions just now, with regard to the manufacture of gas, indicates a great want somewhere, and if such a want exists it cannot be long before it is met and satisfied. Whether any of these present schemes are tending toward this satisfaction it is premature to say; this much may, however, be said, that hasty condemnation upon insufficient evidence is as much to be lamented and avoided as exaggerated and untruthful statements.

All mention of the commercial success of any of the above inventions has been avoided, as it was not intended, at the outset, to make this paper anything but an examination from a scientific point of view of such inventions. Doubtless there are those who are able to form an excellent judgment upon such matters as comparative cost of material, plant, labour, etc.; and this part of the subject must at all times have an exceedingly important influence upon any expressed opinion as to the profitable nature of such undertakings.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Shop Hours' Regulation Bill.

Tuesday, June 24.

The following petition against the Shop Hours' Regulation Bill was presented by Mr. W. H. Smith:—

"To the Honourable the Commons of Great Britain and Ireland in Parliament assembled.

"The petition of the Pharmaceutical Society of Great Britain humbly sheweth, that your petitioners view with considerable alarm a Bill now before your honourable House for regulating the hours of labour of children, young persons, and women in shops.

"Your petitioners represent the chemists and druggists of this country, who are compelled to supply at any time whatsoever, when required, medicines for the alleviation of human suffering and the saving of human life; and the provisions of the said Bill, which would render it compulsory to close the shops at which such medicines are usually obtained for half a day in every week, and prevent assistants and apprentices under twenty-one years of age supplying medicines in such shops on several days in the year, would cause great inconvenience and hardship not only to your petitioners, but to the public.

"Your petitioners venture humbly to express their feeling of dismay at seeing such attempts as are made by this Bill to draw sharp lines not only between masters and servants, but also between parents and children, and predict the worst possible consequences from such legislation.

"They therefore humbly pray your honourable House to reject the said Bill.

"And your petitioners will ever pray, etc.

"Signed on behalf of the Pharmaceutical Society of Great Britain,

"Thomas Hyde Hills, President."

Petitions against the Bill were also presented from Margate, Canterbury, and Ipswich, and one in its favour from Rochdale.

The second reading of the Bill is again postponed until Tuesday, July 1.

Prosecutions under the Adulteration Act.
Alum in Bread.

At the Nottingham Town-hall, on Tuesday June 24th, a baker of the town, named George Gill, was charged, under the new Adulteration Act, with selling adulterated bread and flour. On the 7th of May last the officer appointed under the Act went to the defendant's shop and purchased a loaf and a small quantity of flour, which he took to the borough analyst, Dr. Truman, who analysed them, and found alum in the flour to the amount of 10 grains to a 4lb. loaf, and in the bread at the rate of 26½ grains, thus rendering the articles injurious to health.

Mr. Belk who defended, urged that the defendant when purchasing the flour had no means whereby to detect the presence of alum.

The Town Clerk, who prosecuted, was willing to admit that, but contended that the Act of Parliament threw the responsibility of knowing that the articles they sold were pure upon the retail dealers, who could have their remedy in prosecuting the wholesale dealer and suing him for damages.

The bench took a similiar view of the case, but, as this was the first conviction under the Act, inflicted the mitigated penalty of 40*s*. Notice of appeal was given.

At Lambeth, on Tuesday, June 24, three cases under the Adulteration of Food Act were heard. Mr. Marsden, Vestry Clerk of Camberwell, attended to prosecute.

The first case was that of John Finch, baker, High Street, Peckham. A 2lb. loaf was purchased by Charles Wood, one of the inspectors. On being tested by Dr. Bernays, Professor of Chemistry, St. Thomas's Hospital, it was found to contain alum. The defendant said he had been twenty years in business, and never had used alum in making bread. He then called a man who had been in his employ, and who confessed that he had put alum in the bread unknown to his master. For doing so he had been discharged. Mr. Marsden then said he did not press the case, and the summons was dismissed.

William John Druce, baker, Wyndham Road, Camberwell, was summoned under the same Act. He pleaded "Guilty;" and said the flour supplied to him was bad. Dr. Bernays said the bread bought at the defendant's shop contained alum, and was injurious to health. Mr. Ellison inflicted a penalty of £5, saying he wished it to be understood that in future the full penalty would be imposed.

John Grimble, baker, Cator Street, Camberwell, was the third defendant. A half-quartern loaf purchased at the defendant's shop was found to contain 28 grains of alum. The defendant denied having any alum, and his foreman said he had never seen any on the premises. Perhaps the miller put it into the flour. Mr. Ellison said bakers should have the flour tested. He fined the defendant £1 and costs.

Poisoning by Prussic Acid.
Mistake in Dispensing.

An inquest was held in the male convalescent ward of the Royal Berks Hospital at Reading, on Monday, June 16th, before the Borough Coroner (W. Weedon, Esq.), on the body of Mary Corps, 32, spinster. The body having been viewed, the Coroner in drawing the attention of the jury to this inquiry, said they must inquire whether the person who administered the draught which caused the death of the deceased was guilty of manslaughter; if the poisoning was caused by gross carelessness or negligence, that person was guilty of manslaughter.

Mr. Rising watched the inquiry for the relatives of the deceased.

William Robinson Hadwin (having been cautioned by the coroner) said: I am dispenser here; I have been here four years and two months. I had been busy on Saturday, but not more busy than usual on Saturdays, as that is a very busy day. I had to make a draught for the deceased similar to those I had before made for her. I do not remember what time this particular draught was made up. I have seen a part of the draught since; there were two draughts in the bottle. It appeared to contain hydrocyanic, or prussic acid. I had not been using the acid in any former draughts, but had been using it frequently during the day. It was in the place in which it is usually kept, and was within a few inches of the bottles which I required for this draught. I cannot account for taking the wrong bottle, except by supposing my attention was called off for the moment, and that I took the bottle during that time. There was a boy in the dispensary with me, but he was not helping me make up draughts. I do not know the deceased, and have never seen her; I knew nothing about her. I was in my usual health on that morning, and not more flurried than usual. The bottles of chemicals were all labelled; there was a small poison label on the prussic acid bottle, quite large enough to be distinct. There was a similarity between the labels of the two bottles; that on the bottle I should have used was printed by myself in large letters, and that on the other was printed from type. I have been a dispenser for many years, and never had a misfortune of this kind before. I had more than 100 in-patients and about 80 out-patients to dispense for on Saturday; the out-patients were dispensed for first, and then the in-patients. I suppose I began dispensing for the latter about one o'clock, but might possibly have made up this draught previously, while waiting for prescriptions for the out-patients. I have seen the bottle with the draught in it, and have no doubt it is the bottle in which I put up the draught on Saturday. The deceased and her relatives are all strangers to me, and I have therefore no ill-will towards her. I heard of her death on Sunday morning; she was to take half of the draught at bed-time.

The bottles were then produced and identified.

Cross-examined by Mr. Rising: The bottles are kept on the same shelf. [The one from which the draught was taken was labelled poison, with an orange coloured label, and was larger than the other.] The small bottle also contained poison (chloral hydrate), but is not labelled as such. Twenty grains were prescribed. I suppose four drachms of prussic acid were given; the chloral hydrate and acid are always used in solution. About 40 grains were used in the mixture. The bottle is labelled "half to be taken at bed time," and it was the duty of the nurse to give it. The prussic acid bottle was in its usual place, and I am sorry I had not moved it, as I have at other places.

Mary Ann Cox, nurse at the hospital, said the deceased was not in my charge. I had charge of the ward in which she was on Saturday evening. I took the draught from the window and gave it to the nurse who I saw give it to the deceased. The bottle was labelled with the name of the deceased, and with directions for giving the draught. I saw the nurse pour half the contents into a glass and give it to the deceased. She was immediately taken with a burning heat, and said it tasted very different from what she had had before. She asked for some water, and as I rinsed the cup she became stiff. I laid her down and sent for the matron, who came directly and sent for the house-surgeon. He was there in less than five minutes after she had taken the draught; the bottle produced was that which contained the draught—it was left half full. Deceased died about half-an-hour after she had taken the draught.

In answer to questions from Mr. Rising and the jury, witness said she believed the writing was in the dispenser's handwriting; deceased had been a patient about a fortnight, and had a draught every night but one. The draught was given about ten minutes to ten, and deceased died at 10.20; she complained of the draught burning her, and asked for some water, and was then unconscious till she died. She had suffered a great deal of pain.

Mr. Hadwin, re-called, said: The bottle produced is that which has been used for deceased's draughts ever since her admission; the label is in my writing, and was put on when the bottle was first used.

Mr. Richard Galpin, house-surgeon, said: The deceased was admitted about a fortnight ago, suffering from disease of the bronchial tubes. I was called to her two or three minutes after ten on Saturday night; the matron said she had suddenly been taken faint. I saw she was in a dying state, and on questioning the nurse I found she had been better all the evening. Deceased became insensible, and I then took up the bottle and immediately perceived by the smell that it contained prussic acid; the symptoms were those of poisoning by prussic acid, and I have no doubt that was the cause of her death. I believe that is the general opinion of the medical gentlemen who have seen deceased. I have been here three years, and Mr. Hadwin was here before me; I have always found him very careful indeed in his dispensing, and never heard any complaint against him.

Cross-examined: The dispenser *might* have smelt the prussic acid, which emits a strong effluvium, but, unless he smelt it specially, he most likely would not have done so, as there were so many other chemicals in the room. There is a great difference between the smell of the prussic acid and the chloral hydrate, but in the dispensary they would be neutralized.

Re-examined: A *post-mortem* examination would enable us to say certainly what was the cause of death. The quantity of prussic acid was sufficient to account for it. I did not apply the stomach pump, as she would have died while I was using it. The time deceased lived was not very unusual.

Edward Wells, Esq., M.D., said: Deceased was a patient here: I saw her every alternate day and have seen the body since her death. We cannot detect the presence of prussic acid by the smell of the body, and I can only say what was the cause of death from what I have heard. I have known the dispenser ever since he has been here—four years—I have always found him an extremely careful and punctual man; he has had the management of the dispensary. Several members of the committee have sanctioned my saying that Mr. Hadwin has always been a very careful man. I think a *post-mortem* would not throw much light on the subject, as there is no question as to the administration of the dose, or as to the quantity. The dose given was a necessarily fatal one; therefore deceased's life could not possibly have been saved.

This being the whole of the evidence, the Coroner said the jury must first decide what was the cause of death. Mr. Hadwin had made up the draught and the nurse had administered it, so there could not be much doubt on that point. They must then decide whether the dispenser was guilty of gross carelessness; if so, they would be justified in bringing in a verdict of manslaughter.

The jury consulted for about ten minutes and then returned a verdict that "The deceased met her death by poisoning by prussic acid, administered by misadventure." The jury suggested that the dispenser should have more assistance on the busy days.

Mr. J. H. Wilson said, the recommendation of the jury would be conveyed to the Board at their meeting on Tuesday, and on the behalf of the committee who investigated the case that morning he begged to assure the relatives of the deep sympathy they felt at the loss they had sustained, especially as it was the first death of the kind which had occurred since the hospital had been opened. He also wished to express the sympathy of the committee with Mr. Hadwin.—*Berks Telegraph.*

Death from an Overdose of Paregoric.

On Tuesday, June 24th, Mr. F. Price, coroner, held an inquest at Salford respecting the death of a child named Newton, aged seven weeks. It appeared from the evidence that, the child being very cross, the grandmother put two tablespoonfuls of warm water into a bottle which had contained paregoric, and in which a few drops were left, and after shaking the bottle, poured the liquid upon some sugar, and told the mother to give half of it to the child. The mother, however, gave the whole, and the child became ill, and died the same morning. The jury returned a verdict that the deceased died from an overdose of paregoric, and the coroner cautioned the mother and grandmother to be more careful in future.—*Manchester Courier.*

Review.

Pharmacopœia of the University College Hospital. Published by Authority of the Medical Committee, 1873. Edited by William Martindale, Pharmaceutical Chemist, etc. London. 1873.

The practice now generally adopted by the London hospitals of publishing the forms for the administration of medicines used by their respective medical staffs, has its advantages, although something might perhaps be said against it. The principal object, we presume, of compiling these hospital Pharmacopœias is that of economizing time in prescribing as well as dispensing the medicines ordered for the hospital patients. There may also be another object, namely, that of limiting the number or variety of the medicines used, a selection being made of such as are considered most suitable for the purpose intended. The medical men attached to the hospitals are all eminent in their respective departments of the profession, and it is to be inferred, therefore, that the forms used by them in prescribing represent sound and advanced views in therapeutics and the treatment of disease. Beyond this it would be unreasonable to look for much that is new or instructive in these formularies. Simplicity, consistency, and efficacy we may expect, and we find in the little work before us, as well as in others of a similar sort, that complications and refinements are generally avoided, and the more simple and efficacious medicines principally ordered. It appears, however, that even in hospital prescribing an appeal is sometimes made to the imagination, for we presume it is for such purpose only the mixture of burnt sugar and water, under the name of *mistura flava*, is required, or that cochineal colouring or tincture of lavender is added to a lotion. We have wondered, too what the object is of ordering both calamine and oxide of zinc in a lotion. Surely calamine is never better than oxide of zinc, although sometimes it may be something very different from it, in which case we presume the oxide of zinc is intended to supply the absence of zinc from the so-called calamine. These, however, are small matters which are amply compensated for by the prevalence of a system of prescribing that appears to be more consistent with the special objects in view. In addition to diet scale, and instructions for reporting cases, the book contains 97 prescriptions, 39 of which are for mixtures, and the rest for various other forms for the administration of medicines. The principal peculiarities in this hospital formulary as compared with others are that the quantities of ingredients ordered for mixtures (the most numerous class of preparations prescribed) always represent one dose of a fluid ounce, and that weights and measures are expressed according to the British, and also according to the metric system. We think, however, that the method adopted of giving the equivalents of the British weights and measures, not in exact, but only in approximate, quantities according to the metric system, is by no means a commendable one. We object to the practice of representing the French gramme as 15 grains, and the fluid ounce as 30 cubic centimetres, as calculated to establish incorrect ideas.

"Professional Patronage"—A Caution.

Sir,—A few nights ago I was aroused from my slumbers by a loud knocking at the door and a violent ringing of the night bell. On my hastily throwing up the bedroom window, a gentleman called out that he was a medical man, and requested that I would come down directly and supply him with some medicine that he required. On his entering the shop he asked for $1\frac{1}{2}$ oz. of chloroform, made from pure, not methylated spirit, and at the same time wished for a glass of water. After drinking about a pint of cold water he seated himself on a chair, and, taking a piece of lint from his pocket, saturated it with the chloroform and commenced rapid inhalation. Very quickly he was fully under its influence and snoring. Not liking the appearance of things, I rang for one of my assistants, and requested him to look out for a policeman. After a lapse of about twenty minutes, and during the absence of my assistant, my nocturnal visitor roused himself. I thought it probable he would now make a move, but no such luck; he vigorously plied himself with another "go" of chloroform, and again became insensible. I hesitated to "tackle" him alone, for in addition to a determined look, he carried a formidable stick in his hand, and I felt that I could not afford to have my head broken. At last my assistant returned with a policeman, to whom I explained the circumstances, at the same time requesting that he would at once remove him. With a little vigorous shaking, but still in a semi-stupid state, we got him into the street, and finally into a cab. I retained the bottle of chloroform, from which about half an ounce had been used, and even that he said he had no money to pay for. He was dressed in a suit of grey, and had a real or assumed contraction of one hand. From three to four o'clock in the morning this pseudo medical man kept me cooling my heels in attendance on him, and I have just been informed by my friend, Mr. Taylor, of Baker Street, that he has also been favoured with a similar visit. To prevent others parting with their chloroform and losing their night's rest in a similar manner is the object of this communication.

Thomas Greenish.

20, *New Street, Dorset Square.*

*** Since receiving the foregoing letter another chemist has written to the *Times* as follows, under the heading, "A Dishonest Dipsomaniac:"—

"On Sunday night last, or rather at 2.30 a.m. on Monday, I was aroused by the ringing of my night bell. As is my usual habit, I looked out from my bedroom window and saw a man waiting at my door. In answer to my inquiry as to what he wanted, he told me he was a medical man and required medicine. I dressed myself and came down into the pharmacy, and on opening the door was asked if I could supply some chloroform. I stated that it was not my practice to retail such a preparation to those I had not the pleasure of knowing, but if he were a medical man and would give me his name and address, I would let him have it. He told me he was Dr. ——, of —— Terrace. The address I purposely suppress, as I find there are respectable practitioners residing on the same terrace, and I have since discovered that the name and address were both false. He was evidently *au courant* with his subject, for he described the particular kind of chloroform he required, and which was to be that made by Messrs. Duncan and Flockhart, from pure alcohol. I told him that I supposed I ought to feel flattered (which I did not) at his selecting my pharmacy when he must have so many chymists nearer his own home than I was, but presumed that he required it for some accouchement in this neighbourhood. No, he wanted it for himself, as he suffered from epileptic fits, and felt that he then had one coming on, and that nothing relieved him but the inhalation of a few drops of chloroform. I expressed my surprise that he did not keep such a remedy by him, but was met by the ready excuse that on going to his bottle he found it had all evaporated, and that he had been to half a dozen different druggists before he came to me, and that not one of them would get out of bed. They were wiser than I was. However, it ended by my letting him have the chloroform. As soon as I handed it to him he sprinkled a drachm or so on his white cambric handkerchief, and seating himself comfortably began to inhale it. I suggested to him the expediency of his employing the remedy in the privacy of his own chamber, but it was in vain, he would not move. I told him I was anxious to get to my bed, and that I was getting tired of a reception that had been forced upon me at an unseasonable hour of the night. Affairs began to assume a disagreeable aspect. I opened the door wide, and looked up and down the street for a stray policeman or a passing cab, but in vain; not a soul could I see, and I could not readily summon any of my own household. He was a tall powerful man, and I felt how unequally matched we should have been had it ended in a trial of physical force. He had not inhaled enough to thoroughly satisfy him, but sufficient to make him an exceedingly disagreeable visitor. At last, by dint of threats and persuasion, I induced him to leave, but he flatly refused me the slightest remuneration, and reeled off with my bottle in his pocket.

"Now, this man is evidently a confirmed dipsomaniac; he has not the means of indulging in the usual stimulants resorted to by that class, neither does he care to pay for his chloroform. He has cunning enough to know, as a rule, that at the dead of the night only one would attend the summons of a chymist's night-bell, and that he would have a favourable field for his plans.

"For the information of my professional brethren, I would mention that he is a well-built, broad-shouldered man, about six feet high, dressed in a light tourist suit, and with large flowing whiskers—such, I think, as are technically termed "Piccadilly weepers." Should such an individual present himself at night to any of my fellow chymists, I hope they will not allow themselves to be swindled of their goods and robbed of their night's rest as I was. "John Taylor, Chymist.

"13, *Baker Street, Portman Square, W., June 24th.*"

We have also been informed that a person answering the above description, between the hours of nine and ten p.m. on the 14th June, went to a West End house and wrote a prescription, ordering 1 oz. of chloroform, of which he inhaled two drachms and became insensible. The same person has also practised this trick at other places.

J. Abraham (Liverpool).—Your communication has been received with thanks.

M. Doughty.—Your communication shall receive attention next week.

Messrs. T. H. Smith and Co. will find, on referring to our report of this case, and the editorial remarks upon it, that the particulars they mention respecting themselves were fully pointed out.

C. Kidd, M.D.—The opinion expressed as to the comparative safety of the two substances would find a more appropriate place in the pages of one of our medical contemporaries.

"*Lamium.*"—(1) Lamium purpureum. (2) Nepeta glechoma. (3) Veronica anagallis. (4) Senecio Jacobæa. (5) Fumaria officinalis.

"*Botanist.*"—(1) Juncus Gerardi. (2) Scirpus maritimus. (3) Nepeta glechoma.

T. A. Wedge.—Your letter has been handed to the publishers, who will communicate with you upon the subject.

"*Calyx.*"—We do not think that there is any deficiency in the supply of works similar to that described by you.

X. Z. Y. is referred to the rule respecting anonymous communications.

"*Theta.*"—(1) Section xii. of the Pharmacy Act, 1852, provides that it shall not be lawful for any person, not duly registered as a Pharmaceutical Chemist, "to exhibit any name, title, or sign implying that he is" a member of the Pharmaceutical Society. (2) Yes. (3) Yes; by virtue of having been in business before August 1, 1868.
