THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from* Vol. II. *p.* 1025.)

Pyrethri Radix.—Sections of this root can only be examined to advantage in fluid, and should be put up in glycerine or glycerine jelly for preservation. Owing to the thinness of the cell walls and the loose texture of the root generally, it suffers much distortion (structurally) in drying; so that it is almost impossible to make a proper examination of the dried root.

The *medulla* is present, and somewhat largely developed, and is irregularly septate, the cavities between the septa being somewhat large. The cells of the medulla are very thin-walled modified globose cells, adhering somewhat intimately to each other, and varying much in cross-sectional outline. Many of these cells display *pseudo*-reticulations, due to unequal shrinking during exsiccation, which may easily mislead a beginner.

The *medullary rays* are very large, exceeding sometimes by three times the breadth of the wood wedge; they are complete and incomplete in nearly equal proportion. Their cells resemble those of the medulla, becoming more cubical as they approach the cortex.

The *wood wedges* are hardly worth their name, as they are merely composed of cubical parenchyma cells and vascular (pitted) vessels. These vessels are almost scalariform, but do not otherwise possess any features of interest, and are out of all proportion, as to size and number, to the *pseudo*-wood cells. The only cells in which secondary deposits are traceable are the liber cells of the cortical layers, which are not otherwise interesting, except in being very numerous. The cortical layers consist of cubical parenchyma; colouring matter receptacula, which are cubical cells also; liber cells; and the compressed cells of the external layer. Starch is present in very small proportion. The granules are roundish, and of small medium size.

Pareiræ Radix.—As is tolerably well known, the so-called root of Pareira of British pharmacy is really the stem, generally of *Cissampelos Pareira*, but often of some other species. The structure of the B. P. so-called root is exceedingly interesting and characteristic. I describe the true *Pareira Brava* from a portion of a stem about half an inch in diameter.

Medulla.—The medulla is very visible to the naked eye, is often very eccentric, and throws out radiating processes (medullary rays) to the bark. These are also visible without a lens. The cells of the medulla are of medium size, are somewhat irregular, and variable in size and shape; some contain a darkish yellow colouring matter, nearly all contain starch. The starch granules are very variable, both in size and shape. The large ones may be best described as flatly compressed lenticular granules, with a strongly marked longitudinal hilum. By polarized light these granules give a decided single black cross. The smaller granules are much too variable to be grouped under any one characteristic, unless it were rounded-off polyhedrons. Acicular raphides, or more correctly perhaps, as they have not pointed ends, elongated prismatic raphides, are contained in specialized cells near the exterior of the medulla, and very occasionally, but they are then much smaller, in the cells of the medulla itself. The true medulla cells are distinctly pitted with oval pits, the cell walls are slightly coloured yellowish brown, and are evidently considerably thickened by secondary deposits. They are generally egg-shaped, often globose; towards the circumference they become more angular, and when the medullary rays strike off, become much longer in proportion to their other dimensions.

Medullary Rays.—These are, as has before been stated, very well marked. Their cells are somewhat loosely attached to each other, and are somewhat less angular than usual. Raphide-receptacula abound in the rays.

Vascular Bundles.—Owing to the great size of the medullary rays, the wood masses are well isolated on two sides. They are composed of porous wood fibres and pitted vessels; these latter being of the large size common to all climbing plants. The wood fibres are themselves of the nature of vessels, from the largeness of their central cavity and the small extent to which their walls have been thickened. They are fragile, adhere closely to each other, and are of considerable length, slightly tapering towards each end; oval in cross section, and closely pitted. The pits are usually in the centre of a relatively large ring, and are oval; they do not contain either starch or raphides. The vessels vary much in size, and are exceedingly interesting. The largest are reticulated in an intricate manner; the pits oval, and in a central bordering follow the pattern of the reticulation somewhat closely, the axis of the pore lying often parallel with the course of a supposed spiral wound within the cell. The ends of these ducts are, as Quekett remarked long since, somewhat flattened; are often closed with a double septum, or more correctly with septa, being the unabsorbed membrane of the respective cells. The reticulations on these septa are often very remarkable, and resemble very closely those of *Sanseviera guineensis*, being much more elaborate and less regular than those of the spiral cells of orchids with which most microscopists are familiar. In the older ducts the membranes between the reticulations often have been absorbed, and we have a true reticulated fibrous vessel. In the smaller ducts these reticulations are not easily discernible, sometimes they are absent. The polariscopic reactions are very marked; few slides would be more beautiful than a good longitudinal section mounted in balsam, and viewed with the aid of a blue selenite whose optic axis is inclined 13° to 27° from the plane of primitive polarization; the long axis of the ducts must be at right angles to that plane. Under these conditions the play and succession of colour as the polariser is revolved are astonishing, and, I need hardly say, exquisitely beautiful. It unfortunately happens that good sections are very difficult to make. The larger vessels are usually stained deep yellow; alongside lie, in special cells, bundles of raphides.

Cortical Layers.—An adequate discussion of these would occupy more space than I can afford, as they happen to be somewhat complex.

The points of interest are the liber cells, which are usually full of yellowish-brown colouring matter, the somewhat unusually shaped cells of the epiphlœum, the bundles of raphides in their receptacula, and, specially, certain stellate cells. These latter are unusually interesting. Their centre is porous, as may be seen if the colouring matter with which they are usually filled be removed, the pores passing through the very thick layers of sclerogenous deposits and communicating with the contiguous cells. The details of structure in these cells can be best made out, if they be isolated by means of sulpho-chromic acid from the surrounding tissue. The action of the acid is very energetic, and care must be exercised or the section will be spoiled. The beginner had better commence by using nitric acid; and when he has succeeded with that, pass to the use of the sulpho-chromic.

HYPODERMIC INJECTIONS.

BY M. ADRIAN.

In the preparation of a solution for hypodermic injection, the choice between the normal alkaloid and its salts is not an indifferent one. When medicaments so powerfully active are injected under the skin, it appears necessary to define clearly the relation that exists between the alkaloid itself and its combinations with acids. In medical practice sufficient importance is not always attached to this distinction; and instances are sometimes met with where the same doses of hydrochlorate, sulphate and acetate of morphia, or of hydrochlorate and sulphate of strychnia, are prescribed, although the constitution of these various salts assigns to them a sensibly different proportion of the active principle that is employed. This will be seen by an examination of the following numbers:—

One gram of	Crystallized Alkaloid.	Water necessary for Solution.
Hydrochlorate of Morphia contains	0·80	20
Sulphate of Morphia . .	0·76	10
Acetate of Morphia . . .	0·86	5
Sulphate of Strychnia . .	0·75	10
Hydrochlorate of Strychnia	0·83	8

According to this table, one gram of acetate of morphia contains ten centigrams more of morphia than the same weight of the sulphate, and a similar difference exists between the hydrochlorate and sulphate of strychnia.

Of course it is because of their greater solubility in water that the preference is given to the saline combinations over the alkaloids. But the preparation of these solutions is not so easy as at first sight might appear, and certain difficulties are met with in the operation which might possibly lead to a notable error in the final result, and so modify consequently the composition of the medicament. Thus in operating with the salts of morphia, it is found that their solubility is variable, and it is necessary sometimes to have recourse to elevation of temperature, or the addition of a fresh quantity of acid, to obtain a solution. This difference may arise from an impurity in the salt, or more frequently from the greater or less amount of dehydration it has undergone in its preparation. On the other hand, it is rarely that the solution is sufficiently clear, and it becomes necessary to filter it through paper. But what then happens? The filter absorbs a portion of the liquid; and although the precaution may be taken of well washing the filter, there is no proof that the whole of the active principle is carried off in the washing, so that in pouring 10 grams of distilled water containing 30 centigrams of hydrochlorate of morphia upon a filter weighing 50 centigrams, only 8·20 grams of the solution is recovered, being a loss of 1·80 gram, or nearly one-fifth.*

Solutions intended for hypodermic injection, prepared as they usually are, present another defect, namely, the alteration which they undergo after a time. Small fungi are seen to form upon their surface; then the liquid becomes turbid and gives rise to a copious deposit. The experiments which the author has made with the object of avoiding this alteration, have led to the following results.

The solutions of atropia and codeia are decomposed more readily than the others. Also, when they are prepared in the cold they change more rapidly than when they are obtained with boiling distilled water. Liquids containing the alkaloids dissolved with the help of sulphuric acid are preserved better than those in which hydrochloric acid is used. Finally, solutions containing glycerine to the extent of one-fifth of the total volume may be kept for a long time without undergoing the least alteration.

Based upon these observations, the author has been led to consider the following conditions to be desirable in the preparation of solutions for hypodermic injections.

(1.) To use exclusively alkaloids of vegetable origin in a state of purity. These are always well defined, stable and uniform in composition, whilst their salts vary according to the equivalent of the acid which is used in their formation, and according also as they contain more or less water of crystallization.

(2.) To use as a vehicle boiled distilled water, containing twenty per cent. of glycerine.

(3.) To give the preference to sulphuric acid, diluted in the proportion of one of acid to ten of water, above all other acids.

---

* In a memoir upon which the author is engaged, he proposes to indicate the change of composition to such a liquid through the absorption in the filter.

(4.) To substitute measurement by volume for measurement by weight.

Mode of Operation.—After having verified the purity of the alkaloid, reduce it to powder, and weigh a quantity corresponding to a determined volume. Place the powder carefully in a graduated flask holding 10, 20, 50, or 100 cubic centimetres. After having added some drops of glycerined water to suspend the powder, the acid is poured in of the strength indicated above. The solution may be made in the cold, but more often it is necessary to raise the temperature a little in order to accomplish it. When the solution has cooled, it must be made up to the necessary volume with the glycerined water. Solutions may be prepared by these simple means that will be clear and of uniform composition, and have the advantage of keeping a long time without alteration. This result having been recognized, it remains only to indicate a formula which will enable the medical man to know the quantity of alkaloid contained in the solution, so that he may vary the dose at his will. The following proportions appear to the author to be the most suitable:—

Morphia	1 gram.
Sulphuric Acid (10 per cent.)	2·50 grams.
Distilled Water containing twenty per cent of glycerine	q. s. to make 100 c. c.

If the syringe be gauged to one centimetre, and it require twenty half turns to empty it, then each half turn will equal one half of a milligram. By augmenting the proportion of the morphia and that of the acid, without changing the total volume, solutions containing one to two milligrams to the half turn may easily be obtained. If necessary, the quantity may be increased to ten grams to the hundred cubic centimetres, but when the solutions are too concentrated they crystallize, and the composition of the liquid is thus modified.

The formula for Codeia is as follows:—

Crystallized Codeia	1 gram.
Sulphuric Acid (10 per cent.)	1·50 ,,
Distilled Water containing 20 per cent. of glycerine	q. s. to make 100 c. c.

Each half turn of a syringe gauged to one cubic centimetre will correspond to half a milligram.

The other alkaloids may be treated in a similar manner.

The following are the approximative quantities of sulphuric acid required to dissolve one gram of the substances named:—

Alkaloids.	Acids.
Aconitine (Duquesnel)	1 gram.
Atropia	2·50 ,,
Narceia	7·50 ,,
Strychnia	2·50 ,,
Veratria	2·50 ,,

The author gives the following formula for the preparation of hypodermic injections of the crystallized digitaline of M. Nativelle, although he does not think that digitaline should be used in this manner, since it causes intense irritation.

Crystallized Digitaline	1 centigram.
Alcohol (95 per cent.)	5 cubic centim.
Dissolve and add	
Distilled water	5 cubic centim.

One cubic centimetre will contain one milligram of crystallized digitaline; by dissolving two centigrams of digitaline, each cubic centimetre will contain two millimetres.—*Bulletin Thérapeutique.*

DUGONG OIL

Among the many attractive portions of the International Exhibition, none is perhaps more worthy of attention than the Queensland Annexe, which has, we believe, been erected at the cost of that young but vigorous colony. The evidence of great material wealth in gold, copper, coal, wool, cotton, sugar and tobacco, to say nothing of arrowroot, tea, coffee, etc., are enough to show us that much may yet be expected of this portion of Australia. On one table are exhibited a large number of tins of preserved meat, and a case containing specimens of the bones, flesh, skin, meat and oil of the dugong.

As we have received several letters recently, containing inquiries respecting this animal and the economical products obtained from it, we take this opportunity of laying before our readers such information as we have been able to obtain.

Near the case in question is a specimen of a "Dugong sucking calf;" lent, as a card attached to it informs us, by Professor Flower, of the Royal College of Surgeons, Lincoln's Inn Fields. This "calf," which is between four and five feet long, has a very curious head, and flippers instead of fins.

In the case are the skull and some of the rib bones of a full-grown dugong cow, a piece of the dried skin, nearly an inch in thickness, several teeth and tusks, a piece of dried meat, stated to be a piece of a calf, and which looks and, we were assured, tastes precisely like bacon, and a few bottles of a white substance not unlike lard or dripping, labelled "Dugong Oil," which is announced as "the great Queensland remedy for consumption." It appears to have been first prescribed for that disease by Dr. Hobbs, of Brisbane, who was led to use it in his practice through observing the wonderful effects the mere eating of the flesh of the animal had on the aboriginals when suffering from lung diseases. It is claimed for this oil that it is not only quite equal to cod-liver oil in the treatment of affections of the lungs, but that it is also a remedy for diseases of the stomach and bowels and general debility, indigestion and biliousness, as well as chronic coughs and wasting in children. But its chief peculiarity is reported to be that, far from partaking of the nauseousness of cod-liver oil, it is actually pleasant to eat as an article of food, and can thus be taken by people of a delicate appetite when the stomach entirely revolts from cod-liver oil.

At a dinner given by Mr. Danetree, the Agent-General of Queensland, in the Annexe, on the 10th inst., dugong oil bore a very prominent part in the *menu.* Both pastry and biscuits were introduced, in which the oil took the place of butter or lard, and we are informed that the general opinion was that it was in every way a success. The London correspondent of the 'Newcastle Daily Express,' in writing to that journal, says, "Lighter or more delicious pastry than that in which this oil had taken the place of lard, I never tasted. The same thing may be said of the biscuits, which were everything that biscuits ought to be."

The fish, or, more properly speaking, the animal, from which this oil is procured, is a herbivorous cetacean, and would probably be ranked by naturalists midway between the whale and the seal. It is found in very large numbers in the waters of Northern Queensland, and more infrequently in the southern portions as far as Moreton Bay, beyond which it does not appear to go. It is also said by various authorities to be found in the Indian Archipelago and Indian seas as well as at Mauritius. It grazes on the thick grass which in those warm latitudes grows on the shallows between the islands and along the coasts, where it usually feeds in from one to four fathoms of water, coming up to breathe at short intervals. It is not amphibious, but comes in and goes out with the tide, feeding only during high water. Like most other animals of this order, it is gregarious, and vast mobs of many hundreds and even thousands are frequently seen.

The dugong varies in length from seven to twelve feet, and its weight may be averaged at from six to seven hundred weight. The head is not unlike that of an ox lacking the horns, while the skin more nearly resembles that of the pig. The dam or cow brings forth its young alive and suckles it at the breast, holding it there with her arm-like flipper. All authorities join in attesting the wonderful attachment the female dugong has for her young, so much so that if the calf be killed, the mother makes no attempt to escape, but falls an easy prey. The skin averages from one to two inches in thickness, and the bones are perfectly solid and very similar to ivory, being very heavy, probably to assist the animal in sinking easily to its pasture. The fat meat from which the oil is procured lies next the skin, and is not unfrequently mixed with layers of lean, giving it a perfect resemblance to bacon, like which it also tastes. Some eaten at the dinner before alluded to in the exhibition was pronounced to be very fair ham. The lean meat is said to be very similar to tender lean beef, and is readily sold in its salt state as a breakfast relish in Queensland.

It will be apparent that an article having the advantage claimed for dugong oil, that it is capable of being taken as an article of food, will command a large sale if only its medicinal properties are such as is asserted. As yet there has been no opportunity for testing the oil to any extent in England, but several very strong testimonials as to its value as a medicine, given by colonial medical men, are published by the firm interested in its sale. In the pamphlet are narrated cases of dyspepsia, debility, consumption, liver complaint, indigestion, biliousness, etc., which are stated to have been cured by its use. The oil certainly deserves a trial by the profession with a view to arriving at its actual value.

We believe we are correct in saying that at present there is not any attempt being made to introduce dugong oil to the English market. The gentleman who exhibits it at the International Exhibition has only imported a small quantity in order to bring it under the notice of the medical profession. At present the demand in the colony is quite equal to the supply, and before that can be greatly increased a much larger capital will have to be invested in the fishery. With a view to fostering this enterprise (which in Queensland is looked upon as likely to become of very great value), the Government proposes granting special rights for a few years if a certain amount of capital is invested, so that those who go to the expense attendant on creating a new industry and introducing this novel medicine to the world, may have a fair opportunity to repay themselves for their outlay. Arrangements are now in progress to take advantage of this concession.

THE CHEMISTRY OF THE HYDROCARBONS.*

BY C. SCHORLEMMER, F.R.S.

It is now nearly 200 years since Lemery, in his celebrated 'Cours de Chymie,' separated mineral bodies from vegetable and animal substances, and since that time chemistry has been divided into organic and inorganic chemistry. Such a division appeared quite natural at a time when chemistry formed only a part of descriptive natural science; yet even at that period the founders of the phlogiston theory considered it unscientific to divide chemical substances according to their origin, and they endeavoured to justify such a classification from a chemical point of view. Thus Becher says, "The elements occurring in the three natural kingdoms are the same, but they are combined in mineral bodies in a manner more simple than they are in vegetable and animal substances." Stahl thought that in minerals the earthy principle preponderated, whilst organic bodies contained more phlogiston and more of the aqueous principle. If we translate these definitions into our present chemical language, we find that they are identical with views which were held not long ago.

When, with the discovery of oxygen, the era of quantitative chemistry commenced, the distinction between organic and inorganic bodies was still kept up, because it was observed that compounds formed by the vital process possess certain peculiarities by which they can be easily distinguished from mineral substances.

"Whilst formerly," as Kekulé says, "chemistry was divided because a boundary was seen, afterwards such a boundary was looked for because it was found convenient to have one (Kekulé's 'Lehrbuch,' i. 8). This appeared easy enough at first; chemists then understood both how to decompose mineral compounds into their constituent elements, and also how to build them up again.

But such was not the case with organic bodies; their composition could be easily ascertained, but all efforts made to effect the synthesis of such compounds failed; and hence Berzelius assumed that "the elements present in living bodies obeyed laws totally different from those which rule inanimate nature." It was said that organic bodies might be changed by chemical processes into other organic compounds, but it was thought to be impossible to obtain any such body by synthesis.

The further development of chemistry soon showed that these views were erroneous. As soon as a clear insight into the chemical constitution of organic bodies was gained, methods were found by means of which bodies hitherto formed only by the vital process could be built up from their elements.

Now, when the fact was established that the same chemical laws rule alike animate and inanimate nature, the difficulty presented itself of fixing a boundary line by which inorganic bodies might be separated from organic compounds. I need not dwell here upon all the views brought forward to explain the difference between these two divisions. You all know how the definitions of organic chemistry were changed from year to year, until in 1848 Gmelin first called attention to the fact that carbon was the only element essential to organic compounds. He said, "If we regard as organic those carbon compounds which have hitherto been classed among inorganic substances, viz. carbonic oxide, carbonic acid, sulphide of carbon, phosgene, cast iron, etc., we might define organic compounds simply as the compounds of carbon. But the organic compounds are still further distinguished by containing more than one atom of carbon. Hence the term *organic compounds includes all primary compounds containing more than one atom of carbon*" (Gmelin's 'Handbook,' vii. 5).

At that time the true atomic weight of carbon was not known, and thus the above compounds were separated

* A lecture delivered before the Chemical Society, April 4th, 1872. Reprinted from the 'Journal of the Chemical Society' for June, 1872.

from organic substances, whilst methyl and formyl compounds were included amongst them. As soon as the true atomic weight of carbon was established, Gmelin's definition fell to the ground. It was then said that organic chemistry was simply the chemistry of the carbon compounds. Kekulé, who first distinctly advocated this view, says ('Lehrbuch,' 1), "There is no natural boundary line between organic and inorganic chemistry, and if we still retain this division, it is only as a matter of convenience. We treat the carbon compounds separately on account of their large number and their importance."

Erlenmeyer expresses similar views. He thinks (Lehrb. d. Org. Chem. 5) "that a division of labour is requisite in the interest of teaching." "Besides," he adds, "it cannot be denied that by reason of certain properties possessed by carbon, the carbon compounds exhibit several peculiarities in their chemical behaviour, so that their study requires in many respects other methods of investigation than those employed in the study of the compounds of the other elements, and thus the necessity for a division of labour has also made itself apparent in the interests of scientific research."

Butlerow also says (Lehrb. d. Org. Chem. 5), "Organic chemistry must now be defined as the chemistry of the carbon compounds. If such a definition is somewhat unnatural and not exactly correct, it is still very convenient." I think, however, that such a division is more than a mere matter of convenience. The compounds of carbon do really differ from those of the other elements, because carbon itself exhibits certain properties which no other element possesses.

Kekulé, who first showed that carbon is a tetrad element, pointed out at the same time that the existence of such an immense number of carbon compounds can be easily explained by assuming that the atoms of this element have the property of combining with each other. The same view was expressed by Couper.

This property is also possessed by other polygenic elements, as sulphur and oxygen; but whilst, in the case of the latter elements, the number of atoms uniting together in this way is very limited, we have not yet found such a limit to exist in the case of carbon.

It is, therefore, most characteristic for tetrad carbon that a large number of its atoms can be linked together to form a group, which in a great many reactions remain together, and act like a single atom.

But carbon possesses yet another property in common with no other element. *All the combining units in such a group, which are not saturated with carbon, can be saturated with hydrogen.*

Thus, whilst most of the metals do not combine with hydrogen at all, and the other elements form only one or two, or at the most three compounds with hydrogen, we find not only that very many hydrocarbons exist, but that their number is daily increased by the discovery of new ones.

The hydrocarbons are not only the most simple of the carbon compounds, but, from a theoretical point of view, also the most important, because all other carbon compounds can be regarded as derivatives of them, or as being formed by substitution of other elements for hydrogen. This is shown by the fact that a considerable number of vegetable and animal substances can be prepared artificially from hydrocarbons. On the other hand, as soon as the constitution of a carbon compound is understood, we are in a position to convert it into the hydrocarbon from which it has been theoretically derived.

In the majority of carbon compounds occurring in nature, a portion of the hydrogen of the original hydrocarbon is replaced by oxygen, and in others by nitrogen; all the other elements can, however, be introduced artificially into carbon compounds. But there are only a few cases in which all the hydrogen can be replaced.

Thus, the number of carbon chlorides is much smaller than that of the hydrocarbons. With oxygen, carbon forms only two compounds, and with nitrogen it unites in only one proportion. From this it follows that the great majority of carbon compounds contain hydrogen,—that there is present in them a residue of the original hydrocarbon.

We may, therefore, define that part of our science which is commonly called organic chemistry as the *chemistry of the hydrocarbons and their derivatives.*

I now propose to lay before you, in a short sketch, how far our knowledge of the hydrocarbons has advanced.

(*To be continued.*)

SULPHOZONE, A SUBSTITUTE FOR SULPHUR.*

BY CHARLES ROBERTS, F.R.C.S., ETC.

Sulphur in the sublimed, precipitated, or powdered form, is extensively employed by medical men, veterinary surgeons, and horticulturists, for destroying the animal and vegetable parasites infesting man, animals, and plants. The substance to which I have given the name of sulphozone (from its strong smell and powerful chemical action), in order to distinguish it from the sulphur of commerce, is a preparation containing free sulphurous acid as its active and essential principle.

For many years past large quantities of sublimed and powdered sulphur have been used in this country and on the Continent, for the destruction of the mildew and blight attacking vines, hops, roses, fruit and other trees; and it is now, I believe, almost the sole remedy employed for that purpose, as no other has been found so generally effectual or so convenient of application.

From careful and often repeated series of experiments, I have arrived at the conclusion that the beneficial action is to be attributed to the presence of a small but variable quantity of free sulphurous acid (occasionally hyposulphurous acid), which exists as a constant impurity in the sulphur of commerce. Sublimed sulphur contains more acid than powdered crude sulphur, and is more certain in its action, while precipitated sulphur, being almost, or altogether, free from acid, is quite useless. I find that when substances are carefully purified from all traces of sulphurous acid by repeated washing with spirit and water, they are equally ineffectual in destroying mildew and other vegetable and animal organisms, and that seeds germinate as quickly and vigorously when sown in pure sulphur as in fine sand, and that moulds grow on the surface when a little organic matter, as flour, has been mixed with the sulphur. I find also that cheese mites are not destroyed by pure sulphur, but live and multiply indefinitely in cheese covered with sulphur; though they are immediately destroyed by commercial sublimed sulphur. On the other hand, when pure sulphur is impregnated with sulphurous acid, it destroys mildew, and other minute organisms with an energy proportioned to the quantity of acid it contains, and it does not appear that one form of sulphur possesses any advantages over the others, provided the quantity of acid is uniform. Many other substances which contain no sulphur, when impregnated with sulphurous acid in a similar manner, and to the same extent, are equally effectual in destroying mildew.

It has been observed that when a piece of silver-leaf is suspended over a roll of sulphur, it is slowly converted into the sulphide of silver, and it has been inferred therefrom that sulphur vapourizes at ordinary temperatures; and the theory has been advanced by a well-known vegetable physiologist, that the oxygen given off by the leaves of plants to which sulphur has been applied, oxidizes it and produces sulphurous acid, and thus the action of sulphur in destroying vegetable organisms

* Paper read at the Meeting of the Royal Horticultural Society at Birmingham.

may be accounted for. But this theory is not borne out by my experiments. When silver-leaf is suspended over pure sulphur it does not tarnish more rapidly than when suspended in the air, and its conversion into the sulphide by the roll sulphur may be explained by the fact that that substance contains free sulphurous and hydrosulphurous acids, and sulphuretted hydrogen, which are constantly escaping from it. When pure sulphur is applied to the leaves of plants, no evidence of oxidation can be detected by either litmus, or starch and iodine paper. If oxidation were to take place under such circumstances, the product, if sulphurous acid in the first instance, would be immediately converted into sulphuric acid by further oxidation, and it could not escape detection. Further precipitated sulphur, being in a much finer state of division than sublimed sulphur, would be more easily oxidized, and ought to prove the more potent agent; but practically it is found to be the least so.

Sulphur in various forms is used by medical men and veterinary surgeons for the destruction of the itch and other insects, and in the treatment of various diseases (as ringworms), caused, or accompanied by fungus growths, infesting the skin and hair of men and animals; but sulphurous acid, in solution, is in many instances substituted for them on account of its more certain action. Many surgeons, indeed, believe that the beneficial action of sulphur ointment in the treatment of itch, is to be attributed to the grease of which it is made, rather than to the sulphur it contains, and this is probably true, as the quantity of sulphurous acid is exceedingly small, and I find the action of the ointment is remarkably increased when the sulphur has been strongly impregnated with acid previous to being made into ointment, and this is equally true of its other applications in medicine.

In addition to its destructive action on organized bodies, sulphurous acid possesses a powerful chemical action on the organic and inorganic products of decomposing animal and vegetable substances, and the emanations from persons and animals suffering from infectious diseases; hence it is one of the most potent and valuable disinfectants we possess, and it appears to prevent the spread of smallpox, diphtheria, cattle plague, etc. Its qualities as a deodorizer are also very considerable. It attacks and destroys sulphuretted hydrogen, and neutralizes the strong smell of ammonia and other alkaline bases, but without losing its antiseptic properties, or destroying their manurial value. (Crookes.)

From my experiments and observations, and from the well-known properties of sulphurous acid, I conclude, therefore, that it is the acid, accidentally present in the sulphur, which is the active agent in the destruction of mildews and blights, and that the sulphur is only the medium for its application. This is a fact, not only of scientific interest, but of great practical and commercial importance, for under the mistaken impression that the sulphur itself is the active agent, great care and expense have been incurred to secure its freedom from acidity, which is by no means necessary.

Sulphur, like charcoal and many other substances, possesses the power of absorbing a large quantity of sulphurous acid, and by a modification in the refining process the acidity may be considerably increased, and the quantity of sulphur correspondingly diminished, and a more certain and uniform agent produced. For horticultural purposes, however, it is necessary to limit the quantity of sulphurous acid, or it will prove destructive to the plant as well as the parasite. This limit I have established practically by experiments made on rose trees infested with mildew, and as the rose mildew is with difficulty destroyed by common sulphur, except by repeated applications, this preparation (to which I have given the name of sulphozone, for reasons given above), may be considered to be of the maximum strength, and four or five times stronger and more potent than sublimed sulphur. In substituting it, therefore, for sulphur' a great saving will be effected in the cost of sulphur, its carriage, and the time and labour of applying it. There will, moreover, be the additional advantage of not loading the foliage with a large quantity of sulphur powder, which must in some measure impair its health by its mere mechanical presence, and in the case of hops, the brewers will have less ground for objecting to the quality of the produce. Sulphozone, being a fine dry powder like sulphur, may be applied in a similar manner, and with the same apparatus, care being taken to use a much smaller quantity (*i. e.* about a quarter of that of sulphur).

For medical, veterinary and sanitary purposes, a very strong sulphozone has been prepared to take the place of sulphur in the officinal preparation, and for use as a disinfecting powder. This substance is exceedingly destructive to organic life, and is not adapted for horticultural purposes except for dressing the stems and branches of deciduous trees in the winter, and for destroying insects where it can exert no deleterious influence on surrounding vegetation, or for disinfecting and deodorizing manure heaps, etc., for which purpose it is better adapted than any other disinfecting powder, as the sulphurous acid fixes the ammonia—the most valuable constituent of manure—and makes it available for gardening and farming purposes, while chlorine and other disinfectants destroy it, and reduce the value of the manure in proportion to the extent of their action in deodorizing it.—*Gardeners' Chronicle.*

DETECTION AND ESTIMATION OF PARAFFIN IN STEARIN CANDLES.

BY M. HOCK.*

Makers of stearin candles mix paraffin with the fatty mass in quantities up to 20 per cent. Paraffin candle makers also mix stearic acid with their paraffin and attribute valuable properties to such a mixture, as far as candle-making is concerned. The attempt to determine if paraffin be present, and if so, to get some approximate idea of the quantity, in a sample of stearin and *vice versâ* by means of the comparison of the melting-point and specific gravity of such a mixture is shown to be useless, as these vary according to the source from which the paraffin is obtained, as also in the case of the stearic acid, since the pure commercial article is by no means a chemically pure article.

A good method for detecting the presence of stearic acid in paraffin has been devised by R. Wagner, viz. by treating a boiling solution of the paraffin in alcohol with an alcoholic solution of neutral lead acetate, when, if stearic acid be present, a dense floccular precipitate appears, but none if it be absent. The best method, and one which can be used quantitatively as well as qualitatively, is described as follows:—Not less than five grams of the candle are taken and treated with warm solution of potassium hydrate, which must not be too concentrated. A soap is formed with the stearic acid, whilst the paraffin is left unaltered. Sodium chloride is thrown into the solution, whereby the soap is separated out as a soda soap, and in precipitating takes down the paraffin with it. The soap obtained is thrown on the filter and washed with cold water or very dilute spirits of wine. Thus, firstly, the sodium chloride is washed out, and finally, the soap is brought into solution and likewise washed through the filter, leaving the paraffin, which is then dried at a temperature below 35° C. so as not to fuse it. The paraffin is then treated on the filter with ether, and after repeated washing with this solvent, the ethereal solution is carefully evaporated in a weighed porcelain crucible, in the water-bath, at a low temperature. The residue consisting of the paraffin is then weighed, and the stearic acid is estimated by difference. —*Journal of the Chemical Society.*

The Pharmaceutical Journal.

SATURDAY JULY 6, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE PRESENT POSITION OF PHARMACY AND PHARMACISTS.

THE privilege of grumbling exercised by Englishmen has long been proverbial; but there can be little doubt that to the disinclination for sitting down contented with things as they are, thus called by an ugly name, is due much of the greatness of which as a nation we are so proud. Therefore, it is not, perhaps, so much matter for regret that, amongst those who are for ever deprecating their particular calling as the most unprofitable and unsatisfactory under the sun, some should be found who so speak of pharmacy. It is no part of our intention to dispute the assertion of such persons; on the contrary, we feel sure that there are many who will agree with us in saying that if it be an exaggerated one, it is, on the whole, much nearer the truth than it ought to be. Nevertheless, nothing will be gained by silence respecting what has been done towards improving the trade, or by ignoring the machinery that exists for carrying on so desirable a work.

That pharmacists stand in a better position now than they did thirty years since is a proposition that would be as difficult to controvert as that the improvement is due primarily to the noble and ungrudged labours of the men who about that time founded the Pharmaceutical Society of Great Britain. And we believe that the present measure of success is only an earnest of what will be attained, should the body continue to produce men worthy of sitting in their vacated chairs.

The state recognition of the fact that the pharmacist requires a special education—a recognition obtained through the efforts of the Society that has done and is doing much to make such education possible—was a great step in advance. Although it was necessary, in order to do justice to the very proper claims of existing rights, to open the doors very wide, the effects of that necessity can last but for a time, and will ultimately cease. Meanwhile, it appears to be to the interest of all pharmacists, by assisting to keep the Society in a vigorous and healthy condition, to ensure the carrying on the work it has so well begun. To persons, who, like a recent correspondent, are able to borrow the Society's Journal weekly without paying for it, and require information as to what other return they would have for their subscription, it would be useless perhaps to offer such an argument. But, fortunately, there are those who believe that in this country, as in France and Germany, a future may be secured for pharmacy in which it will be more properly termed a profession than it is at present.

Much, however, remains to be done; and continually we are receiving letters from assistants, urging arguments and asking questions that are difficult to answer satisfactorily. We cull two or three from a communication just received. "Are our hours as "short as they might be, were our employers to work "in combination?"—"Considering the qualifications "we are supposed to possess, are we sufficiently re-"munerated for our labour?"—"Has there been, "during the last ten or fifteen years, an increase in "our remuneration proportionate to the increase of "expenditure caused by the higher price paid for "labour and material in other departments of trade?" And lastly, "What can we do to place ourselves upon "a pecuniary level with other *employés*."

To the first of these questions the employers in some districts are trying to give a satisfactory answer, and we wish them all success. To the last, the reply depends principally upon the assistants themselves. Considering what is now taking place in many parts of the country, our readers will not be surprised to learn that more than one correspondent has attempted it by suggesting a "strike."

But such a movement, doubtfully beneficial on the part of men content to base their claims upon an assumed equality of labour value, would be positively injudicious where individual acquirements and talent should exercise so much influence upon the terms of an engagement as in pharmacy. Rather let each assistant assert his proper position by exerting himself to attain that scientific knowledge of his business which is now acknowledged to be essential, and by demanding a fair remuneration for the qualifications he may possess, and he will find, if he takes care that those qualifications equal the estimate he may place upon them, that in pharmacy,—certainly not more than in any other calling,—it is not the most skilful that is left unemployed or unrewarded.

PHARMACEUTICAL EDUCATION.

THE first attempt to give a definite form to the opinions that have been current in the minds of many concerning the best method of providing pharmaceutical education in the provinces, will be found at p. 10. We hope that it will receive the attention to which it is entitled, and that in the shape of opinions, criticisms and suggestions respecting this scheme, the columns of this Journal will bear testimony to the interest with which the important subject of education is regarded by the trade generally.

A VICTIM TO SCIENCE.

We take from our contemporary, the *British Medical Journal* the following short account of a very deplorable accident by which science has sustained the loss of a young but active and promising worker:—

"Many sad reflections of much more than personal import attach themselves to the sad announcement of the death of that distinguished young chemist, Mr. E. T. Chapman, whose name is well known as one of the authors of the ammonia-process of water-analysis. He was killed by an explosion in his laboratory at Rübeland, in the Hartz, on the 25th June. Four years ago, Mr. Chapman was the most industrious contributor to the Chemical Society. He will be especially remembered by chemists for his very beautiful researches on "Limited Oxidation," and for his remarkable faculty of performing unpromising chemical operations with quantitative accuracy. Last autumn, he left England to take charge of a large wood distillery in the Hartz, and a short time ago had commenced the manufacture of nitrate of methyl on a gigantic scale. Under certain conditions, nitrate of methyl is terribly explosive; and it is supposed (for no one survives to tell what took place) that the terrible explosion which shivered a bomb-proof building, killing Mr. Chapman and two workmen who were with him, was an explosion of nitrate of methyl. Mr. Chapman was only 26 years old at the time of his death. A few years ago, it would have been deemed a strange thing for England to send out a chemist to take charge of a German factory; but that the most promising of the young chemists of England should have found no room for himself here, and should have taken service in a foreign land and perished there, is melancholy in the extreme."

Mr. Chapman is not the only young chemist of high promise who has been compelled to seek mere livelihood in uncongenial pursuits, and waste a life which might have been devoted under a more propitious fortune to the advancement of science and of civilization.

A few weeks ago we drew attention to the condition in which scientific chemistry finds itself here in England, destitute as it is of encouragement and support from Government, and, what is worse, without pioneers among the men who occupy professional chairs, though in many instances they might be expected to derive some stimulus from the historical associations by which they are surrounded.

Mr. Chapman was among those—and there are not a few such—to whom we referred, who want only means and opportunity to perform their part in restoring to English chemists the reputation which their predecessors so justly enjoyed. It would, perhaps, be an exaggeration to say in his case that

"Chill poverty repressed his noble rage,"

but it would not be difficult to find instances in which this would represent the actual and unpoetical truth. Surely there should be opportunities of extending to such men encouragment and sympathy; and we do trust that in the future some efforts will be made in that direction.

According to a return recently ordered by the House of Commons to be printed, the quantity of methylated spirit sent out by persons licensed to sell the same under the Act 18 and 19 Vict. c. 38, during the year ending 31st December, 1871, was in England, 451,530 gallons; Scotland, 232,174 gallons; Ireland, 12,331 gallons; total in the United Kingdom, 696,035 gallons. The amount of drawback or allowance paid thereon was £200,174. 11s.

A commission has been formed in Victoria, Australia, "to consider and report," in the words of the proclamation, "how far it may be practicable to introduce branches of industry which are known to be common and profitable among the farming population of continental Europe; to specify which of such industries are most suitable to the soil, climate and circumstances, and to report on the best means of promoting their introduction into Victoria, and how far the labour of persons at the disposal of the State may be advantageously used for that purpose; and to further consider and report on the best means of promoting the culture, extension and preservation of State forests in Victoria, and the introduction of such foreign trees as may be suitable to the climate and useful for industrial purposes." From the Progress Report of this commission we find that a large number of medicinal plants are proposed for cultivation, the following amongst others being recommended as quite suitable for, and hardy in the climate of Victoria: — Cinchona, Rhubarb, Aloes, Camphor, Squill, Aconite, Hemlock, Henbane, Foxglove, Belladonna, Buchu, Poppy, Gentian, Chirata, Erythræa, Jalap, Juniper, Liquorice, Uva Ursi, Veratrum, Arnica, Podophyllum, Taraxacum, Senna, Peppermint, Sarsaparilla, etc.

The commission further deems it "desirable that the Government should obtain and distribute genuine seeds of such medicinal and otherwise useful plants, and recommends the distribution of the seeds by means of advertisement." A large quantity of poppy seed was thus distributed gratuitously by a commercial firm in Melbourne, and over 1000 applications were received. A very considerable proportion of the sowings of these seeds have been attended with success in the production of opium, and we are told that it is a fact pretty certain that the poppy, in a short time, will be one of the most extensively cultivated crops in Victoria if the question of juvenile labour can be satisfactorily settled.

The Botanic Garden has effected also the extensive distribution of useful plants and seeds, at least such as are not easily obtainable in the horticultural trade. The great extension of this practice cannot but tend to create and promote new cultures, and to enlarge the resources and wealth of the country.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

July 3rd, 1872.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.
MR. W. SCOTT BROWN, VICE-PRESIDENT.

Present—Messrs. Baynes, Betty, Bottle, Frazer, Greenish, Hampson, Hills, Mackay, Owen, Radley, Sandford, Savage, Schacht, Shaw, Stoddart, Sutton, Urwick and Williams.

The minutes of the last meeting were read and confirmed.

The reporter was requested to withdraw whilst the Council considered the Report of the Committee appointed last month with regard to the reporting. After an interval, he was recalled and informed that in future his reports of the proceedings of the Council must be furnished direct to the Editor, who alone would exercise any supervision over them, and that, subject to this editorial control, he must use his own discretion in condensation or otherwise.

The SECRETARY presented a list of nine members and one associate in business who had paid their subscriptions subsequently to the 30th April, and it was

Resolved—That they be restored to their former status on payment of the nominal fine of one shilling.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Bouttell, Harold .... Sudbury.
Bradford, Cordley .... Spalding.
Jameson, William Edward .... Bristol.
Jasper, Frederick William .... Penzance.
Rammell, Edward .... Crediton.
Shenstone, Wm. Edward .... Colchester.
Townley, Thomas William .... Ambleside.
Warren, William .... Chertsey.

ELECTIONS.

MEMBERS.

The following Pharmaceutical Chemists were elected Members, and their diplomas were stamped with the seal of the Society:—

Hughes, James .... Sydney.
Wilson, John Henry .... Calcutta.

The SECRETARY drew attention to the fact that the two newly elected Members were resident abroad, and stated that the general practice in such cases was for the gentlemen elected to pay the first year's subscription only. He suggested that foreign members should be required to pay a life membership subscription.

Mr. SANDFORD and other gentlemen were of opinion that the Council had no power to make such a regulation. If Members residing abroad discontinued their subscriptions, they would be treated in the ordinary way, and required, in accordance with the Bye-law, to return their certificate of membership.

The following registered Chemists and Druggists were elected Members of the Society:—

Cocker, Benjamin .... London.
Folkard, George Frederick .... Putney.
Goddard, William Henry .... Barrow-in-Furness.

ASSOCIATES.

The following, having passed their respective examinations and being in business, were elected "Associates in business" of the Society:—

Minor.

Adams, Frederick Joseph .... Dover.
Foottit, Charles M. .... Marlow.
Howse, Henry William ...... London.
Upjohn, Francis William .... London.

Modified.

Hepburn, John .... London.

The following, having passed their respective examinations, were elected Associates of the Society:—

Minor.

Bonnett, Frederick .... Bridgend.
Brookes, Frederick James .... Selby.
Colling, Robert .... Stockton-on-Tees.
Dunston, Alfred .... Spalding.
Goldsmith, John Jackson .... Abingdon.
Greaves, Abraham Walter .... Chesterfield.
Jones, Owen Williams .... Flint.
Leake, Thomas Whaplate ...... London.
Newton, Thornton Albert C.... Devonport.
Tansley, Arthur James ...... Cheadle.
Thirlby, William Arthur ...... Ashby-de-la-Zouch.
Watson, William .... Chatham.

Modified.

Binge, Alfred .... Islington.
Biss, John William .... Southsea.
Gorton, Charles .... Whitechapel.
Hilton, William .... Whitefield.
Kitchen, George Seaton ...... Stamford.
Knight, Geo. Edward Moses .. Southampton.
Pride, Arthur Edwin .... Nottingham.
Prytherch, Rees .... Llandovery.

FINANCE COMMITTEE.

The Report of the Finance Committee was received and adopted, and sundry payments ordered.

BENEVOLENT FUND.

The Report of the Benevolent Fund Committee was received and adopted.

Grants of fifteen pounds were made in each of the following cases:—

A registered Chemist and Druggist at Sheffield (2nd grant).
The widow of a late Member at Tring.
A former Member of the Society at Clapham.

The names of George Bagot Kennett and Sophia Pedley Henson were placed on the list of candidates for election as Annuitants in October next.

LIBRARY, MUSEUM AND LABORATORY.

The Report of the Library, Museum and Laboratory Committee was received and adopted, and the following books were ordered to be purchased for the Library:—

Index to Gmelin's Chemistry.
Thudichum's Chemical Physiology.
Smith's Air and Rain.
Stockhardt's Experimental Chemistry, by Heaton.
Marcet's Natural Philosophy.
Atkinson's Natural Philosophy (from Ganot).
Tyndall's Molecular Physics.
Tyndall on Sound.
Nicholson's Biology.
Masters' Botany for Beginners.
Gladstone's Michael Faraday.
Church's Laboratory Guide, 2nd edition.
Grove's Correlation and Continuity.
Mitchell's Practical Assaying, by Crookes.
Hardwick's Photographic Chemistry, 7th edition, by Dawson and Hadow.
Griffith's Textbook of the Microscope.

HOUSE COMMITTEE.

The Report of the House Committee was received and adopted. It recommended improved arrangements for the better custody of Students' coats, etc.; and that estimates be obtained for certain repairs, repainting, etc.

Provincial Education Committee.

The Report of this Committee was read, recommending that the following document, drawn up by Mr. Schacht, be in principle adopted by the Council:—

Principles.

1st.—It is desirable that scientific pharmaceutical education throughout the country be promoted by the Pharmaceutical Society of Great Britain, and be assisted by its funds.

2nd.—It is desirable that such assistance be given to those efforts only that are directed to the *systematic* and *persistent* teaching of the sciences connected with pharmacy.

3rd.—It is desirable that such assistance be distributed upon a method as far as possible just and universal.

Scheme.

The Council of the Pharmaceutical Society of Great Britain shall announce that they are prepared to propose an annual vote of money for the purpose of assisting scientific pharmaceutical education throughout the country upon conditions to be enumerated below.

The plan upon which this assistance will be given will consist, essentially, in affording a limited and partial aid or stimulus towards founding and maintaining local pharmaceutical educational associations.

The sciences towards instruction in which aid will be given are chemistry, botany and materia medica.

The processes through which this aid will be given are:—

1st.—Examinations to be held at all places whose local pharmaceutical associations have applied for aid, and which have fulfilled the requisite conditions.

2nd.—Payments of money to the local pharmaceutical associations on the result of these examinations and donations of prizes to the competing candidates.

3rd.—Grants towards the fitting up and illustration of the libraries, museums and laboratories of local pharmaceutical associations, or for any portions of their schemes which have a scientific educational object.

*General Details.**

Every local pharmaceutical Association claiming aid from the Pharmaceutical Society of Great Britain must have been enrolled as "an association in connection" with it at least three months before the date of the annual examination.

The conditions of enrolment shall be that it be a *bonâ fide* association of chemists and druggists, acknowledging a fixed set of rules and a money subscription for membership; that it possess a responsible committee of chemists and druggists whose names are on the register, a chairman and a secretary; that it includes in its scheme courses of lectures by competent teachers upon chemistry or botany, for the use of its members and associates, of not less than twenty-five lectures, on different days, of one hour's length; and that it is prepared to carry out in its integrity the educational system of the Pharmaceutical Society.

The Pharmaceutical Society of Great Britain will hold annually, about May, through the agency of the enrolled associations, examinations in chemistry and botany in any place in England, Wales, and Scotland, from which a proper application has been received. On the results of these examinations payments will be made to the enrolled associations, and prizes will be awarded to the students themselves.

There will be two grades of success, the first and the second. All candidates who succeed in passing in the second or lowest class will earn for the association with which they are connected £1 each; all who pass in the first class, £2 each. All who pass in the first class will also earn for themselves a prize.

Persons eligible to earn prizes and payments for results will be chemists and druggists, their apprentices, pupils and assistants, with the exception of such as have passed the Major or Minor examination of the Pharmaceutical Society of Great Britain.

Students presenting themselves for examination in the same subject a second or third year will still be considered as entitled to earn payments for results; but if they have already earned one payment, subsequent payments earned in the same subject will be one-half the original amount, and will not be repeated beyond the third payment; nevertheless students may present themselves for examination in any subject as many times as they please.

Payments for results and prizes will only be awarded where the evidence is sufficient to show, on the one hand, that good systematic teaching has been supplied, and, on the other, that the candidate has been a diligent student. It will be necessary, therefore, in the first case, that the local associations are careful to provide really efficient teachers, and that a proper daily record be kept of the pupils' attendances at each lecture. Forms for these purposes (   ) will be supplied, which must be returned when application is made for examination papers. It will be imperative that at least twenty lectures shall have been attended by each candidate.

Examinations.

When an enrolled association wishes to participate in the aid granted by the Pharmaceutical Society, an application, stating on what subject or subjects examination will be required, and giving the precise number of candidates to be examined in each subject, must be made by the secretary of the enrolled association on a printed form (   ) and sent to the Secretary of the Pharmaceutical Society   days before that fixed for the examination.

The local association will then provide a proper room with the requisite accommodation for carrying out the detailed instructions which will be sent them (   ), and a committee, consisting of the secretary and one other responsible chemist and druggist, not personally interested in the result (but not the teacher), must attend in the room throughout the examination to see that perfect fairness prevails, and that the printed details are absolutely complied with.

On the morning of the day appointed for the examination a packet containing the lists of questions, one for each student, will be received by post by the secretary of the local association, which packet must be opened for the first time when all are assembled in the examination-room and the candidates are in their places. The answers will be collected, enclosed in one wrapper, sealed and forwarded by post to the Secretary of the Pharmaceutical Society.

Instructions for the exact guidance of the committees and candidates during examination will be forwarded at the proper times.

The examination on either subject will be conducted in every locality throughout the country on the same day and at the same hour.

The answers will be examined, and their values estimated, as speedily as possible, and the list of successful candidates will be published in the Pharmaceutical Journal, no mention being made of those who do not succeed in passing.

The claim for payments must be made on a printed form (   ) to be supplied on application. It must be signed by the chairman and secretary of the local association, and forwarded to the Secretary of the Pharmaceutical Society within one month of the time of pub-

* These details are to be understood as incomplete.

lishing the examination-lists; and if found to be correct, the money will be forwarded to the secretary of the local association.

Prizes.

The prizes for those candidates who pass in the first class will consist of books. Candidates will be at liberty to select their own prizes from a list published in the Pharmaceutical Journal.

In addition to these, there will be three medals distributed annually in each subject,—one gold, one silver, and one bronze,—to those whose papers stand respectively first, second and third in order of merit throughout the country, provided the examiners consider them sufficiently excellent to justify such a recognition.

Examiners.

The Council of the Pharmaceutical Society of Great Britain shall appoint a professional chemist and professional botanist to conduct the examinations in their respective sciences. They will be in no way engaged in teaching any class of pharmaceutical students nor be personally interested in the result of the examination.

It will be the duty of the examiner to frame a list of questions, to each of which he will attach a certain numerical value, and he will do his best to keep the questions he has selected a perfect secret.

When the answers are returned to him he will estimate their values also in figures, and those candidates who have earned an aggregate number of marks equal to 80 per cent. of the highest possible number will be placed in the first class, and those whose marks are less than 80 per cent., but equal to 50 per cent., will be placed in the second class. The rest will be considered to have failed.

The examiners will report to the Council the general character of the replies, and will present the names of the successful candidates with the number of marks they have respectively earned.

The fees for the professional services of the examiners will be paid by the Council of the Pharmaceutical Society of Great Britain.

Grants for Museums, etc.

The Council of the Pharmaceutical Society shall have the power to award a grant of money, to the extent of one-half the required expenditure, to any enrolled association in aid of any portion of their scheme which shall have a distinct scientific educational object. For this purpose every application will be judged of on its own merits.

Mr. Schacht having read the above, to the end of the "Scheme," said that the details which he had appended were not to be considered as complete, and it was the opinion of the Committee that if the general principles were adopted by the Council, they should be referred back to the Committee for further consideration and completion. It was also hoped that by the publication of the paper he had prepared, the suggestions of members throughout the country might be available for the Committee. He moved—

"That the Report be received and adopted; that this Council approves generally the principles and scheme presented, and refers the same back to the Provincial Education Committee for further consideration and report."

Mr. Stoddart said he could heartily commend the principle of the scheme, particularly as it did not countenance the idea which was far too prevalent, that young men should be coaxed into study and improvement. The real principle was to afford every facility possible to those who really wished to improve themselves, and therefore, the scheme now brought forward was admirable, if it was considered to go far enough.

Mr. Hills thought the only fault in the scheme was that it was not liberal enough. He did not think they should require from every town a complete account of all the results that had been accomplished, and that if a certain number of men known to the Council would guarantee that the funds should be applied to the object of Pharmaceutical Education, that was all that was required. Referring to his own experience, he had gained more information from a small class to which he belonged than from any other source. If any amount were raised in any locality for the purpose of education, he thought it should be augmented by the Society to a certain extent, either by one-half or one-third of the amount locally raised. He hoped, therefore, that when the Committee reconsidered the details, they would be rather more liberal.

Mr. Baynes heartily endorsed the scheme in its general principle, but suggested that a small capitation fee should be given to associations for students who had attended the classes a certain number of times.

Mr. Brown remarked that the last sentence of the scheme left it open to the Council to make a grant to any association, however small. He thought the system of payment for results would get over the difficulty, which always met them, that the money of the Society might be bestowed on persons who never contributed anything to its funds.

Mr. Mackay also approved of the scheme, though he doubted the propriety of employing lecturers.

The resolution was then carried unanimously.

Parliamentary Committee.

The Report of the Parliamentary Committee was read, stating that they had considered the correspondence with reference to the registration of certain persons as chemists and druggists, and recommended the Council to give the Registrar the necessary authority to remove their names from the Register. The details of several cases were given, in one of which the Solicitor having written to the party concerned, and received no reply, it was recommended that proceedings be at once taken against him for selling poisons, etc., he not being registered as a chemist and druggist. In another case the excuse made was that the party was a homœopathic chemist, and it was recommended that evidence be obtained of his having sold poisons. The Committee also recommended the immediate readjustment of the schedule of poisons with regard to Vermin Killers, and that the first convenient opportunity be taken for obtaining the sanction of the Privy Council thereto.

Mr. Williams regretted that the Committee had not seen their way to recommend proceedings being taken against a surgeon whose false and improper representations had led to the registration of one of the parties now about to be removed.

Mr. Betty thought the nature of the readjustments of schedules should be mentioned.

The President said that was not stated in the Report of the Committee.

Mr. Williams suggested that the last clause of the resolution respecting Vermin Killers should be omitted. This was a very important matter, and the practical result of altering the schedules and putting strychnine in part one, would be to prohibit the sale of Vermin Killers containing such compounds by booksellers, stationers, and other persons not on the Register. This would have the further effect, that Vermin Killers containing those substances would fall into disuse, and only those would be sold containing phosphorus or other poisons. This was a very serious thing effecting the trade and commerce of the whole country, and he hoped it would not be done without consideration.

Mr. Schacht said if the Committee had come to a distinct conclusion, it ought to have been included in the report; and as they had not done so, it must go back to them again.

Mr. Brown said at the last meeting the Council had decided that the Solicitor should be asked to draft a new bye-law which would have the effect of preventing any motion being brought forward at an annual meeting that would affect the legal position of the members without previous notice having been given. The Solicitor had drafted three new bye-laws which he would not now trouble the Council with; but he would move

> "That the proposed additions to the bye-laws, as drafted by Mr. Flux, be referred for consideration to the Parliamentary Committee, who shall also report as to the desirability of an alteration in the bye-law which requires voting-papers to be delivered by post one clear day previous to the annual meeting; also as to any other bye-laws which appeared to require addition or alteration."

Mr. Shaw seconded the resolution, and said he had noticed the inconvenience of the bye-law referred to, which often had the effect of rejecting a considerable number of voting-papers.

The resolution was carried unanimously.

The Report was then received and adopted.

The following names were ordered to be erased from the Register:—

Harriet Buxton ....New Cross.
Thomas Taylor ....Skelton-in-Cleveland.
Shemelds Taylor ....Skelton-in-Cleveland.

REPORT OF THE BOARD OF EXAMINERS FOR ENGLAND AND WALES. JUNE, 1872.

Examinations.	Candidates. Examined.	Passed.	Failed.
Major	13	8	5
Minor	42	26	16
Modified	44	27	17
	99	61	38

Preliminary—Certificates received in lieu of this examination:—

University of Cambridge	2
,, ,, Durham	1
,, ,, Oxford	1
College of Preceptors	2
	6

The President read a letter from a candidate at the recent Major Examination, complaining of the manner in which that examination had been conducted, and asking that he might be allowed to compete for the Pereira medal, notwithstanding that he had not passed with honours.

A considerable amount of discussion ensued, but the general feeling of the Council was, that they could not interfere with the decision of the Board of Examiners.

Appointment of Professors.

Professor Redwood was re-appointed Professor of Chemistry and Pharmacy for the ensuing year.

Professor Bentley was re-appointed Professor of Botany and Materia Medica for the ensuing year.

Professor Attfield was re-appointed Professor of Practical Chemistry and Director of the Laboratory for the ensuing year.

William Augustus Tilden, D.Sc., was re-appointed Demonstrator for the ensuing year.

Mr. John Moss was re-appointed Assistant Demonstrator for the ensuing year.

Mr. Urwick said the expense of the laboratory was a great weight upon the Society, and he believed ten years ago, when the expenses were very much less, better results were shown.

Mr. Williams said he had paid a deal of attention to this subject, and would remind Mr. Urwick that, although the laboratory for the past year had not quite paid its expenses, on taking the average for the last few years, it had been a paying part of the institution; that is to say, it received as much from the students as was expended on the professors and demonstrators.

Mr. Collins was re-elected curator.

North British Branch.

The lease of the new premises at Edinburgh for the use of the North British Branch of the Society was submitted by the Solicitor to receive the seal of the Society, and it was ordered to be appended. Mr. Mackay explained that the Society would not take possession until November, in consequence of the damp weather in the spring having prevented its being in a fit state to receive their specimens and books, which had accordingly been stored in the meantime, and a temporary room was taken when required for examinations. He added that they had power under the lease to leave at the expiration of a year and a half if the rooms were not found suitable.

Benevolent Fund Investment.

Mr. Baynes moved the following resolution, of which he had given notice:—

> "That the sum of £10,000, or thereabouts, part of a large sum now standing to the credit of the Benevolent Fund, in Consols, be invested in real securities, so as to produce a higher rate of interest, and that the Finance and Benevolent Fund Committee be requested to inquire, and if necessary, confer with the Solicitor, as to the best means of carrying out this resolution, and to report to the Council."

He said that the bye-laws restricted the investment of the funds to Government and real securities, or he should have wished that a wider scope could have been given to them, and that Perpetual Preference Railway Stock or India Bonds might have been purchased. Therefore, if any alteration were made in the bye-laws, as was contemplated by the previous resolution, that might be taken into consideration at the same time; but at any rate he thought they should endeavour to get the largest interest possible, compatible with perfect safety, on the moneys invested for the benefit of the Benevolent Fund.

Mr. Shaw seconded the resolution, saying it had often occurred to him that they might get a much larger amount of income than they did from their investments. He had made inquiries in Liverpool with regard to one of the largest insurance companies there, and found that they had invested nearly a million and a quarter of money on mortgage of freehold and leasehold property, yielding 4 per cent.

Mr. Sandford said he objected, as a matter of principle, to dabbling with any other than Government securities, and he was glad to find they were restricted as to investments. He would prefer that the Council veto the matter at once.

Mr. Brown said the better way would be to refer it to the Finance Committee.

After some further conversation the resolution was withdrawn, and the following substituted, which was carried unanimously:—

> "That it be referred to the Finance Committee to consider whether any more eligible investments can be found for the capital of the Benevolent Fund than at present, and to consult the Solicitor thereon and report to the Council.".

The Journal Accounts.

The Secretary read some correspondence which had passed between himself and Mr. Wootton, Editor of the *Chemist and Druggist*, the latter having applied to know whether the accounts of the Pharmaceutical Journal, both during its monthly and weekly publication were open to the inspection of members, and, if so, at what time it would be convenient for him to inspect them; the answer returned to him being that the matter would be submitted to the Finance Committee.

Mr. Shaw said the question was simply whether any member had a right to inspect the account books of the Society, which he presumed was not the case.

Mr. SUTTON said if there was a printed statement of accounts vouched by the auditors, that might be shown to any Member, but he apprehended that nothing further could be seen. They did not wish to keep anything back which ought to be properly open for inspection; they could not, however, have any one looking through their books for all manner of details.

The PRESIDENT said he had examined carefully the Bye-laws and found nothing which gave any Member a right to demand an inspection of the books. As a matter of courtesy he opined that a Member would not be refused an opportunity of looking at the statement of accounts referring to any particular subject, but they could not admit the principle that anybody might come and examine the weekly and monthly Journal accounts.

It was ultimately decided that the printed statement of accounts as passed by the auditors for the last year should be sent to Mr. Wootton.

Mr. BROWN then moved—

"That the best thanks of the Council be given to Mr. Schacht for the scheme for aiding education which he has framed and submitted for consideration; and that a copy be forwarded to every Local Secretary, and published in the Journal."

He said that Mr. Schacht had been at considerable personal expense in this matter; and it was extremely undesirable that any further burden should be thrown upon him. It ought at once to be taken up by the Council and sent out to the Local Secretaries, when he had no doubt that many valuable suggestions would be received by the Committee who would aid them in their future action in the matter.

Mr. BAYNES thought this was a very proper course, and said no doubt the Local Secretaries would communicate with the leading men in the trade, and ascertain what their feeling was, and the Committee would gain valuable information in that way.

The resolution having been seconded, was carried unanimously.

The PRESIDENT stated that he had received from the Société de Prévoyance des Pharmaciens de la Seine a gold medal presented by that Society to the subscribers to the Fund raised for the benefit of the pharmaciens who sustained losses during the Franco-Prussian War. It was resolved—

"That the medal be accepted on behalf of the subscribers to the Fund, and thus become the property of the Society."

Proceedings of Scientific Societies.

SOCIETY OF BIBLICAL ARCHÆOLOGY.

At the meeting of this Society, on Tuesday, July 2, a paper "On the Economic Botany of the Bible" was read by Mr. James Collins, Curator of the Museum of the Pharmaceutical Society. The author began with some remarks on the obscurity in which the subject was involved from the lapse of time, philological and other difficulties rendering it in many cases almost impossible to identify the substances mentioned with those known to us at the present time. The literature, from that cause and from the great interest at all times taken in everything pertaining to the Holy Land, is exceedingly voluminous, and the various statements very conflicting. He then treated the subject under the general heads of—1. Food plants. 2. Medicinal plants. 3. Textile, dyeing and other industrial plants. 4. Plants used in perfumery and incense; and 5. Miscellaneous substances, and concluding remarks. Under these heads the history, uses, etc., of the following substances amongst others was given:—Aloes, Almonds, Balm of Gilead, Bedellium, Calamus, Cassia, Cinnamon, Colocynth, Frakincense, Gall, Galbanum, Lign-Aloe, Mannas, Myrrh, Olive Oil, Palm, Pomegranate, Ricinus, and Spikenard. The paper was abundantly illustrated with specimens of many growing plants, supplied by Messrs. Vietch, and also of the various substances mentioned.

Other papers were also read, "On the Mazzoroth of Job xxxviii., 32," by H. Fox Talbot, D.C.L., F.R.S, and "On the use of Papyrus among the Accadians," by the Rev. A. H. Sayce, M.A.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Public Health Bill.

Thursday, June 27th.

On the motion for going into Committe on the above Bill,

Mr. Stansfeld proposed to commit the Bill *pro formâ* in order to omit some clauses and to insert some amendments.

The House having resolved itself into Committee,

Mr. Sclater-Booth asked for an explanation of the object of the proposed amendments.

Mr. Stansfeld suggested that it would be more convenient for members to judge of them when the Bill had been reprinted. The amendments where mainly based upon suggestions made by hon. members, or deputations which had waited upon him.

Mr. T. Collins thought an assurance should be given that the amendments did not substantially alter the character of the Bill.

The Bill then passed through Committee *pro formâ* with amendments, and the House resumed.

Friday, June 28th.

Mr. Rylands asked the President of the Local Government Board if it was the intention of the Government to proceed with the Public Health Bill this session, and, in that case, if it was proposed to withdraw any of the provisions contained in the Bill.

Mr. Stansfeld said it was unquestionably the intention of the Government to proceed with the Public Health Bill. The Bill was committed *pro formâ* last evening for the insertion of certain amendments. He had unwillingly come to the conclusion that, considering the advanced period of the session and the pressure of public business, it was necessary, in the interest of the bill itself, to do what was sometimes called throwing part of the cargo overboard. He had examined the Bill in order to see what sacrifices it was necessary to make in order to ensure the passing of the Bill. The House would remember that last year they consolidated certain departments of the measure with the Central Government Bill. The Bill as it stood might be divided into three parts, one consisting of provisions organizing the local sanitary authorities, followed by the body of the Bill giving new powers to and imposing new duties upon those authorities; and then came a number of miscellaneous clauses, giving facilities for the proceedings of the local authorities. It appeared to him that the best course would be to stop this year with the creation and consolidation of the local authorities, and to withdraw from the Bill all the clauses relating to nuisances, hospitals, river pollutions, and other matters.

In reply to Mr. Corrance,

Mr. Stansfeld said it was not possible to fix a day for the Committee till the Mines Bill had been disposed of.

Adulteration of Food, Drugs, etc., Bill.

Wednesday, July 3rd.

The House went into Committee on this Bill, but, on the motion of Mr. Rylands, progress was immediately reported.

Poisoning by Cyanide of Potassium taken in Mistake for Medicine.

On Tuesday, June 25th, an inquest was held at the Queen's Head, Chelsea, respecting the death of Mr. John King. Deceased, who was under medical treatment, had his medicine bottle in the bar, and on taking a dose became suddenly faint and died in two hours. It was then found that some cyanide of potassium had been put into an empty medicine bottle, and the label, "To be taken every four hours," left upon it. Edward Jennings, potman to deceased, said he had been in the habit of obtaining twopennyworth of cyanide of potassium about once a month, from Mr. Pasmore, chemist, for Mr. Edward King, who used it for cleaning the metal work of the refrigerator in the bar. The mixture, up till Tuesday in the previous week, always used to be made and kept in a very old dirty bottle, but the regular bottle was then broken. Mr. Edward King, being asked by the coroner how the cyanide of potassium came into the medicine bottle, said, "I put it into that when the other bottle was broken last week. It was a fresh lot that I made up. I took it out of the locker about a quarter after six in the morning, and put it on the shelf to clean the refrigerator with, when it got cool after breakfast. My father must have come in and put his medicine bottle by the side of that, and then taken up the poison bottle in a mistake, but he always knew that we used the cyanide of potassium three times a week, and always on a Saturday. The Jury returned a verdict of Accidental Death.—*Standard.*

Death from an Overdose of Morphia.

On Thursday evening, July 27th, an inquest was held at Morecambe by the coroner, Mr. Holden, upon the body of Mrs. Elizabeth Townsend, whose death was stated to have been caused by an overdose of morphia.

Mr. Tilly watched the inquiry on behalf of the assistant of Mr. Birkett, chemist and druggist.

Miss Ann Lester deposed: The deceased was my aunt and I lived with her. She has been invalided for some years, and for the last three years and a half has been attended by Mr. Metcalfe Johnson. He has sometimes sent medicine from Lancaster, and occasionally written prescriptions. On Tuesday night, about ten minutes past seven o'clock, he saw deceased, and about eight we received some medicine from Mr. Birkett's. It consisted of a small box of pills and a lotion. A boy brought the medicine, and I took it in. I gave my aunt one of the pills about five minutes afterwards. I did not notice that it had any effect upon her for about half an hour, when she said she felt sleepy, and in about ten minutes after that she fell asleep. At ten o'clock I left her for the night. Some time early in the morning my uncle called me to her again. Mr. Metcalfe Johnson was then with her. I remained with her until she died. She never spoke whilst I was with her that I am aware of, and she died about half past six. I did not give her any other medicine besides the pill. I gave the box to my uncle when I had done with it.

Mr. John Townsend, lodging-house keeper, deposed: The deceased was my wife; she was 62 years of age, and had been invalided for the last 20 years. For about three years and a half she had been attended by Mr. Metcalfe Johnson. I went for him on Tuesday morning, and he came between seven and eight o'clock in the evening. He left no medicine with me, but some was left afterwards by Mr. Birkett's boy. My niece subsequently gave me the box, and I returned it to Mr. Birkett's assistant, who came for it about eleven o'clock on Tuesday night. My niece left us about ten, and I shortly afterwards went to the room where the deceased was. I did not notice anything particular in her breathing, until about a quarter of an hour before Mr. Birkett and Mr. Johnson came. Mr. Johnson used means to rouse her, and a messenger was sent to Lancaster for further aid. Mr. Christopher Johnson came a little before four in the morning. She opened her eyes twice, and exclaimed "Oh, dear," and about six o'clock she died.

By Mr. Tilly: About a quarter of an hour elapsed between the intervals of her exclaiming "Oh, dear!"

Mr. John Birkett deposed: I am a registered chemist residing at Morecambe, and Wm. Edmondson is my assistant. He was an apprentice, and is now an assistant, having been with me upwards of eight years. I have been in the habit of making up prescriptions for Mrs. Townsend, given by Mr. M. Johnson. My assistant informed me on Tuesday evening that Mr. M. Johnson had left a prescription to make up, and I told him to make it up. I went out on business for about a quarter of an hour. The medicine was sent out in the ordinary way. Shortly before ten o'clock I discovered that a mistake had been made. Mr. Townsend came and asked, "Shall I be doing right to repeat those pills at eleven o'clock?" [Box produced, the directions being, "One directly, and repeat every four hours until free from pain or sickness."] I called my assistant, and said, "Let me see that prescription." I read it, and found that the dose was one-sixth of a grain for each pill. I told him that he might repeat it if necessary, according to the directions. He mentioned that she had gone to sleep, and said he supposed there would be no harm in it. I said "None whatever." He asked if they were sleeping pills, and I told him they were. After a conversation about the strength of the dose, Mr. Townsend left. Shortly after he had left, my assistant told me the pills contained one grain of morphia each. I knew that Mrs. Townsend was in a very weakly way, and I thought that the dose might be too large for her. I considered it over, and the conclusion I came to was that it would be best to go for Mr. Metcalfe Johnson. I took a cab and went for him, leaving here about a quarter past eleven. I reached home about twenty-five minutes past twelve, and Mr. Johnson came down about a quarter of an hour afterwards. I accompanied him to Mr. Townsend's. Further medical assistance was sent for, and Mr. Christopher Johnson arrived about a quarter to four. She never spoke while I remained, but opened her eyes once or twice. I keep the morphia in a cupboard where all the more active poisons are kept. I know morphia to be an active poison.—By Mr. Tilly: The prescription reads literally, "Take of the acetate of morphia one grain; let six pills be made; one directly, and repeated every four hours until free from pain or sickness." The prescription does not say literally, "Let six pills be made of it," but "Let six pills be made." It is mostly usual to say that the ingredient is to be divided into so many pills, and it would have been a greater safeguard to have said so in this instance. When I read it I saw at once it meant one-sixth of a grain in each pill, taking the prescription as a whole. I have known doses of a grain given. I considered the prescription was perfectly intelligible, but it would have been better to have said the morphia was to be divided into so many pills.

Wm. Edmondson deposed: I am assistant to Mr. Birkett. I have not gone through my examination to qualify myself as a chemist, but am preparing for it. I served my apprenticeship with Mr. Birkett, and have been with him about eight and a half years altogether. I have made up prescriptions for Mrs. Townsend before, but not recently. On Tuesday evening I received the prescription produced from Mr. Metcalfe Johnson. He asked me if I could make it out. I read it, and replied, "Yes." After some verbal directions about the lotion, which I wished particularly to understand, Mr. Johnson pointed to the first part of the prescription relating to the pills, and I understood him that I had to put one grain of morphia in each of the six pills. Immediately on getting into the shop, I wrote down the directions about the lotion, and I then began to make the pills. The box produced contains the remainder of the pills, and they contain one grain of morphia each. I know morphia to be an active poison, and I understood Mrs. Townsend to be dangerously ill; but not in a weakly state. I do not remember ever having previously made up pills containing a grain of morphia each. I knew Mrs. Townsend was suffering from dropsy. When I had made up the pills, I sent them by our boy. About ten o'clock, I was in the shop when Mr. Birkett and Mr. Townsend had some conversation together. Almost immediately after Mr. Townsend had left, I told Mr. Birkett what the pills contained. He replied that it must be a mistake, as Mrs. Townsend was in a very weakly state. He said, "We had better get the pills back, before another dose is given." I went to Mr. Townsend and got the pills back, just as he had reached home.—By Mr. Tilley: There is another form of prescription when we have to make up pills. It says, "Take the quantity, and divide into so many pills."

At this stage of the examination, the inquest was adjourned until Saturday.

On Saturday William Edmondson was re-called. He produced the authorized British Pharmacopœia, in which from one-eighth to half a grain of morphia was prescribed as a dose. He said he knew the book by heart from end to end, and that the extent of the dose according to the Pharmacopœia was half a grain. It did not occur to him until afterwards—when Mr. Townsend came to ask about repeating the dose—that one grain was too much to give. He supposed the reason why it did not occur to him at the time, was that his mind was absorbed with the lotion part of the prescription more than with the pill portion, inasmuch as there were some special verbal directions to attend to.

Mr. Metcalfe Johnson said: I have attended Mrs. Townsend two or three years, or more. She was suffering from dropsy produced by a combination of diseases. On Tuesday last I saw her at six o'clock in the evening. I prescribed for her; the prescription produced being the one I wrote out. I took it to Mr. Birkett's shop, and saw his assistant, William Edmondson. I gave him verbal directions, and intended to convey to his mind that the grain of morphia was to be divided into six pills. He asked no questions upon it, and I left it in his hands to be made up. One grain of morphia is an unusual dose, and only prescribed in very rare cases. I have occasionally left my prescriptions at Mr. Birkett's to be made up. I have not before left any similar prescription at Mr. Birkett's. The morphia was given to alleviate pain, and it is well known that an overdose produces certain death. Children and aged or infirm persons are particularly susceptible of its influence. A little before twelve o'clock the same night Mr. Birkett came to me at Lancaster, and told me what had occurred. I followed him to Morecambe almost immediately. I applied galvanism externally, ammonia through the nostrils, and hot coffee through the mouth. I sent for Mr. C. Johnson at two o'clock in the morning, and he brought additional galvanic apparatus to my aid, but all the means used were of no avail; we never restored the patient to thorough consciousness. The mere exclamation "Oh, dear," twice, I don't consider as consciousness in my sense of the term. She died, I think, about seven o'clock in the morning. The symptoms throughout the night were very pronounced, leaving no doubt that she was suffering from an overdose of morphia. The eyes were for the most part closed, and the breathing was slow—about six times in one minute, instead of twenty. Yesterday I made a *post-mortem* examination of the body, in conjunction with Mr. C. Johnson. I first opened her head and found the membrane very much congested, not very firmly adherent. The brain substance was softened, owing to *post-mortem* changes. There was an excess of fluid in the ventricles, and a large number of bloody points apparent on the section of the brain, showing that the whole organ was much congested. On examining the abdomen I found an enormous tumour, probably weighing between 20lb. and 30lb., which was adherent to the walls of the stomach, parts of the intestines, and the abdominal walls. The lining membrane of the stomach was congested, owing to *post-mortem* changes, and contained a coloured fluid it was not possible to analyse. The liver also contained cysts, and was much congested. The heart was remarkably thin, very soft in texture, and the valves healthy. The lungs were compressed but not congested. All these symptoms made the system peculiarly susceptible to morphia. The condition of the brain corresponded with the symptoms during the last part of her life as to induce me to consider that the immediate cause of death was the action of morphia. The prescription produced is written in an usual form, and written in such a way that I thought it to be quite incapable of being misunderstood. It is not so common to put the word divide in prescriptions as the form I have used. The deceased was not in the habit of taking morphia, and the first dose, would, therefore, act more powerfully. I produce a copy of the certificate of death. In that certificate I attribute death to dropsy from diseased liver, accelerated by an overdose of morphia.

By Mr. Tilly: Deceased could not have lived very long, but I did not consider her on her death-bed. She might have lived a month, or it might only have been a day. I considered her recovery beyond all hope. In the certificate I gave I ascribed death to have resulted from dropsy from diseased liver, accelerated by an over-dose of morphia. In my evidence I ascribe death to the action of the morphia. I have known Edmondson for six or seven years—in fact, I think almost as long as he has been in Mr. Birkett's employ. I have many times had communication with him in the course of my profession, and have found him of fair ability, and intelligent in his business. It is usual to mention in the prescription the material of which the pills are to be made, but it is not usual to say divide. I gave him verbal directions as to dividing the morphia into six pills. It is quite possible that Edmondson misunderstood my verbal directions. It might have made the prescription more plain to have said divide. The remedies were applied immediately I arrived at the house. A grain of morphia is not an unusual dose, but that quantity is not often administered in a pill. A grain of morphia would not kill a healthy person. In cases of delirium tremens two grains are sometimes given. The verbal directions about the lotion were very special.

By the Coroner: I have been 25 years in actual practice and never recollect prescribing a grain of morphia in one dose.

Mr. Tilly, in addressing the jury, said that he hardly thought that the evidence which Mr. Johnson had given that day was reconcilable with the cause of death as stated on the certificate, and the matter would be fresh in his mind at the time he made out the certificate. Mr. Johnson then stated that deceased had died from dropsy, accelerated by an over-dose of morphia, but in his evidence that day he stated that death had resulted from morphia. Supposing the latter supposition to be the correct one, they must all agree that the drug had been administered by mistake, and therefore, he contended, they would be justified in returning a verdict to the effect that death had occurred through misadventure. He thought every one would absolve Mr. Birkett from all blame whatever in the matter; it was not to be expected that Mr. Birkett could personally superintend, or personally make up, all prescriptions that came to his shop,—it would be an impossibility for him to do so; but he had provided an assistant whom they had heard described as possessing full average ability and intelligence for the situation in which he was placed—a young man whom he had had in his employ for eight years—and it might therefore be assumed that Mr. Birkett had done everything that was necessary for the requirements of his customers, and consequently that not the slightest blame or negligence could be attached to him. He thought it was a misfortune that any special directions were given at all; suppose the prescription had been handed over to some one else to make up, what would have become of the verbal directions? The prescription should have contained all that was necessary, and nothing been left to intentions; for it was the verbal directions that the young man had misunderstood. Lamenting as they all did, the painful occurrence, they must nevertheless, be satisfied with the conduct of Edmondson, which had been consistent and straightforward throughout. Supposing he had said nothing about it directly he had found out his mistake, but had got the pills back again and destroyed them, how would they have been able to prove anything against him? But, on the contrary, he came before them and told them candidly how the mistake had occurred—that he had misunderstood the verbal direction which had been given to him. Mr. Tilly concluded by stating that the form of prescription was to his mind somewhat ambiguous, and contended that under the circumstances the jury would be justified in returning a verdict to the effect that deceased had died from dropsy, accelerated by a dose of morphia administered by misadventure or accident.

The coroner very carefully summed up the evidence. He agreed with Mr. Tilley that the certificate as to the cause of death, and the evidence which Mr. Johnson had given that day, were inconsistent with each other. In the first instance, Mr. Johnson was of opinion that death was simply accelerated by morphia; but that day he stated that the immediate cause of death was from the action of the morphia. It was only fair to remember that he was able to speak with more certainty on the latter point from the *post-mortem* examination which he had made. He thought no one could charge Mr. Birkett with any negligence in the matter; he did all that a just and right-minded man could do under the circumstances. On finding out the mistake which had been made he secured the pills, and at once went to Lancaster for Mr. Johnson, and acquainted him with the occurrence. The latter gentleman followed him down almost immediately; and all had been done that skill and diligence could suggest, but, unfortunately, without effect. The prescription might have been more explicit, but Mr. Johnson said it was written in the usual form, and in a way that he thought could not have been misunderstood. The Pharmacopœia said that the extent of a dose of morphia was from one-eighth to half a grain; but when druggists received prescriptions from a doctor prescribing ingredients in excess of what their Pharmacopœia stated,—recognizing the doctors as better qualified to judge than themselves, they did not hesitate to make them up. Edmondson had told them that he understood the pills were to contain one grain of morphia each, and they were bound to believe him; and if they did believe him, then they must acquit him of any offence against the law. The coroner then gave the legal definition of manslaughter as it applied to the case, quoting Lord Lyndhurst, to the effect that if a party having a competent degree of skill and knowledge makes an accidental mistake through which death ensues he is not thereby guilty of manslaughter. On the other hand, a man would be guilty of manslaughter if, notwithstanding he has a competent knowledge of medicine, he be guilty of gross rashness in the application of a remedy, or negligence in attending to the patient afterwards. If the jury believed in the intelligence and skill of Edmondson, that he had used due precautions, and that he read the prescription to mean that the pills were to contain one grain of morphia each, then they would say by their verdict that death was caused by misadventure; if, on the other hand, they thought he had been guilty of gross negligence, then they must find him guilty of manslaughter; but he (the coroner) felt bound to tell them that he thought the evidence would hardly bear out the latter verdict, and that the proper legal verdict would be to say that death was caused by misadventure.

The jury retired, and in about half an hour brought in a verdict that death resulted from an overdose of morphia admininistered by misadventure.—*Lancaster Observer and Lancaster Guardian.*

Poisoning by Methylated Spirit.

The *Standard* reports that on Wednesday night, a pointsman, named John Nutter, employed at the Preston Goods Station on the London and North-Western Railway, was found dead in a break van. Previous to this a breaksman named Robert Fenton had left Preston with a goods train for the north, but was taken so seriously ill at the Carnforth station, a few miles beyond Lancaster, that he was unable to attend to his duties, and was sent back to Preston by the first return train. From him, however, it was elicited that he and Nutter, seeing what they thought was spirit trickling through the bottom of a luggage van, caught a quantity of the liquor in their cans and drank it. The train to which this van was attached arrived at Preston about nine o'clock on Wednesday morning, and on examining it a cask of methylated spirit was found to be leaking. It was this liquor that the unfortunate men had been drinking. It was stated that Fenton was delirious and was not expected to recover.

Excise Prosecution.

At the Exeter Police Court George Pates, chemist and druggist, was summoned by the Inland Revenue officers for keeping a male servant without a licence. Mr. Friend appeared for the defendant. John Satchell, Inland Revenue officer, stated that on Monday, 22nd April, he was passing the defendant's house on Fore Street Hill, and in a room under the shop he saw a boy brushing a man's shoe. On the following day he took Mr. Pates a declaration paper, telling defendant if he kept a male servant he must pay 15s. per year, and told him to read the paper. On the next day defendant returned the paper with "Nothing liable" written on it. Mr. Leckenby called John Salter, a little boy about ten years of age, in the employ of Mr. Pates, who stated that he frequently cleans his master's boots. Mr. Friend called Ann Leach, servant at Mr. Pates's, who stated that it was her place to do the work of the house, but not to clean the shop. Witness had asked the boy to come down and help her, and he had done so. The Bench fined the defendant £5, and recommended a further reduction.—*Exeter Evening Express.*

Review.

The Pharmacopœia of the Hospital for Diseases of the Throat. Edited by Morell Mackenzie, M.D. Lond., Hon. Med. Superintendent. London: John Churchill and Sons, 1872.

The pharmacopœia of a hospital, like that of a nation, reflects the state of both therapeutics and pharmacy in the institution from which it emanates. The Paris Codex, it has been said, shows that French Pharmacy is founded on sugar. The American dispensatories vaunt the virtues of resinoid active principles and syrups of the phosphates, and the present British Pharmacopœia exhibits our growing partiality for pure, definite chemicals for use as remedial agents. In the work before us are enumerated and described the medical preparations employed in the special treatment of throat diseases.

Like the old London Pharmacopœia, and still more resembling that of the London Hospital of 1868, from which several of the formulæ have been abstracted—the editor being also one of the staff of that hospital,—this pharmacopœia is divided into two parts, "Materia Medica" and "Formulæ." Under the head of "Materia Medica" about 160 drugs and chemicals are mentioned, all of which are official in the British Pharmacopœia except the following: — Acidum Lacticum — the specific gravity is not mentioned, or the strength or purity in any way indicated—the article of commerce varies very much in these respects,—Æther Aceticus, Aluminii Chloridum, Oleum Abietes Pectinatæ, Oleum Calami Aromatici, Oleum Folii Pini Sylvestris, Oleum Cassiæ—from what source is not mentioned—we presume that distilled from the bark of *Cinnamomi cassia* is intended, — Oleum Lupuli, Oleum Myrti, Oleum Salviæ, Oleum Santali—the botanical sources of these also are not stated,—Oleum Origani Pallidi,—we are not acquainted with the species *O. pallidum*, but suppose *pale* oil of marjoram (*Origanum vulgare*) is meant, as distinguished from the commercial Oleum Origanum distilled from *Thymus vulgaris*,—Oleum Juniperi Anglic*i*, B.P., is another similar misnomer. In addition to the above are Sodæ Hypophosphis, Pepsina Porci (Bullock's), Thymolis Hydras (thymic acid) and Ferri Persulphas. The last preparation is a rather mythical one; it is stated that it enters into the preparation of Pilula Aloes et Ferri (Lond. Hosp. Pharm.), in which dried ferrous sulphate is ordered,—into Collyrium Ferri Sulphatis, which contains only ferrous sulphate and water,—and into Aqua and Collyrium Ferri Aluminis, in which the only ingredients are iron alum and water. Calcis Carbonas Præcipitata is official under its vulgar name Creta præcipitata—it supplants Creta præparata in Mistura Cretæ. Of creasote, that prepared from beechwood only is to be used. The oil of the mountain pine—Oleum Pumelii—is also mentioned in one of the formulæ. With this preparation we are unacquainted, and its botanical source is to us very obscure. The utility of the first part of the work—the Materia Medica—is not very obvious, unless it be to define and describe accurately the special non-official medicaments used in the second part. In the first part the list of preparations into which drugs enter is very incomplete and often erroneous. As an additional instance, under the head of Ipecacuanha, among the "preparations" are Pulvis Emeticus; referring to the second part we find Pulvis Emeticus thus:—"Take of Sulphate of Zinc 20 grains. *Dose*, 20 grains freely diluted with warm water."

In the second part we have a clear and explicit description of the Vapores—Inhalations, and their mode of use,—(1) as medicated steam inhalations, (2) cold inhalations, (3) atomized inhalations (which are to be applied by means of a spray apparatus), and (4) fuming inhalations, these are produced from nitrated papers which are to be ignited and the smoke inhaled. The Eclectic Inhaler devised and recommended by the editor is also described. As an example of the style of the formulæ we take the following for Vapor Cajuputi.

"Take of

Oil of Cajuput	20 to 30 minims.
Light Carbonate of Magnesia	15 grains.
Water to	3 fluid ounces."

Mix.

"A teaspoonful in a pint of water at 150° F. for each inhalation."

The magnesia is added to keep the oil mechanically subdivided; but we think its use is chemically objectionable. Most volatile oils have an acid reaction, and, therefore, form compounds with magnesia which are non-volatile.

Acetic Acid Inhalation is directed to be prepared by taking Acetic Acid, B.P., and Glacial Acetic Acid, of each one drachm, and adding to a pint of water at 140° F. As Glacial Acetic Acid is exactly three times the strength of Acetic Acid, B.P., we are unable to perceive the advantage that such a mixture as above has over half a fluid ounce of Acidum Aceticum, B.P.

Under the head of poultices, caustics, plasters, gargles, mixtures, etc., appear the usual formulæ. By the way, we may remark there is no such preparation as "Emplastrum Roborans, B.P." The term "aqua" is applied to solutions intended to be sprayed unto the affected part by means of the atomizer, *e.g.* alum 80 grains, distilled water 10 fluid ounces, form "Aqua aluminis." But the most objectionable nomenclature occurs in usurping the term "collyrium," which is now universally understood to be an eye lotion, and applying it to a solution for topical application to the throat by means of a brush. As "Collyrium Argenti Nitratis" contains "60 grains of salt in the fluid ounce of water"! whereas that for the eye is rarely used above the strength of 4 or 6 grains to the ounce, the danger of mistaking one for the other is apparent. "Pigmentum" would be a better designation for such a preparation, and as it has to be applied by means of a *brush*, this would be a consistent term to use, although it is generally applied to iodine applications only.

Mistura Cathartica is made more vile than Mistura Sennæ Composita by the addition of carbonate of magnesia and oil of peppermint, and the omission of extract of liquorice and the tinctures in the B.P. formula. The following is the formula for "Linctus Scillæ":

"Take of

Compound spirits of ammonia	½ a fluid ounce.
Wine of ipecacuanha . . .	2 fluid drams.
Oxymel of squills to . . .	3 fluid ounces.

Mix. Dose, 1 fluid dram."

To avoid all danger of an explosion it will be necessary to dispense it in two bottles, or let the effervescence cease before bottling it.

Pure chlorate of potash will not dissolve to the extent of 24 grains in the ounce of water at ordinary temperatures, as in Gargarisma Potassæ Chloratis; but equal parts of tannic acid and water form a perfect solution if the tannic acid be pure—see Gargarisma Acidi Tannici Forte. The suspension mentioned will be impurity. Among the various formulæ we cannot conceive the utility of the following for Mistura Ferri et Ammoniæ:—

"Take of

Ammonio-citrate of iron . .	60 grains.
Water	12 fluid ounces.

Dissolve. Dose, 1 fluid ounce."

It merely signifies that citrate of iron and ammonia may be given in five grain doses. The same remarks apply to Mistura Sodæ Hypophosphitis, Mistura Aconiti, and Mistura Acidi Hydrocyanici.

Such misnomers as compound spirit*s* of ammonia, for aromatic spirit of ammonia, rectified spirit*s* of wine, and spirit*s* of chloroform strike us forcibly, especially in a Pharmacopœia. We find "spirit*s* of chloroform, *æ*ther, each ½ fluid ounce," which leaves us in doubt whether ether or spirit of ether is intended. The English word ether we find thrice spelt as above, and once *e*ther.

There are twelve formulæ for lozenges, all of which, except that for Trochisci Acidi Carbolici, have *fruit paste* as a basis for medication. In most of the formulæ it is called "*black* currant paste," in others, "*red* currant paste;" which it is the compiler appears to be in doubt, but in a note he states the "lozenge manufacturers are quite conversant" with it. Trochisi Cubebæ are stated to "closely resemble the Brown's Bronchial Troches, which have so much reputation both in America and Europe, but black currant paste is employed, and less gum and sugar." Similar editorial notes are appended to many of the formulæ.

On the therapeutical value of this Pharmacopœia we can offer no opinion, but the high professional reputation in which the editor is held will be sufficient guarantee for the work in this respect,—throat diseases having been a speciality to which he has directed much attention. We regret, however, that the little book has not been more carefully compiled, as an accurate mind will have its faith much shaken in what is novel and good; it would have been much more useful if more generally correct.

Notes and Queries.

COD LIVER OIL AND ESSENCE OF EUCALYPTUS.—M. Duquesnel states (*Journ. de Pharm. et de Chimie* [4] xv. 383) that cod-liver oil, flavoured with essence of eucalyptol in the proportion of one gram of essence to one thousand grams of oil, has neither the taste nor the odour of cod-liver oil. It is taken with facility, only leaving at the back of the mouth and on the tongue the taste of the essence which it contains. He adds that the malodorous eructations, so disagreeable when arising from cod-liver oil, are completely modified.

[317.]—BROWN HAIR DYE. — In answer to F. B. J., the acetate of lead will dissolve easily in six ounces of cold water, and the hyposulphite of soda in the remaining eight—boiling. — JOHN TULLY, East Grinstead.

[319.]—ADULTERATION OF OLIVE OIL.—Can any gentlemen oblige me with a test for the detection of any animal matter in olive oil.—A. P. S. (Exeter).

The Possibility of Effort.

Sir,—I was pleased to see in your last issue a letter on this subject of a far healthier and more encouraging tone than that of Mr. Ince, but I quite expected to have seen some authority step forward and remind that gentleman that of the many who annually pass the examinations, a great proportion do so with scarcely any help other than that derived from the study of the ordinary text-books, and hints from those who have already passed.

Now I wish it fully to be understood that in these remarks I refer to the "Minor" only, for it is with respect to this examination that I observe the greatest anxiety possesses young men. And further, I would guard against being thought to undervalue in the slightest degree the great advantages derivable from courses of lectures, laboratory teaching, or access to a qualified tutor. On the contrary, I place the highest value upon each and all of these aids, but my sympathy with the many apprentices and assistants who are far removed from their influence, induces me to record my impression that individual effort is easily able to accomplish the "Minor." A perusal of either of the previous letters would convey a contrary impression; yet, although my experience must be far less than that of Mr. Ince, every young man in my somewhat extended circle of personal acquaintance, with one exception only, whom I have seen set diligently to work, has accomplished it in periods of from four to twelve months. The ages of these candidates have varied between eighteen and twenty-one years.

With your permission, I would now state by what means the foregoing results were attained, putting my remarks into such form as shall enable the many anxious and comparative outsiders of our community to construct for themselves a line of action.

It is presumed on the part of intending candidates that they possess thorough acquaintance with the construction of prescriptions and methods of dispensing, with the appearance of the various chemicals and galenicals, and with the more common articles of Materia Medica. The possession of such knowledge ought to be a matter of course with all who have been three or four years in the trade; and such as have yet to acquire it, ought to bear in mind that they must qualify themselves thus far for their ordinary duties behind the counter before they entertain any immediate thoughts of submitting themselves to the examination.

The study of the various subjects should proceed simultaneously; but the first step should be the getting together of specimens of the organic materia medica; and when looking these over, reference should be made to any standard work on the subject, with a view of learning the method of obtaining them, their uses, and such knowledge as is set forth in the synopsis of the examination. The galenical preparations of the Pharmacopœia should be learnt by heart, and the processes for the manufacture of officinal chemicals well studied, Attfield's Chemistry being used for their explanation. The reactions of the salts should be studied experimentally. My conviction as to Botany is, that the best beginning in it is to go out into the fields and interest one's self in the wild flowers. The structure of these, carefully studied by the help of a good work on botany, will soon lead up to such a knowledge of structural botany as will ensure confidence under examination, and in all probability, will further lead to the subject being taken up afterwards as a source of amusement.

Briefly, then, it appears that a candidate for the "Minor" is required to show a thorough familiarity with the various aspects of those things which he is called upon to use daily; and for persons of average capabilities who make proper use of their time with a view to render themselves good men of business, a steady application to study in the spare hours after business will soon fit them to undergo the now dreaded ordeal.

E. Nuthall.

Norwich, June 24th, 1872.

Pharmaceutical Curiosities of Medical Practitioners.

Sir,—I do not know where your correspondent 'G. H' hails from, who writes on the above subject in last week's Journal, but I think he has just cause for complaint; and as it is a subject to which I have given some attention, I would like to add a few words to 'G. H.'s' communication, in the hope that some reform may be the result, in our locality at least, viz. the vicinity of the Valley of the Clyde. But in the first place, as I have, partly from curiosity and partly from an enquiring nature, been trying to discover the origin of 'G. H.'s' "Co.2," I beg to offer the following as the reason:—'G. H.' has probably heard of the new chemical notation; but having a large practice, he has not had time to "read up" on the subject; and having an idea that brevity is the soul of wit, has come to the conclusion that all acids are easily distinguishable by such symbols as "SO2," "CO2," and so forth. I shall be glad to learn that my conjecture is wrong.

But my main object in writing is to point out that such obscure prescriptions as those referred to by 'G. H.' are very common; and, if I mistake not, are becoming more common, especially in this district; and I know further that the practice is not carried on by "ignorant" medical practitioners, but by some who have a practice and reputation, as well as social position, which ought to be far above such miserable contrivances. What would 'G. H' think were he to receive such prescriptions as the following?—"Ung. Flav.," "Pil. Asiaticæ," "Lotio Oculi," "Lin. Co.," "Ung. Rub.," "Acid. Tonic. No. 2," "Pil. Nucis Co.," "Tinct. Alterative," etc. Yet these are but specimens of what have gone through my hands since I became connected with the drug business. I might give the initials of the authors of these wonderful cognomens, but deem it advisable for the present to withhold them. I have frequently sent to the physicians for explanations, but, unlike 'G. H.,' instead of finding the prescription coming into the shop in a more extended and comprehensible form, have been horrified by the reply that these could only be got at so-and-so's establishment. I have long since come to the conclusion, however, that the medical profession are not so much to blame in this matter as a certain unprincipled class of our own brethren in trade. If the profession were not encouraged or tempted by a bait of some kind, they would not be so terribly anxious to send patients distances of miles for medicine, which, were the prescription written in full, might be prepared at the patient's own door. This system of secret or tacit understandings between physician and pharmacist ought to be most strenuously opposed by all right-minded members of the trade. I would far rather have surgeon-druggists for my neighbours than such underhand dealers. I know some, however, who have gone into this system, and who would give a good deal now to get rid of it altogether; for they have discovered to their chagrin that the benefit is all on one side, viz. that of the medical practitioners. They have found out that unless they are dishonest by making an extortionate charge for dispensing and withholding the prescription, which they have no right to do, they are simply playing a game at filling the exchequer of the doctor, while they are preventing the money reaching its legitimate source, viz. their own pockets and that of their brother pharmacists. I am further convinced that it is an unprofitable speculation to most chemists who engage in the system, from the fact that in many cases they have to prepare large quantities of these particular medicines, to gratify the whim of the medical man, who, in time taking another notion, gets enamoured with some new nostrum, thus leaving the poor victimized druggist with a stock of, say half a gallon, "Lin. Co.," an article which nobody knows, or cares to know, anything about; and ultimately the doctor forgets all about it himself, and there it lies on the chemist's shelf "dead stock." As a general rule, however, I find that it is the young pharmacist just commencing business, who falls into this grave error, in the hope of procuring in a short time a good going business (though I have instances of old druggists, who ought to know better, not only carrying on the system, but doing all they can to extend it). But the hope of honourably increasing one's business by it is a delusion and a snare; and I would warn my younger brethren to give no encouragement to such a system, which is in many instances corrupting the morals of our young men. Let us ever remember that "It is not all gold that glitters," and that "There is a day of reckoning at hand," when honesty and uprightness shall prevail against all such contemptible expedients.

Ægis.

July 2nd, 1872.

Pharmaceutical Education.

Sir,—The idea of others obtaining benefits which he neither requires nor desires, seems to gripe 'Country Major Associate' very much, and to disturb that peace of mind which his residence in the country ought to afford him. He appears to "lay down the law" pretty stiffly, but I think he would have done better if he had given us more reasons and less axioms. I will, however, endeavour to deal with what little he has given us.

In the first place he declares that to aid country schools is unfair "to the Majors and Minors, who have been induced to proceed to London and elsewhere to acquire a good pharmaceutical training." With regard to this, I would merely ask him if the British Parliament was deterred from making education accessible to all classes, on account of a few who had been to college and had paid £100 for what would be now attainable for one-tenth of that sum? Next, he says that, the aim of the proposed scheme is to make the obtaining of degrees easier and cheaper than it has been to those who have already obtained them. Easier it cannot be unless the standard of the examinations is lowered, which every one knows is not the case. It is harder work for a student to prepare himself for the Minor with the help afforded by the provincial associations established at Bristol, Norwich or Northampton, than it would be at Bloomsbury Square. Cheaper it may be, but is not a man who has passed the Minor from Norwich or Bristol equal to one who has passed it from Bloomsbury? And if cheaper in the country, there will be no necessity for any one willing to work to be at the great expense of going to London to attend the lectures, etc. at the Square, a state of things which I think the Society would not be sorry to see, considering the great loss every year from the educational department; and if it is unfair to help the provincial associations, why help London with the funds of the Society?

Next, 'Country Major Associate' says it is unfair with regard to members in business that their subscriptions should be appropriated for what they do not care to support. I think it has been abundantly proved, both at the Annual Meeting and elsewhere, that the masters are entirely of an opinion that something must be done, the only question being how to be at the same time "just and generous." And is it a matter of indifference to the masters whether their assistants shall be well instructed or not?

'Country Major Associate' says it is unfair to registered apprentices. I believe it is entirely voluntary whether or no they subscribe half a guinea per year to the Society, so I cannot see that it should be unfair to them. Beside, in return they enjoy certain advantages which unregistered apprentices do not, and therefore let them be satisfied with that, and not seek admission into provincial associations at half price, so as to entail heavier expense upon the other members.

Then, lastly, 'Country Major Associate,' makes one sweeping denunciation that is "unfair to every one enrolled into the Society on account of its not being a good general scheme." Certainly, after such a bold assertion as this, one looks for something to back it up, but 'Country Major Associate' gives really nothing. He asks why should Tadcaster contribute to the support of an association at Manchester. Certainly they should not do so without receiving anything in return, but I think it ought to contribute to Manchester just as much as to London. Why should London have the advantage? But under the system of payment for results, Tadcaster might earn sufficient to carry on a school of its own, and though to a certain extent Tadcaster would contribute to Manchester, it would receive more from Manchester than it contributed. In the face of all this, I cannot understand what 'Country Major Associate' means by saying that the scheme has been shown to be neither "fair, possible, or general." There are several schemes being at present brought forward—which one does he mean? or does he mean that giving any aid at all to provincial associations is not 'fair, possible, general, or practicable?"

With regard to the system of payment for results, 'Country Major Associate' had better leave it in the hands of Mr. Schacht, as I do not think he can find abler ones to grapple with it.

Perhaps 'Country Major Associate,' or any other gentleman, can give me a reason why £600 a year should be granted to the London School of Pharmacy, and why Manchester and Norwich, as well as Tadcaster, should contribute towards it, and not receive anything in return?

Most cordially do I endorse the proposal contained in the last lines of 'Country Major Associate's' letter. No one could give better ideas of what is required than those gentlemen who have had such a large experience of teaching in that school which is the model after which all provincial associations are designed.

June 17th, 1872. G. T.

"*A Registered Student of the Society.*"—(1) Only plants collected in their native habitats are admissible. (2) None but British plants are allowed. (3) Lindley's 'School Botany" would not meet the requirements of the collector; the work used must be one on British Botany, as indicated in the published regulations for the Botanical Prize.

W. Dixon.—See Professor Bentley's paper on *Prunus Virginiana*, Pharm. Journ., 2nd ser., Vol. V. p. 97.

A. Wood.—(1) You can obtain the information you require by applying to Mr. Cooper, 28, Duke Street, Westminster. (2) We do not know of such a test.

"*Atropa Belladonna.*"—We have been favoured with the following note by Mr. R. Goodwin Mumbray, of Richmond:—

"The interesting paper on Belladonna contained in a recent issue directed my attention to a specimen in my garden, now in the third year of its growth.

"I brought the plant from Dorking, but it languished almost entirely away; at last it was cut down, and seemed quite dead. Having noticed that the soil in which it grew was calcareous, I gave the root a dressing with old mortar, which produced the best results, for the plant threw up three goodly stems; and last summer it grew to the height of $3\frac{1}{2}$ feet. This season it is at least 6 feet high, and has 22 stems, one of which I send for your inspection.

"Notwithstanding its deadly nature, the *Atropa Belladonna* does not escape the attacks of various caterpillars and aphides. It has also been visited by their natural enemy, the *Hemerobius*, the remains of whose curious eggs are apparent upon one of the leaves; the minute larvæ are no doubt busy with their prey."

H.M.—You appear to be under a mistake in assuming that the Pharmacy Act prohibits widows from carrying on the business of a chemist and druggist otherwise than it prohibits all unregistered persons from doing so. On the contrary, the 16th clause of the Act specifically states the means whereby a chemist and druggist may provide for his widow retaining and carrying on his business should he so desire. The other subject referred to in your letter is one which we think it inexpedient to notice, unless we see some distinct prospect of its being dealt with satisfactorily.

R. Clement.—Such a book, if published, might be obtained through Messrs. Williams and Norgate, Henrietta Street, W.C.

Morton.—The Preliminary examination is not at all dependent upon apprenticeship. All that is necessary is that you should possess a moderate knowledge of the English language, of Latin, and of Arithmetic.

"*Minor Associate*" is thanked for his suggestion, but we think it is one that could not be adopted in this Journal.

"*Non Liquet.*"—(1) See the answer to '*A Medical Student*,' on p. 1044 of the number for June 22nd. (2) The crystallized form is the best to use. The water of hydration is the same in both kinds.

W. J. S.—(1) Care is required in making the addition of water, if all that has been previously added has evaporated, and the temperature of the mixed plaster, oil and glycerine has been increased much above 212° F. If then water be added, steam is generated, which causes the explosion mentioned. (2) We do not know. It is not likely to occur if the Pharmacopœia directions are attended to.

"*Tyro.*"—We do not see much reason to object to the conclusion, provided the observations referred to were properly made. We consider the general character of the advertisement that you send, to be decidedly unwholesome.

"*Mel.*"—We think No. 1 is unobjectionable; but it is a question for a lawyer whether that is the case with No. 2.

Communications, Letters, etc., have been received from Mr. Southall, Mr. Whimpray, Professor Soubeiran, Mr. Thorp, Mr. Rimmington, "A Chemist," "Esse."

A. P. S. and "*X.*" are referred to the rule as to anonymous communications.

ANTISEPTIC PHARMACY.

BY WILLIAM MARTINDALE, F.C.S.,

Dispenser and Teacher of Pharmacy at the University College Hospital.

In a paper read at the Evening Meeting of the Pharmaceutical Society held on December 2nd, 1868,* I drew attention to some pharmaceutical preparations used as dressing in the antiseptic system of surgical treatment. Since then the views and medical appliances of the great apostle of that system, Professor Lister, have undergone considerable modification; the experiments of Professor Tyndall with cotton-wool, and the remarks of Professor Huxley and others on "Spontaneous Generation," together with a more extended trial of the preparations then in use, showed that the exclusion of atmospheric air from wounds under these dressings, was not necessary, provided it were freed from septic matter—the germs of putrefaction. I propose on the present occasion to explain the applications now used by him in the Royal Infirmary, Edinburgh, and also adopted in many of the London and provincial hospitals. In order to make the use of them intelligible, the field of medicine proper must be crossed, and that of surgery much encroached upon.†

In describing these preparations which I have had opportunity of seeing largely used, I am making free use of the description of them given by Professor Lister, in Holmes' Surgery,‡ and also of his Inaugural Address in Surgery, at the Meeting of the British Medical Association at Plymouth, 1871.§ He thus explains that—

"The main principles of the antiseptic system are well illustrated by a case of simple fracture, say a fracture of the leg from direct violence. Such an injury, though subcutaneous, is a most severe, contused and lacerated wound; and the interstices between the mangled tissues are loaded with extravasated blood. With the sole exception, that the skin is not divided, so as to expose the injured parts to the atmosphere, there are present in an aggravated form those conditions which we used to regard as inevitably involving violent inflammation, followed by the separation of sloughs under suppuration, with corresponding constitutional disturbance and serious attendant risk of fatal blood-poisoning. Yet, thanks to the unbroken integument, all proceeds quietly and surely towards recovery; the effused blood is absorbed; and the portions of the tissue killed by the violence are similarly disposed of; while repair is effected by a process which, though more slow, in consequence of the larger amount of effete material to be worked off, is identical with that of union by the first intention, which is commonly supposed to demand cleanly-cut surfaces, with accurate apposition. If, therefore, the effects of the atmospheric exposure could be avoided, primary union ought to occur under circumstances hitherto believed to be inconsistent with it, and our wounds, whether incised or contused, should follow the same safe and tranquil course as subcutaneous injuries. In order that we may attain that all-important object, the first essential is that we understand clearly how the atmosphere exerts its baneful influence. If an open contused wound is treated in the ordinary way, say by water-dressing, or fomentations, we know, as a matter of observation, that the blood within it undergoes putrefaction as if exposed to the air at the same temperature in a vessel of glass or other material. This fact explains the whole train of bad consequences. The products of putrefaction are irritating and poisonous substances; and though perfectly harmless when applied to a sore covered with granulations, which constitute a protecting layer destitute of sensibility and readily excited to suppuration instead of absorption, act very differently upon a recent wound, which violently resents the contact of the poison, yet helplessly imbibes it into circulation: the inevitable result being local inflammation and febrile disturbance. Meanwhile such portions of the tissue as have been killed by the violence of the injury, instead of retaining their original bland character, and serving as pabulum for their living neighbours, become constantly more and more acrid from progressive putrefaction in their substance, and not only irritate the weakened parts in their vicinity and retard their recovery, but operate on them with caustic effect, and thus extend the loss of vitality greatly beyond its original limits. The persistent abnormal stimulation at length gives rise to suppuration, which weakens the patient in proportion to its amount, and in severe cases often carries him off by hectic and occasionally pyæmia."

The numerous experiments made by Pasteur, Liebig and others, proving the origin of fermentation in saccharine and other fluids to be caused by germs of organisms undergoing a further development when placed in a suitable nidus, led physiologists to believe that the putrefaction occurring in wounds is caused by a similar action, and that the blood and serum of an exposed wound form a convenient hatchment in which germs, either floating in the atmosphere or otherwise brought into contact with these fluids are further developed, and in the wounds produce the characteristic inflammation, accompanied by the fœtid sloughing above mentioned; and, further, that the pure atmospheric air, or the oxygen it contains, is not itself an irritant to open wounds. Granting this, it is plain that putrefaction in wounds may be avoided without excluding the air, by dressing them with some agent capable of destroying the vitality of the atmospheric organisms, provided that it does not act with too great a violence upon the human tissues. For the purposes of antiseptic treatment, *volatility* of the germ-poison is an essential requisite, in order that the atmosphere round the dressing may be deprived of septic energy, so that no harm may arise from its introduction into the wound, which it is often quite impossible to avoid. There are many agents which fulfil the conditions of volatility combined with hostility to low forms of life, such as chlorine, sulphurous acid, benzine, creasote and carbolic acid (phenic alcohol). "Any one of these," as states Professor Lister, "I have ascertained by experiment, may be used so as to keep a wound from putrefaction, provided it be employed with the essential object steadily in view, that is to say, to prevent the possibility of a single living putrefactive organism being left in the wound at the conclusion of the first dressing, or getting access to it subsequently."

On studying Tyndall's experiments on the filtration of air by means of cotton wool, he thought the application of this seemed to promise valuable results in antiseptic surgery. Experimenting with it, he found that if cotton wool, impregnated with either chlorine or sulphurous acid, or with the vapour of

* See PHARM. JOURN., 2nd ser. Vol. X. p. 390.

† It will be obvious to the reader that I have no desire that pharmacists should trespass on such ground; the care and attention required even of the skilled surgeon, to ensure good results by this treatment, are such as will deter the amateur.

‡ Holmes' 'System of Surgery,' vol. v. sec. ed. p. 617, *et seq.*

§ 'Brit. Med. Journ.,' vol. ii., 1871, p. 225.

benzine or carbolic acid, was placed upon a wound or granulating sore, after washing the surface with a lotion containing the same agent, although the volatile antiseptic left the cotton in about a day, the blood or pus still effused beneath the cotton remained free from putrefaction for an indefinite time, provided that the discharge was not sufficiently copious to soak through the cotton and appear at the surface, in which case as the meshes between the fibres afforded ample space for the microscopic organisms to develope in, putrefaction spread in a few hours throughout the moistened part of the mass. This circumstance greatly interfered with the practical utility of the dressing, and it has since been superseded by the 'antiseptic gauze' (hereafter described); but the facts seemed to him important with regard to the germ theory. The cotton wool, though it lost its chemical antiseptic virtue in a day, yet kept out putrefaction for a month or more. It could not possibly keep out any atmospheric gas, which was necessarily diffused freely between its fibres, and got in for the same reason that the volatile antiseptic got out. That which it did exclude could only be the suspended particles of l ust. It followed, therefore, as a matter of certainty, that the cause of the putrefaction, through atmospheric influence, of blood or pus, or in other words, such materials as the surgeon has to deal with in treating wounds, are not the atmospheric gases, but dust. And the fact that this dust is deprived of its putrefactive energy by agents which are chemically so unlike as chlorine, sulphurous acid, benzine, and carbolic acid, but which agree in having a common hostility to animal and vegetable life confirms the view that the putrefactive particles are really organisms. Professor Lister used benzine because he knew that the entomologist employed its vapour to kill insects.

Of the antiseptic agents used by Prof. Lister and others, none have given such general, almost universal, satisfaction as *carbolic acid*. Its chemical properties are such, that it possesses in an eminent degree the *sine quâ non* for use in these dressings,—volatility; and it dissolves freely in such heterogenous solvents as fixed oils and fats, melted resins, alcohol, ether, glycerine and water. Its action is decidedly antiputrefactive; it checks the decomposition of dead animal matter, and (what is of grea importance to the comfort of patients in hospital wards where this system of treatment is pursued) it prevents the evolution of those fœtid gases which arise from decomposition, and it keeps the surrounding air sweet and healthy. The crystallized acid, which can now be had very pure, can be liquefied by immersing the vessel containing it in a hot-water bath; if then about six per cent. of water be added and agitated with it, it becomes hydrated, and when cooled will remain permanently liquid at ordinary temperatures. One fluid part of the hydrated acid will dissolve in twenty parts of water, forming a perfect solution. With a less quantity of water it forms an oily mixture, not a solution.

Water holds the particles of acid very feebly, and therefore liberates them readily to act upon any other substance. Hence a watery solution, besides being a very cleanly lotion, is very potent in immediate action, but very transient,—exactly the properties required of it for an application to a wound designed to kill once for all any septic organisms that may have got lodged upon it, and then leave the tissues free as possible from further irritation. Common resin, on the other hand, holds the acid with remarkable tenacity, and even at the temperature of the body gives it off very slowly; so that a large proportion of the antiseptic may be kept stored up in the resin in a form which acts very mildly, but for a long period. These are the qualities required for an external dressing to guard against the penetration of putrefactive fermentation from without; while the insolubility of the resin in water prevents it from being washed away in the discharges. The fixed oils occupy an intermediate position as regards their hold upon carbolic acid, and there are circumstances in which they form a most convenient vehicle for it. Carbolic acid has also the advantage of being a local anæsthetic, exercising a soothing influence upon a raw surface to which it is applied; while the disagreeable smell, which at one time was a serious objection to it, has been almost entirely removed by purifying it of the stinking compounds associated with it in the crude product.

(To be continued.)

THE GENUS EUCALYPTUS: ITS ACCLIMATIZATION AND USES.

Perhaps one of the most remarkable successes in the science of acclimatization, and one that promises to produce important results in the industrial and sanitary history of many European countries, is that which has attended the attempts made during the last twenty years to introduce the various species of *Eucalyptus*. The subject has been taken up with great warmth by the Société d'Acclimatation of Paris, and from an elaborate memoir, in which M. Raveret-Wattel recently presented to the members all the available information upon the subject,* we abstract the following particulars.

For many years various species of *Eucalyptus* had figured in the botanical gardens of Europe, and travellers who had seen the gigantic trees in their native country had been unanimous in their praise of the elegance and rapid development of these magnificent representatives of the Australian flora. But it was not until 1854, when M. Ramel, being in Melbourne, had his attention called to the growth of a young blue gum tree (*E. globulus*) by Dr. Ferdinand Mueller, the indefatigable Director of the Botanical Gardens there, that any extensive attempt was made at its naturalization in other countries. M. Ramel was not content with admiring the tree. In 1856 he sent some seeds to Paris, which were followed in 1857 and 1860 by other supplies. These were distributed, and the tree is now propagated and naturalized, not only throughout southern Europe, but in many localities in Asia, Africa, and America.

The *Eucalyptus globulus* is the species that has up to the present time principally attracted the attention of the public, from the elegance and exceptional vigour of the tree. But the greater portion of its numerous congeners are equally interesting from various points of view. Some produce resins, others yield oils susceptible of being employed in industry or therapeutics, and science is far from having said her last word respecting the part that may be played by these useful plants.

* L'Eucalyptus: Rapport sur son Introduction, sa Culture, ses Propriétés, Usages, etc. Par Raveret-Wattel. Paris: Bulletin de la Société d'Acclimatation, 1871–1872.

It would be out of place here to enter into a detailed botanical description of the members of this large genus. For such our readers are referred to Mueller's 'Fragmenta Phytographiæ Australiensis' or Bentham and Muellers' 'Flora Australiensis.'* We shall only allude to a few of the species, with their more striking characteristics, and in a further notice mention some of the products that they yield which have more particular therapeutic and chemical interest..

Like all the Myrtaceæ, the Eucalyptus is an evergreen, but it presents the peculiarity of changing its aspect at three or four years of age. The leaves, at first large, sessile and horizontal, take then an oblique direction, or even hang vertically to the roots, at the end of long petioles. To speak more exactly, they are only simple petioles much dilated and presenting on both sides a uniform organization. These modified leaves, or phyllodes, peculiar to a great number of Australian plants, are generally coriaceous and appear to be fitted to resist atmospheric accidents, such as tempests, the sirocco, or hail. They contain numerous pellucid glands, filled with an essential oil that diffuses an odour which is strong and penetrating without being disagreeable. These aromatic emanations are esteemed as possessing properties assisting the respiration and neutralizing marshy miasmas; the absence of fevers in Australian settlements where the tree is found being attributed to their influence. The bark, flowers and fruit are all equally covered by glands containing a very odorous essential oil.

The growth of the Eucalyptus is prodigiously rapid, even when transported far from its normal habitat, and nearly all the species early attain gigantic proportions. A tree ten years old ordinarily presents the development of a well-grown oak of a century, and it is not rare to meet in Australia with specimens in their fiftieth year 160 to nearly 200 feet high and 50 to 60 feet in circumference at the base. But notwithstanding this remarkable growth, the wood has a solidity that rivals the hardest woods of India, and has been used on the Australian coast for constructing quays, jetties etc., that admirably resist the action of water. It has also been utilized successfully in shipbuilding and for railway sleepers in India. One plank that was sent for the London Exhibition of 1851, but arrived too late, was 47 metres long, 3·50 metres wide, and 8 centimetres thick; and another, that was prepared for the Paris Exposition of 1855, but for which no vessel capable of conveying it could be found, was 51 metres long.

Apart from the valuable properties they possess, and considered simply as ornamental plants, the trees of the genus Eucalyptus are of great interest from their beautiful appearance and the singularity of their foliage. And here, the first place must be awarded to the *Eucalyptus globulus*, so named from the form of its flower bud when covered by the operculum. Elegant when young, majestic when it attains the colossal dimensions of mature age, this tree has always a superb decorative effect. The trunk from which the exterior cortical layers are often detached, as in the plane-tree, is smooth and ash-coloured, sometimes surrounded at the base by old fibrous bark. Its leaves, of a tint rather blue than green, play in the wind with effects of light and shade that recall those of the aspen. The odour of the bark, flowers, leaves and fruits is analogous to that of *Salvia officinalis*. On rocky hills by the sea shore, where it is exposed to the weather, it forms bushy shrubs that flower and fructify abundantly. But in sheltered places it attains a height of from 60 to 70 metres, and trees have been measured more than 100 metres in height. In the forests the larger branches rarely commence below 30 metres, and many trees may be seen with their straight tapering trunks unbranched to a height of 60 metres. In Australia the Eucalyptus has proved of much service in providing food for the honey bee, which has been introduced into the colony and increased in immense numbers. It is hoped that it will be of equal value in other countries where bee culture is carried on, especially as it provides the food at a time when other sources fail; for in changing its climate the Eucalyptus still obeys the calendar of its native hemisphere; with it the spring commences in September. Impervious to the attacks of insects, harder and more elastic than any other, their wood surpasses in specific gravity that of the teak and the Paul tree (*Shorea robusta*), long considered as presenting the maximum of density that could be acquired by ligneous fibre.

The *Eucalyptus Acajou* (*E. Mahogany* or *marginata*), popularly called in Australia the "Jarra" or "Djaryl," also merits attention. It has a vigorous growth, attains a colossal height, and furnishes a wood harder perhaps than that of *E. globulus*. This wood is principally employed in maritime works, and better than any other resists the attacks of insects and the teredo. In India it has been used largely on the railways for replacing the teak sleepers that had been destroyed by the dreadful ravages of the white ants. The wood is also susceptible of a high polish, and the markings are similar to the mahogany after which the tree is named.

The *E. rostrata*, Schlecht., or red gum-tree, is another large tree, furnishing a hard wood of a fine red colour, which is much used by the cabinet-maker. The bark yields an abundant supply of material to the paper-makers, which is utilized for packing-papers and pasteboard; filter-paper and blotting-paper of fair quality are also made from it.

The *E. amygdalina*, Labill., or narrow-leaved peppermint-tree, generally attains a height of 150 feet, but some have been met with in Australia measuring 480 feet in height. Its wood is very close grained, and elegantly veined. This species produces the largest proportion of odoriferous oil in the leaves, the yield being from two to four per cent. of the weight of the fresh leaves and young branches.

E. obliqua, L'Hér, or stringy bark-tree, is a very large tree, having a very strong wood. The fibre of the bark is employed largely by the paper-makers. Other species are the *E. microtheca*, Muell., or "black box" and *E. Stuartiana*,, F. Muell., or "apple-tree," both large trees, the latter furnishing good material for the manufacture of pasteboard; *E. corymbosa*, Sm., with very resinous wood, and bark yielding good paper material; *E. goniocalyx*, or spotted gum-tree, Muell., with leaves rich in volatile oil, and bark yielding excellent paper material; *E. inophloia*, Muell., *E. leucoxylon*, Muell., and *E. dealbata*, Cunn., trees of a similar description; *E. sideroxylon*, Cunn., with bark containing a peculiar resinous substance, which is obtained by distillation

* Vol. iii. pp. 185-261.

under the form of vegetable naphtha; *E. viminalis*, Labill., or "manna gum-tree," so called from a sweet saccharine substance, a sort of manna, that it excretes abundantly in the spring time from the leaves and young branches; *E. citriodora*, Hook., or "citron-scented gum," deriving its name from a very abundant volatile oil, easily obtained by distillation; *E. melliodora*, Cunn.; *E. odorata*, Schl.; *E. persicifolia*, Lodd., or "blackbutt," the leaves of which yield an agreeably-scented volatile oil by distillation; and *E. oleosa*, "or Mallee-tree," which, under the name of mallee-scrub, covers immense tracts in Australia. This last species contains a considerable quantity of essential oil in its leaves; and one of the towns that spring up as by enchantment in the gold regions, was for a long time lighted by gas extracted from this source. In the summer, the leaves and young branches are covered with a saccharine substance, sometimes so abundant that it resembles hoar frost. It is an excretion produced by the punctures of myriads of larvæ of a hemipterous insect.

We have thus briefly referred to some of the principal species of *Eucalyptus* mentioned by M. Wattel as more or less capable of acclimatization in Southern Europe, Algiers, Egypt and similar lands. In a further notice we propose to give some details respecting some of the economic products of the genus that may be supposed to be of more particular interest to pharmacists.

THE SPONGE FISHERY ON THE TUNISIAN COAST.*

Sponges are found on the whole length of the Tunisian coast, but, apparently, not in sufficient numbers to render their collection profitable, except in the shallows of Karkenah, Jerbar, Zarsis, and Biban. These shallows extend from Ras Kadijah and Bir Capoudia to Terna, a length of 45 miles. Those of Karkenah jut out 18 to 20 miles; these of Jerbah from 15 to 20, and the Biban shallows, being off an open beach, only from 3 to 4 miles. The maximum depth of these waters ranges from 12 to 75 feet. The Zarsis bank is about 18 miles from the coast. The shallows of the Island of Jerbah, the Zarsis Bank, Ras el Ghzira, Biban, Chneies and near Gilis have sandy and rocky bottoms, whilst those of the other fishing grounds are muddy.

Sponges grow either on rocky, sandy, or muddy bottoms, but the greater the depth the better the quality, both as regards texture and shape. In winter good sponges are fished off Karkenah, Agir, to the South of Jerbah, and Biban, and in summer on the Zarsis Bank and off Sefia and Legim; but the best are found on the rocks of the Islet of Camontes and off the village of Hataj el Scherki near Karkenah. The inferior qualities are procured from the shallows off Scebba and Luesa, whilst those coming from Chneies and Marabut, in the Gulf of Khabs, are the least esteemed of all, owing to their roots being red and quite rotten.

Tunisian sponges are of the quality generally known in trade as "horse sponges," and are used for washing house-floors, carriages, horses, etc. They are somewhat similar to those from the Bahamas, and other West Indian islands, although they are stronger, more elastic, and absorb a greater quantity of water, whereby they have a higher market value than the American sponges. In a natural state they are black, covered with a kind of slime and contain a certain quantity of mud and sand; their texture is coarse and the honey-combing large. No fine straw-coloured sponges, such as those coming from Benghazi, Asia Minor, and Greece, are found in Tunis waters, although the native fishermen procure in rocky places near Karkenah, Chneies, and Jerbah, small yellowish sponges of a fine texture; but these, known under the name of "haggemi," are comparatively of little value, owing to their small size, and seldom realize more than from 25*s.* to 35*s.* the cwt. The Tunis sponges received honourable mention in the London Exhibition of 1851.

The Bey claims fishery rights over all the above named waters, and for many years past a third of all the sponges fished, whether landed or not on Tunisian territory, have been considered as belonging to the revenue of the Regency, but as the duty is levied with difficulty, its collection has generally been adjudged to farmers for triennial periods in conjunction with the polypi fishery, which is carried on in the same waters. These branches of the Revenue have also been conceded by the Bey for the benefit of the Tunisian bondholders, and the Finance Commission has thought it advisable not to change the mode of utilizing it. MM. Colombel Frères et Devisme, of Paris, when the sponge and polypi duties were sold last year by public auction for a term of three years, were declared the highest bidders, and they consequently pay to the Finance Treasury an annual sum of £2200.

It appears, however, that MM. Colombel Frères et Devisme find it expedient to follow the example of their predecessors, and reduce the duties from a third to a quarter on all the sponges collected by the Greek and Sicilian fishermen, who are the most expert and industrious, and who, if they had to give up too large a share of their earnings, might abandon the fishery or have recourse to evasion of the farmers' duties. The foreign fishermen pay the duty in kind, the sponges being already washed.

Besides the annual payment of £2200 to the Tunisian Exchequer, the farmers have a yearly outlay of about £650 for agents and guards. In order, therefore, that they should not be losers by the undertaking, the two fisheries should produce at least £11,000 per annum. It is also necessary that they should themselves be engaged in the sponge trade, for they cannot calculate upon the native boats, which number from 250 to 300, collecting more than £3500 value of sponges in a season, and consequently if other merchants do not send for Greek and Sicilian fishermen, the farmers must do so, in order that an average harvest may be assured.

The markets for the sale of sponges are held at Sfax and at Jerbah from November until March. The sponges are generally unwashed, and disposed of in lots of 100 each, of all sizes, including "dead" sponges, viz., those detached by natural causes from their place of growth and found either floating on the sea or washed on the beach, and pieces of torn sponges strung in bunches. Each lot, therefore, varies in value, according to the quantity of "scarti," or refuse, it may contain; but, as a general rule, to form 1 cwt. of good, washed sponges, it is necessary to purchase ten lots, or 1000 unwashed and unsorted sponges, thus bringing the price to about 3*s.* 11*d.* per lb., as will be perceived from the following approximate statements:—

	Piastres.	Piastres.
1 cwt. assorted and washed sponges formed out of ten lots of the unwashed and unselected article, bought at . . . . per lot	80	= 800
Preparing the Sponges . .	10	
Export duty on 1 cwt. . .	31½	
		41½
		841½
Brokerage, etc., 5 per cent. . . .		42
		883½ = £22. 1*s.* 9*d.*

* Abstracted from a 'Report on the Tunisian Fisheries,' by Mr. Green, Her Majesty's Vice-Consul at Tunis.

Unwashed sponges are exported to Malta and Sicily, realizing from £4 to £6 the cantaro (175 lb.) at the former, and about £7 10*s*. the cwt. on the latter island. Occasionally the scarto thrown out from the washed lots, prepared by the Sfax merchants, is imported into Sicily and there sold at from £7. 15*s* to £10 the 110 lb. This scarto, it must be understood, is superior to the unwashed sponges mentioned as selling at £7. 10*s*. the cwt., for the sponges of which it is formed are only not of a sufficiently good quality for the Paris and other principal markets. The vast majority, however, of washed sponges is sent direct to Paris, where the large firms engaged in the trade have their head-quarters. Tunis sponges are sold there from 12 fr. to 13 fr. the kilogramme, so that the prices generally prevailing in the native markets leave a very fair margin to the advantage of the foreign merchant.

The fishery is most actively carried on during the three months of December, January and February, for at other seasons the localities where the sponges exist are over-grown with sea-weeds. The storms during November and December destroy and sweep away the thick marine vegetation, and leave the sponges exposed to view. The fishery is divided into two seasons, *i. e.*, summer and winter, the former commencing in March and ending in November, and the latter as I have noted above. But the collection of sponges is not very productive in summer, as it is confined to the operations carried on with diving apparatus that can only be used on rocky and firm-bottomed localities, or to the success of native fishermen, who wade along the shores and feel for sponges with their feet amongst the masses of seaweed. The sponges thus collected by the Arabs are also of an inferior quality, owing to the small depth of water in which they have grown. As, nevertheless, calm weather and a smooth sea are essential for the success of the fishermen, the winter season, although lasting three months, does not generally afford more than forty-five working days. The Arab inhabitants of the coast, Greeks—principally from Kranidi, near Nauplia (Napoli de Roumania)—and Sicilians are chiefly employed in the sponge fishery; the Greeks, however, being the most expert fishermen, whilst the Arabs are the least skilful.

Sponges are either obtained by spearing with a trident, diving, with or without the assistance of an apparatus, and by dredging with a machine somewhat similar to an oyster-dredge. The latter process, although only essayed in Tunisian waters this season (1871), promises to supersede all the others. The Arab fishermen, principally natives of Karkenah and Jerbah, employ boats called sandals, manned by four to seven persons, one of whom only is the harpooner or spearman, whilst the others manage the sails, etc. The spearman watches for the sponges from the bows of the sandal, and the boat is luffed round on his perceiving one, so as to enable him to strike it. The depth of the sea in which the Arabs fish is from 15 to 35 feet.

Although the Greeks are most expert divers, the majority of them use the spear. They employ small and light boats sufficient to carry a spearman and a oarsman. The boat is rowed gently along whilst the spearman searches the bottom of the sea by means of a tin tube of 14 inches in diameter by 19 inches in length, at one end of which is placed a thick sheet of glass. This tube is slightly immersed in the water and enables the fisherman to view the bottom undisturbed by the oscillations of the surface. The spears used by the Greeks are shorter than those employed by the natives and Sicilians, but with wonderful adroitness they are enabled to reach sponges covered by 60 feet of water. They hold in their hands from three to four spears, and dart them so quickly and with such precision, one after the other, that before the first has time to disappear under the surface, the second strikes its upper extremity, and thus gives it additional impetus to reach the sponge aimed at. I have had no opportunity of witnessing personally the dexterity of the Greek fishermen; but I am reliably assured that the above description of their method of fishing is correct and not exaggerated.

The Sicilians also fish with a spear and in small rowing boats, but do not understand the employment of the tube, and have not acquired the knack of the Greeks in using three or four spears, they consequently seldom secure an equal quantity of sponges, although they are always more successful than the Arabs.

The European sponge merchants send to Greece and engage the Greek fishermen for the winter season, and they contract to fish in the shallows of Karkenah and Jerbah, and to deliver up to the merchant all the sponges they may obtain, properly washed and dried, and free from stones and sand, at an approximate rate of 2*s*. 10*d*. a lb., all the local dues being borne by their employers. The spearmen receive an advance of £20 and the oarsmen £8 each before departing from Greece, but as they have to find the means of transport for themselves and their boats to the fishing grounds, the merchant is obliged to make a further advance of £8 to each boat's crew, which, during the season, is supplemented by another £8 to provide for the subsistence of the two men. From ten to forty of these boats are carried on board a single vessel, which not only conveys them to the fishing grounds, but remains there during the whole of the season, acting as a depôt for the fishermen and their produce, and ultimately as a means of repatriating them. From the foregoing it results that the merchant advances for every boat £44, therefore, for him to recover his outlay, he must receive about 340 lb. of washed sponges from each boat; but the debt is seldom cleared in one season, and the men have to engage to fish for a second term. The average produce of a Greek boat, in a season of forty-five working days, is 200 lb. of washed sponges of the value of £28, and as the farmer's dues are paid by the merchant, the boatmen have only to clear in the following season a balance against them of £16.

The Sicilian fishermen are also engaged by the Sfax sponge merchants in their own country; but, instead of the agreement being made separately with each fishing-boat, the merchants contract with the owners of vessels, who have from two to six boats, properly manned and and equipped. For every six boats an advance of £50 has to be made before departure from Sicily, and the merchants have also to furnish the fishermen with the means of subsistence during the fishing season; but if they happen to require more money than is absolutely necessary for their maintenance, it must be advanced, and a moderate charge is made for interest. The Greeks are only called upon to deliver their sponges on board their depôts; but the Sicilians must land theirs at Sfax, properly washed and dried, and consign them, without "scarti" (torn pieces), and free from sand and stones, to their employer, at the rate of £18. 15*s*. the cwt., after the farmer has withdrawn his quarter share. This is of considerable advantage to the merchants, who can exercise a closer supervision as to the manner in which the sponges have been washed and dried. Every cwt. of such sponges costs about £21, including the export duty of 15*s*. 9*d*., and all packing and shipping charges. Owing to the vicininty of their home, and their extreme frugality, the Sicilian fishermen are seldom in debt to their employers at the end of a season. The native fishermen rarely enter into special agreements with the merchants, but prefer selling their sponges unwashed, and by public auction, at Sfax.

The sponges collected by the Greeks and Sicilians, as I have already observed, are washed before delivery to the merchants; but those bought from the natives have to be prepared by the purchasers. The process of washing is very simple. The sponges are attached by strings of a dozen each, to poles driven in the sea near the beach; and in two or three days the wash of the tides clears them of their black coating. They are then hung up to dry and bleach in the sun.

The export duty levied on sponges is 15*s.* 9*d.* the cwt.; but the Custom-house returns do not afford a proper index of the quantities exported yearly, as nearly the whole of the sponges fished by the Greeks are not landed, but shipped direct from the depôts, on board each of which, however, there is a representative of the sponge farmer, to withdraw or dispose of the share due to him.

From the information I have been able to gather, it appears that the produce of this fishery is susceptible of considerable augmentation, by an increase in the number of fishermen; and, it is stated that, a new sponge is reproduced within a year wherever one has been removed.

THE CHEMISTRY OF THE HYDROCARBONS.*

BY C. SCHORLEMMER, F.R.S.

(*Continued from page* 5.)

Paraffins.—Kekulé first pointed out that when two atoms of carbon combine, the most simple, and therefore the most probable case, is that one combining unit of one atom enters into combination with one combining unit of the other atom. The group C_2 thus formed is consequently a hexad. When more than two atoms of carbon are linked together, they may combine in a similar manner, one-fourth of the combining capacity of one atom being saturated by one-fourth of the combining capacity of another. By saturating the free combining capacities of such a group with hydrogen, we obtain a series of hydrocarbons, having the general formula C_nH_{2n+2}, to which the name *paraffins* has been given. This name was originally applied to the solid members of the series, on account of their chemical indifference; but, as the gaseous and liquid members exhibit the same character, it appears convenient, as H. Watts has suggested, to apply the term paraffin as a generic term for the whole series.

The most characteristic property of the paraffins is that they are not capable of uniting with any other bodies, and for this reason they have also been called *saturated hydrocarbons.*

We are at present acquainted with a considerable number of paraffins, amongst which there are found many isomerides. To explain the isomerism in this series two assumptions have been made.

One, which found many advocates up to the year 1864, was that the four combining units of the carbon atom have not the same value or the same function. This assumption was made in order to explain the existence of two isomeric hydrocarbons having the formula C_2H_6, it being believed at that time that methyl gas was different from ethelhydride. But Crum-Brown has shown that there is a certain degree of inconsistency in this hypothesis (Trans. Roy. Soc. Edin. xxiii. 707). Butlerow, in endeavouring to explain the isomerism of these two hydrocarbons, argued that in methyl gas the two atoms of carbon were combined by two combining units of the same kind (which he called secondary affinities), each being the combining unit which in methyl iodide is saturated with iodine. In hydride of ethyl the carbon atoms are united in the same way as in other ethyl compounds, and therefore probably as in the acetyl compounds, one of which is acetonitrile or methyl cyanide; the one is therefore the combining unit of methyl, and the other that of cyanogen. These must be different, because the two hydrocarbons are not identical. To indicate this, Butlerow calls the free combining unit of cyanogen a primary affinity. We have thus in methyl gas two secondary affinities united together, and in hydride of ethyl a primary united to a secondary. "But by carrying this argument a little further, we arrive," says Crum-Brown, "at an absurdity; thus the carbon radical of acetic acid is the same as that of oxyacetic acid, and that again is the same as the carbon radical of oxalic acid, and therefore as that of oxalic nitrile or cyanogen gas. In cyanogen gas, however, we have the two carbon atoms united by two primary affinities; but we have before proved that in the acetic acid series they are united by a primary affinity of the one to a secondary of the other. It is obvious, then, that at least one of our assumptions is false."

About the same time I proved by experiment that methyl gas or dimethyl is identical with ethyl hydride; and since that time a few chemists only have made use of the above hypothesis in order to explain certain cases of isomerism.

If the four combining units of the carbon atom have the same value, isomerism in the paraffin series can only be caused by a different grouping of the carbon atoms; and in this case it is easy to find out the number of isomerides which can exist in the case of each member of the homologous series. According to this theory, the first three members are not susceptible of isomeric modifications, whilst the four-carbon paraffin, C_4H_{10}, can exist in two, and the five-carbon paraffin in three isomeric forms, etc.

This theory is completely borne out by facts. Of the three lowest members, no isomeric forms are known, but we are acquainted with two containing four atoms of carbon, and with three containing five atoms.

Some time ago I showed that all the paraffins of known structure may be divided into four groups:—

1. Those in which each carbon atom is directly combined with at most two carbon atoms.
2. Those in which one carbon atom is united directly with three others, or which contain the group isopropyl.
3. Those containing the group isopropyl twice.
4. Those in which one carbon atom is combined directly with four others.

Of these groups, the first, which I called normal paraffins, was at that time only imperfectly known. Indeed, the structure of some of the members was not proved at all; they were placed there only because it appeared for several reasons probable that they possessed a very simple structure. Since that time, however, I have increased their number, and proved that the hydrocarbons placed in this group are really normal paraffins.

The only means we hitherto possessed for determining the constitution of a paraffin was either to obtain it from an alcohol or other compound of known structure, or to convert the paraffin into an alcohol, and then endeavour to find out the constitution of the latter.

The latter method, however, has been surrounded by such difficulties that it appeared almost impossible to make use of it. I have, however, succeeded in overcoming some of those obstacles, and been able to obtain much larger quantities of the alcohols than formerly, so that I could study fully their products of oxidation. An investigation of the paraffins contained in Pennsylvanian petroleum showed that they belong to the first group, as the alcohols derived from them, as well as the acids obtained by oxidizing the latter, were found to be normal compounds.

Before I take leave of the paraffins, I have to say a few words about the paraffins *par excellence*, viz., the solid paraffins. These bodies, which resist so energetically the action of chemical agents that they have obtained their name from this fact, appear to be very unstable bodies at a high temperature, although, curiously enough, they are produced by destructive distillation. Thorpe and Young have shown (Proceedings of the Royal Society, xix. 370), that by distilling solid paraffin under pres-

sure it is almost completely resolved, with evolution of but little gas, into hydrocarbons which remain liquid at the ordinary temperature, and consist principally of olefines.

(*To be continued.*)

THE MEASUREMENT OF TEMPERATURE BY ELECTRICITY.*

BY C. WILLIAM SIEMENS, D.C.L., F.R.S., M.R.I.

The truth recently revealed to us by one of the younger branches of physical science has divested heat and electricity of their mysterious character, and has taught us to regard them simply as "modes of motion."

Light also has been shown to be identical in its nature with heat, and the only remaining physical agency, "chemical affinity," has been recognized as a force differing only in "quality of action" from the others. According to these views, force, in whichever type of action it presents itself, is as *indestructible as matter itself*, and is therefore capable of being *stored* up and *measured* with the same certainty of result. We have a unit of force or the foot lb., and a unit of heat, or the heat necessary to raise the temperature of 1 lb. of water through one degree Fahr., and it has been already proved that 722 units of force are the equivalent value of one unit of heat. Again, the chemical force residing in 1 lb. of pure coal is equal to about 14,000 heat units, or $14,000 \times 772 = 10,808,000$ ft. lb. $= 4825$ tons lifted one foot high.

Questions regarding the quantitative effects of heat present themselves, however, much less frequently for our consideration than questions regarding its *intensity*, upon which depends the nature of the phenomena surrounding us at every step, both in science and in ordinary life. The instrument at our command for determining moderate intensities or temperatures, the mercury thermometer, leaves little to be desired for ordinary use; but when we ascend in the scale of intensity, we soon approach a point when mercury boils, and from that point upward we are left without a reliable guide. The result is, that we find in scientific books on chemical processes, statements to the effect that such or such a reaction takes place at a *dull red* heat, such another at a *bright red*, a *cherry red*, a *blood red*, or a *white* heat—expressions which remind one rather of the days of alchemy than of chemical science of the present day. There are pyrometers, it is true, but these are either of a complex nature, or little reliance can be placed on them.

An instrument which fulfils, in principle, all the conditions essentially necessary in thermometry, and is, at the same time, the very first instrument that was ever proposed for measuring temperatures, is the air thermometer of Galileo. Theoretically, the expansion of a permanent gas at constant pressure is the most perfect index of temperature, it being the degree of energy of the atomical motion in an elastic fluid which determines its volume and constitutes at the same time its temperature.

This air thermometer consists simply of a bulb of glass with a long tubular stem, open to the atmosphere at its extremity. If the bulb be heated,—by dipping it, for instance, in boiling water,—and put into a holder with the hollow stem reaching downward into a cup of mercury, the air within the bulb will no longer communicate with the atmosphere, because the mercury is interposed. If the air within the bulb be now cooled by the external application of iced water, its heat motion will diminish, and its volume would be reduced proportionally if the external atmosphere could enter freely to fill up the vacancy thus created. But inasmuch as the external air cannot enter, a reduction of pressure will take place, which, according to the law of elasticity by Boyle, must be proportionate to the reduction of volume at constant pressure. The difference of pressure thus created between the bulb and the external atmosphere will be balanced by the column of mercury rising up into the tube, and the elevation to which the mercury attains is a true index of the temperature to which the air in the bulb had been previously heated. This is true with regard to all temperatures, from the lowest to the highest, and the instrument may be termed a universal thermometer. If the bulb could be cooled down to 273° Centigrade below the zero point, it would follow by the law of Charles that the elastic pressure of air would be reduced to nothing, that is to say, the motion of the particles of air, which we call heat, would have ceased, and we should have reached the point of absolute zero, a point which has been theoretically established also by other means.

Practically, such an instrument would be most inconvenient; its indications would have to be corrected by calculation for barometrical variations; the capacity of the descending tube, which contains air not subjected to variation of temperature, would have to be taken into account, and no reliable observations could be arrived at, without taking special precautions, such as are only within reach of the experimental physicist.

As the result of occasional experimental research, spread over many years, an instrument has been constructed by Mr. Siemens, by which he aims to accomplish a double purpose, the measurement of high temperatures and the measurement with accuracy of temperatures of inaccessible or distant places. If "electrical resistance in conductors" be substituted for "expansion of gases," this instrument presents many points of analogy with the air thermometer. Both these effects are functions of temperature, increasing with the temperature according to progressive laws; in the case of gases called the "law of Charles," in that of conductors "the law of increase of electrical resistance with temperature." The latter law, which is of recent origin, had been already partially developed by Arndsen, Swanberg, Lenz, and Werner Siemens, when in 1860 the author's attention was directed towards an application of it to the measurement of temperatures of places inaccessible to the ordinary thermometer.

The conductivity of a wire of platinum or other metal is greatly influenced by temperature. If the current of a galvanic battery be directed through two branches of equal resistance, each branch consisting of a free spiral wire of platinum and one of the coils of a differential galvanometer, no deflection of the needle occurs as long as the temperature of both branch circuits is the same. But if a flame or even a warm hand be brought in contact with one of the platinum coils, the electric resistance of the heated wire is increased, and the current through the cooler circuit preponderating, the needle on the face of the galvanometer is immediately deflected. A small instrument, constructed by winding thin insulated wire of any pure metal upon two small cylindrical pieces of wood, and enclosing the spirals in silver casings, taking care that the extremities of the spiral wires are soldered to thicker insulated wires leading to the battery and to the galvanometer respectively, might be employed with advantage in physiological research. If one case, which need not be larger than a small pencil-case, be placed in the part the temperature of which is required to be measured, and the other placed in a convenient medium, such as water, when, by the abstraction or addition of heat, the needle of the galvanometer is brought to an undeflected state, the temperature of such medium will be identical with that sought, and may be taken by a thermometer in the usual way, and the temperature may be read from time to time without disturbing the patient. It will be evident that such an instrument, modified to meet particular circumstances, might be used for measuring the temperature of

* Abstracted from a Paper read at the Royal Institution, March 1st, 1872.

inaccessible places, such as the interior of stores or cargoes of materials liable to spontaneous combustion; of points elevated above the surface of the ground; or of great depths below for meteorological purposes, or for measuring deep-sea temperatures.

In order to realize a pyrometer by electrical resistance, it is necessary to rely upon the absolute measurement of the electrical resistance of a coil of wire which must be made to resist intense heats without deteriorating through fusion or oxidation. Platinum is the only suitable metal for such an application, but even platinum wire deteriorates if exposed to the direct action of the flame of a furnace, and requires an external protection. The platinum wire used has, moreover, to be insulated and supported by a material which is not fused or rendered conductive at intense heats, and the disturbing influence of leading wires has in this case also to be neutralized. These various conditions are very fully realized by the following arrangement:—Thin platinum wire is coiled upon a cylinder of hard-baked porcelain, upon the surface of which a double-threaded helical groove is formed for its reception, so as to prevent contact between the coils of wire. The porcelain cylinder is pierced twice longitudinally for the passage of two thick platinum leading wires, which are connected to the thin spiral wire at the end. In the upper portion of the porcelain cylinder the two spiral wires are formed into a longitudinal loop, and are connected crossways by means of a platinum binding screw, which admits of being moved up or down for the purpose of adjustment of the electrical resistance at the zero of Centigrade scale. The porcelain cylinder is provided with projecting rims, which separate the spiral wire from the surrounding protecting tube of platinum, which is joined to a longer tube of wrought iron, serving the purpose of a handle for moving the instrument. If the temperatures to be measured do not exceed a moderate white heat, or say 1300° Centigrade = 2372° F., it suffices to make the lower protecting tube also of wrought iron to save expense. This lower portion only, up to the conical enlargement or boss of iron is exposed to the heat to be measured. Three leading wires of insulated copper united into a light cable connect the pyrometer with the measuring instrument, which may be at a distance of some hundred yards from the same. They are connected by means of binding screws at the end of the tube to three thick platinum wires passing down the tube to the spiral of thin platinum wire. Here two of the leading wires are united, whereas the third traverses the spiral, and joins itself likewise to one of the two former, which forms the return wire for two electrical circuits, the one comprising the spiral of thin wire, and the other returning immediately in front of the same, but traversing in its stead a comparison coil of constant resistance. The measuring instrument may consist of a differential galvanometer as before, if to the constant resistance a variable resistance is added. If the pyrometer coil were to be put into a vessel containing snow and water, the balance of resistance between the two battery circuits would be obtained without adding variable resistance to the coil of constant resistance, and the needle of the differential galvanometer would remain at zero when the current is established. But on exposing the pyrometer to an elevated temperature, the resistance of its platinum coil would be increased, and resistance to the same amount would have to be added to the constant resistance of the measuring instrument, in order to re-establish the electrical balance. This additional resistance would be the measure of the increase of temperature, if only the ratio in which platinum wire increases in electrical resistance with temperature is once for all established.

It has been necessary to undertake a series of elaborate experiments in order to ascertain what is the relation between the resistance and temperature in heating a platinum wire, with a view of finding a ratio of general application. Coils of thin wire of platinum, iron, copper and some other metals, were gradually heated and cooled in metallic chambers containing the bulbs of mercury thermometers, and for higher temperatures of air thermometers, and the electrical resistances carefully noted. The progressive increase of electrical resistance was thus compared directly with the increasing volume of a permanent gas (carefully dried) between the limits of zero and 470° C. A formula was established according to which the electrical resistance is constant at the absolute zero, and progresses in a ratio represented graphically by a tipped-up parabola. Although the comparison with the air thermometer could only be carried up to 470° C., the general correctness of this ratio has been verified by indirect means.

On the occasion of bringing this subject forward at the Royal Institution, Mr. C. W. Siemens showed the working results of the pyrometer by measuring the temperature of a mixture of ice and water, boiling water, molten lead, and the fire by which the lead was melted. The readings were respectively 2° C., 98° C., 330° C. and 860° C., the last representing a "cherry heat."

SORBITE, A SACCHARINE MATTER ANALOGOUS TO MANNITE, FOUND IN THE JUICE OF MOUNTAIN-ASH BERRIES.*

BY J. BOUSSINGAULT.

Mountain-ash berries, like cherries, plums, apples, etc., do not yield alcohol in proportion to the amount of saccharine matter which they contain. In a quantity of juice from these berries, containing 372·96 grams of saccharine matter, and fermented under favourable conditions, only 296·17 grams were decomposed, and the quantity of alcohol produced was but 135·09 grams, instead of 151·37 grams required by calculation.

The liquid containing the undecomposed saccharine matter yielded a crystalline substance, having, when dried, at 110°, the composition, $C_6H_{14}O_6$, and to which the author has given the name of *sorbite*.† It is isomeric with mannite and dulcite, but in the form of its crystals, in its melting point and other properties, it differs greatly from both those substances. Sorbite separates from aqueous solution in crystals containing $2C_6H_{14}O_6 . H_2O$, which melt at 102°. The anhydrous substance melts at 110°–111°, whereas mannite melts at 165°, and dulcite 182°. Sorbite is not a fermentation, as it can be obtained from the juice immediately after expression.—*Journal of the Chemical Society.*

FORMATION OF ASPARAGINE IN VETCHES.‡

BY A. COSSA.

Piria found asparagine in vetches which had been grown exposed to bright light, as well as in those grown in darkness. Some years after Pasteur (*Ann. Chim. Phys.*, 1857) grew a large quantity of vetches in the garden of the Academy at Strasburg, but did not obtain a trace of asparagine from 200 litres of the sap, whilst he found abundance in vetches grown in the same soil in a cellar. The author, therefore, grew some vetches in the month of July, and from a kilogram of those which had been exposed to light, he obtained 16·25 grams of pure asparagine, and from an equal weight of those grown in a cellar, he obtained 13·50 grams, the asparagine being proved to be identical in both cases; similar results were obtained in the months of August and September.

Piria's want of success probably arose from the circumstance that the sap of vetches, especially when grown exposed to light, readily ferments, the asparagine being decomposed and ammonium succinate being formed.—*Journal of the Chemical Society.*

* Compt. Rend., lxxiv 939–942.

† Pelouze, in 1852 (*Ann. Chim. Phys.* [3], xxxv, 292), obtained from mountain-ash berries, a crystallizable, non-fermentable sugar, called *sorbin*, having the composition of glucose.—*Ed. Journ. Chem. Soc.*

The Pharmaceutical Journal.

SATURDAY JULY 13, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE FREAKS OF THE FACULTY AND THE DUTIES OF DISPENSERS.

THE subject from which our text is taken is forcibly and unhappily illustrated on page 14 of the last number of the Journal, under the heading "Death from an overdose of Morphia." It will be remembered that this death originated in a misunderstanding as to the meaning of a prescription; the prescriber intending one grain of acetate of morphia to be made into six pills, instead of which the dispenser supplied six pills, each containing one grain of that salt. A correct copy of the prescription is printed at the foot of the page,* and we place it before our readers as a document well worthy of attentive consideration. Is this prescription clearly, comprehensibly, conventionally or carelessly written? We submit that it is not perfectly clear, inasmuch as candour compels us to confess that a very literal (though not very pharmaceutical) individual might (and did) read grain, instead of sixth-grain, doses. It is, however, according to our own belief comprehensible to a mind properly imbued with a knowledge of drugs and of the British Pharmacopœia; it is certainly conventional in form and expression, and we cannot declare that it is carelessly written.

But, to begin with the prescriber's part of the business, there was a want of strict accuracy in the whole proceeding. It is a very common freak of the faculty to rush into a chemist's shop, commit a prescription to paper, and supplement it by a string of verbal directions which the dispenser, also in hot haste, anxiously endeavours to commit to paper, and does it as best he may. The man certified to kill is gone, and the man certified to compound is left, and it is much to the credit of the latter that he does not oftener unwittingly appear in the witness-box in a case of (so-called) misadventure. Verbal directions of any sort or kind, in the prescribing of drugs, should be neither given nor taken. But the dispenser's part of this lamentable business is not by any means free from blame. It is his duty to know the British Pharmacopœia from beginning to end. He is reported to have possessed this knowledge, but we are fairly privileged to doubt it, when he is found compounding a dose that is known to be, under general circumstances, far more poisonous than the well-known "ounce" of Laurel Water. Mr. DISRAELI once told us that it was impossible to account for the marvellous eccentricities of stupidity, but it would appear, now and again, equally impossible to account for the eccentricities of thought. For, indeed, it requires no sophistry to show that (on the supposition that he knew his alkaloids and the rest of the Pharmacopœia) either the chemist was incapable of applying knowledge to proper purposes, or in too great a hurry to do so. The particulars connected with this sad occurrence give us an opportunity of reiterating the conviction that medical men should never give, and chemists should never receive, verbal directions in connection with the dispensing of medicines.

One directly, and repeated every four hours if pain or sickness require."

PHARMACEUTICAL EDUCATION.

WE desire to call the special attention of our readers to the letter of Mr. G. F. SCHACHT at p 39. The request there made that every member of the pharmaceutical body who has any suggestion to offer concerning the proposed scheme for the assistance of provincial pharmaceutical education should communicate it to these columns, or directly to the Committee charged with the subject, is one that we hope will be freely responded to. As an instalment to the discussion which we suggested last week, we have been favoured with the following proposed resolutions from Mr. FRAZER, of Glasgow, who describes the circumstances under which they were drawn up in a letter printed at p 39.

PROPOSED RESOLUTIONS ON THE BEST MODE OF AIDING PROVINCIAL EDUCATION.

"That in consideration of the proved inadequacy of the machinery at present existing in the provinces for promoting such a Pharmaceutical education in them as will qualify our students and assistants for passing the various examinations, now required by law, before they can become Associates or Members of our Society; and, in consideration of the proved impossibility of finding any one system of educational appliances that will meet the exigencies of widely differing populations, and believing that the Members of our Society resident in the provinces are themselves the parties likely to be best qualified to determine how to take the utmost advantage of any scientific schools or institutes already existing in their respective neighbourhoods, or, where such are wanting, to initiate such schools or lectures as will best meet their special necessities, this Council* shall award a grant of money to the extent of one-third or of one half of the required expenditure to any enrolled or duly recognized association in aid of any portion of their scheme which shall have a distinct scientific educational object, and that whether in providing a library, a museum, or lecture-room, or in payment of the fees of the teachers or lecturers employed by the said associations.

"And, further, with a view to making the grants not only more liberally than hitherto, but more systematically than they can otherwise be made, as well as to

* Here I quote from Mr. Schacht s closing paragraph.

secure that the Society shall not at any time incur greater pecuniary responsibilities than its funds for the time being will properly warrant, in future all applications for money votes for educational purposes, for the year, shall be lodged with the Secretary of the Society not later than the first day of *July* annually, and that the Council shall decide on the reply to be given to each application at its usual monthly meeting in *October*. In the interval between the date of the applications and that at which the Council shall give their decision upon them the Local Secretaries, or other parties appointed for the purpose by the Council, shall examine into the respective merits of each case, and report on the same to the Council, for its guidance in duly proportioning the amount to be granted to each applicant."

Those of our readers who are interested in the important question of pharmaceutical education will be glad to learn that in deference to the desire which has been expressed for the opinions of the Professors in the Society's School of Pharmacy, Professor Attfield intends to read a paper at the meeting of the British Pharmaceutical Conference at Brighton, on the 13th August, which it is hoped will lead to a general discussion on the whole subject.

THE SCIENTIFIC MEETINGS AT BRIGHTON.

As the month of August approaches, during which the annual meetings of the British Association and of the British Pharmaceutical Conference are to be held, the central and local officials of those Societies are giving evidence of their intention, so far as possible, to make 1872 a notable year in their history.

The Secretaries of the Pharmaceutical Conference are preparing for issue a circular to members, in which it is stated the Meeting for 1872 will be held in the Royal Pavilion, under the presidency of Mr. H. B. Brady, F.L.S., F.C.S. On Tuesday. the 13th, at 10 A.M., the President will deliver an address; the reading and discussion of papers on pharmaceutical subjects will then commence, be continued in the afternoon till 4.30, and be carried on during Wednesday; an adjournment from 12.30 till 2.0 each day.

The meeting room will be open as a reception room for members, from 9 A.M. to 6 P.M., on Monday, August 12th, Tuesday, August 13th, and Wednesday, August 14th.

Members intending to be present are requested to communicate at once with the Local Secretary of the Conference, Mr. T. Glaisyer, 11, North Street, Brighton, or the local Vice-President, Mr. W. D. Savage, 4, Park Road East, Brighton, who will give all information concerning hotel accommodation, railway routes, etc., and engage rooms for any members.

Brighton is generally well known and much appreciated for the extent and beauty of its sea-front: from Hove on the west to Kemp Town on the east is a drive of three miles unequalled in the kingdom. The promenades (East and West), with the two piers, each extending nearly a quarter of a mile out to sea, are favourite resorts. The Marine Aquarium, the largest in the world, is expected to be opened in time for the visit of the British Association and the British Pharmaceutical Conference. The Public Free Library and Museum, a building of considerable extent erected on the Pavilion Estate by the Town Council, is fully expected to be opened in the course of a few weeks. The contents of the old Museum, with considerable additions, will be transferred to the new Buildings, and from sources of great attraction.

In the neighbourhood of Brighton is the old county town of Lewes, with its numerous churches, and a portion of the old castle containing an antiquarian collection; also Arundel Castle, Keep, and Park, the property of the Duke of Norfolk. From the Devil's Dyke, five miles from Brighton, a fine view, extending over portions of seven counties, may be obtained.

The proximity of Brighton to London, and the railway facilities specially offered for the occasion, will probably ensure a large attendance of members and contribute to the success of the meeting for 1872.

The general secretaries also announce that the local members of the Conference at Brighton propose to invite their brethren from a distance to a dinner, on Tuesday evening, August 13th.

Several papers are already promised for the meeting, and the subject of Pharmaceutical education will probably be very fully discussed.

The Secretaries of the British Association have also issued a circular stating that the forty-second meeting will commence at Brighton on Wednesday the 14th August, on which day Professor Sir William Thomson, LL.D., F.R.S. will resign the chair, and Dr. W. B. Carpenter, LL.D., F.R.S., will assume the Presidence and deliver an address. The various sections will then meet for the reading of papers at 11 o'clock, A.M., on the 15th, 16th, 17th, 19th and 20th August. On Thursday evening, August 15th, at 8 P.M., there will be a Soirée; on Friday evening, August 16th, at 8.30 P.M., a Discourse; on Monday evening, August 19th, at 8.30 P.M., a Discourse; on Tuesday evening, August 20th, at 8 P.M., a Soirée; on Wednesday, August 21st, the Concluding General Meeting will be held at 2.30 P.M. On Thursday, August 22nd, excursions will be made to places of interest in the neighbourhood of Brighton.

We are informed that a lady recently deceased has left a legacy of £500, free of legacy duty, to the Benevolent Fund of the Pharmaceutical Society. We believe that similar legacies have been left to the Royal Free Hospital, The Samaritan, St. George's, Westminster, St. Thomas's, Middlesex, Great Northern, Charing Cross, King's Cross, and the Brompton Cancer and Consumption Hospitals, and various other benevolent institutions.

CINCHONA CULTIVATION IN JAVA.

Professor J. Leon Soubeiran, of Paris has kindly placed at our disposal an extract from a letter that he has received upon the above subject from M. Van. Gorkom, of which the following is a translation:—

"Our cultivation of *Cinchona* prospers wonderfully and our medical men employ with advantage the barks and their extracts, but principally the 'quinium.' Thanks to the recent nomination of a chemist, M. Moens, as director of the manufactory which I have established in the midst of our plantations, we have the hope of soon being able to obtain directly the alkaloids necessary for use in our hospitals.

"Last May, there was a public sale at Amsterdam of 6000 kilogs. of our barks, at an average price of from two to three florins. The remarkable state of preservation of these barks, of which the odour and colour were very fine, was established. The annual expense of the cultivation is at present balanced by the production, and before 1876 all the cost of introduction will be covered. The individual plantations continue to multiply and very soon the barks of Java will seriously compete with the American barks in the European markets."

PERSIAN OPIUM.

According to information on the opium trade, collected by Colonel Pelly and furnished by that officer to Mr. Dickson, Her Majesty's Secretary of Legation at Teheran, Persian opium gives from two to eight per cent. of morphia. It is principally cultivated in Yezd and Ispahan, and partly in some of the Khorassan districts. The Yedz opium is considered the best. The crop of 1871 was computed at 1200 chests only, owing to the drought, but a good year's crop may produce 2500 chests. About 200 to 300 chests are said to be annually exported to London, 200 chests to Singapore, 200 to Java, and the remainder to China.

We have received an intimation that Mr. E. Alfred Webb, grandson of the late Mr. John Evans, has been admitted into the firm of Evans, Lescher and Evans. Mr. Webb studied at the School of Pharmacy, and was a prizeman in 1871.

The first number of a new periodical, and which it is proposed to make a monthly record of cryptogamic botany and its literature, has been received. It is under the able editorship of Mr. M. C. Cooke, and is called by the appropriate name of "Grevillea." It contains sixteen pages of text, and an excellent coloured plate, the drawing being executed by the Editor, and it is published at a price that is perhaps unprecedently low.

The Juries Bill, as amended by the Select Committee to whom it was referred, has been reprinted. It is satisfactory to find that the exertions of the Council of the Pharmaceutical Society have so far been successful, and that registered chemists and druggists are still included amongst the exemptions.

Provincial Transactions.

NORWICH CHEMISTS' ASSISTANTS' ASSOCIATION.

On Thursday, July 4th, the members who had regularly attended the lectures delivered at the rooms of the above Association, were kindly invited by Mr. Thompson to go for an excursion into the country. Accordingly about eleven started at 6 p.m. in a waggonette for Mulbarton Common, accompanied by Mr. O. Corder, who had kindly undertaken to assist them in examining any plants they might find. On their arrival, the party divided, to ramble through the fields for about two hours to search for specimens, and then returned to the inn, where Mr. Thompson had most liberally provided a substantial meat tea.

After thoroughly enjoying the delicacies displayed, they spent the remainder of the evening in playing various games, and strolling about the beautiful garden attached to the inn. At 10 p.m. the members reassembled, and after cordially thanking Mr. Thompson for his great kindness, proceeded home, having spent a most enjoyable evening.

Mr. Thompson, in his invitation, stipulated that only those who had attended regularly at the lectures should be present on the occasion, as he wished particularly to encourage uniform attendance on the part of the students.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, June 20th.

Deacon's Method of Obtaining Chlorine as Illustrating some Principles of Chemical Dynamics.

BY H. DEACON.

The Lecturer said that about two years ago, at Liverpool, he had given an account of his process for the preparation of chlorine from a heated current of hydrochloric acid mixed with air, which since then had been the subject of a great amount of research, with the object of ascertaining how this could be effected continuously, readily and at the smallest cost. This problem may be resolved into the following:—

1. As to the most suitable active or catalytic substance.
2. Whether the mass or the surface of the substance was the active agent.
3. As to the effect of temperature.
4. As to the best arrangement of the substance.
5. As to the effects produced by variation in the velocity of the current of gas.
6. As to the effect of various proportions of air or oxygen and HCl.

He had observed that the heated mixture of hydrochloric acid and oxygen or air does not yield chlorine, unless it is in the presence of some substance capable of being attacked by the hydrochloric acid, amongst which the copper compounds were eminently active.

Sulphate of copper was fixed upon for economic reasons; and almost all the experiments mentioned in his lecture had been made either with the pure sulphate or with pumice-stone or fragments of clay saturated with it. In experimenting, two clay tubes were generally employed, of different bores, glazed externally, and coated internally with sulphate of copper, placed side by side, and passing through the cork of a glass tube sealed at the other end. The mixed gases, on entering, first traversed the glass tube, and then passed out by the clay tubes. In the more recent experiments this apparatus was placed in a thick massive iron tube, heated externally by a furnace, so as to maintain a uniform temperature. This was measured by the change in electrical resistance of a fine platinum wire, and also by a mechanical pyrometer. The mixed gases were contained in gas-holders worked with strong sulphuric acid, both the amount of hydrochloric acid passed and the amount of chlorine produced being ascertained by passing the gases into a solution of caustic soda.

The Lecturer then explained the numerous diagrams and tabulated results of experiments with which his discourse was illustrated, from which it would appear that there is a certain comparatively small range of temperature, between the critical limits of which the percentage of hydrochloric acid decomposed varies greatly, and that this is not the same for the chloride as for the sulphate of copper, being higher for the latter, although it is the same whether solid sulphate of copper be used or merely pieces of brick saturated with it. This shows that the action is essentially a surface action. It is, however, remarkable that in experiments on a large scale, this temperature is invariably lower than in the laboratory experments, usually 100° or 150°; also, that when the mixed gases are passed through a series of parallel tubes, an increased velocity in the flow of the gas yields only about one-third the increase of the amount of chlorine produced that an irregular porous surface does under like circumstances.

From the results of all the experiments contained in the tables, the speaker inferred—

1. That with the same mixture of gases, at the same temperature, the amount of hydrochloric acid decomposed by the aid of a molecule of the copper salt, in a given time, depends upon the number of times the molecules of the mixed gases are passed through the sphere of action of the copper salt.
2. That in long tubes of the same diameter the number of opportunities of action in the same time are nearly the same at all velocities.
3. That in long tubes of different diameters the number is the same when the velocities of the currents of gas are in inverse proportion to the square of the diameters.
4. That in porous masses the opportunities of action increase with increased velocities, in nearly direct proportion.
5. That, other conditions remaining the same, the percentage of hydrochloric acid decomposed varies with the square root of the proportionate volume of oxygen to hydrochloric acid.
6. That the $CuCl_2$ formed bears no definite proportion to the amount of chlorine produced.
7. That as the sphere of action includes molecules not in contact with the copper salt, therefore hydrochloric acid must be decomposed under circumstances where the union of either element with the copper salt is impossible.

The President said he need scarcely ask them further to record their thanks to the lecturer, for the clear and comprehensive account he had given them of his numerous and interesting experiments on the mutual action of hydrochloric acid and oxygen in the presence of salts of copper. The process for preparing chlorine, at present used, was essentially clumsy and unscientific; the hydrochloric acid given off from the salt cake was first dissolved in water, and then treated with manganic peroxide in order to liberate the chlorine, giving rise at the same time, to a large amount of waste products, which were thrown into our streams and polluted them. As especially interested in our rivers, he sincerely hoped the process would prove a commercial success.

Dr. Williamson said he would like to ask a question or two for his own information. He understood that the mixture of air and hydrochloric acid was heated before being passed into the decomposing chamber; was it cooled again before it went into the chambers containing lime for the preparation of chloride of lime, and was the undecomposed hydrochloric acid previously removed by washing?

Dr. Debus would like to know whether the sulphate of copper was found to be unaltered after having been exposed to the action of the mixed gases for a considerable time, and also whether, when he used straight tubes with the mixed gases passing through at different velocities, the gas in both instances had attained the same temperature when it came in contact with the sulphate of copper.

Mr. Stevenson remarked that he had no practical acquaintance with Mr. Deacon's process; but he thought that if the old process continued to be used, we possessed a great advantage in Mr. Weldon's method for revivifying the manganese, so that, in this revolutionary period of the manufacture, we had the benefit of both processes.

Dr. Voelcker said the lecturer had made an allusion to the action of chromium on the mixed gases in the early part of his lecture; would he, perhaps, kindly explain what was its especial peculiarity?

Dr. Gladstone observed that many interesting points started up in one's mind in connection with the subject, and he should like to know more fully why the lecturer believed the sphere of action to include molecules not in contact, and that the decomposition was not due to direct chemical action. It appeared to him that it was unnecessary to suppose the cause to be the mechanical striking of the molecules of the gas against the sulphate of copper surface, in their passage through the apparatus, and therefore depending on the flow; for it must be remembered that, when a gas was mechanically in a state of rest, the molecules composing the gas are in a state of motion, and that when we heat that gas this rate of motion of the molecules amongst themselves varies, although the gas is still mechanically at rest.

Mr. Deacon replied that it was one thing to express clearly what one had carefully thought over, and another to answer offhand questions that embraced a wide field of inquiry; moreover, he had come there to speak simply on the scientific aspect of his subject, and he thought it would save the time of the Fellows present, and avoid going over old ground, if they would permit him to put aside all technical questions, and reply only to those which had a scientific interest.

In the first place, there is a definite range of temperature where chlorine is freely formed, but no chloride of copper; although at a higher temperature, the sulphate of copper is partly converted into chloride. This only applies to pure sulphate of copper, which, even after the action had been continued for six months, contained but mere traces of chlorine. In the presence of clay, however, the sulphate of copper is decomposed, and chloride formed, probably owing to its containing some base which combines with the sulphuric acid.

In the case where the exterior glass tube contained two clay tubes of different diameters, the gas coming in contact with the copper salt certainly had the same temperature, although moving with different velocities.

With regard to his allusion to chromium, he had expected—from the well-known oxidizing power of chromic acid—that it would have been very active, but, on the contrary, he had found that it was reduced to oxide of chromium, which is one of the most inactive substances.

With respect to the theory he had laid before them, without vouching for its correctness, he could say that it was the only way he knew of accounting for the results he had obtained.

BRITISH PHARMACEUTICAL CONFERENCE.

A Meeting of the Committee was held on Tuesday, July 2nd. There were present:—Messrs. Attfield, Carteighe, Greenish, Hanbury, Mackay, Moss, Savage, Schacht and Williams.

The Hon. Sec., Professor Attfield, read the minutes of the last meeting, which were confirmed, and then laid before the Committee the following report of the business transacted since last meeting:—

Year Book, 1871.—Since the previous meeting of the Committee 2000 copies of the Year Book of Pharmacy, 1871, had been printed; of these there remained in hand 257 copies. Of the 1743 which had been distributed, 1,600 had been delivered to members, 115 had been sold, and 28 presented to Journals and Societies.

Subscription.—Professor ATTFIELD further reported that in November, 1871, he had issued 1600 applications for subscriptions; in May, 1872, he had found a repetition of the applications necessary to the extent of 400, and on June 21st, 1872, had a third time applied for 300 of the subscriptions. At the end of the year, June 30th, 214 remained unpaid.

Subjects for Research.—In March of the present year, 1900 copies of the List of Subjects for Research, 1872, were posted to members. This list, before printing, was revised and extended by Professor Attfield, and a few questions added by some members of the Committee.

Finance.—Professor ATTFIELD reported that after paying all expenses for the current year, including the editing, printing, binding, publishing and delivery of the Year Book, a fresh expense of £9. 12s. 6d. for foreign journals required by the editor of the Year Book, general printing, and salary to Assistant Secretary, there remained a balance in hand of £47. 4s. 1d.

This amount was about the same as that left at the end of last year. It would thus be seen that the income of the Conference just balanced its expenditure.

Year Book, 1872.—The editor of the Year Book had reported to Professor Attfield that the MS. of the Year Book for 1872 was in a forward state; it would be completed quite as soon as that of last year. The printers had promised to produce the volume in a shorter space of time than before.

Mr. SCHACHT then read the following letter from T. H. Hills, Esq.:—

"338, *Oxford Street, June 6th*, 1872.

"DEAR MR. TREASURER SCHACHT,—At the meeting of the British Pharmaceutical Conference, held at Exeter, 1869, I had the good fortune of presenting to your then Treasurer and now the President, my friend Mr. H. B. Brady, a cheque for fifty guineas, suggesting that the Executive of the British Pharmaceutical Conference should present books or chemical apparatus of the value of £10 or guineas, to the Association of the Chemists and Druggists in the city or town in which the Conference met, for the purpose of assisting apprentices and assistants in their studies, and for the advancement of Pharmaceutical Chemistry.

"As this fund must be nearly exhausted, and as I learn or understand, that the experiment has proved useful, I venture to ask you, on behalf of the President and Council of the British Pharmaceutical Conference, to accept the accompanying (4) Russian bonds of £50 each, producing an income of £10 a year, which, I trust, may be kept as a permanent fund; the interest of which, £10 a year, can be used yearly for the purchase of books or apparatus, and presented to the Associations of Chemists and Druggists in the cities or towns in which the British Pharmaceutical Conference meets.

"Although I make these suggestions, I give the bonds without conditions otherwise than that the interest of the same shall be spent yearly for the advancement of Pharmaceutical education and research, under the direction of the President and Council of the British Pharmaceutical Conference.

"I remain, dear Mr. Treasurer Schacht,
"Yours very sincerely,
"T. H. HILLS."

The CHAIRMAN moved, and Mr. SAVAGE seconded the acceptance of Mr. Hills' gift, and that the letter be entered on the minutes of the meeting.

Moved by Mr. SCHACHT, seconded by Mr. MACKAY, and carried unanimously,

"That the members of the Executive Committee of the British Pharmaceutical Conference hereby record their opinion that the thanks of the entire Pharmaceutical community are due to Thos. Hyde Hills, Esq., for his munificent gift, which they regard as calculated to be of lasting benefit to the cause of scientific pharmacy.

"As representing the section of pharmacists which constitute the British Pharmaceutical Conference, they declare their high appreciation of the confidence reposed in them by Mr. Hills in thus constituting their Association the medium of his generosity, and they beg him to accept the assurance of their gratitude, and the expression of their warmest thanks."

After some discussion on the best mode of applying Mr. Hills' gift, it was resolved that a note be addressed to Mr. Hills to the effect that, bearing in view the fact that the Council of the Pharmaceutical Society is at present engaged in furthering some scheme for promoting Pharmaceutical education, the Executive Committee of this Conference prefers to postpone decision upon the principles of the process by which his generous gift shall be distributed.

The following gentlemen were unanimously elected members of the Conference:—

Adams, Frank; Adlington, W. B.; Appleby, Calvert; Balls, J.; Barrett, E. L.; Berry, E.; Berry, T.; Blake, A.; Bland, H.; Booth, W. G.; Brooke, Chas.; Brown, A. H.; Bremridge, R.; Chapman, F.; Chantler, R. P.; Cocksedge, H. B.; Cook, Richard; Cornelius, J.; Cosway, E. C.; Crawford, S.; Cross, William, M.D.; Davenport, G. A.; Delves, George; Dunkley, E.; Evans, J. O.; Eve, Charles; Foulger, S.; Garner, J.; Geary, —.; Goodliffe, G.; Gopal, Pandurang; Goodwin, J.; Green, S.; Greves, J. B.; Gunn, W.; Hadingham, J. W.; Hardy, S. C.; Higgins, W.; Hobbs, D.; Hodgkinson, C.; Hogg, J., F.R.G.S.; Horner, Edward; Horner, Edward, jun.; Howlett, W. H.; Huskisson, H. O.; Iliffe, T. P.; Kirkman, C. J.; Lazenby, J. W.; Lewis, R.; Lingwood, W.; Lloyd, Edward, jun.; M'Naught, A.; Marcham, J.; Martin, T.; Matthews, F.; Meldrum, D.; Moyle, J.; Newport, W.; Nickson, J.; Palmer, G. D.; Pattinson, J. S.; Pearce, C., M.D.; Pocklington, H.; Powell, W. A.; Pratt, W.; Probyn, C.; Purdy, J. T.; Rawlings, T.; Rich, S. W.; Richardson, T. J.; Riches, W. J.; Skoulding, W.; Slinger, F.; Smith, J., M.D.; Smith, J. S.; Smith, P. S.; Speechly, E.; Symes, E. W.; Thompson, G. B.; Todd, T.; Townshend, R.; Vizer, E. B.; Watts, C. C.; Wells, W.; Whitla, J.; Wills, E.; Wilford, J.; Wilkes, J. S.; Wright, T.; Young, J., M.D.; Young, T.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

THE JURIES BILLS.

The House is to go into Committee on the Amended Bill on Monday, July 15th.

THE PUBLIC HEALTH BILLS.

The Committee on these Bills has been deferred till Friday, July 12th.

ADULTERATION OF FOOD, DRUGS, ETC. BILL.

This Bill, which has already been printed (Vol. II. p. 715), is set down for Committee on Thursday, July 11th. Lord Eustace Cecil has given notice of amendments in clauses 4 and 5 that would have the effect of making compulsory the appointment of analysts and the duties of inspectors in procuring samples of suspected articles for analysis. He also proposes to add the following definition of adulteration:—

"The word 'adulteration,' shall mean,—

"1. The admixture of any mineral substance (excepting the harmless compounds of potash, soda and ammonia) with any article of food or drink.

"2. The admixture of anything with an article of food or drink for the purpose of increasing its bulk or altering its natural strength or flavour, unless such admixture is declared by the dealer or vendor to the purchaser at the time of sale, or unless such admixture is clearly set forth in a label upon the article."

PAPERS PRESENTED TO PARLIAMENT.

Report of Sulphur Purification at Beckton Gasworks by the Gas Referees.

This Report has been made by the Gas Referees to the Board of Trade, in consequence of the disappointing failure of the sulphur purification at the magnificent gasworks at Beckton. For a considerable time there has been great dissatisfaction in the City of London with the gas supplied by the Chartered Company, in consequence of the large quantity of sulphur present in it. A correspondence, sufficiently acrimonious in some parts, accompanying this report, shows that for the last three years this point has been urged upon the attention of the responsible parties, and that the time of the completion of the large gasworks at Beckton has been looked forward to as the time when a satisfactory answer would be given to the complaints. But it is mortifying to find that, notwithstanding the care, skill and capital that have been brought to bear towards the solution of the problem how best to rid the gas of its impurities before its delivery to the consumers, the sulphur detected in the gas supplied from the new works when opened was more in proportion than in that from the older works. Of course, such a result was immediately made the subject of investigation, and various experiments were tried in order to remove this grave defect; but these were mostly of special interest only to the gas engineer; and we shall confine ourselves to mentioning some general conclusions at which the gas referees arrived, and which they hope will exercise a beneficial influence on the gas manufacture in the future.

The report relates exclusively to the sulphur in gas which exists in other forms than sulphuretted hydrogen. Of sulphuretted hydrogen not a trace has ever been found in the gas supplied from the Beckton works, although the test slips are now used for three or four hours continuously, instead of one minute, as prescribed by the Act of 1860. But the other forms of sulphur impurity have hitherto baffled the efforts of the ablest and most experienced gas engineers and gas chemists to eliminate them from the gas, or even to devise any certain method by which they may be materially reduced and efficiently controlled. The "purifiers" at the Beckton works are larger in proportion to the make of gas than at any other gasworks in the country; and it was hoped that the hitherto insurmountable difficulty would be at an end; but the result, described by the gas referees as a "complete and most startling failure," shows how little the subject is yet understood.

Opposite opinions have been maintained as to the best manner of using lime and oxide of iron in combination as purifying agents; one opinion being that the oxide should be placed before the lime, the other that the lime should be placed first. At Beckton, the former plan was adopted; but experiments made by the gas referees having convinced them that the gas should pass through the lime first, in June last the conditions were, at their request, reversed.

The new mode of purification came into operation in the beginning of August. At the outset the result was most successful and gratifying, the sulphur for some weeks averaging only 10 and 15 (instead of 43) grains per 100 feet of gas.

The superior efficiency of this arrangement over the other consists in this, that *clean* lime has no appreciable effect in eliminating the "sulphur," *i. e.* the sulphur compounds other than sulphuretted hydrogen; the lime has to be fouled by sulphuretted hydrogen (*i. e.* converted into sulphide of calcium) before it has this effect. Now, this "fouling," or conversion of the lime into sulphide, cannot be attained if the oxide of iron is used *before* the lime, for the sulphuretted hydrogen is taken out by the oxide; so that the lime, through which in this case the gas passes subsequently, is never converted into sulphide, and therefore cannot act upon the "sulphur." But when the gas is passed into the lime before passing through the oxide of iron (in other words, while the gas is still charged with sulphuretted hydrogen), the lime absorbs the sulphuretted hydrogen, thereby becoming sulphide of calcium, in which condition it tends to absorb the sulphur as it exists in the gas in other forms than sulphuretted hydrogen.

Unfortunately and most unexpectedly, the favourable change was only transient; for towards the end of September the sulphur again increased in quantity, and ere long became as great as before.

Another point to which the attention of the referees was directed was the temperature under which the gas was distilled from the coal. It may be roughly stated that a high heat causes the coal to yield a greater quantity of gas, though of inferior illuminating power. When the retorts are over-heated the hydrocarbons are more quickly given off, leaving the coke to be roasted, in which case a larger amount of "sulphur" would be produced than usual. According to the ordinary estimate, about one-half the sulphur originally in the coal remains in the residuary coke; but unquestionably the higher the heat to which the coke is subjected the larger will be the proportion of the sulphur driven off. Moreover, the hydrogen, having been already driven off, the sulphur vapour from the coke will tend to combine with the glowing carbon, forming bisulphide of carbon, *i. e.* the "impurity other than sulphuretted hydrogen." Although it would appear that on the whole the heat used at Beckton is lower than at other London gasworks, it is thought possible that part of the excess of sulphur may result from the overheating of particular retorts.

Sulphur exists in coal chiefly in combination with iron, as pyrites, and also to a small extent in union with lime and magnesia, as sulphates; but as the two latter compounds do not readily part with their sulphur, even under the high temperature of the retorts, it is only the sulphur which exists in the coal as pyrites that is given off in the gas, forming sulphuretted hydrogen, bisulphide of carbon, and it may be to a small extent other compounds not yet ascertained. It is the accepted belief in gasworks that some kinds of coal produce more bisulphide of carbon in the retorts than others; but it seems to the referees that it would be more correct to say that these kinds of coal only *tend* to produce more "sulphur" in the gas by yielding more or less of other products (NH_3 CO_2, etc.), which, as will appear in the sequel, considerably affect the action of the purifying processes upon the "sulphur" impurity.

This is a point that has never hitherto been noted, but in the proper elucidation of which the referees believe will be found an explanation of part of the failure.

The process of cooling and condensing the gas by a long series of pipes placed under ground (such as was mainly employed at Beckton), although possessing some important advantages over the other processes, especially as regards the illuminating power (*e. g.* 1, by preventing any sudden cooling of the gas; 2, by keeping the tar for a longer time in contact with the gas; and, 3, by being free from those sudden variations of temperature to which condensers in the open air are exposed), is, nevertheless, very defective as regards the main work of cooling and condensation, which is indispensable to perfect purification. If the gas is not properly cooled in the condensers before entering the scrubbers, the absorbent power of the water in those vessels is diminished; while if tarry vapour in large quantity is carried forward into the scrubbers, the scrubbing material (as sometimes happens) may be suddenly "fouled" to a degree which seriously affects the purifying action of the apparatus.

Scrubbers are used in gasworks mainly for the purpose of taking out, and retaining, the ammonia in the gas (a process which is a highly profitable one for gas companies); and they also eliminate a considerable portion of the sulphuretted hydrogen impurity. But, besides the ammonia and sulphuretted hydrogen, the scrubbers are capable of taking out a large portion of the carbonic acid in the gas; and this is the important point here. The portion of the carbonic acid not taken out by the scrubbers, of course, goes forward with the gas into the purifiers. Now, in the case of lime purifiers, the entrance of carbonic acid is of all things the most detrimental to their action; for it converts the lime into carbonate of lime, which has no effect upon the sulphur in the gas at all. However large or numerous the purifying vessels may be, in so far as the lime contained in them exists in the form of carbonate, they are perfectly useless; and, as already stated, *clean* lime also (though quickly absorbing sulphuretted hydrogen) has hardly any action upon sulphur in other form than SH_2.

These two facts show how it may happen that neither magnitude of the purifiers, nor frequent changes of the lime, have any corresponding effect in purifying the gas from "sulphur," which has hitherto been the case at Beckton. It is only when the lime exists as sulphide of calcium that it acts upon "sulphur;" hence the larger proportion of lime in the purifiers which can be maintained in the form of sulphide of calcium, the more efficient will be the purification from "sulphur."

When the lime is used before the oxide of iron (as since August has been the case at Beckton), the sulphuretted hydrogen in the gas, if it have a free field to act, will speedily and certainly convert the clean lime in the purifiers into sulphide of calcium; but, along with sulphuretted hydrogen in the gas, comes carbonic acid, which at this stage of purification exists in the gas in larger quantity than the sulphuretted hydrogen, and which has also a greater affinity for lime than the sulphuretted hydrogen has; consequently, the sulphuretted hydrogen can only seize upon that portion of the lime in the purifiers which the carbonic acid is not in sufficient quantity to occupy. In this way, only a small portion of the lime may be in the form of sulphide, the remainder being carbonate. Say that only one-fourth of the lime in a purifier exists as sulphide, then a purifier of one-fourth the size, if its contents existed wholly in the form of sulphide, would do as much work upon the "sulphur" as the larger one. As lime in the form of carbonate does not take up sulphur in any form, it follows that as soon as the remainder of the lime is occupied by the sulphuretted hydrogen, the purifier can take up no more sulphuretted hydrogen, and consequently becomes "foul," the sulphuretted hydrogen thereafter passing through it unabsorbed. Moreover, carbonic acid, having the greater affinity for lime, as it continues to enter the purifier, invades the part of the lime which exists as sulphide, expelling the sulphuretted hydrogen from the lime and taking its place; so that the contents of the entire purifier would ultimately be converted into carbonate, which, as already said, does not act upon sulphur in any form. Thus a purifier may be "foul" without being saturated with sulphuretted hydrogen at all; its contents existing wholly as carbonate of lime, and therefore powerless to absorb sulphur in any form. Such an excess of carbonate in the lime-purifiers, proportionately nullifying their action, is unquestionably, in the opinion of the referees, the true cause of the recent and unexpected failure in this branch of the gas-purification at Beckton.

Careful observations at Beckton show the temperature of the gas as it enters the scrubbers has averaged 100° F. throughout the past year; whereas in several of the London gasworks the temperature at the same stage of purification is only 60° or 70° F. Water at the temperature of 60° F. (barometer 30°) is capable of absorbing 780 times its own volume of ammonia, fully $2\frac{1}{2}$ times its volume of sulphuretted hydrogen, and one volume of carbonic acid. These figures show that water has a lesser affinity for carbonic acid than for the two other mentioned gas impurities; so that a very large quantity of ammonia and a considerable quantity of sulphuretted hydrogen may be taken up by water when the temperature is such that no portion of the carbonic acid in the gas is absorbed at all. As heat impairs the absorptive power of the liquor, it is obvious that the higher the temperature of the scrubbers the larger will be the quantity of carbonic acid (as well as of ammonia and sulphuretted hydrogen) which escapes from them unabsorbed and passes forward with the gas into the purifiers.

Thus, independently of experiments, it is perfectly certain that carbonic acid must enter the purifiers at Beckton in greater quantity than is usual in gasworks; and so far as any testings have been made, these testings corroborate this most important inference.

It is therefore evident that wherever lime purifiers are used, it is important above all things to keep out carbonic acid. Indeed, the anomaly observable at the Bow works, where two lime purifiers in winter are as efficient as the whole three are in summer, is probably to be accounted for on this ground; the temperature of the condensers and scrubbers being lower in winter than in summer, and consequently more carbonic acid (and also more sulphur) is taken out of the gas *before entering the purifiers* in the former case than in the latter. The difference also between the kinds of coal which have respectively a good or a bad name as regards "sulphur" may arise more from the amount of carbonic acid which they contain than from the amount of sulphur.

The referees think the prime object to be sought is to utilize and perfect the existing processes of purification; for, if these can be made to yield satisfactory results, the interests of the public require that this should be accomplished in preference to the introduction of other processes which would increase the cost of gas manufacture. They feel confident that such a result is attainable. Experiments which they have made show that lime in the form of sulphide of calcium (*i. e.* saturated with sulphuretted hydrogen) is a perfectly adequate purifying agent for "sulphur." In their laboratory experiments, they are able in this way to wholly remove the sulphur (about 26 grains per 100 feet) from the gas supplied to their office. So complete a result, of course, cannot be expected in gasworks; indeed, even in their laboratory experiments, they found that the purifying power of the material decreased on each subsequent day, owing, doubtless, to the carbonic acid in the gas (about 1 per cent.) gradually nullifying a portion of the material by converting it into carbonate of lime. Nevertheless, making due allowance for the difference between laboratory experiments and purification on a manufacturing scale, the referees feel assured that perfect results would be obtainable from the lime process of purification if carbonic acid were excluded from the purifiers; and also that the result will be adequate to the requirements of the public if the carbonic acid which enters the purifiers be kept down to the lowest point actually attainable in gasworks.

The problem to be solved is, how to take out all the carbonic acid from the gas without simultaneously taking out all the sulphuretted hydrogen? which latter element is needed to convert the contents of the purifiers into sulphide of calcium. And the essence of the difficulty consists in the fact that carbonic acid exists in the gas in very much larger proportion than sulphuretted hydrogen does; while there is no chemical substance which absorbs carbonic acid without also absorbing sulphuretted hydrogen.

Suicide by Cyanide of Potassium.—The Sale of Poisons.

On Wednesday, July 3rd, Mr. W. H. Garrington, the borough coroner, held an inquest at Portsea relative to the death of Charles West, sapper in the 32nd company of Royal Engineers.

Thomas Lawrence, a sapper, said he was at work in the tailor's shop, at Anglesea Barracks. At about six o'clock on Tuesday morning, West entered the room and asked him for a penny, saying he had got one penny and wanted another. Witness told him he had not got a penny to give him, upon which he went over to the shelf running across the room and took up one of the bottles there, asking, at the same time, whether there was cyanide in it. On being told that it contained cyanide of potassium, West put the bottle to his mouth and commenced to drink. Witness got off his board immediately and took the bottle away from him, but not before he had taken a good mouthful of the cyanide, about half a wine glassful. West then ran downstairs to the pump in the backyard, from which he pumped some water into a basin and drank it, but he almost immediately fell down. West struggled very much whilst on the ground, and froth came from his mouth. He became insensible when he fell, and his face became very yellow, whilst his lips became black. He was taken into a room and attended to by a surgeon, who directed his removal to the garrison hospital. It was customary to keep cyanide of potassium in the room; it was used for cleaning gold lace The bottle from which deceased drank belonged to witness, and was used by him in cleaning the gold lace on the non-commissioned officers' uniforms. On the 7th of June he sent for 6*d.* worth of cyanide of potassium, which he mixed in half a pint of water and placed in the bottle produced. There was no label on the bottle to indicate its contents. He often obtained cyanide of potassium at druggists' shops at other places where he had been stationed, and had never experienced any difficulty in getting it, on signing his name in the druggists' books.

A juror said he was in the habit of using cyanide of potassium, and he had always great difficulty in obtaining it from chemists in Portsea. It was almost a slur on the chemists of the town, but he knew they were very particular.

The Coroner said the witness referred to other places, as he had not yet bought any in Portsea.

Mr. Patrick Walter Stafford, assistant surgeon on the Staff of the Portsmouth Garrison, said that when he first saw West, he was in a dying state, in fact he died two minutes afterwards. Witness had made a *post-mortem* examination of the body, and found the stomach half filled with semi-coagulated fluid, which had a strong penetrating odour of prussic acid. He had analysed the contents of the two bottles produced, and found them to be a solution of cyanide of potassium of considerable strength.

Some evidence was given tending to show that the mind of the deceased was affected.

Thomas Kent, sapper, said he recollected being sent by the first witness (Lawrence) on the 7th of June to buy some cyanide of potassium. He went to the shop of Mr. Woollons, chemist and druggist, in Queen-street, Portsea, and asked for six pennyworth. Witness was in uniform. The person in the shop asked him if he knew what it was used for, and witness replied for cleaning gold lace and chains. He was not asked his name, and saw no entry made in the book of sales of poisons; he signed no book. He was supplied with the article he asked for without further demur, except that he was cautioned that it was a rank poison.

The Coroner said the law was that a person to whom a sale of poison was made should enter his name in a book, and, he believed, the purpose for which he required it.

A juror said he was in the habit of obtaining it, and he had to sign his name in a book and to say the purpose he wanted it for, and he knew of an instance in which a person could not obtain the poison until he took some friend with him.

The witness said there was a label marked "Poison" on the packet given him.

The Coroner, in summing up, said the only point for the jury to consider was the state of the mind of the deceased when he took the poison, as the evidence was so clear and conclusive of his having taken it, and there was no question that was the cause of death. They had the evidence of the last witness that he purchased the poison at the shop of Mr. Woollons. It was in very constant use, and no doubt druggists were frequently called on for it, which rendered it the more incumbent on them to surround the sale of it with all the precautions the law demanded. In the Sale of Poisons Act there were certain provisions that when any poison was sold the sale should be entered in a book, and Mr. Woollons, or whoever sold the poison, had clearly committed a breach of the law in that respect. If any one asking for the poison was not known to the person to whom he went, he must take some one with him to prove he was the person he pretended to be, and also to satisfy the vendor he required it for a legitimate and proper purpose. Chemists were required to keep a book in which to enter the dates, the names of the article and the quantity, the purpose assigned for its purchase, and then the signature and residence of the person buying it. That was, so far as he recollected, what was required, but all druggists were bound to enter any sale of poison. Mr. Woollons was not there to make an explanation, and it would be unfair and unjust for him to make any further comments on this point. The Coroner next referred to the fact of the poison having been kept in the tailor's shop, as it was—the bottle being carelessly placed on the shelf, without any mark on it to denote it was poison. He pointed out how easy it was for any one to abstract it, and also the danger likely to occur by a person half drunk, and therefore with a natural craving for drink, mistaking it for gin or something else, and taking up the bottle and drinking from it. Accidents of that sort had occurred. He hoped that Lawrence would have this concoction, or anything else which was deleterious or poisonous, which he was obliged to use in his business, labelled and kept in a place of security.

The jury, after a short deliberation, returned a verdict that deceased died through taking the poison, but that there was no evidence to show the state of his mind at the time. The foreman stated that the jury endorsed the opinion of the Coroner, both in regard to the sale of the poison and also as to the easiness of access to it in the workshop.—*Portsmouth Times.*

Suicide of a Chemist by Prussic Acid.

An inquiry into the circumstances attending the death of Mr. Frederick Stockman, aged 41 years, who committed suicide by poisoning himself, was held at Gosport on Saturday last, by Edward Hoskins, Esq., county coroner. The widow of the deceased deposed that the deceased was formerly a chemist and druggist, living in Forton Road, and on Thursday she last saw him alive. He had been suffering from mental depression for some time. At dinner time witness sent one of the children into the shop to ask him to come to dinner, but he told the child to go away, whereupon witness herself went out. He told witness to serve the customers; but she replied, "There is no one here to serve," and added that she would not go indoors without he accompanied her. She, however, at his request, went in; and in about two minutes, hearing a strange noise in the shop, she proceeded there, and found her husband sitting in a chair insensible. Thinking he had fainted, witness sent for a next door neighbour, who afterwards summoned a doctor; but witness thought, before medical aid arrived, the deceased was dead. He had been for some time past troubled in business matters, and witness thought this had turned his mind.

Mr. George Perfect, a retired chemist, residing at Southsea, stated that he had known the deceased for the past thirty years, and he was generally of a desponding disposition. Witness knew that he had recently had great trouble in pecuniary matters, and also in his business, which he purchased in September last. It did not come up to his expectations, and in consequence he showed considerable despondency. Witness last saw him on Tuesday in London, where they had been trying to arrange his affairs, but they found they had gone so far that a trial was inevitable. He (deceased) was so excited that at times he was incoherent, and displayed great absence of mind. From his last interview with him, witness did not believe he was in his sound senses.

Mr. William B. Smith said he knew deceased, but had never noticed any peculiarity about him. On the Thursday afternoon witness was called to the house, and found him in a chair behind the counter, breathing very heavily. Witness applied restoratives to the nostrils, but they were ineffectual, and deceased died about two minutes afterwards. As they were laying him on the floor, Mr. Smith detected a strong smell of prussic acid, and on looking round, he found the bottle produced, from which the smell proceeded, standing on the counter almost empty.

Dr. John Butcher, of Spring Gardens, said on Thursday he was called to see the deceased, and on examining him found him to have died from taking prussic acid,—such a large quantity, he thought, as to produce almost instant death.

The Coroner, in summing up, characterized the case as a lamentable one, and left the question for their determination whether or not deceased was in a sound state of mind when he committed the act. The evidence certainly tended to show that he had been, in consequence of his affairs, in a state almost, if not quite, bordering on insanity.

The jury immediately returned a verdict of suicide while of unsound mind. —*Hampshire Telegraph and Sussex Chronicle.*

Review.

Air and Rain: The Beginnings of a Chemical Climatology. By R. Angus Smith, Ph.D., F.R.S., F.C.S.

The science of chemical climatology promises to be an extensive and important one, since this large volume, containing the results of an enormous number of experiments, which have occupied the author during the last eight or ten years, is still truly only concerned with the beginnings of the subject. The book is very well written, and is remarkably free from errors of the press. The hieroglyphic on the cover is rather puzzling, and is apparently not explained in any part of the work; but it seems to be the symbol for "Air" suggested by Bergmann in the last century.

The introduction gives a terrible list of the substances commonly to be found in air, including carbonic acid, hydrogen and its compounds, hydrochloric, sulphuric and sulphurous acids, sulphuretted hydrogen, the multiform *débris* of living things, living things themselves, chloride and sulphate of sodium, nitrate of ammonium, lime salts, iron, phosphates, iodides, "and probably a little of everything, at times, . . . which the sea or the surface of the land may contain;" so that the author says, "instead of thinking it nothing, we are now inclined to go nearer to the other extreme."

A very important correction is made of the statement, often found in works on physiology, that air can support respiration until it contains ten per cent. of carbonic acid. It is shown by a number of careful experiments that human beings cannot long endure an atmosphere containing more than four per cent., the higher numbers having probably been obtained by experiments of very short duration. But although as much as two or three per cent. of carbonic acid causes but little annoyance, it is shown that this is only true when other impurities are absent. The senses detect the difference between the air of the streets and of the parks of London, where the difference of the carbonic acid is only ·004 per cent., the real annoyance arising from organic matter and gases from putrefaction. Hence the quantity of carbonic acid found is significant, "because it almost always comes in bad company."

The passage on page 67 should be commended to the attention of the authorities concerned. It is there shown that the atmosphere of a London law court contained a less amount of oxygen than any place above ground except the gallery of a theatre which had been extremely crowded for a whole evening. Dr. Smith says deliberately that this court was worse than a midden, that it was not to be voluntarily borne, and that the feeling of relief on coming out was remarkably pleasant. The air of the lantern of the same court was worse still. Can it be reasonable to expect justice to be administered by men working in such a "black hole of London," especially as the judges are seated aloft, and so subjected to the atmospheric sewage of all present?

It is somewhat surprising after the numbers in the earlier part of the book showing that, as far as oxygen and carbonic acid are concerned, the air of the western parts of London is rather better than that of the remainder of the metropolis, to find that the rain-water of the western and west central districts contains a much greater proportion of chlorides, sulphates, and free acid than that of other districts.

The paragraph at page 414, on the sense of smell, is extremely important, and to the chemist raises the question whether a laboratory, with its atmosphere almost always charged with varying odours, is a proper place in which to exercise it. Ought not things whose odour is to be examined to be first carried into the open air? Dr. Smith says, in order to give the sense of smell a fair field, "The organ must work in pure air, and the substance to be tested must be put to it for a short time only."

Perhaps the most valuable part of the whole book is that devoted to the subject of ventilation, of which people talk so much, and know and do so little. We are told that the amount of organic matter exhaled into the air increases with the temperature, while the carbonic acid does not; and as the latter is not perceptible when not in excessive quantity, we ventilate freely in warm weather to get rid of the active annoyance of organic matter, but are careless on this point in the cold season; so that the result of want of ventilation is in summer a feeling of closeness, and in winter of drowsiness caused by the accumulation of carbonic acid and consequent lowering of vitality. This is principally spoken of in connection with public places of assembly, but is also true of private houses. We are told that ·16 per cent. of carbonic acid affects a candle sensibly; what then is likely to be the effect on the human frame of the atmosphere of a bedroom which contains ·23 per cent., as in Pettenkofer's analysis given on page 49? Yet it is true that for a great part of the yearthe majority of bedrooms are entirely without adequate ventilation, and many are carefully made as nearly air tight as possible. An oppressive and powerfully odorous atmosphere is submitted to from a dread of injury from night air, which is, rightly or wrongly, supposed to be eminently deadly. It would be a very great service to mankind if medical men would investigate and speak fully and freely on this point. Dr. Smith appears to think that the air of the night is rather better than that of the day; and it seems impossible that it can be so harmful as that in a room without ventilation.

It seems hard to give any adverse criticism on a book so full of valuable information as this, but there are two points which call for notice. On page 274 it is said that sulphuric acid or sulphate "increases inland, even without smoke, on account of the decomposition of vegetable and animal matter. This is best seen in the table of proportions." But in the table on page 273 (which appears to be the one referred to) the inland Scottish places contain the smallest quantity given in the whole table; and inland English places contain much less than English country places, or the average of Scottish country places. The statement may be true, but it does not follow from the results here given.

Then on page 509 the statement that a porous soil removes offensive material "by an agency within itself," is likely to convey a false idea. The action in question depends upon a sufficient supply of oxygen being afforded; and if this is not done, the soil has little or no power within itself to remove organic matter. The overloading referred to on the preceding page is in most, if not in all, cases due to the excess of organic matter over the oxygen, and if the latter be abundantly supplied, the amount of organic matter which can be destroyed is almost unlimited. In the paragraph on the application of sewage to soil, the same important item is again omitted, although porosity of soil would be of little use if the aeration were insufficient; and sewage itself never contains enough dissolved oxygen to burn the whole of the organic matter.

These, however, are but slight faults in view of the weighty merits of the book, which cannot fail to have a most important and valuable influence on sanitary science. We rarely meet with books so amply filled with experimental results, and so notably free from dogma.

Obituary.

REUBEN CRAVEN PAYNE.

We regret to have to record the death of another of those gentlemen against whose names in the calendar the date "1841" shows that they were "founders" of the Pharmaceutical Society. Mr. Reuben Craven Payne, Pharmaceutical Chemist, of Bridgewater, died on Thursday, June 28th.

Mr. Payne was born in 1808 at Tottenham. Himself a prominent member of the Society of Friends, he was the son of Mr. Peter Payne, a "convinced Friend;" his mother being of the well-known Quaker family of Pryor. He was educated at the school of Joel Lean, situated at Frenchay, near Bristol, which had a deservedly high reputation as the first Quaker school of the time. After leaving school he studied for some years the business of chemist and druggist at the establishment of Messrs. Allen, Hanburys and Barry, of Plough Court. While in London he formed an intimate friendship with Dr. Martin Barry, F.R.S. (after whom one of his sons was named); and with Alexander Barry, F.R.S., who died from an explosion that occurred whilst conducting some scientific investigations at Furnival's Inn, as well as with John Thomas Barry, who was a partner in the above-named firm. He continually frequented the debates in both Houses of Parliament, especially those having reference to the improvement of the criminal code. In after years he often told, in his family circle, interesting anecdotes of episodes in the House and its lobbies in connection with the passing of these great measures.

Shortly before 1836, Mr. Payne purchased a business that had been established at Bridgewater. In 1837, he married, and afterwards lived in the comparative seclusion that is usual among members of the Society of Friends, especially those of the old school. Amongst his few intimate friends at Bridgewater were two or three neighbouring clergymen and Mr. Andrew Cross, the electrician.

Mr. Payne was very fond of art, and himself painted in oil, both landscape and figures, with considerable power. Passionately fond of nature, there was not a rare bird or flower, or beautiful view in the county that he did not know perfectly. To wait for the kingfisher along some stream that it haunted; or, in the evening, to wait under a tree frequented by the nightingale; or, indeed, to watch the habits of any beast, bird or insect was his delight.

Mr. Payne leaves two sons,—Mr. John Horne Payne, M.A., barrister, and Dr. Martin Henry Payne, who is now in New Zealand,—and a daughter, recently married to Mr. Lewis Thompson. Anxious to give his children the best possible education, he had them educated at home, until the age of fifteen, by resident tutors. To complete their education, his sons were afterwards sent to travel on the continent for some time. In 1852, Mr. J. Horne Payne was sent to University College; he took his B.A. degree with double honours at the London University, in 1857, and in 1860 the degree of M.A. in Branch II. mathematics.

Mr. Payne's kindness to the poor was such that none but his immediate relations mourn him more, and his funeral was accompanied to the grave, not only by a large number of the well-to-do inhabitants of the town, but by numbers of the poor who showed by their tears their regret at his loss. During the cholera season which visited the town some years ago, *none* was more unremitting in aiding by personal attendance on the sick poor from very early morning till late at night; but, generally speaking, his aid was quietly and unobtrusively given, though he never refused to render it.

For two months previous to his decease Mr. Payne was confined to his bed, and his death, from gradual paralysis, was preceded by insensibility for several hours.

We regret to have also to record the death of Mr. Pickering (of the firm of Butler, Pickering and Beckett), of Leicester, who was found dead in bed on Sunday morning, July 7. On Saturday evening, before retiring to rest, he vomited blood and complained of being unwell, saying at the same time he would go to bed. His son, who was sleeping with him, on awaking about half-past one, found him quite dead. Mr. Pickering has been a member of the Pharmaceutical Society since 1842.

PROVINCIAL PHARMACEUTICAL EDUCATION.

Sir,—Will you kindly further the purpose which the Council had in view in publishing the outline of their scheme for promoting Provincial Pharmaceutical Education, by giving the best prominence you can spare to these few lines.

Their object is to urge upon every member of our body who has a thought upon the subject to communicate it at once, either through your columns or by letter to some member of the Committee.

It may not be possible to reply to each individual correspondent, but I am sure that every suggestion will receive careful consideration.

The Council are most anxious to devise a scheme that shall prove generally satisfactory to the trade at large; and, as in this matter they are treading upon almost strange ground, they feel that the way would be largely prepared for them, and their labours would be much assisted by the fullest expression of opinion upon every point bearing upon the question.

G. F. SCHACHT.

Clifton, July 10th, 1872.

Sir,—As a contribution to the forming a judgment by the members of the Pharmaceutical Society on the above all-engrossing topic of the hour, I shall esteem it a special favour if you can find space in the Journal for some proposals on on the subject that I had intended to submit to the Council at its last meeting as an amendment upon an intended motion on the subject by one of my fellow-councillors.*

In asking a consideration of my own proposals, I cannot avoid expressing the deep sense I have of the great obligations under which our Society is laid to Mr. Schacht for his very valuable paper on the subject, as published in the Journal of to-day. It will amply repay the most careful study of its contents. It embraces all I advocate on the subject, and I venture to place my own proposals before the Society with no view of detracting from its merits, but solely because, in some aspects of it, it may, as it appears to myself at all events, be more readily appreciated and carried into actual operation.

DANIEL FRAZER.

Glasgow, July 6th, 1872.

P.S.—It is due to Mr. Schacht to add that though I, after reading them in the committee on the previous day, omitted to bring the following resolutions before the Council on Wednesday, largely because of the withdrawal of the motion to which I had intended to move them as an amendment—as notified to the Secretary some days previously—I did not so even more because of the fact, brought out in our discussion in committee, that his scheme really does embrace all that mine does. I may also add that I have now the best reason to know that before Mr. Schacht again brings his scheme before the Council, this feature of it will be made even more explicit.

Sir,—At the last meeting of the Council, on July 3rd, I see, from the report in the Journal that Mr. Schacht has propounded a most able, very comprehensive, and highly practicable scheme for promoting scientific pharmaceutical education throughout the country. I rejoice to find that the Council has accepted the principle of it. By doing this they have wiped away the reproach which was very generally felt that, as far as this subject is concerned, they were an organised hypocrisy to the country members of the trade.

The scheme itself is an admirable one, and with some slight alterations in details, and with the additions so nobly and so judiciously proposed by Mr. Hills, especially that of assisting small classes, it may be made to comprehend the requirements of the entire trade throughout the kingdom. I consider that assistance to small classes should be made one of the "Principles of the Scheme." The suggestion of Mr. Baynes, that a small capitation grant should be given to associations for students who had attended the classes a certain number of times is well worthy of attentive consideration.

I see from the report of the discussion which followed the introduction of the scheme that a member of the Council, whilst approving of it, doubted the propriety of employing lecturers, a statement which I have read with considerable surprise, coming as it does from an old member of the trade. My own opinion is that the success of a school of pharmacy is, to a very large extent, dependent upon the ability of its lecturers. What would the medical profession think, if one of its members should express a doubt as to the wisdom of employing lecturers on anatomy, surgery, and other branches of science!

I am also glad to find that Mr. Baynes has proposed reinvesting some of the funded property of the Society. I trust he will persevere until he has reinvested the whole of it. I cannot see the wisdom of investing money at three per cent., when large Insurance Companies invest immense sums of money on real security at four per cent. There are times when Railway Debenture Stocks and Guaranteed Perpetual Preference Stocks may be bought to pay four and a half per cent., securities quite as safe as Consols. This would make a very important addition to the income of the Society.

ATKINSON PICKERING.

Hull, July 8th, 1872.

Sir,—The scheme proposed by the Council to promote pharmaceutical education in the provinces is undoubtedly a step in the right direction, but it does not go far enough. It deals unfairly with all apprentices and assistants not in connection with an educational trade association; in fact, it is modelled too strictly on the Government Science Classes principle. It may be necessary in conducting the government classes, that the student should be under the supervision of a properly constituted committee, which is to see that the payments are made only on account of those for whom the classes are intended. But such regulations are unnecessary with the body of chemists. Of course the grants of the Society must be paid to pharmaceutical students only; and this can be secured without making it necessary for students to belong to any association or to be under the control of any committee during his studies. If all registered apprentices, and perhaps assistants, eligible to pass the Modified examination, be entitled to receive payments on results, in aid of pharmaceutical education, then, and then only, will the Council be acting in fairness to those young men residing in those districts where there are no such associations or classes. If a registered apprentice passes the necessary examination, he should receive the grant to reimburse him the expenditure he must have incurred to gain the requisite knowledge, which in other more favoured places, would have been borne by the masters as a body. If a student belongs to such an association as is contemplated in the scheme, then the grant should be paid to that body which has given the student increased means for study. Let any one take a map of England and Wales, and mark each place having, or even likely to have, classes for pharmaceutical students, and the unfairness of the scheme will at once be apparent. There are many assistants and apprentices residing fifty or sixty miles away from any such educational centre, and it is impossible for them to attend classes at such a distance; I think even ten or twelve miles will generally be found an inconvenient distance.

RALPH ROBINSON.

Rochdale, July 10th, 1872.

Sir,—In answer to 'G. T.' respecting money spent on the School of Pharmacy at Bloomsbury, I would remind him of what has been more than once stated in your pages. First, that the reason money is spent at all on Education by the Pharmaceutical Society is that, up to the present time, pharmaceutical education has not been able to pay its own expenses. Second, that whatever amount of money belonging to the whole Society has thus been expended has been spent for the benefit of the whole trade, four-fifths of the students coming from provincial towns, such as those mentioned by 'G. T.' The School of Pharmacy in London is not the London School of Pharmacy, it is a school for the whole country. This distinction has not been made by 'G. T.' and other correspondents.

N. D

* See p. 29.

Reporters at the Council Table.

Sir,—And so the skies have not fallen yet! And that antiquated gentleman who dates his membership before the deluge, will be able to add to what must be a long and varied experience! He will have attained the knowledge that the Council of the Pharmaceutical Society have permitted an independent report of their last meeting to be made without showing themselves to be either fools or conspirators. But I dare say that he has found out before this time that we all "live and learn."

The *rôle* of Nestor has been reverenced for many centuries, and gentlemen whose grey hairs have become a crown of glory—how white must be the hair of the gentleman in question!—are rather partial to attempting the part. This is on the whole a fortunate thing for the world; but it is necessary that they should be correct as well as concise in their pragmatical utterances, or they will lose reputation as prudent counsellors and persuasive orators, and their crinal crowns will be mistaken for caps and bells.

What does our ancient friend mean by saying that it is "usual for the deliberations of representative bodies, charged with administrative and executive duties only, to be conducted privately?" Does he go to sleep and only wake up once in a millennium? Did his last somnolence commence before the publication of newspapers? If so, I hope that before he takes his next nap he will make a note that in the present day there are such bodies as school boards, boards of works, and vestries,—bodies that although they are charged with "administrative and executive duties only," conduct their deliberations in public.

On the other hand, the remark that "legislative functions, on the contrary, are properly exercised in public, but these are not within the function of the Council," is peculiarly unfortunate. For if it can be said of any body that Parliament has delegated to it legislative powers, such may be said of the Pharmaceutical Society. And, I agree with the opinion expressed by a speaker at the Annual Meeting of 1871, that "it is a very proud privilege, a great distinction, to have been associated with Parliament in making laws for our own government." As to the evident sneer about boards of directors and committees of trades unions, I must confess that I do not see the force of it, unless they had representatives in the days of Noah who bore as bad a reputation as they do now. Perhaps your correspondent belonged to an antediluvian limited liability company, and lost one of his earlier fortunes by it.

But seriously, Sir, I congratulate the Council upon what they have done, although it will require tact and judgment on the part of the chairman to avoid the bringing forward of matters better discussed in committee. It will also throw extra responsibility upon yourself, but I am sure that will be undertaken cheerfully under the circumstances. The result I believe will be a great gain to the Society, by the creation of a more active current of opinion between the members and their representatives; whilst those individuals whose tender consciences and timorous dispositions have hitherto compelled them to stand aloof—reaping all the advantages without assisting in purse or person—will be relieved from that painful necessity. They will see that our councillors are not persons who are continually plotting the injury of outsiders, but gentlemen who look upon the welfare of the Society as identical with the welfare of the whole trade.

A Post-Diluvian.

Death from an Overdose of Morphia at Morecambe.

Sir,—Mr. Johnson, in his evidence before the Coroner says, "it is usual to mention in the prescription the materials of which the pills are to be made; but it is *not usual* to say divide." Allow me to inform him that it is *most unusual* not to say divide, for in 441 prescriptions which I have before me, selected from Neligan and Druitt, in *no instance* are the ingredients given for more than one dose of either pills, powders or draughts without the word "divide" or "forma;" and where ingredients are directed to be mixed with mucilage, syrup, etc., "q.s. ut fiant pilulæ xij," or, as the case may be, is the invariable custom. It is also most unusual to give verbal directions for dividing pills, when the prescription for their ingredients has been handed to the dispenser. I have dispensed prescriptions for surgeons in different parts of the country for the last fourteen years, and during all my experience, I never came across a similar instance to this. Had the writing of the prescription been completed in the usual way, I think there is every probability this lamentable accident would not have occurred.

Alexander Ellis.

Skelton-in-Cleveland, July 9th, 1872.

The Benevolent Fund and its Donors.

Palmam qui meruit ferat.

Sir,—In the Calendar of the Pharmaceutical Society, 1871, the subscribers and donors to the above-named Fund, are marked by an asterisk. Many of our junior members may not be aware that at the commencement of our Society, for four years, the annual subscription of members was two guineas, viz., 1841, 1842, 1843, 1844, and the object was that a moiety might go the Benevolent Fund.

In the First and Second Volumes of the Journal the members are styled "Founders;" and the context shows that they were considered founders both of the Society and of the Benevolent Fund. Their annual subscriptions formed the nucleus of both Funds. This subject is fully admitted in the Journal for November, 1844, Vol. IV. p. 198, etc.

Now, under these circumstances, why is the honour now taken from the old members? In the Calendar, why is not a star of the first magnitude attached to their names?

Joseph Leay.

Chilcompton, Bath, July 1st, 1871.

Dispensing Prices.

Sir,—A few days ago the following prescription was brought to me by a retired surgeon to be dispensed:—

℞. Acid. Nitro-Mur. dil. . . . ℥ss
Extracti Cinchon. Flavæ liq. ʒij
Tincturæ Lupuli . . . . . ℥iss
Liquoris Taraxaci . . . ad ℥vj
M. ft. Mist.

and for which I charged the very low sum of two shillings, cutting it as I imagined as fine as possible, which he thought remarkably high; in fact, more than he ever paid for a similar mixture during a practice of over thirty-five years.

When he required a repetition, and at the same time being desirous of obtaining the same at a reduced price, he went to a "quasi"-wholesale and retail establishment—at one time an eminent house in the City; they asked one shilling and ninepence for a single bottle, but would make a reduction if two were taken, dispensing double quantity for three shillings, being, in fact, within two or three pence per mixture of what the ingredients cost wholesale.

All that I have to remark is, that if such once eminent firm is satisfied with so small a percentage of profit I am not, as I have not yet discovered the valuable secret of buying and selling at the same price so as to make it pay.

Ægles.

Clifton.

"*Inquirer.*"—We should recommend you to make it according to the B. P. formula, omitting the sugar.

G. E. Crick.—(1) Wanklyn and Chapman's 'Water Analysis' and Sutton's 'Volumetric Analysis.' (2) The article on "Organic Analysis," in Watts's 'Dictionary of Chemistry.'

S. E. Pritchard.—Probably Bentley's 'Manual of Botany,' published by J. and A. Churchill, would meet your requirements.

"*Chemist and Druggist.*"—You appear to have misunderstood the purport of the circular. It is not said that persons not carrying on business are liable to have their names struck off the Register, but that failure to reply to the question as to present address will, after a certain time, become a legal justification for the Registrar striking off the names of persons so failing.

"*Invalid.*"—Probably you would obtain the information you ask for from any respectable surgical instrument maker.

Communications, Letters, etc., have been received from Mr. Odling, Dr. F. Porter-Smith, J. W. Yates, Mr. H. C. Mason, Mr. R. J. Davis, Mr. Balmanno Squire, W. B. S., "Minor Associate," "Glasgowensis," "Alpha."

ANTISEPTIC PHARMACY.

BY WILLIAM MARTINDALE, F.C.S.,

Dispenser and Teacher of Pharmacy at the University College Hospital.

(*Concluded from p. 22.*)

When a surgical operation has to be performed on a previously unbroken integument, the part being first well cleansed with an aqueous solution of carbolic acid, Professor Lister then imbues the atmosphere surrounding it, both previously, while the incision is being made, and as long as the cut surfaces are exposed, with a cloud produced by a spray apparatus from an aqueous solution of carbolic acid, one part in 100.* A rag or "guard" soaked in the carbolic solution is employed to cover the wound while the spraying from the atomizer is discontinued, but this should be commenced again before the removal of the "guard." At the conclusion of the operation, the wound and adjacent parts are thoroughly cleansed from blood, etc., by sponging them with the same carbolic solution. Thus it is ensured that no putrefactive organism has the chance of entering the wound alive. The same precautions are necessary at each fresh dressing of the wound.

The wound being thus free from the elements of putrefaction at the completion of the operation, it remains to carry out the other division of the antiseptic treatment, viz., to apply such external dressing as shall securely guard for the future against the penetration of septic ferment from without. "For this purpose," says Professor Lister, "the most convenient material I have yet arrived at is the 'Antiseptic Gauze,' made by impregnating a cotton cloth of open texture—a kind of book-muslin—with a mixture of carbolic acid, resin, and paraffin, in which the resin serves as a vehicle for the acid, while paraffin is added to prevent inconvenient adhesiveness." The proportions which he has found best for carbolizing this material are the following; it is manufactured on a large scale by Messrs. J. F. Macfarlan and Co. of Edinburgh:—

Antiseptic Carbolic Gauze.

Take of

Carbolic Acid, in Crystals . . .	1 part.
Common Resin	5 parts.
Paraffin	7 parts.

Having melted the acid and resin together, the carbolic acid is added and dissolved. In this mixture the muslin, in six yard pieces folded to fit the press, and previously warmed by placing it in a hot stove, is immersed until the whole of its fibres are thoroughly permeated by the carbolized vehicle, the latter being kept liquefied in a trough heated by steam. A number of these impregnated clothes are then placed in a hydraulic press between hot metallic plates and the pressure applied quickly, so that the cloth is left with rather less than its own weight of the mass; the individual fibres being charged, but the interstices left open. For hospital purposes Professor Lister states the clothes may be washed and recharged over and over again to save expense. "The saving of expense" is rather doubtful, as the difficulty in washing them free from the resin, paraffin and the discharge from the wounds, and the attendant danger of not getting them free from the latter before recarbolizing, are such as almost prohibit this kind of economy, because the fabric itself can be purchased for about the cost of labour expended in cleansing that which has once been used. The gauze when freshly carbolized is soft and slightly moist to touch, but on exposure to the atmosphere it becomes somewhat harsh and crisp; it should, therefore, be kept closely packed, and as little exposed to the air as possible.

This carbolized dressing, while it absorbs the discharge, holds the antiseptic firmly lodged in its fibres, where it is retained by the insoluble resin, and it is to this circumstance that it owes its superiority over most other porous applications. It is wrapped round the wound folded into a pad of about eight layers, and surrounded by a piece of impermeable tissue—that known as "hat-lining." This compels the effusion of serum from the wound to travel along the whole extent of the antiseptic investment (which should reach several inches beyond its margin) before the discharge can come in contact with the open air. The hat-lining is generally placed within the outermost layer of the antiseptic gauze. While the discharge is free the dressing should be changed daily, but as it diminishes, the intervals may be increased till, when it is merely a few minutes in the twenty-four hours, the gauze may be left undisturbed for a week together.

The gauze is also extremely useful in the form of antiseptic bandages. These are employed to secure and complete the dressings. They are to be had, cut by machinery, of the firm above mentioned, in six-yard lengths three inches wide.

Antiseptic Catgut for Ligatures.

Take of

Carbolic Acid, liquefied by the addition of 6 per cent. of water .	1 part.
Olive Oil	5 parts.

Mix by agitation; this forms an emulsion, not a perfect solution on account of the presence of the water. Immerse the catgut for two months in the emulsion contained in a covered vessel, taking care not to let the hanks of gut touch the bottom of the vessel, by having a few pebbles or a perforated diaphragm on which to rest it. Should it come in contact with the water which separates from the emulsion, it becomes soft and slippery, and will not bear the requisite strain or keep its hold when tied. The advantage which sutures of this kind possess is that, in time the parts of them imbedded in the tissue are absorbed and, therefore, do not require removal—the exterior portion and knots then fall off with a touch. This circumstance renders the cat-gut unfit for sutures intended to retain their hold for a considerable period, for which a material less amenable to absorption by the tissues is to be preferred, such as the silk thread generally used for sutures, carbolized in the following manner:—

Antiseptic Silk for Ligatures.

Take of

Carbolic Acid, in crystals . . .	1 part.
Beeswax	9 parts.

* Since writing the above, I learn that Professor Lister now recommends this solution to be of the strength of one part in 40. He used it of this strength a few years ago, but thought that it was then unnecessarily active and caused some irritation; he has, however, returned to it, as he finds the weaker is not always sufficiently antiseptic. A modified kind of putrescence having occurred in some cases, which he attributes to this source when the weaker lotion and spray were used.

The acid is dissolved in the melted beeswax. In this solution the silk is then placed, and when thoroughly steeped, it is drawn through a cloth to remove the superfluous wax.

It is always to be remembered that the action of the antiseptic is itself injurious, so far as its direct influence upon the tissues is concerned. If carbolic dressings be used they retard cicatrization; they also operate with especial energy on the cuticle; and even when far too dilute to produce excoriation, that is to say, to destroy the perfect epidermis, they will, if applied direct to a wound often entirely prevent the production of young epithelial cells. It is therefore necessary to protect the cicatrizing part by interposing between it and the gauze a layer of some impermeable material. But carbolic acid is a remarkably penetrating substance, passing through, by a kind of endosmose action, gutta-percha and india-rubber with the utmost facility, though not dissolving them; it has thus been difficult to devise an efficient protective. That now used is the *protective oiled silk*. Oiled silk is first coated on both sides with *copal varnish*, and when dry brushed over with a mixture of

Dextrine	1 part.
Starch, in powder	2 parts.
Aqueous solution of carbolic acid (1 in 20)	16 parts.

The granular starch enables the dextrine solution to apply itself better to the varnished surface, and the solution of carbolic acid is used rather than mere water for the same purpose. When used, a piece slightly larger than the open wound is previously dipped in the aqueous solution of carbolic acid to free it from any septic poison and applied as a "protective" of the parts from the irritation of the exterior carbolized dressings. The dextrine mixture reconciles the varnished surface of the oiled silk to the aqueous solution of carbolic acid, so that when immersed in the latter before application to the wound, it has an even superficial aqueous layer; this prevents any danger of the varnished oiled silk adhering to the margin of the wound.

Carbolized Oil.

Take of

Carbolic Acid, in crystals . .	1 part.
Olive Oil	from 4 to 19 pts.

Heat the carbolic acid till liquefied, and add it to he olive oil. It is used of various strengths for different purposes. The surgical instruments, previous to use, are generally wiped with a piece of lint dipped in carbolized oil.

Carbolized Collodion.

Take of
Carbolic Acid, in crystals,
Collodion, of each equal parts.

Liquefy the crystals by a gentle heat, add the collodion and agitate till a jelly is formed. This is a useful application to an aching carious tooth.

Injection of Chloride of Zinc for Sinuses.

Take of

Chloride of Zinc	40 grains.
Distilled Water	1 fluid ounce.

Dissolve.

Mr. Campbell de Morgan, of Middlesex Hospital, introduced the above, which has the peculiarity of producing a persistent antiseptic action upon a cut surface, the effect of a single application prevents the occurrence of putrefaction for days together, in spite of the immediate vicinity of active septic agency. This is most strikingly exemplified by its effects on wounds resulting from the removal of tumours of the jaw. It is used by Professor Lister to inject the sinuses which may be left in the unhealthy parts after an operation; the carbolic dressings are applied externally in conjunction with it.

Oakum.—It was this substance employed at a surgical dressing during the American War which suggested to Professor Lister the more refined application, 'antiseptic gauze.' The commercial oakum—that prepared from old tarred ropes—has been found generally not sufficiently antiseptic in its action. The article known as *marine lint*—tow impregnated with wood-tar—is more efficacious, but not so agreeable or manageable a dressing as the 'antiseptic gauze,' although it is often useful as a padding in conjunction with the latter. These preparations containing wood-tar will of course owe their antiseptic properties principally to the creasote this contains.

Among the other antiseptic remedies the *sulphocarbolates of soda, potash, lime, ammonia* and *zinc* have been noticed in the columns of this Journal. Of others, again, such as *boracic acid, oil of juniper* and *thymic acid*, the applications have not yet come into such general use as to merit notice.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from page 2.*)

Gentianæ Radix.—On a cursory glance the root of Gentian is seen to consist of two portions separated from each other by a tolerably well-marked brownish-yellow ring. The tissues within this ring consist of parenchyma cells and vascular tissues; without it, of parenchyma cells, a few ligneous cells, and the usual cells of the cortical layers. The cells of the centre vary considerably in size and shape. Those forming in some specimens the false medulla are very large, sinuous in transverse section, and thin-walled. Those cells more intimately intermingled with the vascular tissues have thicker walls, but wholly free from secondary deposits, and are much more globular in shape. The distribution of the vessels is in irregular wedges, whose bases form the yellowish brown ring already spoken of, but isolated vessels occur in what would otherwise be entitled to be called the medulla. The vessels are rarely accompanied by the ligneous cells commonly found as components of vascular tissues. The vessels themselves are very interesting, but it is somewhat difficult to give them a distinctive name. They may perhaps be regarded as transitional between the ordinarily well-marked pitted vessel and the "spiral," as there are in many of them as it were attempts on the part of the sclerogenous deposit to break away and form the true spiral, which, however, I have not found to occur in any of the very numerous sections I have examined. The "pitting" or reticulations in many of the vessels is complicated by sudden breaks and the commencement of an entirely different pattern for some distance, when the former is recurred to or a third entirely new pattern commenced, but there is little or no interlacing of reticulations as in *Pareira* and very markedly in the non-Pharmaceutical *Sanseviera*. The original membrane between the thickening layers or bars of the larger cells is very thin and easily broken, and unless great care is exercised in making sections, will cause the observer to conclude that true spirals are not only present, but very abundant, but it does not appear ever to be wholly absorbed so as to form perforate vessels. The elongated parenchyma cells (sometimes woody fibre) which accompany the not common laticiferous vessels, forming with the vessels the vascular system of this root, are commonly stained brownish yellow, the colouring matter being easily removed by boiling water. The cell contents are starch granules of slightly variable shape and size, generally round, with a very indistinct hilum, and small. They are not sufficiently characteristic to require description. The cortical layers consist, beginning at the innermost layers, of multiangular parenchymatous cells with thick walls, and not very intimately attached to each other, with frequent very small intercellular spaces. Nearer the bark these cells are smaller, have thinner walls, and become more sinuous until the immediately sub-cuticular layers are reached, where their shape approximates to the normal cubical type, which, however, only occurs in the layer below the highly coloured cells of the sub-cuticle. The outermost cells are difficult to make out; and do not differ in any way from the usual type.

The root of Gentian is a good subject for the moderately advanced microscopist to try his hand upon, as it is somewhat complicated, without presenting special difficulties.

THE GENUS EUCALYPTUS: ITS ACCLIMATIZATION AND USES.

(*Concluded from p.* 24.)

When M. Ramel first called attention to the immense value of the *Eucalyptus* as a forest-tree, he claimed for it as one of its most valuable properties, an anti-miasmatic action in marshy districts. This theory, received at first with some doubt, was tested by planting the tree in three Algerian stations that had become notorious for their unhealthiness. The result has been that among the workmen who, four or five years since, were sorely tried by fevers, not a single case now occurs. The trees have absorbed the excess of humidity in the soil, and caused the total disappearance of the morass.

Its success as a therapeutic agent is also now well established, and has been recently referred to in this Journal.* So popular has an infusion of its leaves become as a febrifuge, especially in cases where quinine has not been successful, that M. Alunnada says that his trees were completely stripped of leaves, and he was still unable to supply many people that came to him for the remedy.

Employed as an antiseptic, the essential oil will be very useful in putrid fevers, fœtid suppurations, etc. Dr. Gimbert states that, mixed with albumen or fresh fibrin, it prevents decomposition; injected into the veins of an animal, it prevents or retards putrefaction for a long time. Clots of blood of injected rabbits and rats have been kept three months without alteration; the tissues were dried, mummified, and exhaled the eucalyptic odour. Some drops evaporated in an apartment corrected bad odours that had been persistent for several days, and it has been successfully employed for embalming.

In an alkalimetric investigation made by Baron von Mueller he found that the ashes of the Eucalyptus wood contained a larger proportion of potash than the elm or the maple, which are the trees most esteemed for that purpose in America. The yield from the latter trees is estimated at 10 per cent. of the ashes, while that from the Eucalyptus is as much as 21 per cent.

The products obtained by the destructive distillation of Eucalyptus wood are similar to those obtained from other woods,—pyroligneous acid, tar, methylic alcohol, carbonaceous residues, etc. Besides the various solid and liquid substances, certain gaseous products are collected, which are more or less abundant according to the relative constituent elements of the wood. The leaves and young branches are particularly rich in hydrocarbons, and are sometimes employed in the preparation of gas for lighting purposes.

The barks of various species, as has been already mentioned, furnish ample materials for the papermakers. They are also used in Australia, and in Spain and Portugal, on a large scale for tanning. Nearly all are possessed of energetically astringent properties, due to their richness in tannin, and probably many other principles yet undefined. M. Hoffmann, of the laboratory attached to the Melbourne Botanic Gardens, while engaged in estimating the tannic acid contained in various Eucalyptic barks, has sought to determine the value of the numerous astringent principles accompanying the gum resins produced by these trees. The following figures give the proportion of tannic and gallic acids in four species:—

	Tannic Acid.	Gallic Acid.
E. Stuartiana . . .	4·6	0·7
E. longifolia	8·3	2·8
E. corymbosa	2·7	0·8
E. odorata	20·4	0·8
E. dealbata	4·9	0·4

It has been found, however, that there is a great difference in barks of trees grown in different places, for while M. Cloez found the bark of a tree grown in the Jardin des Plantes, Paris, gave scarcely any indication of tannic acid with persalts of iron and solution of gelatine, in Egypt, M. Maillard de Marafy has found it so abundantly that he is of opinion it will surpass the accessory products in importance. Leaves of *E. globulus*, taken from a plantation near Alexandria and pulverized like sumac, when used upon cotton and wool in the same proportion as the best Sicilian sumac, gave an intense black that left nothing to be desired.

According to Dr. Sicard, the leaves and young branches yield by distillation (1) a distilled water, opaline in colour, bitter in taste, and having the odour of the bruised leaves, but more pungent; (2) an essential oil with a fragrant odour resembling that of lavender, but more penetrating, and a special perfume; (3) a yellow gum, having an agreeable aromatic taste, sweet at first, but bitter and styptic after a short time.

* Volume II. (1871-72) p. 703.

M. Cloez has investigated the essential oil, and a summary of his results has already been given.* The subject has also been studied by Messrs. Johnson and Bossito at the request of Baron von Mueller. In France, these essences have scarcely yet gone beyond the laboratory, but in England they have been used in various ways, principally in perfumery. Each species seems to yield its peculiar essence, but they only present slight differences; they are, therefore, classed in groups based upon similarity of odour, and some other characters they possess in common. With rare exceptions they are of a yellowish colour, due to an oleo-resin, a product of oxidation, which they hold in solution; the paler essences—poorer in oleo-resin—have the characteristic odour in the highest degree. All are obtained by aqueous distillation of the leaves and young branches. The following are the best known:—

Essence of E. Amygdalina.—*E. amygdalina* is one of the species yielding the most essence, about 3 litres from 100 lb. of leaves or young branches. The utricles containing the oil may be seen by holding the leaf between the eye and the light. The essence is a clear, transparent, pale yellow liquid, of piquant odour, resembling essence of citron, and fresh sweet taste, and after-taste like camphor. It boils at 330° F. It does not evaporate so quickly as turpentine. Iodine forms with it a brown solution which, when warmed, gives off vapours that are yellow, red, violet, green and blue by turns. It is soluble in all proportions in turpentine, volatile and fixed oils, benzine, naphtha, ether, chloroform, absolute alcohol and rectified spirit. With agitation, water will dissolve 1·1 per cent. of its own weight. This essence does not take fire readily in contact with a flame unless warmed, but burns brilliantly and with much smoke. Like all the other essences it possesses great solvent powers.

Essence of E. oleosa differs but little from the preceding in its physical and chemical properties; it is very limpid, pale yellow in colour, and sweeter in taste than others of its class. Its odour is similar to that of mint. Boiling-point 170° C., rising gradually to 177° C., and then remaining stationary. It burns with a smokeless, scentless flame. The yield is about 20 oz. from 100 lb. of leaves or young branches. It is a good solvent of resins.

Essence of E. sideroxylon resembles in taste and odour the preceding. It is very limpid, and of a clear straw colour. It takes fire with difficulty in an open vessel, but burns in a lamp with a very luminous flame. Yield about 16 oz. from 100 lb. of leaves.

Essence of E. goniocalyx.—Pale yellow, with a strong, pungent, rather disagreeable odour, and strong repulsive taste. It burns with a brilliant white flame without either smoke or smell. Yield about 16 oz. from 100 lb. of leaves.

Essence of E. globulus.—Very limpid, and nearly colourless, when prepared from young leaves; the utricles containing the essence being in them larger, but less numerous than in the developed leaf, and the yield less in quantity.

Essence of E. corymbosa.—Colourless, with an odour sweetish when compared to the others, and recalling the essence of *E. amygdalina*, combined with a trace of oil of roses, but with neither its pungency nor freshness. The taste is slightly bitter, leaving an after flavour of mint irritating to the throat.

Essence of E. fabrorum.—Limpid, transparent, reddish-brown, with a sweetish odour, not quite so disagreeable as *E. goniocalyx*. 100 lb. of fresh leaves yield about 8 oz. of essential oil.

Essence of E. fissilis.—Resembling the preceding; and the yield being the same. Odour less strong and comparatively agreeable. Good solvent for resins.

Essence of E. odorata.—Yield variable but inconsiderable; colour pale greenish-yellow; odour resembling camphor.

Essence of E. Woollsii.—Odour of camphor; taste sweet and aromatic; yield 3 oz. from 100 lb. of leaves.

Essence of E. rostrata.—Not very abundant, 100 lb. of leaves yielding scarcely 1 oz. It varies in colour from pale yellow to a reddish amber tint. Odour and taste similar to that of *E. odorata.*

Essence of E. viminalis.—Colour yellowish green; odour disagreeable; taste similar to that of *E. odorata.* Yield inconsiderable.

These essences are employed in the manufacture of varnish. Some resins do not dissolve in them at ordinary temperatures; but all or nearly all, dissolve upon the application of heat. Gutta percha, which resists for a long time their solvent action in the cold, dissolves when the temperature is raised, but a portion is deposited upon the cooling of the liquid.

The Eucalyptus yields as many gum resins as there are species, but they are all very similar in their physical characters. They are found in trees of all ages, in cavities running in the direction of the grain of the wood. They might be obtained in a liquid state by means of incisions, but this method has not hitherto been practised. When solid they form little angular masses, occasionally striated and enclosing pieces of the wood; the colour is usually a deep red-brown, sometimes veined with yellow or olive green and dull in appearance; sometimes of a beautiful uniform red shade, transparent and brilliant. Dried in a water bath they lose 20 per cent. of their weight; present a vitreous fracture and are easily powdered. They have a styptic taste, without bitterness, colour the saliva red, and adhere to the teeth. All are not equally soluble in water; the gum of *E. fabrorum* being completely soluble, even in the cold, while that of *E. corymbosa* is insoluble without the addition of a few drops of ammonia. In aqueous solution all the gums give an acid reaction with litmus paper, but with other reagents they offer points of difference. The precipitate obtained with solution of gelatine does not appear to correspond in quantity with the strong astringent taste; sometimes no precipitate is formed at all. With acetate of lead an abundant gelatinous precipitate is formed; salts of iron give rise to various shades of green or black. The mineral acids cause a thick flocculent deposit. Some of these gums, especially that from *E. resinifera*, are imported into this country under the name of "Botany Bay Kino."*

Finally, there are two varieties of a peculiar substance commonly called "Eucalyptus manna." One occurs in small, rounded, irregular opaque white masses, having an agreeable sweet taste. It is exuded abundantly in summer through punc-

* Volume I. (1870-71) p. 78.

* See Pharm. Journ. Third Series, Vol. II. p. 102.

tures or wounds made in the leaves and young branches of *E. viminalis*. It consists principally of grape sugar containing about 6 per cent. of mannite. The other variety is the secretion of a hemipterous insect, and is found at certain seasons in abundance upon the leaves of *E. dumosa*. It is in little white or yellowish cones, covered with woolly filaments, in which are deposited the larvæ of the insect.

THE CHEMISTRY OF THE HYDROCARBONS.*

BY C. SCHORLEMMER, F.R.S.

(*Continued from page* 27.)

Olefines.—By abstracting two atoms of hydrogen from the paraffins we obtain the second group of hydrocarbons, called by Guthrie the olefines.

These olefines exhibit in their physical properties, as specific gravity, boiling-points, etc., great resemblance to the corresponding members of the paraffin series. They are, however, easily distinguished from the latter by the fact that they combine with great energy with the elements of the chlorine group, for which reason they have also been called non-saturated hydrocarbons.

To account for their constitution there exist three hypotheses:—

1. They contain carbon atoms with free combining units.
2. One of the carbon atoms is no longer a tetrad, but a dyad.
3. One carbon atom is linked with two combining units to two combining units of another.

The first hypothesis found many adherents some years ago. Amongst these, Lothar Meyer has very clearly stated the reasons why the hypothesis that the so-called non-saturated compounds contained free combining units was much more probable than the view adopted by Kekulé, that a double linking of carbon atoms occurred in them. He says ('Ann. Chem. Pharm.,' cxxxix. 285) "that in the first place this hypothesis offers no philosophical difficulty; that it cannot be astonishing that under certain conditions one or more affinities remain unsaturated; on the contrary, it would be wonderful if such non-saturated affinities did not exist."

"For certain compounds this theory is even unavoidable, as for nitric oxide, carbonic oxide, the vapour of mercury, cadmium," etc.

Now, according to this theory, the most simple olefine known, ethylene, C_2H_4, ought to exist in two isomeric forms, viz.:—

$$\begin{array}{ccc} CH_3 & \qquad & C\ \ _2\text{—} \\ | & & | \\ CH\text{=} & & CH_2\text{—} \end{array}$$

However, experiments made by Meyer and by Tollens for the purpose of obtaining an isomeride of ethylene failed. But although the two isomeric modifications of ethylene have not been obtained, yet it was stated that two different chlorine-substitution products of ethylene exist, viz., *monochlorethylene* or *vinyl chloride*, obtained by Regnault, and *chloracetene*, which Harnitz-Harnitzky prepared by the action of phosgene upon aldehyde. As both compounds had been repeatedly investigated by other chemists, their existence could hardly be doubted, and could only be explained either by assuming free affinities or by the theory of dyad carbon. The existence of a compound isomeric with chlorethylene is certainly of the highest importance to the theory, because, as Kekulé has pointed out, if the existence of dyad carbon is proved in such a simple case, the same assumption is at least admissible in more complicated cases. Kekulé, in conjunction with Zincke, therefore repeated Harnitzky's experiments ('Ann. Chem. Pharm.' clxii. 125). They said that from their theoretical standpoint, the existence of chloracetene not only appeared improbable, but that the properties ascribed to this body, as well as the reaction by which it was formed, were so remarkable that it appeared necessary to make the personal acquaintance of chloracetene. Although it appeared improbable that this body was really isomeric with Regnault's vinyl chloride, yet it might be a polymeride, which by dissociation yields a lighter vapour. It was also possible that vinyl chloride had not been obtained in a pure state, and was identical with chloracetene, and there was also the probability that all the statements about this latter compound were erroneous. The result of this investigation was that the last view was the correct one. They found that the most remarkable property of this remarkable compound was its non-existence.

According to the theory of dyad carbon, only one ethylene can exist having the constitution CH_3—CH. But that the known ethylene has not this constitution is proved by the fact that its chlorhydrin yields by oxidation monochloracetic acid ('Zeitschr. f. Chem.' [2], vii. 263).

Another proof against the existence of free combining units, or of dyad carbon, is found in the fact that only one propylene is known, of which hydrocarbon four modifications ought to exist, according to the theory of free combining units, viz.:—

$$\begin{array}{ccccccc} CH_2\text{—} & \quad & CH_2\text{—} & \quad & CH\text{=} & \quad & CH_3 \\ | & & | & & | & & | \\ CH_2\text{—} & & CH\text{—} & & CH_2\text{—} & & C\text{=} \\ | & & | & & | & & | \\ CH_2\text{—} & & CH_3 & & CH_3 & & CH_3 \end{array}$$

or only the latter two in the case of the dyad carbon theory.

Friedel and Ladenburg, as well as Butlerow, failed to obtain an isomeride of common propylene. The two former chemists tried to obtain the last of the four forms by acting with sodium upon the so-called methylchloracetol, $CH_3-CCl_2-CH_3$, but obtained, instead of it, only the well-known propylene, which was formed by a molecular change taking place.

From these and other examples, we must conclude that the olefines contain neither dyad carbon nor free combining units, and that they are really saturated compounds, containing two carbon atoms linked together by two combining units of each.

Butlerow has some time ago added a fresh proof of the correctness of this hypothesis; of this I shall have to speak when I come to the next group.

The number of isomeric olefines capable of existing is larger than that of the corresponding paraffins, as the double linking of the carbon atoms can take place in different parts of the hydrocarbon. Thus there exist only two butanes, but three butylenes, viz.:—

$$CH_3\text{—}CH_2\text{—}CH\text{=}CH_2$$
$$CH_3\text{—}CH\text{=}CH\text{—}CH_3.$$
$$\left.\begin{array}{l} H_3C \\ H_3C \end{array}\right> \text{=}CCH_2.$$

The number of isomerides known is, however, not large at present; nearly all those which have been better investigated contain the two carbon atoms, which are linked together by two combining units situated at the end of the chain. These may therefore be considered as being derived from ethylene by the substitution of a monad alcohol-radical for one atom of hydrogen, thus:—

$$\begin{array}{ccccccc} CH_2 & \quad & CH.CH_3 & \quad & CH.C_2H_5 & \quad & CH\left\{\begin{array}{l} CH_3 \\ CH_3 \end{array}\right. \\ \| & & \| & & \| & & \| \\ CH_2 & & CH_2 & & CH_2 & & CH_2. \end{array}$$

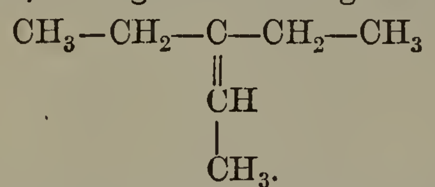
---

* A lecture delivered before the Chemical Society, April 4th, 1872. Reprinted from the 'Journal of the Chemical Society' for June, 1872.

The constitution of these olefines has been fully proved by experiment. On combining them with hydriodic acid, secondary iodides are formed, which, when converted into alcohols, yield acetones, containing the group methyl, as an oxidation they yield acetic acid, besides another fatty acid. Now Popoff has established the law that when an acetone is oxidized, the more simple alcohol-radical always remains combined with the group carbonyl, whilst the other is oxidized by itself, yielding a fatty acid containing the same number of carbon atoms as the alcohol-radical itself (*Ann. Chem. Pharm.*, cxlv. 283, and clxi. 285). Thus when hexylene, obtained from mannite, is subjected to the above reactions, we obtain acetic acid and butyric acid:—

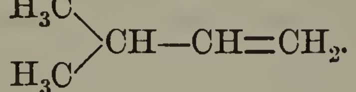
Hexylene, or butyl-ethene.	Secondary hexyl-iodide.	Secondary hexyl-alcohol.	Methyl-butyl-ketone.	Butyric acid.
C_4H_9	C_4H_9	C_4H_9	C_4H_9	$C_4H_{10}O_2$
				Acetic Acid.
CH	CHI	$CH.OH$	CO	$CO.OH$
CH_2	CH_3	CH_3	CH_3	CH_3.

Besides these olefines, Butlerow has lately described some in which carbon atoms situated in the middle of the chain are linked together by two units. The constitution of these bodies, which were obtained from tertiary compounds, is easily understood, as the constitution of the alcohols from which they have been derived is well known. Thus, on acting with alcoholic potash on the iodide of triethyl-carbinol, $CI(C_2H_5)_3$, a pseudoheptylene is obtained, having the following constitution:—



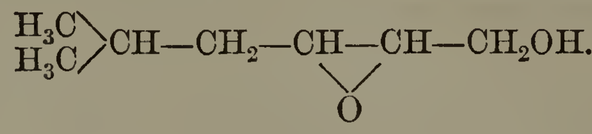
Besides the olefines which are derived from compounds having the general formula $C_nH_{2n+1}R$ (R representing a monad radical), by the abstraction of HR, there exists another group, formed by the polymerization of the members of the first group. Of these poly-olenes, as Schneider calls them, only one, diamylene, has been more closely studied by this chemist (*Ann. Chem. Pharm.*, clvii. 185). This hydrocarbon, which is most readily formed by shaking amylene together with cold dilute sulphuric acid, yields, as the first product of oxidation, diamylene oxide, which by further oxidation splits up, with formation of carbon dioxide, acetic acid, and amethenic acid, $C_7H_{14}O_2$, a peculiar compound which is isomeric with œnanthylic acid, from which however it differs by exhibiting only very feeble acid properties.

Erlenmeyer has shown that amylene has the following constitution:—

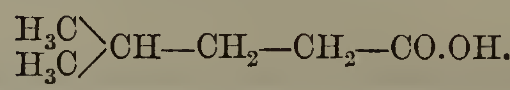


Now as diamylene combines as easily with bromine as amylene does, it would appear as most probable that in the former compound two carbon atoms are combined in the same manner as in other olefines, thus:—

(1) 
(2) 
But if either of these two formulæ expressed its constitution, two atoms of hydrogen would have to change places during its formation from amylene. This, however, appears improbable, as diamylene is so easily formed in the cold. By assuming the first formula as correct, the constitution of amethenic acid would be—

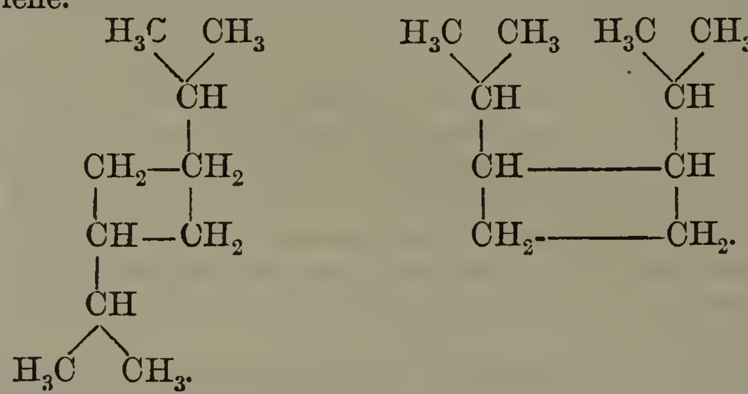


which represents an alcohol and not an acid. Accepting the second formula, we should have for amethenic acid—

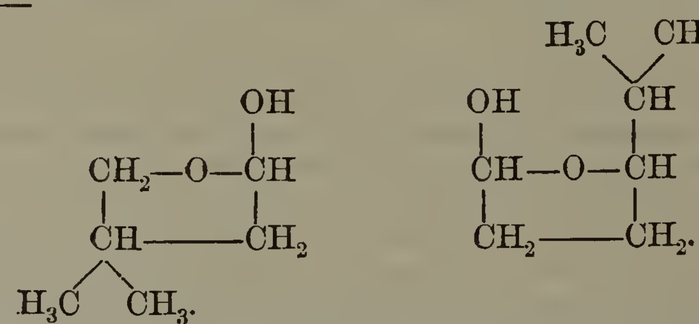


which would be a strong acid, because it contains the group carboxyl, and, moreover, no acetic acid could be formed at the same time.

It appears, therefore, most probable that one of the following formulæ represents the constitution of diamylene.



The acid would then have one of the following formulæ:—



Both explain equally well why this singular compound is so weak an acid, as both contain the group $HC{=}O$ | CH or carboxyl in which half an oxygen atom is replaced by hydrogen.

THE LAST NEW METAL, INDIUM.*

BY WILLIAM ODLING, ESQ., M.B., F.R.S.

The word "element" is used by chemists in a peculiar and very limited sense. In calling certain bodies elements, there is no intention on the part of chemists to assert the undecomposable nature or essence of the bodies so called. There is not even an intention on their part to assert that these bodies may not suffer decomposition in certain of the processes to which they are occasionally subjected; but only to assert that they have not hitherto been proved to suffer decomposition; or, in other words, to assert that their observed behaviour under all the different modes of treatment to which they have been exposed, is consistent with the hypothesis of their not having undergone decomposition.

The entire matter of the earth then, so far as chemists are yet acquainted with it, is composed of some sixty-three different sorts of matter that are spoken of as elementary; not because they are conceived to be in their essence primitive or elementary, but because, neither in the course of nature nor in the processes of art, have they been observed to suffer decomposition. No one of them has ever been observed to suffer the loss

* Lecture delivered at the Royal Institution, Jan. 19, 1872.

of any substance different from the substance of its entirety, so as to leave a residuary substance different from the substance of its entirety. Thus chemists are incapable of taking away from iron, for example, a something that is not iron; or of taking away from it anything whatever, so as to leave a residue that is not iron; whereas they are capable of taking away from iron-pyrites a something which is not iron-pyrites but is sulphur, so as to leave a residue which is not iron-pyrites but is metallic iron.

The notion of all other material bodies being constituted of, and decomposable into a limited number of elementary bodies, which could not themselves be proved to suffer decomposition or mutual transformation under any circumstances whatever, but could, on the contrary, be traced respectively through entire series of combinations, and be extracted at will from each member of the series, is a notion which, undergoing in course of time a gradual development, was first put forward in a definite form by Lavoisier; until whose time, some residue of the great alchemical doctrine of the essential transmutability of all things—that the substance of all things was the same, while the form above was different—still prevailed. To Lavoisier is due the enunciation of the principle,—departed from, however, in a few instances by himself,—that all bodies which cannot be proved to be compounded, are in practical effect, if not in absolute fact, elementary, and are to be dealt with accordingly.

Of the many definite substances known to chemists before the discovery of hydrogen gas, the following were afterwards recognized by Lavoisier and his colleagues as elementary. First, the seven metals known to the ancients, namely, gold, silver, mercury, copper, iron, tin, and lead, distinguished respectively by the signs of the sun, moon, and planets; and each conceived to have some mystic connection with the particular orb or planet of which it bore the sign, and not unfrequently the name. Then three metals which became known at the latter end of the fifteenth or beginning of the sixteenth century, namely, antimony, discovered by Basil Valentine in 1490; bismuth, mentioned by Agricola, 1530; and zinc, mentioned by Paracelsus, ob. 1541. An elementary character was also assigned to the non-metals carbon and sulphur, which had been known from the earliest times; to phosphorus, discovered by Brandt, of Hamburg, in 1669; and to boracic acid, now known to be a hydrated oxide of boron, first discovered by Homberg in 1702, and still occasionally spoken of as Homberg's sedative salt. The list was further swelled by four metals which, in Lavoisier's time, had been but recently discovered, namely, cobalt and arsenic, identified simultaneously in 1733 by George Brandt, of Stockholm; platinum, discovered in 1741 by Woods, assay-master at Jamaica; and nickel, discovered in 1751 by Cronstedt.

The only other bodies known before 1766, and afterwards included in the class of elements, namely, the alkalies and earths, had during the quarter of a century immediately preceding been made the subjects of especial study. The differentiation of potash from soda, both previously known by the common name of alkali, was indicated by Duhamel in 1736, and more completely established by Marggraf in 1758. The differentiation from one another of lime or calcareous earth, silex or vitrifiable earth, alumina or argillaceous earth, and magnesia or bitter earth, was accomplished by the labour of many chemists, more particularly Marggraf, Bergmann, and Scheele; prior to whose researches silex, alumina and magnesia, together with their different combinations and commixtures with each other and with lime, were held to be but impure varieties of lime. The nature of the difference between the caustic alkalies and earths and their respective carbonates, was made known by Black in 1756; while the real constitution of the alkalies and earths, as metallic oxides, though suspected by Lavoisier, was not established until the beginning of the present century, by Davy and his contemporaries and followers.

1863	Indium.	Reich and Richter.

The successive recognition of the elementary gases, quickly following Black's remarkable discovery of earbonic acid gas, began with the identification of hydrogen by Cavendish in 1766. This was succeeded by the discovery of nitrogen by Rutherford in 1772; of chlorine and fluoric acid, the latter now held to be a fluoride of hydrogen, by Scheele in 1774; and of oxygen by Priestly in the same year.

Thus prior to the discovery of the first of the elementary gases, twenty-three kinds of solid matter, and one liquid body, mercury, were known, which afterwards became recognized as elements. Between then and the present time, thirty-three kinds of solid matter, and one liquid body, bromine, have been added to the list—the discovery of the earliest of them occurring almost simultaneously with, or even just preceding, that of the last discovered of the elementary gases.

Among the number of bodies discovered prior to 1803, when Davy effected the decomposition of the alkalies, several, at first thought to be elementary, are now known to be compounds of oxygen with other bodies still regarded as elements; and conversely, two bodies, namely, chlorine and fluorine, at one time thought to be oxides, have since become regarded as elementary; but in none of these cases did the discovery of what is now considered to be the real constitution of the bodies add or subtract an element to or from the list.

From the period of the modern or Lavoiserian conception of elements and compounds down to the beginning of the nineteenth century, the recognition of new elements occurred with much frequency, at short but varied intervals. After then, the discoveries became somewhat less frequent; but even within the last fifty years, no fewer than twelve new elements have been added to the list, being at the rate of one new element every four years. Throughout, the periods of discovery have been somewhat irregular in their occurrence. Thus in the years 1802 and 1803, six new elements were discovered, namely tantalum, cerium, palladium, rhodium, iridium and osmium; within the succeeding fourteen years only one new element, but that a very important one, namely, iodine; and in the fifteenth and sixteenth years, three new elements, namely, lithium, selenium and cadmium. The longest barren interval, one of thirteen years duration, took place between the discovery of niobium, by Rose, in 1846, and that of cæsium and rubidium, by Bunsen, in 1859. The last discovered of the elements, namely indium, being fully seven years old, and there being no reason to consider our present list as anything like complete, or to apprehend any cessation of additions thereto, it is now quite time for some other new element to be made known. For we may reasonably anticipate the discovery of new elements to take place at irregular intervals possibly for centuries to come, and our list of the elements to be increased at least as much in the future as in the past.

The fresh discovery, however, of any abundant elementary constitutent of the earth's crust would seem scarcely now to be expected, seeing that of the thirty-two elements which have become known since the year 1774,—the year of the discovery of chlorine and oxygen and manganese and baryta,—the great majority belong to the class of chemical curiosities; while even the four or five most abundant of the since discovered elements are found to enjoy but a sparing although wide distribution in nature, as is the case, for example, with bromine and iodine; or else to be concentrated but in a few specially localized minerals, as is the case, for example with strontium and chromium and tungsten. Of course it is difficult to appraise the relative abundance in nature of different elements; more especially from the circumstance of those which are put to commercial uses being everywhere sought for, and those not put to commercial uses being habitually neglected,—save indeed by the man of science, to whom the peculiar properties of some of the less familiarly known elements, as palladium, osmium, erbium, didymium, uranium and thallium, render them objects of the highest interest.

A very notable point with regard to the last-discovered four elements, namely, rubidium, cæsium, thallium and indium, is their successive discovery within a few years of each other, by one and the same process, namely, that of spectrum analysis. This process, invented and made available as a means of chemical research by Bunsen and Kirchoff in 1856, consists simply in allowing the light given off by different ignited gases and vapours, limited by means of a fine slit, to pass through a prism or succession of prisms; and in observing the so-produced, brightly-coloured, widely extended image of th- slit. It has been known from the days of Newton, thae by the passage of heterogeneous light through a prismatic highly dispersive medium, its differently refrangible constituents become widely separated from each other, so as to furnish an elongated coloured spectrum. But whereas the spectra of incandescent solid and liquid bodies are continuous, and not distinctive of the particular luminous bodies yielding them, the spectra of incandescent gaseous or vaporized bodies are found to be discontinuous, and to consist of one or more bright lines of different colour, thickness and position, according to the nature of the particular incandescent gases or vapours from which the light through the slit is proceeding. In this way it is found that the spectra of the different chemical elements, alike when free and in combination, are perfectly definite, and characteristic of the particular elements vaporized and made incandescent.* And in many cases, the spectra or portions of the spectra of particular elements, even when present in the most minute proportion, are so extremely well marked and distinctive, that the presence or absence of these elements is determinable with the greatest ease and certainty, by a mere inspection of the emission spectra yielded by the incandescent gases or vapours under examination. Moreover, gases and vapours are further capable of affecting heterogeneous light which is passed through them; and of thus yielding absorption spectra, in which the characteristic lines of the above-described emission spectra are reversed, so as to appear, unaltered in position, as black lines or intervals in an otherwise continuous band of colour.

A SIMPLE QUICKSILVER LUTE.

BY H. KARSTEN†

In cases where tubes cannot be connected by india-rubber, corks, etc., the author makes a gas-tight junction by making the two tubes to be joined vertical, the lower one capable of sliding within the other; when in this position the open end of the upper or outer tube is surrounded by mercury retained by a cup, through the bottom of which the smaller tube passes. The whole apparatus is most easily constructed, and can readily be taken to pieces and put together again.—*Journal of the Chemical Society.*

THE ACTION OF BONE CHARCOAL IN SUGAR MAKING.

BY C. WERNEKINCK.‡

The author, starting from previously known facts, frames an hypothesis to account for the action of animal charcoal in decolorizing vegetable solutions and in absorbing lime from a solution of sugar-lime. He connects the undoubted fact that such charcoal absorbs and condenses large quantities of the atmospheric gases with the powers named, by assuming that the decolorizing power is due to the oxidizing power of condensed oxygen, and the lime absorbing action to the carbonic acid contained in the pores. He does not quote any experiments in support of his view.

The abstractor states that animal charcoal deprived of its gases by heating to redness in a Sprengel vacuum is capable of decolorizing a solution deprived of dissolved air (and retained *in vacuo*) as perfectly as the ordinary material.—*Journal of the Chemical Society.*

* For some qualifications of this statement, *vide* Roscoe's 'Spectrum Analysis.'

The Pharmaceutical Journal.

SATURDAY JULY 20, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PHARMACEUTICAL EDUCATION.

THE acceptance by the Council of the principles of Mr. SCHACHT's scheme for promoting pharmaceutical education, and the wish that has been expressed for free criticism and discussion of the whole subject in order that it may now be settled upon a durable basis, will no doubt increase the growing interest which has been taken in the question for some time past. As we have before suggested, the columns of this Journal afford a convenient medium for interchange of opinions.

In order, however, to make the discussion as profitable as possible, it will be necessary that those who take part in it should have a clear conception of the object entertained by the founders of the Pharmaceutical Society. If this were more perfectly understood, not only by the trade generally, but even by members of the Society, there would be no occasion to comment upon the sentence in Mr. ATKINSON PICKERING's letter last week to the effect that the Council, as far as this subject was concerned, had been an organized hypocrisy to the country members of the trade, and it is probable that sentence would not have been written.

This statement was put forward by a leading actor in the education movement as expressing an opinion very generally entertained, but without any disparagement to its author, we have no hesitation in declaring that it has no foundation in fact, nor indeed any excuse, save the writer's enthusiastic appreciation of the need there is for better means of educating the rising members of the trade.

We can appeal to no higher authority upon this point than the printed words of the prime originator and founder of the Society, Mr. JACOB BELL. In a paper entitled "The Constitution of the Pharmaceutical Society of Great Britain," read by him at the Introductory Evening Meeting of the Pharmaceutical Society, May 11th, 1841,* he said :—"The ultimate objects contemplated in this Society are the "union of the Chemists and Druggists of Great "Britain into one ostensible, recognized and independent body; the protection of their general "interests, and the advancement of the art of Pharmacy. They consider that their own interest, as "well as the safety and welfare of the public, demand "that no person shall become an apprentice in their "business who has not had the advantage of an "adequate fundamental education; and that no person shall dispense medicines who has not undergone an examination as a test of his competence "to perform that important office. But in order to "afford ample means of acquiring the requisite qualifications, and in order to ensure the greatest possible uniformity in the system of education, the "chemists and druggists consider it expedient to "establish a School of Pharmacy as a prominent "feature of their Society."

* Pharm. Journ., 1st ser. Vol. I. p. 7

Here there is a definite purpose kept in view; the raising of the body of chemists and druggists from the uninfluential and unsatisfactory position which it then occupied. A better and more available means of education was seen to be the principal requisite, and for this purpose, and for fixing a standard sufficiently high, a school of pharmacy was established. At no time was a promise held out that this education should be provided for those who were not prepared to pay for it, or that by facilitating the entrance into the trade of the largest possible number of persons, the Society should become a machine for increasing competition amongst those in business, or for providing an unfailing supply of "assistants" on the lowest possible terms; and without fear of being tedious, we may supplement this prospective sketch with some reference to the subsequent proceedings of the Society in regard to education.

In the Report presented by the Council to the first Annual Meeting of the Pharmaceutical Society, the following sentences occurred:—

"It should be considered that the Society is established for the *general* good of the trade, and that "the solid advantages which are ultimately to emanate from it will benefit the members in the "country as well as those in the metropolis. . . . "It is only by the joint assistance of the whole body "that an establishment for conducting the business "of the Society can be maintained—that its library "and museum can be established and kept up—and "that the foundation can be laid for an economical "and systematic education of the rising generation. "This latter advantage is principally for the "younger branches of the Society, who will have "to incur an *additional expense*, in proportion to the "extent to which they avail themselves of it; but "the plans of the Society are intended to diffuse "general benefit, by furnishing throughout the "country a supply of competent assistants to the "trade, and well-qualified Chemists and Druggists "to the community at large. . . . The Members "will perceive that it has been the object of the "Council to commence their educational plan upon "a scale compatible with the present means and convenience of the trade generally, which plan may be "modified and enlarged, as circumstances may ren-

"der expedient. Much of the usefulness of the 'Society depends upon the prosperity of the School "of Pharmacy, and that can only be secured by the "value of the instruction it affords, and by the en-"couragement afforded to it by the Members and "Associates.

So far the Society has succeeded in its main object: the necessity of special educational qualifications in the pharmacist has been recognized by the public. As a result of this recognition, if as much wisdom be shown by the pharmaceutical leaders of the future, as by those of the past, a few years will bring round the time when the practice of pharmacy will be a monopoly of examined men, a monopoly no less beneficial to the public than to those possessing it. Therefore, in this as in other cases, there is no reason why special technical training should be provided at too low a cost; neither has the man who seeks such training any right to assume that it shall be provided for him at less than its market value.

We do not lose sight of the desirability that pharmaceutical pupils should have within reach means for acquiring a knowledge of the scientific principles upon which the art of pharmacy is based. But we must again reiterate what was well put by Mr. Nuthall in his letter, page 19, that the essential foundation of this knowledge is to be acquired by experience in the shop, and that it should be a matter of course for all who have been three or four years in the business, and not a thing that they begin to seek for the first time after the lapse of that initiatory period. However, there can be no doubt that, even where the pupil has the advantage of a master capable and willing to instruct him, he will be benefited in supplementing such practical instruction by hearing scientific principles systematically enunciated by other persons. With this end in view, and true to its original policy, the Council of the Society has ever sought, and still seeks to know how it may assist to the attainment of the best education possible those who have already helped themselves. But this would be more effectually accomplished if, instead of four-fifths of the "country members of the trade" remaining outside the Society and resting satisfied with expressing dissatisfaction with the efforts of the Council, they came forward and helped in providing for the want which they so readily recognize. In fact, it may fairly be said that the Society, as a voluntary association, has already completed its labour in the cause of education, and that, in having succeeded in making education compulsory, it has done the work it originally projected. It is now the time for those who have been at best mere lookers-on to come forward and give their aid in making the advantages of that work accessible to all.

It may be as well to remark that the use of the phrase "payment for results" has in some quarters led to complete misapprehension of the object sought; an instance of which occurs in an opinion expressed last week by a correspondent that the grants of the Society must be made to "pharmaceutical students only." It is ridiculous to suppose that the Society will ever pay students for acquiring that which is of benefit to themselves. But the proposition is, that where a local association has organized educational machinery, and as a result produced students who are able to pass the examinations, then the Society shall make a grant to such local association in proportion to the work it has accomplished.

It would be a pity, however, if the discussion of this subject should tend to make any student dubious as to what may be accomplished without such extraneous help. We quite agree with Mr. Nuthall's opinion that "individual effort" is easily able to accomplish the "Minor," in which the candidate "is required to "show a thorough familiarity with the "various aspects of those things which he is called "upon to use daily." Those who are disposed to try the experiment, may be encouraged by knowing that the test is not an excessively stringent one, as is evident from the fact that the failures during 1871 were less than 37 per cent. of the whole number examined, a small proportion when compared with the recent matriculation examination at the London University, when only 196 candidates passed out of 512, more than 61 per cent. having failed.

THE PHARMACEUTICAL CONFERENCE.

A sentence in the circular just issued by the Secretaries of the British Pharmaceutical Conference, to which we alluded last week, must be our apology for referring to a subject which we think is worthy of the attention of the leaders of that body. It is stated that the local members of the Conference at Brighton intend inviting their brethren from a distance to a dinner on the evening of the first day's meeting. We by no means wish to cavil at the kindness intended, nor to suggest in the remotest degree that it is not offered in the heartiest manner; but we do consider that it is a matter of serious doubt whether it is politic to allow such a practice to become established, as it may sometimes prove extremely onerous to those who have to carry it out. The fact is, in accordance with the idea of the originators of the Conference, its place of meeting has hitherto been, and probably will be in the future, ruled rather by the decision of the British Association than by any special invitation; and although a hearty welcome and reception have never been lacking, we think it should be understood that all which is required or expected from the resident pharmacists is that they would kindly assist in the organization of the necessary arrangements for securing a successful meeting. We believe that a well-conducted excursion, which every member might attend or not, as he pleased, and to the expenses of which each should contribute his share, affording as it would greater freedom of intercourse and better opportunities for making acquaintances, would be far preferable to allowing the local members to be called upon to act more or less in the character of hosts.

THE COSTS OF THE BETTS SUITS.

The defence of the Betts Suits has proved to be no exception to the general rule, that even when most successful in repelling an attack in the law courts the defendant is severely punished in having to pay the difference between the real and the taxed costs. We are sorry to learn that there is still a balance of upwards of £700 due to the Solicitors for the expenses incurred in defending the above suits. The sum is a large one; and the gentlemen who so generously and promptly came forward as guarantors of the funds necessary for meeting the common danger should be at once relieved from the responsibility. As was shown by the number of suits actually commenced, no chemist and druggist, perfumer, oilman or tradesman selling capsuled bottles, was free from the risk of one, and if all those who have had their battle so well fought for them was to send at once a contribution to the Chairman of the Defence Fund, Mr. W. T. Cooper, 26, Oxford Street, W., or to the Treasurer, Mr. Lionel Newbery, 37, Newgate Street, the necessary sum would soon be raised. In reply to former appeals of the Committee, donations to a considerable amount were promised, many of which remain unpaid to the present time. It is hoped that now the final result is known, these may be forwarded without further delay to either of the above gentlemen.

On Monday last, Mr. G. H. Savage, M.D. Lond., a son of Mr. W. D. Savage, of Brighton, was elected to the office of Junior Physician to Bethlehem Hospital from a large number of candidates.

Many of our readers will hear with regret that the present is the last session in which the School of Pharmacy at Bloomsbury Square will have the services of Dr. W. A. Tilden as Demonstrator in its Laboratory, that gentleman having been recently appointed Lecturer on Chemistry in Clifton College.

Dr. Quain has given notice that at the next Comitia of the College of Physicians, he will move that the list of "recommendations" to the Committee of Reference as to the working of the Conjoint Examination Scheme shall be openly discussed. It has recently been decided that an abstract of the proceedings of each meeting of the College shall be suspended in the hall of the building, and thus an officially correct record of all the business which is transacted at the Comitia will be accessible to the Fellows and Members and to the medical press.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN EDINBURGH.

July 10th, 1872.

Present—Messrs. Ainslie, Aitken, Buchanan, Kinninmont and Young.

Professor Maclagan was also present on behalf of the Privy Council.

Three candidates presented themselves for the Major Examination; of these, *one* failed. The following *two* passed and were declared duly qualified to be registered as Pharmaceutical Chemists:—

*Metcalfe, Wilson	Sheffield.
Munro, John Morrison	Bridge of Allan.

Ten candidates presented themselves for the Minor Examination; of these, *three* failed. The following *seven* passed, and were declared duly qualified to be registered as Chemists and Druggists:—

*Gordon, John	Aberdeen.
Marshall, James	Over.
Macmillan, James	Perth.
Bremner, Allan Hugh	Edinburgh.
Tocher, John	Aberdeen.
Fingland, William	Wavertree.
Davidson, James	Falkirk.

The above names are arranged in order of merit.

The following presented themselves for the Modified Examination, and passed, and were declared duly qualified to be registered as Chemists and Druggists:—

Beattie, Walter	Portobello.
Forsyth, James	Montrose.
Hutchison, John	Irvine.
McKenzie, William	Glasgow.

PRELIMINARY.

The following is the result of the Examination held on the 1st instant:—

England and Wales.

Two hundred and eighty-two candidates presented themselves for this examination; of these, *ninety-two* failed, and the following *one hundred and ninety* passed and were duly registered as Apprentices or Students.

	Whyte, Alexander	London.
	Jeffries, Benjamin	Brixton.
Equal.	Heritage, Julius Harvey	London.
Equal.	Jones, Thomas Pryce	Wrexham.
	Walker, Charles Henry	Liverpool.
Equal.	Campbell, Henry	Hammersmith.
Equal.	Davies, Samuel	Swansea.
Equal.	Bowler, William James	London.
Equal.	Ronchetti, Thomas Angelo	Stockton-on-Tees.
Equal.	Webb, William James	Melbourn.
	Starling, William Egerton	Tunbridge Wells.
Equal.	Francis, James	Liverpool.
Equal.	Row, George Commins	Braintree.
	Cox, Frederick John	Newark.
	Whewell, Herbert	Birmingham.
Equal.	Hircock, George Walter	Kettering.
Equal.	Simpkins, George Star	Minchinhampton.
Equal.	Powell, Walter Morris	Wrexham.
Equal.	Thomas, Arthur Wm. Wynne	Bala.
Equal.	Crook, Arthur Williams	Preston.
Equal.	Lodge, Arthur William	Merthyr Tydvil.

* Passed with Honours.

	Crowden, Francis	Keswick.
	Judd, Arthur Woodward	Portsmouth.
	Breese, Thomas	Norwich.
Equal.	Brunt, George Henry	Norwich.
	Gourd, William	Devonport.
	Havelock, Thomas William	Hexham.
	Toon, William	Haslar.
	Higson, John	Blackburn.
	Robertson, John	Plymouth.
Equal.	Mason, William Drury	Louth.
	Jones, Thomas	Tenby.
	Foster, Robert Kossuth	Bolton.
Equal.	Ellis, George Waddington	Great Yarmouth.
	Hall, Charles	Melton Mowbray.
	Parsons, Henry	Shaftesbury.
Equal.	Hapworth, William Stone	Preston.
	Taylor, James Bennett	Bedford.
	Livesey, James Thomas	Preston.
	Downing, Henry Francis	Leeds.
Equal.	Fisher, Sidney	Wolverhampton.
	Marris, Wm. James Graburn	London.
	Curnow, William Albert	Swansea.
	Howells, Thomas Rees	Aberdare.
	Richardson, William Henry	Boston Spa.
	Newton, Robert Smart	Sunderland.
	Squire, Frederick John C.	Plymouth.
Equal.	Cocksedge, Ernest	Royston.
	Giles, William Egbert	Merthyr Tydvil.
	Moore, Joshua	Preston.
	Smith, Joseph	Manchester.
	Stacey, Alfred	Ramsbottom
Equal.	Easton, William Coryndon	Braintree.
	Knight, Ramsey	Birmingham.
Equal.	Robinson, Stanley	Stalybridge.
	Walton, Charles Foster	Manchester.
Equal.	Dixon, Walter Henry	Aberdare.
	Jenkyn, Thomas	Penzance,
	Norfolk, John William	Beverley.
	Rudkin, Stephen James	Sileby.
	Waddington, John William	Kettering
	Woolston, Thomas Henry	Faversham.
Equal.	Davies, Philip Henry	St. Asaph.
	Parnall James B.	St. Austell.
Equal.	Miller, Edward	Oakham.
	Whitaker, John	Southport.
Equal.	Ashbourne, Charles	Birmingham.
	Billinge, Mark	Hyde.
	Dale, James Francis	Coleshill.
	Paul, Wm. Edmund	Scarborough.
	Price, James	Market Drayton.
Equal.	Chattwood, Joseph	Manchester.
	Harding, Edward	Manchester.
	North, Josiah	Reading.
Equal.	Edwards, David	London.
	Miller, Alexander Kenneth	London.
Equal.	Clark, Walter George	Leeds.
	Elkington, Walter Thomas W.	Leicester.
	Everingham, William	Beverley.
	Jones, William	Oswestry.
Equal.	Andrew, Frederick Wm.	Falmouth.
	Looker, John Evans	Altrincham.
Equal.	Coleman, Walter Wallace	London.

Hyde, Charles .... Fareham.

Scotland.

Forty-two candidates presented themselves for this examination; of these, *twenty-four* failed, and the following *eighteen* passed and were duly registered as above:—

White, Thomas Lee .... Edinburgh.
McNaught, Louis Arthur .... Dumfries.
Cairnie, David Dandie ...... Perth.
Robertson, William .... Peebles.
Gardner, Robert .... Dollar.
Brown, Walter .... Kirkpatrick Fleming.
Kirkpatrick, John Stuart .... Dumfries.
Billing, Charles Edward ...... Edinburgh.
Arthur, Charles .... Edinburgh.
Stewart, Hamilton .... Musselburgh.
Welch, George .... Leith.
Mudie, Isaac .... Dundee.
Keith, Alexander Reid ...... Arbroath.
Murdoch, John McGill ...... Glasgow.
Loudon, William T. .... Dunfermline.
Flint, Charles Bruce .... Glasgow.
Cross, Robert .... Glasgow.
Blaine, Thomas James Stewart. Hawick.

The following certificates have been received in lieu of this examination:—

Certificate of the College of Preceptors.

Palmer, Stephen .... Cambridge.

Certificates of the University of Cambridge.

Bateman, Frederick A.N. .... Great Yarmouth.
Fell, John James .... Lancaster.
Wilkerson, William James.... Epsom.

Certificate of the University of Edinburgh. (?)

Murray, Robert Dalzell ...... Edinburgh.

Erratum on p. 9, col. 1, line 34.—Shenstone, Wm. Edward, should have been Shenstone, William Ashwell.

The following is a list of the Towns at which the Examinations were held, with the numbers of Candidates annexed:—

The Questions for Examination were as follows:—

Latin.

Translate into English two or more of the following sentences:—

1. Ad hæc Ariovistus respondit. Jus esse belli ut qui vicissent, iis, quos vicissent, quemadmodum vellent, imperarent: item Populum Romanum victis, non ad alterius præscriptum, sed ad suum arbitrium, imperare consuesse.
2. Hac oratione habitâ, mirum in modum conversæ sunt omnium mentes, summaque alacritas et cupiditas belli gerendi innata est; princepsque decima legio per tribunos militum ei gratias egit, quòd de se optimum judicium fecisset: seque esse ad bellum gerendum paratissimam confirmavit.
3. Tere Myrrham cum Carbonate in vase prius calefacto; tum adjectâ sulphate, iterum tere, dein omnia simul contunde ut fiat massa.

4. Misce.—Cochleare unum singulis horis exhibeatur, quâque vice phialam agitando, ut permisceatur pulvis.
5. How many degrees of comparison has the Adjective? Give two examples of regular, and two of irregular comparison.
6. In what case is *duration of time* put? Give two examples.
7. Write the genitive singular of each of the following nouns:—Electuarium, confectio, phiala, nox, mens, robur, ramus, pyxis, quercus, stamen.
8. Give the infinitive present of each of the following verbs:—Doleo, dormio, fingo, frico, misceo, rogo, scribo, capio.
9. Decline the noun Ætas.

ARITHMETIC.

10. Multiply £6. 12*s*. $4\frac{1}{4}$*d*. by 345.
11. Bring 4298 farthings to pounds.
12. If 17 bushels and 2 pounds of roses cost £3. 0*s*. 8*d*., how much will it be per pound and per bushel, reckoning 6 pounds to the bushel?
13. Add $\frac{1}{5}$, $4\frac{1}{3}$, and $\frac{4}{5}$.
14. From 270·2 take 76·4075.

ENGLISH.

15. What is a *common noun*, and under what condition does it obtain the force of a proper noun? Give two examples.
16. What is meant by collective names? Give two or more examples.
17. Write the female of the following nouns:—Abbot, tiger, cock-sparrow, bridegroom, testator, marquis, ram, earl, Francis, and monk.
18. In the Structure of Words, explain the meaning of roots and derivatives, and give examples.
19. Correct the following:—I should not differ with them, if I was him. This is the friend which I love, and that is the vice as I hate.
20. Write from fifteen to twenty-five lines upon *one only* of the following subjects:—
    A. The Pleasures of a Garden.
    B. The Study of History.
    C. The Books I have read.

Proceedings of Scientific Societies.

PHILADELPHIA COLLEGE OF PHARMACY.

At the meeting of this College on June 24th, 1872, the President, Dillwyn Parrish, in the chair, the following communication from the Philadelphia College of Physicians was read, and after discussion referred to a Committee:—

"*Preamble and Resolutions passed by the College of Physicians of Philadelphia, May* 1st, 1872.

"Whereas, cases of accidental poisoning and of the internal administration of medicines intended only for external use are so common; and, whereas, every possible safeguard should be employed to prevent such accidents, therefore,

"Resolved, by the College of Physicians of Philadelphia, that it be recommended to all druggists to place all external remedies in bottles, not only coloured so as appeal to the eye, but also rough on one side, so that, by the sense of touch, no mistake shall be possible even in the dark.

"Resolved, that all bottles containing poisons should not only be labelled 'poison,' but also with another label, indicating the most efficient and convenient antidote.

"Resolved, that a copy of these resolutions be presented to the American Medical Association, to the College of Pharmacy of Philadelphia, and to the American Pharmaceutical Association, and that their assistance be asked in bringing about so desirable a reform."

A communication was also read to the effect that the committee appointed at the last meeting of the Convention of the teaching Colleges of Pharmacy of the United States, held at St. Louis in September last, had agreed to recommend the following questions for discussion at the next meeting of the Convention, to be held in Cleveland, Ohio, in September next:—

1. Analytical Chemistry. Is it essential for a thorough pharmaceutical education? If so, should it not be embraced in the curriculum of the Colleges of Pharmacy, and how much time should at least be devoted to the lectures and to laboratory instruction?

2. Would it not be advisable that the questions at the examinations in writing for the degree of graduate in pharmacy be annually reported and, if deemed necessary, discussed by all the colleges represented in the Convention of the teaching Colleges of Pharmacy, for the purpose of establishing, as nearly as may be possible, a uniform standard for graduation?

3. Pharmaceutical degrees. In order to stimulate the acquirement of scientific attainments amongst graduates in Pharmacy, is it not advisable to establish one or more higher degrees? If so, upon what basis ought such degrees to be conferred?

The following delegates were elected to represent the College at the next session of the American Pharmaceutical Convention, to assemble in Cleveland, Ohio, on the 3rd of September next, viz.: Wm. Procter, jun. Prof. John M. Maisch, Prof. Edward Parrish, Joseph P. Remington, Edwin McC. Boring.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

The Juries Bill.

Monday, July 15*th*.

In answer to a question as to the arrangement of business for the remainder of the session, Mr. Gladstone enumerated various bills which the Government proposed to abandon for the present session, one of them being the Bill for the Amendment of the Law relating to Juries.

The Public Health Bill.

Tuesday, July 16*th*.

On going into Committee on this Bill, Sir M. Lopes said that sanitary improvement was a national matter, and the whole expense of it ought not to fall on local funds. This, however, he limited to the common charges—Medical Officers, etc.—admitting that sewage and water were strictly local matters. The question ought not to have been mooted until the previous controversy about local taxation had been settled. On the whole, however, though he would have preferred a wider measure, on the principle that half a loaf is better than no bread, he acquiesced in the Bill going on, and refrained from proposing an amendment of which he had given notice.

Mr. Vernon Harcourt, speaking on behalf of borough authorities, declared that they would prefer to pay for their own officers and be free from central control, and called on Mr. Stansfeld to declare that he would not interfere perpetually with local control.

Lord R. Montagu regarded the Bill as an obstacle to a comprehensive measure of sanitary reform, and criticized specially the provisions relating to the local authority. The Town Councils were generally composed of men who broke the law by polluting the rivers, and Guardians had no other object but to keep down the rates. He was in favour of an intermediate central authority to control the local boards, and to act as a "buffer" between them and the State.

Colonel Barttelot having protested vigorously against the country being handed over to an army of doctors,

Mr. Stansfeld defended generally the course he had taken with regard to the Bill, and particularly his selection of the local authorities. He repudiated any desire to override the local authorities, and assured Colonel Barttelot that there was no intention of creating a great medical hierarchy, though he pointed out to him that the assistance of the medical profession was indispensable.

Mr. Disraeli remarked that the question now was, not whether the Government could have passed a more complete and comprehensive measure if they had given their minds to it at the beginning of the session, but whether this Bill would make the sanitary legislation of the country more efficient. No candid mind could doubt this, and as Mr. Stansfeld's reasonable concession had removed the financial objections to the measure, he advised the House to pass it at once as a preparatory step.

Mr. Newdegate and Mr. Read spoke against the Bill, and Mr. Henley expressed a decided opinion that the ratepayers would not thank the House for what it was about, and that the Bill would hang up and stop all sanitary improvements until next year. The House then went into Committee, but the Committee immediately adjourned until Thursday.

Alleged Poisoning by Arsenic.

At the Chelmsford Assizes, on Monday, July 15th Ellen Day Kittel was put on her trial before Baron Martin for the wilful murder of Elizabeth Kittel by poisoning her in October last.

The case for the prosecution was, that on the 5th of October last year the prisoner gave the deceased some beer in a bottle, and immediately after taking it she became very sick, and died on the Tuesday following. The prisoner was represented to have uttered threats against the deceased, and to have told several persons that she intended to be married to her husband before the following Christmas; and this was actually carried out, for in less than two months after the death of the unfortunate woman the prisoner was actually married to him, and they were living together at the time the present charge of wilful murder was preferred against her. When the death took place a coroner's inquest was held, the father of the prisoner being the foreman of the jury, and a verdict of "Natural Death" was returned. A good deal of talk, however, appeared to be going on in the neighbourhood in reference to the affair, and the marriage of the prisoner with the husband of the deceased so speedily after her death, and other circumstances, led to the matter being taken up by the authorities, and the result was that the body of the deceased was exhumed, and the contents of the stomach were sent to Mr. Stephenson, Professor of Chemistry at Guy's Hospital. It was then ascertained that a very large quantity of arsenic was present in the body, and this poison was no doubt the cause of death; and, after a long inquiry by the local magistrates, the prisoner was committed to take her trial upon the present charge. There did not appear to be any doubt that poison was the cause of the death of the deceased, and evidence was given that a relative of the prisoner's father was a vermin killer and sheep dresser, and that he was constantly in possession of arsenic for the purposes of his occupation, and the case for the prosecution was that the prisoner had visited him shortly before the death of the deceased, and that she could have easily obtained possession of poison if she had wished to do so.

The following is the evidence more particularly referring to the obtaining and detection of the poison:—

Mr. Cook, a surgeon at Manningtree, proved that he was called in to attend the deceased on Sunday, the 9th of October, and she complained of vomiting and purging. He prescribed for her. She died on the 10th October, and witness was examined at the coroner's inquest. No *post-mortem* examination was made at this time. After the body had been exhumed witness made a *post-mortem* examination in conjunction with Dr. Nunn, and he subsequently delivered the stomach, a portion of the bowel, and the spleen, liver, and kidneys to Professor Stephenson, of Guy's Hospital.

Cross-examined—Witness only saw the deceased once. She told him that she had been suffering from her liver for several years. Witness gave a certificate that she died from liver disease, and at the time he certainly concluded that this was the cause of death. He also believed that syncope, occasioned by loss of blood from an accident she had sustained in her bedroom, had accelerated her death. The deceased made no complaint of having taken beer or anything else that had disagreed with her; but she did say that she had been gathering sloes in a field and had eaten them. Sloes would very often occasion vomiting and purging. Supposing she had not taken any poison at all, in the condition of debility in which she was on Sunday, the syncope would fully account for the death. There was nothing whatever on the Sunday to indicate that the deceased had taken poison. He only knew by report that the prisoner, at the present time, was far advanced in pregnancy.

Re-examined—The symptoms he observed on the Sunday were symptoms of arsenical poisoning, but they might have been produced by other causes. If he had been aware that there were as much as five grains of arsenic found in the body of the deceased after her death, he should have certainly come to a very different opinion with regard to the cause of death, and he should not have given the certificate he did.

Mr. Frederick Norman, a farmer, residing at Somersham, in Suffolk, proved that the prisoner was distantly related to him, and she was in the habit of visiting him occasionally. She had been at his house to take charge of the place during his wife's confinement, and when she was going away she asked him to give her some poison that he had promised her mother. He had promised her mother some poison to kill vermin. He went home with the prisoner, and took some arsenic in a bottle. The arsenic was mixed with grease, and it was of a brown colour. He had got the poison from a person named Vincent. It was not mixed at that time, and witness mixed it with grease. It was not the same colour as the ingredient that was in the bottle now produced. Witness subsequently gave Fuller, a police-constable, some arsenic that he had purchased of a person named Wiggins, and he also gave him some grease.

Cross-examined — He used the poison for washing sheep. The prisoner usually came to visit him with her mother in the spring of every year, and upon one occasion the mother said they were very much troubled with mice, and she should like to have some poison. He volunteered to make her up some, and did so, but she went away without it. The prisoner told him that her mother wished particularly to have the poison for the mice, but he did not give it to her, but took it to the house of the prisoner's father. There was arsenic in the stuff he took to them. It was mixed with rough dripping or ham fat, and the jar was labelled "Poison" by himself. He took no arsenic in powder to the prisoner's house; it was all mixed with grease. It was a very nasty, offensive mixture. He should not like to have used it for cart wheels.

Mr. Vincent was then called, and he proved that he had supplied some arsenic to the last witness; but when he did so it was mixed with verdigris. The arsenic was supplied by him in the spring of 1871.

Dr. Nunn, surgeon, of Colchester, proved that when the body was exhumed he made a *post-mortem* examination, and he discovered traces of arsenical poisoning.

The effect of arsenic in the human body was to preserve the viscera in a very extraordinary manner, and this appeared to be the case in the body of the deceased.

Dr. Thomas Stephenson, of Guy's Hospital, said he examined and tested the contents of the stomach and other portions of a human body that were brought to him by Dr. Cook on the 4th of April. The effect of the analysis to which he subjected these matters was to produce a portion of white arsenic. The stomach was washed with pure water, and that water subsequently yielded nearly half a grain of arsenic. He also picked off the stomach nearly two and a half grains of almost pure arsenic. The total quantity of arsenic he discovered altogether in the stomach and the other portions of the body that were brought to him, was about five grains, which was quite sufficient to destroy life. The brilliant yellow colour, and the state of preservation of the stomach, at once excited his suspicions as to the presence of arsenic. Some particles of arsenic were imbedded on the coats of the stomach, and very extensive inflammation had been thus created; and he was of opinion, from all the appearances he observed, that some of the arsenic must have been administered within twenty-four hours of death. The conclusion arrived at by him, from all the appearances that presented themselves, was that the death was caused by white arsenic, and that some portion of the poison must have been administered within twenty-four hours of death. Where one fatal dose of arsenic was administered, death generally ensued from twelve to eighteen hours, but in this case the quantity of arsenic amounted to several fatal doses, and in his opinion it was impossible for the deceased to have lived for more than a few hours after such a quantity of arsenic had been administered. He could not discover in the body any other cause of death than the administration of arsenic. Dr. Stephenson then went on to say that the arsenic supplied by the witness Vincent to Norman was of the same description as a portion of the arsenic found in the stomach of the deceased. There was a trace of copper in the stomach, copper being an ingredient of verdigris.

Serjeant Parry called for the production of the portions of arsenic found in the body of the deceased and those supplied by Vincent to Norman, and he asked that they might be shown to the jury, and said it appeared to him that they were as dissimilar as two things possibly could be.

In further cross-examination Dr. Stephenson said that arsenic mixed with verdigris would have a very nauseous and unpleasant taste. Arsenic by itself would not. It would have rather a sweet taste.

The trial was then adjourned until the next day, but upon the reassembling of the Court it was announced that the prisoner had been delivered of a child, and the trial was, therefore, adjourned until the 24th of October and the jury was discharged.

Obituary.

HENRY ARGLES.

It is with much regret we announce the death of Mr. Argles, of Maidstone, which took place somewhat suddenly at his residence on the Ashford Road, Maidstone, on Saturday, the 6th inst., at the age of seventy-two. The deceased gentleman was held in high esteem amongst his fellow-townsmen, both for his public and private virtues. Mr. Argles was a Justice of the Peace, and had twice filled the office of mayor. He was one of the founders of the Pharmaceutical Society, having joined it in 1841, and continued his connection with it up to the time of his death.

Correspondence.

Provincial Education.

Sir,—One of Mr. Schacht's "principles" is, that the distribution of the Society's aid shall be "as far as possible just and universal," and I believe his scheme, as a whole, admits of as wide an application as is practicable. But, as it still falls short of being quite universal in its application, it is regarded by some as unsatisfactory and unfair.

The greatest conceivable good is undoubtedly the bringing of means of systematic pharmaceutical education within reach of every apprentice and assistant; this we all know to be impossible. The next best thing is to bring it within reach of as many as we can. Are we not justified in hoping that this result will be attained by the new scheme?

If I understand rightly, the object in view is less to reduce the cost of pharmaceutical education to the student, than to increase and improve the means of which he can avail himself, though some of your correspondents appear to think differently. The last clause of Mr. Schacht's document affords a wide field of action which I trust may not be curtailed. Beyond making grants to associations (however small those associations may be) there is but one step to granting aid to individuals; such grants would necessarily be so small as to be practically useless. It would be absurd for the Council to receive applications from apprentices for "5*s.* towards an Attfield's 'Chemistry,' or a Bentley's 'Botany.'"

I apprehend that the pecuniary value of the prizes intended to be given to students themselves will be but nominal. It certainly does not seem to me desirable to foster the idea that young men are to be paid for doing their duty, to be enticed by promises of prizes and reimbursements to gain knowledge, which is its own reward; or the whole matter might be simplified by giving £5 to every man when he passes his Minor, and £10 for his Major. We must hope for a healthier and more independent spirit.

A strong point in the proposed scheme is the encouragement it gives to the formation of Provincial Pharmaceutical Associations. There is nothing, I believe, more likely to elevate the whole trade than this combination for educational purposes. There are few towns of 10,000 or 15,000 inhabitants in which such might not exist, and though these cannot include the whole trade, they may a very large proportion. Assistants now migrate so frequently from one town to another, that there will be no great difficulty in every one bringing himself under the influence of one of these associations, the least of which may establish a small library. I am glad to see that Mr. Hills advocates a proposition I recently made in your columns, that the grants towards furnishing libraries, museums, etc., should bear some proportion to the sum actually collected locally, and with characteristic openheartedness he suggests "half or one-third." This, I believe, will be better than making the sum granted dependent on the "required expenditure" only; at all events, the amount should not only be "required," but the association's share raised before the grant is made.

I do not doubt but the country will appreciate the liberality of the new scheme, and that one of the results of its adoption will be a large addition to the membership roll of the Pharmaceutical Society. There are many who will hail this movement as a return of the Society to its first love—the educational advancement of the whole body of chemists and druggists, and will feel ashamed not to contribute something to that by which they will now be great gainers.

F. Baden Benger.

1, *Market Place, Manchester,*
July 15th, 1872.

Sir,—Though I have not hitherto taken any conspicuous part in the discussion of how to aid pharmaceutical education in the provinces, I think I may still be considered to have shown a practical interest in this subject, having delivered three courses, each consisting of twenty-four lectures, on pharmacy; and having been thus engaged six months in the year for the last three years, the subject has naturally come before me in various different phases.

I confess I have felt no inclination to join in the clamour for help which has been raised by or on behalf of those who are called (I fear too often unworthily called) the students of the present day; and I must say I feel a great contempt for those who, having passed their examinations, are jealous of there being advantages provided for others which they did not enjoy, or enjoyed only at a much greater cost.

We can only hope to come to a satisfactory conclusion when these petty considerations give way to a broad and liberal spirit, and when students evince that earnest and independent manliness which would be ashamed to complain of difficulties which are not now anything like so great as those which have been passed through by the better part of the pharmacists of the present day.

The report on provincial education which appears in the Journal for November, 1870, page 389, has certainly not been equalled for wisdom, justice, and breadth of view by anything you have published since, unless I make exception in favour of Mr. Reynolds' remarks at the meeting in Leeds, reported in the Journal for March, 1872, page 751. It appears to me that an impartial critic could scarcely examine the former with subsequent proposals and not come to the conclusion that the project as developed by Mr. Reynolds was the most statesmanlike, and was well worthy of a fair trial. It can scarcely be urged with any fairness that the Act making examinations compulsory has taken by surprise any engaged in pharmacy, seeing that it was only the consummation of the struggle carried on by our Society for nearly thirty years, and latterly very freely discussed by outsiders as well as members of the Society. But, even if this is to be granted, it is only those who have been so blind, and now find that they must pass the Minor examination, who have the faintest claim upon the Society to lighten their burden; and as they will naturally cease to exist in the course of a few years, the Society should not be expected to promote education at less than its legitimate cost for more than a brief period. To provide the student with lectures or instruction of any kind for a payment which is not remunerative to the teacher is to pauperize the student and retard the advancement which should take place in the status of the pharmacist.

Now that the qualification is fixed, the next thing should be to experience such a demand for education in pharmacy as would naturally lead to the supply being provided by those who are competent and willing to sell their services. No school can be considered satisfactory which is not self-supporting, and on this point only have provincials a ground of complaint againt the central institution,—the lectures, costing £600, are only met by fees amounting to £200.

The lecture fees at Bloomsbury Square ought to be raised till they cover the stipends paid to the lecturers. I think 1*s.* per lecture could not be regarded as too much for students to pay, and if the instruction they require cannot be purchased for that, it only remains for them to pay so much more. And, on the other hand, if the lectures are not worth as much as they cost, why continue them? That students are prepared to pay liberally for instruction which they can appreciate, is evident from the fees paid in the laboratory. I believe it only requires a trial to prove that the students would willingly pay such fees as would make the lectures self-supporting in London. And as to lectures in the provinces, I think it would require much discrimination and judgment, and a careful examination of the merits of each provincial institution, to know which were worthy of the support which it would be creditable and judicious of the parent body to give. A clear prospect of permanence and efficiency should be the first consideration, and the next should be a class of students each paying at least 1*s.* per lecture. If these fees did not provide remuneration to the lecturer to the extent of 21*s.* per lecture free of necessary expenses, I think the Society would do wisely in making up the deficiency.

In the report presented by Mr. Schacht, the third of his "principles" appears to contain some ambiguity and the root of discord. It appears to me that justice is to an exceedingly small extent involved in the question. The student class have contributed little or nothing to the surplus £2000, and cannot be said to have any claim upon it. If the Council were to pay handsomely to Durham in support of education there, that would not involve any injustice towards the students in Newcastle; they would still get all they pay for, and would be at liberty to buy their instruction in the best market. If it involved injustice at all, it would be towards those who, having contributed considerably towards the Society on the understanding that its object was "to advance chemistry and pharmacy and promote a uniform education among those practising the same," and who might consider that this object was not best carried out by establishing a school in Durham. It is not justice so much as policy which demands our consideration, and the question is simply, taking a comprehensive view of the matter, what is best to be done with the surplus income of the Society?

I also must protest against the attempt at anything like an approach to universality. I think nothing is so far removed from wisdom as thus scattering our efforts. I would rather that Newcastle should be excluded from the operations of this scheme, on the ground of its being insufficiently important, than that its school should trail out a languid and unhealthy existence, kept alive by sucking its parent's milk, when it ought to be living on the healthy food of earnest and numerous students. I think there is more fear of injustice being done to those who are wishful to establish schools upon the only permanently satisfactory basis, that of being self-supporting, than to any others connected with the question, and that injustice will arise, first, out of the competition with those who give gratuitous lectures,—a class which I am happy to think will not long come in competition with those who look for and work for remuneration,—and it will arise, secondly, out of the idea which students are likely to imbibe, from the recent tone of the discussion, that they cannot be expected to pay a fair price for their instruction.

The objectionable features of Mr. Schacht's scheme all appear to result from his endeavour to be "just and universal;" and I do not feel it necessary either to criticize it in detail or to attempt suggesting a better, so long as the scheme advocated by Mr. Reynolds two years ago, and which I consider so much superior, yet remains untried.

BARNARD S. PROCTOR.

11, *Grey Street, Newcastle,*
July 16th, 1872.

Sir,—The subject of provincial pharmaceutical education has for many years occupied the attention of our leading men. Long before the Minor and Major examinations became the legal tests of qualification for occupying the position of Chemist or Druggist and Pharmaceutist, efforts were made by various associations of chemists and druggists in our large towns to provide means by which apprentices and assistants might raise themselves to the standard required for the efficient discharge of the duties devolving upon them, and for afterwards occupying a much higher position as pharmaceutists than their predecessors had done. These efforts took the direction, in the first place, of meetings for the discussion of subjects connected with pharmacy. Afterwards they extended to courses of lectures on chemistry, botany, materia medica, or pharmacy, the formation of libraries, collection of museums, and other means. The results, however, as regards lectures, were discouraging; few availed themselves of the opportunity afforded (sometimes at a nominal cost); and pecuniary loss was the almost invariable conclusion of each attempt.

When, however, the attainment of such a standard became compulsory before commencing business, it might have been expected that young men would have gladly made use of every means at their disposal for the acquisition of knowledge, and that whenever provincial associations in large towns made arrangements for the delivery of lectures by thoroughly qualified gentlemen, on such subjects as chemistry, botany, materia medica and pharmacy, the classes would have been well attended, the students eagerly in earnest in mastering the subjects brought before them, and the results satisfactory and encouraging to the managers. Has this been the case? Let those who have been connected with such movements and the reports, which, from time to time, appear in the Journal of their proceedings return the answer, which will, I believe, be in almost, if not quite, every case,—No. This being so, and there being no other school of pharmacy worthy of the name in this country than the one in London, the want of such schools being on all hands admitted, and the necessity for them becoming daily more urgent, the question presents itself, what is to be done? Many crude suggestions have been made on this point, most of which seem to take it for granted that a sufficient expenditure of money will secure the end in view.

Even in London, however, young men seem to avail themselves very sparingly of the splendid opportunities at their disposal. Supposing that every London candidate who passed the Minor and Major examinations between July 1, 1871, and June 30, 1872, had been a student at Bloomsbury Square, the number would only have been 43 (36 Minor and 7 Major), against 242 from the country (201 Minor and 41 Major), of whom I think I may assume two-thirds have benefited by the lectures or laboratory, either in this or previous sessions; so that even if the country finds most of the money, it gets most of the benefit.

To return to the question: How are the means of systematic pharmaceutical education (beyond what is generally attainable in the ordinary routine of business) to be brought within the reach and means of provincial students? and how are the largest and most satisfactory results to be attained with the least expenditure of money.

I think Mr. Schacht has solved the problem, or at least, laid down correct principles for its solution, in his scheme before the Council, its chief feature being payment on results. In my opinion, this plan, in its main features, and so far as it goes, is unobjectionable, and I also think more feasible than any other yet brought forward. The plan of giving a money grant to any local association applying for it, without any control over its expenditure, or complete account of the results of that expenditure, is impracticable. Where is the local association, a majority of whose committee is known to the Council? According to Mr. Hills' suggestion, this would be required, as the "certain number" who are to give a guarantee that the money shall be properly expended are to be known to the Council, and in order to carry out the guarantee, they must constitute a majority of the managing body. The Council ought to have some control over the manner and as to the objects for which their grants are laid out; and the difficulty of securing this control in any other way than as proposed by Mr. Schacht, seems insuperable. If this plan is carried out, applications for assistance will only be received from large towns, such as those named above. In all such towns there is the requisite machinery for carrying on the work; and it is only there that anything like "systematic and persistent teaching" by means of lectures can be successfully carried on. Courses of lectures, delivered and illustrated by competent teachers, are generally very expensive, and the expense would be almost the same for 10 students as for 50, although the amount received for fees, and grant earned, would probably only amount to one-fifth. In short, a few good schools of pharmacy spread over the country under efficient management, and with first-rate teachers, are more to be desired and will yield far better results than schools in every small town where a dozen chemists can agree to form an association and apply for a grant expended at random upon incompetent teachers, and with very little good results.

There are one or two points on which Mr. Schacht's scheme may, in my opinion, be amended and extended. For instance, I should strongly object to any one on the register of chemists and druggists or pharmaceutical chemists being allowed to earn payments for results, and still more strongly to their being allowed to compete with assistants and apprentices for prizes. Chemists and druggists who have earned their title by passing the Minor examination, ought not to be placed in a worse position than those who are such, simply because they happened to be in business before 1868. Both should be excluded from earning either prize or grant.

What I look upon as the greatest defect in the scheme is, the exclusion from competition of all young men who do not, from any cause, attend the required lectures. These will, I think, be not less than one half of the entire number of assistants and apprentices in the kingdom. Even supposing that lectures were delivered in every little town mustering half-a-dozen chemists' assistants and apprentices, still a very large number would be left unprovided for. It is only fair to suppose that many of these are making good use of the limited means available, and using every exertion, to raise themselves to the required standard. Again, large numbers in towns would not be able, from a variety of causes, to attend lectures, and yet, many of these may be constantly and earnestly engaged in learning what it is requisite for them to know. I am supposing in these two cases, that the young man is struggling against difficulties, including indifference or even opposition on the part of his employer, who may be unable or unwilling to render any assistance. There are besides these, a large number under the care of masters in town and country, who endeavour to discharge the duty they have undertaken by imparting "systematic and persistent teaching" to their pupils, in other ways than lectures, and far more efficiently, too; for the chief use of lectures to the student is to mark out the path to be pursued along which he is himself to travel, and not to be carried by his guide. This guidance, direction, as well as assistance, can be given better by a competent master, who does not wish to shirk his duty, but whose desire and pride it is to thoroughly prepare his pupil, so that at the conclusion of his apprenticeship he may at once pass, at least, the Minor examination. Now, why are young men like these to be altogether shut out from the same examination as the lecture attenders are admitted to? and why are their masters to be deprived of the credit which is justly their due, for the honest discharge of their duty, and the successful results following therefrom? The former ought to be admitted to examination for prizes; and if no grant can be made to the employer in case of success, his name ought at least to be published in the pages of the Journal.

I agree with a suggestion made by one of the Council, that in the case of unsuccessful candidates, a small capitation grant might be made to the local association, say 5*s.* for each one who obtained under 50 and not less than 30 per cent. of marks. The requirements in Mr. Frazer's amendment are, it seems to me, fully provided for by Mr. Schacht's scheme in its last clause; and in every case, great care should be taken that each grant made is faithfully expended on the object for which it is given. In most of the large towns, great progress has been made in providing libraries and museums, so that grants for these objects will be chiefly required by the smaller associations where there is not a sufficient number of young men to warrant the cost of lectures, but where small classes for mutual study and assistance, would derive great benefit from a little help in this direction, which the local association, from the smallness of its numbers, may be unable fully to supply.

I would suggest that the Council collect and publish statistics respecting local associations now in existence; such as the number of chemists in business in their respective districts, and of assistants and apprentices, the number of members and associates, amount of subscription, what attempts have been made in the direction of establishing lectures or classes, and by what success attended. What educational appliances are already available, such as libraries, museums, apparatus, rooms for lectures, etc. These statistics would be of great utility in discussing the great question in hand.

THOS. D. WALKER.

Dresden, Staffordshire.

Sir,—As every one with a thought upon pharmaceutical education is now directly appealed to, I have resolved to give you mine, which do not seem to have occurred to any of the numerous and able speakers at the late Annual Meeting.

The question appears to be, how to give our young men the best education at the least cost. Under existing circumstances, the scheme of most intelligent country apprentices appears to be to pick up what they can during their apprenticeship, and then, if possible, to procure a situation in London, where, by giving the larger portion of their time to business, they may secure enough to provide for board, lodging, and other expenses, while they can at the same time attend a portion of the lectures, and occasionally the laboratory, at Bloomsbury Square. Practically, perhaps, no better or more economical plan for securing a succession of average competent chemists could be devised; but, unfortunately, London itself will not afford sufficient area for all the improvers to secure the required position; hence the agitation for provincial schools.

But are things taking the right course? Is there not a tendency to spread over too much ground?—and will not the end be best attained by giving up any attempt to provide general and organized instruction during apprenticeship, and to confine our attempts to enlarge the means, to make it more attainable for two or three years afterwards?

I would suggest that no attempt be encouraged to organize provincial instruction in any town with a population of less than 80,000 or 100,000 inhabitants. We may then have several really efficient centres, where young men, after their apprenticeship, might secure an efficient and thorough education; and the area would be considerably extended in which they might seek partial employment, and thereby practical improvement in the trade.

By this means, instead of having a mere form of education in doses of science and water, with a little of the sugar of experiment to make it palatable, administered to a class just able to keep itself alive, by an amateur professor, who could only snatch the fag ends of his days from business to devote to such an object, there would be distributed through the country centres of efficient education where the entire services of competent men might be secured. Over this extended area, young men just out of their time would surely be able to secure situations as student assistants, while the opportunity of securing the services of a cheap yet efficient class of assistants ought to induce the resident chemists in such towns to subscribe liberally at first to start these provincial colleges of pharmacy in a really efficient manner.

The Society could also afford to be more liberal in its grants than if every town of twenty thousand or so makes an attempt to start a small school of its own. These grants, too, could be better made in apparatus than money if judiciously done. For this purpose it would be then worth while for the Bloomsbury staff to include a man who knew how to get to the inside of the London apparatus trade, as most apparatus may be secured at about half the price that country chemists could purchase it for.

There is another consideration: such efficient schools as I suggest could certainly secure men as teachers, who could command South Kensington certificates, and thus the prizes, etc., given by that body would be available. Such institutions, without losing an atom of their special pharmaceutical efficiency, may become the centres of scientific instruction to the public generally.

W. Symons.

Sir,—In this scheme for "Provincial Education," based upon the principle of "aid for result," what are "results?" and what are the "provinces?" The answers gathered from the "details" are that the provinces are the large towns, and the results are, first, the formation of local pharmaceutical associations, and secondly, the passing of examinations. The title of the scheme should include as its main object the formation of local associations; and this object practically restricts the operation of the scheme to large towns; for in such only are associations, on the stringest conditions of the proposal, feasible. Experience in the effort to form associations in smaller towns is not calculated to stimulate to more of the toil of Sisyphus. Entire counties might be instanced where one or two associations at the utmost could be formed. Whence are lecturers to come? and who are "competent teachers"? Is the number of the letters of the alphabet appended to a name the guarantee? and why should the value of lectures be measured by a chronometer? Men of "degrees" can sometimes "talk" for an hour "and say nothing" (as a Midland phrase has it), while men of far less note, but more "apt to teach," might convey more information to the student in half an hour. Supposing students are only twelve miles distant from the favoured association (and this is far below the mark of many localities), how can more than one be spared from the same establishment for twenty lectures? and "cui bono"? If half the lectures are sufficient for one pupil, why should he suffer penalties for his clearer intellect, or more careful study, and perhaps his more slender means, provided he can come up to the standard of examination? Ought not the much-vaunted "results" to be sufficient evidence of competence on the part of the teacher, and of "systematic and persistent" study on the part of the pupil? unless, indeed, the number of hours is to be a pledge that the drones of the class have had adequate opportunities. If such be the case, where is the security for their attendance?

The scheme seems inconsistent with its third principle of generality, since its benefits will be confined to the large towns unless the smaller ones clamour for doubtful aid, in *formâ pauperis*, under the indefinite "last sentence of the scheme." And it is the old question, how far it would be "just" to apply funds derived from the country at large to the favoured towns? Aid associations by all means, but add a capitation grant—not as payment, but as an honorarium or "stimulus" for *all* successful candidates. Let there be room in the scheme for the words so often seen in the reports of the London University examination "private study." Or, perhaps better still, as the Pharmaceutical Society has attained the goal of its ambition in compulsory examinations, let it prepare to relinquish its educational functions, and confining itself to examination, let it leave education to the law of supply and demand, and reduce subscriptions in proportion to its saving in consequence.

So far as the scheme is yet developed, it does not contain promise enough to beget in a country chemist very profound gratitude, which is said to be "a lively sense of favours to come." These first and hurried thoughts, Mr. Editor, in response to your earnest invitation for expressions of opinion may assume better form and tone on a future occasion.

Henry H. Pollard.

Ryde, July 15th, 1872.

Sir,—I am induced by Mr. Schacht's request to the members of the Pharmaceutical Society to express my opinions upon the scheme propounded for the education of our young men in your Journal of the 6th inst.

As the representative of a business of about fifty-four years' standing, I beg to offer mine, as one whose wish is that all members of the pharmaceutical body may occupy a better position in the estimation of the medical profession and the public than they do at present.

The able and comprehensive manner in which Mr. Schacht has delineated his scheme does him very great credit; but I must express my strong disapprobation of his plan for disposing of the funds of the Society.

Our subscriptions are intended for imperial, and not local objects,—that is, to keep a Council of our most able and experienced members in London, who can confer with the Government on any legislative measures which may affect us as a body; to keep up a school of pharmacy worthy of the nation, and a laboratory second to none, for the benefit of the United Kingdom and the Colonies, but not for any local district. We should keep up an institution in London which, with its museum, library, etc., will stand comparison with those of the Colleges of Physicians and Surgeons, and with whose members our Council could meet on equal terms with regard to their scientific knowledge and acquirements. If our funds be devoted to teach elementary knowledge, the great object of our Society will be ignored, and we shall raise up a body of chemists with mediocre abilities, pretty much the same as the International Society is now endeavouring to reduce the working men of Europe to one dead level.

Presuming that Bristol will have the benefit of pecuniary aid from the parent Society, what advantage will it be to Cornwall, Devonshire, Dorset, East Somerset, or the six counties of South Wales? It will give immense advantage to the young men of Bristol, at the expense of the general body, to have lectures on botany, chemistry, and pharmacy, by competent teachers, which will be denied to all who live beyond ten miles of that city.

It is with regret I observe the paucity of young men who pass the Major examination of the Society, which is very detrimental to its interest, as the Minor certificate has not so much influence with the medical profession or the educated part of the public as a three years' recommendation from the well-known dispensing establishments of Corbyn's, Bell's, Allen and Hanburys', Squire's, Godfrey and Cooke's, etc., whose names are household words throughout the land; and unless the Council offer powerful inducements to young men to study the higher branches of the pharmaceutical sciences thoroughly the position of our craft will not be improved.

To accomplish this object, let us say twenty scholarships be annually given, by examination in London, to registered apprentices throughout the kingdom, and a sufficient sum of money be granted to cover their board, lodging, and instruction during the session or two they are required to study; and let twenty more be given to those who have passed the Minor examination with the greatest credit, on the same terms. We shall then have healthy competition among the young men, when they know there is equal fair play to all alike.

If this plan could be carried out by the Council, in a few years the kingdom would be illumined by a race of Schachts, who would be an honour to their Alma Mater, and who would command the respect of the medical profession and the public by their knowledge and scientific acquirements.

Thomas Hughes.

Llandilo, South Wales, July 16th, 1872.

When Ought a Grain Dose of Morphia to be Dispensed?

Referring to the Morecambe poisoning case, and your leader of last week, I cannot but think, looking at the matter from a dispenser's point of view, that there was at the inquest, as there often is in these cases, an inclination to saddle the wrong horse. Since the publication of the prescription we can judge the case more clearly. According to its strict grammatical construction, it is ambiguous. Anglicized, it reads thus: "Take of acetate of morphia, one grain. Let six pills be made;" not necessarily *of it*, but it may be read *like it*. Edmondson, who knew the dose well enough it appears, would never have read the latter but for the confusing—to him corroborating—verbal instructions.

In my own experience, the following case occurred. A lady, whom we were well acquainted with as a customer, brought a prescription which was handed to me to dispense. On it were a bromide of potassium mixture, and the following formula for pills:—

"℞. Morphiæ Muriat. . . . . gr. j
Cons. Rosæ q. s.
M. ft. pil. Mitte iv.
One to be taken at any time if in much pain."

This was quite explicit; but as the dose was unusual, I hesitated and consulted my *confrère*, and also our employer. The lady had been taking a "sedative mixture" occasionally containing liquor opii sedativus, in ordinary doses. She had brought the prescription herself, and did not appear to be suffering at the time. We knew the prescriber, who was always most accurate in his prescriptions; but on that occasion I was under the impression he intended to have ordered the pills to contain a quarter of a grain of the morphia salt. However, it was ruled otherwise, and I dispensed it, having a witness to the weighing and division of the pills. I felt a little anxious about them till the next morning, when the lady came again and said she had taken one of the pills on retiring to rest, but it had not relieved her. I may state I was then in the habit of preparing weekly six dozen powders, each containing two grains of acetate of morphia, for a patient, who continued to take this quantity for years. The moral I draw from the case is not so much against *verbal* instructions as for *explicit written* ones.

Wm. Martindale.

University College Hospital, W.C.,
July 17th, 1872.

Dr. Mackenzie's Throat Hospital Pharmacopœia.

Sir,—I notice that, in your review (in to-day's Journal) of Dr. Morell Mackenzie's valuable Throat Hospital Pharmacopœia, you take exception to the use of magnesia in the composition of the concentrated preparations of essential oils, a teaspoonful of which is directed to be used (in a pint of water) for an inhalation.

You say, "The magnesia is added to keep the oil mechanically subdivided, but we think its use is chemically objectionable. Most volatile oils have an acid reaction, and therefore form compounds which are not volatile."

Permit me, therefore, to suggest a method of preparation which will obviate this inconvenience: although the method is incompatible with the advantages of the concentrated method of dispensing described in the Throat Pharmacopœia.

I notice in this Pharmacopœia, a copy of which I have before me, that the solutions of the essential oils when prepared for actual use by the admixture of a drachm of concentrated liquid with a pint of water are, at least in most, and possibly in all, of the examples given, not too strong for the method I propose, which is simply this:—

Put the quantity of oil directed for the inhalation into the pint of water, shake it up for a minute and repeat the shaking three or four times at intervals of half an hour. Then filter.

This is a method which I have long had in use at the British Hospital for Diseases of the Skin, as an economical and effective mode of preparing Aqua Menth. Pip. and other similar preparations. Previous to its introduction we had been in the habit of purchasing the various aromatic waters ready-made; and I find that it is the usual practice of pharmaceutical chemists either to purchase such articles of the wholesale chemist at a very unnecessary expense, or to prepare them themselves by the equally unnecessary and troublesome process of distillation directed by the British Pharmacopœia. Such preparations are so largely used, and if bought are so bulky in proportion to their value, and rendered so additionally expensive by the item of carriage, that a process by which they may be by far more economically prepared than by the usual way, cannot, I think, but prove of some interest to your readers.

Balmanno-Squire.

July 6th, 1872.

[**** This plan might be convenient in the preparation of waters for hospital use; but when they are required for the public, a far more pleasant and satisfactory article is produced by distillation.—Ed. Pharm. Journ.]

Pharmaceutical Curiosities of Medical Practitioners.

Sir,—I am heartily glad your correspondent from 'the vicinity of the Valley of the Clyde' ventilates some of the grievances we have to contend with in this part of the country; but I am sorry he did not say a few words about another matter which is in much need of reform, viz., prices. For the benefit of my Southern brethren I will give a few of the prices charged at one of the principal establishments in Glasgow:—a 12 oz. bottle of Genuine Newfoundland Cod-liver Oil, 1*s.*; 1 oz. Ponderous Calcined Magnesia, 4*d.*; 1 lb. Bishop's Citrate of Magnesia, 3*s.*; 1 doz. Compound Rhubarb Pills, 2*d.*, and so on at corresponding rates.

But, my inducement to write to you at present was because a prescription I have just received corroborates some of the statements made by your correspondent. The following is a copy of the prescription:—

℞. Acid Tonic No. 1.

and on the back of the prescription is lithographed the name and address of a firm having retail shops, but also doing a large wholesale business. "Ægis" remarks that "I have long since come to the conclusion that the medical profession are not so much to blame in this matter as a certain unprincipled class of our own brethren in the trade." I believe this to be true; but to me the curiosity has always been not so much why certain firms openly practise this mode of doing business, as that the retail chemists by patronizing such firms give a tacit support to the principle.

The only solution I can find is that pease meal, brose, and porridge are articles of diet in common use, can be got cheap, and in this climate are sufficient to keep soul and body together.

Glasguensis.

W.B.—We do not know of any law prohibiting such a proceeding, but recommend you to apply to the Secretary of the College of Surgeons.

"*A Registered Apprentice.*"—We are not prepared to say that the present practice of allowing registered apprentices to attend the Lectures at half fees is one that will be long continued. It was established for the special benefit of apprentices, but has not been so extensively taken advantage of as might have been expected.

"*Chemicus.*"—There have been numerous articles on the subject in the present series of this Journal. (2) We are not aware of the existence of such a patent.

"*Alpha*" is recommended to apply to the Editor of the 'Journal of Gas Lighting,' Bolt Court, E.C.

"*Senex.*"—(1) Apply to the Board of Examiners. (2) Apply to the Secretary.

"*Alpha.*"—The information could be best obtained from the Secretary of the Linnean Society.

E. Widdowson.—The terms of the additions to Schedule A, as published in the 'London Gazette,' which we think admit of no misinterpretation, are that, among other articles, "every compound containing any poison within the meaning of the Pharmacy Act, 1868, when prepared or sold for the destruction of vermin," ought to be deemed a poison within the meaning of that Act, and that, "of the same," preparations of strychnia "ought to be deemed a poison in the first part of the Schedule A to the said Pharmacy Act, 1868."

Communications, Letters, etc., have been received from Mr. W. D. Savage, Mr. S. W. Cleaver (Shanghai), Mr. W. Tearle, Mr. R. W. Protheroe, Mr. R. W. Giles, Mr. H. Recks, Mr. S. Willson, Mr. Barnard, Mr. J. R. Jackson, Mr. A. H. Mason, Mr. J. Davidson.

THE DUBLIN EXHIBITION.

The usefulness of exhibitions to manufacturers is somewhat doubtful. It is evident that to be of much value they should not be too frequent, and should at least be international. The Dublin Exhibition of 1872 is too soon after the excellent one of 1865, therefore there is very little novelty in the manufacturing portion, whilst the foreigner is unrepresented.

In spite of this, however, it will probably be a success, owing to the great attraction of the Loan Museum and the Fine Arts collection. Although there is very little that is new in the chemical and allied branches of manufactures, still some products of interest present themselves; and it is time well spent to watch the slow changes observable even in the fashions of chemical and pharmaceutical products. As we enter the west gallery from the southern stairs, almost the first thing the visitor stumbles across is a little case of some interest to the pharmaceutical chemist. It is in the form of wire-weaving contained in the case of Messrs. Bryan, Corcoran, Witt and Company, Mark Lane, London. Brass wire for sieves is shown containing 150 holes in the square inch; but this is greatly exceeded in fineness by the iron wire. Gauze made with this wire is shown containing 10,000 holes to the inch; although used for flour dressing, it might be applicable to special pharmaceutical purposes.

Messrs. Boileau and Boyd, Dublin, exhibit a pretty case of chemical and pharmaceutical products, the most striking of which is a sample of theine made from damaged tea. It is an extremely pretty specimen made by crystallization, not sublimation. Theine, or caffeine, as it is often called, has been frequently suggested as a valuable medicine; but whether our familiarity with it in the form of infusion has bred contempt or not, certain it is that it does not enter into the ordinary practitioner's materia medica. Although theine acts on the ganglionic nervous system, it has no action on the brain. It is used in doses of 1 to 4 grains as a tonic stimulant.

Mining Company of Ireland, Dublin.—We cannot pass without noticing the magnificent case of the Mining Company of Ireland, the chief attraction of which is the lead and silver in all its stages, from the undressed ore until we get the finished articles in the form of a massive block of silver-lead, in the form of shoot, pipe, and sheet; but this company are also of interest to the chemist from being large manufacturers of litharge and red lead. The first of these is procured during the refining of silver-lead—the silver in which is concentrated to its highest point by Pattinson's patent. The litharge, got by this process, at the Ballycorus Works, is particularly pure and valuable for plaster making.

A. Jellet's Saccharometer is exhibited, but the price is restrictive, viz., £29. We want to see some enterprising manufacturer bring out this instrument in a form in which it can be sold for £5 or £6. It is the best of all saccharometers. The only restriction to the more general use of this instrument is its price; its applications to technical chemistry and pharmacy are not confined to mere estimation of sugars, but it can be used to determine the admixture of turpentine and other hydrocarbons of this class, and the estimation of some of the alkaloids.

Messrs. Holt, Nerwich and Co., Vauxhall, London, exhibit a pure oil soap which is not made for pharmaceutical purposes, it being prepared for the use of dyers in dyeing silk or wool. Why not use such a soap, however, for linimentum saponis of the pharmacopœia?

Mr. E. Stanford, Edinbarnet.—It would be superfluous to dwell upon the *Nitro-carbon Manure Company's* case. As under that name we find Mr. Stanford exhibiting his ingenious and valuable process for the manufacturing of the products procured from seaweed. Mr. Stanford's process, as our readers are no doubt aware, is essentially this: Instead of burning the seaweed on the shore, and producing the well-known kelp, the weed is burned in closed retorts, by which means all the by-products or products of destructive distillation are saved—these are naphtha, ammonia, charcoal, etc. One important point in connection with this process is the fact that iodide of potassium is volatile at a bright red heat, and that therefore a considerable loss of iodine is prevented. Such a loss arises from the ordinary method of burning kelp. Such a saving must be doubly important at the now very high price of iodine and the iodides. One of the most valuable by-products seems to be the charcoal, which possesses most extraordinary decolorizing properties. The charcoal procured approaches animal charcoals in this respect, and does not seem to resemble the ordinary vegetable carbons.

Marine Salts Company of Ireland, Dublin and Galway.—We have a second exhibitor of iodine and bromine in the Marine Salts Company of Ireland. This company procures its kelp from the west coast of Ireland. Besides showing all the potash and other salts derived from the kelp, they have specimens of the different weeds arranged according to their iodine value; thus *Laminaria digitata*, and *Laminaria saccharina* "rich in iodine;" *Fucus serratus* "poor in iodine," etc.

Mr. John Somerville exhibits a case of the products from the destructive distillation of coal, including the anthracine products and the ammonium salts, including the nitrate now used for the making of nitrous oxide.

Messrs. Berger, Spense and Co., Manchester, exhibit a magnificent crystal of alum of gigantic proportions, but it is really curious to observe that it has a decided amethystic tinge, due probably to the presence of a trace of iron, which produces the well-known appearance of iron alum.

Some handsome specimens of crystallized salt are exhibited by the Newry Salt Company, including specimens of the rocksalt, which are beautifully free oxide of iron. So pure are these natural specimens that if they were simply ground, they would form a white and first-class table salt. The crystals shown are hopper-shaped, cubical, and the ordinary granulated table form.

Messrs. Bewley and Draper, Dublin. — Mr. Draper, of the firm of Bewley and Draper, is here with his "dichroic ink," which is certainly a novelty in its way, and quite unlike the ordinary inks. If he can surprise the Yankees, as he seems to have done, it really must be out of the common.

Price's Patent Candle Company, London.—The above firm is here in all its glory,—that is to say, besides this company's candles, they exhibit glycerine, the article of all others to which they owe their fame. The process which gave to the world pure glycerine, also produced a revolution in the manufacture of soaps and candles. By one process they split up the saponifiable fats in the fatty acids and glycerine. The first are in the most perfect state for producing soaps and candles, whilst the possibility of distilling glycerine was first chemically demonstrated by this patent. Their patent is now out, but very few glycerines can compete with the article made by this firm. Glycerine can be redistilled by superheated steam, and is generally so treated for the better qualities.

(*To be continued.*)

NOTE ON PILL EXCIPIENTS.

BY WALTER TEARLE.

At the last November meeting, Mr. J. B. Barnes read a paper on a new pill excipient—boro-potassium-tartrate, or soluble tartar. When carefully evaporated to a mucilaginous consistence, a solution of this salt possesses that weight and plasticity which are necessary to form certain untractable bodies into pills. Yet it presents an objectionable feature, for pills made up with it soon acquire that flinty hardness, which, in a medical sense, at least, is prejudicial.

While looking for some such thick heavy substance as this, but which would not so readily solidify and get hard, I was led to try a neutral solution of citrate of potassium in syrup and glycerine; this solution was very heavy and of the consistence of treacle, and possessed sufficient adhesiveness to form nitre and chlorate of potassium into pills without the aid of tragacanth; but from the deliquescent nature of this excipient, the pills could not be kept for any time without getting moist. A solution of soluble cream of tartar was next prepared and evaporated to a thick consistence, and then rediluted with syrup and a small proportion of glycerine till sp. gr. was about 1·420. One ounce of this was then mixed with half an ounce of the above citrate of potassium solution, and dilution with syrup continued till the sp. gr. of the mixture was 1·400, and a liquid of the consistence of mucilage was obtained. This liquid possessed sufficient adhesiveness to form sulphur, antimonial powder, bismuth, gallic acid, benzoic acid, rhubarb, Dover's powder, etc., into pills without the aid of tragacanth, the pills being very small compared with the amount of drug present:—thus 7 grains of sulphur, 6 grains of rhubarb, 5 grains of gallic acid, 5 grains benzoic acid, and 8 grains saccharated carbonate of iron were all formed into pills no larger than the ordinary 5-grain size. These all present a handsome appearance, keep well in boxes in contact with lycopodium, and without being hard retain their shape admirably.

For forming chloral, nitre, and other soluble salts into pills, this solution will not take the place of simple soluble tartar, but for substances not readily soluble, and of which it is required to get as much as possible in an ordinary sized pill, it possesses some advantages over the tartar, one very important one being its ready solubility in cold water.

There is no advantage in having the excipient thicker than mucilage as the drops would not flow freely from the bottle, and would be inconveniently large for most purposes; in fact the value of these solutions, as pill excipients, obviously depends upon their being equal in thickness with those in common use, such as glycerine, syrup, and mucilage.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from page 43.*)

Colchichi cormus.—The fresh corm of *Colchichum autumnale* stripped of its coats, sliced transversely and dried at a temperature not exceeding 150° F. These particulars must be borne in mind when examining commercial specimens of Colchichum root in comparison with freshly gathered specimens, as the starch granules are subject to great modifications as to shape, size, and form of hilum when subjected to desiccation. The structure of the sliced corm is simple; thin walled, somewhat large parenchyma cells, containing starch and raphides in abundance, make up nearly the whole substance of the corm. The starch granules are compound, two, four and more, easily separable and with "a large and beautiful" central cavity and radiate hilum, somewhat exaggerated in the drawing in the English translation of Schleiden's 'First Principles.' Single granules are nearly round; the shapes of the component granules of the compound granules are modified by the ultimate shape of the combination too variously to be grouped under any two or three formulæ. The type of the separate granules, as Schleiden has remarked, is quite similar to that of the starch of most Leguminosæ, but differs in having the very "beautifully radiated opened central cavities." In this respect the starch of Colchichum is quite characteristic. A black cross is given by polarized light, the hilum forming the point of intersection of the arms of the cross.

Hemidesmi Radix.—The natural order of the Asclepiadaceæ is as interesting to the structural botanist as almost any other half-dozen natural orders taken together, and will furnish him with as many enigmas towards the solution of which he may profitably devote the best years of his life. The small portion of the plant belonging to this Order now under notice is rather more free from these unsolved enigmas than most other portions, but there are points of interest.

Medulla.—Obsolete or reduced to one or two cells.

Wood Zone.—The wood zone consists of large pitted vessels, wood cells principally pitted, and a few medullary rays and unpitted vessels containing a yellow colouring matter which is probably milky in its nature during the life of the plant. Each of these component structures requires more discussion than limited space will permit. I will briefly point out their more salient features, beginning with the pitted wood cells. These are many times longer than broad, with rounded-off ends, are much thickened and are minutely pitted. Very delicate spiral threads which intersect each other traverse the walls of these cells, but require great delicacy of manipulation and observing skill to detect their presence satisfactorily. The pitting is in the centre of an indistinct disc and is regularly arranged. The unpitted wood cells have spiral fibres which are more easily discernible. The large vessels are much pitted with somewhat minute, slightly oval pits in the centre of a raised disc, are frequently septate, and are not usually of great length, the distance between each septa being frequently little more than the diameter of the vessel. In cross-section the vessels and wood cells are nearly circular, rarely more than slightly oval, and their walls are of considerable thickness, rarely perforate. The direction of the axis of the pits is transverse to the length of the vessel or cell, and is little affected by the septa or the occasional spiral fibre. Many of the vessels are much stained with yellowish-brown colouring matter, and a few contain a minutely granular matter of an apparently semi-albuminous nature. The cells of the medullary rays possess somewhat novel features. They are nearly square with rounded off corners, have thick walls and are closely but minutely pitted. The pitting is indeed excessively minute, and in the centre of a relatively very large disc. The rays are incomplete and rarely do more than extend from the bark partly across the wood zone. The existence of a spiral thread in these cells is probable, but I have not been able to satisfactorily settle the matter. Considerable quantities of starch, sometimes compound granules of small size, compounded regularly according to the simple type we are already familiar with, frequently separate granules, and all possessing a distinct hilum, but apparently no central cavity. The doubtfully branched semi-liber semi-laticiferous vessels which contain the colouring matter may profitably occupy the student, but would lead me too far afield were I to enter upon their discussion here.

Cortical Layers.—The cells of the cortical layers are very varied. Those near the wood zone are angular, somewhat thick-walled and contain starch in considerable quantities. Nearer the bark these cells become smaller and sometimes contain yellow colouring matter. In some a spiral thread is doubtfully visible. The cells of the outer layers afford the student an excellent opportunity for studying the effect produced by an unequal deposition of secondary deposits, and will remind him of the well-known drawing of the bark cells of Viscum in Mohl's 'Vegetable Cell.' Hemidesmus is much more interesting to the micro-botanist than to the micro-pharmacist.

(*To be continued.*)

THE PREPARATION OF ATROPINE FROM THE LEAVES OF THE BELLADONNA.

BY M. J. LEFORT.

The employment of belladonna in therapeutics has long shown that all the parts of the plant contain atropine; but the authors who have indicated particular processes for the preparation of this organic base, have hitherto given the preference to the root as being more convenient than the leaves for chemical manipulation. The root, in fact, requires less alcohol than the leaf for the separation of the natural salt of atropine; moreover, the presence of chlorophyll in the alcoholic tincture of the leaf is a real hindrance to the decoloration of the product obtained, and finally it has always been supposed by them that the root was more rich in the alkaloid than the leaves.

The numerous analyses which the author undertook for the purpose of his former memoir on the distribution of atropine in the leaf and root of the belladonna,* showed that the leaf, which is fairly constant in composition, contained an average of 4·50 grams of atropine per kilogram of dried leaf, whilst the root contained quantities varying from two to five grams, according to the age of the plant.

This last fact was already known to manufacturers preparing atropine on a large scale, and they had also remarked that the root coming from Germany or Switzerland, was richer in atropine than the root collected in France, but this the author ascertained to be due to the greater care taken in the collection and selection of the roots. The collection of the leaf being in France much more easy and productive than that of the root, and as the former contains nearly as much atropine as the latter, M. Lefort sought by following the indications of MM. Stas, Vée and Duquesnel for the separation of alkaloids by means of tartaric acid, alkaline carbonates and ether, to devise a method for using the leaves in the preparation of atropine on the large scale. The following is the result of his investigation.

The dried leaves, coarsely bruised, are exhausted of all their soluble principles by boiling water containing ten grains of tartaric acid per kilogram of leaves. This addition of acid assists considerably the solution of the atropine existing in a state of combination in the vegetable cells. After straining, the decoction is evaporated to the consistence of a soft extract, the product averaging about 200 grams of aqueous extract from a kilogram of leaves. This is treated with concentrated alcohol and heated in a water-bath to about 50° C., to dissolve all the tartrate of atropine. The 200 grams of aqueous extract requires only one litre of alcohol, which is added in three or four separate portions; the strongly coloured brown tincture which results is then placed in a distillatory apparatus and the menstruum recovered.

The alcoholic extract so obtained is reduced to the consistence of syrup, which then weighs about 50 grams. It is next put into a well-stoppered bottle with a quantity of ether, and agitated from time to time. The ether quickly becomes slightly greenish-yellow coloured, from the presence of a small quantity of resin and chlorophyll dissolved in the original decoction, whilst the tartrate of atropine not being soluble in ether remains in the extract. Usually a single treatment by ether is sufficient to purify the alcoholic extract from these substances. Eight grams of caustic potash dissolved in half its weight of water, so as to make a concentrated alkaline solution, is then added with a fresh quantity of ether. As the organic alkali is displaced by the mineral alkali, it dissolves in the ether if the mixture be shaken.* The extract is repeatedly exhausted by successive quantities of ether, and the ethereal tinctures are united, and the ether distilled off. The residue left in the retort is a semi-solid, yellow-brown, transparent extract, which is dissolved in water acidulated by sulphuric acid. A small quantity of resin, which gives to the crude atropine an opalescent appearance, is thus separated. This solution of sulphate of atropine is concentrated, and bicarbonate of soda is added till effervescence ceases. Ether then dissolves all the atropine set free, and the spontaneous evaporation of the ether yields the crystallized atropine.

The author states that, notwithstanding these

* See PHARM. JOURN., Series 3, Vol. II. p. 1029.

* There is a perceptible odour of ammonia given off upon the addition of the caustic potash to the extract, due to the presence in the extract of an ammoniacal salt contained normally in the plant.

numerous details, the preparation of atropine from the aqueous extract of the leaves is as quickly and easily performed as when the root is used. It is necessary, however, in order to facilitate the solution by the ether of the atropine set free by the caustic potash, that the extract should be of the consistence of syrup, that is, sufficiently concentrated to run slowly. If there be too much water present, although the ether will dissolve the atropine which is undissolved, yet since that organic base is soluble also in water, there will arrive a time when placed between two liquids, having over it the same solvent power, it will resist them equally, and a much larger quantity of ether will be required to remove it from its aqueous solution. For this reason caustic potash is employed, since, neither the neutral carbonate or the bicarbonate of potash would decompose all the tartrate of atropine if the extract were too concentrated.

Alcohol is doubtless the best solvent of all the salts of organic alkalis contained in plants, since it has no action upon the starch, albumen, gum, sugar, etc., while water to a certain extent dissolves them. But the author thinks that the substitution of the aqueous decoction for the alcoholic maceration, will allow of a much more economical manufacture of atropine, from the smaller quantity of spirit used; only about a litre being required for a kilogram of leaves, the whole of which is recovered by distillation, as also is the ether used for washing the alcoholic extract. — *Journal de Pharmacie et de Chimie*, [4] vol. xv. p. 417.

COTTON ROOT.

BY PROFESSOR E. S. WAYNE.

The root of the cotton plant (*Gossypium herbaceum*) has for some time past been accredited with possessing the properties of an emmenagogue, parturient and abortive, and said to promote uterine contractions with as much efficiency and more safety than ergot.

As yet no analysis has been made of the root to determine its proximate principles, and to ascertain whether it contains any of the principles found in ergot, such as propylamin, or alkaloids such as ergotina and ecbolia, found in that substance by Wenzell.

The fluid extract of cotton root is a preparation largely used in the Western States of America, and highly spoken of as above by some practitioners. It is very prone to deposit a peculiar red precipitate a short time after it is made; and the frequent complaints made respecting this has induced me to make some investigations as to the cause and nature of the deposit, and, at the same time, of some of the proximate principles existing in the root, or, more properly speaking, of the bark of the root.

For this purpose one pound of the root bark, in suitable powder, was exhausted with alcohol of 76°; the resulting percolate was of a pale amber colour. This was distilled to separate any resin present in it. After distilling off the alcohol, there was left in the still a dark red aqueous solution of extractive, etc., and a dark red resinous mass.

The resinous mass was removed and reduced to a coarse powder, and washed with water as long as anything was taken up by it, then dried and reduced to a powder. It then resembled very much in appearance powdered cochineal.

The change that had taken place in the colour of the original percolate by the action of heat during the distillation, was a matter of much surprise to me; the resulting aqueous solution and separated resin being so different in colour to that of the original percolate, from a pale amber colour to a dark red, resembling in appearance that of a solution of kino.

The red resin obtained from one pound avoirdupois of bark weighed 210 grains.

Upon examination of the dark resinous mass, it was found to be insoluble in the following menstrua: alcohol, chloroform, ether, aqua ammoniæ. It was soluble in solutions of caustic potassa and soda; the solution, a dark purplish-red colour being precipitated unchanged on the neutralization of the alkali by acids.

A portion of the precipitate that deposited by standing in the fluid extract of cotton root was filtered off, washed and dried, and submitted to the action of the same solvents as the resin mentioned, and with like results.

The watery solution left in the still was, as mentioned, also of a dark red colour, and gave the following precipitates with solutions of metallic salts. With mercuric chloride, red; with argentic nitrate, purplish red; with plumbic acetate, purplish-red, and with ferric sulphate, purplish-black.

The remaining portion, after making the above tests, was precipitated with plumbic acetate, which precipitated the red colouring matter, and left it of a light yellow colour; then treated with sulphydric acid to remove excess of lead, and, after filtration to remove the sulphide of lead, was evaporated to dryness in a water bath. The extract mass left was of a light yellow colour, and exceedingly hygroscopic. A portion of it was dissolved in water, and tested for the presence of an alkaloid with solution of iodohydrargyrate of potassium, but gave no indications of the presence of any.

With Trommer's copper test, it gave an abundant precipitate of cuprous oxide, indicating the presence of sugar.

A portion was also agitated with ether, and another with chloroform, and, after separation had taken place, the ethereal and chloroform solutions separated and left to spontaneous evaporation, no crystallizable proximate principles were separated. To a quantity of the powdered bark was added a solution of caustic potassa; there was no development of propylamin, as with ergot.

From the above experiments, it would seem that cotton root bark contains no substances similar to those of ergot, upon which its therapeutic value rests, nor any other peculiar alkaloid or proximate principle except the red resinous mass spoken of, or a substance colourless as in the original percolate, and by oxidation changing to this red substance. This red matter seems to be a peculiar one—an acid resin, insoluble in alcohol, chloroform and ether, forming coloured precipitates with metallic salts, and soluble in solutions of caustic potassa and soda.

The red colour of the watery solution described is also due to this, being held in solution through the solvent action of organic matter present, as is often the case in such solutions, and sometimes with difficulty got rid of.

The substance that produces this red-coloured acid resin, seems to exist in all parts of the plant—in the flowers and in the seeds—the purplish tint at the base of the petals is due to it, and in the seeds the dark red spots there found. It is this which gives to crude cotton-seed oil its dark colour, and it is removed in the process of refining the oil by the solvent action of caustic alkalies. From the solubility of this substance in alkalies, and forming well-marked and characteristic precipitates with metallic solutions, it has claims to be classed an acid, and I would propose for it the name of gossypic acid.

Having satisfied myself as to the nature of the substance that composes the precipitate in the fluid extract of cotton root, and the identity of the precipitate with the resinous mass that was left in the still, as mentioned, I would say that it is impossible to prevent the same from forming in it, as it is caused by a chemical change taking place in a peculiar proximate principle in the plant, insoluble in the alcoholic menstruum.

Whether the addition of glycerine or sugar would prevent this, I have not determined, and will report experiment at some future time.

Query: Is this acid or the substance from which it is produced the active principle of cotton root?

The cotton-seed cake (the mass left after pressing out the oil) contains more or less of it, and I am informed by Dr. John A. Warder that cows fed upon it will abort, otherwise it is a nutritious food for cattle. Some of the substance I have placed in the hands of practitioners for practical test, but as yet have had no report concerning it.—*American Journal of Pharmacy.*

THE LAST NEW METAL, INDIUM.*

BY WILLIAM ODLING, ESQ., M.B., F.R.S.

(*Continued from page* 48.)

Now the salts of the alkali-metals, lithium, sodium and potassium, and certain of the salts of the alkaline-earth metals, calcium, strontium and barium, being very readily volatile, upon heating these salts, in the non-luminous flame of a Bunsen gas-burner for example, they undergo vaporization, and their vapours become incandescent and capable of yielding the characteristic emission spectra of the particular metals. In examining in this way the alkali-salt residue of a mineral water from Durkheim, Bunsen observed in the spectrum before him certain coloured lines not belonging to any one of the then known alkalies, potash, soda or lithia; and yet necessarily belonging to some substance having the general characters of an alkali, since all other bodies than alkalies had been previously removed from the residue under examination. In full reliance upon the certainty of this conclusion, Bunsen evaporated some forty tons of the water in question; and from the alkali-salt residue succeeded in extracting and separating salts of two new alkali-metals, each characterized by a well-marked pair of lines in the blue or indigo, and one of them having in addition a pair of well-marked lines of extremely small refrangibility in the red of the spectrum. From its yielding those red lines one metal was named rubidium; the other, of which the bright blue lines were especially characteristic, being called cæsium.

The very general distribution in nature of these two elements was speedily established, and salts of each of them were with much labour eventually prepared in a state of purity and in reasonable quantity. From certain of their respective salts the metals themselves were obtained by the usual processes, and together with their salts, were submitted to detailed chemical examination. And no sooner was this examination made, than the position of the newly discovered elements, as members of the alkali-metal family, at once became apparent. Rubidium and cæsium were found in all their properties to present the most striking analogy to potassium, and evidently to stand to this metal in the same relation that strontium and barium respectively stand to calcium; while they differ from sodium, much as strontium and barium respectively differ from magnesium. This relationship in obvious properties was further borne out by the relationship of their atomic weights, thus:—

Mg 24	Na 23	F 19	O 16
Ca 40	K 39	Cl 35·5. . . .	S 32
Sr. 87	Rb 85	Br 80	Se 79
Ba 137	Cs 133	I 127	Te 129

It is observable that the sequence of atomic weight in the thus completed alkali-metal family, is strictly parallel to the previously well-known sequences in the alkali-earth metal family, and in the halogen and oxygen families respectively. Moreover, just as the basylity of the alkaline-earth metals increases in the order of their several atomic weights—calcium being less basylous than strontium, and far less basylous than barium—so also is the basylity of potassium inferior to that of rubidium, and the basylity of rubidium inferior to that of cæsium, which is indeed the most powerfully basylous, or oxidizable, or electro-positive element known.

Since 1860, both rubidium and cæsium have been recognized as minute constituents of a considerable number of minerals and mineral waters, rubidium having been met with for the most part in a larger proportion by weight than cæsium. Unlike potash, originally known as vegetable alkali, cæsium has not been recognized in the vegetable kingdom; but rubidium has been found as a very common minute constituent of vegetable ashes, as those of beetroot, oak-wood, tobacco, grapes, coffee, tea, etc. On the other hand, cæsium, free from rubidium, has been found in a tolerably well-known, though rare, mineral from the Island of Elba, to the extent of 32 per cent. by weight of the mineral. The history of this mineral is curious: from the circumstance of its always occurring in association with another mineral, a variety of petalite, the two were called Castor and Pollux. Castor was found to be substantially a silicate of alumina and lithia; pollux a silicate of aluminia, and, as it was thought, of potash. The constituents of pollux, namely, silica, alumina, and potash, with small proportions of ferric oxide, lime, soda and water were duly estimated; but the quantities of these constituents found in 100 parts of the mineral, instead of amounting to 100 parts or thereabouts, amounted only to 88 parts, there being somehow a loss of 12 per cent. in the analysis. After Bunsen's discovery of the new alkali-metals, pollux was analysed afresh by Pisani, who soon perceived that what had formerly been taken for potash, and estimated as potash, was not potash at all, but cæsia. Then calculating out his own analysis with cæsia instead of potash, substituting the one for the other in the proportion of of 133 + 8, or 141 parts of cæsia, for 39 + 8, or 47 parts of potash, he found that the quantities of the different constituents furnished by 100 parts of the mineral yielded by their addition the full sum of 100 parts required.

In submitting to spectroscopic examination a certain residue left by the distillation of some impure selenium, Mr. Crookes, early in 1861, recognized in the spectrum before him a brilliant green line, from which he inferred the presence in the above residue of a new element; and by the end of the same year, he had succeeded in establishing the tolerably wide distribution of this element, to which he gave the name of thallium; in procuring it, though but in small quantity, in a separate state; and in satisfying himself of its metallic character. Soon afterwards, and without knowledge of Mr. Crooke's later results, the metal was obtained by M. Lamy on a comparatively large scale, and was exhibited by him in the form of small ingots at the London exhibition of 1862. He procured it from the fine dust met with in some oil of vitriol factories, as a deposit in the flues leading from the pyrites burners to the leaden chambers. In these deposits, the minute proportion of thallium contained originally in the pyrites becomes concentrated, so as to form in some instances as much as 8 per cent. by weight of the dust. Independently, moreover, of its occurrence in iron pyrites, thallium, though never forming more than a minute constituent of the different minerals and mineral waters in which it occurs, is now known to be capable of extraction from a great number and variety of sources. But from no other source is it so advantageously procurable as from the above-mentioned flue deposit; and so early as the autumn of 1863, at the meeting of the British Association in Newcastle, the then mayor, Mr. J. Lowthian Bell, exhibited several pounds, and Mr. Crookes no less than a quarter of a hundredweight of thallium obtained from this comparatively prolific source. In one respect, the discovery of thallium presented even a greater degree of interest than attached to the discovery of cæsium and rubidium. For whereas these two elements were at once recognized as analogues of the well-

* Lecture delivered at the Royal Institution, Jan. 19, 1872.

known metal potassium, thallium can hardly be said even at the present time, to be definitely and generally recognized by chemists as the analogue of any particular metal, or as a member of any particular family of elements. With each of such differently characterized elements as potassium, lead, aluminum, silver and gold, it is associated by certain marked points of resemblance; while from each of them it is distinguished by equally well-marked points of difference. Hence the necessity for subjecting thallium and its salts to a thorough chemical examination, so as to accumulate a well ascertained store of facts with regard to it. And thanks to the careful labours of many chemists, more particularly of Mr. Crookes in London, and of Messrs. Lamy and Willm in Paris, our knowledge of the properties of thallium and of its salts may compare not unfavourably with our similar knowledge in relation to even the longest known of the metallic elements. Still it was not until our knowledge of indium had culminated in the determination of its specific heat only last year, that the position of thallium as an analogue of indium, and a member of the aluminum family of elements became unmistakably evident.

Indium was first recognized in 1863, by Drs. Reich and Richter, in the zinc blende of Freiberg in Saxony, and by reason of the very characteristic spectrum afforded,—consisting of two bright blue or indigo bands; the brightest of them somewhat more refrangible than the blue line of strontium, and the other of them somewhat less refrangible than the indigo line of potassium. Since its first discovery, indium has been recognized in one or two varieties of wolfram, and as a not unfrequent constituent of zinc ores, and of the metal obtained therefrom, but always in a very minute proportion. Indeed, indium would appear to be an exceedingly rare element, far more rare than its immediate predecessors in period of discovery. Its chief source is metallic zinc,—that of Freiberg, smelted from the ore in which indium was first discovered, containing very nearly one half part of indium per 1000 parts of zinc. A considerable quantity of indium extracted from this zinc, was shown in the Paris Exhibition of 1867; and an ingot from the Freiberg Museum, weighing 200 grammes, or over 7 ounces, has within the last few days been kindly forwarded by Dr. Richter himself, for inspection on the present occasion. To Dr. Schuchardt, of Goerlitz, also, the members of the Institution are indebted for his loan of nearly 60 grammes of metallic indium; and of fine specimens of other rare chemical products, prepared with his well-known skill, in a state of great purity and beauty.

When zinc containing indium is dissolved not quite completely in dilute sulphuric or muriatic acid, the whole of the indium originally present in the zinc is left in the black spongy or flocculent residue of undissolved metal, with which every one who has prepared hydrogen gas by means of zinc and acid is so well acquainted. Besides some zinc, this black residue is found to contain lead, cadmium, iron and arsenic, less frequently copper and thallium, and in some cases, as that of the Freiberg zinc, a small proportion of indium. From the solution of this residue in nitric acid, the indium is separated by ordinary analytical processes, based chiefly on the precipitability of its sulphide by sulphuretted hydrogen from solutions acidulated only with acetic acid; and on the precipitability of its hydrate both by ammonia and carbonate of barium. From its soluble salts, metallic indium is readily thrown down in the spongy state by means of zinc. The washed sponge of metal is then pressed together between filtering paper, by aid of a screw press, and finally melted under a flux of cyanide of potassium.

Thus obtained, indium is a metal of an almost silver-white colour, apt to become faintly bismuth-tinted. It tarnishes slowly on exposure to air, and thereby acquires very much the appearance of ordinary lead. Like lead, it is compact and seemingly devoid of crystalline structure. Moreover, like lead and thallium, it is exceedingly soft, and readily capable of furnishing wire, by the process of "squirting" or forcing. The specific gravity of indium, or 7·4, is very close to that of tin, or 7·2; and much above that of aluminum, 2·6, and below that of lead, 11·4, and that of thallium, 11·9. In the lowness of its melting-point, namely, 176° C., indium occupies an extreme position among the metals permanent in air; the next most fusible of these metals, namely tin and cadmium, melting at 228°; bismuth at 264°; thallium at 294°; and lead at 235°. Though so readily fusible, indium is not an especially volatile metal. It is appreciably less volatile than the zinc in which it occurs, and far less volatile than cadmium. Heated as far as practicable in a glass tube, it is incapable of being raised to a temperature sufficiently high to allow of its being vaporized, even in a current of hydrogen.

Indium resists oxidation up to a temperature somewhat beyond its melting-point, but at much higher temperature it oxidizes freely; and at a red heat it takes fire in the air, burning with a characteristic blue flame and abundant brownish smoke. It is readily attacked by nitric acid, and by strong sulphuric and muriatic acids. In diluted sulphuric and muriatic acids, however, it dissolves but slowly, with evolution of hydrogen. Oxide of indium is a pale yellow powder, becoming darker when heated, and dissolving in acids with evolution of heat. The hydrated oxide is thrown down from indium solutions by ammonia, as a white, gelatinous, alumina-like precipitate, drying up into a horny mass. The sulphide is thrown down by sulphuretted hydrogen as an orange-yellow precipitate, insoluble in acetic but soluble in mineral acids. The hydrate and sulphate of indium, in their relations to fixed alkali solutions more particularly, seemed to manifest a feebly-marked acidulous character. Chloride of indium, obtained by combustion of the metal in chlorine gas, occurs as a white micaceous sublimate; and is volatile at a red heat without previous fusion. The chloride itself undergoes decomposition when heated in free air, and the solution of the chloride upon brisk evaporation, with formation in both cases of an oxichloride.

But the chief point of chemical interest with regard to any newly discovered element, and consequently with regard to indium, is the establishment of its atomic weight; which, in the case of a metallic element, is based primarily upon the determination of the ratio in which it combines with oxygen and chlorine. Now the quantity of indium which unites with 8 parts by weight of oxygen and with 35·5 parts by weight of chlorine, has been found by Winkler to be 37·9, and by Bunsen to be 37·8 parts. But this determination of combining ratio falls far short of the definite establishment of the atomic weight of the metal. For example, the quantities of silver, mercury, bismuth, tin and tantalum, which exist in the best-known chlorides of these metals combined with 35·5 parts of chlorine, are 108, 100, 70, 29, and 37 parts respectively. Nevertheless, the atomic weights of these metals are taken to be not 108, 100, 70, 29 and 37, but 108, 200, 210, 118, and 184 respectively, the chlorides of the several metals being expressed by the formulæ $Ag\,Cl_1$, $Hg\,Cl_2$, $Bi\,Cl_3$, $Sn\,Cl_4$, and $Ta\,Cl_5$, respectively. Accordingly, in order to deduce the atomic weight of indium from the ascertained composition of its chloride, we require first to know whether its chloride is a mono-, di-, tri-, tetra- or penta-chloride. Now, in the case of a metal forming only one definite chloride, the constitution of the chloride as a mono- or poly-chloride, may frequently be determinated by a consideration of the analogies presented by the metal and its compounds to some other metal and its compounds, of which the atomic weight and molecular formulæ respectively are well established. But it is obvious that analogy can afford but little help in the case of a newly-discovered element, of which the analogies have still to be determined.

Failing analogy, a more sure guide to the establishment of the molecular formula of a metallic chloride is afforded in some instances by a determination of its vapour density,—tantamount to a determination of the quantity of chlorine by weight, contained in a given volume of the gas or vapour of the chloride experimented on. Thus, having estimated the quantity of chlorine contained in a given volume of heated muriatic acid gas, the quantities of chlorine contained in the same volume of the vaporized chlorides of mercury, bismuth, tin and tantalum, under the same circumstances of pressure and temperature, are found to be 2, 3, 4, and 5 times as great, whence the formulæ $H Cl_1$, $Hg Cl_2$, $Bi Cl_3$, $Sn Cl_4$, and $Ta Cl_5$, respectively. Now indium chloride being volatile at a red heat, there is no reason, save that resulting from the rarity and value of the body, why the density of its vapour should not be ascertained. As a matter of fact, however, no estimation of the vapour density of indium chloride has yet been made, and any evidence that might be deducible from it is consequently not forthcoming.

BULLOCK'S BLOOD—A NEW REMEDY.

In the practice of medicine, as in other worldly matters, certain things are in fashion for a certain time. Bleeding and mercury have had their day; cod-liver oil and chloral hydrate are already on the wane; alcohol and bullocks' blood are now in vogue among the Parisians,—the former for fevers and all inflammatory affections, and the latter for anæmia and pulmonary phthisis. It is a curious sight to see the number of patients of both sexes and of all ranks and ages who flock to the slaughter-house every morning to drink of the still fuming blood of the oxen slaughtered for the table. I was struck at the facility with which young ladies take to it, and I have heard many say that they prefer it to cod-liver oil. I shall not enter into any theoretical speculations as to its *modus operandi*, but what I can vouch for is, I know of several cases of anæmia that have been cured, and some of phthisis pulmonalis greatly benefited by the treatment,—at least, as much as they would be under cod-liver oil. For the more fastidious, however, a pharmacien has prepared an extract of blood, which is administered in the form of pills, each of which, weighing about three grains, is said to be equivalent to about half an ounce of pure blood.

M. Boussingault, a distinguished chemist, lately read a paper before the Academy of Sciences, giving an account of his researches on the composition of the blood, and expressed his surprise that, containing as it does all the constituents of a perfect aliment, it is not more generally employed as food. This is a subject worthy the consideration of philanthropists, especially in these days, when the price of meat is everywhere steadily increasing, —at least, among the meat-eating population; and it strikes me that the rivers of blood that are daily spilt on the ground in slaughter-houses might be utilized as food. In Europe, pigs' blood is the most generally consumed in the form of sausages; but that of all animals, without distinction, might in this way be more usefully employed. It is well known that in the steppes of South America the natives have for a long time used as food the blood of the animals they chased, which they previously coagulate and season with different condiments.

According to M. Boussingault, of all nutritive substances the blood of animals contains the greatest quantity of iron; and, although varying in different animals, it is in physiological conditions found in certain fixed proportions in the blood. In man, to 100 grammes of blood, M. Boussingault found 51 milligrammes of iron; in that of the ox, 55 milligrammes; of the pig, 59 milligrammes; and in that of the frog, 42 milligrammes. But it was not only in red blood that iron was found; the worthy *savant* detected it even in colourless blood; and after some experiments he found that the blood of snails contained as much iron as that of the ox or calf, and this he thought was sufficient to demonstrate that the red colour of the blood is not due, as is generally supposed, to the presence of iron in that liquid.—*Correspondent of Medical Times and Gazette.*

THE CHEMISTRY OF THE HYDROCARBONS.*

BY C. SCHORLEMMER, F.R.S.

(*Continued from page* 46.)

Hydrocarbons of the Acetylene Series.—By again abstracting from the olefines two other atoms of hydrogen, we obtain the third group of hydrocarbons, of which acetylene, C_2H_2, is the first member. This body is remarkable as being the only hydrocarbon which has been obtained by the direct union of its elements.

A general method of obtaining the hydrocarbons of this series is to abstract two molecules of hydrobromic acid from the bibromides of the olefines. As this mode of formation is quite analogous to that by which paraffins are converted into olefines, it appears most probable that the acetylene-hydrocarbons have a constitution similar to that of the olefines. In acetylene the two carbon atoms are linked together by three combining units of each atom—

$$CH \equiv CH,$$

and its homologues contain a monad alcohol-radical in place of one atom of hydrogen.

I have already mentioned that Butlerow has made some experiments for the purpose of proving the correctness of the theory which assumes that the non-saturated hydrocarbons contain carbon-atoms linked together by more than one unit of their combining capacity (Journ. Chem. Soc. [2], ix. 214). According to him, isobutylene, $(CH_3)_2C{=}CH_2$, could not, by the loss of two atoms of hydrogen, yield crotonylene, C_4H_6, but an isomeride with a closed group of three carbon atoms.

He found, however, that by the action of sodium ethylate upon monobrom-isobutylene, $(CH_3)_2C{=}CHBr$, no hydrocarbon is formed, but ethyl-isocrotyl, ether $\left.\begin{matrix}C_2H_5\\C_4H_5\end{matrix}\right\}O$. Instead of hydrobromic acid being taken out, bromine was replaced by oxethyl.

The number of isomeric hydrocarbons in this series is very small. They are hexoylene and diallyl, C_6H_{10}, and decenylene and rutylene, $C_{10}H_{18}$. Of these, hexoylene and decenylene are strictly homologous to acetylene—

$$\text{Hexoylene}\ \begin{matrix}C.C_4H_9\\|||\\CH\end{matrix} \qquad \text{Decenylene}\ \begin{matrix}C.C_8H_{17}\\|||\\CH.\end{matrix}$$

The constitution of diallyl is also known, as we know that of the allyl compounds—

$$CH_2{=}CH{-}CH_2{-}CH_2{-}CH{=}CH_2$$

Rutylene has been obtained from diamylene; its constitution is, therefore, probably similar to that of the latter hydrocarbon, which has already been fully discussed.

Hydrocarbons of the Series C_nH_{2n-4}.—Of this group only two have been artificially prepared, by abstracting hydrogen from the corresponding members of the preceding series. One of these, valylene, C_5H_6, has been studied very little; the other, $C_{10}H_{16}$, which has been obtained from rutylene, is isomeric with a large number

* A lecture delivered before the Chemical Society, April 4th, 1872. Reprinted from the 'Journal of the Chemical Society' for June, 1872.

of hydrocarbons, called the terpenes, existing in plants, chiefly in coniferæ and citrus species.

I need not here dwell upon the peculiar properties of this remarkable group of isomerides; I wish only to point out what we know of their chemical constitution, on which just lately a little light has been thrown.

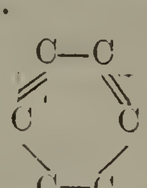
All terpenes possess the property of being easily converted by several chemical agents into new isomeric modifications, and these may be changed again into new isomerides, but all yield at the end one and the same product, called *terebene*, the most characteristic property of which is that it forms with hydrocloric acid a semi-hydrochloride, $(C_{10}H_{16})HCl$.

Now, according to Bauer and Verson ('Ann. Chem. Pharm.,' cli. 52), the hydrocarbon, $C_{10}H_{16}$, formed by heating rutylene dibromide with an alcoholic solution of potash, exhibits all the characteristic properties of terebene, and appears to be identical with it. As the constitution of amylene, from which rutylene is derived, is known, we are in a position to draw some conclusions as to the constitution of terebene, of which I have to say more further on.

On oxidizing terpenes, terephthalic acid is always formed, amongst other products. This compound is also a product of oxidation of several hydrocarbons of the aromatic group. This fact points out that the terpenes must be nearly related to the aromatic hydrocarbons, and this has been quite recently fully proved by Oppenheim, who has shown that, by abstracting two molecules of hydrobromic acid from the dibromide of turpentine, cymene is formed.

Aromatic Hydrocarbons.—These hydrocarbons, as well as their derivatives, have been very fully investigated during the last few years. We owe to Kekulé our present theory of the aromatic compounds; he first called attention to the following points:—

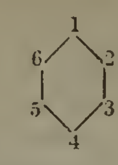
1. All aromatic compounds contain a common nucleus, consisting of six atoms of carbon.
2. These six atoms are linked together in such a way that six combining units remain unsaturated.
3. All aromatic compounds are formed by saturating these free units with other elements or radicals.
4. The differences observed in certain groups of isomeric aromatic compounds are caused by the different relative position of certain elements or radicals in the nucleus.
5. The carbon-atoms forming the aromatic nucleus are united together by one and two combining units alternately.



Although several chemists have proposed certain modifications of this hypothesis, all the facts with which we are as yet acquainted prove that Kekulé's view is the most simple and most probable.

The most simple aromatic hydrocarbon is benzene, C_6H_6; its homologues are derived from it by substitution of monad alcohol-radicals for hydrogen. The number of isomerides amongst these hydrocarbons is very considerable. Thus, the hydrocarbon C_8H_{10} exists in four different modifications, viz., ethyl-benzene, $C_6H_5.C_2H_5$, and three different dimethyl-benzendes, $C_6H_4\left\{\begin{matrix}CH_3\\CH_3\end{matrix}\right.$, the isomerism of the latter being caused by the different position of the two methyl-groups.

By representing benzene as a hexagon, and numbering the six corners, where the carbon-atoms are supposed to be, we can easily see the possibility of the existence of three dimethyl-benzenes—



The positions of the methyl groups being—

1 : 2; 1 : 3; 1 : 4.

No further different positions of the methyl groups are possible; for 1 : 5 = 1 : 3; and 1 : 6 = 1 : 2.

As the isomeric aromatic hydrocarbons have generally a great resemblance in their physical properties, it is of the highest importance to have means for distinguishing them from each other. This can be done by studying their products of oxidation.

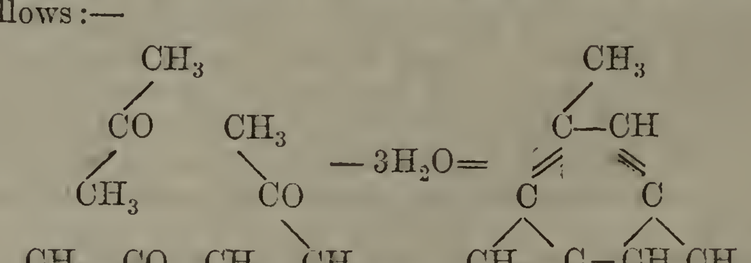
When an aromatic hydrocarbon is heated with very dilute nitric acid, one of the alcohol radicals is oxidized to carboxyl. Methyl-benzene, ethyl-benzene, amyl-benzene, and all other hydrocarbons containing only one alcohol-radical yield one and the same product, viz., benzoic acid, $C_6H_5.CO.OH$. The formation of this acid proves, therefore, the existence of only one alcohol-radical in a hydrocarbon. The three methyl-benzenes, as well as methyl-ethyl-benzene, yield isomeric methyl-benzoic acids, $C_6H_4\left\{\begin{matrix}CH_3\\CO.OH\end{matrix}\right.$, whilst diethyl-benzene gives ethyl-benzoic acid.

By acting on the hydrocarbons or their first oxidation products with stronger oxidizing agents, such as dilute chromic acid, every alcohol-radical is oxidized to carboxyl; the three dimethyl-benzenes, as well as methyl-ethyl benzene and diethyl-benzene, yielding bibasic acids, having the composition $C_6H_4\left\{\begin{matrix}CO.OH\\CO.OH\end{matrix}\right.$, etc.

But we are not only able to fix the number of alcohol radicals present in an aromatic hydrocarbon, but we can also determine their relative positions. Thus we know that in these dimethyl-benzenes the positions of the methyl-groups are—

Orthoxylene.	Isoxylene.	Methyltoluene.
1 : 2.	1 : 3.	1 : 4.

This has been proved in the following way:—Three bibasic acids are known, having the composition $C_6H_4\left\{\begin{matrix}CO.OH\\CO.OH\end{matrix}\right.$ viz., phthalic acid, isophthalic acid, and terephthalic acid. In phthalic acid the two carboxyls occupy the position 1 : 2; this we see from the fact that this acid is produced by oxidizing naphthalene, a hydrocarbon in which, as will be shown further on, two atoms of carbon are linked to two adjoining carbon-atoms of the aromatic nucleus. Isophthalic acid has been obtained by oxidizing isoxylene, and isoxylene has been derived from mesitylene, $C_6H_3(CH_3)$, a trimethyl-benzene in which, as Baeyer first pointed out, the three methyl-groups have the symmetrical position 1 : 3 : 5. This follows from the mode of formation of this hydrocarbon, which is obtained by heating acetone with sulphuric acid. Three molecules of acetone lose three molecules of water, and the residues join together as follows:—



By oxidizing mesitylene with weak nitric acid, we obtain monobasic mesitylenic acid, $C_6H_3\left\{\begin{matrix}CH_3\\CO.OH\\CH_3,\end{matrix}\right.$ which, when heated with lime, splits up into isoxylene and carbon dioxide. From this it follows that in isoxylene as well as in isophthalic acid, the two radicals occupy the positions 1 : 3 (or, which is the same, 1 : 5 or 3 : 5). As we now know the constitution of phthalic acid and isophthalic acid, we know also that of terephthalic acid, in which the two carboxyl groups must be in the positions 1 : 4; and the two methyl groups in methyl-toluene are in the same position, because it yields terephthalic acid on oxidation. Hence in the only remaining dimethyl-benzene, viz. orthotoluene, the methyl groups must occupy the only other remaining positions 1 : 2. Thus, although the direct proof of the oxidation of this hydrocarbon to phthalic acid is wanting, because this acid is easily further oxidized by chromic acid, we still are able to arrive at a conclusion respecting its constitution.

To illustrate by an example how we can ascertain the constitution of an aromatic hydrocarbon by means of the above facts, I choose the following. There exist three isomerides having the formula $C_{10}H_{14}$, which on oxidation yield terephthalic acid, and consequently contain alcohol-radicals occupying the positions 1 : 4.

Of these three hydrocarbons two have been obtained by synthesis, viz., diethyl-benzene and propyl-methyl-benzene; the third, called α-cymene, occurs ready-formed in Roman cumin-oil, and in the oil from the water-hemlock, and has also been produced by the action of phosphorus pentasulphide upon camphor. Now as α-cymene differs both from diethyl-benzene and propyl-methyl-benzene, it must be isopropyl-benzene, no other isomeric form being possible. This view is confirmed by several facts. 1. α-cymene boils at a lower temperature than propyl-methyl-benzene, and we always find that isopropyl compounds boil at a lower temperature than the corresponding normal-propyl compounds. 2. Isopropyl compounds readily yield propylene, and thymol, or the phenol of α-cymene (Journ. Pract. Chem. [2], iii. 50) is easily decomposed into propylene and γ-cresol, by heating it with phosphorus pentoxide (Zeitsch., 1869, 615). (3.) That α-cymene contains isopropyl appears also probable from the analogy of cumene (See Supplement of Watts's Dictionary, 295 and 302).

(To be continued.)

THE SALTPETRE DEPOSITS OF PERU.

In travelling eastward through Peru, from the sea to the Cordilleras, on the 20th parallel of south latitude, seven zones are crossed, the third of which, the Pampa of Tamarugal, and the fifth, Serrania Alta, or the inner chain (Upper Peru or Bolivia), are explored for saltpetre. The treeless Pampa, a plain somewhat depressed in the centre, has a very scanty vegetation, and the only thing which grows there is a single variety of lucerne grass (*Medicago*); the cultivation of even this is attended with difficulty, on account of the large proportion of common salt, borax and saltpetre in the soil. It serves in part for the support of the beasts of burden used for transporting to the coast the salts and metallic minerals found here. In the south of the Pampa is a large deposit of borax, pieces of which weigh on an average from 100 to 200 grammes; soda saltpetre is found on the borders of Pampa and Serrania, but too far distant from the sea. On the western slope of the Cordilleras, salt is only found in small quantities; but in Upper Peru, where frequent rains wash it together into great lakes, there are large quantities of it. The saltpetre mines consist of different strata. The surface of the ground is composed of silicates, sandstone and pieces of lime. At a depth of from 8 to 16 inches very regular prisms are usually found, which sparkle with a mass of very small microscopic crystals; the stratum below this, which is of rocky hardness, consists principally of common salt, with a little chloride of potassium and soda saltpetre, mixed with earth and pieces of silicates and carbonates, and has a thickness of 20 to 25 inches. Beneath this crust is the pure soda saltpetre, in more or less perfect crystals, from 20 to 40 inches long, and 3 to 7 feet in diameter. Guano is seldom found there, and only in small quantities; and it always occurs just below a stratum of salt. It is not in a powder, like that of the Chincha Islands, but adheres together, and is of a brown colour, containing the bones and remains of birds and insects, and has an ammoniacal smell.

The chloride of sodium and lime present furnish mineral constitutents required for the formation of the saltpetre. According to Thiercelin, the guano furnishes the nitrogen; but since the guano is always found below the salt crust, Kœnig is compelled to refer the nitrogen to some other nitrogenous organic bodies, from whose decomposition ammonia is formed, and this in turn is converted by the action of the air and organic bases into nitric acid. Besides the three substances named, all the conditions favourable to the formation of saltpetre are found in that neighbourhood, namely, a pure, dry atmosphere, absence of rain to wash away the saltpetre when formed, and the regular night fogs. The latter, leaving the salt undissolved, dissolve the saltpetre and filter it through this stratum, under which it crystallizes.

The search for saltpetre is conducted thus: The workman recognizes its presence by certain undulatory elevations of the ground, and numerous lumps of lime and disintegrated sandstone. He bores a hole some 12 to 18 inches in diameter, going down till the mineral is plainly visible. When the lowest layer is reached, the hole is widened to about three feet, filled with charcoal and sulphur and fired. The explosion breaks and tears up the ground for twice that distance around, and then properly begins the bringing up of saltpetre. The crude article varies considerable in compactness, colour and quality, and is named accordingly. The so-called sulphuret, which owes its name to its mode of manufacture, is the purest. The porous, earthy and the congealed are different in quality. If the raw product contains less than 50 per cent., the mine is abandoned as not worth working; a yield of 70 to 80 per cent. is exceptionally good. The raw material is transported on pack animals or waggons to the factory, where it is refined in two different ways. One method is to break it up in pieces and put it into an iron kettle half full of water, which is then heated over a fire for an hour, the insoluble matter removed and a fresh quantity of raw material added until the solution is saturated. The clear solution is run off into crystallizing vessels, the crystals collected when formed and allowed to dry in the sacks in which it is shipped. In the second method, steam heat is employed; the crude material is put into perforated iron baskets and suspended in boiling water, and the process repeated until the liqour is saturated. The saltpetre prepared in this way contains less than 1 per cent. of common salt, while that obtained by the former method contains upwards of 2 per cent. Large quantities of iodine are annually reclaimed from the mother liquors of the saltpetre works of South America. —*Scientific American.*

HEAT AND THIRST, AND SOME OF THEIR POPULAR ANTIDOTES.

By the Author of a "Report on Cheap Wines."

Heat and thirst have mighty effects on health and morals. Hot and thirsty people drink, and the effects of temperature on health are largely modified by the quality of the liquids consumed. So long as the choice lies between a gulp of lukewarm Thames water from the cistern of a lodging-house and a cool half-pint of beer, who can blame the man who has a penny in his pocket if he spend it on the beer? Thirst is overwhelming; and if it be a "vicious indulgence" to quench it with beer, we ought not to blame the thirsty man till we can show him the way to something better.

Thirst, as I showed the world when I wrote on cheap wines, is of three kinds. There is, first, the real thirst, from want of liquid, especially when a copious sweat exhales from the skin during honest labour in the heat; and this cannot be relieved without water in some shape. Then, secondly, there is that dreadfully painful clammy state of the tongue—the dry mouth caused by mental anguish, or bodily pain, as of wounds; that which occurs, too, in fevers and other diseases. This is not caused by mere lack of water, but by a defective or depraved and nauseous state of the secretions of the tongue and fauces under the influence of a worried nervous system. This is not relieved by water alone; on the contrary, water may excite loathing and disgust. This kind of thirst is relieved by those readily acting and and comforting varieties of food which are known as "stimulants" of various kinds. And inasmuch as there is seldom much thirst without some exhaustion, so the addition of some stimulant to common drink is expedient. The last kind of thirst is the craving for mental stimulation—the desire of a torpid brain to have its imagination roused, its feelings of benevolence, sociality, and self-esteem excited and gratified. This is what men drink for in company *in convivio*—at the times when each man shares with his neighbour the true delights of life; *convivium*—a word sacred by association, and immeasurably superior in moral force to the Greek *symposium;* a remark which, whether borrowed from Marcus Tullius Cicero, or from the judicious Hooker, slips my present memory.

A true "thirst extinguisher," then, as may we deduce from the foregoing principles, must be something more than the mere tepid water which is accessible to the population of our towns.

The most obvious "potential" stimulant is cold; "potential" because, whilst adding no material, it alters the distribution of the blood, and allays the restlessness arising from heat that cannot pass off. Whoever desires to convert our population to water-drinking should supplement those great boons, the street fountains, with some contrivance for cooling the water. A small glass of really *cold* water will quench thirst better than six times the quantity of lukewarm. But *iced* water and ice in its various forms sometimes create heat and dryness of the tongue.

With cold ranks carbonic acid as the most grateful and wholesome of stimulants—pungent to the tongue, grateful to the stomach, and felt with a grateful coolness as it escapes from every pore of the skin. How soon it was used in medicine I cannot tell; nor whether the delicious sparkle of natural aerated waters, or the briskness of a fermenting drink, or the effervescence with acids was in any degree known to the ancients. During the seventeenth and eighteenth centuries the effervescing draught was known by the name "cordial julep of Riverius," and, so far as I know, this great physician was the inventor of the draught, and the discoverer of its efficacy in allaying sickness. He thus describes it in one of his volumes of "Observations:—

"That excellent man, Laurence Bosch, apothecary, of Montpellier was ill with that epidemic which they call purple fever, in the month of December, 1622. Amongst other symptoms was obstinate sickness, so that he rejected water, wine, medicine, everything but weak broth; his inside was burnt up and his tongue dry. This so grave symptom was relieved by the following slight remedy:—℞. Of salt of wormwood a scruple; of fresh lemon-juice one tablespoonful. These were mixed at once in the spoon and administered. The vomiting at once ceased, and from that moment the patient took what he liked and kept it down.*

The draught of Riverius soon became, and has ever since continued, one of the most popular and useful of medicines. No matter whether soda be substituted for the "salt of wormwood," *alias* carbonate of potass; no matter whether citric or tartaric acid be substituted for the lime-juice, nor whether the nicety of modern pharmaceutists enables the ingredients to be mixed in a powder, or a granular salt, cheap, portable, and nicely flavoured—the principle is that of Riverius, and to him belongs the honour. About the time when our native Scottish royal family made their last desperate effort to eject the house of Hanover, Sir John Pringle, in his work on the 'Diseases of the Army,' speaks in high tones of the efficacy of the effervescing draught of Riverius, but regrets that it is too expensive for common soldiers. How he would bless modern applied chemistry if he saw the powder of soda, tartaric acid, and sugar, flavoured with essence of lemons, now sold in all the *low* neighbourhoods, and called Persian sherbet, one penny the glass!—*Medical Times and Gazette.*

* Lazari Riverii, 'Observationes Hagæ Comitum,' 1656.

COMPLIMENTARY DINNER TO DR. TILDEN.

The announcement of the retirement of Dr. Tilden from the office of Demonstrator in the Society's Laboratory, in Bloomsbury Square, was marked by an invitation from a few of his friends to a complimentary dinner, which took place on Thursday evening last. The occasion was taken advantage of by the officers and professors of the Society for the presentation of an Address, of which the following is a copy:—

"The undersigned officers and professors of the Pharmaceutical Society of Great Britain desire to offer to William Augustus Tilden, D.Sc., on his retirement from the office of Demonstrator in the Laboratory of the School of Pharmacy their hearty good wishes for his future welfare and happiness, accompanied by the expression of their high appreciation of his scientific attainments, and an acknowledgment of the success with which he has fulfilled the duties of his office, and also of his urbanity and kindness to all with whom he has been associated." The Address bore the signatures of the President, Vice-President, Treasurer, and the other officers of the Society, as also of all the Professors.

PHARMACEUTICAL EDUCATION.

A meeting of the chemists of Rochdale was held in the Committee-room of the Public Hall, on Wednesday evening, July 17th, 1872, to consider the scheme proposed by Mr. Schacht for promoting pharmaceutical education in the provinces, the report of the committee, and also the expediency of forming a chemists' association in Rochdale.

Mr. Councillor Booth occupied the chair.

After Mr. Schacht's scheme had been carefully gone through, clause by clause, it was moved and carried:—

"Whilst this meeting approves of the principles laid down by Mr. Schacht in his scheme for promoting pharmaceutical education in the provinces, it also considers that registered apprentices and assistants who, by reason of distance or other circumstances are unable to attend classes of any local association, should be eligible to be examined, and receive the grants of the Pharmaceutical Society."

"That in the opinion of this meeting, in order to give facilities for the increase of Class 1, the required agregate number of marks be reduced from 80 per cent. to 75 per cent."

The report of the committee appointed at a previous meeting to inquire into the best means of forwarding pharmaceutical education in Rochdale was next read. It recommended the formation of a chemists' association, the taking of a suitable room or rooms for the meetings of the members and classes, and advised the joining the chemists' classes to the Government Science Classes, so as to conduct them more economically. The report was approved of, and the committee was requested to prepare details of a scheme in accordance with its recommendations, and to report to a future meeting.

The Pharmaceutical Journal.

SECRET ALLIANCES.

The letter of our correspondent "Ægis" in the number for July 6th, has supplied materials for a leading article to our contemporary, 'The Medical Press and Circular,' under the appropriate heading, "Going Snacks." No title could be more fitting; it exactly conveys the idea of a partnership, of which the partners are ashamed, for the secret partition of contraband gains. We have already discussed the subject of secret alliances between medical practitioners and pharmaceutists from the pharmaceutical point of view, and have taken occasion to express our dislike to an arrangement which cheats pharmacy of its dues and provokes jealousies amongst pharmaceutists. We do not know that we have much to add to the opinions then expressed, though we might illustrate them afresh in as many forms as Proteus ever wore; but we hail with satisfaction any endeavour to bring further influence to bear in discrediting these equivocal combinations.

We need not now revive a discussion upon the equity of chemists' charges. At all proper times we are prepared to meet criticism upon that point, with confidence in the issue; but it is germane to the present question to say that, unless existing prices are unfair to the public, a system which gives a douceur often amounting to one third of the whole to the medical colleague cannot be profitable. It is therefore doubly incumbent upon the Pharmaceutical body to discourage these alliances, for they are injurious to the interests as well as to the reputation of their order. But there is even a stronger reason for condemning them than either of these, and it is to be found in the underhand manner in which they attack the business and the business character of brother pharmacists, and in the inevitable return of ill-will which such covert injuries excite. When it is disingenuously asserted by Mr. Plausible that his prescription cannot be dispensed by any other than the privileged Mr. Blank, and Mrs. Plastic is deterred from entrusting her mixture of Epsom salts and peppermint water, obscured under the cabalistic designation of Mist. Purg. Cardiac., to her accustomed chemist, it may be difficult to prove the corrupt nature of the transaction, but the secrecy observed does not diminish its immorality.

It is no justification for the depreciatory imputation that competent and upright pharmaceutists can not be trusted to compound medicines from *any prescription*, that the writer has purposely disguised its meaning with the object of making it unintelligible. It is as though the Board of Examiners should compile a secret Pharmacopœia and pluck the candidates who fail to describe its formulæ.

The editor of the 'Medical Press' feels a natural reluctance in believing that members of an honourable profession will so far lower themselves as to enter into these compacts for a direct money payment. We agree with him in thinking that it is of little consequence whether the *quid pro quo* is paid in malt or meal, and it seems like splitting hairs to question where the restraints of professional decorum will arrest the man who is at all events guilty of the gravamen of the accusation. We fear that the experience of Chemists will not permit them to entertain any doubts upon the subject, nor is the secret so well preserved as to escape the knowledge of the medical profession.

The existence and extent of the abuse is really not a matter of dispute; the practical question is how best to put a stop to it. And here our advice to our readers would be in accordance with the fable of the young larks nested in the ripening corn. If you want a thing done, do it yourself. It is in your own hands, and you need neither the help of Jupiter nor of the medical profession to enable you to accomplish it. Medical ethics provide for the good manners of the profession *inter se;* we can scarcely expect them to take cognizance of pharmaceutical etiquette, which is as yet governed by no laws, and has no claim to propose rules to the medical profession. Mutual respect and mutual forbearance will do more to preserve good relations than any amount of well-intended interference. We may, however, hope that the sensible suggestions of the 'The Medical Press' will receive attention, and that "going snacks" will be included in the catalogue of misfeasances unbecoming a professional man and a gentleman. It remains for us to consider whether it should be permitted in a liberal trade; and we hope that those who occupy honoured positions in our ranks will set the example of discountenancing this and every other form of ungenerous competition.

We advocate no unreasonable interference with the freedom of medical men honestly used for the good of their patients; we make no fantastic appeal to manufacturers to make public property of their secret formulæ. Neither patient nor dispenser is hurt by the prescribing of secret preparations which it is open to the whole world to procure, *e. g.*, Battley's Solution or Brown's Chlorodyne; but when such empiricisms as Pilula Asiatica are prescribed, and the formula is withheld by the prescriber, the practice of medicine is degraded, and the fetish of charlatanry installed in its place. To such false gods it becomes not true men to do homage; and we seriously offer a suggestion by which unwilling accomplices may honourably escape from the dilemma. Let them endorse upon the prescription the formula of whatever occult ingredient they may have been instructed to prepare, and the prescription will then become what it ought to have been from the first, viz. an intelligible exposition of the prescriber's intention.

THE BRIGHTON ARRANGEMENTS.

As each week passes and brings nearer the time fixed for the scientific festival of 1872, evidences multiply that the people of Brighton intend to do all they can to secure the comfort of their numerous expected visitors. Not a little of the pleasure to be obtained at such a gathering depends upon the accommodation which each person secures in the way of board and lodging, and the price he has to pay for it. This has not been lost sight of by the Town Committee, and they have issued a list of hotels and boarding houses, and the average rate of charges, which gives a choice of—

> "Houses of all architectures you please,
> From the Greek and the Gothic, Sir, down by degrees,
> To the pure Hottentot, or the Brighton Chinese."

Any information or assistance in respect to this matter may be obtained of the Agent, Mr. J. W. Hemmings, 4, Duke Street, Brighton.

Another phase of the subject of accommodation bears scarcely so promising an aspect. Although the dignitaries of the town appear to be anxious to keep up its reputation for hospitality by inviting the more notable visitors to become their guests, there appears to be a desire in some quarters to go beyond this, and at a recent meeting of the town council the sub-Committee on the reception of visitors, in their report, spoke of the few offers of hospitality to "unknown visitors" that had reached them. In the discussion which followed, one of the speakers evidently referred to the apostolic injunction as to the entertainment of strangers and its possible reward. But there appears to be a feeling that even scientific angels would be all the more welcome if they came properly labelled. Nor is this unreasonable, and if the reception committee will assist visitors in finding places where they may have what they want upon payment, and will take every possible precaution against extortionate charges, we feel certain that no more will be expected or desirable. All offers of hospitality should be spontaneous and every appearance of touting or compulsion should be carefully avoided.

An announcement has been made that the 'Brighton Daily News' will contain full and accurate reports of the proceedings from day to day, and that a special edition for the twelve days will be supplied daily, by post, for 2*s*. 6*d*.

The special railway arrangements will affect principally those who wish to attend the whole of the meetings of the British Association throughout the fortnight, and first class tickets will be issued to members of the Association, and other learned societies, upon presenting their card of membership at the London Bridge or Victoria Stations, entitling the holder to travel by all trains between London and Brighton, for two weeks £2. 10*s*., for one month, £4. In reference more especially to the Conference Meeting we are informed by Mr. W. D. Savage that the time for ordinary return or excursion tickets will be extended from two days to three weeks. Upon the same authority we are also able to state that a private room for the use of members of the Pharmaceutical Conference will be provided at the Clarendon Hotel.

NEWSPAPER SCIENCE.

The picturesqueness and force with which the progress of armies in the field or the details of state ceremonies are now described in our first-class newspapers, require such varied knowledge and such power of using it correctly that there need be little wonder if now and then there should be a trip. We might instance the description in the editorial columns of the *Times* of the recent visit of the Prince of Wales to Bethnal Green Museum, where the writer, evidently referring to the irruption of fashionable visitors into Bishopsgate Street, speaks of people who had never heard of Crosby Hall, apparently forgetting a passage in a certain author named Shakspeare with which probably most people are acquainted. Another style of error more frequently met with, is where the penny-a-liner affects the scientific style, instances of which we have in the various accounts of the case of poisoning recorded at p. 14, in which different reporters have attributed the death to the effects of "potash and sulphuric acid," "oxalic acid," and "cyanide of potassium." But a more ludicrous class of errors arise when the penny-a-liner is developed into what a contemporary has facetiously called a "young lion of the press," and in a gushing leader proves that a little knowledge is a dangerous thing. The following, from the 'Gardeners' Chronicle,' refers to an article of this nature which possibly caused surprise to many of its readers, but which is referred to as "at once interesting and sensible" by a contemporary which has an amiable weakness for considering itself one of the pioneers of pharmaceutical education:—

"Our excellent contemporary, the *Daily Telegraph* has a reputation for fine writing, and, to use an Americanism, 'slops over' on occasions. Quite lately the readers of that journal have been treated to a lecture on the advantages to be derived from a knowledge of botany —the occasion being the sad fate of two lads at Chester, who died in consequence of eating the roots, as we suppose, of Water Hemlock—*Cicuta virosa*, or perhaps of

Œnanthe crocata. Our contemporary, however, speaks of the poison as having been afforded by the roots of the common Hemlock, Conium maculatum.' 'Those who have seen a Celery bed in full seed,' says the *Telegraph*, will know how difficult it is for any but a practised botanist to distinguish the deadly *Conium maculatum* from its harmless [?] sister Umbellifer, *Apium graveolens*.' There is a little mistake here, as the writer would find if he indulged too freely in the 'sister Umbellifer' in its wild state. A parallel is then drawn between the case of these poor boys and that of Socrates, the symptoms are agonizingly detailed, and their severity explained by the fact, that 'Hemlock, with scarce an exception, is the most deadly plant in our English flora' [?]—an opinion backed up by a quotation from Gerarde's 'Herbal.' Our contemporary probably means Water Hemlock, though he distinctly says *Conium maculatum*, which is poisonous no doubt, but not nearly so much so as the *Cicuta* or the *Œnanthe*. To give further point to his remarks the leader writer in the *Telegraph* goes on to tell us of ladies mistaking wild Garlic for Lily of the Valley! and has a hit at 'crass gardeners' for mistaking the root of 'deadly Monkshood' [Aconite] for Horse Radish, a mistake that has unfortunately too often been made, but not, we venture to assert, by any 'gardener,' for, contrary to our contemporary's assertion that it would puzzle Gerarde himself to distinguish the two roots [! !], we venture to think that to any one at all accustomed to look at plants no two things can well be more dissimilar than the root of Aconite and the root-stock of Horse Radish. Certainly no gardener properly so called would ever make so terrible a blunder. In the same strain our contemporary descants on other poisonous British plants, including the wood Hellebore, 'Spring's White Rose' [! !], 'the sweet viscid pericarps of the Yew, and the black deadly wild cherries of the *Atropos belladonna*' [! !], etc. A disquisition on the origin of evil follows, and the article ends with a passage with the spirit of which we thoroughly sympathize:—

"'Surely, then, in addition to the sage old rule, which warns us to let all strange plants alone, we should do well to impress upon children, and especially upon schoolboys, a little—a few simple truths—of the natural history of our indigenous plants. No pursuit is more fascinating than is botany, in spite of the hideous phraseology with which it is encumbered. We do not speak here of the botany which is to be learnt from books, and the chief use of which is to enable a candidate to gain a certain number of marks in an examination for the Indian Civil Service, but of that botany which is acquired face to face with Nature, and under the broad canopy of heaven. It needs no tall talk in barbarous dog-Latin to show a lad the umbrella-like structure of the Umbellifers, and to teach him the simple and practically true generalization that all Umbellifers are deadly [?]. It was for want of some such simple wisdom that George Dobson and Albert Kinsey perished. How long will it be before we recognize that a little knowledge of Nature and her ways is worth all the idle lore with which pedants, learned and unlearned, have encumbered the history of the Heptarchy and of the early Roman Kings?'

"We have only further to remark, for the consolation of our contemporary, that he may safely eat Carrots and Parsnips, Carraway, Coriander, Aniseed, Fennel, Angelica, Chervil, Samphire, Umbellifers though they be; and to express a hope that before our contemporary parades his botanical lore again he may take the precaution of studying the books he affects to despise, and so save himself from falling into a tissue of blunders, the like of which we have rarely met with, even in 'newspaper science.'"

Perhaps after this our readers will not be surprised to learn that the plant was neither the *Cicuta virosa* nor *Conium maculatum* but the *Œnanthe crocata*.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

July 17th, 19th and 22nd, 1872.

Major.

Seventeen candidates were examined; of these, *eight* failed. The following *nine* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

*Tilden, William Augustus	Barnsbury.
*Hick, George	Bradford.
*Parson, Henry James	Birmingham.
Walker, Joseph	Dresden.
Mills, Robert	London.
Badcock, Daniel	Barnard Castle.
Powell, Thomas Henry	Hornsey Rise.
Ashworth, Amos	London.
Young, John Rymer	Warrington.

Minor.

Seventy-eight candidates were examined; of these, *thirty-eight* failed. The following *forty* passed, and were declared qualified to be registed as Chemists and Druggists:—

	*Pickard, William	Yeovil.
Equal.	*Baynes, James, jun.	Sheffield.
	*Edwards, David	London.
	*Ekins, Arthur Edward	Cambridge.
	*McJannet, James	North Walsham.
	*Oxley, Herbert Lister	Leeds.
	*Russell, Charles Harridge	Blackheath.
	Cooper, Herbert Hudson	Birmingham.
	Margetts, Usher	Eastwood.
Equal.	Frowd, Edward Francis	London.
	Outred, Thomas Benjamin	Colchester.
Equal.	Hart, Thomas	Manchester.
	Minett, Thomas Samuel	East Grinstead.
	Sykes, Joseph Spencer	Sheffield.
Equal.	Ellison, John Clement	Ashton-under-Lyne.
	Shapley, Charles	Torquay.
Equal.	Rimmington, George	Bradford.
	Williams, William	Merthyr Tydvil.
	Daves, William	Torquay.
Equal.	Harrison, John	Sheffield.
	Pearse, William Francis	Great Yarmouth.
Equal.	Jackson, Alfred Henrick	Manchester.
	Twist, Edward Herbert	Prescot.
Equal.	Findlay, James	London.
	Plimmer, William Thomas	Uttoxeter.
	Norton, Thomas	Stafford.
	Micklem, Austen	Reading.
	Barlow, Frederick	Macclesfield.
Equal.	Brown, John Ephraim	Grantham.
	Smith, Charles Clapcott	Rye.
Equal.	Chadwick, James	St. Helens.
	Fletcher, Joseph	Brigg.
	Thring, Edmund John Henry	Trowbridge.
	Walton, Major Foulds	Sowerby Bridge.
	Jameson, Walter George	Reading.
	Rowcroft, Albert Edward	Gravesend.
Equal.	Bowker, William	Bolton.
	Harsant, Frank Worsley	Epsom.
	Norton. Charles	Plymouth.
	Hill, Ernest	Weymouth.

The above names are arranged in order of merit.

* Passed with Honours.

Provincial Transactions.

TYNESIDE CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of the above association was held on Thursday evening, the 18th of July.

In the absence of the President, Mr. Marshall was voted to the chair. The paper announced was by Mr. Crozier, on "Camphor," and it proved to be both instructive and interesting. The discussion was carried on to a considerable extent by Messrs. B. S. Proctor, Marshall, Spence, Foggon, Kerse and Crozier, after which a vote of thanks was proposed by Mr. Heslop, seconded by Mr. Anderson, and carried unanimously.

Parliamentary and Law Proceedings.

HOUSE OF LORDS.

The Petroleum Bill.

On Friday, July 19th, their Lordships having gone into Committee on this Bill, the Earl of Morley proposed an amendment postponing the operation of the test until the 1st of February, 1873, so as to enable the stocks of petroleum now in hand to be disposed of, which was agreed to, and the Bill as amended passed through Committee.

On Tuesday, July 20th, the reports of amendments was received, and the third reading is fixed for Thursday, July 25th.

Adulteration of Food, Drugs, Etc., Bill.

On Tuesday, July 23rd, this Bill was brought from the Commons, read a first time and ordered to be printed.

HOUSE OF COMMONS.

Thursday, July 18th, 1872.

The Metric System.

In answer to Mr. J. B. Smith,

Lord Enfield said that the French Government have intimated that the International Commission on the Metrical System, the sittings of which were interrupted in 1870, will meet again on the 24th September next. It is understood from the Board of Trade that Mr. Chisholm and Professor Miller will attend on behalf of this country.

The Public Health Bill.

The House having resolved itself into Committee on this Bill, Clauses 1 and 2 were passed without discussion.

On Clause 3, which divides the country into urban and rural sanitary districts, Mr. Goldney said that the proper and successful carrying out of the provisions of the Bill would depend much upon the selection of a suitable body in whom to vest the powers. Boards of Guardians had failed to discharge the duties imposed upon them by previous statutes, and he believed that a County Board would perform the duties created by the present Bill in a more effective manner. Its accounts would be regularly published, and its proceedings would receive greater publicity and be more widely criticized than those of the guardians, the only effectual check to whom would be the Local Government Board. The County Boards he proposed would be formed of county magistrates elected at quarter sessions, with an equal number of representatives elected by Boards of Guardians. These would have under their supervision the sanitary arrangements of the county; and he thought there would be a great advantage to the ratepayers that such a Board should have to deal with an extensive area.

Mr. Corrance concurred in the amendment, as also did Mr. Dalrymple; and in reply to a remark made on a former occasion as to the power the Bill would place in the hands of the medical profession, the latter gentleman said that without the aid of that profession sanitary reform would be nowhere. There were some hierarchies that were probably worse than a hierarchy of doctors. There was the hierarchy of engineers, who thought the earth was created that they might operate upon it, and it was even possible to have such a thing as a hierarchy of lieutenant-colonels.

Sir M. Beach thought the Bill eminently unsatisfactory in the choice of local authorities, and was opposed both to Town Councils and Boards of Guardians.

Sir C. B. Adderley, on the other hand, was strongly in favour of Boards of Guardians, which, among other advantages, existed already, and could be set to work at once. If County Boards were created they would be split up into Local Committees, and would, in fact, soon become identical with the Boards of Guardians.

Mr. Stansfeld, in defending the Union as the unit of administration, denied that the Guardians had failed to do their duty, and stated that he had ascertained that the majority of them were prepared to undertake these sanitary functions.

Mr. Hunt objected to Boards of Guardians, which had been tried and found wanting. He preferred a County organization.

Mr. Whitbread, one of the Commissioners, supported the plan for taking Boards of Guardians.

Mr. F. Powell, also a Commissioner, supported the clause; and, Mr. Goldney having withdrawn his amendment, the opinion of the Committee was taken on an amendment moved by Mr. Corrance to Clause 5, which raised the point in a more direct form. On a division, the Committee decided in favour of Boards of Guardians by 84 to 7.

The House remained in Committee until long past two o'clock, and succeeded in disposing of all the clauses up to Clause 41. Many verbal changes were made, but the amendment of most importance was to constitute (in Clause 18) the Corporation of London the Port Sanitary Authority for London. This was done, Mr. Stansfeld explained, at the instance of the Corporation, which had offered to bear all the necessary expenses out of the Corporation funds. Colonel Hogg, the chairman of the Metropolitan Board, thankfully accepted the offer on behalf of the ratepayers, and expressed a hope that the public spirit of the Corporation would not stop here.

In Clause 32, which transfers to the Local Government Board certain statutory powers now vested in the Board of Trade, Mr. Kay-Shuttleworth moved to include in the transfer the powers exercised under the Metropolitan Water Acts. Mr. Clay, on behalf of the Water Companies, objected to the transfer, and Mr. Crawfurd spoke in the same interest.

In the next clause, the Borrowing clause, Mr. R. Gurney proposed to extend the term of repayment from thirty to fifty years. Mr. Stansfeld at first accepted the amendment, but objection being taken by Sir M. Beach and others, he proposed that the period should be limited to the term of years prescribed by the existing Acts.

Friday, July 19th.

The consideration of this Bill in Committee was resumed, Mr. Russell Gurney having proposed as an amendment the extension of the time of repayment of borrowed money from thirty to fifty years, Mr. Stansfeld assented to it, coupled with a proviso that in determining the time of repayment of a loan, the Local Government Board shall have regard to the probable duration and continuing utility of the works in respect of which the loan is required. This amendment was, upon division, carried.

Sir M. Lopes moved as an amendment that not more than $3\frac{1}{2}$ per cent. interest should be paid for money borrowed from the Loan Commissioners.

Mr. Gladstone objected that Government sometimes had to pay more than that rate, and upon a division the amendment was lost.

Mr. Gladstone then said that as "$3\frac{1}{2}$ per cent." would not be the minimum, he would propose to insert after those words, "or such other rate as may in the judgment of the Lords Commissioners of the Treasury be necessary in order to enable the loan to be made without loss to the Exchequer." This was agreed to.

The remaining clauses were then amended and agreed to, and the Bill passed through Committee. The amendments are to be considered on Thursday, July 25.

Monday, July 22nd.

Adulteration of Food, Drugs, etc., Bill.

This Bill was read a third time, and passed.

Public Health and Local Government Bill.

The order for going into committee on this Bill was read and discharged and the Bill withdrawn.

Suicide by an Enormous Dose of Arsenic.

An inquest held on Tuesday, July 2nd, at the Bristol Infirmary, upon the body of Mrs. Jarrett, who had committed suicide by taking arsenic.

The husband of deceased deposed that some years ago, he was a porter in the employ of an ironmonger. At the death of his employer he assisted the son of that employer in the sale of drugs. Some of the drugs were given to him to dispose of at a commission, and among them was a bottle of arsenic. He was not able to find a purchaser for the arsenic, and, as his employer told him either to throw it away or keep it, he labelled it "Poison," and used it for killing mice. This occurred seven years ago.

Other evidence was given that the deceased was in very low spirits in consequence of an accident which had temporarily disabled her husband, and that she was found in bed in a dying state, with the bottle of arsenic by her side.

Dr. Shingleton Smith, house surgeon at the Infirmary, said the deceased woman was taken to the Infirmary about a quarter to two on Sunday last. She appeared to be suffering from intense irritant poisoning, and was in a state of profound collapse. The bottle of arsenic and glass were brought to the Infirmary with her. It was pure arsenic, unadulterated in any way. The deceased never rallied after her admission. He had made a *post-mortem* examination of the body, and found a large quantity of arsenic in the stomach. He found about four ounces in all, $2\frac{1}{2}$ ounces of which was congealed in one mass. Four grains were a sufficient dose to prove fatal, and the deceased had taken at least 1000 grains, so that she had swallowed a dose sufficiently powerful to kill 250 persons.

The jury returned a verdict to the effect that deceased committed suicide while in a state of temporary insanity. —*Western Daily Press.*

Accident near Dunfermline.—An Assistant Drowned.

On Friday last a sad case of drowning occurred at Limekilns, near Dunfermline. It appears that about four o'clock, Mr. John Kemp, who was employed as assistant to Mr. Brown, druggist, High Street, proceeded to take a bathe in what is called "the basin," not far from Limekilns harbour, accompanied by two boys. The tide was receding at the time, and Mr. Kemp had not been long swimming in the water, when he gave indications of having been seized with cramp, on observing which the boys gave the alarm. Help was quickly on the spot, but meanwhile Mr. Kemp had sunk. The body was recovered in a short time, and medical assistance obtained, but life was extinct. Mr. Kemp was a native of Inverness-shire, and came to Dunfermline about four months ago, and during that time he gained the esteem of all who came in contact with him, on account of his very unassuming and courteous disposition, and the thorough knowledge of his profession which he displayed.

To the above extract from a Dunfermline newspaper, we may add that a notice had been received from Mr. Kemp of his wish to compete for the Pereira medal during the present week.

Supposed Poisoning of a Family.

A case of supposed accidental poisoning of a family occurred on Monday in Birmingham. It appears that after dinner a quantity of lemon-kali was purchased, of which the mother and four children drank, and in a very short time afterwards symptoms of poisoning exhibited themselves by excessive vomiting. The youngest was immediately taken to the Queen's Hospital, the others being at first too ill to be removed, but they were subsequently also taken to the hospital. The children, who were very prostrate and suffering a great deal from shock, an indication of poisoning, were detained at the institution as in-patients, but the mother, after the proper remedies had been administered, was able to return home. At a late hour the children were lying in a somewhat critical condition. The lemon-kali unconsumed will be analysed in order to discover whether it contained any poison. The husband, who was from home at the time of the occurrence, states that nothing was kept in the house likely to produce the effects from which his family are suffering.—*Echo.*

Poisoning by Turpentine.

At Birkenhead, on Tuesday, July 23rd, a child five months old, named Eliza Russell, was poisoned with a dose of spirits of turpentine administered by mistake. It appeared that the child was crying, and the father told his daughter to give it some peppermint, and took down the bottle for this purpose, and poured out a spoonful of the liquid, but it proved afterwards to be spirits of turpentine. The child quickly died, with all the symptons of poisoning. A coroner's inquest will be held, and the matter will be investigated by the magistrates.—*Liverpool Courier.*

Suicide by Carbolic Acid.

On Monday the Liverpool borough coroner inquired into the circumstances attending the death of a woman thirty-nine years of age, named Elizabeth M'Dowell, the wife of a bricklayer. From the evidence of her husband it appeared that the woman was in the habit of drinking to excess, and he described her as sometimes queer in her ways and furious in her temper. When he went home to dinner on the previous Wednesday his wife went upstairs. A few minutes afterwards she called to him, and on his going into the room, she held up a glass, saying, "Jim M'Dowell, here's your very good health." Before he could interpose, she drank about a wineglassful of what proved to be carbolic acid, and then said, "You're too late." She did not speak afterwards, and having thrown herself on the bed, died in about half an hour.

A verdict was returned that the deceased committed suicide while labouring under temporary insanity.—*Liverpool Daily Courier.*

Poisoning by Vitriol.

On Monday, July 15th an inquest was held at Battersea, on the body of Henry Wiselthier, aged 3½ years, who died through drinking some vitriol from a ginger beer bottle. A verdict of accidental death was returned. —*Wandsworth and Battersea District Times.*

Death from Drinking Strong Spirits.

According to the account in the 'Preston Herald' of the inquest upon the man whose death was recently attributed to drinking methylated spirit, the spirit in question, upon examination, was found to be a very strong grain whiskey. The quantity drunk is believed to have been about a "noggin." A verdict was returned that deceased died from the effects of drinking too large a quantity of distilled spirit, not knowing the strength.

The Adulteration of Bread with Alum in Melbourne.

We have received from Mr. John Drummond Kirkland, Lecturer on Materia Medica and Practical Chemistry in the Melbourne University Medical School, a copy of the following letter addressed by him to the Editor of the 'Australian Medical Journal,' on the subject of the prosecutions in Melbourne for adulteration of bread, recently reported in this Journal (p. 396):—

"The recent prosecution of several bakers of Melbourne for selling bread adulterated with alum having come to a close, so far as the chemistry of the matter is concerned, I may perhaps be allowed to make a few remarks upon the subject from a chemical point of view, in the 'Medical Journal,' more especially as I had not the opportunity of giving the whole of my evidence in the case.

"It may be remembered that at the District Court, on the 15th September, 1871, I deposed to the fact of having analysed a sample of flour said to contain a considerable proportion of alum, without finding any therein. A process for the detection and estimation of alumina in bread or in flour, the best in use at the time, was described. At the same sitting of the Court, it was determined (not at my suggestion as stated in one of the newspapers) to make up separate samples of flour of one pound each, containing respectively a different and known quantity of alum. Of these samples one was received by myself. During the course of the analysis of the sample, certain phenomena were observed, which rendered it necessary to ascertain the quantitative accuracy or otherwise of the method used, before proceeding further. The results showed that the process, although *qualitatively* correct, was not so *quantitatively*.

"These investigations, and the fact that I could not devote the whole of my time to laboratory work, prevented my being prepared to give evidence on the day set down for hearing. Accordingly notice was sent to that effect to the sitting magistrate, Mr. Call, P.M., and another week stated as being required for finishing the work.

"The trial, however, proceeded, and three gentlemen deposed on the 5th October, 1871, as to the amount of alum found by them, as follows (from the newspaper report), viz.:—

No. I.	found equal to	3·89 grains,	contained	20 grns. per lb.
No. II.	"	8·0	"	15 " "
No. III.	"	25·0	"	10 " "

"During the following week my report was sent to Mr. Call, P.M., in which it was stated that 2·68 grains of alumina, equivalent to 23·6 grains of ammonia alum, had been found in the sample. The analysis was performed after the method, but slightly modified, previously described by me at the District Court.

"I have since requested Mr. Call to be good enough to furnish me with a memorandum for publication of the amount of alum placed in the sample by him; he, however, did not deem it advisable under the circumstances to do so.

"According to a somewhat modified process from that used in the case reported upon, the following results were obtained, viz.:—

	Alum in Flour per lb.	Alum found.
No. I.	60 grains	55·65 grains.
No. II.	30 "	27·12 "

"These numbers show but a slight loss of alumina, when the large proportion of organic matter with which the alum was mixed is considered, and it is remembered that one grain of alumina represents nearly nine of alum.

"It may be observed from the newspaper reports that one at least of the chemists employed calculated the alum from the amount of phosphate of alumina found; if so, the results arrived at cannot by any means be received as correct; from the fact that the precipitate obtained of so-called phosphate of alumina is an indefinite mixture of phosphate of alumina and alumina with possibly some silicate of alumina. Both Watts and Ure in their dictionaries refer to this. Ure says (5th edition): 'The only precipitate which can, under the circumstances of the experiment, simulate alumina, is the phosphate of that earth, which behaves with all re-agents as pure alumina. Such a precipitate, therefore, if taken account of as pure alumina would altogether vitiate a quantitative analysis, if the amount of alum were calculated from it;' *et seq.* Similar remarks are made in Watts's 'Dictionary of Chemistry.'

"Moreover, phosphate of alumina itself varies in composition, under certain conditions of precipitation, and to take it, or any indefinite mixture of it, with alumina, as a basis for calculation is quite contrary to a fundamental and well-known rule in analysis; it being absolutely indispensable that the substance from which calculations are made, should be of known, definite, and unalterable composition, under the circumstances of its preparation.

"The following analysis will show the extreme inaccuracy of such data:—

	Alum in Flour per lb.	Alum found. As calculated from so-called Phosphate of Alumina.	Alum found. As calculated from so-called Alumina.
No. I.	30 grains	17·17 grains	40·86 grains.
No. II.	60 "	38·17 "	98·79 "

"Portions of the same samples analysed by the method now followed by me gave pure alumina equivalent respectively to 27·12 and 55·65 grains of alum to the pound of flour.

"On the contrary, the advantage of the method used in the laboratory of the Medical School consists mainly in calculating the alum from a substance, viz., alumina, the chemical composition of which is definite and invariable, and the purity of which, when obtained, is easily ascertainable.

"In conclusion, it may be confidently stated, that, where any effective quantity of alum has been used in the manufacture of bread it may as surely be detected as the poison arsenic when present in the viscera, or disseminated through the tissues of the animal body; and, on the other hand, where not present, a properly conducted analysis will not discover it."

The Right to Use the Names "Kalydor" and "Odonto."

Rowland *v.* Breidenbach.

Before the Master of the Rolls, July 22nd.

This Bill was filed in December, 1869, by Messrs. A. Rowland and Sons, of Hatton Garden, against the late Mr. Henry Breidenbach, of New Bond Street, claiming an exclusive right in the terms "Macassar Oil," "Kalydor," and "Odonto," as denoting articles manufactured by the plaintiffs under these respective names. The occasion of the suit was an advertisement inserted in the *Times* by the late Mr. Breidenbach, in December, 1869, offering for sale a "Christmas Box," containing 32*s.* 9*d.* worth of "toilet luxuries" for 12*s.*, among such "toilet luxuries" being "Macassarine oil," "Kalydor," and "Odonto," price 1*s.* each. Upon the publication of this advertisement the plaintiffs filed the bill, and obtained an injunction *ex parte*, restraining Mr. Breidenbach from using these terms, except as denoting articles manufactured by the plaintiffs. In March, 1870, this injunction was dissolved on the application of Mr. Breidenbach, as reported in the *Times* of March 25th, 1870. Since then Mr. Breidenbach and the senior partner in the plaintiff's firm have died. The suit was revived by the surviving partners against Mr. Breidenbach's representatives, and now came on to be heard with reference to the terms "Kalydor" and "Odonto" only, it being conceded that Mr. Breidenbach had infringed no right of the plaintiffs by his use of the term "Macassarine oil." The evidence was voluminous, no less than 89 affidavits, containing 900 folios, having been filed by the plaintiffs in support of their contention that they have acquired an exclusive right to the terms "Kalydor" and "Odonto."

Mr. Fry, Q.C., Mr. Day, Q.C. (of the Common Law Bar), and Mr. Bradford appeared for the plaintiffs; Mr. Southgate, Q.C., and Mr. Brooksbank for the defendants.

The Master of the Rolls, who had taken time to consider his judgment, said he was satisfied that the terms "Kalydor" and "Odonto" had become *publici juris*. There was evidence of an article called "Kalydor" having been openly sold by as many as 36 tradesmen besides the plaintiffs since the year 1848, and there was similar evidence before the Court with respect to the article called "Odonto." In fact, any one then in court had as good a right as the plaintiffs to sell "Kalydor" or "Odonto," provided he did not call it "Rowland's Kalydor" or "Rowland's Odonto."

Bill dismissed with costs.—*Times.*

The Right of Scotch Physicians to Practise Pharmacy in England.

A case of some considerable importance to the medical profession recently came before Mr. Macnamara, the judge of the Marylebone County Court. The question, divested of all technicality, was whether a member of the College of Surgeons in England, authorized to practise as a physician by a diploma from the University of Edinburgh, but not qualified as a member of the Society of Apothecaries in London, could recover for medicines supplied without advice or visits. Mr. Macnamara decided that such a practitioner could not recover for medicine supplied which was not auxiliary to a surgical case, although registered both as a surgeon and a Scotch physician. Indeed, according to this decision, such a person is liable to penalties under the Apothecaries' Act. Should this judgment be upheld by the superior court, it will make sad havoc of those who, practising under Scotch or Irish degrees, affect the right to add the practice of pharmacy to their other qualifications, although possessing no licence from the Society of Apothecaries in England. The medical graduates of the old universities practically lay no claim to the practice of pharmacy; the Fellows and Members of the College of Physicians in England are expressly forbidden it by their bye-laws; the medical graduates of the London University are excluded such practice by statute (the Medical Graduates Act, 1854); the Licentiates of the College of Physicians, who have the privilege of compounding and dispensing medicines for patients under their own care, being the single exception among English medical men to the otherwise exclusive privileges of the Society of Apothecaries. Should this decision of the Marylebone County Court Judge have the effect of closing many of the present open surgeries maintained by other than those duly licensed to practise pharmacy, it would add greatly to the respectability of the profession, and save much confusion in the public mind as to the relative qualifications of the different orders of the profession.

The case referred to by Mr. Macnamara, viz. the Apothecaries' Company *v.* Collins, reported in 4 Barnewall and Adolphus, 604, was decided so far back as 1833.

In giving judgment, Lord Denman (Chief Justice) said—"Even English physicians would be included within the 20th section of the Apothecaries' Act if there were not a special exception in their favour in the 29th section." And Mr. Justice Littledale remarked—"The words would include all persons who have taken medical degrees, were it not for the 29th section, which saves the rights of the two Universities of Oxford and Cambridge, the Royal College of Physicians, and the Royal College of Surgeons. But the statute, by expressly exempting the two English Universities, does not exempt those of Scotland also. The Act applies to England and Wales only—Scotland is not in contemplation."

Mr. Justice Parke observed—"The duty of an apothecary as defined by section 5, is 'to prepare with exactness and dispense such medicines as may be directed for the sick by any physician lawfully licensed to practise physic by the President and Commonalty of the Faculty of Physic in London, or by either of the two Universities of Oxford or Cambridge.' A Scotch physician," continued his Lordship, "is certainly not enabled by the Act to perform this duty." The whole contention now is, whether a Scotch physician can recover the price of medicines supplied by him *quâ* medicines; in other words, can he practise pharmacy, pure and simple, by furnishing medicines unconnected with medical attendance? If not, he certainly exposes himself to penalties under the Apothecaries' Act for affecting so to do; and even though, as in the case before us, a member of the Royal College of Surgeons of England, he can only recover for medical attendance as auxiliary to a surgical case.

Such a complication of conflicting interests, especially if the decision of the Marylebone County Court Judge should be affirmed by the superior court, seems at all events to demand further legislation, if only by way of simplifying and amalgamating the licensing bodies throughout the United Kingdom.—*Medical Times and Gazette.*

[321.]—IS THE WOOD OF EUCALYPTUS SUITABLE FOR ENTOMOLOGICAL CABINETS?—I was much pleased with the article on the various species of Eucalypti in the PHARMACEUTICAL JOURNAL, and should be very glad to learn if any of our entomological friends at the Antipodes, or elsewhere, have ever tried the service of the wood for insect cabinets. If *Eucalyptus Acajon* is *entirely* free from any resinous matter. I should fancy that it would be as equally valuable as mahogany, and certainly it ought to be cheaper. The desideratum is to get a hard wood free from resin, and cheap. Have we this combination in any of the eucalypti; and, if so, which species?

[322.]—QUILLAI BARK LOTION.—A. D. would be glad if any one can give him a formula for Quillai Bark Lotion for the Teeth.

POISONING BY BELLADONNA PLASTER.—Mr. C. A. Hemingway reports in the 'British Medical Journal' (June 1st, p. 576), that having prepared a small belladonna plaster, about the size of a crown piece, by spreading the extract with his right thumb upon a portion of adhesive plaster, he was afterwards seized with what appeared to be symptoms of belladonna poisoning. Upon examining the pupils of his eyes in a mirror, he found the right pupil much dilated, whilst the left was of the usual size. These symptoms passed off after a short time. There was no wound or abrasion of the thumb, and the inference drawn by Mr. Hemingway is that the external application of a belladonna plaster of even moderate size, might sometimes be followed by dangerous symptoms. Another correspondent, the following week (p. 628), says that he has frequently of late found poisonous effects follow the external use of belladonna, and he has been led to believe that formerly a very inactive extract was dispensed compared with that which is now produced by improved pharmaceutical processes. See also the cases mentioned in this Journal, *ante*, vol. ii. p. 570.

LEAD POISONING BY A "HAIR RENEWER."—Dr. J. M. Crocker reports, in the 'Boston Medical and Surgical Journal,' that he met with a patient suffering from the symptoms of lead palsy and colic, the origin of which was not at first apparent. Upon inquiry, however, he found that he had been for some time in the habit of using a "hair renewer," made by himself, by mixing three teaspoonfuls of lac sulphur and two teaspoonfuls of sugar of lead in a pint of water. The hair dressing being stopped, and proper remedies administered, the man recovered.

POTASSIUM.—Professor A. E. Dolbear has obtained this metal, in small quantity, by reducing the di-potassic sulphide by means of iron. The salt in question is intimately mixed with iron filings, and subjected to a bright red heat, in a suitable distillatory apparatus, the products of distillation being received in naphtha. The reaction is simple, and may thus be represented:—$K_2S + Fe = FeS + K_2$. The author suggests a similar method for the preparation of sodium.—*American Chemist.*

PROVINCIAL EDUCATION.

Sir,—I have not hastily accepted the invitation given to all members, and especially to local secretaries, to criticize the scheme of education now before the Council. The letter of Mr. Barnard S. Proctor makes my course rather clearer; and since the report and action of the Committee of 1870 still seems worthy of commendation from so able an educationalist, I trust it is not presumptuous in a member of that committee to state that, after two years' interval, he also can look back with confidence in the soundness of the position then adopted by the Society. This question can hardly be dealt with as if it were now heard of for the first time. Without straining the claim of consistency unduly, it may be asserted that a society cannot forget that its historical records define its policy, and commit it to a maintainance of the same until its views are enlarged or changed.

An estimate of the present and future demand for education forms an important element of the question under consideration. Upon reflection, it will be seen that the present demand is much below a normal quantity. The Pharmacy Act of 1868 supplied our starting-point, by clearing from the educational arena all assistants of the age of twenty-one years. (Preparation for the Modified examination can hardly be considered in any scheme.) Our estimate of the amount of educational demand that existed at the middle of 1868 must, therefore, be expressed by—*nil.* At the same period of 1869, it is evident that a certain number of young men had reached the age of twenty-one, forming the nucleus of a body from which our present students are recruited. For the years 1870, 1871 and 1872, three similar bodies of young men have to be added; and hence the aggregate number has increased considerably. But the question of how many probable students we have does not depend merely upon an estimate of how many attain the age at which they are legally eligible to offer themselves for examination, but also upon ascertained experience as to the average at which such young men enter upon the studies preparatory to their examinations. Some will do this immediately after completing their pupilage, but it is evident that from financial and other reasons many will defer this for a few years. Probably an average would fall somewhere near twenty-three or twenty-four years of age. As we have shown that the oldest members of the present student-class will now be but twenty-four years of age, it seems fair to estimate the total number as only one-half of what it will be in a few years. Besides this, a very heavy deduction must be made for the young men of this class who are leaving the trade rather than face examinations not contemplated by them when they entered upon it.

I offer this estimate of our numerical position quite independently of any opinions as to the policy we should adopt. It is the interest of all, however divergent our educational plans, to form some such estimate, and it has a special bearing upon the comparative absence of demand for help which followed the Society's earlier action toward supplying this. If we represent the normal numbers of the student-class by the unit 1·0, I incline to the belief that they do not greatly exceed ·3 at the present time; and further, that whilst our education code No. 1 was in force they never reached ·2.

I now come to the scheme of education laid before the Council and the Society by my friend, Mr. Schacht. That it will be received in all quarters with the most friendly predisposition is well-assured by the private and public esteem which Mr. Schacht enjoys. Possibly, this may even check that independent criticism so desirable for a measure of this kind. I could have wished to find in the "Principles" of the new measure, some statement as to the views of the Council about its permanency or the contrary. If the Society accepts the permanent duty of providing and paying for the education of those who in future offer themselves for examination, it is introducing an organic change of the deepest significance. The Committee of Council in 1870 did not shirk this question, but distinctly avowed that the action then taken was temporary and transitional. Has the Society's policy changed, or has it not?

Let us look at the proposed "payment for results" which forms so large a part of the new scheme, not permitting its elaborate and carefully thought-out mechanical details to satisfy us without a deeper inspection. The system of the Government Department of Science and Art being the model followed by the new scheme, the essential differences in object and situation are to be noted, as well as the close resemblances in mere details. The Imperial Government accepts the duty of paying for such educational results, not as a temporary one, but as one to be further developed from year to year. But, even the Government guards itself against merely saving the pockets of those who can afford to pay for their own education, and only recognizes the artizan-class in its payments. The Department of Science and Art does not pay its money until the student has successfully gone through the pass examination, which it regards as the "result" that justifies the payment. In our scheme, the same students are to be allowed to earn payments for three consecutive years; and as chemists and druggists in business are eligible, it is quite possible that the society may pay for results a dozen times, and yet its examining board may not receive half that number of candidates from the rewarded students.

It cannot be irrelevant to enquire what will be the position of our own examining board when this new *imperium in imperio* is established. The Minor Examination will be infinitely the better test because of its practical section, and, I can imagine bitter disappointments and heartburnings as the result of this double test. If A.B., passing the "Payment Examination" in May, and certified by Professor C. D., of the University of Y.Z., to be competent in chemistry, be plucked on this subject in July by our own board, that body will be placed in an unenviable position. It is impossible to avoid this by making the "Payment Examination" stiffer, for it seems certain that we must aim at making it just a shade easier than the Minor Examination. But, how is this to be done when the examiners are two independent bodies? I fear the answer must be—impossible! Further, this theoretical (though impossible) harmony will be believed in by the candidates, and if A.B. be an average student he will shut up his books after success at the "Payment Examination." This result, when multiplied, will, I fear, lessen the amount of preparation for our Minor Examination.

The difficulty of getting an absolutely equitable system of "payment for results" is seen at many points. It is not surprising that this has induced some of your correspondents to suggest that the payment should be made directly to the student. The journey, logically taken from the "principles," leads to this idea. But, it no sooner enters one's mind than it is displaced by the much simpler one that the Chairman of our own Board of Examiners should fill up a cheque for each successful candidate, and thus pay for results. Seriously, the recognition of the payment as one earned by the student has this tendency; it creates the idea that it is his property, to be returned to him in some way by reducing his fees to a nominal amount. Now, every profession contains some students to whom such mitigation of expenses is acceptable, but I contend that it is neither necessary nor desirable to place all our provincial students in such a position.

The other modes of aid to Provincial Chemists' Associations are disposed of by the scheme in half-a-dozen lines, and yet they involve a possibly large expenditure of money. The engagement to "go halves" with any association in any expenditure with "a distinct scientific educational object" is boid in its scope and dubious in its definition. If an association inclines to pay £20 per annum for rent of premises for its classes, it will claim the same amount from the Pharmaceutical Society, and go into rooms at £40 per annum. Business men recognize the evil of having a large balance at their bankers, and I cannot but think that the invested balance of the Society encourages the proposal of outlay without sufficient scrutiny. I would invite comparison between the present provisions and those of code No 1 of November, 1870, believing that the latter offered much greater security for the ratepayers' money," and was at the same time quite as liberal towards legitimate objects. The laxity of view found in some quarters is perhaps at its maximum when we meet with suggestions for giving sums of money to local committees, and letting them decide upon their appropriation. Under such circumstances, an application from a local committee would be a demand—its refusal would be a personal affront.

Finally, let us recognize the fact that the Society cannot afford to make mistakes a third time. There can hardly be any one who will doubt that it was a mistake to sweep away, untried, the *bonâ fide* Education Scheme No. 1. How this happened is still a mystery, but its substitute in scheme No. 2 was so unhappy that it could not find a friend to defend it when attacked. On no principle of equity can it be permanently settled that the education of future chemists shall be paid for largely by an annual tax upon present chemists. Nor can any precedent for such a course be adduced from the practice of other professional bodies. If the present subscription brings an income larger than can be legitimately expended, let it be reduced. Within reasonable limits, I believe that members of the Society generally will recognize and accept the duty of helping provincial education in its present transitional state, because such condition is the result of the changes which the Society effected in 1868. That Mr. Schacht's scheme of payment by results might lead to the earlier establishment of pharmacy classes in a very few places is possible, but I hold this to be an insufficient reason for establishing an unsound and very costly system, incompatible with our present examinations. The scheme would only operate in towns with students numerous enough to form classes. Its object is, therefore, merely to distribute aid proportionately amongst these few towns. I venture to say that this may be done, and ought to be done, without incurring the evils which must result from following that seductive, but wholly inaccurate, phrase, "payment for results."

RICHARD REYNOLDS.

Leeds, July 23rd, 1872.

Sir,—I have read in the Journal with considerable interest Mr. Schacht's scheme for promoting provincial education, with the comments and wise suggestions made thereon. But it appears to me that what he proposes has, to a great extent, been tried in a few localities under able management and has signally failed, through the apathy of those it was intended to benefit. This plan, however, has its peculiar attractions; and assuming that a much greater interest may be taken in schools established under it, I cannot see how it can meet the case, since none can avail themselves of the lectures proposed to be given unless they be in the immediate vicinity of cities or large towns.

If, on the other hand, your schools are established in many towns, how can the expenses be met? And after every effort has been made, there still will remain a very large number of assistants unable to benefit from such an arrangement, who would look with a jealous eye on money grants from Bloomsbury Square in which they were not benefited.

I am aware many of our friends in the country consider they have a strong claim on the "purse of the Society," because they say "it is our money which fills it." I grant such is the case; but in looking through the list of those who pass the examinations and obtain certificates, I find an equal proportion are from the country who either directly or indirectly have obtained from the school in Bloomsbury Square the knowledge which has enabled them to pass.

I am not opposed to grants when satisfactory local efforts have been made for a special object; say, the purchasing of a good microscope, or books of reference, which may be beyond the reach of individual assistants, subject to certain conditions; but it appears to me injudicious to attempt to establish anything like efficient provincial schools aided to any great extent by the funds of the Society.

I contend a school does exist offering every facility for the education required, and in my judgment was intended by the founders to be so. I advise all those who have the means to enter there for one session, when by diligence and perseverance they may easily pass the two examinations, and thus tend by their acquirements to help to raise the body of whom they form a part, and also greatly improve their future prospects.

This is my plan for the many.

There are, I estimate, within a radius of six miles of the Square, one thousand assistants, eight hundred of whom have passed neither the Major nor Minor examination.

Cannot a considerate and generous arrangement be entered into by their employers, whereby many of their assistants may attend two mornings in each week at Bloomsbury Square, say until one o'clock, to hear lectures, examine specimens, in fact do any thing to promote their improvement, and be allowed an hour or so daily (when business permits), and take one or two hours for study by rising early before business commences.

By some such plan as this a young man of moderate abilities, with a fair preliminary knowledge of his business, could pass his Minor examination the first year; and with a little modification of the arrangement his Major in the second year.

If you take in an additional radius of nine miles, you include towns containing about 300 more assistants, who could attend in a similar manner. These gentlemen, thus qualified, could then obtain better remuneration both in town and country, and make room for a fresh supply from the provinces.

This plan has been carried out most successfully by a few houses, and has created between the employer and the employed kindly feelings, which have been mutually gratifying and advantageous to both parties.

I believe there are many very anxious to help the young men out of their present position; but there must also be a desire on the part of the latter to secure at a sacrifice the advantages of an education which may not long be obtainable on such easy terms.

Turnham Green. BENJAMIN HUMPAGE.

Sir,—In reply to some remarks in your leading article in the Journal for last week, I would observe that the first clause of the Royal Charter of Incorporation, granted on February 18th, 1843, states that it was granted for the purpose of "advancing chemistry and pharmacy, and promoting an uniform system of education of those who should practise the same." This clause was confirmed by the Act for Regulating the Qualifications of Pharmaceutical Chemists, dated June 30th, 1852. In the Act passed July 31st, 1868, to Regulate the Sale of Poisons, to Alter and amend the Pharmacy Act of 1852, and to make examinations compulsory, I cannot find any clause which releases the Council from the responsibility of promoting "an uniform system of education of those who practise pharmacy."

It is my opinion that it is still their duty to encourage, to assist, and to foster it, by every means in their power. If it be not their duty to do so, how can they justify their expenditure over the School of Pharmacy in Bloomsbury Square? Do not let me be misunderstood on this subject. I do not begrudge one penny expended over it. It is a source of regret to many that, so few of the London apprentices and assistants avail themselves of such splendid opportunities for improvement. Many of the older members of the trade would have jumped for joy, could they have had in their youthful days such privileges. I trust it is from no niggardly spirit that the institute in Bloomsbury Square has lost the services of one so eminent in his profession as Dr. W. A. Tilden, the demonstrator in its laboratory.

I cannot subscribe to your belief that "the Council of the Society has ever sought, and still seeks, to know how it may assist, to the attainment of the best education possible, those who have already helped themselves." I think the present Council are anxious to do so, but if I am to state my opinion truthfully, it appears to me that past Councils have not been so. I have no doubt but the Sheffield Association and some others will bear out my opinion on this subject.

The country members of the Society are patiently waiting for results. If those expectations are disappointed, probably another list of candidates at the next election of Council will enable them to realize them. Had Jacob Bell lived, the eminent pharmacist, the patron of the fine arts, the country's benefactor, as the walls of the South Kensington Museum testify, this subject had not remained so long unsettled. However, the cry *peccavi, peccavi,* from some of the members of the last Council gives some hope for the future. May the mantle of Jacob Bell rest upon the shoulders and his large heartedness fill the breasts of the present members of the Council.

Hull, July 22nd, 1872. ATKINSON PICKERING.

[*** Our correspondent appears to have fallen into the now somewhat common error of confounding the promotion of a uniform system of education, and the providing of that education. None, we believe, would dispute the opinion that it is the duty of the Society to promote education, and until Mr. Pickering declared the contrary, we believed that most members of the Society at least gave the representative body the credit of having liberally endeavoured to attain that object. Even Mr. Schacht, and those who have with him urged that the means of education hitherto provided by the Society are inadequate for ensuring that general education which is essential, have never disparaged what has been done by the Society, and we venture to think that the comparatively small extent to which the Society's school has been taken advantage of is strong evidence that the real want in regard to education is the absence of such a demand for it as should exist. In regard to this point it is now essential that the trade at large should come forward and zealously cooperate with the society in the endeavour to make the necessity of education more generally appreciated both by apprentices and assistants, as well as by masters. Mere laudation of the labours of Jacob Bell will not justify patient waiting for results unless there be also on the part of country members of the Society an effort to imitate the zeal and energy with which those labours were directed to the advancement of the trade at large.—ED. PHARM. JOURN.]

THE POSSIBILITY OF EFFORT.

Sir,—Permit me to offer a few remarks on the above subject and in reply to Mr. Nuthall's letter, contained in your issue of Saturday last. I have experienced the fact that individual effort, combined with determination, and with no other help than the ordinary text-books, can pull a candidate through the Minor. I served my apprenticeship in a small country village of 800 inhabitants. My master was a "pharmaceutical chemist,"—at least he had a certificate to that effect, though he knew as much about botany and chemistry as the Man in the Moon. Bentley, Attfield, and he never had the slightest acquaintance. Besides being a chemist and druggist, he was postman, grocer, and general dealer; and as to my passing the Preliminary even, it never gave him a thought. There was no other chemist within twelve miles, and I only saw a drug traveller every three months, so I do not think any young man could be placed in a more unenviable position. However, I determined to try, and if I failed, to leave for some large town where there were classes. I passed the Preliminary easy, and then at once commenced preparing for the Minor. I got one of Evans' Cabinets, and also the various text-books in use. I wrote down in a tabular form (for easy reference) every drug, etc., in the Pharmacopœia—its botanical and zoological name, natural order, part of plant, etc., country, preparations, doses, etc.; this I learnt thoroughly. Then I read 'Selecta e Prescriptis,' and got by heart the composition and dose of every compound tincture, powder, etc. After that I went at Bentley for three months, and mastered a good part of it; then I had other three months at Attfield, and then I had a turn at the 'Metrical System.' This I did with no assistance, except, being puzzled with some chemical equations, I wrote to the local secretary, and he kindly put me right. I then went to Edinburgh, and passed, not easily, but I passed. There were six candidates, I was second on the list, two failed. I am now 23 years of age, and in business for myself. I am about to take an apprentice, and I will not bind him until he passes the Preliminary; and if he does not pass the Minor while with me, I will return the premium. I consider this only right, as if I undertake "to teach him the art and mystery" of a chemist and druggist, I undertake that he must pass the necessary examinations.

Too many masters never consider the moral obligations they are under to their apprentices. However, let us hope that a new era has dawned upon us, that with a new generation a new state of things is about to arise.

Allow me to add that a short time before I left my old situation, I coached a young man for the Preliminary, and he is now studying for the Minor.

I have not written this to boast, only to let intending candidates see what perseverance and determination will do.

July 8th, 1872. MINOR ASSOCIATE, 1871.

EXPERIMENTS ON COMMERCIAL IODIDE OF POTASSIUM.

BY W. B. BISHOP,

Student in the Laboratory of the Pharmaceutical Society.

Some time ago, M. Lepage published in the 'Journal de Pharmacie,' a process for estimating volumetrically, iodide in the presence of bromide of potassium. The method he adopts is based upon the property possessed by perchloride of mercury of precipitating the iodide to the exclusion of the bromide, the bromide of mercury being soluble in water. After having ascertained by previous tests that the iodide under examination is free from chloride, carbonate and iodate, 1 gram of the iodide is dissolved in 30 c. c. of distilled water. A solution of 1 gram of perchloride of mercury in 20 c. c. is also prepared, and the latter dropped from a burette into the solution of the sample to be tested until it ceases to form a precipitate. If the iodide be pure, 16 c. c. of the solution are sufficient for this purpose. From the above data may be calculated the real amount of iodide in the solution. To detect the bromide in the supernatant liquid, it is left some time at rest, then decanted on to a filter so as to obtain it perfectly clear. This is then evaporated in a capsule till its volume is reduced to about 20 c. c.; after cooling, it is poured into a tube and mixed with a few drops of a solution of perchloride of iron. On boiling, the vapour of iodine is given off, and may be easily recognized by placing at the mouth of the tube a piece of starch paper. When the last traces of iodine have been expelled, the solution is filtered, and the clear liquid mixed with a little chlorine water, which sets the bromine at liberty and colours the solution strongly yellow. On agitation with a few grams of sulphide of carbon, the bromine is removed and furnishes a yellow solution in which it can be recognized by the usual tests. This process will answer under careful manipulation and is at first sight a promising one, but it has some defects which interfere with the accuracy of the results obtained by it. In the first place the iodide of mercury does not settle very readily, and even by filtration it is very difficult to remove the suspended red particles. It is, moreover, rather troublesome to have to filter a liquid two or three times on the addition of each drop of the test, and certainly leads to loss. There can also be little doubt that the mercuric iodide is not by any means insoluble in the alkaline chloride and bromide retained in the mother liquor, and thus another source of error is introduced. A more convenient method consists in the employment of a standard nitrate of silver solution in the place of perchloride of mercury. A weighed quantity of the iodide of potassium is dissolved in a little water, and I find a stoppered bottle the most appropriate vessel in which to perform the experiment, as the liquid may be more conveniently shaken in it. The standard solution of nitrate of silver is then run in from a burette, taking care to shake well after each addition. When nearly enough has been added, the precipitate will be seen to coagulate and fall to the bottom. Enough nitrate of silver solution is added to make the supernatant liquid perfectly clear.

The following 10 specimens have been examined by the foregoing process:—

Percentage of iodide of potassm. in the dry salt as indicated by the $AgNO_3$.	Water.	Chloride.	Carbonate.	Iodate.
99·2	·47	none.	very faintly alk.	none.
98·6	·59	none.	alkaline.	large quantity.
102·8	·45	large quantity.	faintly alk.	none.
100.8	·36	trace.	neutral.	none.
100·0	·58	none.	neutral.	none.
98·8	1·58	faint trace.	very alk.	trace.
99·7	·33	trace.	alkaline.	trace.
99·1	·7	none.	alkaline.	none.
100·8	2·1	trace.	neutral.	none.
100·3	1·5	trace.	very faintly alk.	none.

It will be seen that in some cases the percentage of iodide indicated in the table is greater than 100. This arises from the presence of chloride of potassium, for in no case was any appreciable quantity of bromide detected. The equivalent of chloride and bromide of potassium being less than that of the iodide, it follows that these salts will consume more of the solution of nitrate of silver than an equal amount of iodide. Advantage has been taken of this circumstance in calculating the percentage of chloride in bromide of potassium by E. Baudrimont* and Falières† in a recent number of the 'Journal de Pharmacie.'

It will be seen by reference to the tabulated statement of the results obtained by myself that the iodide of potassium of commerce may be considered to be remarkably pure, considering its present high price. It certainly appears to be free from adulteration.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from page* 63.)

Scammoniæ Radix.—With the superficial appearance of this root every pharmacist is familiar. Its microscopic characters are more difficult to become familiar with, and it would occupy more space than can fairly be devoted to it were I to attempt a thorough description of its somewhat anomalous structures and morpho-histological peculiarities. We may briefly classify its various component parts into two groups, those belonging to the cortical or outer layer, and those of the inner or woody layer. The line of demarcation is not clearly marked, and it is doubtful whether the apparently sinuous medullary rays may not more properly be regarded as a sinuous involution of the cortical parenchyma. The structure of the inner zone is somewhat complicated. There is no true medulla. There are no wood wedges strictly speaking. The vascular bundles are irregularly distributed, are large, and of varied constituents. I will describe them first. The vessels are pitted, the cells of which they are formed are not long, but the original membrane which formed the septa between the cells has been completely absorbed, and all that remains to show that the vessels were once short cells is the somewhat unusually slight "horizontal wall" of Schleiden, with a perforation nearly as large as the internal diameter of the vessel. The course

* 'Journal de Pharmacie,' vol. [4] vii. 411.

† Journ. Pharm. [4] xiv. 247; and Pharm. Journ. [3] ii. 541.

of the successive depositions of sclerogenous matter of which this "wall" has been formed can be readily made out without the use of reagents, and the same may be said of all the secondary structures in the root. The vessels are of the usual size and shape common to climbing plants, are coarsely pitted, and, except in the immediate neighbourhood of the "horizontal walls," are somewhat thinly consolidated. These walls are seldom if ever perforate; there are no traces of "reticulations," but some are disposed to tear longitudinally with unusual freedom. The course of the vessels and their accompanying tissues is not directly vertical, but is slightly curved and approximates to the endogenous type, and would induce the young student to refer the root to that class. A more minute examination of the nature of the vessels would of course undeceive him. The woody fibres which enter into the composition of the vascular bundles are pitted chiefly and much thickened, and are fusiform. There are a few unpitted ones. Following the course of the pitted vessels, and separated therefrom by the layers of woody fibres, are short, as broad as long, cells containing a semi-fluid and granular matter. These cells resemble somewhat closely in shape those found in some specimens of English medicinal rhubarb, but are larger. They appear to be closed cells, and to communicate only by transfusion through the double separating cell walls. These cells are arranged in a single linear series; and the walls not in adhesion in the series are often consolidated by several layers of sclerogen, and in this case are porous. Very rarely the separating membrane or diaphragm is also thickened and porous.

The rather spongy parenchyma which forms the medullary rays does not possess any remarkable features. The cells are small, cubic, oblong, with somewhat rounded angles, and have thin walls when in the denser portions of the root. In other positions these parenchymatous cells have very varied features. The prevalent form is the more or less modified simple globose cell with walls of very varied thicknesses. With these are intermixed a few cells with very angular outline, thick walls, porous and somewhat stellate, resembling slightly the porous cells in the petiole of *Cycas revoluta*, or more closely those figured by Schleiden,* and found in the leaves of *Pilularia globulifera*. The globose, oblong, and other of the larger parenchymatous cells are minutely pitted.

Arranged in nearly moniliform series by the side of the resin and other receptacula, and distributed amongst the parenchymatous cells, are rhombic prisms of some inorganic substance of small size, and brilliantly doubly refractive. These, a little starch, and various resins and allied semi-fluid matter constitute the cell contents. The form of the starch granules is tolerably uniform, as also their size. They may perhaps be best described as flattened, slightly lenticular discs with no very decided polariscopic reactions. The cortical layers possess several features of interest. Besides the ordinary parenchyma, which is similar to that just mentioned, there are numerous cells closely similar to those found in the medulla of *Hoya carnosa*, and figured in Schleiden's 'First Principles,' and, scarcely correctly, in Von Mohl's 'Vegetable Cell.'* These cells are porous with a very thick wall, the pores of contiguous cells communicating freely, and they are either globose, oblong, elliptical, or slight modifications thereof. There are also semi-tubular liber cells present in the cortical layers containing a similar, but of a lighter colour, semi-fluid substance as the internal special receptacula. These cells may perhaps be regarded as transitional laticiferous vessels, but their functions are somewhat doubtful. Distributed amongst these cells and grouped closely between the several layers of the "bark" are great numbers of the rhombic prism previously described. The bark layers themselves do not call for special notice.

A few words on the mode of preparing Scammony root for examination, and I pass on to the examination of the resin.

The root must be soaked in water for a considerable period to render it soft enough to be cut. Sections cut longitudinally and transversely should be examined in glycerine without further treatment. Others must be treated with spirit and examined with glycerine also. Further examinations should be made of sections treated with turpentine, benzole and ether. These latter may be conveniently immersed in oil of anise for observation, and if desired to be retained for the cabinet mounted in dammar. The other specimens may be mounted in glycerine or glycerine jelly. The latter is preferable. It is a difficult root to examine thoroughly, on account of the great variety of tissues which enter into its composition. Several unimportant details have probably escaped my description here.

Scammonium.—.—The British Pharmacopœia furnishes directions for the chemical testing of the scammony resin. The microscope will be of service in this, as smaller quantities may be dealt with, and the detection of a lesser amount of adulteration rendered possible. Dr. Hassall† quoting from Pereira's 'Materia Medica,' publishes a list of the "rarer kinds of adulteration which have been detected by different observers."

Calcareo-dextrinous Scammony.—This sort differs (from ordinarily adulterated specimens) in the circumstance that iodine produces a reddish purple tint when added to the filtered decoction after it has become cold. It appears to contain carbonate of lime and dextrine.

"*Selenitic, or Gypseous Scammony.*—This kind has been described by Marquart. Its specific gravity was 1·731, and it contained no less than fifty-two per cent. of gypsum.

"*Bassorin Scammony.*—Marquart met with a Scammony which had a horny consistence and a specific gravity of 1·167. After it had been deprived of its resin and extractive, it swelled up in boiling water. The constituent which thus swelled up was soluble in caustic potash. Marquart regarded it as *bassorin*."

Further specimens are spoken of as consisting of an admixture with scammony of tragacanth, sand, various resins, starches, wax and wood.

The microscopical examination of scammony is simple enough. If not already in the form of powder, it should be finely pulverized and a small portion placed on a glass slip moistened with distilled water and covered with a piece of thin glass. A quarter

* An easily demonstrable similar class of cell may be seen, according to Quekett, in the Sweet Burr-reed—*Sparganium ramosum*.

* Henfrey's translation. Van Voorst.

† 'Adulterations Detected,' page 651.

inch objective will render the detection of the presence of starch very easy, and in some cases also of chalk and sand. The addition of a drop of hydrochloric acid at the edge of the cover, a portion of the water having been abstracted on the opposite side of the cover by means of blotting-paper, will render the presence of chalk visible by the gas bubbles which will gradually appear and make their way to the edge of the cover. The polariscope will demonstrate the presence of sand and facilitate the detection of wood fibres. Starch and chalk appear to be the prevalent adulterants at the present time. A sample forwarded to me lately, labelled "Pulv. Scammon. Virg. (Pure)," was remarkable on account of the variety of starches it contained, many being unknown to me, and of the organic remains* in the chalk with which it was adulterated. This sample was also adulterated with other resins. When the scammony is adulterated abroad by admixture with starch, etc., whilst the resin is soft, it is needful to heat it with ether and spirit before examining it.

(*To be continued.*)

REPORT ON CINCHONA BARK GROWN IN JAMAICA.

By the kindness of J. E. Howard, Esq., we are enabled to print a report made by him upon some samples of cinchona bark forwarded to him by Mr. Sargeaunt, the Crown Agent for the Colonies. The samples included five species grown in the Botanical Gardens, Jamaica, and one from a locality named Cold Spring. Those from the plantation had been planted out three and a half years, the specimens from Cold Spring was supposed to be about eight years old.

Report by J. E. Howard, Esq., F.L.S., etc., *to the Crown Agents for the Colonies on the above samples.*

Sir,—Referring to your letter of the 27th June, † I have to inform you that the samples of cinchona bark from Jamaica have been received and fully investigated; and I am glad to be able to report that the result is highly satisfactory as regards the prospects of cinchona cultivation in that island.

The total contents in alkaloid may be described as quite favourable for the time of growth, with specialities which seem to indicate that some species are more exactly suited than others. The *C. calisaya* is in this case decidedly the most promising, and it has already attained a percentage of quinine which would fit it for the purposes of the manufacturer. This may be owing to a difference in the sort cultivated; if otherwise, it marks a more favourable climate for this species than the East Indies present.

The reverse may be remarked of the *C. officinalis*, which has probably not been planted at a sufficient altitude above the sea.

The *C. succirubra* resembles that grown in India, with the exception of the specimen from "Cold-spring." This latter is thin, and with the appearance of having grown slowly, but is of very good quality, containing quinine, cinchonine, and cinchonidine in almost equal proportions, together with great abundance of the peculiar cincho-tannic acid. It would be exactly suited to pharmaceutical purposes.

The *C. micrantha* and the *C. pahudiana* are of equal value. The *C. micrantha* contains more quinine and less cinchonine than usual. The *C. pahudiana* contains about as much quinine, more cinchonidine, and the same amount of cinchonine as the last.

They are both inferior to those previously named. The three best specimens might be worth from 1*s.* 6*d.* to 1*s.* 10*d.* per lb., for manufacturing purposes, or might command even a higher price for druggists' use. The others would also sell at prices higher or lower, according to the fancy of the purchasers.

I return samples for quantitative analysis, and remain yours, etc.,

(Signed) John Eliot Howard.

* Foramenifera similar to those found in the Gravesend chalk.

† "The samples of cinchona bark have been forwarded, and I shall be glad to receive the report which Mr. J. E. Howard has kindly promised to give on their botanical qualities and commercial values. I enclose an extract from a letter from the Superintendent of the Botanical Gardens, Jamaica, which may be of assistance to Mr. Howard in his examination of these specimens.

"*Extract referred to under date, April* 22*nd,* 1872:—'I send herewith all the species (five) grown here, and also a specimen from Cold Spring. They are all labelled. Those from the plantation are now three years and a half old, that is, from the time they were planted out, when they were four to six inches high. The specimen from Cold Spring is, as nearly as I can make out, about eight years old.'"

THE TRADE IN ALOES.

BY P. L. SIMMONDS.

Our supplies of this important drug do not seem to increase, and an annual import of about 700,000 lb. may now be considered as the average supply from all quarters. Although much useful information has been given from time to time on this subject in medical and botanical works, a few recent notes may be found useful to many.

The simply inspissated juice of the leaves of the various species of the genus *Aloe* constitutes this well-known drug. It is best obtained by using neither heat nor pressure for extracting the sap. By re-dissolving the aqueous part in cold water and reducing the liquid by boiling to dryness, the extract of aloes is prepared. The quality of the product is apparently more dependent on soil, climate and preparation than on any specific difference in the plant itself. A great deal depends on the mode of preparation.

The usual way of extracting the substance is by making a transverse incision in the leaves, or cutting them off at the base; then scraping off the juice as it flows if done in the former way, or allowing it to run into a vessel placed for the purpose if in the latter. Pressure is made occasionally to assist the flow, but as Dr. O'Shaughnessy observes, "by this means large quantities of the mucilage are forced out and mix with the proper bitter juice which is proportionately deteriorated;" for it must be recollected that the aloe contains a great deal of mucilaginous matter, abundant towards the centre of the thick fleshy leaves. The juice, after being received into a vessel, is exposed to the sun or other heat by which means it becomes inspissated.

All species of this genus are highly valuable in countries where they are hardy, and can be used irrespective of their medicinal importance, to beautify any rocky or otherwise arid spot and as hedge plants.

Analysing the official customs returns and taking the imports through Egypt, Bombay and the East coast of Africa to be Socotrine and hepatic, the sources of supply were as follows in pounds:—

	Total receipts.	Cape.	Socotrine.	Barbados.
1867	781,306	630,688	80,906	58,202
1868	725,295	534,108	96,524	69,013
1869	661,559			
1870	701,573			

The deliveries for home use and export from the London warehouses in the past five years were as follows:—

	Cases.	Kegs.	Gourds.
1867	4347	138	1965
1868	3505	34	1858
1869	3451	26	918
1870	3092	83	747
1871	4346	19	804

The stock on hand in London at the beginning of this year consisted of 3538 cases, 98 kegs, and 607 gourds.

Cape Aloes.—*A. ferox*, Lamark, of South Africa, yields the best Cape aloes as observed by Dr. Pappe. *A. purpurascens*, Haworth, is also one of the plants which furnishes the Cape aloes of commerce, and so does *A. spicata*, Linnæus, an exceedingly handsome plant. This species is very common in the Madras Peninsula. The drug of *A. plicatilis*, Miller, acts milder than that of *A. ferox*. According to Thunberg, the finest gum-resin is obtained from *A. linguiformis* (or *angulata*), Miller. *A. Syheri*, Harvey, a magnificent very tall species, is doubtless valuable like the rest.

Dr. Pappe, in his 'Flora Capensis Medicæ Prodromus,' says the Cape aloes are procured from several species of this extensive genus so peculiar to South Africa. The *Aloe ferox*, Lam., a native of Swellandam is generally acknowledged to yield the best extract. That obtained from the *Aloe africana*, Miller, is also equally good, but not so bitter nor so powerful as a drastic. It is the produce of the Eastern districts of the Cape Colony, whence large quantities are annually exported. The drug commonly used by the colonists, is prepared from the *Aloe plicatilis*, Miller, whose extract is a much milder purgative, and much resembles the Barbados aloes. It inhabits the mountainous range near the Paarl Drakenstein and Fransche Hoek. It is much to be regretted that the farmers do not take more trouble in purifying this valuable drug.

Barbados Aloes is obtained from *A. vulgaris*, Lamark, *A. barbadensis*, Miller. It is met with in countries around the Mediterranean Sea, also the Canary Islands, on the sandy or rocky coast. Dr. Sibthorpe identified this species with the *Axon* of Dioscorides; hence it is not improbable that *A. vulgaris* is simultaneously also of American origin, although it is cultivated in the Antilles, and furnishes from thence the main supply of Barbados aloes. In the East Indies this species is also seemingly only existing in a cultivated state. Haworth found the leaves of this and of *A. striata* softer and more succulent than those of any other aloe. It is said to be the only species with yellow flowers among those early known. It is also this species only which Professor Willkolm and Professor Parlatore record as truly wild in Spain and Italy. Barbados aloes is chiefly sent in gourds.

Socotrine Aloes.—*A. Socotrina*, Lamark, is indigenous to the hills of the island of Socotra. It is also cultivated in Barbados and elsewhere, thus yielding the Socotrine aloes. It is difficult to ascertain what is the precise produce of the island now. Our imports are so mixed up with the Indian aloes which comes from Bombay and through Egypt, and from the east coast of Africa, that it is scarcely possible in the official returns to separate Indian and Socotrine produce. The Barbados and the Cape aloes used to be separated in the official trade returns, and all the eastern classed as Socotrine. Within the last year or two the Board of Trade officials have not thought it worth while, however, to classify the supplies, and we now only know the gross quantity received.

The East Indian or Hepatic Aloe, so called from its bright liver colour, is said to be the produce of *A. arabica*, Lam. Some quantity used to be shipped from Madras chiefly to Bengal and Australia. It comes here in casks or kegs. In India an inferior description of aloes is obtained from *A. indica*, Royle, and a better kind is procurable from *A. litoralis*, Kœnig, which grows plentifully at Cape Comorin and the neighbourhood; it is readily distinguishable by the reddish colour of its leaves. The natives attach much value to the juice of the leaves, which they apply externally in cases of ophthalmia, and especially in what are commonly called country sore eyes. The mode of administering it is to wash the pulp of the leaves in cold water, and mix it up with a little burnt alum. In this state it is applied to the eyes, being previously wrapped in a piece of muslin cloth.

IN A QUICKSILVER MINE.

"Grace Greenwood," who has been for some time travelling in the west of America, sends to the *New York Times* the following account of a recent visit to a quicksilver mine.

"It was a brilliant May morning when we set out from San José for the new Almaden Quicksilver Mine, some twelve miles away, in the Santa Cruz range of mountains, and on the Alamitos Creek. This quicksilver mine, the largest and richest in the world, with the exception of the old Almaden in Spain, was first known to white men as long ago as 1824, worked awhile for silver, and then for a long time abandoned. It is the most uncertain sort of mining, there being nothing like a regular vein of ore to follow, but only in many places very slight threads connecting the 'ore-spots,' while some of the deposits are isolated, lying hidden slyly away in nature's most secret drawers and dark pockets. The process of reducing the ore, of rousing the latent mercury from its sleep of a million or so of years, is very interesting and easy of comprehension, even to a woman, when patiently and pleasantly explained, as it was to us. It is simply burnt out of house and home, or its dull old body perishes by cremation, that it may appear in a glorified form, to shine and serve in a thousand beautiful ways. It is compelled to awake and come forth, or as an old miner said, to 'get up and git,' by intense and long-continued heat. The ore is put into furnaces, each holding 15,000 lb., and having in one end the fire, which is kept up for about three days. The vapours from the heated ores pass from the furnaces through small apertures, like pigeon-holes, into condensing chambers, on the cool walls of which the globules of mercury form and glide at once to the floor, where they collect in little gutters and flow out into troughs, which convey them to an iron cauldron, from which they are transferred to the wrought-iron flasks in which they are sent to market. Each flask contains $76\frac{1}{2}$ lb., the equivalent of 75 lb. Spanish measure, and is worth 40 dollars. It was strange to see this fluid treasure come flowing and flashing down like a mountain stream, to see it dipped up like so much spring water. The unstable, illusive character of this costly product is not understood by all visitors. Young and curious tourists have been known to attempt to carry away a thimble full or so in their pockets, and have confessed to having at once experienced a singular trickling, tickling sensation, usually passing like a streak of cold lightning down the right leg and into a boot. One elderly gentleman, by profession clerical, but by temperament mercurial, once succeeded in secreting a portion of quicksilver in his spectacle-case, which he carried in the same breast pocket with his watch. His little theft was not discovered at the time, but the next morning he indignantly proclaimed that he had been robbed. His valuable gold repeater had been taken from his pocket, and a silver watch put in its place. The contents of the spectacle-case had also mysteriously disappeared. Quicksilver in the mass has such a molten look that you shrink from touching it; but it is exceedingly cold. It gives you a strange sensation to plunge your hand into the solid, fluid, heavy, buoyant substance, which has the very chill of death, yet is alive in every infinitesimal globule. There seemed to be something unsubstantial about it, after all. I could clutch it, but not hold it. It was like palpable moonshine. I dipped my hand in up to the wrist, and not a particle adhered to my fingers. Silver never would stay by me. The manager first showed us the reduction works, of which I have tried to give some slight idea. I was surprised at the number of chambers necessary for the thorough condensation of the vapour. It sometimes passes through 10 or 11 before all the quicksilver is precipitated. The uncondensed and deleterious portions are carried on by flues into an immense high chimney, which lets them off when they can do no harm to man or beast. The stories of miners and mules 'perishing gloomily' of mercurial poison; of unhappy smelters 'working out their own salivation with fear and trembling,' are no longer to be credited. From the works we drove up the mountain to the new tunnel, which is the one most worked at this time. It is several hundred feet below the old workings, is about 2500ft. in length, 10ft. wide, and well timbered where it is not cut through the hardest kind of rock. Into this grand tunnel our party was taken in grand style. We rode in ore-cars, on blocks of wood, which made the most reliable sort of seats. We were drawn by a stout and serious-minded mule, and each fellow of us carried a lighted candle, stuck in a split stick. Thus we plunged into the darkness and silence of the inner earth, and woke the sullen echoes with laughter and merry shouts, and called out with our flicking torches momentary gleams from crystals imprisoned in the dull rocks for ages, dreaming of the light. Looking back from the first car in the procession, it had a strange wild look, and we all had a sense of something adventurous and mysterious, and delightfully awful and Arabian Nightish, about the expedition. We should hardly have been surprised to come upon the cave of the 'Forty Thieves,' with all their treasure in it—or, when we turned back to the day, to have found the door of the tunnel closed against us. When about 1800ft. in we left our cars and walked the rest of the way, and a wild, rough, pitfallish way it was, to drifts, where the men are now working at the new discoveries. The ore is very fine, and apparently abundant, the cinnabar showing in wide, long deposits, the rich, red arteries of the heart of the old mountain. The air in the tunnel and drifts we found not impure, damp, or oppressive, yet we were quite willing to return to the outside wind and warmth and sunlight, and drive down to the picturesque country-house built by General Halleck when he was manager of the mine; and then our friend and host proceeded to crown the courtesy which had made for us a day of unequalled enjoyment by having attached to his carriage four fresh, spirited, handsome horses; and so, in such state, he drove us back to our hotel at San José, through the splendours of sunset and the freshness of evening airs. Could anything have been finer or jollier, more nobby or nabobby, than that?"—*Times.*

THE LAST NEW METAL, INDIUM.*

BY WILLIAM ODLING, ESQ., M.B., F.R.S.

(*Concluded from page* 67.)

Lastly, a most important guide to the establishment of the atomic weight of a metal is the determination of its specific heat. In cooling through the same fall of temperature, different bodies, as is well known, give out exceedingly different quantities of heat. In the case of a pound of bismuth and a pound of brass, for instance, both raised to the temperature of boiling water, and then immersed in an excess of ice, the quantity of ice melted by the pound of brass in cooling down to the freezing point, will be found to be more than three times as great as the quantity of ice melted by the pound of bismuth. Now the determination of the specific heats of most of the metals, compared with the specific heat of an equal weight of water as unity, has been made with extreme care and exactitude by Regnault; and on looking at the following list of specific heats, mostly of his determination, it is evident almost at a glance that the specific heats of the metallic elements are inversely as their respective atomic weights. Thus, taking the first and last elements on the list for example, it is observable that the specific heat of lithium, or 0·94, is weight for weight thirty times greater than the specific heat of bismuth, 0·03; but then the atomic weight of bismuth is thirty times greater than that of lithium. And throughout, the product of the specific heat into the atomic weight of one metal, divided by the product of the specific heat into the atomic weight of another metal, is approximatively equal to one, as shown in the fourth column of the following table, in which the product of the specific heat into the atomic weight of silver is taken as the standard dividend. Now, only last year, concordant estimations of the specific heat of indium were made by Bunsen and a Russian chemist, Mendelejeff; the mean of Bunsen's two estimations being 0·0569, which it will be observed is very close to Regnault's estimations of the specific heats of silver, cadmium and tin. Accordingly, the atomic weight of indium must approximate to the atomic weights of silver, cadmium and tin; or, in other words, it cannot be $37·8 \times 1$ or $37·8 \times 2$, but must be $37·8 \times 3 = 113·5$; and the quantity of chlorine combined with this weight of indium being three times 35·5 parts, indium chloride will necessarily appear as a trichloride, and be expressed by the formula $InCl_3$. The determination of specific heats being a matter of direct experiment, with scarcely any ratiocination whatever, it seems impossible for any one to observe the relationship subsisting between the accepted atomic weights of the metals, deduced from experiment by a highly complex train of reasoning, and their directly ascertained specific heats, without recognizing that in the case of the metals, at any rate, the atomic weights of the chemist are something more than vain imaginings, but that they are beyond question the terse expression of a fundamental truth in nature.

The most important chemical characters of indium being thus established, there remains for consideration only the question of its affinities to certain of the previously-known elements. And seeing that the atomic

weights of the elements range from 1, the atomic weight of hydrogen, up to 240, the atomic weight of uranium, there opens out the further question, whether the more obvious chemical properties of the different elements are seriated in any way with their atomic weights; or, to put this last question in another form, whether the varied chemical properties of the elements are distributed among them haphazard, or according to some definite system of which the relationship subsisting between their several atomic weights may possibly serve as a key. Now the atomic weights, as distinguished from the combining proportions of yttrium, erbium, cerium, lanthanum and didymium, must be regarded for the present as quite unknown. Out of the fifty-eight elements, however, of which the atomic weights have been more or less well determined, forty-six have their several atomic weights ranging from 1 to 137, in an almost unbroken succession. Ten of the other twelve have atomic weights ranging from 184, that of tantalum, to 210, that of bismuth; while the remaining two, namely, thorium and uranium, have the closely-approximating atomic weights 238 and 240 respectively. In the above table, the symbols of the forty-six elements having atomic weights ranging from 1 to 137, are set down in the order of the atomic weights of the elements symbolized,—save only in the case of tellurium, of which the symbol is placed immediately above, instead of below that of iodine, and of which the atomic weight may not improbably have been somewhat over estimated. And violating the order of numerical seriation in this small particular only, it is remarkable with what facility the symbols of the forty-six elements may be arranged in parallel lines and columns, corresponding to a natural classification of the elements themselves into analogous groups and series. Indeed, a study of the entire number of elements at present known, would seem to indicate that they are one and all associated with each other by a certain community of relationship; of which the well-known gradation and parallelism in properties and atomic weights, of the members of the alkali and earth-alkali, and of the halogen and oxygen families of elements afford only the most prominent examples.

ELEMENTS, IN ORDER OF ATOMIC WEIGHT.

Taking the second line of the table as an illustration, it is observable that the seven metals symbolized thereon are distinguished from all the others by their common property of forming one chloride only, and that a dichloride; further, that the metals figuring in the uneven-numbered columns of this line, namely, magnesium 24, zinc 65 and cadmium 112, are permanent in the air, are volatilizable in the direct, and basylous in the inverse order of their atomic weights, and are otherwise specially associated with one another; while the similarly associated metals of the alternate or even-numbered columns, namely, calcium, 40, strontium, 87·5, and barium 137, are quickly oxidizable in the air, are practically non-volatile, and are basylous in the direct instead of the inverse order of their atomic weights; and similarly, on the other lines of the table, the elements symbolized are divisible into sub-groups, according to their odd and even positions respectively.

Such being the relationship of the elements placed on the same line, the relationship of those in the same column is of a different kind. Taking the third and seventh columns by way of illustration, it is observable that the consecutive elements in each column have closely consecutive atomic numbers; that the element on the first line forms a mono-chloride; that on the second line, a di-chloride; that on the third line, a tri-chloride; and that on the fourth line, a tetra-chloride; while those on the fifth, sixth and seventh forms oxide or oxichlorides, corresponding to a penta-, hexa-, and hepta-chloride respectively.

By reason of its atomic weight, 113·5, indium is observed to figure on the third line and seventh column of the above table; but its position among the elements is better recognizable by a glance at the table below, containing a portion only of the preceding one, supplemented by an additional column of elements of higher atomic weight than any of those included previously.

In respect of its atomic weight, then, triad indium occupies a position exactly intermediate between the positions of diad cadmium and tetrad tin, to both of which metals it presents a most marked resemblance in properties. They all three have the same extreme degree of fusibility, and much the same oxidizability and reducibility. Their sulphides are alike characterized by a yellow colour, that of cadmium, Cd S, being neutral; that of tin, Sn S_2, being acidulous; and that of indium, $In_2 S_3$, being strictly intermediate.

	3	7	10	Type.
I. . .	Na 23	Ag 108	. .	R Cl
II. . .	Mg 24	Cd 112	Hy 200	R Cl_2
III. . .	Al 27·5	In 133·5	Tl 203	R Cl_3
IV. . .	Si 28	Sn 118	Pb 207	R Cl_4
V. . .	P 31	Sb 122	Bi 210	R Cl_5
VI. . .	S 32	Te 129	. .	R Cl_6

Viewed in another aspect, triad indium occupies a position intermediate between the positions of its remote triad congeners, aluminium and thallium. The mean atomic weight of the three metals being 114·3, the atomic weight of indium is 113·5. The mean specific gravity of the three metals being 7·3, the specific gravity of indium is 7·4. And in respect of purely chemical habitudes, hydrated alumina and hydrated india might easily be mistaken for one another. It is interesting, moreover to remark that the last-discovered two metals indium and thallium—discovered, it will be remembered, by the same process, that of spectrum analysis—should bear to one another much the same sort of relation that is borne to one another by the jovian and saturnine metals of the alchemical or even pre-alchemical era. Just, for example, as the unstable and least-known chloride of lead, $Pb\,Cl_4$, corresponds to the stable chloride of tin, $Sn\,Cl_4$, so does the unstable and least-known chloride of thallium, $Tl\,Cl_3$, correspond to the stable, and as yet only known, chloride of indium, $In\,Cl_3$, as suggested, indeed, by the lecturer some six or seven years ago.

The study of such relationships necessarily suggests many inquiries. Arranging the entire fifty-eight elements of which the atomic weights are known, in a table similar to the preceding one for the forty-six elements having atomic weights not exceeding 137, some twenty or five-and-twenty new elements would be required to fill up the gaps in the different series; but why should not new elements be discovered having atomic weights as much above that of uranium, 240, as its atomic weight is above that of barium, 137?

Again, does it seem probable that bodies capable of being arranged in such a well-marked numerical series, are really elementary and mutually independent; or is it more likely that the gradation of properties and atomic numbers manifested by these bodies, depends on their possession of different increments of common material?

May it not be that the numerical ratio between the atomic numbers of proximate elements, $\frac{x}{y}$ = approximatively $\frac{y}{z}$, is really absolute; and that it will hereafter be proved to be so by a better determination of atomic weights. Seeing that a short time back, cæsium with the atomic weight 133, and rubidium with the atomic weight 85, both occurred as unrecognized impurities in potassium with its atomic weight, 39, who shall answer for the absolute accuracy of even the best established of our present atomic weights?

Again, the mean difference in atomic weight between consecutive analogous elements, is, in the case of the nine following pairs of elements, lithium and sodium, glucinum and magnesium, boron and aluminum, carbon and silicon, nitrogen and phosphorus, oxygen and sulphur, fluorine and chlorine, sodium and potassium, magnesium and calcium, 16·1; the lowest difference being 15, and the highest 17. The mean difference in the case of the four following similar pairs of proximate elements, phosphorus and vanadium, sulphur and chromium, chlorine and manganese, arsenic and niobium, is 19.25; the lowest difference being 19, and the highest 20·5. Lastly, the mean difference in the case of the seven following similar pairs of proximate elements, calcium and zinc, vanadium and arsenic, manganese and bromine, rubidium and silver, strontium and cadmium, silver and cæsium, tantalum and bismuth, is 24·6; the lowest and highest differences, even in the case of these elements of such high atomic weight, being 23 and 26 respectively. Are these differences in atomic weight only approximatively, or are they indeed absolutely, 16, 20 and 24 respectively; and if so, why should the numerical difference between proximate associated elements be 16 in one set of cases, 20 in in another set, and 24 in a third?

TURBIDITY OF LONDON WATER.

In a Report to the City Commissioners of Sewers for the year 1871, Dr. Letheby makes the following remarks on the alleged turbidity of the London water-supply:

"The water supplied to the City by the New River and East London Companies has been invariably bright and nearly colourless; and so also has been that of the Kent and West Middlesex Companies; but that of the Southwark and Vauxhall Company has been turbid on one occasion, that of the Lambeth Company on five occasions, and that of the Chelsea and of the Grand Junction Companies on eight occasions respectively. The turbidity has been at all times due to the presence of a very small quantity of finely-divided clay, in which there was occasionally a trace of vegetable tissue; and no doubt it had been caused by the heavy floods of the river. Although perfectly harmless, a slight turbidity of the water is sure to command attention, and may easily be made the subject of popular clamour."

The *Lancet* in publishing these remarks comments on them as follows:

These statements are so positive, in some respects so improbable, and in all so different from those published by the Registrar-General on the authority of Dr. Frankland, that we are compelled to examine them somewhat critically. And we must confess that the more we examine them the more unsatisfactory do they appear to us. On the mere question whether the waters are clear or turbid, for example, we often find the reports of householders in direct opposition to that of Dr. Letheby. A lady who lives at Wandsworth complained to us the other day that the water supplied to her was never quite clear, and was often "muddy." She is compelled to refilter every drop used in the house, and asserts that the members of her household know the difference in *taste* as well as in appearance between the filtered and unfiltered water. A tumbler of each was brought to us; we saw the difference at a glance, although the weather was dry, and the water in consequence better than usual. How is this to be reconciled with Dr. Letheby's statement, that in 1871 the water of the Southwark and Vauxhall Company was turbid "on one occasion."

Again, with regard to the quality of the turbidity. How can Dr. Letheby prove that of all the foul impurities which mix with the sources of our water-supply only "clay and vegetable tissue" are able to pass through the filters? We all know the difficulty of separating clay from water by filtration, but surely the very fact suggests the idea that other matters, more noxious and less easy of recognition, may be equally difficult to remove. And here, again, the idea is confirmed at once by common observation and by experiment. Our Wandsworth friend informed us that three times in the last few years the water-pipes of her house had been choked up with large eels; and stories of this kind are pretty rife. Does Dr. Letheby reckon an eel as clay or as vegetable tissue? The evidence of experiment is even stronger. Dr. Frankland found that water contaminated with one-five-hundredth of the rice-water discharge of cholera remained opalescent after filtration through paper, or even animal charcoal, both much better filtering materials than the sand used by water companies. That sand should be capable of removing organized germs—spores, ova, or corpuscules—from water which contained them is indeed a notion so improbable as to be almost absurd. Dr. Letheby would seem to concede as much; for he quotes with approval the remarks of Major Bolton, that "it is impossible altogether to get rid of the simplest forms of vegetable life by the most perfect filtration."

The case, divested of all exaggeration, appears to stand thus:—It is highly probable that imminent risk attends upon the use of water which contains in suspension certain low forms of life, though it is conceded that other forms of life are harmless. It is a fact that noxious and probably organized matters are introduced into the sources of our water supply; and it is furthermore a fact that one, at any rate, of the most noxious of these matters—the discharges of cholera—will pass through all filters. How then can Dr. Letheby, or any one else, prove to us that no such noxious matter is ever present in the water supplied to our houses? As we understand it, Dr. Letheby's answer is twofold. Firstly, he tells us he knows by his experience that all dangerous matter must have been destroyed by oxidation in water which has been exposed to the conditions of the London water-supply. This argument we may set aside as a bare opinion. It is obvious that no amount of mere experience can decide the question. Dr. Frankland and Sir Benjamin Brodie have come to a different conclusion, and they are surely as well entitled to have an opinion as Dr. Letheby. Secondly, Dr. Letheby relies on his analysis of the water, which tells him that the quantity of organic matter in it is very small and not noxious. How far his analysis may be trusted for this all-important proof a single example will show. In the report which we have before quoted he says:—"The proportion of organic matter in the water has been very small, for the quantity of oxygen required to act on every description of oxidizable matter has ranged from only 0·01 of a grain per gallon in the chalk water of the Kent Company, to 0·102 of a grain in the Thames water supplied by the Grand Junction Company." Now Dr. Frankland has found that water contaminated with one-five-hundredth of rice-water discharge—that is, water which contains in every gallon 140 grains of the evacuations of a cholera patient—only requires, after filtration, 0·03 of a grain of oxygen per gallon for its oxidation. In other words, such a deadly mixture as this would exhibit under this test less than one third of the pollution of the Grand Junction water!

HEAT AND THIRST, AND SOME OF THEIR POPULAR ANTIDOTES.

By the Author of a "Report on Cheap Wines."

I think I may appeal to experience and the instincts of mankind, that something more than mere water is required to gratify the compound craving called thirst. *Lew*, or as it is more commonly called *luke-warm* water, supplies the place of fluid, and so far does good, but it is not a true quencher of thirst, whilst from its negative properties, being neither hot nor cold, and so incapable of exciting the nerves of sensation, it has become a byword for everything nauseous, disgusting, and contemptible, both moral and physical. "Because thou art lukewarm, and neither hot nor cold, I shall spue thee out of my mouth," says the Apocalyptic writer. A lukewarm ally is usually more disgusting than an open enemy.

Heat is by no means a bad antidote to thirst, if a liquid be sipped which is hot enough to produce some pungent effect on the tongue. This may be effected by tea or coffee, the surface of which is often sipped at a temperature of 130° to 140°. Of course, if the aromatic and astringent and stimulating elements of tea or coffee are present, the nervous exhaustion, of which thirst is a symptom, will be more effectually combated, but even hot water sipped is better than lukewarm. Thirty years ago dyspeptic physicians used to order their patients to sip with their meals water as hot as they could bear it.

But the stimulant effect of cold is far more sought after than that of heat, and is more appropriate. Let it be observed that it is much abused: that ice taken in excess enfeebles the stomach, and that some people are as really intemperate in gulping down unmeasured draughts of cold liquid, for the relief of an unpleasant sensation, as others are in the use of alcoholic drink. To drink to excess for mere pleasure is intemperate, be the beverage what it may.

Next to cold, carbonic acid is the most popular stimulant and the most beneficial. It may be had in natural waters, as the Nassau, Seltzer, and Apollinaris, or in waters aerated under pressure, or in liquids in which it is evolved by fermentation. Of the aerated waters in popular use, some are very vapid; the gas escapes at once on exposure, and the result is hardly more satisfactory than that of pure water. There is an immense difference to the *connoisseur* between such waters as those of Ellis of Ruthin and those which may be got over a confectioner's counter. Perhaps for a mere summer draught it does not much matter; but in the treatment of disease the "seltzer-" or "soda-" water prescribed should be from a good maker, who is careful in the choice of his raw material—the water—and has a first-rate plant for aerating it.

The next and most obvious method of any for evolving carbonic acid is by fermentation; and this method of preparing a popular drink that shall be cold, aerated, subacid and stimulant, deserves not the contempt with which some may be inclined to regard it as beneath the notice of political philosophers. Given heat and thirst, and a natural tendency to allay their effects, it is to the public interest that drinks shall be readily accessible which are better than water, more refreshing, more quenching to the thirst, containing some alcohol, and yet not enough to do mischief. Such a drink is that beer which ought to be brewed in every household, from white sugar, a small quantity of cream of tartar, a little lemon-juice and peel for flavour, and a liberal allowance of infusion of ginger. Such real fermented ginger-beer is very different from a mere ginger-drink aerated by forcing carbonic acid into it. Sugar, which ferments with yeast, yields carbonic acid in abundance, but alcohol even more abundantly; this may be easily produced from ginger-beer by distillation, and ginger-beer is as strong as any other cheap "small" beer. The carbonic acid is better combined, and more telling to the palate. Then there is the ginger, a good stimulant, which substitutes a grateful warmth on the soft palate for the flabby nauseousness of atonic thirst, and which corrects the faults of a cold acid drink. I am perfectly certain that this drink, well prepared and cheap, would be a serious antidote to the public-house bar in summer.

Some years ago I was Medical Officer of Health of the district, and tried hard to get at the secrets of the "poor man's home"—how they live; what they do with their money; whether the obtrusive almsgiving which is practised does good or harm. Now, the time to see the London working classes at home, and as they are, is on a Sunday morning, when all the respectable people are at church; and many a Sunday morning from 11 to 12.30 did I spend in these explorations. One such morning I spent chatting with the keeper of a little "general" shop at the back of Grosvenor Square, and was both amused and instructed by the run of custom that was going on all the while—more especially at the number of women, of the class of mechanics' wives, who came in for ginger-beer. "You see, sir," said the mistress of the shop, "that whilst the public-houses is closed, ginger-beer is the only thing they can drink of a morning, and we sell a good deal every Sunday." It were to be wished that they took nothing worse at other times.

There is a modification of ginger-beer called *pepper-punch*, the receipt for which I learned from a West Indian family, (West Indians, by the bye, are famous for their knowledge of gastronomy), and which I have at times found very serviceable in treating persons fond of taking "too much," with atonic stomachs, nausea, thirst, and the like. It is made as ginger-beer, but heightened in piquancy and endowed with a most agreeable flavour by adding some of the green pods of the capsicum. The West Indian receipt, I am sorry to say, orders the addition of about a teaspoonful of rum to each half-pint bottle. This gives it a finish which few ladies can resist; but, although I urge the use of stimulants and of wine in moderation for the more effectual quenching of thirst, yet I am afraid we must draw a line at pepper punch, and leave out the rum.

The Pharmaceutical Journal.

SATURDAY AUGUST 3, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ADULTERATION OF FOOD, DRUGS, ETC., BILL.

WHEN, at the beginning of the present session, the above Bill, as printed in the last volume at p. 715, was introduced into Parliament by Mr. MUNTZ, it naturally attracted the attention of persons likely to be affected by its provisions. While it was felt that the object sought to be attained was a good one, it was also known that great care and circumspection would be required in working out the details, or the hardships created by such a law would render it a dead letter through the difficulty of carrying it out.

What should constitute an adulteration under such an Act? The question is one that has been asked many times without being satisfactorily answered, and the Bill, as it originally stood, contributed nothing towards the solution of the problem. In fact, one part of clause 2, which provided that "every "person who shall sell as pure and unadulterated any "article of food or drink or any drug which is adulte-"rated or not pure" should be liable to a penalty of twenty pounds and other inconveniences, was, if carried out, sufficient to make the words "pure and unadulterated" a terror to all sensible men.

Curious evidence of the various meanings that might be attached to the words "pure and unadulterated" was given in the slight debate which took place on the second reading. Mr. MUNTZ, himself, pleading for the Bill, said, "If one choose to mix "beans with coffee, or water with milk, no one under "this Act could say anything; but if any baker "adulterated his bread with brickdust, or poison of "any sort, or with plaster of Paris, the clauses of "this Bill would render him liable to severe punish-"ment." On the other hand, Sir D. CORRIGAN objected to immunity attending such processes as mixing water with milk, and said that adulteration meant either adding to or subtracting from an article.

With so much vagueness respecting the principal object of the Bill, it is not surprising that there should have been a general opinion that the subject should be dealt with by the Government in their Public Health Bill, and progress was deferred month after month for this purpose, until further hope was prevented by the mutilation of the Government measure. Then, at the fag end of the session, this important Bill was pushed through its remaining stages in the lower House, and to a second reading in the House of Lords, with no more notice than could be described in six lines of a newspaper report.

This being the case, and the danger being great that the Bill would pass with all its imperfections, and probably become a source of annoyance to chemists and druggists, prompt action was taken by the Parliamentary Committee of the Council of the Pharmaceutical Society. A deputation, consisting of the PRESIDENT, Mr. HILLS and Mr. SANDFORD, sought an interview with the Marquis of SALISBURY, who has charge of the Bill, to urge their objections to certain features of it as it stood; and, fortunately, they succeeded in obtaining his consent to the modification of one or two of its most obnoxious points.

It will occur to many of our readers that the word "pure," in the penal clause, when applied to some drugs, might be so construed as virtually to prohibit their sale. The omission of the words "pure and" removed this danger, but still left the difficulty as to what constituted an adulteration. This it was sought to meet by adding a clause containing a definition of "adulteration," which, especially as it is now qualified by the important word "fraudulently," introduced at the request of the deputation, will have the effect of considerably narrowing the range of interpretation that might have occurred had it been left to the individual opinion of judicial authorities. The following are the words of the new clause:—

"Any person who shall sell any article of food or "drink or any drug, knowing the same to have been "mixed with any other substance with intent *frau-"dulently* to increase its weight or bulk, and who "shall not declare such admixture to any purchaser "thereof before delivering the same, shall be deemed "to have sold an adulterated article of food or "drink or drug as the case may be, under this Act."

There are sundry other alterations, mostly verbal, in the Bill; thus, the duties of the inspectors appointed under it are now made compulsory, also the appointment of analysts, which before was left at the option of the local bodies, is now made compulsory upon the request of certain authorities; but since at the time of going to press the Bill has not been read a third time in the House of Lords, and most of the amendments will have to be submitted to the House of Commons, we refrain from reprinting it *in extenso* until next week.

THE KEW CONTROVERSY.

THE storm which Mr. AYRTON has raised by his treatment of Dr. HOOKER, will probably be sufficient to teach even him that courtesy is as absolutely necessary in the head of a great department as in the humblest functionary under his control. The debate in the House of Lords on Monday night fell rather flat through the absence of the person whose conduct was arraigned. But Lord Derby's speech was temperate and forcible, and its fairness contrasted strongly with the insinuation of Lord Stanley of Alderley, that the celebrated memorial to Mr. Gladstone, signed by eleven leading men of science, was not called forth by sympathy for Dr. Hooker, nor ill-will to Mr. Ayrton, but by the fact that Professor Owen had expressed certain views in a recent Blue Book. This is not the way to meet such a charge as that made against the First Commissioner of Works, in which his colleagues, to judge by a recent Treasury minute, appear to some extent to concur, and most people now think that it is quite time that the person principally concerned had made a reply to it from his place in the House of Commons.

The Calcutta correspondent of the *Times* writes that the Government of India have conferred the title of Rai Bahadoor upon a purely native medical man, Baboo Kanny Loll Dey, teacher of chemistry and medical jurisprudence in the Medical College, Calcutta, and Honorary Member of the Pharmaceutical Society of Great Britain, in recognition of his services to medical science. The *Sunnad* was presented at the inaugural lecture of the session amid much applause, and was followed by very hearty congratulations. The native Press is quite enthusiastic on the subject. The title is equivalent to our order of knighthood, and is highly esteemed in India.

We are informed that, in consequence of an intimation that such a course would be more agreeable, it has been resolved by the Brighton pharmacists to invite the members of the Pharmaceutical Conference to meet them at a cold supper instead of the proposed dinner. Members of the Conference wishing to be present are requested to communicate with the Local Secretary, Mr. Thomas Glaisyer, 12, North Street, not later than Saturday, August 10th, in order that arrangements may be made for a specified number.

Another instance of the manner in which sometimes at the end of a session a Bill undergoes important modification with scarcely any discussion occurred last week. So much of the original Public Health Bill had been sacrificed to the necessity of time that it would have appeared hopeless to expect the introduction of any clauses dealing with the metropolitan water supply. But the proposition of Mr. Kay Shuttleworth, carried by a majority of 177, to transfer the statutory powers of supervision over the companies supplying the metropolis with water, hitherto possessed by the Board of Trade, to the Metropolitan Board of Works, may possibly lead to some improvement. The members of the Board of Works have no personal an interest in the matter, and they have already exerted themselves so well to secure a constant and improved supply, that it may be hoped they may be able to overcome the inertia with which the Companies have so long baulked the just desires of the consumers.

It is a fact beyond dispute that the great International Shows which were inaugurated in 1851 have not been productive to any appreciable extent of new economic or pharmaceutical products. No doubt they have acted as incentives to arts and manufactures, and the annual recurrence of these Exhibitions, confined as each one now is to particular or special objects, will no doubt prove of more lasting value to those whose interest is centred in one or more of the sections.

According to the arrangements at present issued for the next eight years, one section of the Exhibition next year will come more under our own ken than that of the present or last year; for amongst the subjects for 1873, under the general head of "Substances used for Food" will be exhibited drysaltery, grocery, preparations of food, wines, spirits, beer and other drinks and tobacco. Though these are not subjects immediately connected with this Journal, there are off-shoots which will make the exhibition of some interest in a pharmaceutical point of view. It is not, however, till 1880 that we are promised a full recognition of our own direct branches of science, but in that year "chemical substances and products, and experimental pharmaceutical processes," etc., will form one of the most conspicuous divisions.

We are led to these remarks by a consideration of the divided opinion as to the value or otherwise of these international shows, and by the attempt this year of the officials having charge of the Queensland Annexe to introduce a new article to British pharmacy, in the shape of the oil of the Dugong, an account of which we gave at p. 3 of the present volume of the Journal,

In the great Exhibitions of London and Paris from 1851 down to 1867, chemical and pharmaceutical products found a special feature in some of the Colonial collections, and these were duly reported upon by juries of competent men, but the efficacy of the articles or their preparations were never made the subjects of actual tests. An exception, however, to the rule occurred at the close of the Exhibition of 1862, when, at the instance of Baroness (then Miss) Burdett Coutts, the collection of medicinal barks of British Guiana and Trinidad were subjected to the test of actual experiment in the treatment of diseases by Mr. Charles Hunter at the Royal Pimlico Dispensary; but, besides a published report, we are not aware of any good accruing from this investigation, or of further notice being taken of the substances. The success which, it is said, has attended the use of Dugong oil in Queensland, and the sanguine hope of the promoters of its ultimate adoption in this country, is a sufficient recommendation that new articles with strongly reputed medicinal properties should be fairly and satisfactorily tested.

Provincial Transactions.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

At a special meeting of the Council of the Sheffield Pharmaceutical and Chemical Association, held Thursday evening, July 25th, for the purpose of considering the scheme for provincial education proposed by Mr. Schacht.

The following resolution was proposed by Mr. G. B. Cocking, seconded by Mr. Wilson, Local Secretary of the Pharmaceutical Society, and carried unanimously.

"That this Council, whilst assenting to the general principles of Mr. Schacht's scheme for promoting provincial education as adopted by the Council of the Pharmaceutical Society at their meeting, held July 3d, 1872, and published in the Journal of July 6th, are of opinion that the *mere* payments of money on the result of local examinations to the amount of £1 and £2, to students passing in the proposed second and first-class grades, would in this locality prove comparatively insignificant and totally inadequate to the requirements of this association.

"That the proposal to make grants of money towards tthe formation of libraries, museums, etc., is not stated in terms sufficiently explicit; and that the proposed additions thereto by Mr. Frazer as published in the Journal, July 13th, page 29, are much more equitable, and likely if adopted to prove satisfactory to this and many other provincial associations, viz., 'that the award of money in aid of any scheme which shall have a distinct scientific educational object' should *include* the payment of fees to teachers or lecturers employed by such provincial associations.

"They concur with Mr. Hills in his suggestion—(Journal, July 6th) that a complete account of all the results accomplished by any association need not be required, so long as a properly elected committee of management guarantee that the funds at their disposal should be appropriated in furtherance of such scientific pharmaceutical education."

BRISTOL PHARMACEUTICAL ASSOCIATION.

The annual meeting was held on Wednesday, July 31st; Mr. Townsend, President, in the chair.

After a few introductory remarks, the President requested the Hon. Secretary, Mr. Schacht, to read the Report, which was as follows:—

"The Council of the Bristol Pharmaceutical Association have the pleasure of offering the report of another year's proceedings.

"Commencing with the least satisfactory portion of their duty, they have to admit that as yet but little has been done towards the provision of a museum and library, the original difficulty, namely, the want of suitable rooms having still to be overcome. Some progress, however, has been made towards the raising of a fund to start the project with some effect when the favourable moment arrives.

"The monthly evening meetings have been fairly attended. Through the kindness of certain gentlemen, whose interest in the progress of science appears never to halt, the Council have been able to announce some very interesting lectures during the past session. Mr. Stoddart, Mr. Collens, Mr. Harding Warner, Mr. Lant Carpenter and Dr. Tilden have met the association on these occasions, and have delighted and instructed their audiences.

"One of these monthly meetings was set apart for the reading and discussion of papers upon subjects connected with pharmacy. That evening was fully and profitably occupied, and the Council have reason to believe that if more opportunities had been offered, a proportionate number of papers would have been presented.

"With regard to the systematic courses of lectures upon chemistry and botany provided by the Association, the Council are glad once more to be able to point to the evidences of the success that attends the teaching in these classes. The results are most encouraging, and cannot fail to attract larger numbers of students in future sessions.

"For the Botanical Class, nine of our students entered, and the following succeeded in passing the Government examination:—

Structural and Economic Botany.

Mr. Charles Bennett	Advanced Grade	2nd Class.
Mr. Ernest Samson	" "	" "
Mr. Henry Stephens	Elementary Grade	" "

Vegetable Anatomy and Physiology.

Mr. Ernest Samson	Advanced Grade	2nd Class.
Mr. Charles Bennett	" "	" "
Mr. Henry Stephens	Elementary Grade	" "

"For the Class on Chemistry, seventeen of our young pharmacists entered; of these, twelve went in for the Government examination, and all succeeded in passing. The following is the list:—

Mr. A. Little	Advanced Grade	1st Class.
Mr. C. Bennett	" "	" "
Mr. C. J. Miles	" "	" "
Mr. T. Stubbs	Elementary Grade	" "
Mr. J. G. Taylor	" "	" "
Mr. J. Goulter	" "	" "
Mr. W. Crocker	" "	" "
Mr. W. E. Milton	" "	2nd Class.
Mr. J. T. Callis	" "	" "
M. C. G. Boorne	" "	" "
Mr. R. H. Nuttall	" "	" "
Mr. W. H. Wheeler	" "	" "

"These are the results of the ordinary examination in inorganic chemistry. But in addition to the questions of which this was constituted, the examiner, Dr. Frankland, thought right to append others directed especially to the object of ascertaining the *practical* acquaintance of the students with the subject of their examination. These he treated as a separate examination, and gave the following award:—

Mr. A. Little	Advanced Grade	1st Class.
Mr. C. Bennett	" "	" "
Mr. J. Goulter	Elementary Grade	" "
Mr. J. T. Callis	" "	2nd Class.
Mr. R. H. Nuttall	" "	" "

"The Council have, moreover, every reason to believe from communications already received from the Department, that a Queen's medal will be awarded to one of the above students. As the official announcement, however, is not yet received, they reserve for the present the publication of the student's name.

"The Council have also to report that during the past year a most useful course of lectures was delivered by their late president, Mr. Stoddart, upon the Chemistry, Botany, and Materia Medica of the Pharmacopœia, and that it was attended by a numerous and very attentive class. The fees paid by the students who attended this course, and which amounted to the sum of £17. 17*s*., have been set apart as the nucleus of the Museum and Library Fund, and those gentlemen are congratulated upon having so materially assisted in laying the foundation of what is hoped to be a very useful feature in the scheme of the Association. The Council feel that the part taken in the matter by Mr. Stoddart has earned for him the gratitude of every member of the Association.

"The Council also consider that special thanks are due to those who, by their earnest efforts in the cause of 'earlier closing' have done much to secure the provision of a due proportion of leisure for the assistants and apprentices of the trade, and they sincerely hope these increased opportunities will be turned to good account

"The Council, therefore, believe that the general estimate of the proceedings of the past year will, upon the whole, be attended by a feeling of content; and after a careful review of the history of the Association throughout the period of its existence, they are of opinion that its present position and prospects and the work it is doing fairly realize the hopes of its founders and justify the labour bestowed upon it.

"They have, moreover, observed with considerable gratification that the Bristol Pharmaceutical Association is regarded with interest, and is spoken of with some respect by many who are utterly unconnected with the locality; and chiefly, as it would seem, for the prominence it gives to the provision of means for the systematic scientific training of its younger members. Confirmed as they thus are, by the opinion of others as well as by their own experience, in their impression of the wisdom of this feature of their scheme, they once more urge its importance upon the consideration of their fellow-members and beg them to use their best efforts to enlist to the utmost degree the interest of the juniors themselves in the measures adopted to so large an extent for their especial benefit."

The following is the report of the Treasurer:—

The Bristol Pharmaceutical Association in account with
JOHN STROUD, *Treasurer.*

1871.	For the Year 1871 and 1872.	Dr. £ s. d.
July 21.	To Balance received from late Treasurer, Mr. Taplin	19 11 1
,,	,, ,, on Prizes from Mr. Taplin	0 13 6
,,	,, 59 Members' Subscriptions at 10*s*. 6*d*. each	30 19 6
,,	,, 40 Associates' Subscriptions at 5*s*. each	10 0 0
,,	,, Lecture Fees from 18 Associates at 5*s*. each	4 10 0
,,	,, Extra Fees from three Absentees at Examination	0 15 0
		£66 9 1
	To Balance	13 12 5

1871.	For the Year 1871 and 1872.	Cr. £ s. d.
July 21.	By Ledger and Receipt Book	0 8 0
Sept. 5.	,, Cash to Professor Leipner for four Absentees at Examination, 1871	1 0 0
,,	,, ,, Professor Coomber for eight Absentees at Examination, 1871	2 0 0
,, 22.	,, ,, Honorary Secretary for Current Expenses	1 11 6
Oct. 31.	,, ,, Jeffries for Binding four Books	0 10 0
Nov. 2.	,, Lecture Fees to Professor Coomber	7 7 0
,,	,, Lecture Fees to Professor Leipner	7 7 0
1872.		
Jan. 23.	,, Cash to Arrowsmith for Printing	2 10 6
Feb. 2.	,, ,, Honorary Secretary for Stamps, etc.	1 0 0
,,	,, Lecture Fees to Monthly Lecturers	5 5 0
Mar. 18.	,, Carriage of Photographs for Mr. Warner's Lecture	1 4 9

Museum Account.

1872.		£ s. d.
Jan. 23.	To Cash received from Mr. Stoddart for Lecture Fees from seventeen Students who attended his classes	17 17 0
		£17 17 0

Examined the above Account with the Vouchers, and found correct.

WM. HY. COLLINGS, *Auditor.*

The President moved the adoption of the report. The motion having been seconded by Mr. Towerzey, was carried.

The result of the election of members for the new Council was then announced. The names were:—Messrs. Boorne, Boucher, Giles, Isaac, Martin, Player, Pitman, Schacht, Stoddart, Stroud, Taplin and Townsend.

Mr. Collings was appointed to act as Auditor for the ensuing year.

A vote of thanks to the retiring Council was then carried, and the proceedings terminated.

At a subsequent meeting of the Council, the following officers were elected:—President: Mr. Townsend. Vice-President and Treasurer: Mr. Stroud. Joint Honorary Secretaries: Mr. Schacht and Mr. Pitman.

NORTHAMPTON CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The monthly meeting was held on July 29th, 1872; Mr. H. J. Masters, President, in the chair.

The Secretary, Mr. Druce, having read the minutes of last meeting, and a letter which had been sent by Professor Attfield inviting the association to send delegates to the meetings of the Pharmaceutical Conference at Brighton, said that since their last meeting, they had received from Messrs. Evans, Lescher and Evans a very handsome cabinet of Materia Medica specimens; also several specimen prescriptions from various sources.

Mr. Masters, in referring to the invitation sent by Professor Attfield, said he was sure the association would be much gratified if the secretary could make it convenient to represent them. He then continued,—We have met this evening for the express purpose of commenting upon the scheme brought forward by Mr. Schacht; and, while I feel all must be thankful to him for what he has done, I think every one must see it is impossible for the *third principle* to be carried out if the *second process* by which the aid is to be given be adopted. With regard to persons eligible to earn prizes and payments, it seems to me scarcely a pleasant position for a chemist in business to be in, or fair to his apprentice, for both to be striving for the same prize. Then, again, how would it be possible for associations to remunerate qualified teachers if those members who had passed the Minor examination are not eligible to earn money for their association? I believe that associations consisting of apprentices and assistants *only* would be better attended and prove more useful than those which comprise both employers and employed; for, what assistant would like to be asked a simple question in the presence of an employer and be unable to answer it? My opinion is that all that is wanted is what has been already done, only carried out more liberally; that is, to give help where there is a disposition to self-help, and to those who are found either through the local secretary or an inspector to be deserving. I shall now move,—

"That, in the opinion of this association, great credit is due to Mr. Schacht for the interest and trouble he has taken in pharmaceutical education, also that the three principles he has laid down are most excellent; but, at the same time, it would be impossible for them to be carried out if this scheme be adopted, since his proposed plan could not meet the requirements of a great majority of students."

The resolution was seconded, and carried unanimously.

Mr. Lance, in proposing the second resolution, pointed out the disadvantages of having both employers and employed members of the same association, and instanced the objection many assistants would have to attending if their employers were present; he said he had no doubt that his resolution would meet with their hearty approval—

"That as hitherto associations conducted by apprentices and assistants had been equally or more successful than those managed by chemists and druggists, it would not be advisable to compel associations to alter their rules so long as they meet with the Council's or Local Secretary's approval."

This having been seconded, was carried.

Mr. Branson said that it was proposed that no student should be allowed to compete unless he had attended twenty out of twenty-five lecture, Now, how could students, in houses of business where only two were kept, contrive to get out that number of times? How many members of that association would, if that rule were carried out, be eligible? Not more than two or three; and if their employers also were allowed to compete, not one of those for whom this scheme was especially designed would be eligible. He should accordingly move,—

"That as it will be perfectly impossible for more than 25 per cent. of students to attend the lectures a sufficient number of times to qualify them to compete, that this association would suggest that the non-attendance at lectures should not be a disqualification."

After being seconded, it was put and carried *nem. con.*

Mr. Thomas, in a forcible, argumentative, and aptly illustrated speech, moved,—

"That this association, much regrets the invidious distinction made between examined and non-examined chemists, and would suggest that no chemist in business should be eligible for competition in the proposed yearly examination."

This having been seconded, was carried amid much applause.

Mr. Mellor inquired if only a quarter of the number of students were eligible to compete, how many could they look upon as being able to obtain prizes? Not nearly sufficient to pay for lectures upon one, much less two subjects. He also referred to the difficulty of obtaining a sufficiently competent teacher in small towns, and hoped that the meeting would support his resolution,—

"That the proposed system of payment by results will prove totally inadequate to remunerate associations for the great, and in many cases, unnecessary expense which would be incurred in employing paid lecturers."

Mr Wallis pointed out the injustice (if they adopted the payment by results) of depriving an association of those who would be the most likely to obtain money, namely, the students who had passed the Minor examition. He, therefore, moved—

"That the passing of the Minor examination should not disqualify a student from earning money for his association or prizes for himself."

The Secretary observed that the great unfairness of the proposed scheme was its local character; by that he meant that it could be only successfully adopted by the largest towns, and where help was less needed. If the resolution he had the honour of proposing were adopted, a student resident in the smallest town would have the chance of obtaining a prize of books which would much assist him in his praiseworthy endeavours to pass the Minor or Major examination; and why, because he was resident in a small town, though he contributed equally with his brother student in a large town to the Society he should be debarred from competing he could not imagine. He begged to move the following resolution,—

"That no scheme can with any propriety be called 'just or universal' that renders neither assistance nor encouragement to students situate in towns or districts where by no possibility associations can be established. This association would respectfully suggest that if the system of payment by results be adopted, the proposed examination for grants and prizes should be open to all *bonâ-fide* assistants and apprentices of chemists and druggists, even if they should not be connected with an association."

After passing a vote of thanks to Messrs. Evans, Lescher and Evans for their handsome cabinet of materia medica specimens, the meeting terminated.

Proceedings of Scientific Societies.

PARIS SOCIÉTÉ DE PHARMACIE.

A Meeting of this Society was held on Wednesday, June 5th, under the presidency of M. Stanislas Martin.

Referring to a note recently read by M. Godin, calling attention to the solubility of benzoate of iron in oils, M. Méhu said that he had already pointed out this fact in 1868. He added that not only the benzoate of iron, but also the cinnamate, was soluble in oils, whilst the arseniates of iron were insoluble.

M. Limousin, on behalf of M. Ferrand, presented a note on the adulteration of essence of bitter almonds by nitro-benzol. The author heats to ebullition in a test tube three or four c. c. of a twenty per cent. alcoholic solution of potash, together with ten drops of the suspected essence. If nitro-benzol be present, the mixture takes a red colour; if the essence of bitter almonds be pure, it becomes a pale straw colour.

M. Adrian read a report, prepared by himself and MM. Dubail and Boudet, upon the essence of absinthe, which, according to the recent decision of the National Assembly, can now only be sold in the pharmacies. The report made known the composition of the various absinthe liqueurs met with in commerce, and the processes by which they are ordinarily prepared. These processes mainly consist of (1) alcoholic distillation from the fresh plant, and (2) simple mixture of alcohol and essence of absinthe. The report gave rise to considerable discussion.

M. Grassi regretted that the report gave no indication of the pharmacien's duty under the new law. He asked whether it was the pure essence of absinthe, such as is known to chemists, that was in future only to be sold by pharmaciens, and whether the order of a medical man would be necessary for its delivery.

M. Boudet explained the text of the law, from which it appeared that it was the essence of absinthe which was dealt with. The second question he thought would be answered by a public ordinance, similar to that which regulated the sale of poisons. In reply to several criticisms upon the law itself, M. Boudet said that it was made less in a fiscal or pharmaceutical than in a hygienic point of view. It was necessary to restrain the consumption of absinthe liqueur, the abuse of which had led to the most deplorable consequences, and among the means which presented themselves to the Assembly, one of the most certain was to prevent its preparation by the simple mixture of the essence and alcohol.

M. Dubail said that the essence of absinthe was actually supplied to the public on a large scale by the drug trade; also that it was certainly destined for the preparation of absinthe liqueur by simple mixture, and that it was chiefly so used by the small makers.

Some conversation then followed upon the difference which existed in the symptoms produced by the abuse of absinthe and that of alcohol, M. Boudet being of opinion that the more disastrous effects which followed the use of what was commonly known as absinthe liqueur, was due to the anise and other essences frequently mixed with it. MM. Delpech and Adrian said that some recent investigations brought before the Société de Thérapeutique showed that whilst the anise exercised upon animals only a slow, almost insensible influence, the action of absinthe was rapid and most fatal.

M. Poggiale said that although the law might be wanting in clearness as to scientific terms, it was evident that the pharmacien alone would have the right to sell the essence and concentrated preparations of absinthe upon the order of a medical man.

M. Vuaflart read a note upon orange-flower water. The author having observed that orange-flower water, even when obtained from the most respectable pharmacies, lost its odour shortly after being opened, and even acquired a disagreeable smell, was led to think that this was caused by distillation by steam. This method of proceeding he believed to yield a product that is at first satisfactory, but which it is not possible to keep a long time unchanged. Having mentioned this idea to M. Machet, he was informed by that gentleman that he had long renounced the distillation of roses by steam, as he had noticed that the water so prepared did not keep so well as that distilled over a naked fire in an alembic furnished with a diaphragm. The author, therefore, prepared orange-flower water by this method, which he succeeded in keeping unchanged for some years. He so arranged his supply as to be able to use water made the preceding year, in order to give it time to lose a slight taste of the fire, which disappeared completely with the first frost. He considers that distillation over the fire is more thorough, affecting all parts of the flower, and releasing some principles which tend to the conservation of the product. In adopting this process it is necessary, besides the diaphragm, to place in the cucurbit sufficient water to form a kind of bath for the flowers, and so to conduct the distillation as to keep them the least possible time in contact with the heat.

M. Roucher said that the Arabs prepared this distilled water with great care over the bare fire; the liquid, after several cohobations, being well saturated strongly aromatic, and keeping well.

Parliamentary and Law Proceedings.

HOUSE OF LORDS.

Adulteration of Food, Drugs, etc., Bill.

On Thursday, July 25th, this Bill was read a second time; on Monday, July 29th, it passed through Committee; on Tuesday, July 30th, it was reported and the amendments agreed to. The third reading is set down for Thursday, August 1st.

Poisoning by a Vermin Killer.

An inquest was held at Leeds on Thursday, July 25, concerning the death of Kate Groocock, an infant that had been poisoned by Battle's Vermin Killer, administered by its mother, who had also taken some herself, from the effects of which she was recovering. Evidence was given to the effect that the child was found by the servant dead, and the mother in convulsions and suffering very much. Mrs. Groocock told her husband afterwards that she had given the child the contents of a threepenny packet of Battle's Vermin Killer in some treacle, and had taken another herself. It was stated by several witnesses that the mother had for some time past been suffering from great mental depression.

Mr. John Wm. Longley, druggist, North Sreet, said a female came to his shop on the previous Monday and made some purchases. She put down the money for them, and as he was turning for change she said, "I might as well take some Battle's Vermin Killer." Witness said, "You are aware it's poison?" and she smiled, and said, "Perfectly well." He then gave her two threepenny packets, which she had asked for. He put a label on to the packets with his name and address; the word "poison" was already on the packets.

The Coroner asked the witness if he did not know that it was against the law to sell strychnia in this manner? Did he not know that he was required by the Pharmacy Act to observe certain specified regulations?

Mr. J. G. Turner, solicitor, here interposed, and said he appeared for Mr. Longley. He urged that Battle's Vermin Killer did not come within the first part of the schedule, and that when the packets were labelled poison, and had on them the name and address of the seller, that was all that was required.

The Coroner said he had had to warn druggists that the restrictions mentioned in the 17th section of the Pharmacy Act applied to Battle's Vermin Killer as it contained strychnia. Strychnia was expressly mentioned in the schedule of the Act, but he should not discuss the matter there with Mr. Turner, as he could not decide it.

Mr. Turner said that Battle's Vermin Killer was defined by the Pharmaceutical Society (who had the authority so to define) to belong to the second section poisons,* and if that were so he had done all that was required.

The Coroner replied that if that was the case he would have the question settled by the magistrates.

Mr. Turner, after some further conversation, said that if the Coroner gave it as his opinion this composition should be dealt with as a poison—coming within the first part of the Act, he should advise Mr. Longley to act upon that opinion.

The Coroner said that if Mr. Longley would promise that hereafter he would carry out the 17th section in reference to Battle's Vermin Killer, he did not suppose anything more would be said about it.

Mr. Longley said he most decidedly would.

The Coroner then intimated to the jury that the case would certainly have to go to the assizes, as the question of the sanity or insanity of the mother was not one for them to decide. It was desirable to have an adjournment for a *post-mortem* examination. The inquest was accordingly adjourned.

At the adjourned inquest, Mr. Scattergood deposed that he had examined the body and found no natural cause for death, while all the external appearances of the body were consistent with death from strychnia. He found a quantity of blue colouring matter in the stomach which he had set aside for analysis.

* This is incorrect. As we stated recently, under the powers given by Section 2 of the Pharmacy Act, upon the resolution of the Pharmaceutical Council, and the approval of the Privy Council, a list was published in the 'London Gazette' of December 21st, 1869, of articles that ought to be deemed a poison within the meaning of the Pharmacy Act, 1868, which list contained among other articles, "Every compound containing any poison within the meaning of the Pharmacy Act, 1868, when prepared or sold for the destruction of vermin," and then the resolution goes on to say, "and also that of the same, each of the following articles, viz.,—

Preparations of prussic acid,

Preparations of cyanide of potassium and of all metallic cyanides,

Preparations of Strychnine,

Preparations of atropine,

ought to be deemed a poison in the First Part of the Schedule A to the said Pharmacy Act, 1868."

The jury returned a verdict that the deceased died from the effect of poison administered by her mother. The foreman expressed the opinion of the jury that Battle's Vermin Powder should be classed among poisons, and the sale of it placed under greater restriction.

The coroner said that as he observed previously the powder came within the 17th section of the Act of Parliament, and the sale of it ought to be conducted under the regulations and restrictions provided for the sale of poison. If any case of a similar description should come before him after this, he should deem it to be his duty to direct the prosecution of the druggist, for what, he thought, was an offence under the Act of Parliament.

Suicide by Laudanum.

On Monday, July, 22nd, an inquest was held at Tooting upon the body of Charles Messent, veterinary surgeon. It appeared that the deceased, who had lost his temper through some domestic occurrence, was seen to go into the surgery; presently afterwards he came out and wished his family good-bye, saying he had "done it now." They did not believe he had poisoned himself, as he was in the habit of saying so to frighten them. Shortly afterwards he said that he had swallowed half an ounce of laudanum, and as he became insensible medical assistance was obtained, but he died the same evening. A verdict of suicide whilst of unsound mind was returned.—*Wandsworth and Battersea Times.*

Action for Payment for the Supply of Apparatus and Chemicals to a Class.

On Thursday, July 25, in the Sheffield County Court, Mr. Harrison, pharmaceutical chemist, brought an action against the Committee of the Mechanics' Institution in Sheffield, to recover £8. 1s. 2½d., for chemicals and apparatus supplied to the chemistry classes in connection with the institution. The items extended from 1870 to 1871. The plaintiff formerly acted as lecturer to some chemistry classes then existing at the Mechanics' Institution, and as such he supplied a quantity of chemicals and apparatus, which were the subject of the action. In support of his claim he relied upon two resolutions passed by the committee. The first was agreed to on the 29th of June, 1869, and was to the following effect: "That the committee provide Mr. Harrison with a room for the purpose of establishing a chemistry class in connection with the science and art department, Mr. Harrison to receive the money granted by that body for successful students, he providing all materials, etc., required." The second resolution was dated the 21st of August, 1870, and was to the effect that Mr. Harrison continued to conduct the science classes on the same terms as stated in the resolution of the 29th of June, with the exception that the committee provide the apparatus as soon as practicable, and to the extent they considered desirable. The plaintiff contended that the word "apparatus" included chemicals, and that he supplied what was required for the classes under the impression that the committee would repay him. The case for the defendants was that they relied upon the two resolutions, and that they never heard of any claim whatever from Mr. Harrison until they refused to give him £5 for each class, which he was to conduct during the session of 1871. The claim, it was said, was not made until eight months after the last class had ceased to exist, and that when it was made it came upon the committee quite by surprise. His Honour said he must nonsuit the plaintiff. The resolution of August, 1870, was that "the committee were to provide the apparatus as soon as practicable, and to the extent they considered desirable." From that it was clear there was no contract between the parties that the plaintiff was to provide anything, and the defendants to pay for it. The resolution showed that the committee were to be the judges of what was wanted; and that they were to get what was wanted. It was clear the plaintiff found the chemicals and found the apparatus; but it ought to be proved clearly to him (his Honour) that he did so on the understanding that he ought to be paid for it. Some arrangement of the kind ought to be proved. No such arrangement, however, had been proved. It seemed to have been left on the understanding that the committee were to pay for the chemicals and apparatus. But that did not establish a contract to pay, nor did it establish a state of things from which an implied contract arose.—Mr. Clegg (who appeared for the defendants) asked for costs; but his Honour refused the application, saying that it was not a case in which he should grant costs. Mr. Clegg observed that the plaintiff had been paid for what he had done and supplied, by the sum which he received from the Science and Art Department.—The plaintiff denied that that was so, and said all he received during the last year he taught the classes was £2.—His Honour expressed the opinion that the plaintiff supplied the chemicals and apparatus, believing that he was warranted in doing so by the first resolution, but there was nothing whatever in that or the subsequent minute which entitled him to be paid.

Excise Prosecutions.

A case was recently reported from Exeter (*ante* p. 17) of a chemist having been fined for keeping a male servant without a license, the said "male servant" being an errand boy, ten years old, whom a Revenue officer had detected helping his fellow-servant by brushing some shoes. We learn that since then another fine has been inflicted by the Exeter magistrates, the victim again being a chemist and druggist.

Review.

Pharmacopœa Germanica.—Berolini, apud Rudolphum de Decker, 1872.

A change similar to that which was made in this country in 1864, when the British Pharmacopœia was published, has now been effected in Germany by the publication of the Pharmacopœa Germanica. Hitherto several of the German States have had Pharmacopœias of their own, and no one of these has had authority throughout the Confederation. This subject has been under consideration for some years, and at the instigation of the Pharmaceutical Societies of North and South Germany, with a view to the subsequent adoption of an authorized German Pharmacopœia, a work was provisionally issued in 1867, under the title of Pharmacopœa Germaniæ, which was submitted to the governments of the German States for examination, and, if approved of, for public use.

After the establishment of the North German Confederation, the government of Mecklenburg-Schwerin referred to the Federal Council the introduction by authority of a general Pharmacopœia, and on the 19th Dec., 1868, it was decreed that medical men and pharmacists should be appointed to prepare such a work. They met on the 28th of May, 1869, and decided that both the Pharmacopœa Borussica and Pharmacopœa Germaniæ should be used as the basis of the new work, but they also determined to consult medical and pharmaceutical authorities throughout the Confederation with reference to its extent and construction. The proceedings were interrupted by the late war, but on the establishment of the German Empire they were resumed.

By a decree of the Federal Council issued on the 29th of April, 1871, a new commission, including representatives of South Germany, was appointed to prepare the Pharmacopœia. They commenced their labours in September, 1871, and having invited the co-operation of men of eminence in different departments, they completed the task in December of the same year.

The work is written in Latin, and the reasons assigned for adopting that language are, that it is understood everywhere, and that medical men are accustomed to write their prescriptions in Latin.

As in the case of other modern Pharmacopœias, the quantities of ingredients ordered in the processes are represented by proportional numbers, no reference being made to any particular weights or measures; indeed, there is not even a table of weights or measures given in the book, the subject being disposed of with the following remark in the preface, "As to the weights to be used in pharmaceutical laboratories, we have omitted to add a special table, as they are prescribed by law throughout the whole German Empire." At the end of the book, however, there is a posological table in which the doses are expressed in grammes, and in another place it is stated that measures are never to be used, but that the quantities even of liquids are to be determined by weight.

The articles are all arranged alphabetically in one general list, as they are in the British Pharmacopœia.

A table of atomic weights is given, in which the new atomic numbers are used; and in the few instances in which symbolic formulæ are employed, they are constructed according to the new or unitary system. Symbolic formulæ, however, are but very sparingly used—in only some twelve cases throughout the entire work.

The names applied to chemical substances are such as have been used in previous German Pharmacopœias, and they frequently differ considerably from those used in this country. It is stated in the preface that, "with respect to those drugs, whether simple or prepared, which belong to chemistry, it seemed advisable to use chiefly those names that have long been used by medical men and pharmacists, as also in books that record remedies and methods of treatment." It was probably the determination to retain these names that prevented the more general employment of symbolic formulæ, for as the modern system of notation is adopted, this would not accord with some of the old chemical names. Thus, sulphate of iron is *Ferrum sulphuricum*, and sulphate of soda is *natrum sulphuricum*, but the term *natrum* represents the alkaloid soda, and not the metal, which is represented by *natrium*, as in *natrium chloratum*, common salt. Now if the symbolic formula were given for *natrum sulphuricum*, as the new system is followed, it would represent it as sulphate of sodium, and not of soda (Na_2SO_4), thus making the name and the formula inconsistent one with the other. Therefore as the old name is retained, the formula which is founded on new and altered views is omitted. In the British Pharmacopœia, a similar course was pursued with regard to the retention of old names, but to justify the use of symbolic formulæ without involving inconsistency, and at the same time without ignoring the system generally adopted by scientific chemists, it was determined to insert formulæ according to both systems. That course was admissible at the time the last edition of the British Pharmacopœia was published, but it would hardly be so now, as the new notation has almost entirely superseded the other. The authors of the German Pharmacopœia, therefore, had but two courses before them, either to insert symbolic formulæ according to the new system, and to change the names so as to correspond with the formulæ, or retaining the old names to omit the formulæ. They have adopted the latter course. Very slight changes in the names would have removed the difficulty, and this might have been done without altering the general construction of the Latin names hitherto used in German pharmacy, if it had been particularly desired to retain that construction. All that would have been required would be to change *Magnesia sulphurica*, the present name of Epsom salts, to *Magnesium sulphuricum*, and to make other changes in a similar direction. There is, however, one view of the case that tends to reconcile us to what has been done, and it is, that in the prospect of a full discussion of the desirability of having even a more general Pharmacopœia than the Pharmacopœa Germanica, one, namely, that should embody the formulæ of the Pharmacopœias of all nations—an universal Pharmacopœia—the question must necessarily arise as to what nomenclature is the best and should be adopted. And the necessity for settling this question, as well as others of equal importance, such as the strength and composition of compound medicines, in the event of undertaking a Universal Pharmacopœia, supplies a motive for urging that undertaking forward, and adds to the probability of its accomplishment.

If the question of chemical nomenclature as applied to saline compounds were fully considered on its merits, it would probably be found that there are names better suited for pharmaceutic use than those used in German pharmacy. *Kali sulphuricum* is their name for sulphate of potash and *Kalium iodatum* for iodide of potassium, *Kali* standing for the alkali, and *Kalium* for the metal. So again, sulphate of soda is *natrum sulphuricum*, and common salt *natrium chloratum*. In translating these terms into English some doubt might arise whether *iodatum* and *chloratum* signified iodide and chloride or iodate and chlorate, but the latter terms are represented by *iodicum* and *chloricum*.

It is much to be regretted that the chemical nomenclature applied to medicines ordered in different pharmacopœias should differ as it does. Surely medical men and pharmacists might be brought to agree to one general system to be universally used in medicine. There would seem to be less difficulty in accomplishing this object than in getting all to agree as to what medicines should be ordered and how they should be compounded. At present the three great neighbouring nations, France, Germany and England, have three perfectly distinct systems of chemical nomenclature in their pharmacopœias, as will be seen by referring to the following names applied to three chemical substances:—

French.	*German.*	*English.*
Sulphas sodicus.	Natrum sulphuricum.	Sodæ sulphas.
Carbonas calcicus	Calcaria carbonica	Calcis carbonas.
Oxidum ferricum	Ferrum oxidatum.	Ferri peroxidum.

Fortunately synonyms are often given, and these, especially where there is no symbolic formula, assist in explaining what the name is intended to refer to. Thus the name "*Natrum subsulfurosum*" used in the Pharmacopœa Germanica might puzzle even a chemist, occurring as it does without any process being given for its preparation, or any chemical formula representing its composition, if it were not accompanied by a synonym, "*Natrum hyposulphurosum.*" So again the name "*Tartarus natronatus*," although not very unlike the name given in our pharmacopœia, is rendered more clear by having the synonyms appended, "*Natro-Kali tartaricum*" and "*Sal polychrestum Seignetti.*" All will agree in thinking, however, that a symbolic formula would have made this clearer.

Not only is the new German Pharmacopœia very sparing in the use of symbolic formulæ, but also in describing processes for the production of chemical compounds. This omission is accounted for by a statement in the preface that, "as numerous chemical preparations are better and more correctly made in large laboratories from which they are supplied to pharmacists either directly or through wholesale dealers, instructions are only given in the Pharmacopœia for the making of certain chemicals, especially those whose composition or properties are dependent upon some-special method of preparing them." This is no doubt a satisfactory reason for omitting to give *minute* details relating to the manufacture of articles that can only be made on the large scale, such as oil of vitriol, acetic acid, carbonate of soda and alum, and it may be also applied to many other articles that are only made by the manufacturing chemist; but we think it is carried too far in the work before us. We often hear of instances in which chemical processes given in the Pharmacopœia, although seldom used, yet sometimes prove serviceable; and we believe the wholesale omission of such processes would be a subject of regret to many of those who use the Pharmacopœia. If for no other purpose than that of keeping constantly before the notice of those who from day to day are using the articles the methods by which they are produced, the descriptions given in the Pharmacopœia are not without their use. To the pharmacist, the Pharmacopœia is, or should be, something more than a work of reference; it is his daily companion, and information contained in it which he might otherwise miss or forget is forced upon his attention and kept fresh in his memory. We think, therefore, that some account should be given of the origin and mode of production of every article described in the Pharmacopœia. This may sometimes be very brief, as in the descriptions given in our Pharmacopœia of arsenious, benzoic, carbolic, nitric, and sulphuric acids, but still in connection with the characters and tests, which are more fully described, it supplies what is required in those cases. Now, referring to the descriptions of those articles given in the German Pharmacopœia, we find that in only one instance, that of benzoic acid, is there any reference made to their origin or mode of production. The same thing might be said in a great number of other instances in which, although minute details are not required, something more might with reason be looked for than is given. But there are some cases in which the want of a process with even minute details, is an obvious defect. Thus, for instance, *Acidum chromicum*, is described as a red crystalline acid, the characters and tests of which are given with sufficient minuteness, but nothing is said as to its source or mode of production; yet chromic acid, when used as a medicinal agent, as it sometimes is, might be required to be made, and might without difficulty be made, by the pharmacist, if proper, and they should be minute, instructions were given for the purpose of enabling him to do so.

But while there is reason, we think, to regret the absence of some information which would be acceptable, and the omission of which has surprised us the more, because German pharmacists used to be required to make many preparations that are not generally made by the same class in this country, and we were, therefore, prepared to look to the German Pharmacopœia for processes suitable to such cases, yet, notwithstanding some disappointment in this respect, we find much to satisfy us in other respects. Especially we commend the copious reference made to the use of tests, and the general tendency manifested and progress made towards the simplification of old complex formulæ for galenical preparations.

Before referring more minutely to that class of preparations, however, we must allude to the strength of the mineral acids. Sulphuric acid is ordered in four different states. First, we have *Acidum sulfuricum fumans*, Nordhaussen oil of vitriol, the strongest fuming acid, sp. gr. 1·86 to 1·90. Then we have *Acidum sulphuricum crudum*, common unpurified oil of vitriol, sp. gr. 1·830 to 1·833. Then we have *Acidum sulphuricum*, or distilled oil of vitriol, sp. gr. 1·840. And, lastly, we have *Acidum sulphuricum dilutum*, sp. gr. 1·113 to 1·117. This diluted acid is made by mixing one part by weight of sulphuric acid, sp. gr. 1·84, with five parts of water; it is much stronger than our diluted acid, the sp. gr. of which is only 1·094, but both the crude and rectified acids are less concentrated than the sulphuric acid of the British Pharmacopœia. There are also four sorts of nitric acid described. The strongest is *Acidum nitricum fumans*, a fuming reddish-brown acid, of sp. gr. 1·520 to 1·525. This is the most concentrated nitric acid that can be obtained, but no process is given for its preparation, which we think is a mistake, for it does not keep well, and should be prepared when wanted, by distilling a mixture of commercial nitric acid and oil of vitriol. *Acidum nitricum crudum* is common *Aqua fortis*, sp. gr. 1·323 to 1·331. The *Acidum nitricum* of the Pharmacopœia is described as a colourless acid, sp. gr. 1·185, and containing only 30 per cent. of true nitric acid (HNO_3); it is, therefore, a very weak acid as compared with ours. *Acidum nitricum dilutum* is prepared by mixing equal parts by weight of nitric acid and water. Its sp. gr. is 1·086 to 1·089; it is, therefore, weaker than the diluted nitric acid of our Pharmacopœia. Hydrochloric acid is ordered in three different states. *Acidum hydrochloricum*, the strong pure acid, is weaker than our strong acid, the sp. gr. being only 1·124. It contains 25 per cent. of anhydrous hydrochloric acid. *Acidum hydrochloricum crudum* is about the same strength as our pure acid, sp. gr. 1·16 to 1·17, and percentage of anhydrous acid from 30 to 33. *Acidum hydrochloricum dilutum*, made by mixing equal parts by weight of hydrochloric acid and water, has a sp. gr. 1·060. It is rather stronger than ours.

We may perhaps infer that sulphurous acid is in less repute in Germany than here, as it is not in any form included in the German Pharmacopœia, unless, indeed, we consider hyposulphite of soda to represent it. But the omission of sulphurous acid is amply compensated for by the introduction of a considerable number of chemical remedies not mentioned in our Pharmacopœia. Among these are boracic, chromic, lactic, succinic, and valerianic acids, acetic ether, petroleum ether, Dutch liquid (under the name of *Œthylenum chloratum*), nitrate of silver and potash, chloride of gold and soda, valerianate of bismuth, bisulphide of carbon, hydrate of chloral, iodoform, etc.

Of course there are many preparations that we are not familiar with, and there are methods new to us for making preparations with which we are familiar. *Ammonium carbonicum pyrooleosum*, the existing representative of the old *Sal volatile cornu cervi*, which is now made by mixing carbonate of ammonia with the disgusting Dippel's oil, is a remnant of ancient pharmacy which we might soon hope to have seen the last of. In the same category might also be included *Aqua fœtida antihysterica*, *Decoctum sarsaparillæ compositum Zittmanni*, and *Electuarium Theriaca*.

With reference to decoctions, it may be well to remark that, unless otherwise directed, they are to be so prepared that ten parts of strained product are obtained from one part of the drugs operated upon; if, however, concentrated decoctions are ordered, the solid ingredients are to be increased to one half more; and for the most concentrated (concentratissimus) they are to be increased to double. The decoctions are made by heating the ingredients together for half an hour in a steam-bath.

In making infusions the same proportions of solid ingredients to the water are ordered as for decoctions, and as in the case of decoctions, there are three strengths, the two strongest of which are distinguished as "concentrated" and "most concentrated." They are made by pouring boiling water over the ingredients in a suitable closed vessel, and immersing this in a steam-bath for five minutes. The shortening in this way the duration of the process of infusion or digestion, is certainly an important consideration if the results should be found to be equally good.

A somewhat similar mode of operating is directed to be adopted in making some of the tinctures. All tinctures are made by maceration or digestion, continued for eight days, the ingredients being confined in partly-filled bottles, and shaken every day. Maceration is conducted at temperatures ranging from 59° to 68° Fahr., and digestion at temperatures between 95° and 104° Fahr. Tinctures of wormwood, aconite, aloes (compound and simple), arnica, assafoetida, orange-peel, benzoin, cascarilla, catechu, bark (simple and compound), cinnamon, and a great many others are made by digestion; while tinctures of belladonna, cantharides, capsicum, castor, digitalis, euphorbium, and many others are made by maceration. It is not explained how the temperature is to be maintained between 95° and 104° Fahr. night and day, for eight days, which we presume would be the principal difficulty in conducting the process by digestion.

One of the peculiar features in this pharmacopeia is the small number of pill masses ordered. Besides the *Pilulæ odontalgicæ*, intended merely for local application, there are only three formulæ given for pills, under the titles of *Pilulæ aloeticæ ferratæ*, *Pilulæ ferri carbonici*, and *Pilulæ jalapæ*. This forms a marked contrast with the twenty different sorts of pills ordered in our Pharmacopeia; and we should be glad to think it indicated an improvement in the practice of physicians, in prescribing other forms of medicine for their patients. The *Pilulæ jalapæ* of the German Pharmacopœia are composed of resin of jalap, soap, and powdered jalap; and notwithstanding the number of formulæ for pills we have already in the British Pharmacopœia, we are disposed to think that this or a simliar form might with advantage be introduced, omitting at the same time some of those we have, for while pills with aloes are repeated over and over again, we have no purgative pill without aloes.

Obituary.

EDWARD PALK.

We have to record this week the death of another of the founders of the Pharmaceutical Society, in the person of Mr. Edward Palk, Pharmaceutical Chemist, of Southampton, who died on Thursday, July 25th, at the age of seventy-three.

Mr. Palk was born at Portsmouth, but early in life removed to Southampton, where he was apprenticed to Mr. Gillmour, of the High-street. He afterwards commenced a business on his own account, which he carried on for more than fifty years. During that time he always threw himself heartily and zealously into every movement for the public good, and became prominently identified with the benevolent institutions of the town, and with the discharge of the public duties associated with municipal government. In 1847 he was elected alderman, and held that office until 1865, when upon the cessation of his connection with their body, the Council passed a vote of thanks to the ex-alderman for the important services he had rendered to the borough; and the inhabitants marked their appreciation of his labours on their behalf by subsequently presenting a testimonial to Mr. Palk in the form of a handsome gold watch, a timepiece, silver salver, and candelabrum, at a large public meeting held at the Philharmonic Hall. In 1858 he was elected mayor of the borough, and served the office with the utmost advantage to the community. In 1856 he accepted the appointment of a justice of the peace for Southampton.

Mr. Palk was also for thirty-two years churchwarden of the parish of Holy Rood, in which he resided. In connection with the religious, benevolent and philanthropical institutions of the town, his labours were unceasing. In conjunction with other zealous workers he founded the ragged school, of which he became treasurer, and was regarded as the father of an institution which has accomplished an inestimable amount of good among the poorer classes of the town. He also took a deep interest in the Female Penitentiary, was a Governor of the Royal South Hants Infirmary; Vice-President of the Southamptom Dispensary; and Honorary Vice-President of the Southampton Athenæum, etc.

The deceased gentleman was one of the earliest members of the Pharmaceutical Society of Great Britain—his membership bearing date 1841—and for many years he acted as its local secretary for the district.

During the last three years Mr. Palk suffered from a painful internal disease, for the relief of which he on the 11th June last underwent an operation. This was considered to have been very successfully performed, but the long period of suffering he had undergone had undermined his naturally vigorous constitution, and after returning to Southampton he gradually got weaker until his death. On Saturday last the magistrates of the borough held a special meeting, and passed a vote of condolence with the bereaved family, and on Monday, they, together with the Corporation and an immense concourse of his fellow townsmen, paid a further mark of respect, by attending the funeral.

Notice has been received also of the following deaths:—

On the 15th July, Mr. William Paine, Pharmaceutical Chemist, of St. Margaret's Street, Canterbury. The deceased gentleman had been a member of the Pharmaceutical Society from 1842 till the time of his death.

On the 10th July, Mr. Richard Lewins, Chemist and Druggist, of Morpeth.

On the 14th July, Mr. Richard Hardy, Chemist and Druggist, of Dicconson Street, Wigan.

On the 18th July, Mr. James Waits, Chemist and Druggist, of Poplar.

Correspondence.

Provincial Education.

Sir,—If they have taught us nothing else, the discussion and correspondence on the Education Scheme now before the Council, as well as the scheme itself, are calculated to arouse in the minds of all pharmaceutists a sense of profound humility.

If we regard the very modest requirements of the Preliminary examination, and notice the large proportion of candidates who are rejected, if we consider the elaborate schemes that have been and are propounded to enable young men to pass such easy examinations as the "Minor" and even the "Major," we must acknowledge that the day is far distant when we can hope to take the position that some of our body are sanguine enough to think the practitioners of pharmacy ought to take in this country.

I am not saying in the present state of things that it is either desirable or possible to make either the Minor or Major examinations more difficult, and we might go far to find a better Board of Examiners than we now have, still the fact remains, as everybody's experience will testify, that it is possible for a young man to pass his examinations whose general education is wofully deficient, and who knows but little of his business. Only the other day an assistant of 26 years of age (who I need hardly say only stayed a day with me), and who had lately passed his "Minor," was constrained to confess that he had never silvered a box of pills in his life, and he directed some pills that were to be taken "si opus possit" to be taken "with posset."

I sympathize with Mr. Schacht's philanthropic endeavours to help those young men who entered the business before the passing of the last Pharmacy Act, although I question if the scheme he advocates, for reasons amongst others lately given by Mr. Reynolds, will be found in practice to work well. I earnestly hope, however, that it will be decided that any help that is given by the Society will be given only to those who entered before the passing of the Act.

To do otherwise, I cannot but think would defeat the very object we have in view, and instead of raising would tend to lower our already very low standard by holding out inducements to boys and young men of deficient education to join our body.

It is not by being able to call ourselves members (by examination if you will) of the Pharmaceutical Society that we shall gain the confidence and respect of the public, but by showing that we are men of an education at all events a little higher than that of the mere huckster, and only so shall we be able to attract boys of a better class into our ranks.

It seems to me, and every one is invited to give his opinion, that what we have to do is to make the Preliminary examination a really effectual bar to the entrance of the ill-educated. By taking care that only those who have had a fair general education are admitted, we may rely upon it we shall hear no more about difficulties in passing the Minor and Major; and instead of offering premiums for ignorance, the plethora of money at "The Square" may be much better expended by establishing scholarships available for three to six months in the laboratory for those who pass the best Preliminary examination.

Charles Ekin.

Bath, July 30th, 1872.

Sir,—At the risk of being considered hard-headed, a characteristic common to north-countrymen, I am induced to address to you a few more remarks on the subject of Provincial Pharmaceutical Education. In my last letter, I endeavoured to show by the Society's Charter, and by the Acts of Parliament which they have been instrumental in passing, that it is their duty "to promote an uniform system of education of those practising pharmacy." I think I have satisfactorily made out my case.

It is now my object to endeavour to prove that the Society has not attempted to promote or to provide a uniform system of education adapted to the requirements of the country members of the trade. It is now nearly thirty years since their charter of incorporation was granted to them for this purpose. With the exception of a few donations, amounting in the aggregate to a very small sum, they have never attempted anything of the kind, until the meeting of the Council on November 2nd, 1870, when the scheme proposed by Mr. Richard Reynolds was adopted in principle by the Council. Had this been faithfully carried out, there was much in it that was well calculated to effect the object in view. Had the Council of that day had sincerely at heart the success of this object, the result would have been very different from what it has been. But the Committee to which this scheme was referred so mutilated and mangled it, and utterly destroyed its usefulness, that its author did not know his own scheme again. They produced one in the place of it, soulless, useless, and impracticable; the paternity of which no person has ever owned, and nobody ever will. Those who read it, cannot come to any other conclusion than that it was admirably adapted to defeat the object it had in view, and it at the same time conclusively proves that the Committee of that day were utterly incapable of grasping and dealing with so important a question.

The country members of the trade are thoroughly roused on this subject. They will never rest until assistance is given for the instruction of their apprentices and assistants, in all those subjects on which they are required to pass examinations. They will no longer tolerate the useless waste of money by allowing the surplus income, amounting to about £2000, to be annually invested in the Three per Cents. for the benefit of posterity. A luminary in our town council once asked, "what has posterity done for us that we should have so much regard for them?" The age for endowments is quickly passing away. What is the use of saving for posterity that which is absolutely required for ourselves? I have a strong impression that posterity will be able to hold its own quite as well, and perhaps better than ourselves. In my next letter, if time permit me, I will endeavour to show why the Council should assist provincial pharmaceutical education, and how they can do it.

Hull, July 29th, 1872. Atkinson Pickering.

[*** We are at a loss to understand the meaning of Mr. Pickering's remark that the amended scheme to which he refers was admirably adapted to defeat the object which it had in view, and do not see that his letter contains any justification of the charge he has brought against the Council. We are glad however to hear, upon Mr. Pickering's authority, that the country members of the trade are thoroughly roused upon this subject. We trust they will continue their exertions until there is a satisfactory solution of the very difficult question of education, and meanwhile, we shall be glad to publish Mr. Pickering's views as to the measures which ought to be taken with that object.—Ed. Pharm. Journ.]

Sir,—You invite opinions upon the scheme for provincial education of druggists' apprentices. As I understand the motives assigned for the establishment of our Society, I think that so far as the members are collectively concerned, they are not more competent to form an opinion than any other portion of her Majesty's subjects. All that we, or rather the Council which represent us, have to do is to see that each candidate for admission to the honour of membership has received a liberal scientific education; and, further, that the candidates are able to pass such examination as they in their wisdom think fit. But I certainly protest strongly against the Pharmaceutical Society paying either directly or indirectly any portion of the expenses of educating any present or future apprentices.

One of the objects of the promoters of the Society was, I think, to raise the status of chemists and druggists; and I think, and venture to hope that others will think with me, that the apprentices to chemists, like pupils to surgeons, etc., should pay the expense of their own education; and I would further suggest for the consideration of the Council that no person other than men who have been in business prior to the passing of the Act, should be eligible for examination until they had attended a course of lectures at the Pharmaceutical Society for twelve months and upwards after their pupilship or apprenticeship shall have been completed. The Council might in their discretion offer prizes of free membership to the Society for such pupils receiving certain certificates to be hereafter arranged; and all the balance moneys, or rather profits, should and ought to be placed to the credit of the Benevolent Fund, which, by the bye, should be for members and not outsiders, who, in my humble opinion, have no claim to its bounty.

I also strongly object to any distinctive marks in the diploma granted by the Society distinguishing between examined and unexamined members. I contend membership should be equal, never forgetting that had it not been for the unexamined members the examined would never have existed; and after years of toil, expense and trouble, it is too bad that the junior members should take advantage of their seniors, whose grey hairs they frequently insult, instead of honouring, by remarks in your columns which do not do them credit. If education teaches foppishness and insult to the founders of the Society to which they are proud to belong, better, I say, had they never received it. I think the Council should introduce bye-laws to the effect that all members, by paying a certain sum *down*, in addition to that already subscribed, should be life members, and that no person be hereafter admitted, except as a life member, and that no distinction should be made between examined and unexamined members, the latter claiming their right to membership by Act of Parliament. Depend upon it, the distinction is invidious, uncalled for, unexpected, and tends to lower rather than heighten the moral tone of the Society. I think the interest of the public, so much prated about, is not sincerely meant, otherwise, we should endeavour to simplify our prescriptions by refusing to make up any which had not the full directions written plainly in English, the drugs and quantities, as now; it would appear more in consonance with a wish to avoid errors than to write in Latin, and then educate up to the mark. Besides, the instructions are for the patient, and not for the exclusive use of the druggist, and physicians should also write the quantity of drugs for the whole, and not one dose; it would be truthful, and frequently prevent mistakes.

X. Y. Z.

Sir,—With regard to the subject of payment for results, 'G. T.' states (July 6th, 1872) that I had better leave the matter in abler hands. What authorizes 'G. T.' to say so? Although I write anonymously, it is not that I am unqualified to write. Permit me to tell 'G. T.' that I was till last year a science teacher, and that I have had very large science classes under my instruction; that I know every part of the Government system; and that I speak as a practical man.

I should like Mr. Schacht to say why he favours the Government system. He ought not to favour it simply because it is adopted by our Government. Were Mr. Schacht to tabulate the results of the Government schools of these last three years, and notice the narrow escape the system had from a collapse—at the same time the secession and disgust of both teachers and students, as well as the disadvantages of the scheme—he would, I think, recommend anything but it.

I much regret that others of practical experience have not spoken against the imitation of the Government scheme. Mr. Schacht has yet to show that the scheme adapted (even if it were so) to the Government is adaptable to the Pharmaceutical Society. I should have been glad to see more originality—some scheme that the Pharmaceutical Society has really given birth to.

Would Mr. Schacht be disposed to reconsider his scheme, and leave out such parts as are objectionable, or such parts as are not adaptable to the Pharmaceutical Society?

The system of payment for results is hateful to every one who has experienced it. I fancy that the scheme cannot be adopted into our Society, simply from the objection of examined men to allow some of the interest of their money deposited in the Society to be distributed to the students of the country.

Mr. Reynolds and I are not the only persons who consider that it is neither necessary nor desirable in every case to mitigate the expenses of students.

The time may come when there will perhaps be no occasion for any country schools. To bear out this remark, I will advance my own case. I am an examined pharmaceutist, and delight to teach. On my assistants wishing to attend the local association, I reply that there is no necessity for it; that in my pharmacy are more specimens than in the local museum; that in my library, which all my young men are invited to use, are more books and better ones than in the local library; that if they require instruction, I am happy to give it; that when they converse about the examination subjects, I am happy to converse with them. In these respects my case (now that the Society has in the field a magnificent army of trained men, which army is increasing year by year) is not unparalleled.

As I write, Mr. Schacht's system seems to me more like the oolite system of geologists than anything else. The oolite at one time teemed with life; now it is a mass of of dead things fossilized. The Government system was full of life; now it is dead, or fossilizing, as may be proved by the revolt of teachers and other circumstances. What the geologists do of the oolite we, can also do of Mr. Schacht's system, viz., give an ideal representation of the society, committee, teacher and student under it.

I am glad to observe Mr. Schacht's remark, "Details to be understood as incomplete."

A COUNTRY MAJOR ASSOCIATE.

MICROSCOPICAL SPECIMENS ILLUSTRATIVE OF THE MATERIA MEDICA.

Sir,—Mr. D. Hanbury having very kindly sent me a copy of "Möller's Price-list of Microscopic Preparations," I am able to give your microscopical readers information I have reason to believe many of them will be glad to receive, namely, that specimens well-mounted and reliable, illustrating the structure of pharmaceutical roots, etc., may be procured at a moderate cost. Möller gives on page 24 of his catalogue a list of what he calls expressively "Pharmacognostische Präparate," numbering 144 slides, many of which contain from two specimens and upwards. The list comprises the starches and arrowroots commonly met with, and the principal roots, barks, fruits and seeds. Sections of "Radix Sarsaparille Caracas, S. Honduras, S. Lissabon, S. Veracrux," in my possession, are without exception the finest specimens of the art of mounting I have ever seen, and present the peculiarities of the structure in a manner our English preparers would do well to imitate.

I have not been able to learn that these slides are procurable in England otherwise than by order. Möller's price is "32 Thalers for the collection of 144 specimens." 6⅔ thalers is equal to 20s. English. Single slides cost 8 silver gr., of which 10 equals 1. Microscopico-pharmaceutical Associations could easily arrange to procure as many as their members might require direct from Möller. The postage of small parcels is heavy. Möller's address is "Institut für Microscopie, Wedel in Holstein (per Hamburg).

HENRY POCKLINGTON.

Hull, July 29th, 1872.

EXAMINATION FEES.

Sir,—I have no wish to detract attention from the discussion as to educational assistance, of which the students in the trade seem very much in need (judging from the results of the recent examinations); but I am of opinion that, as the Society have funds and to spare, the present is a time when they ought to reconsider the question of examination fees.

For the right to practise medicine, dispense prescriptions, and sell drugs—poisons included—the Apothecaries' Company claim six guineas, and for their Assistants' examination in dispensing, pharmacy, etc., two guineas, whilst the Pharmaceutical Society charge ten guineas, and five for a certificate, merely to dispense prescriptions and retail poisons. We must remember that there is not any restriction as to the selling of drugs—any one may do that.

July 29th, 1872.

DUGONG OIL.

Sir,—In your impression of the 6th ult. a notice appears regarding the great value of Dugong oil as exhibited at the Queensland Annexe of the International Exhibition, and that you believe at present there has not been any attempt to introduce the oil to the English market. I must inform you that for many years past I have brought it to public notice, and endeavoured to introduce the oil from the East at a reasonable price. Its medicinal import is well known at the hands of my medical friends and myself, the introducer, as most valuable in cases of phthisis, pulmonary, and scrofular diseases. I would merely refer you to Mr. Hill, of Bell and Co., Oxford Street, the well-known chemists, in confirmation of my exertions to bring the oil to England at a cheap rate, in which I have hitherto failed. I intend to make the acquaintance of Mr. Daintree regarding his importation; and if we can unite our exertions to cheapen the oil, a most valuable boon will be conferred on the public.

J. McGRIGOR CROFT.

Mandarin Villa, St. John's Wood, N.W.
July 18th, 1872.

X. Y. Z. entirely misunderstands the object we had in view in the remarks to which he refers.

R. H.—Apply to the Secretary for a pamphlet entitled 'Hints to Apprentices and Students.'

R. F. Moreom.—You can obtain the information at the College of Surgeons.

W. C. M.—(1) A rudimentary knowledge of chemistry would enable you to answer the question without any special work on arithmetic. (2) We are informed that a new edition is in preparation which will be ready in the autumn.

"*Tere Bene.*"—Probably of any respectable dealer in druggists' sundries.

"*A Constant Reader.*"—The subject of your suggestion has already been under consideration, and arrangements have been made for partially carrying it out. The chief obstacle is the difficulty in getting information.

Curiosities of Labelling.—A correspondent has sent us a label, on which the following words occur in red upon a black ground:—

"In conformity with the Sale of Poisons Act, 1868, this preparation must be labelled
POISON,
but its composition remains unaltered"
LAUDANUM.
[Name and address of seller follows.]

COMMUNICATIONS, LETTERS, etc., have been received from Mr. J. Mackay, Mr. C. R. C. Tichborne, Mr. Stone, Dr. Porter Smith, Mr. J. Bienvenu, Mr. Glaisyer; "Oxonian".

THE BRIGHTON AQUARIUM.

In this country the tradition that Britannia rules the waves is a popular and cherished one; but it must be confessed that the rule is very superficial, since she sees little and knows less of the myriads of living creatures which live beneath them. Nor are we likely to be able much to increase our knowledge of these creatures by visiting them at home, and probably we shall have to content ourselves by noting the habits of those which, under more or less compulsion, play the part of visitors with us. Slight exaggeration would it be to say that at the present time it would not be difficult to find many persons who have never seen a starfish except in a picture, and who if shown a common barnacle would be puzzled to say whether it were fish, flesh, or fowl. Even among the many thousands who now flock every year to our fashionable watering-places, acquaintance is generally confined to what may truly be called the "common objects of the seashore." It is, therefore, a matter for congratulation that we can point to a bold attempt to follow the good example set first by the Zoological Society of London, about the year 1852, when they began to exhibit a collection of aquatic animals within their grounds, and subsequently by the Crystal Palace Company, in so far as those efforts are now to be supplemented by an aquarium at Brighton constructed on a larger scale than has ever before been attempted.

Although not forming one of the subjects for the Preliminary, or Minor, or even the Major, the fact that this new experiment is intended to be inaugurated during the coming scientific gathering at Brighton, must be our apology for alluding to it in these pages, for, independent of the interest it must present to all scientific men, it may be presumed that it will there be a special attraction to many of our readers. Notwithstanding its popular aspect as a show, the possibility of such an aquarium is due entirely to scientific observation. It may afford additional interest to know that some of the earliest and most valuable information on the subject of aquaria dated from Apothecaries' Hall, and came from the pen of the late Mr. Robert Warington. In a paper read before the Chemical Society, March 4th, 1850,* that gentleman described some of the difficulties he met with in his attempts to keep gold fish. Having placed in the glass vessel containing them a small plant of *Vallisneria spiralis*, he found that after a time the decaying leaves produced a slime which began to affect the fish injuriously, and that it was necessary this impurity should be got rid of, He therefore introduced five or six pond snails (*Limnea stagnalis*), which soon removed the nuisance and restored the fish to a healthy state, thus perfecting the balance between the animal and vegetable inhabitants and enabling both to perform their functions with health and energy. The fish became lively and bright, the *Vallisneria* became extremely luxuriant, and the snails, depositing enormous quantities of gelatinous masses of eggs, afforded a large quantity of food to the fish in the form of young snails. Mr. Warington thus sums up the results of his experiment:—"We have an admirable balance sustained between the animal and vegetable kingdoms, and that in a liquid element. The fish, in its respiration consumes the oxygen held in solution by the water as atmospheric air; furnishes carbonic acid, feeds on the insects and young snails, and excretes material well adapted as a rich food to the plant and well fitted for its luxuriant growth. The plant, by its respiration, consumes the carbonic acid produced by the fish, appropriating the carbon to the construction of its tissues and fibres, and liberates the oxygen in its gaseous state to sustain the healthy functions of the animal life—at the same time that it feeds on the rejected matter, which has fulfilled its purposes in the nourishment of the fish and snail—and preserves the water constantly in a clear and healthy condition. While the slimy snail, finding its proper nutriment in the decomposing vegetable matter and minute confervoid growth, prevents their accumulation by removing them; and by its vital powers converts what would otherwise act as a poison into a rich and fruitful nutriment, again to constitute a pabulum for the vegetable growth, while it also acts the important part of purveyor to its finny neighbour." This paper was followed by several others on the subject of the aquarium, which appeared principally in the 'Annals of Natural History,'* and conveyed much information respecting principles that must not be lost sight of by any one wishing to successfully superintend an aquarium, whether marine or fresh water, and amongst these we must no omit reference to Mr. Allchin's paper on the construction and management of aquaria for the preservation of leaches.†

But to return to the aquarium which is more particularly the object of our notice. The site of the building is close to the Chain Pier, just below the cliff. Its length may be roughly stated as being over 600 feet; its width sloping off from about 120 feet in its widest part to about 60 feet in its narrowest. At the principal entrance there is a flight of granite steps by which the visitor descends to an entrance court (60 feet by 40 feet) and an entrance hall (80 feet by 45 feet), arcaded, and composed of terra cotta and ornamental brickwork, and near to which is a commodious dining and refreshment room. From the entrance hall the visitor passes to the aquarium proper. On each side of a corridor 220 feet long and 23 wide, divided in the centre by columns of serpentine, polished granite, and Bath stone, alternately, the caps and corbels of which are elaborately carved with designs of shells, fish, sea-birds, etc., and support a groined roof, are ranged the tanks for exhibition, varying in size from 11 feet 6 inches by 20 feet to 103 feet by 40 feet. At the end of this corridor, which runs nearly from west to east, is the "conservatory," 70 feet long by 23 feet wide, the eastern end being designed to form a rockwork waterfall, with ledges, dropping well, small aquaria, ferns, etc. A short passage running north and south leads to the second main corridor, 160 feet by 23 feet, also running from west to east, and containing twenty tanks, part for the exhibition of fresh-water specimens and part for tropical specimens requiring a higher temperature. A portion of this corridor is arranged for small table aquaria requiring minute inspection. Beyond are the engine rooms, for pumps, machinery, etc., while underneath the corridors are large sea-water reservoirs communicating with a well in the engine-room. The water is pumped to an upper reservoir, from which a supply can be passed to each tank at any required rate, the surplus water passing off from the tank

* 'Quarterly Journal of the Chemical Society,' iii. 52.

† Pharm. Journ. 1st ser. xv. 453.

through stand-pipes when it reaches a certain level. Outside the building, terrace promenades are con structed over the corridors; these are decorated with flowers, ferns and shrubs, and are reached by flights of stone steps from various parts of the building.

As to the specimens themselves, it is too soon to say much, since here it is necessary to reverse Mrs. Glass's celebrated maxim,—first catch your hare,—for, as in this case, the fish are not caught to be cooked, it is necessary to provide a suitable domicile before catching the fish. The collection, therefore, will be one that will require time to bring to perfection. But among the specimens at present in it are many of great interest. In the tanks will be found a large angel-fish or monk-fish (*Squatina Angelus*); a scad or, as it is sometimes called, a "horse mackerel" (*Caranx trachurus*), from a fancied resemblance to the resplendent colours of the ordinary mackerel (*Scomber vulgaris*); the grey mullet (*Mugil sp.*), with its long cylindrical body, the surmullet (*M. surmuletus*), and the red mullet (*Mullus barbatus*), all of them delicacies of the table and much esteemed by the Romans, who feasted their eyes on the dying colours of the latter before feasting on its body; the hungry whiting (*Merlangus vulgaris*) and its black brother, the coal-fish (*M. carbonarius*); a pouting bream; curious-looking "picked" dog-fishes (*Acanthias vulgaris*), belonging to the shark family, each with a poisonous "pick" or spike in front of its dorsal fins; wrasse; rocklings; two or three species of the brilliantly coloured but odd-looking gurnards or pipers (*Trigla sp.*), owing their name to the curious sound they sometimes emit; that delight of the Cornishman, the pilchard; basse, or sea-dace (*Labrax lupus*) whose voracity gained for them the name of "wolf" from the Romans; various long slender pipe-fishes, the male of which have the credit of acting as wet-nurses, carrying the eggs laid by the female in a kind of pouch in the belly until the birth of the infant fry; and a sixteen-spined stickleback. Besides these, there are lobsters, crawfishes, crabs, prawns, shrimps, etc., too numerous to mention. We may remark that a description by Mr. Warington,* of the habits of the stickleback,—reward of many a city arab's piscatorial excursion,—and his account of the building of its nest and the care it takes of its young, gives such a glimpse of the interest to be found in an aquarium that we regret space will not allow of its quotation.

In the table tanks are the anemones, the flora of the sea, and some very handsome specimens of the curious and beautiful "dead men's fingers" (*Alcyonium digitatum*). Here, too, are the blennies, a common variety of which is reputed to act as a tide indicator, by, if possible, throwing itself out of water at the time of low water, and regaining its element when the tide rises; also two turtles from the Isle of Ascension, young lobsters, and the latter being certainly among the earliest, if not the cleverest adepts at corking and capping serpulæ.

The successful carrying out of experiments like the Sydenham and Brighton aquaria must tend to promote a taste for such studies; and, as sometimes a marine aquarium may be desiderated at an inconvenient distance from the sea, a knowledge of a ready method of producing artificial sea-water will probably be of service to some of our readers. We, therefore, conclude our notice by extracting a recipe furnished by P. H. Gosse, F.R.S.,* for a compound which he has successfully used for the purpose:—

Chloride of Sodium.	$3\frac{1}{2}$ oz.
Sulphate of Magnesia	$\frac{1}{4}$ oz.
Chloride of Magnesium	200 grs. Troy.
Chloride of Potassium	40 grs. ,,

To these salts, thrown into a jar, a little less than four quarts of (New River) water was added, so that the solution was brought to a density of about 1026. This formula is based upon an analysis of the Channel seawater, by Schweitzer, bromide of magnesium, sulphate of lime and carbonate of lime being omitted, because of the minute quantity required. It was criticized by Mr. Warington a few months after its original publication;† but, as Mr. Gosse has since republished it in his 'Handbook to the Marine Aquarium,' we may presume that he has found it satisfactory.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from page* 83.)

Veratri Viridis Radix.—The rhizome of *Veratrum viride* will not detain us long, as it is interesting to the micro-botanist rather than to the micro-pharmacist, and not specially interesting to him. The type of structure is strictly that of ordinary rhizomes. The vascular system is composed of simple pitted vessels and unpitted wood fibres, and its distribution, being necessarily determined by the rootlets, is too varied to permit description. The vessels are small, the pits are long and transversal. The walls of the vessels are little thickened, and they are usually little, if at all, coloured. When coloured it is by transfusion from the accompanying laticiferous vessels. The parenchymous cells are of considerable size with firm walls in the rhizome, with very thin walls and spongy consistence in the root fibres, and contain great quantities of an amorphous starch. Under a low-angled quarter but slight evidences of granulation are apparent, and the use of iodine is needful to satisfactorily demonstrate the presence of starch. Some of these cells appear to contain a dextrinous matter. The other cell contents of importance are true raphides (acicular), and a dark brown colouring matter which is present in the laticiferous vessels. The raphides are contained in special cells, and are very much more common in the rhizome than in the rootlets. Sections stained first with iodine and then with a dilute solution of magenta, form very interesting and instructive objects, but the persistence of the staining cannot be relied on. When thus treated, the starch-bearing cells are stained the blue-violet peculiar to iodide of starch, the vascular vessels and secondary deposits are stained a brilliant magenta red, and the *bioplasm* in certain other cells is also stained, so that the various structural elements are well demonstrated. The cells of the cuticle are stained naturally a deep brown, and appear to resist the action of the magenta. They possess no feature of interest.

Aconiti Radix.—This root does not come into commerce in any adulterable form where the use of the microscope is required, but as it is occasionally used in mistake for the roots of *Cochlearia Armoracea*, it is desirable that the analyst should make himself familiar with its structural peculiarities as compared with those of the latter root. Fortunately the structures of the two roots are as distinct as, or more distinct than, their botanical characteristics. The medulla of *Aconitum Napellus* is large, angular, and usually well defined by a more or less dark ring. The medullary sheath, or more correctly, for there is no true sheath, vascular environment of the medulla is very incomplete; and the vascular bundles, which are small and wedge-shaped, are principally situate in the angles of the medulla, and are composed of thin-walled pitted vessels, small in diameter with oblong transversal pitting, and of wood fibres, unpitted, and of long vessels, apparently transitional laticiferous vessels containing a dark brown (when the root is dry) colouring matter. The cells of the medulla are large, sinuous in cross section, with moderately thick cellulose walls, and containing great quantities of starch granules. The starch granules are aggregate in three or more, or single, variable in shape with a distinct punctate hilum. A very decided black cross is given by polarized light. The cells of the outer layers differ widely in shape and size. In the immediate neighbourhood of the vascular bundles they form a transitional pleurenchyma with thick-walled cells, only partially attached by their parietes. The more truly parenchymatous cells of this layer are ovate, slightly angular, thick-walled cells, with irregular parietal adhesion, so that numerous intercellular spaces exist, not only at the angles of the cells, but along the sides and ends, but are very minute in the latter position. The contents of these cells are starch granules imbedded in semi-albuminous (?) matter, which becomes deeply stained if a section be immersed in dilute magenta for a short time. Immersion in a weak iodine solution will be found helpful to the elucidation of the more difficult points in the structure of the cell walls and intercellular spaces the more so if the section be transferred from the iodine solution to glycerine jelly, which causes a slight contraction of the then deeply coloured cell contents, and throws the cell wall into decided prominence. The cuticle layers and the layers contiguous thereto, are much more compressed; those of the cuticle itself possess some interesting features, arising out of their number and the nature of the deposits on the primal membrane of the cell walls. Immediately below the cuticle a few liber cells are found entirely isolate, oval sometimes, extremely elliptical in cross section, and with central cavity.

The whole of these characteristics would be discernible in the scraped root if prepared for table in mistake for horse-radish, and most of them could be detected, with a little care, in partially digested contents of a stomach in the case of a toxological investigation.

Armoraceæ Radix. — The root of *Cochlearia Armoracea*, more commonly known as horse-radish, is both botanically and structurally very distinct from the root of Aconite, the 'Daily Telegraph' notwithstanding.

Medulla.—There is no true medulla, A group of vascular bundles probably represents an aborted medulla and medullary sheath.

Wood Zone.—The wood zone is relatively very large and occupies upwards of two-thirds of the diameter of the root. Its structure is simple and easily made out. Little consolidated, or entirely unconsolidated, oblong, or cubic cells, a few wood cells, and vascular bundles enter into its composition. The vessels are large, much pitted, and rarely reticulated, are distinctly cellular, the diaphragm or septum in some cases being unabsorbed, often only partially absorbed. They are arranged in bundles, are variable in size, and irregularly distributed. The oblong and cubic semi-prosenchymatous cells are unpitted, with no visible pores, and contain great quantities of starch. The wood cells are unpitted, often of considerable length, with central cavity, and are probably to be regarded as transitional laticiferous vessels, or wood cells acting as such. The starch granules are ovate or sub-ovate, somewhat free in the cells and with a very limited variation in size. They are very dissimilar to those of Aconite.

Cortical Zone.—The cells of the cortical zone are according to their situation, globose, sub-globose, and cubic. The few liber cells present have no special features, and, like the cells of the bark layers, are strictly of the usual type.

The chief points to be borne in mind are, the shape and size of the starch granules, the size, number, and general characters of the vascular bundles, and the tissue of the "wood zone" with the semi-prosenchymatous character of its cells.

Belladonnæ Radix.—A vascular bundle replaces the medulla in this root also, and consists of pitted vessels and wood cells. . . .

Wood Zone.—The wood zone possesses none of the usual characteristics of wood zones, except the presence of irregularly distributed and not numerous vascular bundles. The cells are parenchymatous excepting at the outer margin, where they become semi-prosenchymatous. The distribution of the vascular bundle is irregular, their chief aggregation is at the outer margin of the zone, where, elliptical in shape, these are arranged more regularly and form an interrupted ring. Thus the wood zone has partially the characteristics of the ordinary medulla. The cells of which it is in chief part composed are modified cylindrical cells, with somewhat tapering or oblique ends. They are very thin walled, excepting quite near the cortical layer, where they are slightly thickened. They suffer much change of form in drying, and do not wholly resume their original shape when re-moistened. The wood cells enveloping the vascular system are unpitted, with a central cavity. The vessels are pitted with small oval pits, are thin walled, not septate and imperforate, with no spiral fibre, discs, or reticulations. The larger cells of the "wood zone," and the cells of the cortical layers, contain small, or medium (rarely large) quantities of starch, excessively variable in shape, but slightly variable in size, and with a "furrow" hilum and no central cavity. In certain cells the starch appears to be aggregated into a large compound granule, composed of very many granules, each of which suffers the usual modification of form consequent upon such aggregation. But this is probably entirely due to cementation with the protoplasmic contents of the cells, as the granules separate immediately upon immersion in warm water, and do not otherwise display the characteristics of compound granules. The whole of the granules give a distinct cross, necessarily variable in form, by polarized light.

Cortical Layers.—The cells near the margin of the "wood zone" are very similar to those within the zone. The middle cortical layers are composed of much larger cells, elliptical in shape, sometimes oblong and angular, with thin walls. The outer layers are of the usual type. Liber cells are infrequent, oval in cross section, with a central cavity.

(*To be continued.*)

LIQUID EXTRACT OF YELLOW CINCHONA.

BY S. W. CLEAVE, SHANGHAI.

The process indicated for the preparation of this important liquor is extremely unsatisfactory in practice. The exhaustion from the bark of its medicinal constituents cannot be accomplished by water alone; and the evaporation of so large a quantity of aqueous extract at 160° is not only a tedious operation, but one likely to damage the alkaloidal constituents from the prolonged exposure to the atmosphere. The U. S. formula is undoubtedly a good one, but from 16 troy ounces of bark the product is 40 fluid ounces, while we require it to be but 4 fluid ounces from 1 lb avoirdupois. The process which I now use produces a thoroughly reliable preparation which represents the remedial properties of the bark in every particular and keeps well. It is the following:—

Powdered Yellow Cinchona Bark 1 lb. avoirdupois.
Proof Spirit . . . . Oij.

macerate four days and percolate with proof spirit to lb. ij, then percolate the residue with three pints of distilled water; boil the marc in three pints more of distilled water, and express. Evaporate the decoction, add the aqueous percolate, and continue the evaporation. Then add the spirituous percolate and distil off the spirit; evaporate the residue on a water-bath to 4 fluid ounces, add 1 fluid ounce of glycerine, evaporate to 3 fluid ounces, and strain through muslin; and lastly, add 1 fluid ounce of rectified spirit. After a week, filter through paper to 4 fluid ounces.

LOSS OF AMMONIA AND PHOSPHATES.

BY H. MACCORMAC, M.D.

I am not an agricultural man, but I take the utmost interest in agricultural progress. The loss of ammoniacal ingredients and phosphates of transition I have long deplored, and very often have I intended to draw up some observations on the subject. I have now done so, and describe the means by which I would purpose to accomplish the important result of effectively rescuing the now lost azote lime and phosphorus of transition. Without further preface, therefore, I shall proceed to read my essay on "The Economic and Effective Arrest of the Lime Phosphorus and Azote of Transition, through the Medium of a prepared Humus or Soil, and their Application, along with that of ordinary Excreta, to Purposes of Agriculture." The liquid phosphate of lime now sells for some £20, and ammonia at from £80 to £100 per ton. Vast quantities of these important substances are imported from abroad, and very largely fabricated at home. But whatever be the actual amount made use of, the supply of animal and mineral phosphates and preparations of ammonia falls far short of the requirements of the soil. Everything, speaking of alimentary substances, which the earth is made to yield ought to be returned in some shape to the soil. This plain and indubitable canon is nevertheless violated continually. What the land gives is very insufficiently and sparingly returned to the land. Fluid and solid feculence, instead of being deposited in the soil, is suffered to pollute the earth's surface, and the interior of human dwellings as well; or, gathered in cesspools or trailing sewers, contaminates the atmosphere, violating self-respect and human dignity, and everywhere promoting discomfort and disease. Agriculture, properly conducted, would enrich the earth, whereas it positively impoverishes it, so that foreign ingredients, apatite from Spain or America, and guano from the Chincha or other islands, are needful to prevent the land from wearing out, a spectacle which Maryland and Virginia, as I have witnessed, furnish on a large scale. As it is, the yield is vastly less than are our requirements, and much, very much, less indeed than what, with proper management, our 40 to 50 millions of acres might be made to afford. The better the soil is treated the more it will return, and the worse and more grudgingly it is treated the less it will return. Bad treatment involves bad and insufficient returns, whereas good treatment involves copious returns—abundant corn and green crops, plenty of milk and butter and eggs, any amount of legs and shoulders of mutton, ribs and rounds of beef, flocks of poultry, flitches of bacon, and well-nourished instead of half-starved impoverished men and women. The food supply in these islands, though relatively less both in quantity and quality than what it ought to be, is still absolutely very considerable. Taking the returns made in June last, there were then, fractions omitted, some 9,000,000 of horned cattle on hand, 31,000,000 sheep, and 4,000,000 swine, irrespective of imported cattle and preserved meats. And yet of the 31,500,000 constituting the population of the United Kingdom, very considerably more than one-half almost never taste butchers' meat at all, and of those who do, the meat supply might often be most advantageously increased. With spade labour or machine labour the equivalent of spade labour and house feeding, the corn yield and the meat yield of our acres might be doubled, possibly trebled, at once. Of course, stalled animals would be the better for a little daily outing, with strict attention to stall ventilation and stall cleanliness as well. As at present conducted, the feeding of stock, horned cattle and horses alike, is conducted with the greatest possible waste—the land is not adequately utilized, and the manure supplies, or possible manure supplies, are in a great measure dissipated and lost. Now, as manure is of quite as much moment as the soil itself, and as manuring ought to be carried to as great an extent as the soil will profitably take it in, it is of the very greatest urgency that no available particle of compost should be wasted. It is quite as important to save manure as to reap grain or to feed stock. One, in fact, is the needful correlative and complement of the other; and yet the collection of manure is most imperfect, and what is actually stored past is exposed to almost every element of waste and decay, at once over head and under foot. In addition to the proper storage and preservation of manure, in respect of which the practice of the Chinese Colonists in Java seems to me deserving of special attention and consideration, I propose that the solid and fluid excreta of man and brutes should be commingled with a prepared humus or soil, consisting of the following ingredients, as well calculated to ensure the desired results:—

Prepared Humus.	lb. or parts.
Perfectly dry humus or soil	100
Calcined gypsum powder, from	10 to 20
Common alum, from	1 to 5
Copperas, from	1 to 5
Sulphuric Acid, from	1 to 5

These ingredients—and the proportions hold equally good for 1000 or 10,000 tons as for a single hundredweight—duly comminuted and commingled, constitute a very effective disinfectant and deodorizer and vehicle. The cost of 1000 tons of earth or soil I need not specify, but I may mention that common gypsum may be had at some 30s. per ton, sulphuric acid and sulphate of iron at 7s. 6d., and alum at 10s. per cwt. The humus or soil has its own great especial merits, while the three sulphates, along with the sulphuric acid, combine their several utilities and constitute an admixture well adapted to the objects in view, namely, the effective and inoffensive conservation of the products of animal waste and decay until they can be returned to the soil. This admixture will grasp the ammonia compounds, whether in *esse* or in *posse*, firm and fast: and as for the phosphates, they will likewise be laid hold of and retained. Every farm steading, according to its dimensions and requirements, ought, at the outside of every year, to be provided with hundreds or thousands of tons of this prepared humus, properly stored, and at hand in order to be effectively utilized. The ordinary summer soil, dried and levigated, answers every purpose as a main ingredient; clays, however, calcined and levigated, might be resorted to. The waste refuse of brick and limekilns, road dust, turf, and coal ashes, charred seaweed, and charred peat, so far as the supply sufficed, might also be had recourse to. The foregoing effective and economic compound might further be advantageously employed wherever animal waste was liable to be deposited, as in provision stores, slaughter-houses, sheep-pens, fowl-houses, catgut factories, knackers' yards, pigstyes, stables and stable yards, pork and fish curing establishments, and the like. The water now employed in the closet system, leading as it does to extended cesspools, beneath the level of the streets, fouling the rivers and foreshores of the sea, ought to be entirely superseded by sanitary humus instead. The importance of common soil as a deodorizer and disinfectant, as we find from Roman and Israelitish records, was not unknown to the ancients. By the moderns its utilities have been strangely neglected. The inhabited surfaces of India are dense with trodden-down ordures. The towns and villages of Europe are in little better case. And yet feculence, of whatever description, ought to be consigned to the soil, and never for a moment suffered to pollute our dwelling-places, or those of the creatures whom we associate with us. In my treatise entitled *Moral Sanitary Economy*, published some twenty years ago, the subject was dwelt upon in the strongest terms. The resultant admixture of sanitary humus and feculence, fluid and solid, might be preserved until needed in suitable receptacles, slate or brick lined, or dried, as in the sample now exhibited, by a moderate temperature, in kilns or otherwise. The sooner, however, the procedure here described could be resorted to, the better would it prove—at least, if we are to realize the great objects to be accomplished. The recent bones of a horse or ox weigh, let us say, from 80 to 100 lb.; of a man, from 11 to 15 lb.; of a sheep or swine, from 10 to 15 per centum of its living weight. Now, all the phosphorus—or, if we prefer the expression, all the phosphates of the bones, brain, and nerve structures generally, along with all the azotized excreta, or possible ammonia, which, guided by the laws of tissue metamorphosis, I calculate at one-half the amount of phosphates—that is to say, all the bones and all the flesh of any given animal—find complete transit from within to without in about ten weeks or so, mainly through the kidneys and allied structures, and, owing to our present treatment of them, are almost utterly lost and dissipated. The proportions and the time as above stated, though not absolutely, are approximately true, inasmuch as tissue change is much more rapid with some than others, but with young animals and children at least twice as rapid. Otherwise, the calculations are founded on physiological data, and in the main correct. Suppose we take the horse or ox in illustration. During each and every year of its life, then, this animal, and other animals in proportion, sheds or expends, be the same more or less, 1000 lb. avoirdupois of the phosphates, and about 5 cwt. of nitrogenous compounds, both of which all-important substances, human wants and the requirements of the soil regarded, are now as effectively lost and dissipated as if that phosphorus and that nitrogen were actually thrown into the great deep—a destination, indeed, which, for the most part, they positively incur, or as if the annual tens of millions sterling which the lost phosphates and ammonia of transition may be supposed to amount to were squandered similarly. By the judicious application of sanitary humus, the nitrogenous and phosphatic compounds, the amount furnished by the individual multiplied by the grand aggregate of living beings, might, I believe, be effectively saved and utilized, thus supplying a mine of wealth to which all the Potosis and Golcondas in existence were the merest trifles in comparison. In effect, animal waste, both fluid and solid, could be turned to full account, the general health and well-being prodigiously enhanced, and the yield of the soil multiplied to an extent to which I am quite incompetent to fix a limit.—*The Gardeners' Chronicle.*

THE CHEMISTRY OF THE HYDROCARBONS.*

BY C. SCHORLEMMER, F.R.S.

(*Concluded from page* 69.)

Besides the aromatic hydrocarbons having the general formula, C_nH_{2n-6}, there exist others containing less hydrogen. The constitution of these can also be readily ascertained. Thus styrolene, C_8H_8, obtained from styrax, yields on oxidation benzoic acid, a proof that it contains only one radical, combined with the aromatic nucleus. Its constitution is therefore $C_6H_5.C_2H_3$, or it may be considered as ethylene, in which one atom of hydrogen is replaced by the group, C_6H_5, and indeed in many of its reactions it behaves exactly like an olefine, combining with one molecule of bromine, etc., and being easily converted into polymeric modifications.

When styrolene dibromide is acted upon by alcoholic potash, two molecules of hydrobromic acid are abstracted from it, and acetenyl-benzene, $C_6H_5.C_2H$, is formed. This reaction corresponds exactly to the formation of acetylene from ethylene. Acetenyl-benzene shows, in fact, very great resemblance to acetylene, forming, like the latter, metallic derivatives, as $C_6H_5.C_2Na$; $C_6H_5.C_2Ag$., etc.

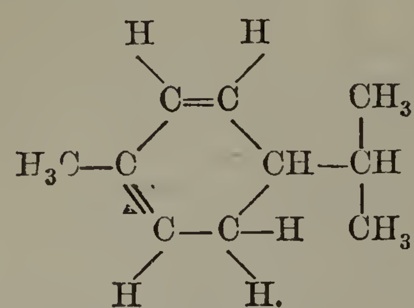
Although the hydrocarbons which are homologous with benzene, behave in most of their reactions, like saturated hydrocarbons, yet, under certain conditions, they can be made to combine directly with other elements, like the olefines, and other so-called non-saturated compounds. Thus benzene can combine with one, two, and three molecules of chlorine. These chlorine addition-products still contain the carbon-atoms combined together in a closed chain; they are very unstable bodies, and are again readily converted into compounds in which the carbon atoms are linked together, as in benzene itself.

Also hydrogen can combine with aromatic hydrocarbons, but only with those which contain alcohol radicals. The number of the atoms of hydrogen combining with such a hydrocarbon, appears to depend, not only on the number of the radicals present, but also on their relative positions. Benzene does not take up hydrogen; methyl-benzene combines with one molecule, dimethyl-benzene (isoxylene) with two, and trimethyl-benzene (mesitylene) with three molecules.

Oppenheim has shown (Deut. Chem. Ges. Ber., v. 94) as I have already mentioned, that oil of turpentine belongs to these addition products. By abstracting two atoms of hydrogen from it, the hydrocarbon $C_{10}H_{14}$ is formed, which must be either diethyl-benzene, or

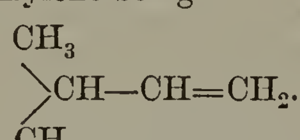
* A lecture delivered before the Chemical Society, April 4th, 1872. Reprinted from the 'Journal of the Chemical Society' for June, 1872.

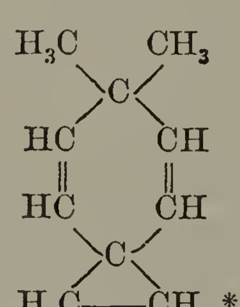
methyl-propyl-benzene, or α-cymene, because oil of turpentine yields terephthalic acid on oxidation. It appears most probable that it is α-cymene, as it has the same boiling point as the latter, and moreover oil of turpentine, as well as α-cymene, occur ready-formed in plants. The constitution of oil of turpentine is therefore probably the following:—



Oil of turpentine, therefore contains the aromatic nucleus, in which the connection between two carbon atoms has been loosened, and thus two combining units, which in the aromatic nucleus were linked together, are now saturated with hydrogen. As Baeyer has shown, such a loosening of the connection between two carbon-atoms takes place most readily between those which are combined with alcohol radicals.

It has been already stated, that by abstracting four atoms of hydrogen from diamylene, a terpene is formed which seems to be identical with terebene. It has, however, not been yet shown whether this artificial terebene yields terephthalic acid on oxidation. If this is found to be the case, the constitution of this hydrocarbon would be as follows, amylene being



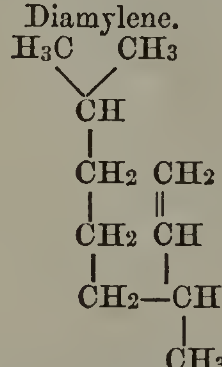


The other isomeric hydrocarbons of the terpene group have, doubtless, constitutions similar to those above given, differing from each other either by containing different radicals, or by the different positions of the latter.

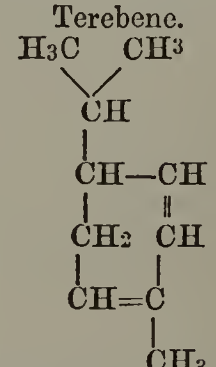
Besides the hydrocarbons containing one aromatic nucleus, there exist also several in which this group occurs twice or more times. As most of these bodies, however, are obtained by well-understood reactions, I need not discuss them here.

* Since the above has been written, von Richter (Deut. Chem. Ges. Ber. v. 334) has published a note on the condensation of diamylene to rutylene and terebene. He thinks that von Schneider's formula of diamylene does not explain either the property of this hydrocarbon of forming additive compounds, or its conversion into rutylene and terebene. He gives the following formulæ as much more probable:—

Diamylene.



Terebene.



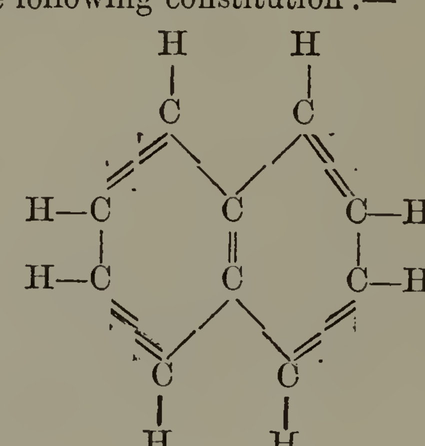
The formula of terebene is, as will be seen, the same as that which Oppenheim has given for oil of turpentine.

I only have to mention a most singular reaction by which some of them are formed, discovered by Zincke (Ann. Chem. Pharm., clix. 367). This chemist intended to obtain dibenzyl by acting with finely-divided copper or zinc-dust upon benzyl chloride. In order to moderate the violent reaction, he diluted the benzyl chloride with ether and with paraffins, but under these circumstances no reaction took place. However, by employing aromatic hydrocarbons as diluents, action set in; but instead of dibenzyl being formed, he obtained a mixture of several other hydrocarbons, in the formation of which the aromatic hydrocarbons, in other respects so stable, take part with great energy. It is not possible to give an explanation of this fact, as all the products of this reaction have not yet been studied. But the fact exists that aromatic hydrocarbons, when heated with zinc-dust and benzyl chloride lose hydrogen and take part in the formation of new hydrocarbons. Thus, on employing benzene, one of the products is *diphenyl-methane* or *benzyl-benzene*, $CH_2{}^{C_6H_5}_{C_6H_5}$, which is formed according the equation—

$$C_6H_5.CH_2Cl + C_6H_6 = C_6H_5.CH_2.C_6H_5 + HCl.$$

Further researches will no doubt throw more light upon this singular subject.

Amongst the products of the destructive distillation of coal and other substances, there always occurs *naphthalene*, $C_{10}H_8$, a hydrocarbon which in its chemical character bears so great a resemblance to benzene that it must have a constitution very similar to the latter. Some years ago, Erlenmeyer pointed out that it had probably the following constitution:—



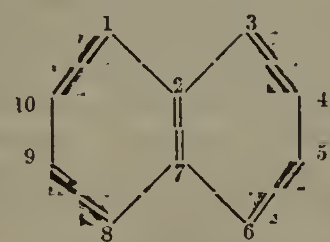
Naphthalene, therefore, would consist of two aromatic nuclei, which have two atoms of carbon in common. Graebe, who adopted this view, has proved the correctness of this hypothesis in a very ingenious way (Ann. Chem. Pharm., cxlix. 21). His reasoning is as follows:—When naphthalene is oxidized, phthalic acid, $C_6H_4(CO_2H)_2$, is formed; this acid can be obtained in two different ways from naphthalene; viz., either by destroying the one or the other aromatic nucleus. Such an experiment cannot, of course, be made with naphthalene itself, because we have no means of distinguishing between the two groups. It appears, therefore, necessary, first, to replace hydrogen in one of the nuclei, and then find out which is attacked and which not.

On oxidizing dichloronaphthaquinone, $C_{10}H_4Cl_2O_2''$, phthalic acid is formed, a fact proving that in this quinone all the oxygen and chlorine are combined with those four atoms of carbon which are oxidized, the formula of dichlornaphthaquinone being, therefore, $C_6H_4.C_4Cl_2O_2''$. By acting with phosphorous pentachloride on this compound, the dyad group, O_2'', is replaced by chlorine, and, at the same time, one atom of hydrogen is substituted, pentachlornaphthalene being formed—

$$C_{10}H_4Cl_2O_2'' + 2PCl_5 = C_{10}H_3Cl_5 + HCl + 2POCl_3.$$

Now, if by the oxidation of pentachlornaphthalene the same carbon-atoms are attacked as in the quinone, monochloro-phthalic acid would be formed; but Graebe has shown that the product is tetrachlorophthalic acid, which proves that the second aromatic nucleus has now been destroyed, a complete proof that naphthalene has really the constitution assigned to it.

Whilst amongst the mono-substituted benzenes, no isomeric forms occur, we find that the monosubstitution products of naphthalene can exist in two isomeric modifications. This can also be easily explained from the constitution of this hydrocarbon. By representing it by two hexagons and numbering the corners, representing the carbon atoms—



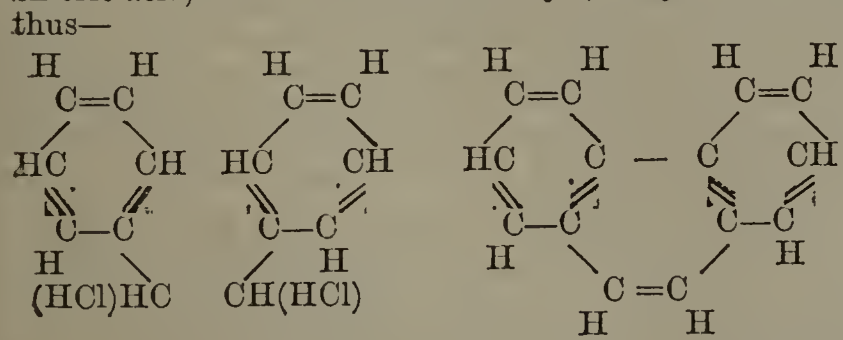
we find that each of the atoms 1, 3, 6, and 8, is combined with another atom (2 or 7) in which all the combining units are saturated with carbon, whilst the atoms 4, 5, 9, and 10 are combined with carbon atoms to which hydrogen is attached. The functions of the atoms 1, 3, 6, and 8 will, therefore, differ from those of the four latter. This also explains the existence of two dinaphthyls, one of which has been obtained by the action of sodium upon monobrom-naphthalene, and the other by passing the vapour of naphthalene through a red-hot tube.

In most kinds of coal-tar containing naphthalene there occurs also *anthracene*, $C_{14}H_{10}$, a body exhibiting in its chemical relations great resemblance to benzene and naphthalene. The constitution of this hydrocarbon has been ascertained by Graebe and Liebermann by their beautiful researches on alizarin (Ann. Chem. Pharm. Suppl., vii. 257).

Baeyer found that by heating phenols and compounds allied to them with zinc-dust, they are reduced to the hydrocarbon from which they are derived. By making use of this reaction, Graebe and Liebermann found that alizarin was a derivative of anthracene, and were thus enabled to effect for the first time the artificial preparation of a natural dye-stuff.

This example shows better than any other the correctness of the definition of organic chemistry "as the chemistry of the hydrocarbons and their derivatives".

The fact that alizarin is a derivative of anthracene enables us, as these chemists pointed out, to discuss the constitution of this hydrocarbon. From Limpricht's synthesis of anthracene from benzyl chloride it might be inferred that it is diphenyl-acetylene, $C_6H_5.C\equiv C.C_6H_5$. But this formula has to be rejected, because on oxidizing alizarin we obtain phthalic acid; and as further benzene, naphthalene, and anthracene form a series, each member of which contains C_4H_2 more than the preceding, it appears most probable that anthracene is built up from three aromatic nuclei in the same way as naphthalene from two. The formation of anthracene from two molecules of benzyl-chloride can now be easily explained. Each benzene nucleus loses one atom of hydrogen, and each of the groups CH_2Cl loses a molecule of hydrochloric acid, and the two residues $C_6H_4.CH$ join together thus—



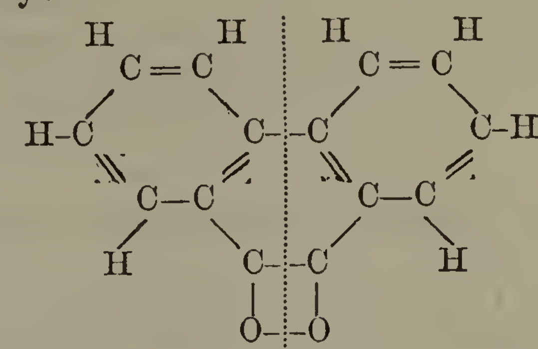
The complete reaction which takes place by heating benzyl chloride with water, takes place according to the equation—

$$4(C_6H_5.CH_2Cl) = C_{14}H_{10} + C_{14}H_{14} + 4HCl.$$

A further proof of the correctness of this view is, that by fusing anthraquinone with caustic potash, benzoic acid is formed.

$$C_{14}H_8O''_2 + 2KOH = 2C_7H_5KO_2,$$

The molecule of anthraquinone splitting up in the following way:—



The highest boiling portions of coal-tar contain, besides anthracene, two other hydrocarbons, *pyrene* $C_{16}H_{10}$, and *chrysene* $C_{18}H_{12}$, which have been also studied by Graebe and Liebermann (Ann. Chem. Pharm., clviii. 285 and 299). They have found that these bodies exhibit in their chemical properties so close an analogy to anthracene, that their constitution must be very similar to that of the latter hydrocarbon. Both yield quinones on oxidation, which proves that they also consist of closed chains of carbon atoms. According to Liebermann, a similar constitution is possessed by *idrialene*, $C_{22}H_{14}$, a hydrocarbon occurring in idrialite, a mineral found in the mercury mines of Idria (Deut. Chem. Ges. Ber., iii. 154). This hydrocarbon forms the last member of a series which are derived from benzene by the successive addition of C_4H_2—

Benzene	C_6H_6.
Naphthalene	$C_{10}H_8$.
Anthracene	$C_{14}H_{10}$.
Chrysene	$C_{18}H_{12}$.
Idrialene	$C_{22}H_{14}$.

Pyrene, which does not belong to these series, is isomeric with *diacetenyl-phenyl*, $C_6H_5.C\equiv C—C\equiv C.C_6H_5$, a hydrocarbon discovered by Glaser, who has pointed out that of all known hydrocarbons it contains relatively the greatest amount of carbon, viz., 95 per cent., or more than coal or anthracite.

I have now finished my task, and have only to regret that the magnitude of the subject did not allow me to dwell longer on certain points, whilst others, such as Berthleot's remarkable researches on the formation of hydrocarbons at a high temperature, and the transformation of all carbon-compounds into hydrocarbons by means of hydriodic acid, could not be mentioned at all. But the latter investigations alone would be sufficient to form the subject of a separate lecture.

There is perhaps no branch of our science which shows better the progress made by chemistry during the last thirty years, than that which I have brought before you to-night. And to what cause do we owe this rapid advance in our knowledge? I think this mainly due to the atomic theory, which found birth in Dalton's speculative mind, and has been gradually expanded and developed to its present state by the efforts of many eminent chemists.

But the atomic theory is generally accepted not only by chemists, but also by physicists, who have thought it of the greatest importance to find out the nature of an atom itself. Sir William Thompson has lately shown us how to solve a problem never dreamt of by chemists, viz., how to ascertain the absolute weight and size of an atom ('Nature,' 1871, nos. 22, 31). Is it not, therefore, strange that we find chemists who desire to kick from under them the ladder by the aid of which, in no small degree, so great a progress has been achieved?

Such attempts are, however, not only of recent date. In opposition to Dalton and Berzelius, Wollaston introduced the term equivalent instead of atom. But whilst

Dalton's original atomic weights were at the same time equivalents, the so-called equivalents of Wollaston's were no equivalents at all. By this a confusion arose between equivalent and atom, which was for a long time very detrimental to the progress of our science. It was only after Liebig had again pointed out the difference between equivalents and atoms, that theoretical chemistry advanced with rapid strides, and amongst those to whom we owe this speedy progress, I can only mention Laurent, Gerhardt, Williamson, Odling, and Kekulé.

NOTE ON SPRENGEL'S MERCURIAL AIR-PUMP.

Professor Dewar recently exhibited before the Royal Society of Edinburgh two modifications of Sprengel's pump adapted to lecture illustration. In both instruments the mercury receptacle is made of iron, and instead of the india-rubber joint of the original, a well-ground iron stopcock is substituted, the portion of iron tube before the stopcock terminating in a Y-shaped piece bored out of the solid. In the one form the drop-tube is of glass, attached by means of marine glue; in the other, of carefully made india-rubber tube four or five millimetres in thickness, of a very small uniform bore made expressly for the purpose by the Edinburgh Rubber Company. The iron funnel-shaped receptacles are ground at the inner apex, so as to fit perfectly finely-ground iron tubes. By means of these tubes the preliminary exhaustions are made by a hand pump, and then they are withdrawn. This device saves a separate joint. The barometer tubes are attached to solid T-shaped pieces of iron tube, and between these pieces and the main tubes each has a small glass bulb. Both forms work for all practical purposes well as glass, and suit admirably for Frankland's water analyses, Professor Graham's experiments, etc.

MODERN CHEMISTRY.

In reviewing the Supplementary Volume to Watts's 'Dictionary of Chemistry' in a recent number of the 'Athenæum,' attention was called to what the reviewer considered to be a great evil in the study of chemical science at the present day, viz., the comparative neglect of analytic in favour of synthetic chemistry. In his opinion the modern chemist has so nearly approached the tempting position of being himself a creator, that he has forgotten his true place is to be the interpreter of Nature. In his opinion the facility with which new combinations are made—by putting C H N and O together, in all possible proportions, and under ever-varying conditions—is not conducive to the advance of chemical philosophy, and he considers the synthesis of our modern schools to be not very different from the empiricism of the alchemists. The opinions thus expressed in the review have been very justly criticized by Mr. Watts in a letter from which we make the following extract:—

"The writer's complaints seem to amount to this: that the chemists of the present day have departed from the safe and philosophical methods pursued by their predecessors, particularly in substituting, to a great extent, the synthetical for the analytical mode of research.

"Now, in the first place, every one acquainted with the actual state of the science, must be aware that analytical chemistry was never more actively cultivated than at the present time. Every new compound produced is carefully analysed; new methods of analysis, and improvements of old ones, are continually appearing; there are journals and numerous manuals specially devoted to analytical chemistry; and the method of volumetric analysis, formerly almost limited to the processes of acidimetry and alkalimetry, has within these last few years, been so far improved and extended as to be applicable to the quantitative determination of almost all the known elements.

"Secondly, with regard to the synthetical method, everybody knows that in inorganic or mineral chemistry, this method is as old as the analytical, the two methods having always gone hand in hand. But in organic chemistry the case is different; and one of the most characteristic features of our modern chemistry is the extension of the synthetical method to the production of a large number of important compounds, which were formerly supposed to be produced only in the bodies of living plants and animals, under the influence of the so-called vital force. The labours of Berthelot, Wurtz, Kolbe, and numerous other chemists in this field, have yielded a rich harvest of the most important and valuable results, which, perhaps, promise more than any others to give us an insight into the structure of the more complex products of the vegetable and animal organisms.

"Now, it is just upon this point that your critic pours out all the phials of his wrath. He says,—

"'*Synthetical* chemistry—that is, the synthesis of the modern chemist—seizes upon those undecomposed bodies to which we have given the name of Elements (we have now upwards of sixty such), and tortures them into combination. The result of this is, the tedious production of an infinite series of intercombinations, which become most bewildering,—which are useless, or only occasionally useful, and which obscure rather than expose the truth,—the admitted aim and the recognized end of science. The Dictionary before us contains a considerable number of examples of this condition of things. The interchanges between CH and NO with Br. Cl., etc., are almost endless.'

"The exact meaning of this last sentence I will not attempt to fathom. *Davus sum, non Œdipus.* But granting that the possible interchanges of elements and compound radicals are endless, and further—to please the critic—that this is a very absurd and reprehensible state of things, I should like to ask, Who is responsible for it? Have the chemists of the present day brought it about by their synthetic machinations? or are they to be blamed for endeavouring, by every possible method, to discover the laws of symmetry which govern these numerous combinations? One really cannot feel anything but pity for a man calling himself a chemist, or pretending to criticize the labours of chemists, who can see no beauty in researches which have enabled us to build up the successive terms of an organic series, step by step, the complex from the simple, and have yielded, amongst others, such magnificent results as the artificial formation of the colouring principles of madder and of the indigo-plant.

"But after all, these lamentations over the supposed decay of science are by no means new, and the cause of them is, perhaps, rather subjective than objective. An elderly gentleman, who in his youth has taken special interest in chemistry or some other science, and followed its results with more or less intelligence, finds at a certain time of life, when the reception of new ideas becomes difficult and troublesome, that his favourite science has outstripped him, and that he no longer feels himself quite at home amongst its cultivators. Of the change in himself which has brought about this somewhat unpleasant result, he is, of course, serenely unconscious: and accordingly he persuades himself, and tries to persuade others, that the existing cultivators of the science in question are a degenerate race, who have sadly fallen away from the glories of their fathers.

"To those who are at present engaged in the active pursuit of chemistry, such criticisms as those to which I have endeavoured to reply must appear simply ridiculous; but as I have before said, they may tend to give a false idea of the actual state of the science to those who receive its results only upon trust; and it is for this reason that I am induced to trouble you with the present communication."

The Pharmaceutical Journal.

SATURDAY AUGUST 10, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PERFUMED SPIRIT.

WE have recently had for inspection a few samples of spirits of wine which were denominated by the vendor "perfumed spirit," but which in reality contained no flavouring matter at all. The price at which this spirit was sold was very low, and the low price, coupled with the evident misrepresentation as to the character of the spirit, led us to entertain a suspicion that something was wrong. A short time after our examination of the spirit, we were informed that a quantity of spirits of a like kind had been seized in Scotland by the Inland Revenue officers, on the ground that it was ordinary spirits of wine sent out without permit or certificate, and we now find other seizures have been made in London or a similar evasion of the law.

For the information of our numerous readers we have been anxious to obtain a knowledge of the real facts of this interesting case, and inquiries have been set on foot to discover how such spirit could be sent into consumption in large quantities without being accompanied by the usual official documents to show that it had actually been sent from a licensed dealer, and that the full duty of excise or customs had been paid upon it. We have been told that this spirit was formerly perfumed spirit imported at the time when the duty upon such spirit was fourteen shillings a gallon, and that as the quantity of alcohol actually present was sufficient to render it liable to duty at the rate of nearly seventeen shillings a gallon, the difference between these rates afforded an ample margin of profit to admit not only of the spirit being purified, but also sold below the ordinary market price. We were also informed that there was no necessity to issue a certificate to accompany it, as the Customs never issued such a document with perfumed spirit. To business men, not acquainted with some of our laws regulating the importation of goods liable to duty, it will seem incredible that there should ever have been such a difference between the Excise and Customs duty on such spirit, but it is nevertheless true that up to 1870 all perfumed spirits which is usually imported at a strength of 65° over proof, was charged at the rate of fourteen shillings per bulk gallon, whilst spirit made in this country of the same strength was charged sixteen shillings and sixpence. The home manufacturer was consequently placed at a great disadvantage, and we have known cases where spirit was actually exported from this country to the Continent to be perfumed, and then brought back again for the simple purpose of being charged with duty at the lower rate, because it was foreign perfumed spirit. Such a state of things was intolerable to the home manufacturer, but as he could state his grievance in figures as well as words by showing how the intelligent foreigners got the advantage over him, he obtained redress; and the Customs now charge duty on perfumed spirit at the same rate as on plain spirit of home manufacture, but with perfumed spirit they do not issue a certificate to show it has paid duty, as it is considered unfit for use as a beverage. Unfortunately, however, there is no standard as to the constitution of perfumed spirit, and consequently no strong line of demarcation can be drawn between perfumed and plain spirit.

Now the case under consideration affords distinct proof that the present system of sending into consumption perfumed spirit without certificate is unsound, because as soon as the spirit is delivered from the Custom House it comes under the surveillance of the Excise, and if it be not distinctly perfumed spirit, it is seized as illicit, whilst if accompanied by certificate it is not liable to seizure. In the present instance the persons who have purchased the so-called perfumed spirit are made to suffer great inconvenience and loss; for although on satisfactory proof being given that the spirit seized has actually paid duty, it will doubtless be restored, still full proof will have to be supplied by the persons from whom the goods were seized, which in this case may be very difficult, as the spirit has not only passed through several hands, but there is also reason to believe that some of it, at least, is illicit spirit manufactured in London. If this be proved, the whole is liable to forfeiture.

Whilst such a large national income is required the spirit duty must be protected very strictly, and we do not object to necessary regulations. But in a case like the present we have an illustration of how wrong may be inflicted on innocent people, and we consider it our duty to direct public attention to the subject, in the hope that the Customs authorities may alter their present practice and issue certificates to accompany both plain and perfumed spirit. By so doing another obstacle will be put in the way of the illicit distiller getting rid of his spirit, and at the same time the honest and inexperienced trader will be protected.

Whether the spirit has ever been perfumed spirit it is difficult to say; but from information obtained in the course of this investigation, there is reason to believe that much of this spirit has been manufactured at an illicit distillery recently discovered by the Revenue officers in the east of London. It is so unlikely that perfumed spirit should have been purified for sale to manufacturing chemists for their own use, that to believe such a statement stronger proof is required than we have been able to obtain. As, however, truth is sometimes stranger than fiction, the charitably disposed, and those from whom the spirit has been seized, may still cling to the hope that it is perfumed spirit, even though it be in disguise; but we fear that, at no distant day, it will be proved to demonstration in one of our law courts that this cheap spirit is none other than illicit spirit of home manufacture, and that the Customs regulation as to sending into consumption perfumed spirit without certificate has been made a cover for fraud.

We would once more direct attention to the danger there always is in purchasing commodities much below the regular market price. Usually, there is sufficient competition in all branches of trade to keep prices down, and the spirit trade is not an exception to this rule. To be able to purchase spirits of wine of full strength at a little more than the duty is certainly remarkable, and such an offer should always be looked upon with suspicion as not being a legitimate transaction. One of two things must necessarily be the cause, either that there is reckless trading, which must end in ruin, or the revenue is being defrauded of the duty on the spirit.

As we have before stated, we believe in the case of this perfumed spirit the revenue has been defrauded; and if this be so, we should have been glad to have seen proper punishment overtake the real offender only; but we fear innocent persons will also suffer for the faults of others, and the Revenue authorities will probably place the receiver of illicit spirit on the same footing as the actual manufacturer of them.

BRITISH PHARMACEUTICAL CONFERENCE.

There is every indication of a large gathering of members at the Annual Meeting of the Conference on Tuesday and Wednesday next at Brighton. The Executive Committee will assemble in the Conference Meeting-room in the Royal Pavilion at Seven P.M. on Monday. The President will deliver an address on Tuesday at Ten A.M., and the reading of papers will follow. The sittings will be continued from 10 to 4.30 on Tuesday and Wednesday, an adjournment from 12.30 to 2 taking place each day. On Tuesday evening there is to be a supper. We are informed by Professor Attfield that the following papers are in hand or already promised:—

Pharmaceutical Education; Mr. Julius Schweitzer, Brighton. Notes on Education; Mr. B. S. Proctor. Pharmaceutical Education; Professor Attfield. General Discussion on Pharmaceutical Education. Calabrian Manna; Daniel Hanbury, F.R.S. The Occurrence of Manganese in Certain Drugs; Professor Flückiger. *Succus Scapi Taraxaci*; Mr. H. Barton, Brighton. Pill Coatings; Mr. T. Haffenden, Brighton. Notes on Green Extracts; Mr. Richard W. Giles, Clifton. Pharmaceutical Ethics; Mr. S. R. Atkins, Salisbury. Guaiacol; Mr. J. Williams, F.C.S. Laboratory Notes; Mr. Edward Smith, Torquay. Alchemy; Mr. W. D. Savage, Brighton. On Tinctures; Messrs. Stoddart and Tucker. Trade Specimens of Sulphate of Copper; Messrs. Stoddart and Tucker. *Quæ Quondam*; T. B. Groves, F.C.S. On Kamala; T. B. Groves, F.C.S. New Derivatives from Morphia and Codeia; Professor Wright, D.Sc. Orris Root; Mr. Henry Groves, Florence. On Tincture of Perchloride of Iron; Mr. T. Hustwick, London. Koegood; a new Drug from South Africa; Mr. G. A. Keyworth, Hastings. Pharmacy as a Pursuit; Mr. G. A. Keyworth, Hastings. Researches on the Constituents of Aloes: Part I., Dr. Tilden; Part II., Dr. Tilden and Mr. Rammell. A Cheap Disinfectant; Edward C. C. Stanford, F.C.S.

Transactions of the Pharmaceutical Society.

MEETING OF COUNCIL.

August 7th, 1872.

MR. A. F. HASELDEN, F.L.S., PRESIDENT IN THE CHAIR.

Present: Messrs. Atherton, Baynes, Betty, Bottle, Greenish, Hampson, Hills, Owen, Radley, Sandford, Savage, Schacht, Shaw, Stoddart, Sutton, Urwick and Williams.

The minutes of the last meeting were read and confirmed.

A letter from the Privy Council was read approving the appointment of the Boards of Examiners in England and Scotland.

The President read the following letter from Professor Flückiger, of Bern, acknowledging the receipt of his diploma of Honorary Membership of this Society:—

"*Bern*, 22*nd July*, 1872.

"Dear Sir,

"I have for many years attentively noticed the admirable progress of the Pharmaceutical Society of Great Britain, and have been highly satisfied to see how much they have improved the pharmaceutical profession in its scientific as well as in its practical and social direction. No other pharmaceutical association, as far as I know, has succeeded in obtaining so happy and so vigorous an influence on the development, both educational and legal, of pharmacy.

"These considerations have since long led me to devote my full sympathy to your Society. I, therefore, accept with the most grateful feelings the diploma, and beg to inform the Council of them. I am proud indeed to be associated in this way to English pharmacy in addition to personal friendship with several of its members.

"The Society may be sure that I regard the diploma as a permanent stimulus in endeavouring to become more and more a worthy, although a distant, collaborator in their noble work,

"Believe me to remain, dear Sir,

"Yours very sincerely,

"Prof. Flückiger."

"A. F. Haselden, Esq., F.L.S., etc.,
President Pharm. Soc. of Great Britain."

Letters of a similar nature were also read from Professors Balfour and A. Crum Brown, of Edinburgh, acknowledging the receipt of their diplomas of Honorary Membership.

The following being registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Ashworth, Amos ....London.
Badcock, Daniel ....Barnard Castle.
Hick, George..................Bradford.
Metcalfe, Wilson ....Harrogate.
Mills, Robert..................London.
Munro, John Morrison ....Aberdeen.
Parson, Henry James ....Birmingham.
Powell, Thomas Henry ....Hornsey Rise.
Tilden, William Augustus, D.Sc., Clifton.
Walker, Joseph ....Dresden.
Young, John Rymer............Warrington.

Elections.

MEMBERS.

The following *Pharmaceutical Chemists* were elected members of the Society:—

Bradford, Cordley ....Birmingham.
Smart, Alfred ....Steyning.
Tilden, William Augustus, D.Sc. Clifton.
White, William Edwin ....London.

Mr. Urwick suggested that Dr. Tilden might be elected an honorary member in acknowledgment of his past services to the Society.

Mr. Williams said that such a compliment, although very consonant to his own feelings, would have the effect of preventing Dr. Tilden accepting the office of Examiner, which he hoped he might do at some future time.

The following registered *Chemists and Druggists* were elected members of the Society:—

Adlington, William Benjamin London.
Cocking, Frederick John......Teignmouth.
Duncombe, William Pauncefort Wincanton.
Garner, Thomas ....London.
Jenkins, David Morris........Treherbert.

Two gentleman were restored to membership on payment of the subscriptions for the present year, and a fine of one shilling in each case.

ASSOCIATES.

The following, having passed their respective examinations, were elected "Associates in business":—

Minor.

Atkinson, David ....Cullercoats.
Fox, William Albert ....Stratford.
Fuller, John William ....King's Lynn.
Oxley, Herbert Lister ....Palermo.
Redpath, William ....Norwood.

Modified.

Higgins, William............Farnham.
Spalding, William Richard....Walthamstow.

The following, having passed their respective examinations, were elected "Associates":—

Minor.

Baynham, William Bevan ....Bath.
Bowker, William ....Bolton.
Brown, John Ephraim........Grantham.
Cleaver, Edward Lawrance....London.
Cooper, Herbert Hudson......Birmingham.
Davidson, James ....Falkirk.
Edwards, Charles............London.
Ekins, Arthur Edward ......Cambridge.
Findlay, James..............London.
Frowd, Edward Francis ......London.
Hart, Thomas ....Manchester.
Hills, Ernest................Weymouth.
Jackson, Alfred Henrick......Manchester.
Jones, David................Rhyl.
Lewis, Edward ....Sandown.
McJannet, James............North Walsham.
McMillan, James ....Perth.
Minett, Thomas Samuel ......East Grinstead.
Pearse, William Francis......Great Yarmouth.
Rimmington, George ....Bradford.
Rowcroft, Albert Edward ....Gravesend.
Shapley, Charles ....Torquay.
Smith, Charles Clapcott ......Rye.
Sturton, Richard ....Cambridge.
Taylor, Henry Francis ......Exeter.
Thring, Edmund John Henry Trowbridge.
Walton, Major Foulds........Sowerby Bridge.
Williams, William ....Merthyr Tydvil.

Modified.

Bannister, Theophilus Mayo ..Nottingham.
Beattie, Walter..............Portobello.
Fenner, Edwin ....Brighton.
Guest, George Frederick......London.
McKenzie, William..........Glasgow.
Thomas, William............St. Leonard's.

Finance.

The report of the Finance Committee was received and adopted, and sundry payments ordered.

Benevolent Fund.

The report and recommendations of the Benevolent Fund Committee were received and adopted.

A grant of £10 was made to a former member of the Society, who is at the present time in distressed circumstances; and a grant of £20 was made to the widow of the late Frederick Stockman, of Gosport, the amount to be handed over to the Fund now being raised by public subscription on her behalf.*

Library, Museum and Laboratory.

The report and recommendations of the Library, Museum and Laboratory Committee were received and adopted, and the following books recommended for the library were ordered to be purchased:—

Hassall's Food and its Adulterations (a second copy).
Pharmacopœia Græca, 1868.
Pharmacopœia Fennica, 1863.
Grevillea; by M. C. Cooke.

House.

The report of this Committee was presented. It included an estimate which had been obtained for repainting the outside of the premises, etc., and making certain alterations.

After a brief discussion it was decided that the main portion of the work referred to should stand over for the present, such painting only being done under the direction of the Committee as was requisite for the preservation of property.

Resignation of Dr. Tilden.

The Secretary having read a letter from Dr. Tilden, resigning his office as Demonstrator of Practical Chemistry in the Laboratory,

---

* See *ante*, page 36.

It was moved by the President, seconded by the Treasurer, and unanimously resolved:—

That this Council accepts the resignation of Dr. Tilden with regret at the loss of his valuable services, and desires at the same time to express its great satisfaction at the zealous and able manner in which he has for nine years discharged the duties devolving upon him in the Educational Department of the Institution, and its sincere good wishes for his success in the new sphere of duty upon which he is about to enter.

The appointment of a successor to Dr. Tilden was referred to the Library, Laboratory and Museum Committee.

PARLIAMENTARY.

The Report of the Parliamentary Committee was read, the most important item being a paragraph having reference to Vermin Killers, and recommending the addition of some explanatory words to the "Regulations required by the Pharmacy Act, 1868, to be observed in Selling by Retail and Dispensing Poisons," which were issued to the trade about two years since. The additions recommended were as follows:—

In the tabular statement of the "List of Poisons within the meaning of the Act," in Part 1 insert,

"**Vermin Killers.** (Every compound containing a "poison" in Part 1, and sold for the destruction of vermin.)"

In Part 2, the paragraph under the head "Vermin Killers," to read as follows (the addition is in Italics):—

"**Vermin Killers.** (Every compound containing a "poison" *in Part* 2, and sold for the destruction of vermin.)"

The report also stated that the amendments in the Food, Drink and Drugs Bill were satisfactory to the deputation who waited upon Lord Salisbury. The Secretary added that the Bill had now passed the House of Lords.

Mr. BETTY moved the adoption of the report, saying that he hoped this vexed question of vermin killers might be grappled with, and settled at last once for all. The great necessity for it had been shown more fully week by week since it had been first discussed, many reports of poisoning by means of vermin killers having been published in the newspapers. At the time when the letter was drawn up for the instruction of coroners as to the working of the provisions of the Act of Parliament, it was not considered politic to send any official communication on this subject unless the table issued to their own trade, relating to the sale of poisons, were not only complete in itself and easily understood, but so arranged as not to be liable to misinterpretation. He therefore thought it his duty to urge upon the Parliamentary Committee the great necessity of some more explicit directions being given to the trade with regard to the sale of vermin killers. During the last two or three months, the Act of Parliament had been read in a different light by two legal gentlemen, one coroner having laid it down that all vermin killers could be sold under part 2, whilst another was decidedly of a contrary opinion. No doubt, some little misunderstanding existed as to the meaning of the Act of Parliament, and, therefore, he thought it would be a wise thing to issue another table to every member of the trade, in which attention should be especially drawn to the provisions under which these articles might be sold. The alteration or addition which he would make to the table previously issued was simply that described in the report, introducing vermin killers, in both part 1 and part 2, so that by bringing them into juxtaposition, chemists and druggists throughout the country might better see under what restrictions such vermin killers ought to be sold. Thus, in part 1, he would insert after "Strychnine and its preparations," "Vermin killers or compounds containing poisons, in part 1, and sold for the destruction of vermin." He concluded by reading a few lines from the judgment of the coroner at Leeds, in a case in which the chemist pleaded by his counsel that vermin killers could be sold under part 2. The coroner said that the articles came within the 17th section of the Act of Parliament, and the sale of them ought to be conducted under the restrictions provided for the sale of poisons, and if any case of a similar description came before him after that, he should deem it his duty to direct the prosecution of the druggist for acting in contravention to the Act of Parliament. He would therefore move the adoption of the report, and also that the Secretary send a short letter to each member of the trade calling their attention to the matter.

Mr. HAMPSON seconded the motion.

Mr. STODDART thought this action would only lead to more difficulty. If all chemists would do as he did himself, when anybody came to buy a vermin killer treat it as if it were in part 1, there would be no difficulty, and no accident could arise. At any rate they would not be open to such observations on the part of coroners. A chemist might have half-a-dozen kinds of vermin killers in his shop, and he was not supposed to know what they contained until they were analysed. If therefore they could advise every one to enter these articles in their poison books as if they came under part 1, whether they absolutely did so or not, they would be perfectly safe. He had spoken to several coroners on this subject, being somewhat engaged in analytical chemistry, and he found some looked upon it in one light and some in another, but whatever view they took there was no convincing them they were in error.

Mr. WILLIAMS said if the sale of vermin killers could be confined to registered chemists and druggists it would be all right, then there would be no difficulty, but that was not the fact. He should be very glad to do what Mr. Stoddart suggested, but it was impossible to say what a vermin killer was without actual analysis, and the question was, were they to attempt to prohibit the sale of vermin killers by any one who was not a registered chemist and druggist.

Mr. SUTTON thought it would be a good plan if they could get the Government to adopt the French system, and to require the manufacturers of vermin killers to state what was the chief poisonous ingredient in their composition, there would then be no uncertainty as to how they should be dealt with.

Mr. ATHERTON said if the "Regulations" previously issued were indefinite, the sooner the matter was put right the better. No doubt chemists were at the present time running a risk in sending out these poisons under part 2. There would be a great disadvantage in agricultural districts in putting them into part 1, for the sale in such neighbourhoods was enormous, in some cases amounting to hundreds in a day. At the same time it was necessary to be secure, and therefore, at all events, those containing strychnine should be put into part 1.

Mr. HAMPSON said the very fact of vermin killers being sold for the purpose of destroying rats, and being represented as extremely destructive, tended to show that they contained deadly poison, and he thought the majority of chemists would for their own safety treat them as being under part 1. Unless they did so, they might find themselves in a great difficulty. It would no doubt be a good thing if Government passed an Act obliging the makers to state what the constitution of their article was, but still he thought Mr. Betty's resolution was a step in advance, and no doubt would have a beneficial effect.

Mr. RADLEY supported the view of Mr. Stoddart, thinking it would only be perpetuating a difficulty to have the new regulations under both heads, 1 and 2. They must remember that throughout the country there were many persons engaged in the trade who were very imperfectly acquainted with the mode of conducting analysis, and who would not be able to decide under which schedule the vermin killers should be placed. He thought the necessities of the case would be met if all vermin killers were put in part 1, without any reference to part 2 whatever.

Mr. Bottle said it was absolutely impossible for the Council to put articles in part 1 which were not placed there by Act of Parliament, but still he thought that an addition might be made to the note which Mr. Betty had suggested, recommending that in all cases of doubt the poisons should be treated as under part 1.

Mr. Betty said Mr. Stoddart's observations related solely to his judgment in conducting his business, and did not touch the state of the law, which it was the object of the Council to make as clear as possible to chemists and druggists throughout the country. They had no power to put anything either in one schedule or the other which was not there *de facto* by the Act of Parliament; and, therefore, all they could do was to declare how the Act worked. The table was simply explanatory, saying that vermin killers must be sold under part 1 or part 2 according to the poison which they contained. It was quite true that if there should be any doubt in the matter, any chemist who had any judgment would sell it as coming under part 1; but it was no part of their duty to advise him so to do. As to the observation that vermin killers were sold by booksellers, drysalters and others, that was rather an argument in favour of the resolution, because they would thus be drawing attention to the fact that these articles contained poisons, and should only be sold by qualified persons.

Mr. Sandford said he was doubtful how far they were authorized to issue any interpretation of the Act of Parliament. He thought it would be better to let each man interpret it for himself.

Mr. Stoddart said the most popular vermin killers did not always contain the same ingredients.

Mr. Atherton said that one circular having gone out on this subject, which it appeared was not quite clear, it was their duty to do what they could to set it right.

After some further discussion it was resolved—

That the Report of the Parliamentary Committee be received and adopted, and a copy of the revised 'regulations' be sent to every chemist and druggist with a note by the Secretary, by order of the Pharmaceutical Council.

General Purposes.

The Report of the General Purposes Committee on the Reports of the Board of Examiners and Professors on the competition for the Jacob Bell Scholarships and Sessional prizes, was received, and the following awards made.

JACOB BELL MEMORIAL SCHOLARSHIPS.

The Board reported that *three* candidates presented themselves for the Senior Bell Memorial Scholarship, and *nine* for the Junior.

Neither of the candidates for the Senior Scholarship obtained the requisite number of marks for its award.

The Committee therefore recommended that two Junior Scholarships be awarded.

It was resolved "That Junior Bell Memorial Scholarships be awarded to

Sydney Plowman
and
Edward Lawrance Cleaver.

with free laboratory instruction and materials for the Session 1872–73.

SESSIONAL PRIZES.*

The Board reported that during the past Session *fifty-three* candidates had passed the Minor, and *fifteen* the Major examinations in honours, of whom *eleven* competed for the Prizes of Books and four for the Pereira Medal. The Committee recommended, and it was resolved —That the

PRIZE OF BOOKS

be awarded to George Claridge Druce.

That the

PEREIRA MEDAL

be awarded to William Ashwell Shenstone.

On the Reports of the Professors on the results of the competition for the prizes offered by the Council, the Committee recommended, and it was resolved—That the following rewards be made:—

CHEMISTRY AND PHARMACY.

Silver Council Medal	Robert Higgins Davies.
Bronze Council Medal	Edward Rammell.
Certificates of Honour	Joseph Walker. William Ashwell Shenstone.
Certificates of Merit	Frederick Arthur Crisp. Arthur Brownhill Cortis. Martin Luther Hetherington.

BOTANY AND MATERIA MEDICA.

Silver Council Medal	Robert Higgins Davies.
Bronze Council Medal	Edward Rammell.
Certificates of Honour	Frederick Janson Hanbury. William Ashwell Shenstone.
Certificates of Merit	Arthur Brownhill Cortis. Joseph Walker. Charles Harridge Russell.

PRACTICAL CHEMISTRY.

Silver Council Medal	William Ashwell Shenstone.
Bronze Council Medal	Robert Higgins Davies.
Certificates of Honour	Joseph Walker. Richard Trist. Frederick Janson Hanbury.
Certificates of Merit	Daniel Badcock. Walter B. Bishop. James Herbert Midgley. Arthur Brownhill Cortis. David Edwards.

BOTANICAL PRIZE.

Upon the Report of the Professor of Botany the Committee recommended, and

It was resolved—That the Silver Medal be awarded to Frederick Janson Hanbury for his Herbarium.

REPORTS OF THE BOARD OF EXAMINERS.

England and Wales.

July, 1872.

Examinations	Candidates. Examined.	Passed.	Failed.
Preliminary	283	191	92
Minor	78	40	38
Major	17	9	8
	378	240	138

Preliminary.—Certificates received:—

College of Preceptors	1
University of Cambridge	3
	4

* The Sessional prizes and certificates will be distributed at the Evening Meeting on the 2nd October next. Successful candidates will be expected to attend. An address to the students will be delivered by Mr. Stoddart, of Bristol. Ladies are invited to be present.

SCOTLAND.

Examinations.	Candidates. Examined.	Passed.	Failed.
Preliminary	42	18	24
Minor	10	7	3
Major	3	2	1
	55	27	28

Preliminary.—One certificate received in lieu of this examination.

REPORT ON THE EXAMINATIONS BY THE GOVERNMENT VISITOR.

The following letter and report were read:—

Medical Department of the Privy Council Office,
20th July, 1872.

Sir,—I am directed by the Lords of Her Majesty's Council to forward to you, for the consideration of the Council of the Pharmaceutical Society, a copy of the report made by Dr. Greenhow, to the Lords of the Council, on the Society's Examinations in England in the year 1871.

I am, Sir,
Your obedient Servant,
JOHN SIMON.

E. Bremridge, Esq.,
Secretary to the Pharmaceutical Society,
17, Bloomsbury Square.

Report on Examinations of the (No. 12) *Pharmaceutical Society conducted in London during the year* 1871.

During the year 1871, the Board of Examiners of the Pharmaceutical Society held twenty-four meetings for the examinations of candidates, namely,—

Four for the *Preliminary* Examination in Latin, English and Arithmetic, after passing which candidates are registered as apprentices or students; and

Twenty meetings for the Technical Examinations, *Modified, Minor* and Major, qualifying candidates who have passed the Modified or Minor examination to be registered as Chemists and Druggists, and those who have passed the Major as Pharmaceutical Chemists.

Of these twenty meetings (at twelve of which I was present), four were held for the "*Modified*" examination of candidates who had been actually engaged in the dispensing and compounding of prescriptions as Assistants to Pharmaceutical Chemists or to Chemists and Druggists for a period of not less than three years previous to December 31st, 1868. The other sixteen meetings were devoted to the examination of candidates presenting themselves for the Minor or Major qualifications.

At the four *Preliminary* examinations, 1101 candidates presented themselves, of whom 714 passed and 387 were rejected. The proportion of rejections at this first stage of examination has therefore been at the rate of 35 per cent., showing that, as yet, no improvement has taken place in the previous general education of the candidates since the passing of the Pharmacy Act of 1868. The standard of the examination is in no respect too high. It comprises the translation into English of two short sentences from either the first book of Cæsar, Pereira's 'Selecta e Præscriptis', or the last edition of the London Pharmacopœia; four or five simple questions in Latin Grammar; five or six sums in the first four rules of Arithmetic, simple and compound, and in Vulgar Fractions and Decimals; and five or six questions in English Grammar and Composition.

It is certain that no youth who is unable to pass this elementary examination can with safety to the public be allowed to dispense medicines, involving as this does the reading of prescriptions written in abbreviated Latin, and frequently the calculation of the respective proportions of the several ingredients of a prescription, in order to dispense a larger or smaller quantity than that prescribed. Even of the candidates who have passed this Preliminary examination, a considerable proportion subsequently fail to acquit themselves well in reading Latin prescriptions; for I must now repeat what I said in my first report, that many of the candidates coming up for the Minor examination are unable to read with accuracy the Latin prescriptions submitted to them, although these prescriptions have been without exception already dispensed in chemists' shops.

The total number of marks given for the Preliminary examination is 300, allotted in equal proportions to the three subjects, Latin, English and Arithmetic. In order to pass the examination, candidates must obtain a total of at least 150 marks, but a candidate who obtains less than 25 marks in any one of the three subjects is rejected, even though he may have obtained a greater total than 150 marks in the three subjects collectively. A very careful analysis of the numbers of marks obtained by candidates at the Preliminary examinations during the year 1871, has been made by Mr. Haselden, the President of the Pharmaceutical Society, and forms the basis of a special report from the Board of Examiners to the Council of the Society. It appears from this analysis that during the past year no less than 170 candidates obtained less than one fourth of the number of marks for Latin; whilst in English and arithmetic only 64 and 44 candidates failed to obtain one fourth of the marks for those subjects respectively. Again, in Latin, 362 candidates fell below one half the number of marks for that subject, in English 275, and in Arithmetic only 204. These numbers clearly prove exceptional deficiency in knowledge of Latin, and it is in fact stated in the report that arithmetic has been in many cases the means of passing candidates, the large number of marks obtained for it making up for deficiency in the other subjects. Considering, however, the absolute necessity of a sufficient knowledge of Latin to secure the accurate understanding of prescriptions, I am of opinion, with these facts before me, that it deserves consideration whether a higher number of marks should not be given for Latin, or whether a larger proportion than one-fourth of the number now allotted to that subject should not be required for passing both the Preliminary and the subsequent examination.

With respect to the Preliminary examination, I must further observe that at present young men are not required by law to pass this examination before engaging in the responsible duties of dispensing medicines in chemists' shops, in the capacity either of apprentices or assistants. I am indeed informed that many masters, nevertheless, require their apprentices and assistants to have passed it, but the Pharmacy Act not rendering it compulsory on them to do so, a great many youths are at present still employed in chemists' shops who have not given proof of having received even the moderate amount of education implied by their having passed this examination. It would, in my opinion, greatly conduce to the advantage equally of masters and apprentices, if a general understanding could be arrived at, that no young men should enter on employment, either as apprentices or assistants, who had not previously passed the Preliminary examination, and I am glad to observe that this opinion is shared by the Board of Examiners, in whose report, already referred to, it is recommended that indentures of apprenticeship should not be signed until the apprentice have passed either the Preliminary examination of the Pharmaceutical Society, or one of the other examinations approved of in its stead.

At the four meetings held during the year for the *Modified* examination, 163 candidates presented themselves, of whom 103 passed and 60 were rejected; giving a proportion of failures amounting to nearly 37 per cent. This class of candidates will soon cease to exist, and it was, perhaps, to be expected that a larger proportion would year by year be found incompetent; most of those who thought themselves well qualified having probably come up for examination soon after the passing of the Pharmacy Act.

Sixteen meetings were held during the year for the Minor examination, and at these meetings 323 candidates presented themselves, of whom 204 passed, whilst 119, or 36 per cent., were found incompetent. Many of these failures were obviously due to defective early education, especially in Latin; the candidates, although they had passed the Preliminary examination, having failed when required to read Latin prescriptions. Many other candidates failed from ignorance of the elements of chemistry and from inability to recognize the commonest drugs. In my first report on the examinations of the Pharmaceutical Society, I stated that the Minor examination was, in my opinion, as stringent as could with fairness and practical advantage be enforced at that time. Three years have, however, now elapsed since the provisions of the Pharmacy Act came into operation, and there could be no hardship, provided due notice were given beforehand, if at the end of another year candidates for the Minor examination were to be examined practically as to their ability to determine by means of the proper tests the presence of the acid and base in solutions of one or more of the salts commonly used in medicine, or to ascertain the purity and strength of some of those officinal articles most likely to be impure or to vary in strength. This addition to the present subjects of examination seems the more desirable when it is considered that candidates who have passed the Minor examination, and been registered as chemists and druggists, are thereby qualified to keep shops for the retailing and dispensing of medicines, and need not, unless they choose, present themselves for the Major examination; and that, in fact, only a comparatively small number of them do subsequently present themselves for that examination, at which such evidence of practical skill is required as I now consider should be necessary for passing the Minor examination.

At the *Major* examinations which were held on the same days as the Minor, 67 candidates presented themselves during the year, of whom 47 passed, and were registered as pharmaceutical chemists, whilst 20, or nearly 30 per cent., were rejected. In my first report I stated that the examiners intended to require candidates for this examination to determine the strength of one or more given pharmacopœial solutions by volumetric analysis, and in my last report, with the view of assisting the Board to carry out their intention, I suggested that the requirement of this proof of practical skill should be at once enforced. I read to the examiners the passage in my report which contained this suggestion, and from that time I have been gratified to find that volumetric analysis has formed a part of the *Major* examination.

The Major examination occupies two days. On the first day candidates have hitherto been required to write answers to questions in chemistry and pharmacy, and to perform under the eyes of the examiners a certain amount of practical testing, to which I have already adverted. To these subjects has now for nearly a year been added the volumetric analysis of such officinal solutions as hydrocyanic acid, solution of ammonia, etc., the candidates being supplied with the necessary apparatus and tests, and being required to perform the analysis and to work out the calculated results in the presence of the examiner.

It is, perhaps, desirable to explain with reference to the very large apparent numbers of candidates rejected at the examinations of the Pharmaceutical Society, that very many of the candidates rejected in one examination present themselves again on subsequent occasions, and that of these many ultimately pass. Hence the number of the candidates who finally fail to pass each stage of examination is smaller than would appear from the proportions I have given above in analysing the results of separate meetings for the various examinations.

Having given in my previous reports many details respecting these examinations, unnecessary to be repeated here, it only remains for me, in conclusion, to confirm from my observations of the past year the opinion I have given on former occasions, that the examinations of the Pharmaceutical Society are conducted in such a manner as to afford a satisfactory guarantee for the competency of persons admitted to registration under the Pharmacy Act of 1868.

(Signed) E. Headlam Greenhow.

14*a*, *Manchester Square*,
March, 1872.

Mr. Urwick then brought forward the following resolution, of which he had given notice:

> "That all Registered Chemists and Druggists be admitted members of the Pharmaceutical Society on payment of the annual subscription of £1. 1*s*., subject to the same rules that at present govern the election of members, excepting only the entrance fee."

He said he moved this resolution upon policy, self interest, consistency and liberality—liberality to those who were sailing in the same boat with themselves, and who had the same interests to protect and the same rights to defend. With regard to the policy, he was struck with the necessity of it last year when he formed part of a deputation who waited on Mr. Forster on behalf of the trade. He then found there was one weak point about their action, which was that the Pharmaceutical Society did not represent the whole trade, but merely a minority, and a minority which, he was sorry to say, was very small. The whole body on the Register amounted to about 12,000, whilst the members of the Society were only 2466, and it was with a view of inviting, if possible, many of those gentlemen who were now outside the Society to join in promoting the cause of Pharmaceutical Education that he moved this resolution. There might of course be objections to many of these being admitted, on the grounds that they were not fully qualified or eligible in other respects, but these objections would be met by the same rules which at present governed the elections. As to the point of self interest, he believed it would tend to increase their funds and give them a better position generally. In the year 1871 it appeared they were entering on a period of decadence, for while the number of Pharmaceutical Chemists on the Register was 5029, only 2054 of these were members of the Society, showing that those who were admitted did not for some reason or other join the Society, and no longer supported it, either with funds or by their influence. On the ground of consistency, he would only add that they had in many ways done all they could for the benefit of those outside the Society—in the Juries Bill, for instance; and on the same principle, he thought they should use every effort to get these men to join the Society.

Mr. Hampson seconded the resolution, thinking it very important that some attempt should be made to bring the chemists and druggists throughout the country and the Pharmaceutical Society into closer union. From the statistics read by Mr. Urwick, it seemed to be a melancholy fact, that the great majority of chemists could not in any way be identified with the Society, not one-twentieth of them being members, and he could not conceive of the Society being a stable representative institution while such a state of things existed. He did not say whether this resolution would meet the difficulty, but, at all events, it was an attempt to do so; and on those grounds he should support it.

Mr. Atherton suggested that as time was rather limited, and the matter was an important one, it should be adjourned to a future meeting.

The PRESIDENT said the resolution could not be carried, because it would be tantamount to an abrogation of one of the bye-laws, therefore the shortest way to settle the matter would be if they were going to consider the bye-laws in general, to refer this to the same Committee.

Mr. URWICK said of course he had contemplated that if his resolution were carried, the bye-law would have to be amended accordingly. He added, that he had no objection to adjourn the discussion to a future period.

Provincial Transactions.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The Half Yearly Meeting of the above Association was held at the rooms, Halford Street, on Thursday, August 1st, Mr. W. Bradley, President, in the chair. The following report, having been read, was unanimously adopted:—

"The committee, in meeting the members of the Association at the close of the session ask their attention to the following statistics: During the half year meetings have been held twice a week, at which papers have been occasionally read upon subjects of great importance to students, the greater number of evenings having been devoted to the systematic teaching of botany, chemistry, materia medica, and dispensing. The committee take this opportunity of tendering their warmest thanks to the class lecturers for their efficient aid, particularly as the large attendance at these attests the interest taken in them. Whilst giving their hearty thanks to the principals who so kindly promised papers at the beginning of the session, the committee regret that some of these were not read, through the very pressing claims of business upon Leicester chemists during the last few months; in this way some little harm has been done to the Association. During the half year four members have passed the Preliminary examination, and one the Minor; in addition to this, two gentlemen (members of the Association from the formation to the end of the last session) have passed the Major, one of them being first in honours. The classes have met forty-three times, the average attendance at each being 10·5. Seventeen Assistants have been members in the half-year, and sixteen Apprentices; whilst twenty-seven principals have been subscribing honorary members. The committee beg to return thanks to those chemists who have adopted the custom of closing their shops not later than eight o'clock, as on this account the meetings at Halford Street have terminated at an earlier hour than formerly, which has given general satisfaction. Finally, in closing one of the most satisfactory reports ever presented to the Association, the committee beg to draw attention to the balance in the hands of the Treasurer, the expenses of this session of the year being far in advance of the receipts."

A vote of thanks was then passed to the committee for the able manner in which they had discharged their duties during the half year.

The prizes for attendance were then presented by the Chairman to Messrs. Bishop, Butler, and Gray, these having attended every meeting of the Association.

A very hearty vote of thanks was then carried unanimously to the President for his kind and able conduct in the chair during the half year; also for his assiduous attention to the interest of the botany class.

The Secretary having read the names of those nominated to form the new committee, several having declined to stand, the following seven were elected by ballot, who afterwards chose their own officers:—

President, S. H. Cadoux, A.P.S.; *Vice-President*, W. B. Clark, P.C.; *Treasurer*, E. H. Butler, A.P.S.; *Hon. Secretary*, W. Thirlby, A.P.S.; W. T. Elkington; E. J. Bishop; C. Raynor.

A Programme of Classes, meeting twice a week, till February, 1873, has been issued by the Society.

Parliamentary and Law Proceedings.

HOUSE OF LORDS.

ADULTERATION OF FOOD, DRUGS, ETC., BILL.

Thursday, August 1st. This Bill, as amended, was read a third time and passed.

THE PUBLIC HEALTH BILL.

Friday, August 2nd. On the motion of Lord Ripon, this Bill, brought up from the Commons, was read a first time.

On Monday, August 5th, the Bill was read a second time, and on Tuesday it passed through Committee.

On Wednesday, on the motion for the third reading, Lord Buckhurst expressed a regret that so important a Bill should have been sent up to their Lordships at a period of the session when it was impossible to discuss it. The complaint was concurred in by Lord Redesdale.

After a few words of explanation from Lord Ripon, the Bill was read a third time and passed.

HOUSE OF COMMONS.

THE PUBLIC HEALTH BILL.

Thursday, August 1st. On the motion for the consideration of this Bill as amended, Mr. Knight moved that it be considered that day month. He said that, although not quite so objectionable as when it was first introduced, the Bill formed part of a scheme to subject the whole of the local government of England to a central board in London. Of the clauses of the Bill, 18 might be classed under the head of "tyranny" and 23 under the head of "Taxation."

Mr. Gregory, Mr. Corrance, Mr. Hurst and Mr. Newdegate spoke against the Bill, but after a short reply from Mr. Stansfeld, the amendment of Mr. Knight was negatived by 168 to 16.

Various amendments were then proposed by Mr. Stansfeld and agreed to,—the Bill was reported to the House, and ordered to be read a third time on Friday, Aug. 2.

On Friday, August 2nd, the Public Health Bill was read a third time and passed.

THE PETROLEUM BILL.

Thursday, August 1st. Lord Sandon asked the Secretary of State for the Home Department whether at this period of the session it was his intention to proceed with the Petroleum Bill.

Mr. Bruce said the only point in the Bill which was opposed was that relating to the testing of petroleum. Opposition to the Bill, he was aware would disappear if the testing clause were withdrawn; but the Government could not consent to that alteration consistently with a regard for public safety. It would therefore be impossible to proceed with the Bill if the opposition to that part of it were continued.

On Friday the Bill was read a second time and withdrawn.

SUICIDES BY VERMIN KILLERS.

At Chorlton-on-Medlock, an inquest has been held on William Patch, aged 20. It appeared that the deceased, who had been some time depressed in his mind, from a fear that he was insufficiently educated for his calling as an accountant's clerk, took a portion of a packet of vermin killer in some water. A verdict of suicide while in an unsound state of mind was returned.

Another inquest was held at Hackney, on Thursday, to inquire as to the cause of the death of Sarah Chandler. Evidence was given that the deceased, who was a married woman, had complained of pains in her head, and on Sunday was found in a dying state. In reply to questions, she said she could bear them no longer, so she had taken poison; and it was subsequently ascertained that she had taken a large quantity of Battle's Vermin Killer. A verdict was returned of "Suicide whilst of unsound mind."—*Echo.*

Poisoning by Barium Compound.

An inquest has been held at Salford on the body of Patrick Kennedy, a dyer. It appeared that the deceased was employed at the works of Messrs. Walker and Norris, Adelphi, and after complaining of a pain in his chest, went to the storeroom, in which was kept a supply of sago and several kinds of salts, and obtained about three ounces of a whitish powder, which he supposed was "heavy salts." He made a solution of this in a small vessel, and drank it. The powder was in reality compounded of several drugs used in the dyeing process, and its principal ingredient was chloride of barium. This compound had recently been introduced into the works, and the foreman stated at the inquest that every *employé* had been warned of its poisonous nature. The deceased went to the dispensary and told the house surgeon that he had taken "heavy salts." An emetic was given him; but he died. Mr. H. Latham, house surgeon at the Dispensary, said he had made a *post-mortem* examination of the deceased, and was convinced that he had died from the effects of poison. He added that a much smaller quantity of chloride of barium than the deceased was said to have swallowed was sufficient to cause death. Other witnesses said that the deceased had no business in the storeroom whatever. The jury returned a verdict of poisoned by chloride of barium taken in mistake.

Conviction of a Begging Impostor.

At the Police Court, Cardiff, on Friday, August 2nd, William Mackley, formerly a chemist's assistant, was charged with begging and being an impostor. Mr. F. W. Joy, chemist, Duke Street, said that the prisoner came to his shop on Wednesday, and said he was a Mr. Teear, a chemist, of Leicester, and that he had been broken down by ill-health. He was making his way down to Neath to his wife's relations. Witness believed the story, and gave him 1*s.*, and also recommended him to a house for a night's lodging. He came again on Thursday, and said he had seen Mr. Kernick, who had proposed, amongst the members of the profession, that his (the prisoner's) wife should have her railway fare paid to Neath, and that they would pay the fare between them. Witness then went to two or three chemists in the town soliciting their contributions. He had previously told the prisoner that if he found everything right, he would give him the tickets for the journey to Neath. Witness could not find the address of the prisoner's brother-in-law at Neath in any directory as given by the prisoner, and telegraphed to the Local Secretary of the Pharmaceutical Society at Leicester, and got a reply, in consequence of which he gave the prisoner in custody. The prisoner said he was formerly an assistant in the employ of Mr. Teear, a chemist, of Leicester, and previously to that time he was four years in the British service. He had since been very unfortunate, which had led him to falsify his name and to tell lies. He was down in the world and could not get into his profession again. He had even tried to get an honest living by hay-making, but he could only earn 1*s.* 8*d.* a day. He was sentenced to seven days' imprisonment with hard labour.—*Western Mail.*

Embezzlement by Wholesale Druggists' Clerk.

Frank Gypson, 36, a respectable looking man, was placed at the bar before Mr. Benson, at the Southwark Police Court, for final examination, charged with embezzling about £160, received by him for and on account of his employers, Messrs. Yates and Co., wholesale chemists, Park Street, Southwark.

Mr. Redpath appeared for the prosecutors, and said the prisoner had been in their employ as ledger clerk at a salary of £150 a year. It was not his duty to receive money; in fact, he was forbidden to do so. Notwithstanding, he had collected various sums from customers; in one instance intercepting a letter enclosing a cheque for £9. 18*s.*, and converting it to his own use. They had discovered deficiencies amounting to upwards of £160, which had been going on for three years past.

Mr. Yates was called, and said the prisoner had no right to receive any moneys, and whatever he may have taken he should have paid over immediately to the cashier. He had gone through the books, and found the deficiencies to amount to above £160.

Three witnesses were called, who proved paying the prisoner various sums which he had not accounted for. The landlady of the Queen's Head Tavern, in the Borough, produced the cheque for £9. 18*s.*, which she cashed for the prisoner and paid into her bankers.

The prisoner here said he pleaded guilty, and threw himself on the mercy of the court and the prosecutors. He trusted they would deal leniently with him for the sake of his wife and family.

The prosecutors wished his worship to deal with him, and not send him for trial.

Mr. Benson told the prisoner he had a good situation and a good salary, and that ought to have kept him honest. He sentenced him to six months' hard labour. —*Echo.*

Notes and Queries.

NUTS.—I must remind Mr. Simmonds that the *Tung-shu* tree of the Chinese Mat. Med., is an *Elæococcus* or a *Jatropha* according to the province. The *Paulownia imperialis* (which yields no oil) is called the *Tung* tree. The *Aleutrites triloba*, or "Stone Chestnut," is called *Shih-lih* in Chinese. The Buddhist creed, which teaches compassion for human and *animal* life, has induced the Chinese to work up the vegetable sources of oils and fats to an enormous extent.—F. Porter Smith.

*** The following is Mr. Simmonds' reply to the above note:—

"I thank Mr. Porter Smith for his corrections and suggestions as to the brief allusion which I made in my lecture "On Nuts" to the Tung-shu or Jung-shu. The name seems to have an extended signification to several plants in China I took my information from one of our Consular Reports, but am quite aware that *Elæococcus verrucosus* is the recent botanical name of Brown's *A. cordata*.—P. L. Simmonds.

Provincial Education.

Sir,—Allow me to make a few remarks on the question of spending a portion of the funds of our Society in the provinces, a subject which has been, and now is, very properly occupying the attention of the Council and other parties interested in the result.

Certain principles have been enunciated, and more than one scheme proposed, in order that action may be taken and money grants made.

With very few exceptions, a feeling has been expressed that the Society should become more an educating body, or, in other words, pay sums of money to lecturers in certain districts of the country.

Another feature, apparently gaining favour, is that of local examinations, competition for prizes, and payment for results.

Believing that it is alike the duty and privilege for all who are interested in the well-being of the Society to offer opinions or make suggestions, I beg to submit the following, premising that, being alone responsible, I trust, however much I may disagree with others on some points, I will receive credit for honestly stating my views in regard to the advancement of young pharmacists at present existing, and even looking forward to those of the future.

I therefore at once affirm that as a Society we ought not to pay lecturers, or even supplement salaries by payment to teachers. We are not in a state of pauperism, and I fail to see the necessity of spending money in that direction. No college, so far as I know, pays its professors with the view of enabling students to attend classes at a low or reduced rate, and if we are to be placed and kept in our proper position, I think that all who join our ranks ought to be able to pay a fair sum for the knowledge they derive in the lecture-room or the laboratory. It is true there are endowed professorial chairs, but the funds necessary for such endowments have not been drawn from the pockets of past or present pupils, but have been obtained from different sources altogether.

I do not therefore think that even in London there should be paid teachers,—in order that those wishing to attend such prelections might do so, at a price far below what the teaching is really worth. More than one has remarked that our school as at present existing, has been, and really is, supported more by young men from the country than from London and the neighbourhood. Still so far from such a statement weakening my argument, I conceive it rather strengthens it. Take the number of young pharmacists in England, Scotland and Wales, and think how exceptional is the case of students appearing to study at Bloomsbury Square. We have in the metropolis a museum, library, laboratory, and lecture-room. Of these we may be fairly proud. I cannot see why the Council should not appoint professors, one for chemistry and pharmacy, one for botany and one for materia medica, and another for practical chemistry and pharmacy, giving to each the name and free use of rooms, museum and apparatus. But by all means allow these gentlemen to charge a fair remunerative fee for their tickets of attendance. Surely the labourer is worthy of his hire here as elsewhere. But I go further, and suggest that the opportunity now proposed, coupled with the recommendation of the Society, might induce a system of teaching so much superior to that carried out elsewhere in the same branches, that students ought to be attracted to the benches in Bloomsbury Square, in preference to going anywhere else. I also believe that the present system of sessional teaching might be improved. At present the period is ten months, commencing in October and finishing the end of July. Now I ask would one hour a day for chemistry and pharmacy, and the same for botany and Materia Medica, extending over five months, not be an improvement over the present system? Indeed, if required, two courses instead of one might be accomplished each year. If this were done, it becomes a question as to how many more might be able to arrange for a five months' residence in London, who find it impossible to extend their stay during the present lengthened term of ten months.

Our present professors are, in their various departments, clever and highly scientific men, and, from the time they have held their position, may be said to hold vested interests. In this case, it might be left to the Council to determine whether past services ought to be recognized, and if so, to what extent and in what form such recognition might be made.

It will be at once evident that I object to the money payment of teachers in London or out of it. But I would be willing to extend to the provinces the same privileges, but on a smaller scale, which our London friends are supposed to enjoy. I would be glad that our Society assisted in paying for a place of meeting, museum, library, and even apparatus, if the circumstances of the district warranted such a grant. Local effort might form a guide as to the money to be given, while such a system would bring within its scope the smallest town or village where a few of our members were in earnest in carrying out the good work.

We ought never to forget that we as pharmacists differ in many respects from the requirements of those who study at universities. The Pharmaceutical Society does not exact attendance in certain classes and for certain periods. The young man in the country, who by reading, study, and application fits himself for examination, is just as certain to pass the Board of Examiners in London or Edinburgh, as the candidate who may have studied in the larger towns, or even in London itself. A case in point occurred here this spring, where a young man from a town in the far Highlands, not only passed his Major examination, but did so in Honours, while he had never attended a single lecture of any kind in his life. This I had from his own lips.

What the operation and result of local examinations may be is doubtful; but I think they deserve a fair trial, as it is a healthy thing to make it an open competition where prizes are to be gained. Medals or books ought, I think, to be awarded; but in no case should money be competed for, as has been proposed.

The question of lessening examination fees and annual subscriptions has been opened up; but I have a strong feeling that such a proceeding would at the present time be premature. The time may come when such a course might be deemed advisable for the interests of the Society; but a change such as this would require very great consideration before a step so serious could be safely taken.

I feel certain that every existing chemist and druggist would do the right thing if he determined not to bind an apprentice till he had passed his Preliminary examination. He would also be doing an equally just and right thing if he gave the same apprentice time and opportunity to attend classes on chemistry, materia medica and botany, or where such did not exist, to give him time to carry on his studies in these sciences. In such cases, library and museum would be excellent adjuncts to those young men; and by the aid of ordinary perseverance and study, be the means of frequently enabling many of them either at the termination of their apprenticeship, or very soon after, to pass the Minor examination with some degree of satisfaction to their masters and themselves.

In conclusion, I would simply add that if the Council shall so arrange that grants of money are to be spent in paying lecturers, then it will be felt in many places that they have been unjustly dealt with, while past experience has proved the fact that, when the admission to excellent scientific lectures has been reduced to a minimum, few have been found to take advantage of the opportunity so offered, the paucity of attendances, I am sorry to say, being attributable either to disinclination on the part of the students themselves or to the employers declining to give the requisite time.

John Mackay.

Edinburgh, July 31st, 1872.

Sir,—It is to the dogged perseverance of the British soldier that we are indebted for the names of victories which shine so resplendently on the pages of our country's history. It was the same dogged perseverance which wrung from the lips of the great Napoleon the exclamation that a British soldier never knows when he is defeated. I desire to be animated with something of the same spirit, that I may be able to continue the discussion of Provincial Pharmaceutical Education, and to do my share towards bringing it to a successful termination. In my previous letters to you I have endeavoured to prove that it is the duty of the Pharmaceutical Society to promote and to assist in providing an uniform system of education of those practising pharmacy. I think I have conclusively shown that they have done neither one nor the other, for the country members of the trade. I cannot agree with you, in your leading article in the Journal for July 20th, where you say, "it may fairly be said that the Society, as a voluntary association, has already completed its labour in the cause of education, and that, in having succeeded in making education compulsory, it has done the work it originally projected." In my last letter to you, I said that in my next, "I will endeavour to show why the Council should assist Provincial Pharmaceutical Education, and how they can do it."

Thirty years ago the Society obtained a charter of incorporation from the Queen, the first clause of which states that it was granted for this special purpose. Subsequent Acts of Parliament have rendered still more imperative their duty in this respect. It will be a breach of faith, both towards the Queen and towards Parliament, if they do not do so. Nothing can be more unsatisfactory than the present position of pharmaceutical education in the provinces. In truth, there is no such thing as a regular system of scientific education existing there. Nothing has been done by the Society for this purpose. What little has been done, has been by the unaided efforts of its country members. Had Jacob Bell lived, the pioneer of pharmaceutical education and progress, this subject would have received a satisfactory solution long since. It is no argument at all, because the Institute in Bloomsbury Square has not proved the success which it could have been wished (and it reflects no credit on the town members of the trade that such should be the case), that no effort should be made to assist scientific education in the country. A residence of six months in London, to attend a full course of lectures at the Institute, means an expenditure of £100. When you consider the circumstances of the parents from whom the supply of country apprentices are obtained, it is an expenditure which very few can afford. Our apprentices are not drawn from the wealthy members of Society, but are the sons of people of moderate means.

The Society has established compulsory registration and compulsory examination. I think it has started at the top of the tree, instead of the bottom. Had it first provided a universal system of education for a few years, and then made it compulsory, together with examination, it would then have acted in a fairer spirit towards the country members of the trade. What has been the effect of the Act passed in 1868 rendering examination compulsory? Nothing can be more unsatisfactory. Young men who cannot afford a prolonged residence in London, are driven to take advantage of the institutions advertised in the Journal, where the information necessary to pass the Minor is blown into them in a month, and by the same mysterious process for the Major, in three months. Can anything be more unsatisfactory than this? The result of it is seen in the case of the young man, twenty-six years of age, a Minor Associate, reported in last week's Journal, who translated "si opus possit" to be taken "with posset." I think my case is now complete.

I will now endeavour to show how the Society may promote scientific education in the country. My views on this subject have been expressed in a paper on Provincial Pharmacy Schools, read before our local association, and which appeared in the Journal on April 13th; in the few remarks which I made at the Annual Meeting of the Society in May; and in my letters which have appeared in the correspondence columns of the Journal. I advocate the establishment of a number of pharmacy schools in some of the large towns of the kingdom. I would take the provincial medical schools as a standard to go by in founding the schools of pharmacy. These schools ought to be affiliated with the parent Society. A complete curriculum of education satisfactory to the Council, on chemistry, materia medica, practical pharmacy and botany should be required from them. Every lecturer ought to be a certified teacher approved of by the Council. I also think that it would be a great advantage if the Council would prepare a syllabus of the lectures to be delivered each session in every school. No student should be permitted to attend a course of lectures on these subjects until he has first passed his Preliminary examination. No student ought to be allowed to present himself for the Minor examination without producing a certificate signed by a certified teacher that he has attended regularly a certain number of courses of lectures on the above subjects. The number of courses to be determined hereafter by the Council; at the same time he shall also produce satisfactory evidence that he has served an apprenticeship of a certain number of years to a member of the trade. This system, if faithfully carried out, would in a short time produce a body of educated pharmacists. No person should be allowed to present himself for the Major without producing the certificate of a certified teacher that he has attended a further course of lectures on the subjects required for that examination.

I am well aware that pharmacy schools cannot be established in every town in the kingdom. In those cases where they cannot, I think assistance may be rendered to promote class-teaching. After a young man has served an apprenticeship in a town where no such school exists, he should endeavour to obtain a situation in one where he can have these privileges.

The question will now be raised, how are these schools to be supported, museums formed, laboratories established, prizes given and payments for results provided for? I repeat, what I have stated on previous occasions—by liberal grants from the parent Society; by subscriptions from the local members; and by fees from the students. This is the scheme that I submit for the Society's consideration. It would probably have been more satisfactory to the members of the Society in general had the Council, who have seen for many years past the working of their school, been prepared with a scheme of their own.

It may be urged against this scheme that it would revolutionize the trade. I think it is very probable that it would eventually have that effect, and I think it is extremely desirable that it should. The present position of pharmacy in this country, both in its relation to the medical profession and to the public, is in a very unsatisfactory condition. I forbear from entering upon a discussion of it now, for it would open too wide a question for discussion, and reserve my remarks on it for a future occasion.

Atkinson Pickering.

Hull, August 6th, 1872.

Payment by Results and its Working.

Sir,—In order that I may give, as I promised in my last letter, an ideal representation of the Society, local committee, teacher and student, under Mr. Schacht's scheme, I will begin with the Society.

The Society must be like the Committee of "My Lords" of the Science and Art Department, which bestows money grants, gives prizes to students, appoints teachers, and sees that the money in hand is properly expended, the classes properly conducted, and that certificated teachers are appointed to the classes.

The Local Committee.—In order that the designs of the Society may be carried out, it will be necessary that the Society be in correspondence with the local committee, consisting of several responsible persons. Many communications will pass between the two; from the local committee, on the wants of a town or neighbourhood of a school; from the Society on the approving or negativing a demand. The Society will of course have certain plans or regulations laid down for their guidance which every local committee must adhere to.

At the outset these communications will be tedious to each party. The regulations respecting the obtaining of apparatus have been before us some time. A complaint arose that the stipulations or regulations to be gone through made the gift hardly worth the getting.

The Teacher must be an examined pharmaceutist; he must be considered the servant of the committee, although he must, in the first place, be approved of by the Society, and his certificates forwarded to London to know if he be duly qualified to teach a class. In the event of the teacher not being duly qualified, no class can be held, since, it will not have a pharmaceutical teacher.

There is no sweetness in being a servant of a committee; for generally the committee-men know little or nothing of the subjects taught, and, on the teacher asking even for a slight favour, he meets with a "snubbing."

The teacher must adhere to a syllabus of instruction, which the Society will draw out. He must keep a register of attendance, or payments for results cannot be obtained. The number of lessons having been given, the time comes when the students will sit for examination. The teachers will not be allowed to be present at the examination; the other etceteras according to the 'Directory.'

Then the teacher will claim payments according to the positions the students take in the examination. The plan he will adopt in teaching will be this: Knowing that the "stock" questions are printed ('Examination Papers'), and that there is little variation year by year, he will especially dwell upon such subjects as are likely to be involved in such examination —the "vital points" of the examination. He will, moreover, "coach up" the student night by night on anticipated questions. Those questions which are likely to be put to the pharmaceutical student may be obtained from the PHARMACEUTICAL JOURNAL of past years. The professional "crammers" in London, understanding this matter, adopt the same principle. Moreover, the teacher of the class will adopt this principle in order to confine the student's attention to the assailable points, and, prevent the student wasting time in reading upon subjects which may not be wanted in the examination, and, also, to obtain a larger return for himself on the scheme of payments for results.

I am sorry to acknowledge my practical acquaintance with this system. While a teacher I was obliged to adopt it, or my students could not have passed. The keeping the register of attendance, the marking all who have attended 25 lessons, the making of claim for payment and a few other ceremonies, may be considered minutiæ, but they are in practice so tedious that a £10 gratuity to the teacher would not be improperly bestowed. Mr. Schacht is imitating a perishable system, for the 'Directory' says, "Payments to teachers must not be looked upon as perpetual; the amount given is likely to be decreased or eventually withdrawn."

Perhaps the Pharmaceutical Society will consider themselves authorized to do as the Government does, viz., send down an inspector to see that the students are properly instructed, and the examination properly conducted—who may drop in any moment.

The Student.—He will, it is presumed, accept the invitation to attend instruction. He will rejoice that he can obtain instruction with the minimum of expense to himself, and if it be the son of a policeman, coast-guardsman, artisan, or small shopkeeper whose income is under £100 a year, he will have the more occasion to rejoice.

There is a real likeness on this point to the Government system. The Government system aids the lowest class of the people. Mr. Schacht's system will aid, or it is intended to aid, the lowest class of chemists. What a consolation that our responsible profession is to be recruited from the lower orders! That we are even low in the world!

Will Mr. Schacht's scheme do the trade any good? I rather think it will prove very lowering to it. Our Society would be a refuge to all—even to the sons of sweeps and scavengers. Oh, Jacob Bell! Would that thou wert with us. Wouldst thou sanction a scheme like this?

In the Bristol Association report, I read, "The results are most encouraging," I wish I could think so. They will not be encouraging if based on the Government system; but lead to disappointment, for it is very unstable. Mr. Schacht in the same report especially dwells upon the success of the young men the last session,—so they ought to have been; for the examination papers of last session were ridiculously easy; whereas the papers the year before were ridiculously difficult. That is just the way with our government—there is either a loophole or no loophole. "A Queen's medal will be awarded to one of the students," so the report says. This Queen's prizeman, sir, must be a working man's son; he must be the son of some one who has under £100 a year. He may be the son of an ostler!

Will Mr. Schacht kindly tell us if it be his ambition to see our profession ornamented by the sons of such men?

Another association thinks that £1 and £2 payments on results as fixed by Mr. Schacht, "to be insignificant and totally inadequate." Mr. Schacht will see that that was my opinion many week's since. The same association thinks that the Society "should pay all the teacher's fees"! What next? Apparently the whole scheme will be debasing to the Society. It will be disliked by the honest teacher. It cannot be adopted, inasmuch as the Society must have a back-bone of gold—the calls upon it will be unlimited; the demands most extortionate; and the country associations will be further from being satisfied than ever they were.

A COUNTRY MAJOR ASSOCIATE.

August 3rd, 1872.

EXAMINATION FEES.

Sir,—The letter of 'H. B.' in last Saturday's Journal induces me to ask you to publish in an early number the following motion, which, after offering some explanatory remarks, I laid on the Council table on the 3rd of July last:—

"That this Council, fearing that the present rate of examination fees forms an obstacle to many young men entering on the studies necessary for passing these, hereby appoint a special committee to examine into the whole question, and this especially, as to the propriety of reducing the fee for the Preliminary examination by one-half; and also as to giving all candidates for the different examinations who fail to pass the first, to have two other opportunities of passing without the necessity of making any further payment.

"The committee will further consider the question of giving all candidates who have passed the Preliminary the opportunity of passing the Major, or such a modification of it as will embrace all the essential features of the Minor, at once and without the necessity of passing the Minor also.

"But it is to be understood that, in the event of these changes being adopted, there shall be no portion of any of the examination fees returned to the non-successful candidates on their failing to pass the various examinations.

Hoping to move the adoption of these resolutions at the September meeting of the Council, I will only at present add that, should they be adopted by the Council, I propose to modify them so as to secure that all who shall have passed the Preliminary examinations before they come into force shall be admitted to pass the Minor on payment of two guineas, and all who have passed the Minor shall be admitted to pass the Major on the payment of one guinea; thus securing that all Minors shall pass for four guineas, and all Majors for six guineas, instead of, as at present, five and ten guineas respectively.

Glasgow, August 6th, 1872. DANIEL FRAZER.

INEFFICIENT MINORS.

Sir,—The Pharmaceutical Society would have us believe that the Minor Associate is authorized to apply for an assistant's situation, his certificate being his recommendation and qualification. But that it is occasionally neither a qualification nor a recommendation Mr. Ekin shewed last week, by an example, and I also beg leave to show it in a similar manner.

I engaged an assistant a short time ago, whom I discharged because he could not wrap up an eight-ounce mixture *clearly* and *neatly*. This young man then made his way to London; put himself under a "crammer," and in a very few weeks passed his Minor. So far as I could judge this candidate had seen little or no dispensing, and for a certainty he had never been taught to wrap up! If more exercises were set the candidates at the dispensing counter than are set at present, —not with the intention of making the Minor much more difficult than it is, but on purpose to notice the habits conducing to cleanliness, neatness, accuracy and despatch,—masters might not have occasion to look with suspicion on a Minor's degree.

I forget how the Society awards marks on the Examination. If there be any "averaging" of marks obtained in all the subjects, this at once will explain the slipping through of inefficients. The plan adopted by the London University is worth consideration. It is, I believe, this: "That if any candidate do not obtain the maximum number of marks in any subject, he will not be passed by obtaining the maximum numbers in the other subjects." The inefficient minors I need hardly state are not a credit to the Society which granted the degree.

August 3rd, 1872. A MASTER.

F. D.—The latest edition with which we are acquainted was published in 1857, by Messrs. Longmans.

"Oxonian."—The price is absurdly low. It must surely have been a mistake on the part either of the purchaser or dispenser.

James Houlton.—We regret to say that the writer is on the Register, by virtue of having been in business before the passing of the Pharmacy Act, 1868.

C. J. Bell.—Hydrochloric acid is undoubtedly intended.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Moss, Mr. D. Hanbury, Mr. Simmonds, Mr. Gerrard, Mr. Balchin, Mr. Mason, C., R. and J., M., "Inquirer," Syrupus."

THE DUBLIN EXHIBITION.

(*Concluded from page 62.*)

Messrs. J. C. and J. Field, London.—The above firm have many novelties of a mechanical nature. They exhibit in the soap line spermaceti and paraffin soaps. The paraffin tablet must be a mechanical mixture of soap and paraffin, as perfect saponification of the paraffin is out of the question. They also state that the paraffin tablet has a special efficacy in rendering the hands unusually soft and pliant after its use.

The special celebrity at present, however, of this firm is the production of candles from the mineral (if we may use the term) ozokerite. It will, perhaps, not be out of place to give here a short outline of this curious product. This natural hydrocarbon is found in Galicia, in the Carpathian Mountains. The name means a "wax-like smell," which, however, we have failed in perceiving; in fact, the natural product in smell is like some of the liquid hydro-carbons of the higher boiling-points, whilst the purified product is almost devoid of smell. The natural specimens melt from 60° to 80° C.; those of paraffin being about 50°.

It, however, bears a considerable resemblance to paraffin in composition, thus—

	Paraffin.	Moldavian Ozokerite.
Carbon . . .	85·1	85·75
Hydrogen . .	15·1	15·15

Nothing could be more beautiful than the candles made from this unpromising-looking brown ozokerite.

Soaps, candles and perfumery are frequently connected together thus: the soap manufacturer is generally a candle-maker, whilst the perfumer, if not actually a manufacturer, is generally a refiner and maker of the toilet varieties. In candles and soaps the British and Irish manufacturers are before any country as regards cheapness combined with quality, and, as a rule, it will be found that foreign soaps possess a causticity which is most objectionable. We have already referred to Price's Patent Candle Company, and have merely to state further that their case, as an exhibition of these articles, is, if not the finest, one of the handsomest in the building. This, however, is saying a great deal as there are really some very fine cases of this class.

Mr. J. S. Rathbone, Dublin.—Mr. Rathbone's case is full of general interest, and contains a handsome show of candles; but what renders his show of particular interest to us is the fact that he is a refiner of sperm, or, in other words, a manufacturer of spermaceti, and refines sperm oil. He is also a bleacher of wax. The crude sperm oil, as obtained from the head of sperm whale, is at ordinary temperatures semi-solid, from the separation of the cetin. This oil is separated at as low a temperature as possible, because on its freedom from this cetin, depends afterwards the purity and beauty of the refined sperm oil. The cetin, which is essentially the spermaceti, is then submitted to pressure to arrive at the requisite degree of purity. Frequently, on placing two specimens of spermaceti beside each other, a considerable difference in shade will be observed; this is not generally due to dirt mechanically suspended, but to the remains of the oil still present. The specimens of this article shown are beautiful in the extreme, particularly a crystallized pillar of it in the centre of the case. It is curious to observe that really *pure* white wax would in nine cases out of ten be scouted. The appearance is so distinct from the article called *Cera alba*, which is made up of paraffin, spermaceti, or anything you like but white wax.

The General Mining Company of Ireland exhibit some chemicals of considerable interest. Their staple commodity is oxide of zinc. This Company possesses at Silvermines, in the county Tipperary, the largest deposit of calamine ore in the United Kingdom. It is of a red or ochrey character, and from this ore they manufacture oxide of zinc directly in the furnaces. The oxide is generaly made from spelter. By their process, which is a patent, the Company can make oxide of zinc cheaper than most of the other makers; but being made directly from the ore, it contains a trace of lead, which vitiates to a certain extent its value as a pigment, as it gives a yellow hue. The Mining Company are anxious to prevent this by some modification of their process, because if such a change could be brought about they would command the market. The Company exhibit sulphite of zinc, and sulphite of zinc wool for disinfecting purposes, as originally prepared by Mr. Tichborne, of Dublin. Also caustic soda made by a patent process in which the inferior brands of oxide of zinc are utilized for the production of this article. In the ores obtained at Silvermines the zinc is more or less replaced by iron or lead.

Ireland used to be celebrated for making mustard and starch, and the latter article is particularly well represented in the present exhibition both by British exhibitors and the Irish manufacturers. The starch is most generally manufactured in a laundry form in "crystals," as it is technically called. These so-called crystals are simply a prismatic kind of pipe produced by the splitting up of the mass of starch as it dries, and the peculiar way in which the starch breaks. Laundry starch is generally slightly tinted with some blue colouring matter. Most of the starch manufacturers prepare some of it specially for dietetic purposes.

Mr. J. Kelly, Graigue.—The starch manufacturers seem to prefer rice starch. In the first place the cereal is so cheap and contains such a large percentage (Patna rice 78 per cent.) of starch. Secondly, when boiling water is poured upon the rice granules the starch is made; this is not the case with wheat starch, which requires some boiling to bring it to perfection. It is, however, doubtful if the rice starch possesses the same amount of stiffening properties as the old wheaten starch. The sample shown by Mr. J. Kelly is beautifully white.

Messrs. Alex. Crawford and Son, Belfast.—This firm shows starch made for laundry purposes from wheat starch, and they also, under the name of "Irish Corn Flour," prepare a starch of a very good quality for dietetic purposes.

Messrs. Coleman and Son, London, also show their beautiful "crystals" of rice starch. Rice starch is also the constitution of their now well-known "Corn Flour," prepared by them for dietetic purposes.

The other exhibitors of interest, from a chemical, scientific, or pharmaceutical point of view, are as follows:—

Yeates and Son, Dublin.—Astronomical telescopes and philosophical instruments, spectroscopic prisms and microscopes. A very good collection.

J. Spencer and Son, Dublin.—Philosophical instruments.

O'Neill and Thompson, Dublin.—Surgical instruments and appliances.

M'Adam and Corcoran, Dublin.—Surgical appliances.

Dublin Glass Bottle Company.—Bottles and specimens of glass.

Haines' Patent Lead-Encased Block Tin Pipe.—Walker, Campbell and Co., Liverpool. For preventing lead-poisoning. Said to be the same cost as lead pipe of equal bore and strength.

W. Rumsey, London.—Non-mercurial plate powders, chemical polishing paste, detergent powder, etc.

Mr. G. P. Dodge, Dublin (Bermondsey India Rubber Works).—India-rubber in its various raw and manufactured states.

Mr. A. Reekie.—Various polishes.

Mr. D. Tallerman, London.—Various preserved meats, meat extracts, essences, etc.

Mr. J. Tennant, Junior, London.—Specimen of minerals from Nova Scotia, St. Helena, and Algoa Bay, collected during the exhibitor's travels in South Africa and other parts of the world.

Anti-Adulteration Society, Dublin.—Specimens chiefly of substances used for adulterating, and some adulterated manures, etc.

Mr. Thomas White, Dublin.—Charcoal "Pyrolignite" acetates of lime and soda, acetic acids, etc., produced from Irish grown timber.

Mr. Wm. Martin, Dublin.—Various coloured inks.

Messrs. Boyd and Alexander, Dublin.—Chloride of lime, salt-cake, sulphate of soda, commercial acids, and artificial manures. A good display.

Dublin and Wicklow Manure Company.—A very fine case, similar to the above.

Messrs. Cantrell and Cochrane.—Mineral and medicinal waters.

Messrs. McMasters and Hodgson, Dublin.—This firm is chiefly celebrated as oil crushers and refiners. They show fine specimens of linseed and rape oils, also the respective cakes and meals, fluid annatto, and some other proprietary articles.

Mr. Marcus Tertius Moses, Dublin, shows a really fine collection of 60 different kinds of teas, with the locality marked. The teas of China, India, Assam and the Himalayas, Japan and Java, are shown, including even the Brick tea.

JAPANESE WAX AND ITS EMPLOYMENT IN PHARMACY.

BY DR. C. ROUCHER;

Pharmacien Principal de Première Classe.

The vegetable wax, known under the name of Japanese or Chinese wax, is produced by the *Rhus succedaneum.* It is harder than ordinary wax, but much more fusible; the point of fusion indicated by various authors varying from 40° C. to 42° C. It is white, with a slightly yellowish tint, has a feebly rancid smell, and is more friable than beeswax.

As this vegetable wax is now much used in pharmacy, the author has sought to determine the exact point of fusion, and for this purpose examined two specimens, which yielded exactly similar results. This he did by using very thin closed tubes, 15 millimetres wide, in the lower third of which the substance was spread in a uniform layer. The tubes were then plunged into water at various temperatures, and the points noted of opacity, semi-transparence, complete transparence and running against the sides of the glass.

The results obtained with the Japanese wax were as follows:—At from 40° C. to 45° C. the wax remained opaque, provided that the temperature was raised one degree at a time; from 45° C. to 50° C. it became more and more transparent, without becoming mobile; at 53° C. it was transparent and nearly melted; at 54° C. it was completely fused. If the wax be rapidly raised to a temperature sufficiently above its melting-point, and, after cooling, be plunged into water at 42° C., it melts into a transparent liquid. So that this wax has two melting-points—42° C. and 54° C.—separated from each other by twelve degrees; the highest being attained when the temperature is slowly and progressively raised.

Japanese wax is not the only substance presenting such anomalies in fusion and solidification, since, according to M. Duffy, natural stearine under the influence of heat undergoes three distinct modifications, which are produced in a similar manner by heating it beyond the melting-point and then cooling it. The same phenomenon is noticed in monomargarine and the palmitines.

To ascertain whether the wax operated on was constituted by a mixture of two or more substances, the separation of which might influence the phenomenon of fusion, the author dissolved a portion of it in boiling 90° alcohol. Upon cooling, the greater part of the wax separated; this, dried for some days in the open air, still contained a considerable quantity of water, which could be driven off by heat. Deprived of its water, it presented exactly the same points of fusion, 42° C. and 54° C., and comported itself between these two extremes in the same manner as that which had not been treated with alcohol. Beeswax offers nothing similar: two specimens, one white and the other yellow, melting at the single temperatures respectively, of 62·5° C. and 64° C.

The introduction of Japanese wax into pharmacy, and its substitution for bees wax, suggested the following experiments as to the relations of the points of fusion of cerates prepared with these two substances, both being used in the proportion of ten parts of wax to thirty-five parts of olive oil.

(1) *Japanese Wax and Olive Oil.*—At 30° C. it commenced to melt, but quickly stopped and became opaque and solid on the sides of the tube. From 32° C. to 45° C. the cerate, semi-transparent, ran slowly and sluggishly. At 46° C. it melted easily into a transparent mobile liquid. In this state if heated to 50° C., and after allowing it to spread in a thin layer and cooled, it was plunged into water at 32° C., it melted into a transparent syrupy liquid, accumulating at the bottom of the tube. Raised again to 50° C. and placed in water at 30° C. it became transparent, but only ran slowly. Upon repeating the operation with water at 28° C. it became transparent, but did not run, and gradually resumed its opacity. This showed that by the addition of the above proportion of olive oil to Japanese wax, its highest melting-point was lowered

eight degrees—from 54° C. to 46° C.—and its lowest ten degrees—42° C. to 32° C.—the cerate, like the wax contained in it, having two melting-points which are separated by fourteen degrees.

(2) *White Beeswax and Olive Oil.*—At 39° C. it commences to lose a little of its opacity; from 42° C. to 52° C. it becomes more and more translucent; at 54° C. transparent; at 56° C. runs slowly; at 57° C. it runs easily. So that a mixture of olive oil with beeswax in the proportions indicated, lowers the melting-point seven degrees. Just as there is a difference of ten degrees between one of the melting points of Japanese wax and that of beeswax, there is a difference of ten degrees between those of the two cerates.

The observation of the melting-point alone would not be sufficient to distinguish between cerate made from vegetable wax and that from beeswax, as the melting-point might depend upon the proportion of olive oil present. But the existence of only a single point of fusion in beeswax might be a useful indication as to the presence or absence of Japanese wax, or probably of margarine or stearine. A cerate made with beeswax may also be distinguished from one made with Japanese wax by the action of a strong alcoholic solution of caustic potash, which dissolves entirely, even in the cold, a cerate made from the vegetable wax, but only dissolves very incompletely one made from beeswax.

It will thus be seen that from a pharmaceutical point of view the effect of substituting Japanese for beeswax, in medicaments having wax for their base, is a notable lowering of their melting-point; and a cerate made of the proportions indicated above would melt at the temperature of the human body, the mean of its two melting points being about 37° C. or 38° C. It will, therefore, be evident that such a substitution should not be made without the greatest care.—*Journal de Pharmacie et de Chimie,* [4] vol. xvi. p. 20.

ACTION OF PEPSIN ON THE FIBRIN OF BLOOD.*

BY VON WITTICH.

A number of the experiments related in this paper were made by Grünhagen's method, but as the time when the first drop falls from the filter is influenced by the thickness of the paper employed, etc., the author prefers to take the amount of filtrate in a given time as a measure of the activity of digestion. He determines the total amount of the products of digestion by the lævo-rotation of polarized light in a Soleil-Ventzke's apparatus, and the amount of peptones formed, by neutralizing the liquid so as to precipitate para-peptones, and again noting its rotatory power. He assumes that one division of the scale represents 1 per cent. of peptones, or other albuminous substances in solution, with sufficient exactness for comparative experiments. In preparing a glycerin solution of pepsin from the mucous membrane of a stomach, he recommends that the pyloric part should be rejected entirely, as the mucus it contains hinders the filtration of the glycerin extract; and he finds, in accordance with Friedinger and Fick, but in opposition to Haidenhain and Ebstein, that it contains little pepsin. He now finds that pepsin may be extracted from gastric mucous membrane after it has been steeped in alcohol, or from the precipitate which is produced in glycerin extract of fresh mucous membrane by the addition of alcohol. The glycerin must, however, be allowed to remain in contact with the mucous membrane or precipitate for several days, and the negative results which the author formerly obtained were due to his having tested the peptic properties of the glycerin after 24 hours instead of after several days. He is not certain whether pepsin is albuminous or not, for though it does not give the reactions of albumen, this might be due to the excessively small quantity of it present. It differs from albuminous substances in resisting putrefaction; it agrees with them in being almost entirely indiffusible into distilled water. It diffuses, however, very rapidly into dilute hydrochloric acid of 2 per thousand. He thinks this is due to the formation of a diffusible compound with the acid. Fibrin absorbs pepsin most energetically. When put into water into which pepsin can dialyse, it causes it to pass through the parchment more quickly. An excess of fibrin will absorb from artificial gastric juice all the pepsin which has already digested a part of it, and when the undissolved fibrin is taken out and put into fresh acid, the pepsin it contains is generally sufficient to dissolve both it and additional fibrin added to it, while the liquid from which it has been removed has lost all peptic properties. When, however, fibrin is digested upon a filter, the pepsin runs from the filter together with the products of digestion, so that the amount of pepsin remaining with the fibrin on the filter gradually diminishes, and its digestion consequently becomes slower. This circumstance, as well as the fact that the pepsin becomes diffusible in presence of free acid, causes him to believe that the process of digestion begins by pepsin forming a loose chemical compound with the acid, and that this compound is the active agent in the process. He considers that they combine in definite proportions. Deficiency of acid will stop digestion although pepsin be present.

When fibrin is digested with pepsin, not on a filter but in a glass, so that they remain in contact during the whole time of digestion, the amount of fibrin digested is in proportion to the amount of pepsin added. The rapidity with which digestion begins is dependent in the first place on the amount of pepsin. The rapidity with which digestion is performed increases with the temperature up to about 50° C. It goes on, though very slowly, even at such a low temperature as 3° C., attains its maximum rapidly between 35° and 50°, and above this becomes slower. Schiff's statement that the activity of pepsin is suspended at temperatures under 13° is inaccurate. Exposure to 5° for some hours does not destroy the activity of pepsin. The activity of a dilute solution of pepsin is destroyed by exposure for two minutes to 70°, while that of an undiluted glycerin solution was retained after exposure for the same time to 80°.

When digestion stops before all the fibrin in a digestive solution has been dissolved, the arrest of the process is not due entirely to the accumulation of products of digestion, as the amount of those at the time of arrest is found to vary considerably, but is partly due to the want of free acid. His explanation of this is that a definite amount of pepsin and of acid is requisite for the digestion of a given quantity of fibrin. The fibrin which remains undissolved in an otherwise active digestive fluid, has part of the acid which it has absorbed withdrawn from it during the process of digestion, so that the quantity it retains is too small for its digestion, although it has absorbed all the pepsin which has finished digesting the rest of the fibrin. The presence of water is necessary to digestion, and an insufficient quantity of it retards the action of pepsin.

The proportion of the products of digestion which is necessary to stop digestion in a solution increases with the amount of pepsin present.

The relation between the para-peptones and peptones is not constant, and the former are present only at a preliminary stage in the production of the latter, and are

* (Pflügers Archiv. für Physiologie, v. 435–469).

converted into them by an additional amount of pepsin. The amount of peptones formed at the expense of parapeptones increases with the amount of pepsin present.

Digestion is arrested by accumulation of products of digestion, and especially of peptones in the digestive fluid. It is impeded by the presence of 4·3 per cent. of peptones, and probably stopped by 6 or 8·6 per cent.

Dilute acid alone will convert fibrin into peptone, even at ordinary temperatures, but much more slowly than when pepsin is present.

Fibrin soaked in dilute hydrochloric acid till it formed a stiff jelly, and placed in an air bath at 30°–40° C., became fluid in 24 hours, and contained 1 per cent. of peptone.—*Journal of the Chemical Society.*

THE BOTANY OF 'LOTHAIR.'

A remark in 'Lothair' "that all head gardeners are opinionated" appears to have aroused the wrath of one of the readers of the *Gardeners' Chronicle*, and upon the principle that one good turn deserves another, he criticizes some of Mr. Disraeli's references to plants in that celebrated book, and suggests that the talented author should be a little less inexact when he writes on botanical subjects. He commences with a description of Belmont:—"'The last saloon led into a room of smaller dimensions opening on the garden, and which Lothair at first thought must be a fernery, it seemed so full of choice and expanding specimens of that beautiful and multiform plant,' and says, "I would recommend the perusal of this paragraph to those interested in the origin of species, for it clearly assumes that all the species of ferns that go to make up a fernery are multiforms of one plant. The talented author no doubt did not mean it to be in that sense, but he has said it; and those who know ferns—from the tiny filmy fern of Tunbridge Wells (Hymenophyllum tunbridgense), which, when grown to perfection, attains only the height of a bronze penny piece, and weighs when dried about a drachm, to the tree-ferns of Australia, which look so like palm-trees that one has to come near before the difference is seen—well know that these and a legion of others are verily of the fern family, certainly not multiforms of the same plant. The author is very chary of botanical names. The only one I remember to have seen in 'Lothair' is Stephanotus [Stephanotis]—he only gives the generic and not the specific name; and although a proper name, and entitled to a capital letter, it is written stephanotus. Now, if London or Athens were written london, athens, few readers would recognize the capitals of the two kingdoms. Our greatest authors of romance—Disraeli, Dickens, Scott—have all treated horticultural subjects lightly; and the mere labourer unlettered is held up as a gardener. Disraeli's "Hawkins," a nobleman's head gardener, is represented as disobedient to his employer, a dogged hanger on, that only kept his situation by the chaplain's advice and assistance; but if Father Colman is no better informed than the author of 'Lothair' on the subject of the fern family, I fear that 'Hawkins' will not get rich by prizes for his skill in cultivating that multiform tribe of plants. At p. 63 there is a struggle to describe a pinetum—a plantation of spruce firs, but planted wide apart, every tree perfect, huge, and complete, full of massy grace; wondrous groups of juniper, green and spiral—does any one know a spiral juniper? 'The cypress and her spire,' we read of in the poets; does our author mean spire when he writes spiral for a flame-shaped bush? And the whole of Abies and Picea would pass for spruce firs to many observers—

'A spruce fir by the river's brim
Was just a spruce fir unto him
And nothing more.'"

METEORIC STONES.*

BY NEVIL STORY-MASKELYNE, ESQ., M.A., F.R.S..

The substantial unity of the celestial objects distinguished in common language by the names shooting or falling stars, fire-balls, and meteorites, and further the coincidence in many important respects of these with comets, and possibly with the zodiacal light, were suggestions made by Humboldt in the 'Cosmos,' which have received much confirmation from the subsequent advance of science.

The greater apparent velocity with which the ordinary meteors traverse the atmosphere as compared with that with which the less frequent larger bodies are seen to move, the marked periodicity that attends the recurrence of the former in several, and espcially in two, notable cases of meteor-showers, offer an apparent contrast between these classes of meteors; it is not, however, in all probability, a real contrast, for the one class passes into the other by every gradation in the magnitude of the mass or masses of which the meteor consists, and consequently in the grandeur of the phenomena which accompany its advent. If of the material composing the ordinary falling star we have never yet been able to recognize any vestiges as reaching the earth; of the meteorite, on the other hand, the mineral collections of Europe contain numerous carefully collected specimens, which are the fragments that have escaped the fiery ordeal of the transit through our earth's atmosphere, and in these we recognize masses composed either of iron (siderites), or of stone (aerolites), or of a mixture of the two (siderolites). The phenomena associated with such falls of meteoric matter have been described in very similar language by those who have witnessed them in various parts of the world, and these accounts, whether coming from European observers or from Hindoo herdsmen (of which some were read by the lecturer), concur generally in the approach of the meteorite as a fiery mass, emanating from a cloud when seen by day, and exploding often with successive detonations that are heard over a great extent of country, even in certain cases at points more than 60 miles distant, but finally reaching the earth with a velocity little higher than what might be due to the motion of a falling body. Externally these meteoric masses are generally hot when they fall; sometimes, however, they are not so: the discrepancies in the accounts being explained by one authenticated case in which the mass was internally intensely cold, though at first hot externally. The fallen meteorite is invariably coated with an incrustation, sometimes shining as an enamel, generally black, but occasionally colourless where the aerolite is free from ferrous silicates; and this incrustation is seen to have been formed in the atmosphere, since it is found coating surfaces of fragments that have been severed by the explosions in the air.

Aerolites frequently fall simultaneously in large numbers, many thousands of them being in such cases spread over a surface of the country some miles in extent; and such showers of stones seem to have entered the atmosphere as a group, though their numbers must subsequently have been greatly increased by the division accompanying their detonation.

The explanation of the incrustation and of the cloud left by the meteorite, or out of which it seems to emerge, is found in the transformation into heat of the energy actuating a body that enters our atmosphere with a motion of 12 to 40 miles in a second. The velocity of the body is almost instantaneously arrested by the atmospheric resistance, and in a very few seconds the mass becomes, comparatively speaking, stationary. Its surface must, as a consequence, be immediately fused, and the melted matter would be flung off from it into the surrounding air, fresh surfaces continually affording

* A Paper read at the Royal Institution, May, 10th, 1872.

new fused material to form the cloud of, so to say, silicious spray that lingers along and around the path of the meteorite.

When the mass is small,—and in the case of meteoric showers and ordinary falling stars it cannot exceed a few ounces, and may often be but a few grains,—the whole material is thus consumed, and must ultimately fall as an unperceived, because widely-scattered, dust. The meteorite is the residue that survives this wasting action where the magnitude of the mass is more considerable. The cause of the violent and often successive explosions is probably to be sought in the expansion of the outer portions of the mass, while the interior retains the contracted volume due to the intense cold of space with which the meteorite enters the atmosphere.

From time to time these contending conditions of volume may, as in a Prince Rupert's drop, produce explosion, the heated shell in the case of the meteorite flying off in fragments from the internally cold inner core, which, if sufficient velocity remain to the mass, will undergo a recurrence of the same conditions of surface fusion and explosion. The loudness of the detonation is also probably enhanced by the simultaneous collapse of the air on the vacuum that would follow the rapidly moving mass.

The pitted surface characteristic of meteorites probably bears witness to a similar effect of unequal dilatation operating more especially in the freshly-broken surfaces of the mass, small fragments splintering off in this way from the cold and brittle stone under the sudden influence of intense heat.

A remark made by Humboldt, that light and meteorites are the only sources of our knowledge regarding the universe external to our world, points to the true ground for our interest in the waifs and strays of extratelluric matter that thus fall upon our globe.

In physical as well as in chemical characters aerolites resemble at the first aspect some terrestrial volcanic rocks.

The minerals of which they are composed are nearly entirely crystalline, as is evidenced by the colours in polarized light of such as are transparent. These minerals are usually aggregated with slight cohesion, and they present in by far the greatest number of cases a peculiar spherular or "*chondritic*" structure.

In these the spherules are composed of similar minerals to those which enclose them, and even contain metallic iron sometimes in microscopically fine grains disseminated through them.

A section of an aerolite was exhibited by the microscope in which some of the spherules had been broken before being cemented by the surrounding mass, and in another fissures were seen which had been filled with a fused material after one side of the fissure had slidden along the other; facts pointing to events in the history of the meteorite subsequent to its first formation.

The chemical composition and the mineral constitution of aerolites were illustrated by tables showing the elements met with in these bodies, and the minerals in which they were distributed. The former comprised about one-third of the known elements; among them magnesium, iron, silicon, oxygen, and sulphur were conspicuous; calcium, aluminium, nickel, carbon, and phosphorus coming next in importance, the basic elements of most importance by their amount being the same as those which are found by spectroscopic analysis is to be present in the sun—and in those stars which have been the best examined.

The minerals most frequent in aerolites besides nickeliferous iron or troilite (iron monosulphide) and graphite, are bronzite (a ferriferous enstatite) and olivine, both the latter being essentially magnesium silicates. Augite and anorthite also occur (more particularly in the eukritic aerolites of Rose) and some minerals unknown in terrestrial mineralogy have also been met with; such are the different varieties of Schreibersite (phosphides of iron and nickel): calcium sulphide, asmanite (a form of silica crystallizing in the orthorhombic system and having the specific gravity of fused quartz), and a cubic mineral with the composition of labradorite. The crystalline form of bronzite was first determined from the crystals in a meteorite, and was found to confirm the conclusion Descloizeaux had arrived at as regards its system from observations on the distribution of the optic axes in the terrestrial bronzite and enstatite.

The question as to whence the meteorites come is one that we are not yet in a position to answer with certainty. The various hypotheses which suppose for them an origin in lunar volcanoes, or in our atmosphere, or again in a destroyed telluric satellite, or that would treat them as fragments of an original planet of which the asteroids are parts, or as masses ejected from the sun; all these hypotheses seem to be more or less precluded by the known velocities, the retrograde motion so frequently characterizing meteors and meteorites, or else by the chemical conditions that, for instance, are involved in the passage of the meteorite through the sun's atmosphere. Whether meteorites move or do not move in circumsolar orbits is at present impossible to say; because, while with our incomplete knowledge we cannot to-day attach the character of periodicity to any known class of meteorites, we are not justified in founding any conclusion on a negative result with so limited a foundation.

But even if all or some of them may have been, on their encountering the earth, members temporarily or permanently of the solar system, we may with considerable probability consider them as having originally entered our system from the interstellar spaces beyond it. Such at least must be our conclusion if we are to admit the unity of the whole class of phenomena of meteorites and falling stars. For, since the orbits of the two best-known meteoric streams, those namely of August and November, have been identified with the orbits of two comets, and since in regard to one of these (that of November) Leverrier has shown, with great probability, that as a meteoric cloud it entered and became a member of our system only some 1700 years ago in consequence of the attraction of Uranus, while the August meteoric ring only differs in this respect from it, that it had at a much more remote period found an elliptic orbit round the sun; we are constrained on the assumption with which we started to recognize also in a meteorite a visitor from the regions of remote space. And so far as it goes, the observation by Secchi that the November falling stars exhibit the magnesium lines is in harmony with this view.

It may, however, further be said, that the tendency of scientific conviction is in the direction of recognizing the collection towards and concentration in definite centres, of the matter of the Universe, as a cosmical law, rather than the opposite supposition of such centres being the sources whence matter is dispersed into space. In the meteorites that fall on our earth (certainly in considerable numbers) we have to acknowledge the evidence of a vast and perpetual movement of matter in space, about which we can only reason as part of a great feature in the Universe which we have every ground for not supposing to be confined within the limits of the solar system.

That this matter, whether intercepted or not by the planets and the sun, should to an ever-increasing amount become entangled in the web of solar and planetary attraction, and that the same operation should be collecting round other stars and in distant systems such moving "clouds" of star dust as have been treated by Schiaparelli, Leverrier, and other astronomers, or individual masses of wandering stone or iron is a necessary deduction from the view that we have assumed regarding the tendency of cosmical matter to collect towards centres. But in order to trace the previous stages of the history of any meteorite, and, in particular, to determine the conditions under which its present constitution as a rock took its origin, we have only for our guide the actual record written on the meteoric mass itself; and it is in this direction that the mineralogist is now working.

But the progress is necessarily a gradual one. We may indeed assert that the meteorites we know have, probably all of them, been originally formed under conditions from which the presence of water or of free oxygen to the amount requisite to oxidize entirely the elements present were excluded; for this is proved by the nature of the minerals constituting the meteorites and by the way in which the metallic iron is distributed through them.

And one suggestive and significant fact remains to be alluded to; the presence, namely, in some few meteorites of combinations of hydrogen and carbon, which, if met with in a terrestrial mineral, would with little hesitation be assigned to an organic origin. A few grains were exhibited to the audience of such a body, crystallized from ether, which solvent had extracted it to the amount of about 0·25 per cent. from six ounces of the Cold Bokkveldt meteorite.

Similar substances have been extracted by Wöhler, Roscoe, and other chemists from this and other meteorites. It was, however, observed, as pointing to the probability of the comparatively porous meteoric stone having in this case taken up the hydrocarbon as a substance extraneous to it (possibly when in the state of a vapour), that ether extracted it entirely from the solid lumps of the meteorite; pulverization not in any way adding to the amount obtained, or facilitating in any appreciable degree the separation of the substance.

ANALYSIS OF WOMAN'S MILK.

BY A. SCHUKOFFSKY*

The author shows that most methods employed for the analysis of milk do not give correct results, especially in the case of woman's milk.

The casein of woman's milk differs from that of other milk in that it is not curdled thoroughly (if at all) by carbonic and acetic acids. The method of precipitating the casein by magnesium sulphate also gives unsatisfactory results.

The methods in use for the estimation of fat are also imperfect, *e. g.*, those in which gypsum or chalk is added to the milk, the resulting mixture dried, and the fat extracted by exhausting with ether; the presence of fat in the residue may be indicated by the microscope. Apparently the ether is prevented from acting on the fat by the casein envelopes which surround the globules.

Hoppe-Seyler has remedied this source of error by adding caustic potash to the milk, whereby the casein is decomposed. The potash however acts on the milk-sugar, forming decomposition products, which dissolve in the ether together with the fat, and so vitiate the result.

When a sufficient quantity of ether is added to woman's milk, and the mixture is allowed to stand at rest for some days, two layers are formed—an upper one, thick and starch-like, and a lower, which is transparent. Strong alcohol (90–96 per cent.) added to this curdles it and precipitates the casein, whilst the fat floats on the top.

The author, having studied these reactions, recommends the following method for the estimation of fat in woman's milk:—20 c. c. of ether are added to 20 c. c. of the milk; the mixture is stirred, and to it 30 c. c. of strong alcohol are added. This mixture is allowed to stand for about 24 hours, in which time the milk-sugar separates in crystals on the sides of the vessel. The sugar and casein are filtered off and washed with anhydrous ether and strong alcohol; the filtrate and washings are evaporated on a water bath till free from alcohol; and the residue is again treated with ether, then allowed to evaporate spontaneously, and finally dried at 100° and weighed.—*Journal of the Chemical Society.*

BRITISH PHARMACEUTICAL CONFERENCE.

THE SUPPER.

On Tuesday evening, August 13, the members of the British Pharmaceutical Conference were entertained at supper by the Brighton local members at Brighton, in the Banqueting Room at the Royal Pavilion. The chair was taken by Mr. W. D. SAVAGE.

The usual loyal toasts were proposed and duly honoured.

The CHAIRMAN then gave "Continued Prosperity to the Pharmaceutical Conference." He said: Gentlemen, the toast that I am now about to propose is one of especial interest, and it is one that I am sure you will drink in a bumper. We all, and especially those connected with the Pharmaceutical Conference, have heard a great deal in its praise to-day. Nothing has been said, and nothing can well be said, in dispraise of an institution that has done so much good. It is not so many years since the Conference was first projected. Certain sage individuals, some of whom are present with us to-night, shook their heads very ominously, and said that the Conference would possibly, nay, very probably do a great deal of injury to the Pharmaceutical Society. It was said that if the Conference went up, the Pharmaceutical Society would go down. What has the result been? Has the Pharmaceutical Society gone down? Has not the Conference gone up? Still these predictions had weight at one time, and that shows how important it is that we should weigh in all its bearings the consideration of a question of so much importance. We might have rested perfectly satisfied that with Dean and Hanbury and my friend Brady and others, we were in good keeping, and that the Conference would merit support. It has merited that support, and what has been the result? I have gone with it from town to town for several years, and in the various towns it has had a most beneficial local influence. Men have been brought together who never would have thought of meeting under other circumstances. As to us at Brighton, we are certainly not antagonistic. There is nothing antagonistic about us, but we are something like the two poles,—we keep very far asunder. Now, the Conference has had the desired effect of bringing us all together. I express the feeling of the Local Committee when I say that we are delighted to see so many of our friends present to-night.

Mr. BRADY, in reply, said:—

I feel it to be a very great honour to be called upon to reply to a toast like this that has been proposed by my friend the chairman, and so very kindly received by you—the toast of success to the British Pharmaceutical Conference. It is always a pleasant recollection to me that the Pharmaceutical Conference was established in my own native town; and although then as now, and on some former occasions, I have had my name associated prominently with its foundation, I have felt in a guilty sort of way that I was accepting honours that did not belong to me,—that practically I was but the bellows-blower, and I was taking the credit of the organ-player. For what was the origin of the Conference? Was not the original idea of a provincial meeting of pharmaceutists eliminated from the fertile brain of your present treasurer? Did he not first—how many years ago I scarcely know—suggest that the Pharmaceutical Society should hold a meeting annually somewhere in the provinces? Well, Sir, that idea was never acted upon, but in due time there were not wanting those who thought that it was too good to be let drop entirely; and to Mr. Reynolds, far more than to myself, and to the able executive assistance of Dr. Attfield, this Conference owes its origin. It was a mere chance that I happened then to be local secretary of the Pharmaceutical Society in Newcastle; a mere chance, I may say, that Newcastle happened to be the place that year at which the British Association held its meeting, and, therefore, I was the victim, practically, of circumstances, and no credit or the very least belonged to me. Hence I always feel to a certain extent guilty when placed in the prominent position which I have occupied through your favour in past years, and especially through your favour now, in connection with the history of the Conference. Well, sir, we met firstly at Newcastle. We had a little meeting; and it gives me great pleasure to see some here now who were present at that meeting. I see Mr. Dean, Dr. Edwards, Dr. Attfield, Mr. Reynolds, and some one or two others. Our first meeting was a very little one held in the parlour of an hotel, and we have gone on growing ever since. We grew enormously by the time we got to Bath. We went on growing till we went northward again, firstly to Birmingham, and then to Nottingham, and then to Dundee, and then to Norwich, Exeter, Liverpool, and Edinburgh, and now again here. Really I don't know what we shall grow to! When a society beginning with twenty members reaches two thousand, what may it not become in another ten years? I take it that this is simply an evidence that the views of Mr. Schacht, Mr. Reynolds, Dr. Attfield, Mr. Dean, and the rest were emphatically those which fitly met the circumstances of the case, and provided for what was a real and true and veritable want. And we are now at Brighton. We owe much to Brighton. Brighton is vindicating its claim upon the consideration of all scientific men, not only in the reception which the British Association is about to receive, not only in the splendid reception which we, the British Pharmaceutical Conference, have received, but in many other ways is Brighton showing evidence of its regard for science. You cannot look at the great aquarium which they have just built without feeling that, although there may be some slight commercial element concerned in it, there are in that aquarium the elements of what may bring about an enormous advance of science. We have but to refer to the debates in the House of Commons last week; for, was it not the Member for Brighton who brought forward certain resolutions in the House, showing how a poor ill-used man, unable to protect himself, a very sucking dove of a statesman, the present Chief Commissioner of Works, had been violently attacked and scarcely allowed his life, by a ferocious savage from the Himalayas? Was it not shown on that occasion that science was a very small thing when compared to the law? Was there not shown the superiority of forensic considerations wherever questions of the material and immaterial world were concerned? It was left for Brighton, or the Member for Brighton, to unhouse all the disastrous consequences of the savage attacks of scientific men upon statesmen in general, and the present docile and mild Chief Commissioner of Works in particular. Well, gentlemen, I trust I have said enough to vindicate the claims of Brighton to the especial consideration of scientific men; and I am quite sure that we who have occupied the whole day in education have at least been educated up to that point that we are prepared to add our testimony to the claims which Brighton has to the consideration of not only the Pharmaceutical Conference, but of science in general. I can only, sir, in conclusion, thank you most heartily on behalf of the Conference for your reception of us here to-day, for the kind way in which you have spoken of the Conference and that which pertains to it, and for the prosperity which you have wished it. I must also, on my own account, thank you for the kind way in which you have associated my name with the toast.

Mr. Brew proposed "The President and Council of the Pharmaceutical Society," and, in doing so, contrasted the smallness of the Society at its beginning with its present status. He said that there had been many difficulties to contend against, but the persevering efforts which had been made had been rewarded. Much had been done, but much still remained to be done. The interest of the Society depended upon the President and Council; and gentlemen more competent than those now occupying those positions could not be found. The President was a teacher of pharmaceutists, and many of the Council had been pupils of the Society. Though there might be differences of opinion existing in the Council, the sole aim of them all was the advantage and benefit of the Society.

Mr. Haselden, President of the Pharmaceutical Society, acknowledged the toast. He said that he did so with great pleasure, and, although many gentlemen who made after-dinner speeches said that they wished that the duty had fallen into better hands, he himself wished no such thing, for wherever he made his appearance among pharmaceutists he was always received with kindness and favour. A few years ago he became an associate of the Pharmaceutical Society, because he believed it was the right thing to do, and he then made up his mind to follow out a course which would one day, if his life were spared, place him in the presidential chair. He could not claim Bloomsbury Square as his *alma mater*, but he had, nevertheless, attended the lectures of Mr. Fownes at that place at a cost of 10*s.* 6*d.*, and he could say that he had been a student at Bloomsbury Square ever since his connection with the Society, for he never left one of the evening meetings without being a wiser if not a better man. He felt that in his long-coveted capacity of President he had many shortcomings, but he was always well received, and more than well received. At the time the Pharmaceutical Conference was first started he felt that it was a step in the right direction; and although he had some suspicion that it would take away certain papers which ought to be read at the Society, he nevertheless approved of it. It brought the country members into close association with the London members, and such an effect would promote science and promote organization. He believed that he was the first member of the Council of the Society who put his name down as a member of the Conference. He must not conclude without adverting to the kindness with which the Conference had been received at Brighton. Circumstances had prevented his attending any previous Conference, but he had said that when they came nearer to London he would attend, and he now had great pleasure in doing so. He must speak honestly and freely of the kindness which he had received on all hands in this town.

Mr. Stoddart said that he had to propose the health of the officers of the Pharmaceutical Conference. He said that the Conference had led to many friendships. Happy was the man who possessed the friendship of such men as Dr. Attfield, Mr. Benger, Mr. Schacht, and Mr. Reynolds. The success which the Pharmaceutical Conference had met with in its whole circuit was something marvellous. He joined it at Bath; and he could only say that everybody who had derived the same advantage from the companionships to which it led as he had done must be glad of having joined it. He trusted that the success would never be less than it was in the present year. The time might come when the members of the Conference would meet at Bristol. He was sure that Mr. Giles and Mr. Schacht would join with him in promising that when that happened they would try to emulate what their Brighton friends had done. In every place which the Conference had visited they had left nothing but good fellowship behind, and he should be sorry ever to see any record of their having failed to do so. He trusted they would never leave a place without leaving there some little root from which might spring some benefit to the Pharmaceutical Society of Great Britain—an institution which he venerated, and with which he was proud to be connected. He had correspondents in all parts of the world, and they all expressed cordial friendship with that organization. He most heartily proposed the toast which had been put into his hands, because he believed that the success of the Conference had been brought about by the perseverance of the gentlemen mentioned.

Dr. ATTFIELD, in responding, said that as he had told them year after year, it was with very great pleasure that he did anything in support of the Conference. He could give an illustration of the excellent effect which the Conference produced by its various meetings. When it was proposed to visit Dundee, a gentleman who knew Scotland well, said, "I hope you won't go to Dundee. I know the members of the trade there are ready to cut one another's throats. They dare not do that, but depend upon it they will do what they can to cut yours." However, the Conference went to Dundee, and on the second day an excursion was organized for the following day. The excursion took place, and by that time the chemists of Dundee had learned what a pleasant thing it was to shake hands with one another. All the chemists closed their shops on the occasion of the excursion, and spent a jolly day in the Highlands. As regarded his duties as secretary, he had many things to do which might be done by an ordinary clerk. He had no objection to perform such duties, but he believed that if a paid officer could be kept, he himself could serve the Conference more usefully by original research. He had thought that another thousand members would enable that plan to be carried out, but now his hopes had been dashed to the ground by that dreadful rise in the prices of everything, including the printing and publishing of the Year Book. The change, however, might be effected by a still greater accession to the number of members. Next year the Conference might come to some conclusion on this subject.

Mr. BENGER also returned thanks. He said that hitherto his duties had been only nominal, as no work had been sent to him to do; but it would give him the greatest satisfaction to perform any work for the Association which was placed in his hands.

Mr. SCHACHT said that his office was a post of honour devoid of all danger. He hoped that the meeting of the Conference would lead to the formation of a local association in Brighton, that town being eminently qualified for such a purpose. Young men would find the duties of local secretary to be of a most pleasant character.

Mr. REYNOLDS also joined in the acknowledgment of the toast. He said that it was a great gratification to him to know that the chairman of the evening, who had been a warm friend of the Conference from the first, represented the town of Brighton in the magnificent reception which had been accorded to them. He was quite sure that in the records of the Association no meeting would be recorded as a more complete success than the present one. They were under the greatest obligation to the gentlemen of the town.

Mr. CORNISH said that the pleasing duty devolved upon him of proposing the toast of the honorary and other officers of the Pharmaceutical Society, in conjunction with the names of Mr. T. H. Hills, and Mr. E. Bremridge. Every one must be aware that the success of such an association depended in a great measure upon the efficiency of its officers. Mr. Hills had frequently resorted to his purse for the benefit of the Society, and amongst the various treasurers none deserved higher esteem and honour. As to Mr. Bremridge, he had said when Mr. Bremridge was appointed to succeed the late Mr. Smith as secretary, that he would be the right man in the right place, and that had proved to be a right opinion. He had always had faith in the officers of the Society.

Mr. T. H. HILLS, in returning thanks, said that in coming down to Brighton he felt quite at home, for he was apprenticed at Brighton five-and-thirty years ago, and he had many pleasing associations connected with it. The Prime Minister said at the Mansion House the other day that the longer he lived the more he felt convinced that local institutions were very desirable. He (Mr. Hills) was of the same opinion; and he believed that where local institutions existed there were fewer jealousies and imaginary differences. Every town ought to have a local association, and he believed that from this day one would be established at Brighton. He also hoped that the gentlemen from various parts of the country would upon going home organize local associations in their own towns. That would be a first step towards pharmaceutical education. The Council of the Pharmaceutical Society would do all in their power to help such associations. The question of founding lectureships could then be entertained.

Mr. BREMRIDGE said that he fully appreciated the honour which had been paid him and his fellow-officers, but he felt unable to express himself in a satisfactory manner. He might say that each officer had in his department done his best *con amore* for the benefit of the Society.

Mr. R. W. GILES proposed "The Pharmaceutical Associations of America and Canada." He said that he could declare, without the slightest affectation, that he deeply regretted that he was unable to do honour to a toast which he was sure the company would wish to be presented in the best possible form. They might feel some amount of shame when they saw the brilliant examples of research and laborious work which had been performed by their brethren across the Atlantic in the path of pharmaceutical science. The feelings of the two nations were cordial and kind, and although there had been differences in the political horizon, the hearts of the people were united. He would associate with the toast the names of Professor Markoe and Professor Wayne.

Professor MARKOE said that the reception which had been given to him was quite overwhelming. His visit to England had been one of the greatest pleasures of his life. Spite of the newspapers and political hucksters, there was a hearty sympathy between the great masses of the people of the two countries of England and America. Especially was there sympathy on the subject of pharmacy. He had scarcely set foot on English soil before he received attentions of the most marked and flattering kind. Great interest was taken in pharmacy in America, and pharmacists travelled immense distances to attend conferences. The next meeting of the American Pharmaceutical Association would take place in the city of Cleveland, Ohio, in the second week in September. As a Vice-President he invited all the pharmacists in Great Britain to attend that convention, and he would assure those who might be disposed to venture so far that they would receive the heartiest possible welcome from the American pharmacists.

Dr. J. BAKER EDWARDS also responded to the toast in a short speech.

Mr. S. C. BETTY then proposed the "Pharmaceutical Press," coupling with it the name of Dr. Paul. He remarked upon the importance of the services rendered to the pharmaceutical body by the press, both in conveying information and acting the part of mentor, and expressed a belief that it would always be found of great service in assisting them to attain any object they had in view for the furtherance of pharmacy.

The toast having been responded to, the company next drank the health of the Town Council and Pavilion Committee, who had kindly placed the banqueting-room at the disposal of the local committee free of expense. The remaining toasts were "The Visitors," "The Chairman" (Mr. W. D. Savage), and "The Vice-Chairmen" (Messrs. Cornish, Brew, and Schweitzer).

The Pharmaceutical Journal.

SATURDAY AUGUST 17, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

THE BRITISH PHARMACEUTICAL CONFERENCE.

EVERY well-wisher to the progress of pharmacy will be glad to learn that the Ninth Annual Meeting of the British Pharmaceutical Conference, which during the present week has been held in the Royal Pavilion at Brighton, has been a very successful one. Whether regard be had to the number of leading English pharmacists who attended it, the ability displayed in the papers read, the interest attached to the gorgeous building in which the meetings were held, or the splendid hospitality extended by the local pharmacists to their visitors on Tuesday evening, it may at least be said that the meeting at Brighton has not been surpassed by any previous gathering of this now eminently successful organization.

The subject of education, as might have been expected, occupied a prominent position in the business. Forming no small portion of the subject-matter of the presidential address, which is printed on another page, it was also dealt with in papers by Professor ATTFIELD, Mr. SCHWEITZER and Mr. B. S. PROCTOR, and in letters which Professor ATTFIELD had received from Mr. G. W. SANDFORD, Mr. JOHN MACKAY, Mr. GILMOUR, Mr. PETER SQUIRE and Mr. EDWARD SMITH. The reading of the above was followed by a long discussion, lasting the remainder of the day, and only terminated by the necessity for adjournment.

Professor's ATTFIELD's paper, which formed the principal topic of the discussion deprecated the present prevalence of superficial teaching, and advocated that sound education would be best guaranteed by making the examinations more thorough, and supplementing them by demanding from a candidate for the Minor certificates that he has worked for a certain time at practical pharmacy, and that he has attended certain courses of instruction in a recognized school of pharmacy.

But nothing is more remarkable in this discussion than that, with one object in view, scarcely two are agreed as to the best mode of attaining it. As was truly said by one speaker, "*Quot homines tot opiniones.*" This lends weight to the opinion that the question of Provincial Pharmaceutical Education is not yet ripe for settlement. In the meantime, each day brings us nearer to the goal, and it is probable that the real solution of the difficulty of providing Pharmaceutical Education in small towns will, in Mr. ATKINS's words, in the main be found in the slow but certain advances in technical knowledge amongst pharmaceutical employers. This is an opinion which has been before uttered in these columns, and one that is shared by many well qualified to judge. Every perfectly trained pharmaceutical student who leaves the metropolitan or any other school and commences business, himself becomes an important medium for disseminating sound pharmaceutical education.

Wednesday was devoted to the reading of several valuable papers of a more particularly technical character; in several cases the subjects of the papers were discussed with great interest, but the remaining time was too short to allow of this being done to any great extent. The papers read were, Calabrian Manna, by Mr. DANIEL HANBURY, F.R.S.; Occurrence of Manganese in Certain Drugs, by Professor FLÜCKIGER; *Succus Scapi Taraxaci*, by Mr. H. BARTON; Pill Coatings, by Mr. T. HAFFENDEN; Tinctures, by Messrs. STODDART and TUCKER; Guaiacol, by Mr. J. WILLIAMS, F.C.S.; Laboratory Notes, by Mr. EDWARD SMITH; Kamala, by Mr. T. B. GROVES, F.C.S.; New Derivatives from Morphia and Codeia, by Professor WRIGHT, D.Sc.; Orris Root, by Mr. HENRY GROVES; Tincture of Perchloride of Iron, by Mr. T. HUSTWICK; Koegood, a new Drug from South Africa, by Mr. G. A. KEYWORTH; Researches on the Constituents of Aloes, by Dr. TILDEN and Mr. RAMMELL; Notes on Green Extracts, by Mr. RICHARD W. GILES; A Cheap Disinfectant, by Mr. EDWARD C. C. STANFORD, F.C.S.

ADULTERATION OF FOOD, DRUGS, ETC., ACT.

THE Bill to prevent the adulteration of food, drink, and drugs, to which we have before alluded, has become law, with its most objectionable features removed. It will be remembered that originally the wording of Sect. 2 was so ambiguous that it was uncertain whether a man who sold an impure article in perfect innocence might not be liable to severe penalties. We have no sympathy either with the wilful adulterator or with the retailer who, for the sake of a little extra profit, buys an article so much below the market value that common sense must point to adulteration; but when we think of the terrible difficulty which a druggist finds in procuring some drugs positively pure,—notably, scammony, opium and musk,—we cannot but consider that the Deputation from the Pharmaceutical Society which waited on Lord SALISBURY did good service in inducing him to provide that the man, who knowingly and fraudulently sells adulterated articles, *and no other*, shall be deemed guilty of offence. This seems to us to be in the true spirit of English law.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

The Ninth Annual Meeting of the British Pharmaceutical Conference was commenced on Tuesday, August 13, 1872, at the Royal Pavilion, Brighton, under the Presidency of H. B. Brady, Esq., F.L.S., F.C.S. (Newcastle-on-Tyne).

After the reception of delegates, the town of Bradford, in Yorkshire, was fixed upon as the place of meeting for the year 1873.

The following report of the Executive Committee and the Treasurer's account were then read and agreed to:—

Report of the Executive Committee.

During the past year your Committee has held three meetings. On November 1st, 1871, final arrangements for the publication of the Year Book were made, and the position of the Conference in relation to towns proposed to be visited was discussed. On July 2nd, 1872, a report of the work done by the Senior Secretary and Assistant Secretary during the year was received and adopted; the financial condition of the Conference was considered, arrangements for the meeting at Brighton were made; and there was read an important letter from Thomas Hyde Hills, Esq., respecting a munificent gift of £200, to be expended for the advancement of Pharmaceutical education and research, under the direction of the Executive Committee of the British Pharmaceutical Conference. Last evening (August 12th, 1872) the Committee transacted the details of business connected with the present meeting.

The Year Book is an established success. In publishing it the Conference meet a want on the part of pharmacists for an annual *résumé* of all that is new in pharmacy; and, judging from the unanimous public and private expressions of opinion, the want is now satisfactorily supplied. With the continued assistance of the present Editor and of the Secretaries, who edit the Transactions bound up with the Year-Book, your Committee believes that in succeeding issues the high character of the volume will be maintained.

The Committee congratulates the Conference on the continued success of the annual meetings. The combined efforts of the members have extended the field of Pharmaceutical Research, and more thickly peopled it with workers, while in no way impoverishing other organizations for the ingathering of its harvests. For the means of communicating to each other and discussing the results of investigations much credit is due to the Local Committees in the towns visited. To excite in resident pharmacists interest in the objects of the Conference, assist the Secretaries to hire rooms in which to hold the meetings, and to contrive opportunities for public discussion and conversation, are the three ways in which Local Committees can effectively promote the objects of the Conference.

The financial condition of the Conference is satisfactory. From the following statement it will be seen that there is a balance in hand, and that it is about the same in amount as at the end of the previous year:—

The Treasurer in account with the British Pharmaceutical Conference, 1871–72.

H. C. Baildon, Julius Schweitzer } Auditors.

The President then delivered the following address:—

The President's Address.

It seems to have become a recognized duty of your President to open the general proceedings of the Conference by a review, from one standpoint or another, of the progress of pharmacy during his year of office; and when I look back to the addresses that have on such occasions emanated from my predecessors, I may well have misgivings of most serious nature as to my ability to follow in their footsteps without discredit to myself and disappointment to you. Happily, however, there is no necessity strictly to follow precedent, for the duty of summarizing periodically the results of pharmaceutical research, is now undertaken by one far better fitted for the task,—with larger opportunities for its right performance, and not bound by the restraints and limitations incident to a general address,—I allude to the accomplished editor of your 'Year Book.' Concerning his work I will say no more at this moment than to point to it as an explanation of my decision to speak of the present and future, rather than of the immediate past of pharmacy. And I am the more impelled to follow the course thus open to me, for alas! circumstances unforseen when I accepted the post I have the honour to hold, and altogether beyond human control, have placed it out of my power to follow closely the advance either of those branches of science which directly concern us or of the manipulative arts which enter into our daily employment. The report which you have just heard read will satisfy you, as it well may, of the flourishing condition of the Conference. Thanks to recent agitation in the pharmaceutical world, and to the feeling of safety in union engendered thereby,—to the ample return in kind members now receive for their small annual contribution,—thanks, above all, to the energy of your indefatigable secretaries,—the Conference has attained a position in point of size, influence and power for good, which was never dreamt of by those who assisted at its foundation. In so far as the general history of the Conference is concerned, I might have addressed you in terms of simple congratulation; but other questions arise, and I should have been disturbed, whilst dilating on the augmented power and importance both of our own body and of the parent society, by the lurking consciousness that, notwithstanding increased disposition to united action, somehow or other, pharmacy in this country was not so prosperous,—that its higher aspirations were not so vigorous—as the numerical strength and popularity of its representative associations might lead one to suppose. I confess, too, that I am impressed with a fear that had I in preparing my address sought for worthy material of purely scientific sort in the journals, proceedings, transactions, and the like, which have appeared since our meeting in Edinburgh a year ago, I must have relied to a far greater extent on the records of foreign than of home research. The President of the Chemical Society in a recent discourse, adverts in striking terms to the lethargy which has enveloped original chemical investigation in this country; and the words spoken, demonstrably true as to pure chemistry, might be applied with almost equal emphasis to other branches of scientific knowledge bearing on pharmacy. To judge by our publications for the past year or two, pharmaceutical energy in this country has been directed almost exclusively into two channels; firstly, the relations of pharmacy to the State, and, secondly, the more wide-spread provision of facilities for that rudimentary scientific education which recent enactments impose on the pharmacist of the future—both of them difficult, but altogether momentous questions.

It is needless to narrate the process by which the present satisfactory condition of legislation, in respect to pharmacy, has been arrived at. The patient thirty years' labour originated by a few earnest, far-sighted men, seconded, gradually perhaps and not without a safe amount of hesitation and doubt, but in the end, as the subject came to be understood, ably seconded by the body at large, and in due time supported by public opinion—has led at length to the carefully devised and thoroughly practical law which we now enjoy. In a survey of the State relations of pharmacy in the various continental countries, I know not where we should look for a broader or more satisfactory basis of legislation or one so suited to the genius of our institutions, than exists at home. The protection of the public from errors arising out of incapacity and ignorance, is, prospectively speaking (for a generation must pass before the full effect of the law is seen), as nearly complete as legal enactments can ensure, and this is effected without excessive interference with the jealously guarded rights of property or with that exercise of individual judgment which the members of an educated body may justly claim. I allow that the present educational status of pharmacy might have justified greater legislative stringency, but the very basis of the law is *improved education*, and we are, it is admitted, in that transition stage which demands provision for the future rather than the immediate present; behind us is the chaos of chance—before, the substantial guarantee of the Pharmaceutical Society that order shall reign. A Government granting the privileges of the latest Pharmacy Act, could demand no less than this guarantee for the future; respect for the circumstances of those whose means of livelihood depended on the business in which they were already engaged admitted no more. How vexatious and unprofitable any interference with what we call "vested interests" would have been, we may see from the experience of our brethren in New York. The chemists of that city, by an arbitrary police regulation, were, a year ago, compelled, old men and young to come up for examination before a Board constituted on principles that astonish Englishmen; an imposition so onerous and oppressive that pharmacists of all conditions were compelled to unite to obtain its repeal. Herein we find a sufficiently practical reply to those who look no further than the present. If I introduce another point in which circumstances have favoured us, it is only because its importance may have been too little appreciated,—I allude to the practical unity of the examining board, and the practical uniformity of the examinations for diplomas in all cases in England and Scotland. Happily we have not been beset with the complexities that have attended all attempts for the better regulation of the issue of licences in medicine; complexities depending on the rights hitherto enjoyed by a large number of historic corporations, and hitherto exercised without reference to any uniform standard. This want of recognized standard exists in the United States, not only in medical, but in pharmaceutical degrees, with an additional element of confusion in the fact, that except in one or two cities, pharmacy is under no compulsory regulation. There the diplomas, medical and pharmaceutical, of the colleges of the various States are of the same legal value (in so far as they have legal value at all), and as examination fees are a considerable source of income, other inducements must be held out where scholastic advantages are not of the highest sort to ensure full classes. Hence the prospect of a diploma on easy terms is a not unnatural counter attraction. I heard an eminent professor in a New England university lament that, owing to these causes, medicine had ceased to be a learned profession in his country. I do not wish to dwell on these considerations further than is necessary to demonstrate at the outset that the great end of recent political agitation is gained; that pharmacy is now regulated by a law affording sufficient protection to the public by the compulsory education it necessitates, giving larger privileges to those practically engaged in it, free on the one hand from the looseness of voluntary provisions, and on the other from the excessive interference and inspection in vogue in many continental States,—hence that we are in a condition in which we may turn our attention to advancement *from within* rather than to those political topics which have so exclusively occupied the thoughts of our members for the past two or three years. This may fairly be expected of us, and that it is expected I do not hesitate to say.

The address of Professor Huxley, a year or more ago, when distributing the sessional prizes at University College, will be in the recollection of most of you, especially certain passages in which he condemned Materia Medica (apart from therapeutics) as a subject of medical study—a dictum which fell like a thunderbolt in the camp of those who are doing to-day, and will do to-morrow, what they did yesterday, because they did it yesterday. The extraordinary development of some all-important divisions of medical science, notably of physiology and minute human anatomy, renders it impossible to cram into the few brief years of collegiate training a satisfactory amount of knowledge in the whole of the long list of subjects which it has been the custom to embrace in the curriculum of medical study.

It is no part of my business to discuss the relations of inorganic chemistry, materia medica, and botany, to the scheme of medical education; but words uttered in public, by a leader in science, affecting us so closely in their indirect bearing, can hardly be dismissed without a glance at the issues they involve. It is true enough, as was stated by Professor Huxley, that the standard British work on Materia Medica is a treatise *de omnibus rebus*; that, in point of fact, "materia medica" is a mere *nom de convenance* for a heterogeneous mass of facts, referable mainly to biological (chiefly botanical) and chemical science, and whether its details might not be advantageously taught in their natural places, instead of sifting them out for separate treatment, is quite open to debate. But whatever the manner of treatment, the subjects involved must be taught—if not to students in medicine and surgery, then the more certainly to students in pharmacy; and thus a double responsibility rests upon us in respect to these important sections of medical knowledge.

I hold that this utterance of Professor Huxley's contains by inference a fresh and most important recognition of the fact that the scientific attainments of the pharmaceutist must be complementary to those of the medical practitioner, separated only by that sort of line which marks all division of human labour; that, prospectively, the two avocations must be more and more dependent upon each other, the physician looking to the pharmaceutist not merely as the compounder of his prescriptions, but as to one on whom he can rely for assistance in scientific subjects closely allied to those which are his own more immediate concern.

You will ask whereto these reflections lead. In endeavouring to answer the question, I desire before all things to bear in mind that pharmacy from our point of view does not represent a fanciful experimental form of science, meet for the amateur, but primarily, a means of earning a subsistence; and I hope I shall be preserved from making a single remark inconsistent with this fundamental consideration. I trust, also, that I give due weight to the fact that pharmacy only began to assume a definite position in this country with the passing of the Pharmacy Act four years ago. Before that time whatever was done in Great Britain to advance pharmaceutical science—and much was done—was accidental rather than the result of system. It is essential that we keep the past very clearly in view in our endeavour to trace the requirements of the present.

Questions affecting the training of the rising generation of pharmaceutists, pertain to the functions of the Pharmaceutical Society rather than directly to the Conference, as do those also which concern the opportunities which exist for prosecuting pharmaceutical research. But this need not preclude their free discussion here, indeed, they force themselves upon our notice at a time like the present, when educational problems are uppermost in the public mind. The papers promised to the Conference on the former of these subjects will be received with interest, and their discussion may clear the way of some of the difficulties which, though they undoubtedly exist, are unnecessarily magnified by those who would "rest and be thankful" rather than commit themselves to any new exertion.

That the Board of Examiners of the Pharmaceutical Society is fully alive to the importance of a higher standard of preliminary education, we see frequent evidence, but its action has been very properly influenced by consideration for the position of youths who had chosen their vocation before it could be said with any certainty that their future must depend on their ability to pass examinations. But the time when leniency on this ground can be extended without discredit to the Society is rapidly drawing to a close, and an increase in the scope and stringency of the demands on youths entering the profession ought at once to receive serious attention. Neither could there be any complaint of hardship in the adoption of a higher standard if due notice were given of the intention of the Board to raise their minimum requirement. It cannot be too prominently kept in view that the Preliminary examination is not of itself pharmaceutical; that it is but the means of assurance that a youth has sufficient general knowledge to give him the best chance of pursuing the vocation he has chosen, with success to himself and with credit to the body at large. Such examination ought, therefore, to follow immediately on leaving school, so that the mind may be at liberty from the commencement of the term of pupilage for the acquirement of technical and scientific knowledge. It is no part of the duty of a principal to do the work of a schoolmaster. A youth who cannot pass a good examination in the branches of learning comprised in what is usually understood as a liberal education, is not fit to commence his apprenticeship as a pharmaceutist; and a principal who at the present time takes an apprentice without reference to his preliminary training, does a direct injury to the body at large, and performs no kindness to the youth himself. Supposing a boy has to remain a year longer at school, can that be regarded as any real hardship, or is he likely, in after life, ever to regret the slight initiatory delay? Can he possibly, in the long run, be a loser by it? I am far from asserting that our middle-class schools are what they ought to be, however much they may have been improved of recent years; but taking them as they are, it cannot be urged that there is any serious difficulty in obtaining a fair English education, together with instruction in the rudiments of Latin, French, and German. If, as Mr. Benger hinted in his suggestive paper, read before the Conference at Liverpool, our ranks are likely to be recruited from a wealthier stratum of society than hitherto, there is still less excuse for laxity and indulgence. This subject of preliminary education now needs plain speaking; it lies at the root of the whole question of the advancement of pharmacy. Without a wider and deeper foundation than is at present secured no worthy superstructure can be raised.

It appears to me that the liberty to proceed to the "Minor" examination immediately on passing the "Preliminary" is a grave mistake. We have done away with the necessity of apprenticeship, and no longer require the guarantee of practical experience and teaching that the old system of indentures afforded; *perhaps* this is as it should be, but we ought at least to be clear that sufficient time has elapsed after the youth has been able to devote his energies to pharmacy pure and simple, whether bound as an apprentice or not, to enable him to acquire, leisurely and systematically, the knowledge necessary for his technical examinations, and I do not think that an interval of three or four years is too much to insist upon, in order to secure this end.

The Minor Examination demands a moment's notice because, under the present Act, it is the Registration test. The efforts which have been made to render it thoroughly practical would receive fresh support by the adoption of the course I have ventured to suggest. The bane of all examinations is the temptation to "cram"—you will excuse the word, I know of no better—but I conceive that it is very much in the power of the examiners to render mere "cramming" almost or entirely ineffective. No candidate pretends to cram for the dispensing examination, and I speak with some experience when I say that it would be easy to make the botanical section as completely practical as the dispensing. I cannot doubt that the examination in chemistry might in the same way be supplemented by tests to which crammed knowledge would furnish no reaction.

The diploma of the Major Examination ought to be regarded very much in the same light as the Fellowship of the College of Physicians or the College of Surgeons is in their respective bodies, and the value of the degree it confers ought to be as jealously guarded. There can be no reason why the Society should be satisfied with a lower standard that that which has long been in vogue for the "Pharmacien de la Première Classe" in France.

It has been suggested by one whose opinion carries weight with it, that the occasional presence during the examinations of a non-pharmaceutical assessor—say, a scientific chemist of eminence not belonging to our own body—would be in many ways an advantage. The mere "looker-on sees most of the game," and the suggestions of an independent observer could not fail to be of service to the examiners. His criticism would diminish the tendency of the examinations to settle into particular grooves, and would help to give them a wider scope and higher significance. The moral effect would be to increase the confidence of the examiners themselves when obliged to act as their judgment rather than their will might dictate, and to support their decisions in the eyes of the public.

In these observations I know I shall not be understood to express any distrust of the Board of Examiners. My object is to strengthen their hands in the performance of laborious and thankless duties; and I gladly, from knowledge, bear testimony to the ability, and conscientious care, and self-sacrifice which are the very atmosphere of the Board-room.

There is still another subject closely connected with the foregoing, upon which I would say a few words.

I cannot regard with any satisfaction the large unused balance of income which the Pharmaceutical Society has of recent years annually funded. The day is gone by for laying up talents in napkins. A professional or business man is morally bound to put aside part of his income, so that he may rest in after life when his capacity for toil is lessened; but for a public body, no such plea will hold. So long as the Society was on a voluntary basis, and doubt might be supposed to exist as to its pecuniary stability, the executive was bound to provide against many contingencies, and our thanks are due to those who then so economically administered the funds placed in their keeping. But we are no longer beset with the dangers of that period, and beyond an investment sufficient to guarantee the means of carrying out the examining and governing functions entrusted to the Society by Government—a limit long since passed —there can be no excuse for the accumulation of wealth. These constantly recurring investments under our present circumstances represent good left undone—opportunities unaccepted. Nor in this hoarding of money instead of science is the Pharmaceutical Society true to the spirit of its founders. The Society was formed to do in a collective capacity what could not be done by individuals. The chance of recognition by the Legislature, the efficient organization of chemists as a body, the establishment of a central library and museum, are, for instance, all matters depending on the co-operation of numbers. The laboratory and lectureships may be included in the same category, but are only right objects for corporate provision, in so far as they bring what could not otherwise be obtained. But the relation of the Society to these latter departments has entirely changed, and their existence in the old form is becoming, if it has not already become, an anomaly. What they provide, as at present constituted, might even now in great measure be safely left to private enterprise. Far be it from me to underrate what the laboratory instruction and lectures at Bloomsbury Square have been to the Society. The founders saw clearly, that without giving facilities for education which did not previously exist, the establishment of examinations whilst the Society was on a voluntary basis, could meet with no general response. Now the response is certain because it is supported by compulsory powers—hence the co-existence of other schools of pharmacy with that in Bloomsbury Square.

Your excellent Treasurer makes a strong claim in behalf of organization and subsidies for local schools. Such establishments, even in the larger provincial centres, are not likely, at first, to be entirely self-supporting, any more than was that in the Metropolis thirty years ago, and the demand for assistance is nothing more than the maintenance of our first principle—that the corporate Society should help forward Pharmaceutical Education when individual effort is insufficient. The subject is one which may be safely left in the hands of those who have already given so much time and thought to it. I need not here pass any opinion on the relative merits of the various systems which have been proposed for the regulation of money-grants, and I would not willingly weaken the claim of any by my less mature suggestions. One thing, however, must be borne in mind, namely, that the very fact of requiring assistance is an evidence of weakness, and that no school can be said to exist on a permanent or satisfactory basis until it is self-supporting. We must be careful to do nothing to place further away the time when science-teaching amongst us shall be a properly remunerative occupation, and it can only become so when those who reap its benefits are content themselves to pay a remunerative price for it. There is already far too great a disposition to regard education as a thing that should be supplied for nothing, or at least that an increased amount should be obtainable without increased cost. A physician or a lawyer spends his money and time cheerfully upon his technical education, regarding the outlay as capital invested in business; and the pharmaceutist, until he does the same thing in like spirit, has not established his title to professional status or remuneration.

But there is another claim which must be made, not stronger than that which has been alluded to, but one which may well coexist without interfering with it—namely, the provision for higher training, and for scientific research of unremunerative nature. Every one here will, I am sure, support the proposition, that the larger the amount of scientific culture possessed by pharmaceutists, the higher must be the general status of the profession, and, even in a pecuniary sense, the better their position as a body. The recognition of this, to us, new field of usefulness need not imply any neglect of the duties at present recognized as pertaining to the Pharmaceutical Society. Without materially interfering with its existing functions in respect of rudimentary education, a great deal more might be done than has yet been attempted in the encouragement of higher training, and in affording facilities for original investigation. It has seemed to me that the most substantial aid which could be rendered in the direction alluded to would be the setting apart of a number of free benches in the Society's laboratory for students who, having passed the Major examination with credit, might desire to continue their studies. These should even be endowed with a small annual income, under certain conditions, if found necessary. The only primary stipulation should be that, possessing the requisite preliminary knowledge, the recipient should be ready to work for the advancement of pharmacy under the direction of the professor. The Bell Scholarships will, I know, be pointed to as an effort in the direction indicated, but these have failed materially to influence the body, firstly, from their insufficiency, and secondly, from the conditions properly associated with them. They would be more likely to answer a good purpose if they were both applied as the Junior Scholarship now is. In the present state of pharmacy we require not the stringent conditions of competitive examinations to prevent men from carrying forward their studies, but rather the open-handed liberality that will induce students to consider whether they cannot give up another session or two, before commencing business, to that higher sort of education which is not immediately remunerative. The effect of half-a-dozen or a dozen men so trained, sent out annually from Bloomsbury Square, would be to make a British school of pharmacy, the like of which has never existed; and were this carried out, the most serious difficulties in the way of provincial education would resolve themselves in a few years. It may be urged that no demand for a higher scientific culture exists; I reply, how do you know? But if it be so, the sooner you create the demand—and you will inevitably create it if you are in earnest in offering the means of supply, and have the necessary patience—the better for the interests of pharmacy and those who follow it. I do not suppose that a crop of brilliant discoveries would immediately follow the adoption of such a scheme, but we might surely calculate on additions to our knowledge of pharmaceutical subjects, such as have never emanated from the students of the metropolitan laboratory of recent years; and in any case the prestige of the Society must be increased, and the status of pharmacy correspondingly advanced. You will at least have made the laboratory something more than a forcing-house for pass-examinations.

Nor do these proposals represent new or untried modes of fostering research. The present position of Germany in the scientific world is due to nothing so much as the opportunity and encouragement afforded to young men. Laboratories for purposes of research are there open on terms that can debar no one from entering who desires to work in them. In some cases they are absolutely free, not only to Germans, but to students from other countries; and their classes composed of men engaged in similar subjects, in friendly rivalry and emulation, are the seminaries of new aspects of scientific inquiry and of fresh lines of philosophic thought. I am far from wishing to exalt our neighbours at our own expense, but we are bound to read the lessons which their success inculcates. The Pharmaceutical Society has means enough at its disposal; surely it would be better that its pride should rest on constant investments in science and intellectual wealth than in the perpetually swelling assets of its annual balance-sheet.

I have endeavoured to point out that the parent Society is the source whence we have a right to look for the provision to a great extent of *opportunity* for pharmaceutical investigation, and I must now as pointedly allude to the Pharmaceutical Conference as possessing the machinery, easily extended to meet increased requirements, for organizing and systematizing research. In its very first programme the Conference was defined as "an organization for the encouragement of pharmaceutical research," nor can it be said that the means which have been adopted from time to time in furtherance of this purpose have been altogether unsuccessful. The circulation periodically of a carefully revised list of subjects, concerning which further investigations are required, is a plan originally borrowed from the American Association, and is probably as good a means as could be devised for preventing waste of labour. The number of valuable contributions to knowledge which have resulted from suggestions contained in this annual circular, sufficiently attest its positive as well as its negative advantages. But to be entirely successful such a method requires the more general cooperation of the members than it has yet received. The duty of compiling the list ought not to be left to the very few who have hitherto, in default of general assistance, undertaken its revision, still less that of accepting and working out the subjects comprised in its queries.

The Conference too may be made serviceable in collecting information from different portions of the kingdom, and in special cases our members residing abroad might be made use of to similar ends.

In many branches of science difficulties occur in respect to publication, but herein we have no lack. If our own "Proceedings" are too tardy a medium, the Pharmaceutical Society is ready with its weekly "Journal."

Methods other than those roughly indicated for the promotion of scientific culture will, doubtless, present themselves as the subject receives the increased attention it demands. Collective thought and associated action are alike needed to attain the first step—the provision of opportunities. But there is much to do beyond merely clearing the path of external impediments. Year by year some of us have more and more to confess, that it is to younger men with increased advantages, that we must look to take the scientific position we have desired and do but see afar off; and under these circumstances, the attitude of the older to the younger is one of paramount importance. I am reminded of a passage in one of Mr. Ruskin's books containing a powerful statement upon the duties of criticism, and encouragement and guidance, which, though written of and for artists, hardly needs the alteration of a word to make it equally applicable to all who have intercourse with students in the early stages of their career. The mental condition in which right intellectual labour is accomplished is much the same whatever the object in hand; and I need scarcely apologize for quoting the paragraphs as they stand, although the introductory portion may not be exactly to our present purpose.

"What we mainly want, is a means of sufficient and unagitated employment: not holding out great prizes for which the young are to scramble; but furnishing all with adequate support, and opportunity to display such power as they possess without rejection or mortification. . . . . But a more important matter even than this of steady employment, is the kind of criticism with which you, the public, receive the works of the young men submitted to you. You may do much harm by indiscreet praise and by indiscreet blame; but remember, the chief harm is always done by blame. It stands to reason that a young man's work cannot be perfect. It *must* be more or less ignorant; it must be more or less feeble; it is likely that it may be more or less experimental, and if experimental, here and there mistaken. If, therefore, you allow yourself to launch out into sudden barking at the first faults you see, the probability is that you are abusing the youth for some defect naturally and inevitably belonging to that stage of his progress; and that you might just as rationally find fault with a child for not being as prudent as a privy councillor, or with a kitten for not being as grave as a cat. But there is one fault which you may be quite sure is unnecessary, and, therefore, a real and blamable fault: that is haste, involving negligence. Whenever you see that a young man's work is either bold or slovenly, then you may attack it firmly; sure of being right. If his work is bold, it is insolent; repress his insolence; if it is slovenly, it is indolent; spur his indolence. So long as he works in that dashing or impetuous way, the best hope for him is in your contempt: and it is only by the fact of his seeming not to seek your approbation that you may conjecture he deserves it.

"But if he does deserve it, be sure that you give it him, else you not only run a chance of driving him from the right road by want of encouragement, but you deprive yourselves of the happiest privilege you will ever have of rewarding his labour. For it is only the young who can receive much reward from men's praise: the old, when they are great, get too far beyond and above you to care what you think of them. You may urge them with sympathy, and surround them with acclamation; but they will doubt your pleasure, and despise your praise. You might have cheered them in their race through the asphodel meadows of their youth; you might have brought the proud, bright scarlet into their faces, if you had but cried once to them 'Well done,' as they dashed up to the first goal of their early ambition. But now, their pleasure is in memory, and their ambition is in heaven. They can be kind to you, but you never more can be kind to them. You may be fed with the fruit and fulness of their old age, but you were as a nipping blight to them in their blossoming, and your praise is only as the warm winds of autumn to the dying branches." *

I must now turn to matters which you will be disposed to remind me should have occupied a more prominent place in my discourse, but in reality the proceedings of the Conference for the past year seem to call for little comment. The most notable point is doubtless the publication of the second 'Year Book.' This volume, issued with commendable promptitude after the last meeting, has long

* 'Political Economy and Art,' p. 34.

been in the possession of the members; it has been freely criticized by the scientific press, both at home and abroad, and so far as I have been able to gather has been received with unanimous favour. How much of its excellence is due to the gentlemen who constitute the Committee of Publication, how much to the able Editor, it is needless to enquire—my office is rather to congratulate the Conference on being enabled by their exertions to perform so great and so permanent a service to pharmacy, and to express a sense of obligation in which every member of the body will join, to Editor and Committee alike, for the spirit with which they have entered into and carried through a laborious undertaking.

We have again to acknowledge the thoughtful liberality of one of our members who is ever ready to render material aid when the interests of pharmacy may be furthered thereby. Mr. Hills's last gift puts the Conference in possession of funded property, yielding a permanent income similar in amount to the annual instalments of his previous benefaction. To what your Executive Committee has already said in this matter I need add little. The gift has been accepted on behalf of the Conference, and with it the responsibility of its right application, conscious the while, that result rather than words would form the expression of thanks most congenial to the donor.

You will expect a few words from me on another topic of more personal nature. In fulfilment of a long-projected plan, I last year took a somewhat extended holiday in North America. The meeting of the American Pharmaceutical Association was the focus of my travels; and, as I held your commission to represent the Conference as far as circumstances might admit at the St. Louis Convention, I am in some sort bound to report the reception accorded to me on that occasion. In doing so, I need not occupy you at any great length; indeed, I can scarcely add to the little I have already said in public without going into details of greater extent than seems desirable. The hospitality of the American people towards strangers—especially towards travelling Englishmen—is universally recognized, and their desire to stand well in the hearts and esteem of our countrymen exists everywhere, so far as I could find, except in their newspapers. But it needs more than this general acknowledgment of kindly feeling to explain the sort of welcome I received amongst their pharmacists and the attention they so liberally bestowed. That I was with them as your representative may be held to account for the rest. The most hearty reciprocation of your message of good will and friendship has dwelt in my mind whilst the horizon has been clouded by the political strife engendered by clumsy diplomacy—strife which I am pursuaded has no existence, save perhaps in moments of passing irritation, in the hearts of either people.

The American Pharmaceutical Association was accepted as a model when our Conference was founded, and its proceedings, therefore, cannot be uninteresting to us.

Without legal status or recognized powers, the Association exercises a sort of moral influence throughout the country, which is of great importance where there is no control emanating from a central authority—an influence which in ethical questions can scarcely be overvalued.

An illustrative case occurred last year at St. Louis. When the credentials of the various delegates to the Convention were considered, the question was raised whether the kind of pharmaceutical instruction afforded by one of the bodies claiming to send a representative, and the nature of their examinations, were such as the Association could approve and recognize, and it was eventually decided that the delegate from the body in question (the University of Michigan) could not be admitted in an official capacity, and he was was, therefore, debarred from exercising any representative functions.

Another case showing similar care for the true interests and standing of the profession occurred a year or two ago, and will be in the recollection of many of you. An eminent pharmacist prepared and advertised largely an article which he termed "Sweet Quinine." The character of the man was sufficient to disarm suspicion, and an enormous sale for his nostrum was a practical certainty. Circumstances led to an examination of the medicine, and it was found to be a compound containing cinchonine only as an active ingredient. Neither the standing of the pharmaceutist, his activity as a member, his scientific attainments, nor his personal popularity amongst his associates could save him from expulsion. He was one whose co-operation the body could ill afford to lose, but duty to themselves and the public was paramount.

The report of the meeting at St. Louis has already been published, and those who have seen it will hold me excused from making any detailed review of the proceedings, and will be content with the record of general impressions.

Notwithstanding the enormous distances from each other of the chief American cities, the gatherings of the Association are very largely attended, and the number of members who participate actively in the business of the meetings is much greater than I anticipated, judging from our own experience; indeed the amount of scientific matter usually brought forward is such as we could not attempt to grapple with at these brief Conferences. This scientific work consists in great measure of reports on subjects selected from the annually-published list of queries, and is, therefore, directed to points concerning which information is really wanted. The papers were much more satisfactory to my mind than the discussions they evoked, though the latter often made up in spirit what they lacked in order. The custom of reporting in full, and not always very correctly, mere conversational remarks, can hardly be regarded as a happy one.

Altogether, the meeting of the Association is a larger affair than anything we attempt. The sessions extend over about four days, which are very fully occupied, the evenings being generally devoted to social gatherings in one form or other. The frequent presence of ladies at the sittings was a feature that struck me forcibly and favourably. Often when subjects of general rather than purely technical interest were under consideration, the aspect of the assembly was brightened by this absence of exclusive rule. I am sure I need not add that no interruption to the course of business was thereby caused, or that the fairer were models of attention to the sterner portion of the assembly.

The fearful disaster at Chicago, which occurred just as I was leaving America, brought to the surface the deeper seated feelings of our countrymen. The opportunity afforded to pharmaceutists in this country to express in substantial form their sympathy with those of like profession in the far West was not disregarded. Distance is no barrier when common interests are concerned—interests are never more rightly felt to be in common than when one portion of the body is under the cloud of misfortune and suffering.

And now, gentlemen, it is time I released you to attend to the real business of the meeting. In the remarks which it has seemed to me a duty to make, I have spoken with equal freedom of our own body and of the Society from which we sprung. There is no difference in the objects of the two institutions; they are and must be perfectly harmonious and complementary to each other. The particular methods open to them to attain the same end—*the advancement of pharmacy* differ considerably but only as different roads to one goal. Without the Pharmaceutical Society the Conference could never have been; with the establishment of the Conference, the best day of the Society dawned. The success of each must be the chief delight of the other. This is my defence if it be needed for the order in which I have placed my thoughts before you.

One word more. I have spoken of the Conference and its duties, of the Society and what I believe to be incumbent upon it, but let us bear in mind that Society and Conference alike are composed of members, and that no individual member of a body corporate is excused from his share of work. Let me put it rather in the words of Lord Bacon—

"I hold *every man* to be a debtor to his profession; from the which, as men of course do seek to receive countenance and profit, so ought they of duty to endeavour themselves by way of amends to be a help and ornament thereunto."

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The first General Meeting of the members of this Association was held in the Royal Pavilion at Brighton on Wednesday evening, August 14th. The following inaugural address was delivered by the new President, Dr. Carpenter, F.R.S.:—

Address.

Thirty-six years have now elapsed since at the first and (I regret to say) the only meeting of this Association held in Bristol,—which ancient city followed immediately upon our national Universities in giving it a welcome,—I enjoyed the privilege which I hold it one of the most valuable functions of these annual assemblages to bestow; that of coming into personal relation with those distinguished men whose names are to every cultivator of science as "household words," and the light of whose brilliant example, and the warmth of whose cordial encouragement are the most precious influences by which his own aspirations can be fostered and directed. Under the Presidency of the Marquis of Lansdowne, with Conybeare and Prichard as Vice-Presidents, with Vernon Harcourt as General Secretary, and John Phillips as Assistant Secretary, were gathered together Whewell and Peacock, James Forbes and Sir W. Rowan Hamilton, Murchison and Sedgwick, Buckland and De la Beche, Henslow and Daubeny, Roget, Richardson, and Edward Forbes, with many others, perhaps not less distinguished, of whom my own recollection is less vivid.

In his honoured old age, Sedgwick still retains, in the academic home of his life, all his pristine interest in whatever bears on the advance of the science he has adorned as well as enriched; and Phillips still cultivates with all his old enthusiasm the congenial soil to which he has been transplanted. But the rest,—our fathers and elder brothers,—"Where are they?" It is for us of the present generation to show that they live in our lives; to carry forward the work which they commenced; and to transmit the influence of their example to our own successors.

There is one of these great men, whose departure from among us since last we met claims a special notice, and whose life—full as it was of years and honours—we should have all desired to see prolonged for a few months, could its feebleness have been unattended with suffering. For we should all then have sympathized with Murchison, in the delight with which he would have received the intelligence of the safety of the friend in whose scientific labours and personal welfare he felt to the last the keenest interest. That this intelligence, which our own expedition for the relief of Livingstone would have obtained (we will hope) a few months later, should have been brought to us through the generosity of one, and the enterprising ability—may I not use our peculiarly English word, the "pluck"—of another of our American brethren, cannot but be a matter of national regret to us. But let us bury that regret in the common joy which both nations feel in the result; and while we give a cordial welcome to Mr. Stanley, let us glory in the prospect now opening, that England and America will co-operate in that noble object which—far more than the discovery of the sources of the Nile—our great traveller has set before himself as his true mission—the extinction of the slave trade.

At the last meeting of this Association, I had the pleasure of being able to announce that I had received from the First Lord of the Admiralty a favourable reply to a representation I had ventured to make to him, as to the importance of prosecuting on a more extended scale the course of inquiry into the physical and biological conditions of the Deep Sea, on which, with my colleagues Prof. Wyville Thomson and Mr. J. Gwyn Jeffreys, I had been engaged for the three preceding years. That for which I had asked was a circumnavigating expedition of at least three years' duration, provided with an adequate scientific staff, and with the most complete equipment that our experience could devise. The Council of the Royal Society having been led by the encouraging tenour of the answer I had received, to make a formal application to this effect, the liberal arrangements of the Government have been carried out under the advice of a scientific committee, which included representatives of this Association. Her Majesty's ship 'Challenger,' a vessel in every way suitable for the purpose, is now being fitted out at Sheerness; the command of the expedition is entrusted to Captain Nares, an officer of whose high qualifications I have myself the fullest assurance; while the scientific charge of it will be taken by my excellent friend Prof. Wyville Thomson, at whose suggestion it was that these investigations were originally commenced, and whose zeal for the efficient prosecution of them is shown by his relinquishment for a time of the important academic position he at present fills. It is anticipated that the expedition will sail in November next; and I feel sure that the good wishes of all of you go along with it.

The confident anticipation expressed by my predecessor, that for the utilization of the total eclipse of the sun then impending, our Government would "exercise the same wise liberality as heretofore in the interests of science," has been amply fulfilled. An eclipse-expedition to India was organized at the charge of the Home Government, and placed under the direction of Mr. Lockyer; the Indian Government contributed its quota to the work; and a most valuable body of results was obtained, of which, with those of the previous year, a report is now being prepared under the direction of the Council of the Astronomical Society.

It has been customary with successive occupants of this chair, distinguished as leaders in their several divisions of the noble army of science, to open the proceedings of the meetings over which they respectively presided, with a discourse on some aspect of nature in her relation to man. But I am not aware that any one of them has taken up the other side of the inquiry,—that which concerns man as the "interpreter of nature;" and I have therefore thought it not inappropriate to lead you to the consideration of the mental processes, by which are formed those fundamental conceptions of matter and force, of cause and effect, of law and order, which furnish the basis of all scientific reasoning, and constitute the *Philosophia prima* of Bacon. There is a great deal of what I cannot but regard as fallacious and misleading philosophy—"oppositions of science falsely so called"—abroad in the world at the present time. And I hope to satisfy you, that those who set up *their own conceptions* of the orderly sequence which they discern in the phenomena of nature, as fixed and determinate *laws*, by which those phenomena not only *are* within all human experience, but always *have been*, and always *must be*, invariably governed, are really guilty of the intellectual arrogance they condemn in the systems of the ancients, and place themselves in diametrical antagonism to those real philosophers, by whose comprehensive grasp and penetrating insight that order has been so far disclosed. For what love of the truth as it is in nature was ever more conspicuous, than that which Kepler displayed, in his abandonment of each of the ingenious conceptions of the planetary system which his fertile imagination had successively devised, so soon as it proved to be inconsistent with the facts disclosed by observation? In that almost admiring description of the way in which his enemy Mars, "whom he had left at home a despised captive," had "burst all the chains of the equations, and broke forth from the prisons of the tables," who does not recognise the justice of Schiller's definition of the real philosopher, as one who always loves truth better than his system? And when at last he had gained the full assurance of a success so complete that (as he says) he thought he must be dreaming, or that he had been reasoning in a circle, who does not feel the almost sublimity of the self-abnegation, with which, after attaining what was in his own estimation such a glorious reward of his life of toil, disappointment, and self-sacrifice, he abstains from claiming the applause of his contemporaries, but leaves his fame to after ages in these noble words: "The book is written; to be read either now or by posterity, I care not which. It may well wait a century for a reader, as God has waited six thousand years for an observer."

And when a yet greater than Kepler was bringing to its final issue that grandest of all scientific conceptions, long pondered over by his almost superhuman intellect,—which linked together the heavens and the earth, the planets and the sun, the primaries and their satellites, and included even the vagrant comets, in the *nexus* of universal attraction—establishing for all time the truth for whose utterance Galileo had been condemned, and giving to Kepler's laws a significance of which their author had never dreamed,—what was the meaning of that agitation which prevented the philosopher from completing his computation, and compelled him to hand it over to his friend? That it was not the thought of his own greatness, but the glimpse of the grand universal order thus revealed to his mental vision, which shook the serene and massive soul of Newton to its foundations, we have the proof in that beautiful comparison in which he likened himself to a child picking up shells on the shore of the vast ocean of truth; a comparison which will be evidence to all time at once of his true philosophy and his profound humility.

Though it is with the intellectual representation of nature which we call *science*, that we are primarily concerned, it will not be without its use to cast a glance in the first instance at the other two principal characters under which man acts as her interpreter,—those, namely, of the artist and of the poet.

The artist serves as the interpreter of nature, not when he works as the mere copyist, delineating that which he sees with his bodily eyes, and which we could see as well for ourselves; but when he endeavours to awaken within us the perception of those beauties and harmonies which his own trained sense had recognized, and thus impart to us the pleasure he had himself derived from their contemplation. As no two artists agree in the original constitution and acquired habits of their minds, all look at nature with different (mental) eyes; so that to each, *Nature is what he individually sees in her*.

The poet, again, serves as the interpreter of Nature, not so much when by skilful word-painting (whether in prose or verse) he calls up before our mental vision the picture of some actual or ideal scene, however beautiful; as when, by rendering into appropriate forms those deeper impressions made by the nature around him on the moral and emotional part of his own nature, he transfers these impressions to the corresponding part of ours. For it is the attribute of the true poet to penetrate the secret of those mysterious influences which we all unknowingly experience; and having discovered this to himself, to bring others, by the power he thus wields, into the like sympathetic relation with nature,—evoking with skilful touch the varied response of the soul's finest chords, heightening its joys, assuaging its griefs, and elevating its aspirations. Whilst then, the artist aims to picture what he *sees* in nature, it is the object of the poet to represent what he *feels* in nature; and to each true poet, *Nature is what he individually finds in her*.

The philosopher's interpretation of nature *seems* less individual than that of the artist or the poet, because it is based on facts which any one may verify, and is elaborated by reasoning processes of which all admit the validity. He looks at the universe as a vast book lying open before him, of which he has in the first place to learn the characters, then to master the language, and finally to apprehend the ideas which that language conveys. In that book there are many chapters, treating of different subjects; and as life is too short for any one man to grasp the whole, the scientific interpretation of this book comes to be the work of many intellects, differing not merely in the range but also in the character of their powers. But whilst there are "diversities of gifts," there is "the same spirit." While each takes his special direction, the general method of study is the same for all. And it is a testimony alike to the truth of that method and to the unity of nature, that there is an ever-increasing tendency towards agreement among those who use it aright;—temporary differences of interpretation being removed, sometimes by a more complete mastery of her language, sometimes by a better apprehension of her her ideas;—and lines of pursuit which had seemed entirely distinct or even widely divergent, being found to lead at last to one common goal. And it is this agreement which gives rise to the general belief—in many, to the confident assurance—that the scientific interpretation of nature represents her not merely as she *seems*, but as she *really is*.

When, however, we carefully examine the foundation of that assurance, we find reason to distrust its security; for it can be shown to be no less true of the scientific conception of nature, than it is of the artistic or the poetic, that it is *a representation framed by the mind itself* out of the materials supplied by the impressions which external objects make upon the senses; so that to each man of science, *Nature is what he individually believes her to be*. And that belief will rest on very different bases, and will have very unequal values, in different departments of science. Thus in what are commonly known as the "exact" sciences, of which astronomy may be taken as the type, the data afforded by precise methods of observation can be made the basis of reasoning, in every step of which the mathematician feels the fullest assurance of certainty; and the final deduction is justified either by its conformity to known or ascertainable facts,—as when Kepler determined the elliptic orbit of Mars; or by the fulfilment of the predictions it has sanctioned,—as in the occurrence of an eclipse or an occultation at the precise moment specified many years previously; or, still more emphatically, by the actual discovery of phenomena till then unrecognized,—as when the perturbations of the planets, shown by Newton to be the necessary results of their mutual attraction, were proved by observation to have a real existence; or as when the unknown disturber of Uranus was found in the place assigned to him by the computations of Adams and Le Verrier.

We are accustomed, and I think most rightly, to speak of these achievements as triumphs of the human intellect. But the very phase implies that the work is done by mental agency; and the coincidence of its results with the facts of observation is far from proving the intellectual process to have been correct. For we learn from the honest confessions of Kepler, that he was led to the discovery of the elliptic orbit of Mars by a series of happy accidents, which turned his erroneous guesses into the right direction; and to that of the passage of the Radius Vector over *equal areas in equal times*, by the notion of a whirling force emanating from the sun, which we now regard as an entirely wrong conception of the cause of orbital revolution.* It should always be remembered, moreover, that the Ptolemaic system of astronomy, with all its cumbrous ideal mechanism of "centric and excentric, cycle and epicycle, orb in orb," did intellectually represent all that the astronomer, prior to the invention of the telescope, could see from his actual standpoint, the earth, with an accuracy which was proved by the fulfilment of his anticipations. And in that last and most memorable prediction which has given an imperishable fame to our two illustrious contemporaries, the inadequacy of the basis afforded by actual observation of the purturbations of Uranus, required that it should be supplemented by an assumption of the probable distance of the disturbing planet beyond, which has been shown by subsequent observation to have been only an approximation to the truth.

Even in this most exact of sciences, therefore, we cannot proceed a step without translating the actual phenomena of nature into intellectual representations of those phenomena; and it is because the Newtonian conception is not only the most simple, but it is also, up to the extent of our present knowledge, *universal* in its conformity to the facts of observation, that we accept it as the only scheme of the universe yet promulgated, which satisfies our intellectual requirements.

When, under the reign of the Ptolemaic system, any new inequality was discovered in the motion of a planet, a new wheel had to be added to the ideal mechanism,—as Ptolemy said, "to save appearances." If it should prove, a century hence, that the motion of Neptune himself is disturbed by some other attraction than that exerted by the interior planets, we should confidently expect that not an *ideal* but a *real* cause for that disturbance will be found in the existence of another planet beyond. But I trust that I have now made it evident to you, that this confident expectation is not justified by any absolute necessity of Nature, but arises entirely out of *our belief* in her uniformity; and into the grounds of this and other primary beliefs, which serve as the foundation of all scientific reasoning, we shall presently inquire.

There is another class of cases, in which an equal certainty is generally claimed for conclusions that seem to flow immediately from observed facts, though really evolved by intellectual processes; the apparent simplicity and directness of those processes either causing them to be entirely overlooked, or veiling the assumptions on which they are based. Thus Mr. Lockyer speaks as confidently of the sun's chromosphere of incandescent Hydrogen, and of the local outbursts which cause it to send forth projections tens of thousands of miles high, as if he had been able to capture a flask of this gas, and had generated water by causing it to unite with oxygen. Yet this confidence is entirely based on the assumption, that a certain line which is seen in the spectrum of a hydrogen flame, *means* hydrogen also when seen in the spectrum of the sun's chromosphere; and high as is the probability of that assumption, it cannot be regarded as a demonstrated certainty, since it is by no means inconceivable that the same line *might* be produced by *some other* substance at present unknown. And so when Dr. Huggins deduces from the different relative positions of certain lines in the spectra of different stars, that these stars are moving from or towards us in space, his admirable train of reasoning is based on the assumption that these lines have *the same meaning*—that is, that they *represent the same elements*—in every luminary. That assumption, like the preceding, may be regarded as possessing a sufficiently high probability to justify the reasoning based upon it; more especially since, by the other researches of that excellent observer, the same chemical elements have been detected as vapours in those filmy cloudlets which seem to be stars in an early stage of consolidation. But when Frankland and Lockyer, seeing in the spectrum of the yellow Solar prominences a certain bright line not identifiable with that of any known Terrestrial flame, attribute this to a hypothetical new substance which they propose to call Helium, it is obvious that their assumption rests on a far less secure foundation; until it shall have received that verification, which, in the case of Mr Crookes's researches on Thallium, was afforded by the actual discovery of the new metal, whose presence had been indicated to him by a line in the spectrum not attributable to any substance then known.

In a large number of other cases, moreover, our scientific interpretations are clearly matters of *judgment*; and this is eminently a *personal act*, the value of its results depending in each case upon the qualifications of the *individual* for arriving at a correct decision. The surest of such judgments are those dictated by what we term "Common Sense," as to matters on which there seems no room for difference of opinion, because every sane person comes to the same conclusion, although he may be able to give no other reason for it than that it appears to him "self-evident." Thus while philosophers have raised a thick cloud of dust in the discussion of the basis of our belief in the existence of a world external to ourselves,—of the Non Ego, as distinct from the Ego,—and while every logician claims to have found some flaw in the proof advanced by every other,—the common sense of mankind has arrived at a decision that is practically worth all the arguments of all the philosophers who have fought again and again over this battle ground. And I think it can be shown that the trustworthiness of this common sense decision arises from its dependence, not on any one set of experiences, but upon *our unconscious co-ordination of the whole aggregate of our experiences*,—not on the conclusiveness of any one train of reasoning, but on *the convergence of all our lines of thought towards this one centre*.

Now this "Common Sense," disciplined and enlarged by appropriate culture, becomes one of our most valuable instruments of scientific inquiry; affording in many instances the best, and sometimes the only, basis for a rational conclusion. Let us take as a typical case, in which no special knowledge is required, what we are accustomed to call the "flint implements" of the Abbeville and Amiens gravel-beds. No logical proof can be adduced that the peculiar shapes of these flints were given to them by human hands; but does any unprejudiced person now doubt it? The evidence of *design*, to which, after an examination of one or two such specimens, we should only be justified in attaching a probable value, derives an irresistible cogency from accumulation. On the other hand, the improbability that these flints acquired their peculiar shape by *accident*, becomes to our minds greater and greater as more and more such specimens are found; until at last this hypothesis, although it cannot be directly disproved, is felt to be almost inconceivable, except by minds previously "possessed" by the "dominant idea" of the modern origin of man. And thus what was in the first instance a matter of discussion, has now become one of those "self-evident" propositions, which claim the unhesitating assent of all whose opinion on the subject is entitled to the least weight.

We proceed upwards, however, from such questions as the common sense of mankind generally is competent to decide, to those in which special knowledge is required to give value to the judgment; and thus the interpretation of Nature by the use of that faculty comes to be more and more *individual*; things being perfectly "self-evident" to men of special culture, which ordinary men, or men whose training has lain in a

* See Drinkwater's 'Life of Kepler,' in the Library of Useful Knowledge, pp. 26-35.

different direction, do not apprehend as such. Of all departments of science, geology seems to me to be the one that most depends on this specially-trained "common sense;" which brings as it were into one focus the light afforded by a great variety of studies,—physical and chemical, geographical and biological; and throws it on the pages of that Great Stone Book, on which the past history of our globe is recorded. And whilst astronomy is of all sciences that which may be considered as most nearly representing Nature as she really is, Geology is that which most completely represents her as seen through the medium of the interpreting mind; the meaning of the phenomena that constitute its data being in almost every instance open to question, and the judgments passed upon the same facts being often different according to the qualifications of the several judges. No one who has even a general acquaintance with the history of this department of science, can fail to see that the geology of each epoch has been the reflection of the minds by which its study was then directed; and that its true progress dates from the time when that "common sense" method of interpretation came to be *generally* adopted, which consists in seeking the explanation of past changes in the Forces at present in operation, instead of invoking the aid of extraordinary and mysterious agencies, as the older geologists were wont to do, whenever they wanted——like the Ptolemaic astronomers—"to save appearances." The whole tendency of the ever-widening range of modern geological inquiry has been to show how little reliance can be placed upon the so-called "Laws" of Stratigraphical and Palæontological succession, and how much allowance has to be made for local conditions. So that while the astronomer is constantly enabled to point to the fulfilment of his predictions as an evidence of the correctness of his method, the geologist is almost entirely destitute of any such means of verification. For th e value of any prediction that he may hazard—as in regard to the existence or non-existence of coal in any given area,—depends not only upon the truth of the general doctrines of geology in regard to the succession of stratified deposits, but still more upon the detailed knowledge which he may have acquired of the distribution of those deposits in the particular locality. Hence no reasonably-judging man would discredit either the general doctrines or the methods of geology, because the prediction proves untrue in such a case as that now about to be brought in this neighbourhood to the trial of experience.

We have thus considered man's function as the scientific interpreter of nature in two departments of natural knowledge; one of which affords an example of the strictest, and the other of the freest method, which man can employ in constructing his intellectual representation of the universe. And as it would be found that in the study of all other departments the same methods are used, either separately or in combination, we may pass at once to the other side of our inquiry,—namely, the origin of those primary beliefs which constitute the groundwork of all scientific reasoning.

The whole fabric of geometry rests upon certain axioms which every one accepts as true, but of which it is necessary that the truth should be *assumed*, because they are incapable of demonstration. So, too, the deliverances of our "common sense" derive their trustworthiness from what we consider the "self-evidence" of the propositions affirmed.

This inquiry brings us face to face with one of the great philosophical problems of our day, which has been discussed by logicians and metaphysicians of the very highest ability as leaders of opposing schools, with the one result of showing how much can be said on each side. By the *intuitionalists* it is asserted that the tendency to form these primary beliefs is inborn in man, an original part of his mental organization; so that they grow up spontaneously in his mind as its faculties are gradually unfolded and developed, requiring no other experience for their genesis, than that which suffices to call these faculties into exercise. But by the advocates of the doctrine which regards *experience* as the basis of all our knowledge, it is maintained that the primary beliefs of each individual are nothing else than generalizations which he forms of such experiences as he has either himself acquired or has consciously learned from others; and they deny that there is any original or intuitive tendency to the formation of such beliefs, beyond that which consists in the power of retaining and generalizing experiences.

I have not introduced this subject with any idea of placing before you even a summary of the ingenious arguments by which these opposing doctrines have been respectively supported; nor should I have touched on the question at all, if I did not believe that a means of reconcilement between them can be found in the idea, that *the intellectual intuitions of any one generation are the embodied experiences of the previous race*. For, as it appears to me, there has been a progressive improvement in the *thinking power* of man; every product of the culture which has preceded serving to prepare the soil for yet more abundant harvests in the future.

Now, as there can be no doubt of the hereditary transmission in man of acquired constitutional peculiarities, which manifest themselves alike in tendencies to bodily and to mental disease, so it seems equally certain that *acquired mental habitudes* often impress themselves on his organization, with sufficient force and permanence to occasion their transmission to the offspring as *tendencies to similar modes of thought*. And thus, while all admit that *knowledge* cannot thus descend from one generation to another, an increased *aptitude* for the acquirement, either of knowledge generally, or of some particular kind of it, may be thus inherited. These tendencies and aptitudes will acquire additional strength, expansion, and permanence, in each new generation, from their habitual exercise upon the materials supplied by a continually enlarged experience; and thus the *acquired* habitudes produced by the intellectual culture of ages, will become a "second nature" to every one who inherits them.*

---

* I am glad to be able to append the following extract from a letter which Mr. John Mill, the great master of the experiential school, was good enough to write to me a few months since, with reference to the attempt I had made to place "common sense" upon this basis ('Contemporary Review,' Feb. 1872):—"When states of mind in no respect innate or instinctive have been frequently repeated, the mind acquires, as is proved by the power of habit, a greatly increased facility of passing into those states; and this increased facility must be owing to some change of a physical character in the organic action of the brain. There is also considerable evidence that such acquired facilities of passing into certain modes of cerebral action can in many cases be transmitted, more or less completely, by inheritance. The limits of this power of transmission, and the conditions on which it depends, are a subject now fairly before the scientific world; and we shall doubtless in time know much more about them than we do now. But so far as my imperfect knowledge of the subject qualifies me to have an opinion, I take much the same view of it that you do, at least in principle."

The following journals have been received:—The 'British Medical Journal,' August 10; the 'Medical Times and Gazette,' August 10; the 'Lancet,' August 10; the 'Medical Press and Circular,' August 10; 'Nature,' August 10; the 'Chemical News,' August 10; 'English Mechanic,' August 10; 'Gardeners''s Chronicle,' August 10; the 'Grocer,' August 10; the 'Journal of the Society of Arts,' August 10; 'Grocery News,' August 10; 'British Journal of Dental Science' for August; the 'Milk Journal' for August; Longman's Notes on Books' for July 31; 'Florist and Pomologist' for August; 'Practitioner' for August; 'Educational Times' for August; 'Food, Water, and Air' for August; the 'Doctor' for August.

Correspondence.

Provincial Education.

Sir,—It is with no small amount of hesitation that I enter the lists on this question, knowing full well that it will receive thorough discussion at Brighton during the week. And I verily think that had not two of your last week's correspondents made certain statements in their letters, I should have been more than content to have held my peace upon the matter.

For my own part, while fully recognizing the great importance of provincial education, I trust that the Council will not during the present financial year adopt any resolution for the furtherance of any scheme whatever. The subject is not yet ripe for settlement. Let the suggestion which has so frequently appeared in the pages of your Journal, and which is now adopted by Dr. Greenhow in his able report, be carried out, namely, that it shall be compulsory for every youth to pass the "Preliminary" previous to his apprenticeship; then we should obtain a revolution in provincial education, and one of a much more satisfactory and permanent character than that revolution which Mr. Pickering so eloquently advocates, and so complacently contemplates in his quixotic and impracticable details. After the lapse of a few years it would then be quite time enough to consider what further was necessary, should the "individual effort" of the educated apprentice of that period be not found sufficient. My firm opinion is that the scheme of Mr. Schacht, admirable as it is in theory, will fail in practice.

One of the strongest reasons for provincial education, however, is the assistance of those apprentices whose parents have not means sufficient to allow such apprentices to pursue their studies at Bloomsbury. To Mr. Schacht I would wish to convey my warmest thanks for having in his scheme so considered the requirements of that class. Such suggestions can only emanate from a cultivated mind and a generous heart, and contrast mightily with the narrowness of the ideas expressed by a 'Country Major Associate.' The latter gentleman is evidently one of those who, in their advocacy of certain crude notions of professional status, labour under the dismal hallucination that we are a profession, and that the public ought to see it. I wish that such as he could be made to see that we are rendered a laughing stock to our professional brethren by the presumption and ignorance displayed in such correspondence as he has indulged in. But 'Country Major Associate,' carries his views even beyond many of his compeers. He has such high and mighty notions of what he calls our "responsible profession" as to contemplate with virtuous horror the admission of the sons of policemen, ostlers, etc., within the pale of the fold of the disciples of the late lamented Jacob Bell, and fears the disturbing influence of such an accession upon the manes of our noble founder. I have yet to learn that pharmaceutical aptitude and commercial honour and integrity are to be sought for and found only within a certain social line of demarcation, the limits of which 'Country Major Associate,' in his own peculiar wisdom, is alone to define. After this it will scarcely surprise me to see added to our already strange advertisements, which specify stature and gentility, "pedigree required, respectability of collateral relatives absolutely necessary, any connection with sweeps most undesirable."

Mr. Atkinson Pickering, with wonderful pertinacity, gives us further valuable information. Mr. Pickering must be aware that the country cannot be composed of Kingston-upon-Hulls. He must also possibly be aware that there are certain towns in the United Kingdom whose populations are exceedingly limited, but where, nevertheless, druggists may be found, although lectures may be unknown. I cannot comprehend, therefore, why Mr. Pickering, whose liberal notions and proffers of assistance to his benighted and uneducated country brethren are notorious, would place such a tax upon "individual effort" as to exclude young men brought up in the last named class of towns from passing the Minor and Major without certificates of attendance at Mr. Pickering's pet lectures. If Mr. Pickering's scheme should ever be adopted, I may congratulate myself as being one born out of due time, having passed my examinations without having attended lectures either in the provinces or at Bloomsbury.

A Country Pharmaceutical Chemist.

August 12th, 1872.

Plucked for the Preliminary.

Sir,—I am sure it is enough for me to tell you that I have been unsuccessful in passing the Preliminary, to gain me your sympathy. How I failed I cannot say with certainty, but I have a suspicion which I will presently disclose to you. Meanwhile, I am determined to try again, and to this end I keep my Latin fresh in my mind by constant repetition of "hic, hujus, huic, hunc, hoc," etc., until my landlady thinks I am poking fun at her; while in English I believe I have found a clue as to how many classes adverbs of time are divided into, and I am not without hope that I shall soon obtain more correct information concerning the females upon which one of the questions at the last examination turned.

But I am bad at figures; I always was, and, after recent experience, I am afraid I always shall be. Besides a natural inability to calculate, I labour under the disadvantage of having been taught an old-fashioned multiplication table commencing "twice one are two."

Knowing my deficiency, you may guess, when I read their names in the Journal two months since, how I envied those gentlemen whose peculiar skill in figures fitted them for members of the Pharmaceutical Society's Finance Committee. When, therefore, I found in the Journal last week that two of those gentlemen had been favouring the Council with some statistics, I thought—here is a chance to find out the system upon which modern arithmetic is based! One of those gentlemen having stated that there were 5029 Pharmaceutical Chemists on the Register of whom only 2051 were members of the Society, I decided, my master having a copy of the Register, to find out how modern statistics were compiled. First I counted the number of pages,—roughly speaking about 30; next I counted the number of names in each page—average about 82. Thirty-times eighty-two, then, ought to give as a result something near to 5029. But, sir, upon the old system, it would not, and I am ashamed to tell you how far out the answer was. Then I marked the list off in tens and reckoned ten tens to a hundred. Wrong again! Next I counted the names one by one, and by the old system could only make it 2492, and I confess I was fairly puzzled. Suddenly I shouted "Eureka!" (I think that is the word), for it struck me that the other gentleman's figures would throw some light upon the mystery. So as the first gentleman had said there were 12,000 chemists and druggists on the register, whilst there were only 2466 members of the Society; and the second gentleman said that not one-twentieth of the chemists and druggists were members of the Society, I multiplied 2466 by 20, by the old system, and tried to obtain an answer under 12,000. But I couldn't. So will you please give me your advice as to where I can get an arithmetic book based on the new system; or, if you cannot, please put the question in the Notes and Queries column. I want to go on for the Major, but I must get the Preliminary out of the way first, which I cannot hope to do while I am so

Perplexed.

Manchester, August 14, 1872. (?)

M.—We have no qualification for giving an answer upon the subject.

C. J. Bell.—Hydrochloric acid is undoubtedly intended.

J. L. W.—No; the Bill was withdrawn.

R. B.—Yes.

Apprentice.—Apply to the Secretary at 17, Bloomsbury Square, for a copy of a pamphlet entitled "Hints to Students."

Medicus.—Apply at Apothecaries' Hall.

Communications, Letters, etc., have been received from Mr. W. J. Williams, Mr. N. Chifney, Mr. J. R. Jackson, Mr. A. W. Gerrard, "One who has Passed," "A Man," "Machaon," "T. Snooks," C., J. L.

In consequence of the pressure upon our space, consequent upon reporting the proceedings at Brighton this week, we are compelled to defer the publication of several communications.

OLEIC ACID AND SOME OF ITS COMBINATIONS.

BY ALFRED W. GERRARD,

Dispenser and Pharmacist, Guy's Hospital.

The introduction of the oleates of mercury and morphia as remedial agents by Mr. J. Marshall, F.R.S., suggested to me the following as capable of preparation, and as having some therapeutic value:—

Mr. Frank Clowes, to whom Mr. Marshall referred the chemical question of his paper ('Lancet,' May 25th, 1872), mentions that the scales of peroxide of mercury are with difficulty soluble in oleic acid. I find this is not so if the peroxide is previously well levigated. There is no necessity, therefore, for preparing the fresh oxide for solution in the oleic acid.

The oleic acid used in the following preparations is that made at the stearine candle factories, where it occurs as a secondary product. It is contaminated with a variety of impurities the removal of which is a tedious process. It has the colour of olive oil, but a thinner consistence, and a slight tallowy odour; is soluble in all the ordinary fats and oils, alcohol and ether, but insoluble in glycerine. It forms normal and acid salts; the normal salts of the alkalies potash and soda are the soluble soaps of the pharmacopœia.

Professor Miller, in his 'Elements of Chemistry,' part 3, page 363-4, says, "Pure oleic acid, at temperatures above 57°, forms a colourless limpid oil without taste or smell; it does not redden litmus even when dissolved in alcohol; at 40° it concretes into a hard crystalline mass composed of fine needles. When solid it undergoes no change in the air, but when liquid it absorbs oxygen, rapidly acquiring a brown colour, a rancid odour, and an acid reaction upon litmus, its point of solidification gradually becoming lowered until it falls below 0° Fahrenheit."

By reason of the impurities in commercial oleic acid, I find that it cannot be made to unite with the salts used in the following preparations in equivalent proportions; it will, however, form solutions of 20 per cent., and this I have chosen as a suitable strength:—

Oleate of Lead (20 *per cent.*).

Prepared by heating together oxide of lead one part, oleic acid four parts, until dissolved; on cooling, it forms a semi-transparent tenacious mass somewhat thinner than lead plaister. This is not well adapted for direct application, but requires diluting, and as it mixes readily with ordinary fats and oils, I have adopted the following formula for its exhibition:—

Ointment of Oleate of Lead.

Take of
- Oleate of Lead (20 per cent.) 2 parts.
- Oil of Almonds . . . . 1 part.
- Prepared Lard . . . . 1 „

Mix with a gentle heat.

On cooling, this forms an elegant ointment resembling that of spermaceti.

Oleate of Zinc (20 *per cent.*).

Prepared by heating together oxide of zinc one part, oleic acid four parts, until dissolved. During the process of solution some bubbling takes place with disengagement of watery vapour. It is transparent when melted; on cooling, it has the appearance of lead plaister, is hard and friable, and requires to be diluted in the same manner as oleate of lead.

Ointment of Oleate of Zinc.

Take of
- Oleate of Zinc (20 per cent.) 2 parts.
- Oil of Almonds . . . . 1 part.
- Prepared Lard . . . . 1 „

Mix with heat.

This forms an ointment of the ordinary consistence.

Whilst experimenting with the above, I thought that if atropine and aconitine were soluble in oleic acid, they might prove useful preparations. I find they are readily so at ordinary temperatures, whilst the sulphate of atropine is soluble on the application of heat.

I have prepared solutions of the above, which nearly correspond to the ointments of the British Pharmacopœia.

Solution of Oleate of Atropine.

Take of
- Atropine . . . . . . 2 grains.
- Oleic Acid . . . . . 98 grains.

Dissolve.

Solution of Oleate of Aconitine.

Take of
- Aconitine . . . . . . 2 grains.
- Oleic Acid . . . . . 98 „

On economical grounds there can be no objection to the introduction of the oleates, as large quantities of oleic acid can be obtained at a cheap rate, but the chief consideration is whether they present any advantages as remedial agents beyond those of the same kind already in use. This is a question for the therapeutist, and must be left to the physician and surgeon to decide.

My thanks are due to Mr. A. Higgins, of the Borough, for the oleic acid used in the above experiments.

THE BATTLE OF THE DIGITALINES.*

On the 11th of May, 1867, we thus terminated one of our studies in the exhibition;—"In the glass-case of M. Dorvault two new products sparkle in microscopic tubes: crystallized menyanthine and digitaline. Again, ought we not to ask if this last alkaloid is well authenticated; if it is not rather derived from, than an active principle of, digitalis? A number of reasons lead us to believe in the improbability of this marvellous crystallization, a veritable philosopher's stone imposed on the chemists; chemical experience is indispensable to prove the fact. At all events, these discoveries are due to the intelligence and indefatigable energy of M. Nativelle."

In 1869 M. Nativelle declared that his crystallized digitaline of 1867 contained at least two-thirds of inert matter. In 1871 a new process of extraction of the crystallized digitaline, a process verified by Professor Buignet, and rewarded by a great prize of the Academy of Medicine, gave to M. Nativelle the success and recompense due to his incomparable diligence as a manipulator. In May, 1872, as a consequence

* From La France Médicale, July 27.

of the contradictory communications of MM. Marotte and Gubler, the Academy, on the motion of M. Boudet, as organ of the Society of Pharmacy, appointed a commission to inquire into the therapeutical value of the different digitalines. Amongst clinical physicians some were for the digitaline of the Codex, others for the crystallized digitaline of Nativelle and others again for the old preparations of digitalis.

M. Roucher, the learned military pharmaceutist, cleared up the difficulty, or rather perhaps made it more complicated, by assigning a complex composition to digitalines crystallized or amorphous, and by ascertaining physiologically the identity of action of the crystallized digitaline and that of the Codex.

In the midst of these varieties of studies, opinions, actions, affirmations and negations, a young and ingenious chemist, Dr. Blaquart brought to the School of Medicine, in a thesis which was brilliantly supported in spite of a hostile and irritating opposition, a mass of new facts on this much-controverted question of digitaline. This thesis (a critical study on digitaline, from a chemical and physiological point of view) is an original work in its important details, and is enhanced by the clearness and neatness of its style.

The treatise is divided into preface, history of the extraction of digitaline, the discovery of pure crystallized digitaline in ordinary digitaline, its extraction, analysis of ordinary digitaline, results that arise from the analysis of common digitaline, examination of the process of M. Nativelle, the gain of crystallized digitaline to chemical science, physiological review, comparison of the relative activities of different digitalines, experiments with hogs, guinea-pigs, rabbits, toads and sparrows; the solubility of various digitalines in gastric juice, an examination into the physiological activity of other product besides digitaline, extracts of *brute* digitaline and conclusion. This table of contents shows that it is not an ordinary thesis, and that it should be justly celebrated amongst the scientific treatises on digitaline. We would like to make many extracts, but space forbids; we will therefore content ourselves with giving his conclusions:—

"Crystallized digitaline exists in the ordinary digitaline, and we have well ascertained its presence by isolating it in a state of purity. We estimate that it is to be found in the proportion of 10 to 12 per cent., and it has been possible for us to extract almost the half of this quantity. Consequently we deny the assertion that 'the means hitherto employed for the preparation of digitaline do not allow of finding a trace of crystallized digitaline.' The mode of operation that we have followed, and which in no way resembles that of M. Nativelle, is too long and too difficult to even dream of applying to therapeutical uses.

"Ordinary digitaline is a complex product; we propose to give it henceforth the name of *brute* digitaline. By obtaining successive eliminations by means of solvents devoid of chemical action (so that the objection cannot hold that these substances are the products of metamorphoses), we have extracted the following substances:—Crystallized digitaline, amorphous digitaline (which is in the most dominant proportion), digitinose, digitoleic acid, chloride of sodium, acetate of potash, and a red syrupy liquid, which is without doubt complex, and contains sugar.

"As chloroform dissolves neither the acetate of potash, nor common salt, it is supposed that digitaline, purified by this menstruum, is increased in activity. We have found two digitalines, distinct from one another, but the one probably derived from the other, viz. amorphous and crystallized digitaline. The digitaline prepared after the method of the Codex, namely, that which has been purified by chloroform, is not neutral, as has always been hitherto said, but very noticeably acid to litmus paper. The method of M. Nativelle for extracting the crystallized principle of digitalis (that which he described in the report of the commission for the Orfila prize) gave us so much difficulty that we were soon convinced that this mode of operation was not susceptible of practical application; other chemists of greater authority, who have themselves encountered the same difficulties, are of the same opinion. M. Nativelle changed the name of ordinary digitaline to digitaléine. In reality there is no reason for this name, the ordinary digitaline or digitaleine, they being both the same, is a complex substance. We have intimated the volatility of crystallized digitaline; M. Roucher has demonstrated it with great exactness. This property could perhaps be utilized in toxicological researches. Our only essay in this direction was fruitless, and it would be well to attempt a new experiment. Crystallized digitaline comports itself as a glucoside. Crystallized digitaline, amorphous digitaline, and the red syrupy liquid act in the same manner both on cold-blooded and warm-blooded ani-animals, and produce the same characteristic disturbances in the action of the ventricle.

"In our experiments on hogs we discovered that our crystallized digitaline showed itself a little more active than that of M. Nativelle; that amorphous digitaline, equal in action to the crystallized principle, when introduced under the skin in a dry state, produces more rapid and more energetic symptoms of poisoning than when injected in solution; and also that the digitaline of commerce differs almost insensibly from the crystallized, the difference is perhaps slightly in favour of the latter. Observations founded on experiments with guinea-pigs allow us to class our substances as follows:—The digitaline of commerce, amorphous digitaline, and crystallized digitaline. Rabbits gave us contradictory results; the advantages were divided. In our only experiment on sparrows, the digitaline of commerce was greatly excelled by the crystallized digitaline and by the amorphous digitaline, both of which manifested their action at the same time. From all these various results, we were perplexed to know how to arrive at a decided conclusion. After having seen the three substances take by turn, in our classification of their relative energies, the first and the last place, we were led to conclude that in a general way their activity differed little. Further, that the digitaline of the Codex, the crystallized principle, has no effect on toads. In experiments on frogs, digitinose and digitoleic acids have never exercised the least influence on the ventricle.

"To have been complete, our work ought to have been enriched by clinical experience, and we do not deceive ourselves that there is in this respect a great want. But the commission which the Academy of Medicine is about to appoint will not be slow to make science sure on this point. We ought also to have made a comparative examination of foreign digitalines, of the English and the German digitaline. Time was wanted for us to have undertaken this extensive task.

"If it is permitted to us to express a general opinion at the conclusion of our studies, we would say that the introduction into therapeutics of the crystallized principle of digitalis has appeared to us premature in the present state of our knowledge, and we do not hesitate to conclude with one of our learned professors, M. Bussy, that at present the best practical means of concentrating in a small space the active and efficacious properties of the plant is by the process known as that of the Codex of 1866. This process, though it does not give a definite product, and one absolutely pure from a chemical point of view, has not the less furnished to the therapeutist a preparation useful on the same grounds as numbers of officinal preparations, which seem to us to offer to the practitioner at least as great a guarantee as the employment of the tincture or the extract of digitalis. We cannot forget that in these opinions we agree with Soubeiran, Orfila, Rayer, Bouchardat, and Bouilland, opinions consecrated for more than twenty years by therapeutical science."

This thesis is a new proof of the danger of premature assertions in chemical science. Many hundreds of chemists have analysed digitaline, and have affirmed the impossibility of extracting from it a definite crystallized substance; a pharmaceutist, M. Nativelle, gives them the direct denial in attempting and realizing this impossibility; in his turn he declares—and with him and after him another learned pharmaceutist, M. Buignet—that this crystallized digitaline is extracted by treatment with alcohol to the exclusion of exhaustion by aqueous solution, and that in every digitaline hitherto prepared, including the digitaline of the Codex, not a trace of crystallized digitaline could be obtained; but all these scientific allegations vanish before the discovery of Dr. Blaquart. His crystallized digitaline is obtained from the digitaline of the Codex. In solution it is more active than that of M. Nativelle, which, according to M. Roucher, is not certainly homogeneous. Under the microscope, and in contact with reagents, the digitalines of Blaquart and Nativelle appear and act identically the same. The report of M. Buignet to the Academy is therefore weakened in one of its important assertions, viz., that alcohol at 50° is alone capable of extracting from digitalis its active crystallized principle. What becomes then of the watery infusion of leaves of digitalis, and by what magic have the doctors from all time obtained a sedative from this simple decoction? But does it signify? Contradiction has always been one of our least faults. The report of M. Buignet is again criticized by M. Blaquart on the subject of the process for extracting the crystallized digitaline of M. Nativelle. This process, followed with the most scrupulous care, and in its most minute details, did not enable Dr. Blaquart to arrive at the result so skilfully reported by the learned reporter of the Academy. Some few crystals lost in a green mass were the result of three experiments on fifteen kilograms of digitalis. This want of success on the part of Dr. Blaquart is not solitary; similar attempts have been equally unfruitful in many of the laboratories of Paris. We must, without doubt, attribute this failure to the want of a skilful *tour-de-main*. But skill aided by patience, thanks to a coming enlightenment, will, perhaps, some day bring crystals of digitaline to all chemists. Whilst waiting, the possession of some Nativelle prisms is a rare piece of fortune. We hope very soon to be able to offer them. The Academy has already obtained some, three phials of this *rara avis* were brought a short time since to the bureau, and M. Nativelle has placed them at the disposition of the medical body for experiments.

When a substance is of such easy extraction, is it not somewhat strange that a year is necessary in order that a few grammes should be prepared? However this may be, the academical report is silent on this point. Is it in the thousandth or in the ten thousandth degree that digitalis gives its crystallized alkaloid? Until more fully informed, Dr. Blaquart considers crystallized digitaline as a curiosity of the laboratory; and if it is taken into account that the digitaline of the Codex (*digitaléine* of M. Nativelle), his crystallized digitaline, that of Dr. Blaquart, the pyrodigitalic acid of Dr. Roucher are all equally coloured green by hydrochloric acid,—where shall we then find a certain characteristic to distinguish between these four poisons in granules? Is this not the weak point in the armour? Digitaline is only acceptable to the palate of the invalid hidden in sugar; it has to be previously pulverized and mixed in a syrup or a mucilage. It must therefore acquire for the legal physician, the therapeutist, and the pharmaceutist, a special character, an original reaction, so that it may be called by its right name. Otherwise there will be the confusion of the digitalines. It is true that—their physiological action, in spite of a pretended activity four times as great, being identical (to within the difference of a few contractions of the heart)—after the numerous experiments of Blaquart and Roucher, there is reason, with M. Bussy, to hold to the digitaline of the Codex until a new discovery, and to ask, with Professor Gubler, what use can a crystallization have in a medicament of which it weakens more than it increases the action. Will not all these chemical conflicts concerning digitaline result in leading many practitioners to the galenic preparations of this plant, and at first to its leaves freshly pulverized? For, besides throwing doubts into the minds of the medical body, it is rendered more and more impossible for the pharmaceutist to do the work of his ten fingers. Alkaloids cannot be produced except on a large scale; and if year after all the materia medica is to be transformed into very poisonous but beautiful little crystals, and if for every poison crystals of many kinds must be obtained, the great chemists would become artists in poison, and the pharmaceutists their humble intermediaries. All this detracts nothing from the honour due to M. Nativelle, whose great power as an analyst is the admiration of our laboratories. If among the numbers of modern chemists he holds, and has held for many years, a place above the ordinary level, if he has consecrated his long career by a discovery justly acknowledged, the merit is not less for a young doctor who, led by the good tradition of his first master in chemistry, M. Jacquelain of the Central School, has himself alone elucidated the question of the digitaline of the Codex, by retaining it, contrary to all the assertions and all the experiments of the chemists, including even M. Nativelle, as the crystallized digitaline.

This is the principal object of the thesis of Dr. Blaquart, and it must be read to know all the interesting points of the study of digitaline, now made by him as clear as day.

NOTE ON CYSTINE.

BY JAMES DEWAR.*

The following observations on Cystine are a continuation of those formerly communicated to the Society by Dr. Arthur Gamgee and myself, during the course of the session 1869–70, and reprinted with addition in the 'Journal of Anatomy and Physiology' for that year; and although really little of a novel nature to present to the society, still it is necessary to show some additional facts have been observed tending towards the synthesis of this interesting substance.

The most important fact ascertained with regard to the chemical relation of cystine in the memoir referred to was the production of pyruvic acid, when it was treated with nitrous acid. In this reaction the amido residue was not alone eliminated, the sulphur also separating as sulphuric acid, however carefully the experiment was performed. The fear of allowing the action to proceed too far, on the necessary small quantity of substance operated upon, prevented us from purifying the product thoroughly, and consequently, the analysis differed slightly from that of pure pyruvic acid. We had no hesitation in saying, however, the acid agreed better with the chemical characters of the syrupy modification of pyruvic acid than with that of Wischelhaus's carbacet oxylic acid, that we had anticipated would be produced, and that in all probability cystine would be found to be an amido-sulpho pyruvic.

If cystine is directly related to pyruvic acid, it must contain five instead of seven hydrogen atoms (and this supposition agrees well with the published analysis). The formula of the compound will then be, $C_3H_5NO_2S$. On this supposition, we may derive from pyruvic acid at least five isomers, that will all have the general characters of cystine, although there are many other possible constitutional formulæ.

Pyruvic Acid.	1.	2.
CH_3	CH_2NH_2	CH_2NH_2
CO	CO	CO
CO.OH	CO.SH	CSOH

3.	4.	5.
$CH_2(NH_2)$	$CH\begin{matrix}NH_2\\SH\end{matrix}$	CHS
CS	CO	$C\begin{matrix}NH_2\\H\end{matrix}$
CO.OH	CO.OH	CO.OH

Of the five possible cystines formulated, it is impossible to select that of the natural substance, because of our ignorance of the intermediate sulpho-acid. All attempts to replace the amido group alone by the action of nitrous acid having failed, I have tried several experiments, with the object of replacing the sulphur alone, with the small quantity of cystine at my disposal.

If cystine is one of the above five substances, the replacement of the sulphur by hydrogen will generate very different bodies. Theory enables us to predict that, in the case of bodies having the constitutional formulæ of No. (5), we ought to obtain alanine. In that of (3) (β) alanine, and in that of (4) amido-lactic acid (serine), and in that of (2) amido-glycerine; whereas it is difficult to imagine the sulphur in (1) being replaced. A successful experiment in this direction ought to restrict the selection to two possible constitutional formulæ in the worst case, and synthetical processes might then be attempted. It was formerly observed that nascent hydrogen generated in an acid solution, readily liberated sulphuretted hydrogen, and might be used as a test for this substance. The action goes on, however, very slowly, and it was found extremely difficult to get anything like the theoretical quantity of sulphur evolved. With this experience, sodium amalgam suggested itself as being more powerful, and equally likely to act. When cystine is dissolved in caustic soda, and sodium amalgam added, in a few minutes it is easy to detect the presence of a sulphide by the nitro-prusside test. The action was allowed to proceed for several days, being occasionally rendered acid by the addition of hydrochloric acid, and the amalgam renewed. Ultimately the alkaline solution, after being neutralized with hydrochloric acid, was evaporated and treated with boiling alcohol to separate the chloride of sodium, and to dissolve any hydrochlorate of alanine that might be formed. After the filtrate was evaporated the residue still contained sulphur, from the presence of hydrochlorate of cystine. This was separated by treating with water, and the filtrate was boiled with oxide of lead, treated afterwards with sulphuretted hydrogen to precipitate the dissolved lead, and evaporated. The residue was then heated to 200°C. in a tube, with the object of subliming the alanine. No crystalline sublimate was observed; it is probable, therefore, that substances of the constitutional formulæ of 5 do not express the constitution of normal cystine. This result is subject to a certain amount of reservation, from the difficulty of separating a small quantity of substance from a very large amount of secondary material accumulated in the course of the experiment. The battery is far better adapted to give a supply of nascent hydrogen in this case; and an experiment made in this way looks promising, if sufficient material was to be had.

The small quantity of substance left I have employed for the purpose of corroborating the production of pyruvic acid, when it is treated with hydrate of baryta.

Took a decigramme of cystine, treated it in a tube with a solution of hydrate of baryta, and heated it all night to a temperature of 130° C., opened it, and transferred contents to a beaker, boiled to expel the ammonia produced, then added an exactly equivalent quantity of sulphuric acid, filtered from the sulphate of baryta; after boiling to expel the sulphuretted hydrogen, the filtrate evaporated contained a yellowy syrupy acid, which contained a few crystals under the microscope, having the appearance of Finck's uvitic acid. Ammonia was added, and gave a yellow solution, which was evaporated on the water-bath; it was dissolved in water, and gave a white precipitate, with nitrate of silver, which was not distinctly crystalline; it also gave a white precipitate with subnitrate of mercury, and a red colour with a crystal of sulphate of iron, and no precipitate with sulphate of copper. The barium salt was also found to be non-crystalline, the acid lost the power of giving a red colour with ferric salts after treatment with sodium amalgam, and the composition of the silver salt agreed better with pyruvic acid than formerly.

Considerable progress has been made in an examination of the chemical characters and relations of the thio-peruvic acids. Normal thio-peruvic acid has been obtained from the di-chlorpropionic ether. When this ether is treated with excess of alcoholic sulphide of potassium, we obtain at once a precipitate of chloride of potassium and a solution of the potash salt of the new acid. When this is diluted with water, acidulated with sulphuric acid, and shaken up with ether, the acid is obtained in yellow crystalline plates, part of it seems to remain a viscid fluid. The lead and silver salts are white and insoluble, blacken when heated. It precipitates mercurous salts, black from the first. The calcium, barium, iron, cadmium, and copper salts are all soluble. The potassium and sodium salts are intensely yellow, and decompose slightly on exposure to the air. When treated with tin and sulphuric acid, they evolve sulphuretted hydrogen.

The thio-carboxyl pyruvic acid has not yet been obtained in a pure state. When pyruvic acid is treated with pentasulphide of phosphorus, a violent action takes place, associated with much frothing; and when the product is distilled, a large mass of carbon is left in the retort, and a very small quantity of distillate is obtained. It is probable that chloro-pyruvil, when treated with sulphide of potassium, will give a more satisfactory yield. It is the author's intention to make a careful comparison

* Read before the Royal Society of Edinburgh, February 5.

of these two acids, and to transform them into amido-acids, with the object of making an artificial cystine; and the results arrived at will shortly be communicated to the Society.

TINCTURE OF FERRIC CHLORIDE.

BY R. ROTHER.

The numerous vital objections to the officinal process induced the writer to supplant the nitric acid of the formula by the use of potassium chlorate. This alteration removed one of the most disagreeable and unsatisfactory agents ever associated with this preparation. The uncertain action of nitric acid, together with its various other defects in this connection, becomes more thoroughly apparent when compared with the unqualified success attending the action of potassium chlorate.

In the attempt to remedy the defective method of dissolving the iron, the writer resorted to the use of sodium chloride by double decomposition with a mixture of ferric sulphate and chloride and the interposition of alcohol; then to the employment of ferrous sulphate and calcium chloride; after this the trial by double decomposition between ferrous sulphate and sodium chloride in presence of alcohol was made.

Now when atomic proportions of ferrous sulphate, sodium chloride, chlorhydric acid and potassium chlorate are mixed, with a view to obtain ferric chloride and sodium sulphate, and the mixture is then treated with alcohol, a yellowish red solution and a yellowish granular precipitate are obtained. The solution will most usually contain only two-thirds of the intended amount of ferric chloride, whilst the remaining one-third of the iron is carried down with the sodium sulphate in a peculiar state of combination, probably as basic sulphate or oxy-chloride. By washing the precipitate with water most of the sodium sulphate, together with some iron, are dissolved, but most of the iron remains in the residue insoluble in chlorhydric acid. By the above reaction it seems very probable that only two-thirds of the ferric sulphate is decomposed by the sodium chloride.

The trial with calcium chloride is very satisfactory in regard to completeness of decomposition, the only drawback is the bulky nature of the calcium sulphate, which must be carefully washed to secure the whole of the iron. This is attained by pressing the hot mixture through muslin; the process is very expeditious, and could be recommended were it not for the difficulty of handling the precipitate.

The double decomposition between the ferrous sulphate and sodium chloride, in presence of alcohol, results in a green solution and a white precipitate; the green solution when treated with chlorhydric acid and potassium chlorate, yields a solution which corresponds only to two-thirds of the original amount of ferrous sulphate, the remainder is precipitated as ferrous sulphate along with the resulting sodium sulphate and undecomposed chloride. From this it is evident that only two-thirds of the ferrous sulphate is decomposed by an atomic equivalent of sodium chloride.

It was also noticed that in the alcoholic solution of ferrous chloride, a certain proportion of water was necessary to cause the decomposition of the potassium chlorate, whereas, in case of a deficiency, no oxidation would take place through the chlorate.

But originally the writer noticed that metallic iron dissolved more readily in moderately diluted acid; however, as the solution always proceeds immoderately slow, and it was difficult to determine when all of the acid had been saturated, it was found that the process would be much facilitated and hastened by using only the proper quantity of iron to be dissolved, and for this purpose employing the whole amount of the acid at once.

Finding that the ordinary forms of iron were invariably too coarse for rapid solution, the writer resorted to the pulverized iron of the market; this is not the iron reduced by hydrogen, but still a very fine powder, and and can be bought at one-sixth the price of the former. It naturally dissolves very rapidly, and, therefore, in case of necessity, the tincture can be prepared with it in a very short time by the following process:—

Take of Iron in fine powder . . .	1300 grains.
Chlorhydric acid sp. gr. 1.16.	$17\frac{1}{2}$ troy ounces.
Potassium chlorate in pwdr.	475 grains.
Strong alcohol	2 pints.
Water sufficient.	

Dilute the acid with the water to the measure of two pints, then gradually add the iron in small quantities at a time; when complete solution is effected, add the potassium chlorate; stir until dissolved; let stand a few minutes and then mix the alcohol with the solution while yet warm, and filter.—*The Chicago Pharmacist.*

ORGANIC CHEMISTRY AND THERAPEUTICS.*

BY A. W. HOFMANN.

It has been said that chemistry is the most useful of all the sciences, and the assertion is not an exaggerated one. Where indeed in the whole domain of the arts and industry is the field which has not been made more productive by the powerful influence of chemical research, and what resources for our daily wants do we not owe to the development of this science? But, however powerful may be the direct influence which chemistry, in giving us the dominion over matter, has exercised and still exercises every day upon our well-being, it has contributed nearly as much to the progress of civilization by the revolution which it has provoked in all branches of science, and in the region of thought; in one word, in our entire life. In the short space of time accorded to me I should be unable to indicate even in a superficial manner how much chemistry has contributed to the present state of things; considering the learned body whom I am addressing, I might enumerate the services chemistry has rendered to medical science; but the subject would be too vast. I will be content with noticing the advantages which therapeutics has derived and will derive from the development of organic chemistry.

Since only organic chemistry is to be spoken of, it will be well to commence by defining the extent of this portion of the science; the more so, as its extent is much modified with the lapse of time, and that, even now, all chemists are not in accord as to the limits they ought to assign to it. It requires but a superficial study of chemical phenomena to see how few simple bodies possess the power of combining with each other in a great number of proportions. Hydrogen does not combine with chlorine, bromine or iodine in more than one proportion. This same hydrogen forms with oxygen two combinations, and two also with sulphur. Phosphorus and arsenic are remarkable for the facility with which they combine with oxygen, but they only form with it two combinations. In an analogous manner, sulphur and phosphorus combine with chlorine in two proportions only, and it is rarely that an element forms with another three or four combinations; there are, however, three oxides of antimony and of iron, and four of lead and of manganese known. Nitrogen unites with oxygen in a still greater number of proportions,—the number of its well defined oxygen compounds being not less than five,—but these compounds are an exception to the usual law.

But there are two elements which, in this respect, are distinguished from all others, carbon and hydrogen; their combinations are innumerable. This is not saying that the known hydrocarbons are so numerous,—chemists

* Lecture delivered at the Medico-Chirurgical Institute of Berlin

have only yet studied a few hundreds; but the study of the composition and the mode of formation of these compounds induces the conclusion, that nature has scarcely assigned a limit to their production. Already the bodies belonging to this class are ranged in series regulated by a very simple law of derivation, and a knowledge of some members of one of these series enables us to predict the composition and properties of members yet unknown. Further, the comparison of two of these series so established by means of a certain law demonstrates with the greatest clearness the existence of a series of which the members are yet wanting to us, and thus we see unrolled before our astonished eyes a glimpse of the infinite variety of combinations that hydrogen may form with carbon.

These hydrocarbons appear under the most diverse forms. Some are transparent, colourless gases, resisting every attempt made to liquefy them; others, of which the boiling-point is often much below the freezing-point of water, only take the liquid form under the combined influences of strong pressure and a low temperature. A great number exist in the form of liquids, with tastes and odours the most diverse, boiling at all possible temperatures, from the heat of the hand to a red heat, or even not volatilizing at all without decomposition. Finally, others are solid bodies, colourless or coloured, crystalline or amorphous; some fusible at greatly varying temperatures, others infusible; some distilling or subliming at all possible temperatures; others breaking up variously under the influence of strong heat: all differing from each other in taste and smell no less than do the gaseous and liquid carbides. If the hydrocarbons were not distinguishable from other substances except by their number and the variety of their properties, these would entitle them to be looked upon as a group distinct from the rest of chemical compounds; but they present yet other characters which furnish a no less powerful argument for separating them from the bodies which constitute the other groups. Following the analogy of their composition, the members of this group of carbides present in the individual development of their properties an agreement which is not observed in the less extensive groups of combinations.

Under the influence of elementary bodies, the hydrocarbons undergo numerous modifications. Oxygen and nitrogen especially, either alone or combined more or less with hydrogen, possess the faculty of entering into combination with the members of this group. There is thus formed an unlimited number of derivative compounds which, besides the carbon and hydrogen, contain nitrogen or oxygen, or both those elements at the same time, or other elementary bodies, such as chlorine and sulphur. The introduction of these elements into the hydrocarbons modifies the properties of the latter, according to laws the determination of which is the problem presented to the chemist. Already, for many years, the best methods of research have been applied to this study, and if the goal, such at least as is conceived by the enthusiastic searcher, is yet afar off, much has already been done towards attaining to it. Even now, to a certain extent, the changes in the properties of a carbide which the introduction of an elementary body will cause can be determined beforehand. Numerous researches have shown that the modifications that one of a series undergoes in certain circumstances are reproduced in the same circumstances upon all the members of the same series; so that the conquest of a single fact often suffices to throw light upon a series of analogous ones. It follows naturally that each reaction modifying a hydrocarbon in any manner whatever, will produce, when applied to the other hydrocarbons, a class of derivative products between which there will be the same correspondence as between the carbides that gave them birth. There is thus formed, around each carbide, a symmetrical group of derivative compounds, and, the circle always increasing, each of these derivatives may in its turn become the centre of a new system of compounds.

This is not the place to follow further the endless ramification of the hydrocarbons; it is rather sought to recall the exceptional character of the group, and to indicate, though only in a general way, what has led chemists to consider the hydrocarbons and their derivatives, as a whole, to be isolated and distinct from the other combinations.

This group of bodies presents a new interest when it is known that it forms, in great part at least, the substance of plants and the bodies of animals. The hydrocarbons and their derivatives are combustible. In contact with oxygen, under favourable circumstances, they produce oxide of carbon, carbonic acid, and oxide of hydrogen or water; a portion only of the nitrogen oxidizes, the remainder is disengaged in the free state during combustion. Such is the manner in which the substance of plants and animals comports itself. The branch just torn from the tree soon undergoes change; the bark contracts, the leaf fades, and every trace of humidity disappears. If this dry wood be now heated, it will inflame and burn until there remains only a small grey or white mass of mineral substance, incapable of further alteration under the prolonged action of heat. We say then that the wood has burnt, leaving nothing but ash. If a similar experiment be made with a substance of animal origin, a piece of meat for instance, the same phenomena are observed, and of the piece of meat nothing is left but the ash. That part of the wood, or the meat, which can be so burnt, consists of combinations of carbon, hydrogen, oxygen and nitrogen; and these combinations in burning, volatilize under the form of carbonic acid, water, binoxide of nitrogen or free nitrogen.

This similitude of composition between organic matters and the hydrocarbons and their derivatives has led to the latter being designated the group of organic compounds. Moreover, it has been in studying the organic substances, plants and the bodies of animals, that the chemist has become acquainted with these carbides of which we speak. Not more than half a century since the name of chemistry of the organic compounds, or simply organic chemistry, taken from its origin, was given to this new branch of science. Thanks to the talent of the great chemists of this century and the zeal of their scholars, it has developed wonderfully and with marvellous rapidity. Even the first researches led to most unexpected results, and discoveries followed one upon another. The extraordinary number of compounds produced by so small a number of elements captivated the interest of all. It was believed that those compounds formed an entirely new class of bodies, differing from mineral substances by their properties and composition, but above all by their mode of formation. As attempts to reconstitute from their elements these compounds extracted from plants and animals were not at first successful their formation was attributed to the mysterious influence of the vital force, and a boundary line was traced between the products of a mineral nature and those of an organic nature which was thought to be uncrossable. But this line of demarcation was only an artificial one; it has long since disappeared, effaced by new discoveries. Plants and animals no longer monopolize the secret of the formation of organic compounds; science has revealed it. By the aid of the elements alone, the chemist has been able to produce these bodies one after another with all the properties that they present when extracted from the living organism. And if some among them have hitherto escaped this synthesis, and cannot yet be produced except under the influence of the vital forces; if in many cases that result has only been obtained by elaborate processes which nature produces in the most simple manner; nevertheless, known facts justify the hope that the difficulties met with in producing artifically certain bodies found in living organisms will be soon surmounted by the indefatigable zeal of chemists.

The Pharmaceutical Journal.

SATURDAY, AUGUST 24, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE QUALIFICATIONS AND REMUNERATION OF ASSISTANTS.

Whatever difference of opinion may exist as to whether at the present time pharmacy takes rank as a trade or as a profession, it will be generally conceded that much vigilant and persevering work will have to be done before it attains the position it aspires to hold in the future; and since the maximum strength of a chain only equals the strength of its weakest link, the detection and removal of weak points when a long-continued strain is expected is not only wise but necessary.

Such a weak point has been more than once indicated in our correspondence columns, as existing in the present state of the law respecting pharmaceutical assistants. Although the Pharmacy Act of 1868 doubtless permitted many unqualified persons to claim that their names should be placed upon the Register of Chemists and Druggists, it also provided that no further additions should be made except of persons who have so far proved their qualifications for carrying on business as to have passed the Minor examination. But no similar safeguard exists with regard to assistants, and it is greatly to be regretted that even the risk of a business suffering from the effects of mistakes and incompetency is not sufficient to deter some employers from engaging "assistants" who have little qualification beyond the name.

One consequence of this is made evident by the frequent inquiries received as to the legality of registered chemists and druggists keeping one or more branch establishments, and leaving them to the care of such unqualified men. Another is that the assistant who has been to the trouble and expense of passing his Minor is met in competition by the uneducated man; and though there may be little doubt as to which would be chosen by the respectable pharmacist, there is equally little doubt that this competition has an injurious effect upon the rate of remuneration an examined man can command.

Now that the necessity for passing the Preliminary examination before commencing apprenticeship is generally admitted, it would be well if the original idea that the Minor should be a test of fitness for performing an assistant's duties were to become a little more popular. Dr. Attfield justly remarks in his paper (p. 153) that the Major examination was originally designed as the minimum gauge or measure of a man's fitness to conduct business on his own account, the Minor examination being devised as that best fitted to test the capacity and capabilities of an assistant in pharmacy. It does not follow, however, that the examination is lowered, and that education formerly only good enough for assistants is to-day considered good enough for masters, because the Minor is now the *compulsory* test before entering business; for under the Act of 1852 the Minor examination was purely optional, as the Major is now, and there was nothing to hinder an unexamined man calling himself a "chemist and druggist's assistant," or a "chemist and druggist" either.

In a recent number "A Master" instanced a case of an assistant whom he found unable to wrap up an eight-ounce mixture cleanly and neatly, who appeared to have seen little or no dispensing, and whom "A Master" therefore discharged. A correspondent, signing himself "A Man," has favoured us with a letter, which from want of room we are unable to print, in which he suggests that it would be better to sacrifice a quire of white demy than to dismiss an otherwise qualified assistant. This advice, no doubt kindly meant, is scarcely sound, for an assistant should certainly have long before passed so preliminary a stage. With many of the best friends of pharmacy, we rather look forward to the time when every master shall have passed the Major examination and every assistant the Minor. To this point some of our American brethren have already attained, for in the Act recently passed,* regulating the practice of pharmacy in Philadelphia, it is enacted that no person is to dispense prescriptions, except as an aid under the immediate supervision of the proprietor or a qualified assistant, who has not been apprenticed two years and attended one full course of lectures on chemistry, materia medica and pharmacy; and no proprietor is to leave his store in charge of any but a qualified assistant. Were English pharmacy but rid of all uneducated competition, one evil at least would be in a fair way of removal; for the master pharmacist would be better able to comply with the demand, which assistants might then with more assurance make, that their labours should be more adequately remunerated than they are at present.

The following gentlemen have been elected office-bearers of the British Pharmaceutical Conference for the ensuing year:—*President*, Mr. H. B. Brady; *Vice-Presidents*, Messrs. H. Deane, R. Bentley, D. Hanbury, W. W. Stoddart, T. H. Hills, J. Williams, R. Reynolds and F. M. Rimmington; *Treasurer*, Mr. G. F. Schacht; *General Secretaries* Professor Attfield and Mr. F. Baden Benger.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 136.)

At the conclusion of the reading of the President's Address—

Mr. SAVAGE said: Gentlemen, as a local member of the Conference a very pleasing duty devolves upon me; and after the very able and exhaustive address which we have had from our President, I am sure any words from me would fall far short of the expression of feeling which has been manifested here to-day. Throughout it has been an admirable treatise. Commencing in the educational course with the Preliminary examination, it proceeded to deal with the Minor and next with the Major examinations, and these have been supplemented by the ladies,—which comes with an excellent grace from the President, seeing that he is a bachelor. I have now a very pleasing duty to perform. It is simply to move that a vote of thanks be accorded to H. B. Brady, Esq., for the very admirable address which he has now given.

The motion was seconded by Mr. BREW, and carried unanimously.

The PRESIDENT: I feel, gentlemen, that my thanks are rather due to you for the consideration which you have extended to me while reading what I have thought to be a somewhat matterless address. Had circumstances admitted it, I would rather have attempted to make my address correspond in character, if not in ability, with the addresses which have preceded it from this chair. As I stated at the beginning, circumstances have entirely precluded my giving that attention to matters of research and to pharmaceutical matters generally beyond the mere business attention that I have usually endeavoured to accord. But it seemed to me that there was perhaps something to be said on these matters that I have touched upon; and it is gratifying to me that you have received them in the very kindly way you have, although my thanks are due rather to you than yours to me.

ELECTION OF HONORARY MEMBERS.

Mr. HANBURY: I have the honour of proposing that Dr. Edward Squibb, of Brooklyn, New York, and Professor Markoe, of Boston, be elected honorary members of the Conference. One of those gentlemen is now present. The other is a very distinguished pharmaceutist in America, and one whom it would be an honour for the Conference to associate with itself.

The motion was seconded by Mr. Schacht and carried unanimously.

Professor GEORGE F. H. MARKOE: Mr. President and gentlemen of the British Pharmaceutical Conference, this reception is altogether unexpected by me. I came to England not as a representative of the American Pharmaceutical Association, although I have the honour of holding office in that Association, but simply as an American pharmacist, who came to see how his British brethren practised pharmacy. It is altogether impossible for me to say anything which could properly give expression to the feelings which now possess me. I can only bear willing and, indeed, grateful testimony, to the kind attention I have received on every hand from the British pharmacists. Everywhere I have only had to mention that I was a pharmacist from America, and it has been sufficient to secure for me a most hearty welcome and every attention. Although I have not come in an official capacity, I certainly should be false to the American Pharmaceutical Association, as one of its vice-presidents, if I did not extend to one and all the members of this Conference the most hearty welcome to visit the sessions of the American Association at any time when it may suit them. The members of the American Pharmaceutical Association would be most glad to give them a hearty welcome. The President has alluded so eloquently to the subject of American pharmacy and the systems of education practised in America that it is needless to enlarge upon them; and it would be presumptuous for me, a mere stripling in pharmacy, to do so, when there is present at the meeting an American pharmacist of far greater distinction than myself, and who was distinguished in pharmacy before I was born.

PHARMACEUTICAL EDUCATION.

The President said there were several papers on this subject to be read, and suggested that the discussion should be deferred until they could all be considered together.

PHARMACEUTICAL EDUCATION.

BY PROFESSOR ATTFIELD.

Introduction.

No apology is necessary for bringing the subject of pharmaceutical education before the members of the British Pharmaceutical Conference; for the Conference is an organization chiefly for the encouragement of pharmaceutical research, and research is impossible where education does not flourish. Before we can promote pharmaceutical research we must promote pharmaceutical education. Moreover, the Annual Meeting of the Conference affords the only opportunity for discussion of the whole subject of pharmaceutical education by the leading pharmacists of the country.

Some apology, however, is due from myself in explanation of the circumstance that a professional teacher in pharmacy should venture to address pharmacists, not on the aspects of education with which he is supposed to be familiar, but on the principles which underlie the whole question—matters on which some one whose brain is not constantly occupied with the details of teaching might be expected to think and write with greater breadth and effect. Moreover, I am aware that in advocating the cause of pharmaceutical education a professor in a school of pharmacy lays himself open to the charge that his utterances are the offspring of personal and interested motives. To these two points I do not allude for my own sake, but because I feel that if they were not mentioned and explained the force of what I have to say would be diminished, and my subject suffer in consequence. At the outset, therefore, I would state that I only write this paper at the request of many pharmaceutical friends. For the past eighteen months I have been urged privately, and, more recently by correspondents in the Pharmaceutical Journal, to review the question of pharmaceutical education, and to give my opinions thereon. Hitherto I have refused for the above reasons, but repeated solicitation has overcome any reluctance, and I now proceed to write what I had hoped to have seen written before now by some leader in pharmacy occupying a more independent position.

Definition.—By pharmaceutical education I mean such instruction in the principles and practice of chemistry, botany, and materia medica, such a knowledge of practical dispensing or the compounding of medicines, and such acquaintance with all that relates to prescriptions and the galenical preparations of a pharmacopœia, as shall fit a man to be a chemist and druggist or a pharmaceutical chemist.

The Claims to Importance of Pharmaceutical Education no longer need enforcement; they are recognized in almost every civilized country of the globe. England was not the first to acknowledge them; she was preceded or has been outstripped by France, Germany, Russia and Switzerland. In Norway "the study of pharmacy is regulated by a law which dates from 1672," (1. 1. 241).* Still, thirty years and more ago a Society was

* Such figures (1. 1. 241) throughout this paper refer to the series, volume and page of the PHARMACEUTICAL JOURNAL.

founded in Great Britain "for the purpose of advancing chemistry and pharmacy and promoting an uniform system of education of those who should practise the same," as well as for protective and eleemosynary purposes. For these special objects "The Pharmaceutical Society of Great Britian" was granted a Royal Charter of Incorporation in 1843, an Act of Parliament legalizing the title of Pharmaceutical Chemist in 1852, and another in 1868 raising the term Chemist and Druggist to a title only to be acquired thereafter by those possessing such a pharmaceutical education as would stand the test of appropriate examination. The followers of pharmacy, as a body, the Legislature and the public have admitted and recognized the importance of pharmaceutical education.

The Object of the Author of this Paper is, then, not to maintain the importance but to consider the nature and extent of pharmaceutical education in England as gauged by the legal examinations. Two additional questions relating to pharmaceutical education are occupying attention at the present time. The one is how to supply the demand for knowledge which compulsory examination has called forth; the other is the future relation of the Pharmaceutical Society to pharmaceutical education.

But before either of these questions can be usefully discussed, the character of the knowledge required by a candidate for the "Minor" must be considered. To show that this order of procedure is imperative, let me somewhat expand the former question—that which is generally described as the question of Provincial Pharmaceutical Education. Members of the Pharmaceutical Society and other pioneers of pharmaceutical progress are commendably anxious that sound *education* should be provided for the young men who are legally compelled to pass the "Minor" Examination before they can be styled "Chemist and Druggist;" the majority of the young men themselves obtain only such an amount of *information* as will enable them to pass the said examination. Let us here distinguish between things different. The principals in pharmacy residing in provincial towns are asking the Council of the Pharmaceutical Society to aid in the development of local schools of pharmacy, on the assumption that compulsory examination has created a wide-spread demand by assistants and apprentices for pharmaceutical education. Now I assert that such a demand ought to exist, and that under improved organization will exist, but that it does not yet exist. The demand for knowledge which has arisen on the part of the young men is, I regret to say, of a vastly inferior description to that which is rightly embraced under the term education—knowledge of a kind and extent such as would be beneath the dignity of any recognized school to supply. The principals are basing their agitation on a demand for genuine education which does not yet exist; the candidates for the title of chemist and druggist are being supplied with a spurious education without any agitation at all. I shall bring forward proof in support of this statement presently; meanwhile I assert that the Pharmacy Act of 1868 has not created any demand for sound pharmaceutical education that did not exist before 1868, and that consequently any attempt to supply such education before the demand arises will result in that loss of effort, time and money which has hitherto followed nearly every attempt to establish a school of pharmacy in the provinces. If what I state is true, it will be admitted by all that the first question for discussion is the nature and extent of the education which should be possessed by every candidate for examination; and second, what means can be adopted whereby to ensure that a candidate does possess this knowledge. If sufficient means can be devised and employed for rendering certain the acquirement of this knowledge by a candidate, then, and not till then, will a demand for sound education arise. Only when these two questions have been satisfactorily settled will there be any *locus standi* for the third question, namely, how best to provide candidates with means for acquiring pharmaceutical education commensurate with the demand that will then arise; and fourth, the relationship of the Pharmaceutical Society to pharmaceutical education.

Pharmaceutical Education.—Past.

I shall first treat of pharmaceutical education from its birth in this country (1841) to the time of the passing of the Act providing compulsory examination (1868); next, state its lamentable position at the present time; and, lastly, consider the means by which it may be raised to its proper position; a position, that is to say, under which true schools of pharmacy can flourish throughout the country under the fostering care, but not necessarily under the immediate control, of the Pharmaceutical Society of Great Britain.

1841. In the first volume of the first series of the PHARMACEUTICAL JOURNAL (1. 1. 41), one of the leading objects of the Pharmaceutical Society was stated to be "the establishment of a system of education which will give professional character, influence and respectability to the whole body."

1842. After a few preliminary lectures on Botany, delivered in the summer, on account of the facilities for obtaining fresh plants at that season, a School of Pharmacy was opened at 17, Bloomsbury Square, in October, 1842. In the course of an introductory address, the Vice-President, Mr. Charles James Payne, said, "It is greatly to be regretted that so many circumstances have combined to keep the great majority of chemists and druggists in past times to that continuous and unwearied application to the mere mechanical part of their business which commercial habits induce, so that we have constantly had occasion to deplore the lack of information in the principles of our art, which has been betrayed by many who have been brought up to it. Without entering into the various causes of this deficiency, the most striking has certainly been the want of a defined and regular system of education amongst the chemists and druggists as a body, and the absence of some compulsion to avail themselves of it. . . . We conceive that no youth should be allowed to enter upon the study or practice of pharmacy, who has not received such a scholastic education as shall have brought his mind into habits which will prepare him for a pursuit in which the intellect must be brought into exercise continually." After alluding to the Preliminary examination, he says, "We then consider that a young man's professional knowledge should embrace a competent acquaintance with Chemistry, Materia Medica, Botany, and Pharmacy. . . . We are not about to merge the trade in the profession, but to establish the trade upon fixed and scientific principles." In this the first session, a course of lectures on Chemistry was given by Fownes, on Botany and Materia Medica by Anthony Todd Thompson, and on Pharmacy by Redwood.

The Council seems to have recognized the fact that these early morning lectures would only be attended by students residing in the metropolis and suburbs, for in a leader in the Journal (1. 2. 121) occurs the remark that, "When the school in London is completely established and has realized our expectations, it will be time to consider the propriety of forming branch schools in other parts of the country, where the amount of population and the zeal of our brethren in the cause of improvement are such as to give scope for the undertaking. We have received communications from several places on this subject, and have no doubt that when the proper time arrives, the zeal will not be found wanting."

1843. The subject of Provincial Schools of Pharmacy still occupies attention (1. 2. 669). "The necessity of adopting some measures for promoting an improved system of education among the rising members of our body, not only in London but in all parts of the country, appears to be generally felt and acknowledged." Lectures were delivered and proposed to be delivered in

Manchester, Bristol, Bath, Liverpool, Newcastle, Norwich, and Birmingham, and the Editor of the Journal trusts that "the time is not far distant when these and other branches of our Institution will be provided with some means of instruction for students in Pharmacy. The manner in which this is to be effected," he goes on to say, "requires mature consideration. It is evident that the number of country schools must be limited, since no institution of this kind could flourish without a certain number of pupils. The amount and description of assistance afforded by the Council to such measures must also be regulated on fair and equitable principles, and must be dependent on the state of the funds of the Society. In some places, facilities may exist for adopting the lectures of a medical school, in others it may be found necessary to establish separate courses for our students. In these and other particulars, a variety of circumstances must be considered, and whatever plans are adopted, should not be decided on without the most mature deliberation. Our object is to establish an effectual and permanent system of education, in effecting which object, no contingency should be overlooked; and whatever plans are proposed, must be considered with reference not merely to any particular locality, but to the general interests and requirements of the Society at large. We are not yet prepared to go into the details of the subject, but to allude to it on the present occasion in consequence of the communications which we have received from correspondents in the country; being anxious to promote pharmaceutical education by every means in our power, and at the same time to point out the necessity of considering so comprehensive a question in all its bearings."

The foregoing quotation is lengthy, but I am sure that neither it nor the others I have given or shall give, will be considered out of place, for they not only illustrate the rise and progress of pharmaceutical education in this country, but have a direct bearing on the questions of pharmaceutical education in the provinces and in London, which are now occupying so much of the attention of the Council and members of the Pharmaceutical Society.

In the Report of the Council for the year (1842–3), the country members are assured that the establishment of provincial schools and the extension of means for facilitating education throughout the country locally, has not been lost sight of; at the same time they are reminded that a reduction of the annual subscription from two guineas to one, which had been mooted, would deprive the Council of the means of affording pecuniary aid to provincial schools. The erection of a laboratory at Bloomsbury for the practical study of Chemistry is also hinted at; and thus even at this time, while the collapse of local schools is foreshadowed, such an extension of the metropolitan is contemplated as was destined to attract thither pupils from the whole country, and make it a provincial as well as a London school.

On August 15th, 1843, the subject of education was maturely considered by the Council (1. 3. 104). "The Council were unanimous in the opinion that it was imperative upon the Pharmaceutical Society to introduce a more regular plan of education for students in Pharmacy than had hitherto existed in this country, and to extend the benefits of public instruction to all places in which it may be found practicable; at the same time it was thought expedient to proceed with some degree of caution, and to establish schools in such towns only as could be expected from their population and other advantages to support them creditably." Manchester was at once aided by a grant of thirty guineas, which, with the pupils' fees, enabled the local committee to defray all expenses incurred in the delivery of twelve lectures on chemistry, and the same number on general and medical botany. As further evidence that originally there was no intention to confine pharmaceutical education to the metropolis, attention may be drawn to the fact that grants of money purely for educational purposes were also made in 1843 to Bath, Bristol, and Norwich, the total amount thus given to provincial schools during the year being £221. 10*s.* (1. 3. 236 and 567). The reports from the four branch schools were most encouraging, and the editor of the Journal (1. 3. 197) seemed disposed to deduce therefrom an argument in favour of voluntary pharmaceutical education, but he suspends judgment, seeing some indications that ultimately compulsory education may have to be enforced. Ultimately the Council announced (1. 3. 287) their intention of awarding annual grants to branch schools to the extent of one-fourth of the amount of annual subscriptions received from the town or district, and additional small grants towards the purchase of books and collections illustrating Materia Medica. The conditions under which the grants would be made, accompanied the announcement, "In regulating the local privileges of each branch, the first consideration to be attended to is the welfare and improvement of the parties immediately concerned; and if strangers be admitted to any of these privileges, the terms and mode of admission should be such as to give members, associates and apprentices who subscribe to the Society, a decided advantage over others." With regard to the number of such schools, it was considered that five or six in such localities as possessed the greatest facilities for their growth would produce more benefit than a larger number established on a scale too limited to be kept up with spirit (1. 3. 462).

1844. This year, effort in the cause of voluntary education met with the first indications of that want of response on the part of those for whom it was exerted that seems to have attended it from that time to the present. Manchester deplored the indifference of her young men, the attendance at the London school did not equal the expectations of the Council, the reports from the other schools do not seem to have been encouraging. The annual subscription to the Society was also reduced from two guineas to one, effectually preventing any further grants that might have been required for education in the provinces. From various parts of the country, however, came inquiries from learners who seemed anxious to devote a certain portion of their time entirely to study. This stimulated the Council in carrying out their original intention of establishing in London such a laboratory for instruction in practical chemistry as should, with the courses of lectures, library, etc., afford ample scope for the exertions of pupils during a certain number of months prior to their passing the examinations. A laboratory was therefore provided, and a course of practical instruction arranged. Thenceforward the school in the metropolis ceased to be simply a metropolitan school. As a mere London school it probably would, like the other schools, have been closed for want of support, but affording educational occupation for students during the whole of the day, it attracted just a sufficient number of pupils from the whole area of England and Wales to warrant the Council in maintaining it, and from time to time increasing its efficiency. While still the school in London, it ceased to be the London school, but became what it has since continued to be, the School of Pharmacy for the whole of Great Britain. The Pharmaceutical Society was thus enabled to carry out its object of providing means of obtaining pharmaceutical education for the whole of the country, though not in the manner anticipated.

1845. In this year the Council of the Society further develope their scheme of general pharmaceutical education. The school is alluded to as "a *national* establishment for the cultivation of pharmacy and the education of chemists and druggists" (1. 5. 145). Pharmaceutical education itself is also accorded a position commensurate with its importance, and its claims for consideration by the parents of pharmaceutical apprentices urged in a dignified manner. Jacob Bell, the founder of the Pharmaceutical Society, the leader of its Council, and the editor of its Journal, thus speaks of the educational organization of the Society, in words peculiarly worthy of reproduction at the present time. Alluding to attendance on the Society's Courses of Lectures, Laboratory Instruction, etc., he says (1. 5. 105), "These have been instituted for the purpose of enabling young men to become fully acquainted with the theory and practice of pharmacy; and the progress which has been made has demonstrated the benefit to be expected from a continuance of the undertaking. We hope this will become in course of time a regular part of the education of the chemist, and that parents when placing their sons in a house of business, will insist upon the privilege of a season being allowed for this very important study. The apothecary, or general practitioner, is obliged to devote the last two or three [it is now four] years of his apprenticeship to lectures, dissections, and hospital practice, and could not be admitted to examination without producing certificates of such attendance. The education of the chemist ought to be as elaborate in degree as that of the medical practitioner, and it is quite as necessary for him to study in the Laboratory as it is for the medical student to walk in the hospital. There is as much science required in one department as in the other, although the nature of the studies varies with the occupation; and since the medical student is obliged to give up two or three [four] years to the scientific study of his profession, the student in pharmacy has no reason to complain if required to devote a year to a similar object. A parent who could afford to give an apprentice-fee with his son, could equally afford to pay the small additional expenses of instruction in a school of pharmacy. Those who could not defray the necessary charges attendant on a proper education, should bring up their sons to some other business more consistent with their means."

1846. Nothing could better show the devotion of the Pharmaceutical Society to the cause of Pharmaceutical Education, an object which until recent years continued to hold the foremost place, than the fact that in 1846 the Council positively decided to relinquish the Society's functions as an examining body rather than give up its mission as an educating institution. Fearing that Parliament would not grant the powers of compulsory examination to an educating corporation, the Council proposed to transfer its examining powers to what was to be called "The College of Pharmacy of England," to be constituted solely for the purpose, and a Bill was drafted on the principle (1. 5. 557). It was considered that such a college, by creating a demand for pharmaceutical education, would give an impetus to schools of pharmacy: competition between the schools would have a salutary effect, and the emulation thus excited would lead to improvements in the system of education.

1847. Objections to the proposed Bill having been urged, especially by the College of Physicians, (1. 6. 497), the machinery of the Pharmaceutical Society was adapted to the end in view without the co-operation of a second body. These preliminaries had, however, occupied so much time that the opportunity passed for introducing the Bill to Parliament. It served, nevertheless, to stimulate the arrested energies of provincial pioneers in education. Acting on the assumption—then, as now, a wrong assumption—that compulsory examination involved compulsory education, meetings were held in several towns, again, notably, Bristol, with the object of resuscitating local schools of pharmacy.

1848 to 1852. During this period pharmaceutical education made slow but certain progress. The numbers of students at the School of Pharmacy increased, though the average period of study decreased. It continued to be chiefly attended by pupils from the provinces. A school in Birmingham was also attempted, but "the Committee regret that the attendance was neither so numerous nor so regular as could have been wished." Liverpool also started the school which, with varying fortune, has been open ever since.

Once more a Pharmacy Act was sought, and once again the dread that Parliament would not listen to men who had sanctioned such an unholy alliance as that of education with examination induced the Council to raise two spectres,—one, the continuance of the Society as an educating body, and the establishment of a College of Pharmacy for conducting the examinations; the other the adoption of the Society as the examining body and the relinquishment of the school of pharmacy. But the ghosts vanished. A Select Committee of the House of Commons sifted the question, and finding that the school was not only not carried on as a source of revenue, but at a great annual expense; that the professors were not interested in attracting pupils from other schools; and the examiners not interested in favouring candidates who had derived their education from the Society, took no exception to the Society's duplex character.

Parliament thus tacitly sanctioned the very sensible and only possible relationship to education which the Society had hithero followed. The editor of the Journal hoped that other schools of pharmacy besides that at Bloomsbury would eventually flourish and prove remunerative, and that when that result was obtained the Society would gladly resign its educational functions.

The Council also reported (1852) that "If, contrary to past experience, it should be found that Schools of Pharmacy and Practical Chemistry can be supported without endowment or collateral aid, the maintenance of an educational establishment connected with the Society may be unnecessary. At the present time the Council think it would not be right to abandon the proceedings which have contributed to give the Society the character and influence it now enjoys."

1852 to 1868. During the interval that elapsed between the passing of the Pharmacy Acts "The Council of the Pharmaceutical Society continued steadily to persevere, according to its original programme, in the advancement of education, sometimes without much prospect, but always animated by the hope that the object of the Bill introduced in 1852," namely, compulsory education, examination, and registration "would be accomplished; and this period of probation probably furnished the means of success. . . . When the public demanded that certain restrictions should be placed on the sale of poisons, the Council of the Society succeeded in obtaining recognition of the principle they had always enunciated, that education of the vendor was the only safe foundation for a Poison Bill." Midway in this period of sixteen years, pharmaceutical education in this country lost its founder and best friend, Jacob Bell. In life this noble-minded man, never wearied in urging the claims of pharmaceutical education, and at death, besides assigning the valuable copyright of the PHARMACEUTICAL JOURNAL to the Pharmaceutical Society, he munificently bequeathed two thousand pounds "to be expended in establishing or otherwise increasing the efficiency of the School of Pharmacy, or in promoting Pharmaceutical Education in such manner as the Council of the said Society shall deem expedient." The Council having reason to believe that the donor had contemplated such an application of his bequest, erected, with this £2000, the present commodious suite of laboratories at the top of the premises in Bloomsbury Square. The School during this long term still annually cost the Society a considerable sum of money; but if the whole of the country thus contributed to the support of pharmaceutical education, the whole of the country received the benefit, three-fourths of the students every year being provincial pupils. If the members in any one district received more benefit than another, Welshmen and Yorkshiremen may be said to have had the advantage, a session seldom passing without the presence of several representatives from the great northern county and the principality. In short, by supporting the School, the Society did all it could towards the support of pharmaceutical education throughout the whole country.

Pharmaceutical Education.—Present.

What has the Pharmacy Act of 1868 done for pharmaceutical education? Exactly a quarter of a century before that Act was obtained, namely, in 1843 (1. 3. 196), we were told that the schools of pharmacy—there were five in England at that time—were established for purposes of education, the libraries and museums of the Pharmaceutical Society organized for purposes of education, the examinations of members and associates devised for purposes of education, the Pharmaceutical Journal instituted for purposes of education. In 1841, education was to be the lever by which the character, influence and respectability of the whole body of chemists and druggists was to be raised. In 1842, the provinces caught up the cry. In 1843, lectures on pharmaceutical education were delivered in eight large towns. In 1844, to the London School for Pharmaceutical Education was added a laboratory for the pursuit of practical pharmaceutical chemistry. In 1845, the metropolitan was converted into a national school for pharmaceutical education. In 1846, the Pharmaceutical Council elected to retain the power and privilege of educating rather than examining if either were relinquished. During the whole life of the Pharmaceutical Society, its watchword has been *Education.* Compulsory education, compulsory examination, compulsory registration. This is the order in which the three objects of the Society have generally been set forth (1. 5. 246), while education has always been looked to as an object superior to examination. Well, compulsory registration has been obtained, and a strong staff it has proved. Compulsory examination has been granted, and an admirable agent for good it might be made. But compulsory education, which everybody always thought was to follow in the wake of compulsory examination, as a valuable train follows a powerful engine, Where is it? Where? It does not exist. What has the Pharmacy Act of 1868 done for it? Nothing. Emphatically, nothing. Worse than nothing; it has degraded voluntary education from its previous promising position; it has reduced its value by one-half. Prior to 1868, the average period of study of each pupil in the laboratory of your national school of pharmacy was from four to five full months, each student working daily from eight or nine o'clock till five; since 1868 it has been a little over two months. Till 1868, the Professor of Practical Chemistry in the school succeeded in teaching all students chemistry; after 1868, the majority have shown disinclination to learn anything beyond certain facts regarding "the definite chemical bodies of the Pharmacopœia." Class examinations of all candidates for the "Minor" and "Major" were instituted, the Professor taking upon himself the office filled at medical schools by the tutor; but as soon as it was found that these examinations covered the whole area of pharmaceutical chemistry, then the men who most needed them, those who only wanted to learn what was required for "the Minor," contrived to keep away. But worse than all this, the place which every well-wisher of pharmacy expected to see occupied by compulsory pharmaceutical education is filled by that hideous usurper, CRAM. Let me at once say that this is no fault of our excellent examiners. I shall have to use some very strong language in denouncing the practice termed "cramming,' but not one word against the examination for which candidates are crammed. My remedy for cramming, on the contrary, is intimately connected with the elevation of education. I am of opinion that ninety-five per cent. of the cramming now practised can be prevented. With regard to this cramming or "coaching," it is a fact that, during the past ten months, more students have been crammed than have been legitimately prepared for the Minor Examination of the Pharmaceutical Society of Great Britain. There are establishments for cramming which received last session more pupils than sought the aid of the Society's School of Pharmacy. "It is not astonishing that so obvious a demand for 'coaching' should produce a commensurate supply of the abomination, and that we should be unblushingly told by advertisement that an *ignoramus* may be transformed into a *Chemist and Druggist* in a month!" ('Chemist and Druggist,' January, 1872). And what is very terrible, these crammers keep their word in most cases. I know I am helping to advertise them in stating all this, and would not do so but that I trust their days are numbered; added to which any one may know that they do what they promise or they would not flourish as they do. The manner of performing it is as follows: A promise is exacted from every candidate that after passing the examination he shall return to his crammer and reproduce the questions he has been asked. Those brought by first pupils are carefully written down; and thus, in a short time, the crammer has a list of the questions commonly asked by each examiner; the lists are revised from time to time by the aid of subsequent candidates. On the entry of a pupil, a list of questions and answers in each subject is placed before him with the general instruction that the first half of each set is to be learnt by heart, and the second to be acquired if possible. And so, one week is given to what is called "chemistry," one to "botany," one to "materia medica," and one spent over the "pharmacopœia;" and any young man who has previously been in a druggist's shop is thus successfully prepared for the Minor. Nay, even if he has never before seen a prescription, an extra fortnight or so at "practical dispensing" enables him to satisfy the examiners. The successful legitimate candidate knows his subjects; the successful illegitimate candidate knows the questions that will be put to him. Will the Council of the Pharmaceutical Society allow these dreadful odds to obtain much longer? This is not a case of competition, even unfair competition, between one kind of education and another, for education means 'to bring out,' not 'to thrust in;' it is a question of education *versus* cram. Can any language used in describing the latter system be too strong? Can it be characterized by too vile a name? Its true designation has been furnished by one of its own promoters. Eighteen months ago (3. 1. 629), "Charles Gerrard, described as a teacher, living in Lincoln's Inn Fields, together with another man, were charged with inciting a person in the employ of Messrs. Rivington, the printers, to steal an early proof of one of the examination papers of the Apothecaries' Hall. It appeared that the prisoners had for some time been striving to obtain a copy, and at length, by arrangement with the police, the proof-puller was allowed to supply them with two copies, for which he received ten pounds. A detective then immediately arrested the prisoners, while the proofs were in their hands. They were both committed for trial," and subsequently convicted. What is the difference between stealing questions which have been written by the hand of an examiner and those which come from his mouth? Students, I trust the temptation to traffic with the crammer, this destroyer of your self-respect and enemy to your real progress, will soon be removed; meanwhile, pause before you listen to his wiles or purchase his wares, for if you buy you will probably be haunted by the reflection that you have been made receivers of stolen property. There is a vast deal of difference between crammers and private tutors, though all are not private tutors who so call themselves, and all is not cramming that is so termed. Many a student swallows his intellectual food too fast; and honest teachers often have to warn honest pupils against this evil. All this is occasionally described as "cramming;" but the cramming I wish to denounce is the insidious and wicked process I have detailed; the thing which flourishes under the Pharmacy Act as it never before flourished, or can flourish in any other Court of Examiners—the thing which if not uprooted, or even if allowed to continue in its present stage of development, will render provincial schools unnecessary, and your central school the partial success that it has been made by the attendance hitherto of a few admirable pupils annually.

A few admirable pupils annually. Yes, pharmaceutical education is not yet swamped by superficiality or crushed by cram. Good men, most of them pupils of the Society's School of Pharmacy, still present themselves before the Board of Examiners as in the years before 1868. This is nearly all I can say for Pharmaceutical Education—Present. I regret to have to say so much of pharmaceutical cramming, but I could not say less.

I can assure my readers, especially those who, with the great mass of the public, erroneously consider examination to be the panacea for all ignorance, that I have understated the case as regards cramming. I presume no one will doubt the existence of the evil who observes what is going on around him, and if he doubts the extent let him ascertain how many teachers pointedly question their pupils as to what each has been asked by the Board of Examiners, and how many pupils altogether such teachers have had during, for instance, the past session.

Pharmaceutical Education.—Future.

Discussion on the future of pharmaceutical education will be facilitated by a consideration of the causes which have reduced it to its present low position. The statement has been made that the standard of the Minor examination has not been altered; that the Major, if changed at all, has been improved; that the examiners are mostly those who sat before 1868. Why should cram be more rife now than ever? Why does cram flourish at all?

As to the standard of examinations, I maintain that it has been lowered enormously. The examination which the collective wisdom of the leading pharmacists of the country had devised as that best fitted to test the capacity and capabilities of an assistant in pharmacy, and which always with the same object in view, had been altered and improved and made more practical from time to time during nearly thirty years, is suddenly so lowered *en masse* as to be the examination for testing the capacity and capabilities of a principal in pharmacy, while the assistant is no longer asked to pass an examination specially devised for men of his own class. The examination originally designed as the minimum gauge or measure of a man's fitness to conduct business on his own account (the Major) must now logically be considered as indicating that he is somewhat above his business or better than he need be, a distinction so lightly valued that very few more aspire to it now than under the old voluntary system of examination. Of course no one pays the founders of the Pharmaceutical Society such an equivocal compliment as is implied in this state of things; on the contrary, I presume that every one considers that the old standards were wisely chosen and strengthened, and that when the present period of expediency and transition has passed, the old positions will be regained. If this be the policy of the Society it has my concurrence; I quite approve of the tactics by which the Pharmacy Act of 1868 was obtained. I point to the fact that the education formerly only good enough for assistants is now considered good enough for masters, as one that refutes the statement concerning the non-alteration in the standards of examination, and as one that could not do otherwise than damage the cause of pharmaceutical education.

Again, in the days of voluntary examination education was the chief object; examination was considered only as a test of the possession of education, and the passing of the "Minor" was only an incident in the student's career. Now, except by the few, examination is regarded as the end and education the means. Not only have education and examination changed places in general estimation, but while examination has kept its place, education has been forced from above to below—it has lost two places. Looking to the depression of the examination standard that I have already spoken, education has been thrust to a very low position indeed.

Cram now flourishes in pharmacy to a greater extent than it did prior to 1868, simply because the demand for it under a compulsory system of examination is so great that its development on a grand scale is highly remunerative. Why cram flourishes at all at any examination is because examiners are but human and examination at its best a most imperfect machine for ascertaining the nature and amount of a man's knowledge. Why it flourishes to a tenfold extent at our examinations as compared with any other in England or the Continent—and it does so—is because our Examining Board does not possess either of the guarantees against it possessed by other Examining Boards. In all Europe there is no system of examination so liable to abuse as our own. It is not exactly like any other, but approaches in character most nearly to those of the London University and the Medical Corporations. It resembles the general system of the London University (that is, excluding the examinations for degrees in medicine) to the extent of being conducted on principles similar to those by which free-trade is governed. A candidate at either board is not asked where he obtained his knowledge. The assumption acted on is that brain-power can be accurately measured by examination, and that if possessed to the requisite extent its source is immaterial. But at the London University a candidate is liable to be taken over a large area by a special examiner in each subject, the most eminent man as regards his subject that the kingdom can furnish. Even under these circumstances the time allowed to this examiner for *vivâ voce* examination of his candidate, though as long as practicable, is quite insufficient to allow of the whole area being traversed, hence a just decision cannot be given with certainty. Thus an entrance for cram is provided, for it is not brain-power that is measured so much as memory, or the faculty of storing facts. But at the pharmaceutical examinations the area embraced by any one subject is not large, the examiner in any one subject is not, and it is unnecessary that he should be, the most eminent as regards that subject that the country can produce, and the time given to examination in any one subject is quite insufficient for thoroughly traversing even the limited area, nor would it be sufficient if double the present length. Thus even the imperfect guarantee against excessive cramming which obtains at the London University is not possessed by our own Board. Next, our examinations resemble those of the College of Physicians, College of Surgeons and Apothecaries' Hall, in so far as they are conducted by followers of the same profession or calling as that which the candidate aspires to enter. But these boards possess a guarantee against cramming, which, though not perfect, is of great power and value and is wholly wanting at Bloomsbury Square. Every candidate must produce evidence that he has had the opportunity of being properly educated at a recognized school for four years, as well as in preliminary matters, and inasmuch as more than ninety per cent. of the candidates have, for obvious reasons, taken all the advantage they could of these opportunities, cramming is reduced to insignificant proportions compared to the position occupied by education. This supplement to examination is also required by nearly all the pharmaceutical examining boards on the Continent. I repeat that our examinations, as at present organized, especially the Minor, encourage the rank growth of the noisome thing termed cram, and hence discourage the development of pharmaceutical education.

The remedy for this abuse is compulsory education. In this opinion I shall probably be supported by every one interested in the welfare of pharmacy; but as to the form compulsory education shall take there will, I know, be a less unanimous declaration. Respecting compulsory education in the abstract, it would seem from a leading article in the number of the PHARMACEUTICAL JOURNAL published on the day I commenced to write this paper (July 20th, 1872), that everybody considers that this long fought-for and grand object has already been obtained. I read, "In fact it may fairly be stated that the Society as a voluntary association has already completed its labour in the cause of education, and that, having succeeded in making education compulsory, it has done the work it originally projected. It is now the time for those who have been at best mere lookers-on to come forward and give their aid in making the advantages of that work accessible to all." Wrong, a a thousand times wrong. The Society has *not* succeeded in making education compulsory. That the Society will ultimately succeed in so doing I have no doubt, for I have faith in its traditional policy as regards education and in its educational leaders on and off its Council; but that compulsory education is already attained is a statement contrary to all the facts of the case, and one that I shall be astounded to hear maintained by any one who may do me the favour to discuss this paper.

Compulsory education must be obtained in one of two ways. Either the class of experts whence the examiners are drawn must be entirely changed, the time allotted for examination greatly prolonged, and the area of examination considerably enlarged; or, on the other hand, the system may remain as at present, and simply be supplemented by a scheduled statement that the candidate has attended the classes of a recognized school for a stated length of time. Objections may be urged to both plans, but so far as I see, one or other must be adopted. Neither is perfect, but that any friend to pharmacy will reject both I cannot believe.

The "free-studentship" method is open to serious, and to my mind insuperable objections. I like the idea of a man getting his knowledge where and as he likes so that he gets it; but I do not see how the idea is to be embodied in pharmacy without opening a wide door to cram. "A really good examiner," Tait says, in an entertaining and most instructive article on Examination, or "Artificial Selection," as he terms it, in 'Macmillan's Magazine' for March, 1872, "A really good examiner is perhaps the rarest product of civilization. In an unusually large experience extending to each of the three kingdoms, I have met but two, and I see clearly how each of even these might be greatly improved. . . . An examiner ought to possess not merely great knowledge, but enormously extensive knowledge, of his subject and of the various modes of teaching it. . . . The examiner must possess simultaneously, infinite tact and thorough common sense. . . . Even if he be possessed of all these requisites, the examiner must be allowed sufficient *time* to test a man's knowledge. . . . Granting that all these desiderata can be supplied, there still remains the excessive difficulty of examining into the really useful part of one's knowledge. For, in the great majority of cases, the useful part is precisely that which it is least possible to break up into detached fragments, such as those required in the modern process of examination." The writer of this article, perusal of which I strongly recommend to all interested in the subject, further states his fondness for two methods of ascertaining fitness for work, but candidly says that he does not see how either could be applied at present: the first is the system of trial and approval which we apply to servants of every grade from the most menial to the most confidential; the other is to take the certificate of such qualified teachers as have had the opportunity of observing the progress and behaviour of a student. The latter method he considers to be something quite priceless compared with the quickly-formed, and, therefore, at best, dubious judgment of an examiner. For my own part, although I believe in freedom in trade, freedom in thought, and freedom in most things, I do not believe in freedom in education. A few years ago when the agitation in favour of free trade was at its height we could not get a Pharmacy Act because no one would allow free trade in poisons to be an exception to the rule. Even the schedule-of-attendance supplement to the medical systems of examination was said to be on its last legs. It was strongly attacked, but with the best results, for its abuses were remedied. Freedom cannot bind everything however. It has let the valuable agents vulgarly termed poisons loose from its chain and allow them a certain amount of protection. Pharmacists are the last who should agitate for free trade in education.

The method of supplementing our ordinary plan of examination at the "Minor," by requiring the production of a Schedule of Certificates of (*a*) having passed the Preliminary examination, (*b*) worked for a stated period in a shop under a registered chemist and druggist, and (*c*) attended certain courses of instruction at a recognized school of pharmacy, is a long-tried method—a method the details of which are ready to our hands by application to the medical examining bodies in this country, or the pharmaceutical examining bodies on the Continent, and one under which, in our case, less cramming would be practised than by medical students. For the medical students who support the medical crammers are chiefly those whose friends having driven them into medicine against their will, have bribed them by a too-full purse. These men take care to be present in the body at lectures, and hence get their schedules signed, but at other times follow their own foolish ways, and at last have to seek the aid of the crammers. In the nature of things this class would scarcely be represented in pharmacy; and I question if, under the schedule-of-attendance method, there would be a sufficient demand for cram to keep the loathsome thing alive. I have no objection, indeed, I have the strongest desire, to see any possible improvement carried out in the selection of examiners. I do not know that there is at present any weak brother on our Board; if so, let him be displaced by a stronger forthwith. But, on the whole, I do not believe that a more able and patient set of examiners could be found in pharmacy than now sit at Bloomsbury. To go outside pharmacy for examiners, I do not think to be a practicable proceeding. I have no objection, indeed, I have every desire to see, both the Minor and Major Examinations, especially the former, made more practical (3. 3. 115.). To give the public the guarantee of the Pharmaceutical Society of Great Britain that a man is a "Chemist and Druggist," when, perhaps, he has never seen a test tube, and does not know how to detect an impurity, an adulteration, or a falsely-labelled chemical, is an anomaly that cannot much longer be excused: indeed, I know that the leaders in pharmaceutical progress are most anxious that this scandal should be removed with all speed. Let not the most sanguine suppose, however, that a more practical examination would be less liable to the invasion of cram; a crammer has greater command over some practical than over theoretical matters. But neither the selection of examiners, nor any alteration in the examinations, is involved in the adoption of the schedule-of-attendance scheme. It is no part of my intention, nor is it my province, to advocate or decry the slightest interference with the present mode of examination. I simply wish those examinations, as they stand, to be made THOROUGH. I wish them to be so supplemented as to involve the death of cram and the life of education. I select and support that one of the two methods of securing compulsory education which I believe to be effective and practicable. I see no difficulties in the way of the adoption of the principle, but even if fuller administrative powers were required from Parliament, I should with certainty of success proceed at once to obtain them.

In the firm belief that this question of compulsory education, and the form it shall take, will receive priority of discussion at the hands of the members of the Pharmaceutical Conference at the present meeting, and by the leaders of pharmacy hereafter, and priority of organization by the Council of the Pharmaceutical Society, I will now briefly introduce the subjects of *provincial* pharmaceutical education, and the ultimate relationship of the Society to either or all the Schools of Pharmacy.

From data possessed by the Secretary of the Pharmaceutical Society, it is his opinion that in the course of a few years 1000 youths will pass the Preliminary examination annually; that 750 apprentices will annually present themselves as candidates for the title of chemist and druggist, and 600 gentlemen will annually start in business. This calculation is of course based on the present condition of things. There can be little doubt that if the efforts of the Pharmaceutical Society to improve the trade generally by means of education and examination be successful, many young men will be deterred from entering pharmacy, the present excessive number of small shops being greatly reduced. The existing central school of pharmacy can accommodate 150 or 200 students in a session if each studies for a few months; there will therefore be room for three or four, or possible five such schools. France possesses three. That a school of pharmacy can be established in every twentieth town is simply impossible. Moral reasons are said to prevent some people sending their sons to the school in London or other large town. If this is true, such parents should select a calling which can be followed nearer home, though I fail to see how that would meet the difficulty; it is chiefly that which cometh from within which defileth. At the same time I have long urged for other reasons the establishment of residential halls, clubs, in connection with schools of pharmacy. I far more strongly sympathize with the patient and perserving youth who steadily prepares for the Minor by sheer hard work in a country village. It seems unfair to compel such a man to attach himself to a recognized school. The same objection to the compulsory-attendance plan obtains in the medical profession, but it is not found to be an important objection. In truth, I believe, that the number of such men will be very small when the Minor examination comes to be conducted with the thoroughness foreshadowed in the last report on our examinations by the officer of the Privy Council (3. 3. 115). Moreover, I have found that these men of all others are most glad to take advantage of professorial assistance. "There can be no doubt (3. 3. 50), that even where the pupil has the advantage of a master capable and willing to instruct him, he will be benefited in supplementing such practical instruction by hearing scientific principles systematically enunciated by other persons."

The steps by which to establish such schools in the provinces should be undertaken by the Council of the Pharmaceutical Society through the agency of committes and deputations, assisted by, and assisting local committees, all the care and deliberation exercised when founding the central school being observed in establishing the new schools. I am of opinion that such schools would be self-supporting, for I am assuming that pharmaceutical education is made compulsory in the manner suggested. That point reached, their financial connection with the Society would cease, whether the school were located in the metropolis or the provinces; but until that position were obtained liberal support should be accorded. The manner of distributing aid scarcely needs remark; there being only four or five schools, each would be treated on its merits without any elaborate machinery. To spread aid to pharmaceutical education broadcast over the whole country would, in my opinion, prove to be sheer waste of energy and money.

Mr. Benger's proposal (1. 1. 253) to establish special technical schools for boys intending to become pharmacists is important, but is scarcely practicable at present. Moreover, the rapid spread of scientific education in general schools will probably in time render any such proceeding unnecessary. That no chemist and druggist should take an apprentice who has not passed the Preliminary examination of the Pharmaceutical Society is a proposition which has been accepted by all who have spoken or written on the subject. I think it might be urged officially on every chemist and druggist in England as soon as the new and vastly improved Register is published. Mr. Edward Smith's suggestion (3. 2. 301) that only apprentices who have passed the Preliminary examination should be admitted as students at schools of pharmacy has my earnest support; I often temporarily fail in teaching a student some chemical fact or principle through his want of knowledge of arithmetic. Mr. Smith's method of ascertaining which are the deserving recipients of aid from the parent Society by an elaborate system of special examinations, and Mr. Schacht's original plan of carrying out the same object (3. 2. 401) would be attended by a vast deal of trouble, and would not, I think, with any amount of labour be successful. But if successful, such examinations would be open to the abuse of cram. Mr. Schacht's more recent scheme now before the Society extends aid only to provincial associations, having recognized schools similar in kind, and not very different in degree to those, the establishment of which I have advocated in this paper; such a plan was also urged by Mr. Hustwick (3. 2. 499). I have shown that all such schools must fail unless cram be crushed, but assuming this to have been done, then I do not see the need for any separate special examinations, the Minor itself would afford means of ascertaining the relative efficiency of these schools, and thus provide for the distribution of aid so long as aid might be necessary. As to the manner in which aid might be given, it would necessarily differ according to the requirements and amount of local support of the school, but Mr. Reynolds' plan (3. 2. 751) would probably be taken as a basis, "1. To increase the fees of teachers of chemistry, practical chemistry, materia medica, pharmacy and botany. 2. To pay one-half the salary of curator and lecture-assistant. 3. To distribute such duplicate specimens from the Society's Museum as might be available. 4. To make grants to libraries. 5. To grant loans of materials for class teaching, with the power of making them absolute grants. It is clear that provincial schools must mainly be under local management. As a school, metropolitan or provincial, becomes self-supporting much of its connection with the parent Society would naturally cease; but the question whether all connection should lapse may well be postponed. I see no difficulty in providing suitable teachers for future schools of pharmacy. The sources are obvious, but I may mention one not quite so apparent. At present it is cause for constant regret that our Bell Scholarships do good to all other professions except our own; a Bell Scholarship is too often the lever by which a worthy, clever and ambitious young pharmacist so elevates himself that his talents are lost to pharmacy altogether. As a teacher or professor in a school of pharmacy he would find full scope for his skill and energy, and pharmacy not lose the fruit she had taken such pains to mature.

In conclusion, let me beg for the fullest consideration of pharmaceutical education by every pharmacist having the interest of pharmacy at heart. I invite objections to my own views; I ask for criticism; and if neither can be given, three words of approval will strengthen my position. The pharmaceutical press is open to all. I have Mr. Schacht's authority for stating that "The Council of the Pharmaceutical Society are most anxious to devise a scheme that shall prove generally satisfactory to the trade at large; and as in this matter they are treading upon almost strange ground, they feel that this way would be largely prepared for them, and their labours would be much assisted by the fullest expression of opinion on every point bearing upon the question." I have taken some pains to ascertain and, in the former part of this paper, partially to reproduce the opinions expressed several years ago by Council after Council of the Pharmaceutical Society, and other leaders in pharmacy on this same subject of pharmaceutical education. Their statements bear the stamp of much thought and mature deliberations extending over a long period, and are worthy of more careful perusal than has apparently been bestowed on them by most recent writers. My other contributions to the discussion are the views I have expressed in the second and third parts of the paper, and for which I alone am responsible.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE PRESIDENT'S ADDRESS.

(*Concluded from page* 139.)

We have an illustration of this progress in the fact of continual occurrence, that conceptions which prove inadmissible to the minds of one generation, in consequence either of their want of intellectual power to apprehend them, or of their preoccupation by older habits of thought, subsequently find a universal acceptance, and even come to be approved as "self-evident." Thus the first law of motion, divined by the genius Newton, though opposed by many philosophers of his time as contrary to all experience, is now accepted by common consent, not merely as a legitimate inference from experiment, but as the expression of a necessary and universal truth; and the same axiomatic value is extended to the still more general doctrine, that energy of *any* kind, whether manifested in the "molar" motion of masses, or consisting in the "molecular" motion of atoms, *must* continue under some form or other without abatement or decay; what all admit in regard to the indestructibility of matter, being accepted as no less true of force, namely, that as *ex nihilo nil fit*, so *nil fit ad nihilum*.*

But, it may be urged, the very conception of these and similar great truths is in itself a typical example of intuition. The men who divined and enunciated them stand out above their fellows, as possessed of a genius which could not only combine but create, of an insight which could clearly discern what reason could but dimly shadow forth. Granting this freely, I think it may be shown that the intuitions of individual genius are but specially exalted forms of endowments which are the general property of the race at the time, and which have come to be so in virtue of its whole previous culture.—Who, for example, could refuse to the marvellous aptitude for perceiving the relations of numbers, which displayed itself in the untutored boyhood of George Bidder and Zerah Colburn, the title of an intuitive gift? But who, on the other hand, can believe that a Bidder or a Colburn could suddenly arise in a race of savages who cannot count beyond five? Or, again, in the history of the very earliest years of Mozart, who can fail to recognize the dawn of that glorious genius, whose brilliant but brief career left its imperishable impress on the art it enriched? But who would be bold enough to affirm that an infant Mozart could be born amongst a tribe, whose only musical instrument is a tom-tom, whose only song is a monotonous chant?

Again, by tracing the gradual *genesis* of some of those ideas which we now accept as "self-evident," such, for example, as that of the "uniformity of nature"—we are able to recognize them as the expressions of certain intellectual tendencies, which have progressively augmented in force in successive generations, and now manifest themselves as mental instincts that penetrate and direct our ordinary course of thought. Such instincts constitute a precious heritage, which has been transmitted to us with ever-increasing value through the long succession of preceding generations; and which it is for us to transmit to those who shall come after us, with all that further increase which our higher culture and wider range of knowledge can impart.

And now, having studied the working action of the human intellect in the scientific interpretation of nature, we shall examine the general character of its products; and the first of these with which we shall deal is our conception of *matter* and of its relation to *force*.

The psychologist of the present day views matter entirely through the light of his own consciousness: his idea of matter in the abstract being that it is a "something" which has a permanent power of exciting sensations; his idea of any "property" of matter being the mental representation of some kind of sensory impression he has received from it; and his idea of any particular kind of matter being the representation of the whole aggregate of the sense-perceptions which its presence has called up in his mind. Thus when I press my hand against this table, I recognize its unyieldingness through the conjoint medium of my sense of touch, my muscular sense, and my mental sense of effort, to which it will be convenient to give the general designation of the tactile sense; and I attribute to that table a *hardness* which resists the effort I make to press my hand into its substance, whilst I also recognize the fact that the force I have employed is not sufficient to move its mass. But I press my hand against a lump of dough; and finding that its substance yields under my pressure, I call it *soft*. Or again, I press my hand against this desk; and I find that although I do not thereby change its *form*, I change its *place;* and so I get the tactile idea of *motion*. Again, by the impressions received through the same sensorial apparatus, when I lift this book in my hand, I am led to attach to it the notion of *weight* or ponderosity; and by lifting different solids of about the same size, I am enabled, by the different degrees of exertion I find myself obliged to make in order to sustain them, to distinguish some of them as *light*, and others as *heavy*. Through the medium of another set of sense-perceptions which some regard as belonging to a different category, we distinguish between bodies that *feel* "hot" and those that *feel* "cold;" and in this manner we arrive at the notion of differences of temperature. And it is through the medium of our tactile sense, without any aid from vision, that we first gain the idea of *solid form*, or the three dimensions of space.

Again, by the extension of our tactile experiences, we acquire the notion of *liquids*, as forms of matter yielding readily to pressure, but possessing a sensible weight which may equal that of solids: and of *air*, whose resisting power is much slighter, and whose weight is so small that it can only be made sensible by artificial means. Thus, then, we arrive at the notions of *resistance* and of *weight* as properties common to all forms of matter; and now that we have got rid of that idea of light and heat, electricity and magnetism, as "imponderable fluids," which used to vex our souls in our scientific childhood, and of which the popular term "electric fluid" is a "survival," we accept these properties as affording the practical distinction between the "material" and the "immaterial."

Turning, now, to that other great portal of sensation, the sight, through which we receive most of the messages

* This is the form in which the doctrine now known as that of the "conservation of energy" was enunciated by Dr. Mayer, in the very remarkable essay published by him in 1845, entitled 'Die organische Bewegung in ihrem Zusammenhange mit dem Stoffwechsel.'

sent to us from the universe around, we recognize the same truth. Thus it is agreed alike by physicists and physiologists, that *colour* does not exist *as such* in the object itself; which has merely the power of reflecting or transmitting a certain number of millions of undulations in a second; and these only produce that affection of our consciousnses which we call colour, when they fall upon the retina of the living percipient. And if there be that defect either in the retina or in the apparatus behind it, which we call "colour-blindness" or Daltonism, some particular hues cannot be distinguished, or there may even be no power of distinguishing any colour whatever. If we were all like Dalton, we should see no difference, except in form, between ripe cherries hanging on a tree, and the green leaves around them: if we were all affected with the severest form of colour-blindness, the fair face of nature would be seen by us as in the *chiaroscuro* of an engraving of one of Turner's landscapes, not as in the glowing hues of the wondrous picture itself. And in regard to our visual conceptions, it may be stated with perfect certainty, as the result of very numerous observations made upon persons who have acquired sight for the first time, that these do *not* serve for the recognition even of those objects with which the individual had become most familiar through the touch, until the two sets of sense-perceptions have been co-ordinated by experience.*

When once this co-ordination has been effected, however, the composite perception of form which we derive from the visual sense alone is so complete, that we seldom require to fall back upon the touch for any further information respecting that quality of the object. So, again, while it is from the co-ordination of the two dissimilar pictures formed by any solid or projecting object upon our two retinæ, that (as Sir Charles Wheatstone's admirable investigations have shown) we ordinarily derive through the sight alone a correct notion of its *solid* form, there is adequate evidence that this notion, also, is a mental *judgment* based on the experience we have acquired in early infancy by the consentaneous exercise of the visual and tactile senses.

Take, again, the case of those wonderful instruments by which our visual range is extended almost into the infinity of space, or into the infinity of minuteness. It is the mental not the bodily eye, that takes cognizance of what the telescope and the microscope reveal to us. For we should have no well-grounded confidence in their revelations as to the *unknown*, if we had not first acquired experience in distinguishing the true from the false by applying them to *known* objects; and every interpretation of what we see through their instrumentality is a *mental judgment* as to the probable form, size, and movement of bodies removed by either their distance or their minuteness from being cognosced by our sense of touch.

The case is still stronger in regard to that last addition to our scientific *armamentum*, which promises to be not inferior in value either to the telescope or the microscope; for it may be truly said of the spectroscope, that it has not merely extended the range of our vision, but has almost given us a new sense, by enabling us to recognize distinctive properties in the chemical elements which were previously quite unknown. And who shall now say that we know all that is to be known as to any form of matter; or that the science of the *fourth* quarter of this century may not furnish us with as great an enlargement of our knowledge of its properties, and of our power of recognizing them, as that of its *third* has done?

But, it may be said, is not this view of the material universe open to the imputation that it is "evolved out of the depths of our own consciousness"—a projection of our own intellect into what surrounds us—an *ideal* rather than a *real* world? If all we know of matter be an "intellectual conception," how are we to distinguish this from such as we form in our dreams?—for these, as our laureate no less happily than philosophically expresses it, are "true while they last." Here our "common sense" comes to the rescue. We "awake, and behold it was a dream." Every healthy mind is conscious of the difference between his waking and his dreaming experiences; or, if he is now and then puzzled to answer the question, "Did this really happen, or did I dream it?" the perplexity arises from the consciousness that it *might* have happened. And every healthy mind, finding its own experiences of its waking state not only self-consistent, but consistent with the experiences of others, accepts them as the basis of his beliefs, in preference to even the most vivid recollections of his dreams.

The lunatic pauper who regards himself as a king, the asylum in which he is confined as a palace of regal splendour, and his keepers as obsequious attendants, is so "possessed" by the conception framed by his disordered intellect, that he *does* project it out of himself into his surroundings; his refusal to admit the corrective teaching of common sense being the very essence of his malady. And there are not a few persons abroad in the world, who equally resist the teachings of educated common sense, whenever they run counter to their own preconceptions; and who may be regarded as—in so far—affected with what I once heard Mr. Carlyle pithily characterize as a "diluted insanity."

It has been asserted over and over again, of late years, by a class of men who claim to be the only true interpreters of nature, that we know nothing but matter and the laws of matter, and that force is a mere fiction of the imagination. May it not be affirmed, on the other hand, that while our notion of *matter* is a conception of the intellect, *force* is that of which we have the *most* direct—perhaps even the *only* direct—cognizance? As I have already shown you, the knowledge of resistance and of weight which we gain through our tactile sense is derived from our own perception of *exertion*; and in vision, as in hearing, it is the force with which the undulations strike the sensitive surface that affects our consciousness with sights or sounds. True it is that in our visual and auditory sensations we do not, as in our tactile, *directly* cognosce the force which produces them; but the physicist has no difficulty in making sensible to us indirectly the undulations by which sound is propagated, and in proving to our intellect that the force concerned in the transmission of light is really enormous.*

It seems strange that those who make the loudest appeal to experience as the basis of all knowledge, should thus disregard the most constant, the most fundamental, the most direct of all experiences; as to which the common sense of mankind affords a guiding light much clearer than any that can be seen through the dust of philosophical discussion. For, as Sir John Herschel most truly remarked, the universal consciousness of mankind is as much in accord in regard to the existence of a real and intimate connection between cause and effect, as it is in regard to the existence of an external world; and that consciousness arises to every one out of his own sense of *personal* exertion in the origination of changes by his individual agency.

Now while fully accepting the logical definition of cause as the "antecedent or concurrence of antecedents on which the effect is invariably and unconditionally consequent," we can always single out one *dynamical* an-

---

* Thus, in a recently recorded case in which sight was imparted by operation to a young woman who had been blind from her birth, but who had nevertheless learned to work well with her needle, when the pair of scissors she had been accustomed to use was placed before her, though she described their shape, colour, and glistening metallic character, she was utterly unable to recognize them *as scissors* until she put her finger on them, when she at once named them, laughing at her own stupidity (as she called it) in not having made them out before.

* See Sir John Herschel's 'Familiar Lectures on Scientific Subjects.'

tecedent—the power which does the work—from the aggregate of *material conditions* under which that power may be distributed and applied. No doubt the term cause is very loosely employed in popular phraseology; often (as Mr. Mill has shown) to designate the occurrence that immediately preceded the effect; as when it is said that the spark which falls into a barrel of gunpowder is the cause of its explosion, or that the slipping of a man's foot off the rung of a ladder is the cause of his fall. But even a very slightly trained intelligence can distinguish the power which acts in each case, from the conditions under which it acts. The force which produces the explosion is locked up, as it were, in the powder; and ignition merely liberates it, by bringing about new chemical combinations. The fall of the man from the ladder is due to the gravity which was equally pulling him down while he rested on it; and the loss of support, either by the slipping of his foot, or by the breaking of the rung, is merely that change in the material conditions which gives the power a new action.

Many of you have doubtless viewed with admiring interest that truly wonderful work of human design, the Walter Printing Machine. You first examine it at rest; presently comes a man who simply pulls a handle towards him; and the whole inert mechanism becomes instinct with life,—the blank paper continuously rolling off the cylinder at one end, being delivered at the other, without any intermediate human agency, as large sheets of print, at the rate of 15,000 in an hour. Now what is the *cause* of this most marvellous effect? Surely it lies essentially in the power or force which the pulling of the handle brought to bear on the machine from some extraneous source of power,—which we in this instance know to be a steam-engine on the other side of the wall. This force it is, which, distributed through the various parts of the mechanism, really performs the action of which each is the instrument; *they* only supply the vehicle for its transmission and application. The man comes again, pushes the handle in the opposite direction, detaches the machine from the steam-engine, and the whole comes to a stand; and so it remains, like an inanimate corpse, until recalled to activity by the renewal of its moving power.

But, say the reasoners who deny that force is anything else than a fiction of the imagination, the revolving shaft of the steam-engine is "matter in motion;" and when the connection is established between that shaft and the one that drives the machine, the *motion* is communicated from the former to the latter, and thence distributed to the several parts of the mechanism. This account of the operation is just what an observer might give, who had looked on with entire ignorance of everything but what his *eyes* could *see*; the moment he puts his *hand* upon any part of the machinery, and tries to stop its motion, he takes as direct cognizance, through his sense of the effort required to resist it, of the *force* which produces that motion, as he does through his *eye* of the motion itself.

Now, since it is universally admitted that our notion of the external world would be not only incomplete, but erroneous, if our visual perceptions were not supplemented by our tactile, so, as it seems to me, our interpretation of the phenomena of the Universe must be very inadequate, if we do not mentally co-ordinate the idea of force with that of motion, and recognize it as the "efficient cause" of those phenomena,—the "material conditions" constituting (to use the old scholastic term) only "their formal cause." And I lay the greater stress on this point, because the mechanical philosophy of the present day tends more and more to express itself in terms of *motion* rather than in terms of *force*,—to become *kinetics* instead of *dynamics*.

Thus from whatever side we look at this question,—whether the common sense of mankind, the logical analysis of the relation between cause and effect, or the study of the working of our own intellects in the interpretation of nature,—we seem led to the same conclusion; that the notion of *force* is one of those elementary forms of thought with which we can no more dispense, than we can with the notion of space or of succession. And I shall now, in the last place, endeavour to show you that it is the substitution of the dynamical for the mere phenomenal idea, which gives their highest value to our conceptions of that order of nature, which is worshipped as itself a God by the class of interpreters whose doctrine I call in question.

The most illustrative as well as the most illustrious example of the difference between the mere generalization of phenomena and the dynamical conception that applies to them, is furnished by the contrast between the so-called laws of planetary motion discovered by the persevering ingenuity of Kepler, and the interpretation of that motion given us by the profound insight of Newton. Kepler's three laws were nothing more than comprehensive statements of certain groups of phenomena determined by observation. The *first*, that of the revolution of the planets in elliptical orbits, was based on the study of the observed places of Mars alone; it might or might not be true of the other planets; for so far as Kepler knew, there was no reason why the orbits of some of them might not be the excentric circles which he had first supposed that of Mars to be. So Kepler's *second* law of the passage of the Radius Vector over equal areas in equal times, so long as it was simply a generalization of facts in the case of that one planet, carried with it no *reason* for its applicability to other cases, except that which it might derive from his erroneous conception of a whirling force. And his *third* law was in like manner simply an expression of a certain harmonic relation which he had discovered between the times and the distances of the planets, having no more rational value than any other of his numerous hypotheses.

Now the Newtonian "laws" are often spoken of as if they were merely *higher generalizations* in which Kepler's are included; to me they seem to possess an altogether different character. For starting with the conception of two *forces*, one of them tending to produce continuous uniform motion in a straight line, the other tending to produce a uniformly accelerated motion towards a fixed point, Newton's wonderful mastery of geometrical reasoning enabled him to show that, if these *dynamical* assumptions be granted, Kepler's *phenomenal* "laws," being necessary consequences of them, must be *universally* true. And while that demonstration would have been alone sufficient to give him an imperishable renown, it was his still greater glory to divine that the fall of the moon towards the earth—that is, the deflection of her path from a tangetial line to an ellipse—*is a phenomenon of the same order* as the fall of a stone to the ground; and thus to show the applicability to the entire universe, of those simple dynamical conceptions which constitute the basis of the geometry of the Principia.

Thus, then, whilst no "law" which is simply *a generalization of phenomena* can be considered as having any *coercive* action, we may assign that value to laws which express *the universal conditions of the action of a force*, the existence of which we learn from the testimony of our own consciousness. The assurance we feel that the attraction of gravitation *must* act under all circumstances according to its one simple law, is of a very different order from that which we have in regard (for example) to the laws of chemical attraction, which are as yet only generalizations of phenomena. And yet even in that strong assurance, we are required by our examination of the basis on which it rests, to admit a *reserve* of the *possibility* of something different; a reserve which we may well believe that Newton himself must have entertained.

A most valuable lesson as to the allowance we ought always to make for the unknown "possibilities of nature" is taught us by an exceptional phenomenon so familiar that it does not attract the notice it has a right to claim. Next to the law of the universal attraction of masses of matter, there is none that has a wider range than that of the *expansion of bodies by heat*. Excluding water and one or two other substances, the fact of such expansion might be said to be *invariable*; and, as regards bodies whose gaseous condition is known, the law of expansion can be stated in a form no less simple and definite than the law of gravitation. Supposing those exceptions, then, to be unknown, the law would be *universal* in its range. But it comes to be discovered that water, whilst conforming to it in its expansion from 39½° *upwards* to its boiling-point, as also, when it passes into steam, to the special law of expansion of vapours, is exceptional in its *expansion* also from 39½° *downwards* to its freezing-point; and of this failure in the universality of the law, no rationale can be given. Still more strange is it, that by dissolving a little *salt* in water, we should remove this exceptional peculiarity; for *sea*-water continues to contract from 39½° downwards to its freezing-point 12° or 14° lower, just as it does with reduction of temperature at higher ranges.

Thus from our study of the mode in which we arrive at those conceptions of the orderly sequence observable in the phenomena of nature which we call "laws," we are led to the conclusion that they are human conceptions, subject to human fallibility; and that they *may* or *may not* express the ideas of the Great Author of Nature. To set up these laws as self-acting, and as either excluding or rendering unnecessary the power which alone can give them effect, appears to me as arrogant as it is unphilosophical. To speak of *any* law as "regulating" or "governing" phenomena, is only permissible on the assumption that the law is the expression of the *modus operandi* of a governing power. I was once in a great city which for two days was in the hands of a lawless mob. Magisterial authority was suspended by timidity and doubt; the force at its command was paralysed by want of resolute direction. The "laws" were on the statute book, but there was no power to enforce them. And so the powers of evil did their terrible work; and fire and rapine continued to destroy life and property without check, until new power came in, when the reign of law was restored.

And thus we are led to the culminating point of man's intellectual interpretation of nature,—his recognition of the unity of the power, of which her phenomena are the diversified manifestations. Towards this point all scientific inquiry now tends. The convertibility of the physical forces, the correlation of these with the vital, and the intimacy of that *nexus* between mental and bodily activity, which, explain it as we may, cannot be denied, all lead upward towards one and the same conclusion; and the pyramid of which that philosophical conclusion is the apex, has its foundation in the primitive instincts of humanity.

By our own remote progenitors, as by the untutored savage of the present day, every change in which human agency was not apparent was referred to a particular animating intelligence. And thus they attributed not only the movements of the heavenly bodies, but all the phenomena of nature, each to its own deity. These deities were invested with more than human power; but they were also supposed capable of human passions, and subject to human capriciousness. As the uniformities of nature came to be more distinctly recognized, some of these deities were invested with a dominant control, while others were supposed to be their subordinate ministers. A serene majesty was attributed to the greater gods who sit above the clouds; whilst their inferiors might "come down to earth in the likeness of men." With the growth of the scientific study of nature, the conception of its harmony and unity gained ever-increasing strength. And so among the most enlightened of the Greek and Roman philosophers, we find a distinct recognition of the idea of the unity of the directing mind from which the order of nature proceeds; for they obviously believed that, as our modern poet has expressed it,—

"All are but parts of one stupendous whole,
Whose body nature is, and God the soul."

The science of modern times, however, has taken a more special direction. Fixing its attention exclusively on the *order* of nature, it has separated itself wholly from theology, whose function it is to seek after its *cause*. In this, science is fully justified, alike by the entire independence of its objects, and by the historical fact that it has been continually hampered and impeded in its search for the truth as it is in nature, by the restraints which theologians have attempted to impose upon its inquiries. But when science, passing beyond its own limits, assumes to take the place of theology, and sets up its own conception of the *order* of nature as a sufficient account of its *cause*, it is invading a province of thought to which it has no claim, and not unreasonably provokes the hostility of those who ought to be its best friends.

For whilst the deep-seated instincts of humanity, and the profoundest researches of philosophy, alike point to mind as the one and only source of power, it is the high prerogative of science to demonstrate the *unity* of the power which is operating through the limitless extent and variety of the universe, and to trace its *continuity* through the vast series of ages that have been occupied in its evolution.

Parliamentary and Law Proceedings.

Duties of Employers towards their Apprentices.

At the Maldon County Court, on Thursday, August 15th, an action was brought by the Rev. E. R. Horwood and the Rev. G. Tamplin, two of the trustees of Dr. Plume's charity, and Mr. Charles Smith, tailor, Maldon, against Mr. James Henry Trist, of 106, East India-road, Poplar, chemist, for breach of a covenant contained in apprenticeship indenture between the plaintiffs and defendant, and by which Thomas Arthur Smith (son of the plaintiff Charles Smith) was apprenticed to the defendant for five years, from May, 1871, to learn the businesses of a chemist, druggist and dentist.

Mr. A. Evans appeared for the plaintiffs, but the defendant did not attend.

It appeared from the opening statement of Mr. Evans to the jury and the evidence of the apprentice that in May, 1871, the lad went on trial at defendant's shop with a view of entering into apprenticeship. He was there six weeks, and during that time the master expressed himself quite satisfied with all he did, and gave expression to no complaint as to the lad's education, memory, or aptitude for the business, In consequence of this an indenture of apprenticeship was prepared at a premium of £65, £32. 10s. of which was paid down—£15 by Dr. Plume's trustees, and £17. 10s. by plaintiff, Charles Smith. In the indenture the defendant obliged himself "to use his best endeavours to teach and instruct, or cause to be taught and instructed, the apprentice in the several businesses." Almost immediately afterwards defendant commenced complaining of everything which he did, and those things which before the apprenticeship had been done to defendant's satisfaction were afterwards always objected to by him. The employment had consisted chiefly in mixing up and retailing out seidlitz powders, salts and senna, and other small articles, and in mixing pills, the defendant taking care not to allow his apprentice to know the nature of the drugs and ingredients of the latter, or the purpose for which they were made. No books were provided for the lad's reading; and even if they had been he was allowed no time for the purpose, being engaged in the shop from seven a.m. till ten and eleven p.m. In addition to the above duties he had had to clean the shop, the stoves, shake mats, and perform other menial offices usually executed by a shop-boy. Except on two or three occasions no lessons were given by the master to the apprentice, and when any information was sought by the latter of the former it was refused. Matters so continued up till December, when in answer to an application from the father for a report of his son's progress, defendant wrote a letter stating that, in consequence of defective education and memory, the apprentice was not suited for the business, and that a mechanical employment would be more suitable for him; to which the father replied that this did not absolve defendant from performing his covenant. In February of this year, defendant offered to return the premium, but then altered his mind, saying that if any one could make the lad a chemist he could, and should not part with him, but promised the father to put him through a severe course of study, giving not less than three lessons a week. This was not carried out; but from this time till May or June defendant entirely neglected him, and refused to give the slightest instruction; but on the contrary left the shop daily to the care of the apprentice, and at night returned and abused him for not having done more business. In May defendant gave the lad a black eye, and apologized for having done so to the father, and on June 1st the apprentice was sent home by the defendant, and it appeared with as little knowledge of chemistry and dentistry as he had carried with him. No effort had been made to prepare the lad for his Minor examination. Under these circumstances, Mr. Evans submitted that the plaintiffs were entitled to be put into the same position as they were on before the indenture was executed, and that the defendant could not and ought not to be allowed to retain the plaintiffs' money when he had entirely failed to perform the consideration for which it was paid.

As the defendant did not appear, the Judge at once summed up, instructing the jury that if they believed the defendant had not used his best means to instruct they should find a verdict for the plaintiffs.

The jury at once found a verdict for £32. 10*s.*, and his Honour ordered defendant to pay plaintiffs' taxed costs and expense of witnesses, with immediate execution.—*Chelmsford Chronicle.*

Correspondence.

Provincial Education.

Sir,—In justice to myself I must notice a letter from 'Country Major Associate,' in your issue of August 3rd. Your correspondent writes as follows: "With regard to the subject of payment for results, 'G. T.' says that I had better leave the matter in abler hands." Now it is a pity that when he referred to my letter to find out the date, he did not look to see what it was I really did say. If he will take the trouble to look again, he will find the expression used by me runs as follows: "With regard to the subject of payment for results, 'Country Major Associate,' had better leave it in the hands of Mr. Schacht, as I do not think he will find abler ones to grapple with it?" Now this is very different from what 'Country Major Associate' makes me say.

Your correspondent thinks, or rather fancies, that Mr. Schacht's scheme cannot be adopted by the Society, on account of "the objection of examined men to allow some of the interest of their money deposited in the Society, to be distributed to the students of the country." Would it surprise him to learn that Mr. Schacht's scheme has already been adopted by the Council? And though I dare say many ('Country Major Associate' amongst them) would much prefer to see the annual surplus invested in Consols, than spread abroad, doing good to their own class, yet it is a great comfort to think that as they unfortunately happen to be in a minority, they cannot have it their own way.

There seem to be a little "Bunkum" in 'Country Major Associate's' account of his own case. In the present state of the trade, "examined pharmaceutists" are in but a small minority, and of this learned few, how many "delight to teach"? Your correspondent must excuse me if I doubt the statement that his pharmacy contains more specimens than the local museums, or his library more and better books than the local library, at least I should not think that is the case, with respect to the Norwich Association.

In the Journal of the 10th we have served up, cut and dried, an ideal representation of "the Society, local committee, teacher and student," under the scheme of Mr. Schacht. Somewhere or other, I remember to have met with an old proverb, so old indeed, that even if 'Country Major Associate' had met with it, I doubt if he would have paid any attention to it, and it ran something to the effect that, "An ounce of practice was worth a pound of theory," and I think it very applicable to 'Country Major Associate's' ideal representation. For my own part, I cannot see what there is in this representation so formidable that the Society could not overcome it. With regard to his sneer at the lower middle classes, let him remember that from this class have risen, greater, nobler, and better men than from all the wealthy aristocrats put together. Did he never hear of Faraday, of Brindley, or of Stephenson? To my way of thinking it is more creditable for the son of a "policeman, coastguardsman, artisan, or small shopkeeper," to work his way up to a responsible and respectable position in life, than it is for the son of a wealthy man who has no end of advantages in money, tutors, etc. 'Country Major Associate' seems as if he would make worldly prosperity the standard, whereby to judge a man, instead of mental ability. Who are those men whose names stand foremost in Science, Art, and Commerce? They are the men who work, who have stern necessity to spur them forward, and with whom work has become a duty, a pleasure, and a habit. I admire and support Mr. Schacht's scheme because it does what is so distasteful to 'Country Major Associate,' that is, it helps those who need help, those whom 'Country Major Associate' styles the lowest class of chemists, those who with the glorious example of Faraday before them, will in future time form the backbone of our trade, raising it to a high scientific position with a fair commercial prosperity, Ask those who have had experience in teaching of any sort, not particularly pharmacy, who are the hardest workers, and who need the most help, and they will tell you that they are those who have only their hands and head to depend on, and that the son of a coastguardsman or shopkeeper has before now come to stand before "Kings and princes." And this is where Mr. Schacht's scheme so admirably fits in, it does not aid indiscriminately, but the more a student works the more is he helped and rewarded. If there is any fault in the scheme, it is that it makes the interest of the student to a certain degree secondary to that of the local association. I think that every student who can pass the required examination should be rewarded and stimulated to further exertion whether he belongs to a local association or whether he does not.

G. T.

Norwich, August 12th.

C. Hutchinson.—We believe the person mentioned is still living; probably his address is given in the 'Medical Directory.'

J. Barker, F. Clayton, and *J. D. Jenkinson* are thanked for their communication.

In consequence of a press of matter we are again compelled to defer the publication of several communications.

Communications, Letters, etc., have been received from Mr. E. B. Vizer, Mr. D. Hanbury, Mr. W. Geddes, Mr. Severs, Mr. J. F. Brown, Mr. F. Andrews, Mr. W. Smeeton, Mr. E. C. Ellis, Messrs. Gard and Co., Mr. Yewdall, "Chemist," "Quinia," "Secretary of Newcastle Chemists' Assistants' Association," "Ex-Student at Bloomsbury Square," "Not Happy," Z.

The following journals have been received:—The 'British Medical Journal,' August 17; the 'Medical Times and Gazette,' August 17; the 'Lancet,' August 17; the 'Medical Press and Circular,' August 17; the 'Chemical News,' August 17; 'English Mechanic,' August 17; 'Gardeners' Chronicle,' August 17; the 'Grocer,' August 17; the Journal of the Society of Arts,' August 17; Grocery News,' August 17.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from page* 104.)

PODOPHYLLI RADIX.—The structure of the root of *Podophyllum peltatum* is strikingly dissimilar to any I have hitherto described, and presents several interesting features.

The first thing which will strike the observer on examining a thin cross section is the singular roundness of the large cells of which the major portion of the root is composed. The centre of the root is composed of sub-cylindrical cells, sometimes overlapping each other at their junction by a finger-like extension, which in cross section might be mistaken for a large aggregation of the intercellular substances of Mulder. The adhesion of these cells in linear series is remarkable, and it is easy to separate them into long columns by a short maceration in warm water. They contain great quantities of starch imbedded in a semi-albuminous substance, the deportment of which differs slightly from that of the usual protoplasmic cell contents, with which it is probably intimately allied, but is slightly admixed with dextrinous (?) matter.

A very incomplete vascular ring separates this structure from the cortical series. The vascular wedges are usually completely isolated, and are small in proportion to the diameter of the root. The vessels are pitted with long narrow pits, and might almost be considered to be scalariform vessels, were it not that they are oval, or circular, in cross section. Their walls are very thin. With the vessels are associated delicate liber cells and canaliculi, which contain the dark yellowish-brown resinous matter which is sometimes transfused into the vessels and stains them deeply.

The cells of the cortical layers vary in size and shape from precisely similar cells to those of the central portion to the compressed cells of the outermost portion. In no case do they present special features other than already noticed. It follows, as a matter of course, from the circular, or oval, cross outline of the parenchymatous cells that their adhesion to each other is very incomplete. What would otherwise be intercellular spaces are filled, sometimes with intercellular substance of a complex and very variable character, and sometimes with a finger-like protrusion of one of the contiguous cells. This latter is the most rare occurrence by far. The behaviour of the intercellular substance with the usual reagents is perplexing and somewhat contradictory. In many cases nitrate of silver stains it intensely; in other cases, in the same section, this reagent appears inert. Magenta usually, but not invariably, stains it intensely. Iodine always stains it yellow. A solution of iodine and iodide of potassium in water dissolves it and isolates the cells. Sulphuric and nitric acids, in a dilute form, attack it very slowly. Benzole and alcohol have no sensible action upon it.

The starch granules present are usually separate granules, modified in shape by pressure within the cell with a distinct punctate, often radiate, hilum; and are intensely bi-refractive, giving the usual black cross with polarized light.

The sphæraphides abundantly present are remarkable for their great size and beauty, and are arranged linearly by the side of the vascular bundles and distributed, also in linear series, through the central, and innermost cortical portion of the root. Each sphæraphide is contained in a delicate cell, a little larger than itself, and containing a hyaline semi-fluid matter, apparently protoplasmic. The projections of the compound crystal are coated with some substance which can be intensely stained with nitrate of silver if very carefully applied in a weak solution. The isolation of these special cells and their contents is perfectly easy; maceration in water containing a little potash is sufficient, or, and this is not difficult, the cells being large, they may be isolated by simple dissection. Solution of gum arabic in water, to which has been added either camphor or arsenious acid, is the best medium in which to mount either the isolated sphæraphidian cells or sections of the root. The latter do not mount satisfactorily.

NOTES ON PEPSIN AND BISMUTH, AND ELIXIR OF PEPSIN AND BISMUTH.

BY E. SCHEFFER.

Several facts which I published in a previous essay,* impressed on me the impossibility of a preparation such as elixir pepsin, bismuth (and strychnine.) I do not want to speak again about the presence of alcohol in a solution containing pepsin, as I have repeatedly given the results of my experiments, which prove, beyond doubt, that pepsin and alcohol, particularly when the latter amounts to a certain percentage, are incompatible.

The main objection I intended to bring against such an elixir, prepared with ammonio-citrate of bismuth in a neutral or alkaline solution, is the neutral or slightly alkaline state. My experiments prove clearly that pepsin, in neutral solution, does not keep, and that in alkaline solution it loses its digestive properties. In how minute quantities the presence of an alkali destroys the digestive properties of pepsin, will be shown by the following experiments, quite recently made.

Having once taken our well water—which contains carbonate of lime and magnesia—instead of distilled water, to swell the pepsin, before the acid was added, I was astonished to find that the pepsin did not act on albumen. This caused me to repeat the experiment simultaneously with others for control.

A. Pepsin swelled in distilled water; the acid (6 drops of muriatic acid to the fluid ounce) added afterwards.

B. Pepsin swelled in well-water, and 6 drops of acid added to 1 oz. after 2 hours.

C. Pepsin swelled in distilled water, which had been shaken with carbonate of magnesia, for two days, and then filtered; 6 drops of acid added after two hours.

D. Pepsin dissolved in acidulated well water.

Of these four experiments each contained the same amount of acid, the same amount of pepsin, and to each vial the same amount of coagulated albumen was added. After having been exposed to a temperature of 105° Fahr. for six hours, in A and D all the albumen was dissolved, while in B and C the albumen did not appear to have been acted upon.

Therefore, in C, the small quantity of magnesia

* Am. Jour. Phar., Feb., 1872, and Pharm. Journ. [3] ii. 761.

which the distilled water had dissolved, and with which quantity the pepsin had been in contact before the acid was added, was sufficient to modify the pepsin and destroy its digestive action on fresh coagulated albumen. In B, the carbonates of the well water had caused the same result. In D, the carbonates were destroyed by the addition of acid before the pepsin was added, and therefore the albumen was easily dissolved. Such proofs, I think, must necessarily convince the most sceptical.

The physician might wish for a combination of pepsin and bismuth in the liquid state, but another question is, can such a combination be made, or can it exist? Those that manufactured the elixir of pepsin and bismuth (and strychnine), were satisfied to know that they used pepsin in its preparation, but whether it was in it or in an active form, never troubled them, as they never tested for it. They could conscientiously put their label on the bottle, and maintain that they used pepsin in its preparation. The physician prescribed it in good faith, because he had confidence in the firm who made it, and in the name by which the preparation was designated.

Having tested several elixirs of pepsin and bismuth that I was able to obtain I found that even after the addition of hydrochloric acid not the least quantity of albumen was dissolved.

Thinking that an acidulated bismuth solution might, in combination with pepsin, prove more efficacious, containing the pepsin in its active form, my first aim was to find a bismuth salt for that purpose.

Crystallized ternitrate of bismuth dissolves in glycerine, which solution can be diluted with a considerable quantity of water before the subnitrate is precipitated. This salt I dropped from the list, as the solution is too acid, and the taste too styptic.

Freshly precipitated subnitrate of bismuth, prepared with one part of crystallized ternitrate with 40 parts of water was put on a filter, and when entirely drained added to glycerine, in which it dissolves, forming a clear solution, but on the addition of water the clear solution becomes milky after some time.

I now tried the action of acids on ammonio-citrate of bismuth. For that purpose I made two solutions of ammonio-citrate of bismuth of the same strength, with the difference that the one solution was made with water alone, and the other with a mixture of glycerine and water. To these solutions were now added different acids, and the following results obtained: Mineral acids gave in both solutions immediately a precipitate. By the addition of organic acids, such as acetic, lactic and citric, both solutions kept clear, but after a lapse of several hours the pure water solutions became milky, and by longer standing deposited a white precipitate, while in the solutions containing glycerine an opalescence did not show itself before twenty-four hours.

Judging that a small quantity of organic acid, sufficient to dissolve the pepsin, would not give even an opalescence in a solution of ammonio-citrate of bismuth containing glycerine, I thought that a glycerole could be made containing pepsin as well as bismuth, etc.; but by mixing the pepsin solution with the solution of the bismuth salt, the pepsin was precipitated in the same characteristic form as it is precipitated from its solutions by chloride of sodium.

Having at first intended to make the glycerole contain in the pint 128 grains ammonio-citrate of bismuth, 256 grains of saccharated pepsin (respectively 1 and 2 grains to the fluid drachm), 1 fluid drachm of lactic acid, 8 fluid ounces glycerine, and 8 ounces of water, I thought that by making it only half as strong in bismuth and pepsin it might answer, but the pepsin was in this instance also precipitated. The ingredients were put together in four different ways, but in all with the same result.

This negative result proves clearly that the pepsin is precipitated from its solution by the bismuth salt, and as I have proven in my essay (Feb. 1872), that a watery solution of pepsin is precipitated by chloride of sodium in the same way as an acidulated one, we must infer that the bismuth salt acts in the same manner, and that therefore the elixir of pepsin and bismuth, as it was made, *cannot contain any pepsin.*

Abstracting, therefore, from the alcohol, and not speaking of the neutral or alkaline solution, the elixir of pepsin and bismuth is an incongruity, and when patients have derived any benefit from it, it has been from the bismuth it contained, and the stimulating effect of the spirits, but surely not from the pepsin, *as it does not contain any pepsin.—Amer. Journ. Pharmacy.*

ORGANIC CHEMISTRY AND THERAPEUTICS.*

BY A. W. HOFMANN.

(Continued from p. 146.)

There is no need to establish an artificial line of demarcation. The group of hydrocarbons and their derivatives are clearly distinguished from the rest of the chemical edifice. Born from the union of two powerful radicals, carbon and hydrogen, these bodies can, under the influence of a small number of elements, give birth to innumerable compounds, which, spite of the infinite variety of their properties, bear all of them the mark of one indubitable parent; they are the primary matter from which plants and animals are formed. The group unites an assemblage of properties such as are not present in any other class of combinations, and which, if they do not permit the drawing of a well-defined line of demarcation, are sufficient to justify the consideration of these bodies as a distinct group.

But what is the influence which the researches in the field so defined have exercised upon the development of therapeutics? The chief features only of the principal services rendered by chemistry to therapeutics can here be indicated. In his early studies upon the substance of plants and animals the chemist is led to use analytical methods, and at starting it is only by analytical facts that therapeutics profits by the progress of chemistry. The physician is enabled for the first time to recognize the active principles of a series of medicaments long employed with success, and in many cases these active principles when indicated by science have been substituted for the mixture, often so disagreeable, the properties of which have only been discovered by chance or by empiricism.

An interesting example is found in the time when the study of organic chemistry first began to occupy the attention of chemists. The poisonous properties of bitter almonds (*Amygdalus communis*) had been indicated from antiquity. It was known also at the commencement of the eighteenth century that the leaves of the cherry-laurel (*Prunus lauro-cerasus*) furnished an oil possessing poisonous properties, and in the closing years of the same century, cherry-laurel water was already employed as a medicament. But at that time the nature of the active principle contained in bitter almonds and in cherry-laurel water was not yet suspected; and it was only at the commencement of the present century

---

* Lecture delivered at the Medical Chirurgical Institute of Berlin.

that Dohm recognized in water of bitter almonds the presence of prussic acid, discovered in 1782 by Scheele. Soon afterwards Gehlen and Schrader demonstrated that the above waters owed their remarkable physiological properties entirely to the presence of prussic acid, and in 1837 Liebig and Wohler proposed to substitute for these medicaments, always variable and uncertain in composition, solutions of prussic acid of known strength.

In the second decade of our century the labours of Sertürner resulted in a great progress in the same road. The study of the juice of various *Papaveraceæ*, known under the name of opium, led him to the discovery of morphine; to this latter was afterwards added a group of opium bases, among which should be mentioned codeine, discovered by Robiquet. The study of the *Rubiaceæ* and *Strychnaceæ* gave results not less important. Pelletier and Caventou discovered quinine and cinchonine in the cinchona bark and strychnine in the fruit of *Strychnos Nux-vomica* not to speak of other less important bases. In the place of opium, a complex substance, containing not less than six different alkaloids possessed of opposite properties; in the place of the powder or tincture of cinchona; in the place of the tincture or extract of nux-vomica; in the place, in one word, of mechanical mixtures, as variable in their medical properties as in their composition, the physician has now at his disposition morphine and codeine with their well crystallized salts, quinine and cinchonine, and finally strychnine and its salts,—chemical compounds of which the uniform action cannot be denied. Besides these the chemist has extracted from the *Digitalis purpurea* and *Artemisia*, their active principles, and the physician is thus enabled to substitute for the infusions and extracts of those plants digitaline and santonine, which are now obtained pure and well crystallized.

Another investigation, no less important therapeutically, has been that of the valerian root (*Valeriana officinalis*). It was found that its action was due to two different principles, oil of valerian and valerianic acid, both of which merit the attention of the chemist, and either of which is available for use by the physician. For the infusion of coffee or of tea, caffeine (theine) may now be substituted, and in the place of tincture of galls the physician may employ chemically pure tannic acid.

But the researches of organic chemistry have not been confined to substances already recognized as medicines; there is scarcely a plant, flower or fruit which it has not searched for active principles. Chemists discovered veratrine in the white hellebore (*Veratrum album*), atropine in the belladonna (*Atropa belladonna*); and quickly physicians utilized in the happiest manner the neurotic and febrifuge properties of the one, and the faculty of dilating the pupil possessed by the other.

Soon the researches made in the domain of organic chemistry took a fresh direction; they were no longer limited to submitting animal and vegetable matter to the action of solvents like water, alcohol and ether, or exhausting them by bases or dilute acids, or, in one word, decomposing them into their immediate principles. The most energetic reagents; substances greedy for water, such as sulphuric and phosphoric acids; oxidizing agents of all degrees of intensity, from fuming nitric acid, chromic acid, oxide of manganese and peroxide of lead or to oxygen obtained by electrolysis, rendered active by means of platinum black; chlorine, bromine, iodine; ammonia, in the gaseous state or in solution; the hydrated alkalies, in concentrated solution or even in a state of fusion,—all these bodies became the chemist's new instruments of research. And it was no longer only upon the principles already formed in the animal or vegetable organism that his researches were made.

In the presence of such powerful agents of decomposition, the primitive substances underwent more or less profound modifications, and these were the products of the decomposition of the elements of plants which the chemist had then in his hands. Here was an unexpected source of riches for the seekers. The same body, under the influence of different reagents, was found to undergo the most varied metamorphoses; and under different conditions of time, concentration and temperature, the same reagent produced upon the one body the most diverse modifications. Moreover, these products of decomposition of animal and vegetable substances were modified in their turn under the influence of chemical agents, until at last the successive substances led to the simplest combinations or even to the elements themselves. Aided by this new method of investigation, organic chemistry suddenly took a development which for a time completely relegated inorganic chemistry to the second place. But at the same time that the field of research was so enlarged, the number of labourers increased, and from their active hands soon issued the incontestable treasury of facts upon which to-day organic chemistry rests. At first these treasures were in chaos and confusion; men whom chance favoured with a valuable discovery and those who saw long efforts crowned at last by success frequently knew not what to do with their riches. But soon the spirit of order took up the task of classifying the mass of materials; it sought to test them and distinguish that which was important from that which was not, and to unite those which appeared analogous. When once order had taken the place of confusion, the eye was immediately arrested with admiration at the constitution of each substance, and at the marvellous bonds which connected all these bodies with each other.

(*To be continued.*)

THE AIMS AND INSTRUMENTS OF SCIENTIFIC THOUGHT.*

BY PROFESSOR CLIFFORD.

It is my duty to speak to you for a short time about the aims and instruments of scientific thought. It may have occurred (and very naturally too) to such as have had the curiosity to read the title of this lecture, that it must necessarily be a very dry and difficult subject, interesting to very few, intelligible to still fewer, and above all, utterly incapable of adequate treatment within the limits of a discourse like this. It is quite true that a complete setting forth of my subject would require a comprehensive treatise on logic, with incidental discussion of the main question of metaphysics; that it would deal with ideas demanding close study for their apprehension, and investigations requiring a peculiar taste to relish them. It is not my intention to present you with such a treatise this evening. The British Association, like the world in general, contains three classes of persons. In the first place it contains scientific thinkers, that is to say, persons whose thoughts have very frequently the characters which I shall presently describe. Secondly, it contains persons who are engaged in work upon what are called scientific subjects, but who, in general, do not, and are not expected to think about the subjects in a scientific manner. Lastly, it contains persons who suppose that their work and their thoughts are unscientific, but who would like to know something about the business of the other two classes aforesaid. Now, to any one who, belonging to one of these classes, considers either of the other two, it will be apparent that there is a certain gulf between him and them; that he does not quite understand them, nor they him; and that an opportunity for sympathy and comradeship is lost through this want of understanding. It is this gulf that I desire to bridge over, to the best of my power. That the scientific thinker may consider

* Lecture delivered before the British Association at Brighton, Monday, August 19th, 1872.

his business in relation to the great life of mankind; that the noble army of practical workers may recognize their fellowship with the outer world, and the spirit which must guide both; that this so-called outer world may see in the work of science only the putting in evidence of all that is excellent in its own work—may feel that the kingdom of science is within it. These are the objects of the present discourse, and you will see that they compel me to choose such portions of my vast subject as shall be intelligible to all, while they ought at least to command an interest universal, personal and profound. In the first place, then, I want to explain what is meant by scientific thought. You may have heard some of it expressed in the various sections this morning. You have probably also heard expressed in some places a great deal of unscientific thought, notwithstanding that it was about mechanical energy, or about hydrocarbons, or about eocene deposits, or about malacopterygii; for scientific thought does not mean thought about scientific subjects with long names. There are no scientific subjects. The subject of science is the human universe; that is to say, everything that is, or has been, or may be related to man. Let us, then, taking several topics in succession, endeavour to make out in what cases thought about them is scientific, and in what cases not. Ancient astronomers observed that the relative motions of the sun and moon recurred all over again in the same order about every nineteen years. They were thus enabled to predict the time at which eclipses would take place. A calculator at one of our observatories can do a great deal more than this. Like them, he makes use of past experience to predict the future; but he knows of a great number of other cycles besides that one of nineteen years, and takes account of all of them; and can tell about the solar eclipse of six years hence exactly where it will be visible, and how much of the sun's surface will be covered at each place, and, to a second, at what time of day it will begin and finish there. This prediction involves technical skill of the highest order; but it does not involve scientific thought, as any astronomer will tell you. By such calculations the places of the planet Uranus at different times of the year had been predicted and set down. The predictions were not fulfilled. Then arose Adams, and from these errors in the prediction he calculated the place of an entirely new planet, that had never yet been suspected; and you all know how the new planet was actually found in that place. Now this prediction does involve scientific thought, as any one who has studied it will tell you. Here there are two cases of thought about the same subject, both predicting events by the application of previous experience; yet we say that one is *technical* and the other *scientific*.

Now, let us take an example from the building of bridges and roofs. When an opening is spanned over by a material construction, which must bear a certain weight without bending enough to injure itself, there are two forms in which this construction can be made; the arch and the chain. Every part of an arch is compressed or pushed by the other parts; every part of a chain is in a state of tension, or is pulled by the other parts. In many cases these forms are united. A girder consists of two main pieces or booms, of which the upper one acts as an arch and is compressed, while the lower one acts as a chain and is pulled; and this is true even when both the pieces are quite straight. They are enabled to act in this way by being tied together, or braced, as it is called, by cross-pieces, which you must often have seen. Now, suppose that any good practical engineer makes a bridge or roof upon some approved pattern which has been made before, he designs the size and shape of it to suit the opening which has to be spanned, selects his material according to the locality, assigns the strength which must be given to the several parts of the structure according to the load which it will have to bear. There is a great deal of thought in the making of this design, whose success is predicted by the application of previous experience; it requires technical skill of a very high order, but it is not scientific thought. On the other hand, Mr. Fleming Jenkin designs a roof, consisting of two arches braced together, instead of an arch and a chain braced together, and although this form is quite different from any known structure, yet before it is built he assigns with accuracy the amount of material that must be put into every part of the structure in order to make it bear the required load, and this prediction may be trusted with perfect security. What is the natural comment upon this? Why, that Mr. Fleming Jenkin is a scientific engineer. Now it seems to me that the difference between scientific and merely technical thought, not only in these but in all other instances which I have considered, is just this. Both of them make use of experience to direct human action; but while technical thought or skill enables a man to deal with the same circumstances that he has met with before, scientific thought enables him to deal with different circumstances that he has never met with before. But how, you will say, can experience of one thing enable us to deal with another quite different thing? To answer this question we shall have to consider more closely the nature of scientific thought.

Let us take another example. You know that if you make a dot on a piece of paper, and then hold a piece of Iceland spar over it, you will see not one dot, but two. A mineralogist, by measuring the angle of a crystal, can tell you whether or not it possesses this property without looking through it. He requires no scientific thought to do that. But Sir William Rowan Hamilton, the late Astronomer Royal of Ireland, knowing these facts, and also an explanation of them which Fresnel had given, thought about the subject, and he predicted that, by looking through certain crystals in a particular direction, we should see not two dots but a continuous circle. Mr. Lloyd made the experiment and saw the circle, a result which had never been even suspected. This has always been considered one of the most signal instances of scientific thought in the domain of physics. It is not distinctly an application of experience gained under certain circumstances to entirely different circumstances. Now, suppose that the night before coming down to Brighton you had dreamed of a railway accident caused by the engine getting frightened at a flock of sheep, and jumping suddenly back over all the carriages, the result of which was that your head was unfortunately cut off, so that you had to put it in your hat-box and take it back home to be mended. There are, I fear, many persons even at this day who would tell you that after such a dream it was unwise to travel by railway to Brighton. This is a proposal that you should take experience gained while you are asleep, when as the President says, you have no common sense, experience about a phantom railway, and apply it to guide you when you are awake, and have common sense, in your dealing with a real railway. And yet this proposal is not dictated by scientific thought.

Now let us take the great example of Biology. I pass over the process of classification, which itself requires a great deal of scientific talk; in particular when a naturalist, who has studied and monographed a fauna or a flora, rather than a family, is able at once to pick out the distinguishing character required for the subdivision of an order quite new to him. Suppose that we possess all this minute and comprehensive knowledge of plants and animals and intermediate organisms, their affinities and differences, their structure and functions; a vast body of experience, collected by incalculable labour and devotion. Then comes Mr. Herbert Spencer; he takes that experience of life which is not human, which is apparently stationary, going on in exactly the same way from year to year, and he applies that to tell us how to deal with the changing characters of human nature and human society. How is it that experience of this sort, vast as it is, can guide us in a matter so different from itself? How does scientific thought, applied to the development of a kangaroo fœtus or the movement of the sapinexogen, make prediction possible for the first time in that most important of all sciences, the relations of man with man? In the dark or unscientific ages men had another way of applying experience to altered circumstances. They believed for example that the plant called Jew's-ear, which does bear a certain resemblance to the human ear, was a useful cure for diseases of that organ. This doctrine of signatures, as it was called, exercised an enormous influence on the medicine of the time. I need hardly tell you that it is hopelessly unscientific; yet it agrees with those other examples that we have been considering in this particular; that it applies experience about the shape of a plant, which is one circumstance connected with it, to dealings with its medicinal properties, which are other and different circumstances. Again, suppose that you had been frightened by a thunderstorm on land, or your heart had failed you in a storm at sea; if any one then told you that in consequence of this you should always cultivate an unpleasant sensation in the pit of your stomach, till you took a delight in it, that you should regulate your sane and sober life by the sensations of a moment of unreasoning terror; this advice would not be an example of scientific thought. Yet it would be an application of past experience to new and different circumstances. But you will already have observed what is the additional clause that we must add to our definition in order to describe scientific thought and that only. The step between experience about animals and dealings with changing humanity is the law of evolution. The step from calculated places of Uranus to the existence of Neptune is the law of gravitation. The step from observed behaviour of crystals to conical refraction is made up of laws of light and geometry. The step from old bridges to new ones is the laws of elasticity and the strength of materials. The step then from past experience to new circumstances must be made in accordance with an observed uniformity in the order of events. This uniformity has held good in the past in certain places; if it should also hold good in the future and in other places, then, being combined with our experience of the past, it enables us to predict the future, and to know what is going on elsewhere; so that we are able to regulate our conduct in accordance with this knowledge. I want to make a little clearer the fact that what you call the evidence for a thing depends upon the assumption that this uniformity is valid at places and times at which it has not been observed. The aim of scientific thought, then, is to apply past experience to new circumstances; the instrument is an observed uniformity in the course of events. By the use of this instrument it gives us information transcending our experience, it enables us to infer things that we have not seen from things that we have seen; and the evidence for the truth of that information depends, as we have seen, on our supposing that the uniformity holds good beyond our experience.

I now want to consider this uniformity a little more closely; to show how the character of scientific thought and the force of its inferences depend upon the character of the uniformity of nature. I cannot of course tell you all that is known of this character without writing an encyclopædia; but I shall confine myself to two points of it about which it seems to me that just now there is something to be said. I want to find out what we mean when we say that the uniformity of nature is *exact;* and what we mean when we say that it is *reasonable.* When a student is first introduced to those sciences which have come under the dominion of mathematics, a new and wonderful aspect of nature bursts upon his view. He has been accustomed to regard things as essentially more or less vague. All the facts that he has hitherto known have been expressed qualitatively, with a little allowance for error on either side. Things which are let go fall to the ground. A very observant man may know also that they fall faster as they go along. But our student is shown that, after falling for one second in a vacuum, a body is going at the rate of 32 feet per second; that after falling for two seconds, it is going twice as fast; after going two and a half seconds, two and a half times as fast. If he makes the experiment, and finds a single inch per second too much or too little in the rate, one of two things must have happened: either the law of falling bodies has been wrongly stated, or the experiment is not accurate; there is some mistake. He finds reason to think that the latter is always the case; the more carefully he goes to work, the more the error turns out to belong to the experiment. Again, he may know that water consists of two gases, oxygen and hydrogen combined together; but he now learns that two pints of steam at a temperature 150 deg. centigrade will always make two pints of hydrogen and one pint of oxygen at the same temperature; all of them being pressed as much as the atmosphere is pressed. If he makes the experiment and gets rather more or less than a pint of oxygen, is the law disproved? No; the steam was impure, or there was some mistake. Myriads of analyses attest the law of combining volumes; the more carefully they are made, the more nearly they coincide with it. The aspects of the faces of a crystal are connected together by a geometrical law, by which, four of them being given, the rest can be found. The place of a planet at a given time is calculated by the law of gravitation; if it is half a second wrong, the fault is in the instrument, the observer, the clock or the law; now, the more observations are made the more of this fault is brought home to the instrument, the observer and the clock. It is no wonder then that our student, contemplating these and many like instances, should be led to say, "I have been shortsighted; but I have now put on the spectacles of science, which nature has prepared for my eyes; I now see that things have definite outlines, that the world is ruled by exact and rigid mathematical laws; "Kai su, theos, geometreis." It is our business to consider whether he is right in so concluding. Is the uniformity of nature absolutely exact, or only more exact than our experiments? At this point we have to make a very important distinction. There are two ways in which a law may be inaccurate. The first way is exemplified by that law of Galileo which I mentioned just now; that a body falling in vacuo acquires equal increase of velocity in equal times. No matter how many feet per second it is going, after an interval of a second it will be going thirty-two *more* feet per second. We now know that this rate of increase is not exactly the same at different heights, that it depends upon the distance of the body from the centre of the earth; so that the law is only approximate; instead of the increase of velocity being exactly *equal* in equal times, it itself increases very slowly as the body falls. We know also that this variation of the law from the truth is *too small to be perceived* by direct observation on the change of velocity. But suppose we have invented means for observing this, and have verified that the increase of velocity is inversely as the squared distance from the earth's centre. Still the law is not accurate; for the earth does not attract accurately towards her centre, and the direction of attraction is continually varying with the motion of the sea; the body will not even fall in a straight line. The sun and the planets, too, especially the moon, will produce deviations; yet the sum of all these errors will escape our new process of observation, by being a great deal smaller than the necessary errors of that observation. But when these again have been allowed for, there is still the influence of the stars. In this case, however, we only give up one exact law for another. It may still be held that if the effect of every particle of matter in the universe on the falling body were calculated according to the law of gravitation, the body would move exactly as this calculation required. And if it were objected that the body must be slightly magnetic or diamagnetic, while there are magnets not an infinite way off; that a very minute repulsion, even at sensible distances, accompanies the attraction; it might be replied that these phenomena are themselves subject to exact laws, and that when all the laws have been taken into account, the actual motion will exactly correspond with the calculated motion.

I suppose there is hardly a physical student (unless he has specially considered the matter) who would not at once assent to the statement I have just made; that if we knew all about it, Nature would be found universally subject to exact numerical laws. But let us just consider for another moment what this means.

The word *exact* has a practical and a theoretical meaning. When a grocer weighs you out a certain quantity of sugar very carefully, and says it is exactly a pound, he means that the difference between the mass of the sugar and that of the pound weight he employs is too small to be detected by his scales. If a chemist had made a special investigation, wishing to be as accurate as he could, and told you this was exactly a pound of sugar, he would mean that the mass of the sugar differed from that of a certain standard piece of platinum by a quantity too small to be detected by *his* means of weighing, which are a thousand-fold more accurate than the grocer's. But what would a mathematician mean, if he made the same statement? He would mean this. Suppose the mass of the standard pound to be represented by a length, say a foot, measured on a certain line; so that half a pound would be represented by six inches, and so on, and let the difference between the mass of the sugar and that of the standard pound be drawn upon the same line to the same scale. Then if that difference were magnified an infinite number of times it would still be invisible. This is the theoretical meaning of exactness; the practical meaning is only very close approximation; *how* close, depends upon the circumstances. The knowledge then of an exact law in the theoretical sense would be equivalent to an infinite observation. I do not say that such knowledge is impossible to man; but I do say that it would be absolutely different in kind from any knowledge that we possess at present.

I shall be told, no doubt, that we do possess a great deal of knowledge of this kind, in the form of geometry and mechanics; and that it is just the example of these sciences that has led men to look for exactness in other quarters. If this had been said to me in the last century, I should not have known what to reply. But it happens that about the beginning of the present century the foundations of geometry were criticized independently by two mathematicians. Lobatscheffsky and the immortal Gauss; whose results have been extended and generalized more recently by Riemann and Helmholtz. And the conclusion to which these investigations lead is that, although the assumptions which were very properly made by the ancient geometers are practically exact—that is to say, more exact than experiment can be—for such finite things as we have to deal with and such portions of space as we can reach; yet the truth of them for very much larger things, or very much smaller things, or parts of space which are at present beyond our reach, is a matter to be decided by experiment, when its powers are considerably increased. I want to make as clear as possible the real state of this question at present, because it is often supposed to be a question of words or metaphysics, whereas it is a very distinct and simple question of fact. I am supposed to know then that the three angles of a rectilinear triangle are exactly equal to two right angles. Now suppose that three points are taken in space, distant from one another as far as the sun is from Sirius, and that the shortest distances between these points are drawn so as to form a triangle. And suppose the angles of these points to be very accurately measured and added together; this can at present be done so accurately that the error shall certainly be less than one minute, less therefore than the five-thousandth part of a right angle. Then I do not know that this sum would differ at all from two right angles; but also I do not know that the difference would be less than ten degrees, or the ninth part of a right angle. And I have reasons for not knowing.

This example is exceedingly important as showing the connection between exactness and universality. It is found that the deviation, if it exists, must be nearly proportional to the area of the triangle. So that the error in the case of a triangle whose sides are a mile long would be obtained by dividing that in the case I have just been considering by four hundred quadrillions; the result must be a quantity inconceivably small, which no experiment could detect. But between this inconceivably small error and no error at all, there is fixed an enormous gulf; the gulf between practical and theoretical exactness, and what is even more important, the gulf between what is practically universal and what is theoretically universal. I say that a law is practically universal which is more exact than experiment for all cases that might be got at by such experiment as we have. We assume this kind of universality, and we find that it pays us to assume it. But a law would be theoretically universal if it were true of all cases whatever, and this is what we do not know of any law at all.

(To be continued.)

FORMATION OF OZONE BY PLANTS.*

BY C. BELLUCCI.

Scoutetten, Bineau, Kosmann, and De Luca, instituted experiments from the results of which they inferred that plants are sources of ozone, whilst Cloez (Ann. Chem. Phys. 1856) on the contrary shows conclusively that the apparent ozone was due to other causes. He passed the aeriform products from the plants through two tubes placed side by side, and containing iodized test-paper; one of these was exposed to the action of light, and the test-paper became coloured, whilst in the other which was protected from the light, it remained unaltered, showing that the action was due, not to ozone evolved from the plants, but to the effects of moisture, oxygen, and light on the test-paper. The author has carefully repeated the experiments of Cloez, and devised new ones, in which he introduced into a large Woulfe's bottle containing water saturated with carbonic anhydride, and to which a small quantity of potassium iodide and starch was added, sprigs and leaves of the following plants: *Taxus baccata*, *Juniperus virginiana*, *Abies vulgaris*, *Thuja orientalis*, *Prunus Laurocerasus*, *Buxus sempervirens*, and *Chara fœtida*. The apparatus was then placed in bright sunshine, but no change was observable in the liquid, proving that the green parts of plants do not evolve ozone under the influence of the solar rays.

NICOTINE AN ANTIDOTE TO STRYCHNIA.

A case of poisoning by strychnia which was successfully treated with nicotine, has been published in the 'British Medical Journal' by the Rev. Dr. Houghton, F.R.S., of Trinity College, Dublin. When the treatment commenced, the patient, a lad nineteen years of age, was violently convulsed, his pupils were dilated and his arms and legs were rigid. The nicotine was administered in drop doses in whisky-punch every half-hour. After the second dose the paroxysms were less violent; and when he had taken four doses he was much better, and eventually he recovered. The poisoning was caused by the lad picking up and eating an egg which had had strychnia introduced into it, and been placed in a garden for the purpose of poisoning magpies.

BRIGHTON AND ITS RECENT VISITORS.

Now that the British Association, and the British Pharmaceutical Conference have adjourned their pleasant labours until they meet next September, at Bradford, under the presidency of Dr. J. P. Joule, and H. B. Brady, Esq., respectively, it is gratifying to find that the efforts of the people of Brighton worthily to entertain their visitors have been so well appreciated. On every hand, the liberality of the townspeople, and the thoughtfulness and kindness of their representatives, have been the theme of praise. We have already spoken of the hospitality shown to the Conference by the local members of the drug trade, and the heartiness with which the Association has been entertained, is indicated by the fact, that while the promised subscriptions to the local fund amounted to nearly £2000, this money has been forthcoming without any unseemly coercion. This circumstance is justly the ground of some congratulation on the part of the Brighton press, and we are especially glad to notice among the subscribers to the fund the names of several well-known pharmacists. Financially, the Brighton meeting of the British Association has been a great success, the number of tickets issued having been 2533, representing the sum of £2,649; 2,463 tickets issued for last year's meeting in Edinburgh, representing £2,575. The Association has thus been enabled this year to make grants of money for scientific purposes amounting to £2,025. The signatures in the visitors' book of the British Pharmaceutical Conference, were in number more than one hundred. Brighton was for many years unsuccessful in inducing the British Association to visit her, but now that the ice is broken, we venture to predict that she will have a comparatively early opportunity of proving the truth of the Mayors axiom, that "to do a thing well, it requires to be done a second time."

DEODORIZERS, DISINFECTANTS, AND ANTISEPTICS.

The Public Health Bill, having received the Royal Assent, may by this time be looked upon as an established fact, and, as we are informed, it will come into operation almost immediately. This Act is very important to all who are qualified to conduct the operations of analytical chemistry, because it indicates indirectly a vast systematic application of science to sanitary matters with which they must, as a necessary consequence, be intimately concerned. If the medical inspectors who are to be appointed under the terms of this Act do their duty, it should soon, among other things, be practically discovered which are the most efficient deodorizers, disinfectants and antiseptics for common use; which of the materials used for such purposes are the most generally useful, most harmless, and cheapest. We may take it that the deodorizing and antiseptic properties of any agent can be proved without much difficulty, but it is still open to doubt whether, in the present state of physiological science, conclusive proofs of the disinfecting properties of any article can be produced. It is pretty well known to our readers that chlorine and ozone are classed as the best deodorizers; that common salt, chloride of zinc, corrosive sublimate, cold, carbolic acid, and heat (above 140° Fahr. with exclusion of air), are the best antiseptics; and that the permanganates, chlorine, ozone, sulphurous acid, animal charcoal, and lime rank highest among so-called disinfectants. We are neither prepared nor inclined to discuss the respective merits of the last-named series. But it is a remarkable fact, and one worthy of attention, that a special preparation called chloralum does not receive the general attention that it would seem to deserve, if the advertising columns of the daily newspapers, weekly journals, and monthly magazines are to be taken as the gauge of its merits. No chemical or pharmaceutical article has ever been so copiously urged upon the attention of the public, not excepting even the chlorodyne of Dr. Collis Browne or the corn flour of Mr. Polson. We know that chloralum has been authorized by the President of the Board of Trade, and has now therefore to be carried in the medicine chests of all merchant ships (to the exclusion of Sir Wm. Burnett's solution of chloride of zinc), although no directions of any sort or kind are given as to its use in the 'Ship Captain's Medical Guide,' authorized by the Board. We have indeed heard it stated by public officers and others interested in sanitary matters that they have vainly endeavoured to find out the merits of this so-called deodorizer, disinfectant, and antiseptic. Medical men and professional chiefs of public departments tell us that they know little or nothing about it. But it is most humiliating to those engaged in the promotion of sanitary science, to medical men, and to all occupied in work connected with the prevention of disease, that no one even now can say or has said *ex cathedra* whether this preparation is good, bad, or indifferent. There are things that are true, and things that are new. We want to know if the new thing in this case is a true thing, and most naturally appeal to the Medical Department of the Local Government Board, or—if such an officer exist—to the medical adviser of the Board of Trade.

This subject came up for discussion recently at Brighton in the Chemical Section of the British Association. The occasion was the reading of a paper by Mr. W. J. Cooper, who stated that whilst treating the roads of London and other towns with deliquescent chlorides he found that the waste solution running into the drains, had the effect of preventing or retarding the fermentation of sewage, which gives rise to the formation of sewage gases, and he suggests that by the use of chloride of calcium the offensive discharge of gas from sewers may be prevented at a very moderate cost.

It was already well known that the use of deliquescent chlorides in street watering was attended with the result of removing the ammoniacal odour from urea products already formed. The chloride of calcium and carbonate of ammonia, reacting upon each other, a double decomposition occurs, resulting in the formation of chloride of ammonium and carbonate of lime. It was objected by Professor Williamson that there seemed to be something contradictory in the statement that chloride of calcium would prevent a thing being formed and then catch it after it was formed. But the actions claimed for this material are twofold and distinct; first, that when added to fresh sewage it prevents or retards the fermentation which results in the decomposition of urea and the production of carbonate of ammonia; secondly, that when added to sewage which has already undergone fermentation, it combines with the ammonia to form two inoffensive salts.

It is worthy of remark, that similar results have been independently and simultaneously arrived at by Mr. E. C. C. Stanford, and were communicated in a paper read before the British Pharmaceutical Conference. These experiments seem to leave very little doubt that in chloride of calcium we have an extremely cheap and effective deodorizer, and, perhaps, disinfectant.

We take the liberty of calling the attention of our readers to a paragraph on p. 180, respecting an effort which is being made to assist the widow of a chemist and druggist, whose death was recorded in a recent number of the Journal.* The case is a painful one, and its consideration led to a grant from the Benevolent Fund by the Council at their last meeting.

Provincial Transactions.

TYNESIDE CHEMISTS' ASSISTANTS' ASSOCIATION.

A Special Meeting of the above Society was held on Monday, August 12th, for the purpose of considering the advisability of confirming two motions passed by the Committee, at their last meeting.

1st. Proposed by Mr. Shaw, seconded by Mr. G. Heslop, and resolved,—

"That this Meeting is of opinion, after due consideration, that it is impracticable to establish a laboratory, owing to the expense necessary for the purpose, and that for the present the scheme should be abandoned."

2nd. Proposed by Mr. A. Brady, seconded by Mr. Shaw, and resolved,—

"That this Meeting is of opinion that, as the funds of the Association are at present too limited to allow of a laboratory to be made to any good purpose, it would be advisable to commence the Educational Scheme of this year with a Latin class, to be held two hours a week, on separate evenings; the fee to be regulated by the number of pupils."

The President (Mr. A. Brady) in his opening speech said that it was with no little anxiety that the Committee had come to the conclusion they had; he did not consider the expense a great drawback, as he had no doubt but that in a large society such as their own, they could soon overcome that difficulty by a special subscription, but there were other things to be considered; in the first place they would require a demonstrator to instruct the pupils, say once or twice a week, then they would require a person to be in constant attendance upon them to explain all the different reactions, etc. etc. As Latin is the stepping-stone to chemistry, he thought that they should commence with it, so as to lay a good foundation, more especially as a number of the members had not passed their classical examination.

Messrs. Welch, Shaw and Owen all agreed that the time had come when they should do all in their power to establish a class such as that proposed.

Mr. R. D. Spence agreed that a Latin class was an excellent thing to have in connection with the Society, and he for one would have very great pleasure in joining it; at the same time he did not see why they should not have a laboratory in working order as well as the class. He said there were several members working up for their "Minor;" some of them being at lodgings, they found it very inconvenient to work their practical chemistry.

After a considerable amount of discussion, it was unanimously agreed that a Latin master be obtained to conduct the class as proposed in the motion. It was also agreed that a subcommittee be appointed to draw up a scheme for a laboratory, to be laid before the committee at their next meeting.

The President then announced that he had received a reply from the Secretary of the Museum authorities granting the use of the museum for a conversazione to be held in the beginning of October. He said he would be happy to receive anything for exhibition that would be suitable and likely to prove of interest to the assembly. Specimens of drugs, chemicals, etc., for exhibition may also be sent to the Secretary, addressed Mr. G. H. Proctor, 56, Dean Street, Newcastle-on-Tyne.

LEEDS CHEMISTS' ASSOCIATION.

The result of the examinations in chemistry in connection with the Science and Art Department is very favourable, and places the Associates of this Society in the following rank:—

Organic Chemistry.	*Teacher.*	
Severs, S. T.	G. Ward, F.C.S.	1st Advanced.
Smith, C. A.	S. Jefferson, F.C.S.	2nd Advanced.
Inorganic Chemistry.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Tuesday, August 13th, 1872.

(*Continued from page* 156.)

Pharmaceutical Education.

BY J. SCHWEITZER.

Amongst the chemists of the present day, we find some who have passed the Major or the Minor examination, and a great many who have passed no examination at all, a very mixed body of men, many of them far from what we aim at, and what a pharmaceutical chemist should be. I say this without any disrespect to those gentlemen who were in business before the passing of the Act which made a strict and regular examination a *sine quâ non*. They have a perfect right to their present position, but as long as we count a large number of men amongst us of doubtful qualification, so long our position must be of necessity unsatisfactory and anomalous. While we admit these gentlemen on a footing of equality in business matters, and allow them to shape their course as best they can, we have certainly to guard ourselves against judging the past from the present, nor need we, in making provisions and laws for the future, fetter ourselves with unnecessary considerations on their behalf. Indiscriminate admittance into our ranks has ceased now, and a better and more uniform standard of men only will be added to the register, whereby many of the present difficulties will disappear.

The idea that the present system of pharmaceutical education is not what it should be is not at all so well founded as we are made to believe; anyhow, I must differ *in toto* from the plans hitherto proposed as a remedy. I protest against placing on the shoulders of the Pharmaceutical Society the shortcomings of those who for years were strangers, if not enemies, to the Society, and who recently were compelled to join. No new system of education will alter these, and it is wrong to speak and to act as if these men had sprung from or grown up in the Lecture Rooms and Laboratory of Bloomsbury Square, and were a living proof of the insufficiency of this institution. The fact that the Society possesses at present a surplus income of £2000 or £1800 per annum is a proof that it is founded and carried on on sound principles. It is perhaps a little too parsimonious, but the fault, if any, is on the right side. To use this surplus for the introduction of a new and expensive plan of provincial education is a hazardous, wasteful, and wrong step, almost certain, in my judgment, to lead to failure and ruin. It is generally acknowledged that small donations in money or books to provincial associations is so much money thrown away, while the establishment or maintenance of a number of regular schools would be equally ineffective, and only cause greater jealousy, and tend to cripple the parent society.

I do not lose sight of the training of apprentices and assistants, nor of the fact that their want is greater than London alone can supply, and that a successful termination of apprenticeship requires more opportunities than many provincial businesses can afford. But no chemist is compelled to take an apprentice; and I maintain that we have amongst us plenty of intelligent Pharmacists who, in every respect, are competent and willing to take and instruct apprentices. When we demand that the pupil should possess sufficient schooling to pass the Preliminary examination, we may, with greater right, expect that the master should possess also sufficient theoretical knowledge to fulfil his part of the contract, and be able to prepare and instruct his apprentice properly, or so that, when out of his time, he should, without much difficulty, be able to pass the Minor examination. The agreement between master and apprentice is a legal document, wherein one promises to do certain things in return for certain considerations, and it is, of course, the business of the contracting parties to see that they are able to fulfil their promises. I will not trouble you about apprentices who will not learn, nor have I much to say about masters who are unable to teach; the sooner both disappear the better. I feel, also, little compassion for unexamined men who maintain that their business does not afford means to keep an assistant, and, who for such reason, think themselves justified in continuously looking out for apprentices, and are ready to take any comer, uneducated, untrained to study, and unable to pass the Preliminary examination. They accept the premium, employ their apprentices for all sorts of work, save the services of a paid assistant, and clear, in this way, a good round sum every year. Such apprentices, when out of their time, never attempt to pass, or, if they do, fail, as a matter of necessity. If you can put a stop to proceedings like this, do so, but, if you cannot, certainly do not burden yourself with unnecessary responsibility, leave time and circumspection to discover and apply a remedy for individual cases. It is usually masters of this kind that clamour most for help from the Pharmaceutical Society. Not being able to educate their apprentices, they seem to think they have a right to call for help, but their right has no existence, and their difficulty is of their own seeking. If you listen to them you sanction their proceedings, and encourage them to continue in their reprehensible course.

Neither do I think claims of this kind more reasonable or legitimate if, instead of individuals, a town or province should furnish such instances by the score. The establishment and maintenance of a local school requires at least a yearly outlay of from £300 to £600, and even then you do not get a perfect school, while the fair distribution of such establishments over the country must of necessity cripple the Society in London. Establish as many such schools as you like, you would get calls for more, while every new establishment would be a new source of jealousy to the neighbouring towns, and it is not difficult to predict what the end would be. Instead of possessing what we should now have in London, at least, one good effective centre of instruction, provided with the best masters, the largest laboratory, the completest library, and the richest museum, an institution of which all of us can be proud, you would have jealousy everywhere, and a number of elementary schools all good for very little, and all alike contemptible in the amount of knowledge they would diffuse. Gentlemen, I say there is no necessity for such steps; the days of the uneducated amongst us are numbered; in a few years every chemist in business must be educated, and must have proved his knowledge by an examination, and I have no hesitation in saying that every one of such will be able to educate his own apprentices without troubling any Society for assistance. A few years' patient waiting will bring you what you seek, without risk, without much expense. One thing you certainly must always bear in mind; the raising of the standard of the future chemists by subjecting every fresh comer to a strict and proper examination.

I have said before that every intelligent chemist who has passed his examinations will be able to instruct his apprentices, so that when out of his time he could with perhaps very little additional study, pass the Minor examination. But to teach with success you must know more than your bare lesson, and I consider the Minor examination not a fit standard for a chemist in business. The Preliminary or classical examination is the proof of a youth's fitness to become an apprentice; and I think the Minor examination nothing more than a test for the competency of an assistant, but for the master I demand more. The mere word Minor indicates that you do not mean to end your days with such qualification, but that you intend to go a step further and pass the Major. Gentlemen, nobody should be allowed to carry on business on his own account, or be allowed to conduct the business of another, without having passed the Major examination. So long as we cannot enforce this, so long will our position be unsatisfactory, and all our lectures and our schools will be useless, and only waste of time and money. I am prepared to be told that examinations are no real proof of a man's knowledge. To a certain extent I admit this, but only to an exceptional extent. Examination is like a sieve, a few coarse particles may find their way into the sifted powder, and now and then a trace of the fine may be rejected with the coarse residue, but these are exceptional cases, while the result in both directions is most satisfactory and just. Gentlemen, to sum up my ideas in a few words—I consider three examinations necessary. The Preliminary or classical for the apprentice, the Minor for the assistant, and the Major for the chemist in business, or for those appointed to manage businesses. All these examinations, the Major included, should be compulsory, Nobody should be admitted to occupy any place without having qualified himself for it. The master should prepare, or be answerable that his apprentice when out of his time can pass the Minor examination.

With the departure of the apprentice all our responsibility for imparting theoretical knowledge must cease. No chemist in business can be troubled with the instruction of his assistants; they are engaged to help a master in his daily work. The knowledge for the Major examination they may acquire whenever and wherever they like, but without interference or strain on the business; it is their interest to acquire knowledge, as much as that of their masters. Of course, every right-minded master will be pleased to see that his assistant studies in his leisure hours, and will be ready and able to assist and help him over any difficulties that he may encounter. But to establish schools all over the country, and to preach that our assistants must attend there, and, if necessary, be induced by their employers to do so, is against human nature, and neither desirable nor necessary. If an assistant has the wish to learn he can do so at home, with better results, without losing so much time, and without such interruption as attendance at local schools, while engaged in business, would of necessity occasion. But should he desire to spend some time entirely for study, I would wish one thing, namely, that there should be no better, no cheaper place than Bloomsbury Square. If you have a surplus in your income, you could not spend your money more justly or to better purpose than by improving your present establishment at Bloomsbury Square. Pay your officers and professors so that in case of a vacancy you may have the best in the land to apply for it, and when you have them, treat them handsomely that they may willingly stay with you. *Open the laboratory and the whole establishment gratuitously for a limited time to every apprentice and assistant.* Nobody should come to Bloomsbury Square unprepared; and when well prepared by private study, the gaps in his knowledge may well be filled up in a comparatively short time. If you have still funds to spare, find a different place for your examining body, and separate that department altogether from your place of instruction.

Should it ever happen that Bloomsbury Square cannot offer the necessary accommodation to all its applicants, then it will be time to establish a second Pharmaceutical School, as far from London as possible. Perhaps no better place could be found than Edinburgh, but heretofore I have always heard that Bloomsbury Square suffered more from want of pupils than from want of room to accommodate them. Times, however, may alter, the present complaint of non-attendance at places of instruction may cease, and it may be necessary at a future time to find more room for accommodating our students. May we all live to see this, to see a second northern Pharmaceutical School, emulating with Bloomsbury Square, and striving with it to turn out men to become the ornaments and pride of our profession. Unfortunately, at present there exists no such necessity; what we want is more pupils, not more schools.

Note on Pharmaceutical Education.

BY B. S. PROCTOR.

In my letter to the Pharmaceutical Journal of July 20th, 1872, I spoke favourably of the education scheme presented by the committee in 1870. It has since been objected that the project then advocated did not give sufficient detail to enable its merits to be fairly judged. In the letter above alluded to I named two points of detail, viz., that satisfactory lectures delivered under suitable conditions should be paid for to the extent of 21*s.* per lecture. That the students should pay at least 1*s.* per lecture each, the Society, where necessary, making up the deficiency. I now propose to add a few further suggestions, and if they appear arbitrary and open to criticism, they may at least prove starting-points for discussion.

One source of failure in the promotion of a satisfactory condition of pharmaceutical education is the disposition so common in students to shirk persistent study in favour of a violent effort of short duration. The experienced examiner fully appreciates the difference in value between these two processes, and usually can distinguish by which the student under examination has sought to obtain his position, and not unfrequently rejection is the reward of the latter process. But the candidate thinks it an injustice to draw so fine a distinction between those who are well grounded, and others who are well grinded. We must aim at making the distinction more clear and forcible, especially to the student class. This, I believe, will be ultimately accomplished by prescribing a particular course of education as a necessary preliminary to candidature. It appears to me that the required course of education should be something like the following:—After the Preliminary examination, there should be a term of apprenticeship, or pupilage, of not less than four years, followed by attendance on lectures on chemistry, botany, materia medica, and pharmacy, in all not less than x y z lectures, spread over two years. The Minor examination should then be passed, and after a lapse of x months, including y months spent on laboratory work, the student should be qualified to enter for the Major.

A course like this would afford some sort of guarantee that the student had received a fair amount of solid instruction, and not the mere smattering which may be gained to-day and lost to-morrow. But such a course would not be practicable at the present day, because of the want of schools in which the student could go through the required curriculum, and our present step should be to lay the foundation of such schools.

It would be necessary that lectures at *registered schools only* should be acknowledged, but any local school might claim registration on submitting to periodical inspection by the central body, and showing that it provided the requisite quantity and quality of instruction. The lecturers would have to be appointed under the approval of the London Board or Council, and the lecturer's certificate of a student having attended his lectures, would have to include a statement of the number of times he had been present, and how many absent.

Then in respect to the quality of lecturing, nothing could be regarded as satisfactory which consisted of simply reading a lecture. The reading by a lecturer has but little advantage over the reading by the student himself, unless it be illustrated by specimens, diagrams, experiments, or some other species of practical demonstration. The more practical demonstration accompanies a lecture, the greater will be its advantages over those obtainable by simple reading, but we must also admit the greater will be the labour in preparing it; and it cannot be supposed that a guinea will pay for time, anparatus, and material involved in the delivery of a lecture, illustrated with experiments; therefore the project of 1870 proposed to include the payment of part of the salary of a lecturer's assistant, or curator of specimens and apparatus. If some six or eight schools, such as I have roughly indicated, could be established in convenient parts of the kingdom, at a cost to the Society of as many hundreds of pounds per annum, I should regard the money as thoroughly well spent, and the ground prepared for the subsequent enforcement of such a curriculum as sketched above. This, it appears to me, is the right course to pursue, and the only course to promote good, sound, pharmaceutical education in the provinces.

Newcastle, August, 1872.

Pharmaceutical Ethics.

BY S. R. ATKINS.

The advantages derivable from these Annual Conferences cannot be too highly rated, supplying, as they do, an opportunity for the interchange of kindly feeling, and the discussion of questions vitally affecting our interests.

That these meetings are destined to grow in importance, there can be to the thoughtful observer little doubt. It is an age of synods, congresses, and the like. The old conditions of severance and disintegration are giving place to those of combination and confederate action. No class of the community stood more in need of this than the important one represented here on the present occasion. Until recently, the life of a chemist in one of our provincial towns was largely an isolated one, and with that isolation were associated necessarily narrowness and ignorance—ignorance of each other. The character of his business fostered the same result; unlike other tradesmen, the exigencies of *his* business did not require a periodical visit to London, hence he settled down to his life-work in a contracted groove, yet doing that work in an honest, painstaking, persevering spirit, which demands from this generation, with its greater light and superior culture, the most distinct and ungrudging meed of praise.

Tout cela est changé. And whatever may be the extent of conservatism of feeling we cherish as we look back on that past, and whatever may be our regret in witnessing the spirit of unhealthy competition that has invaded our ranks, yet we cannot but recognize in the changes of the last quarter of a century the attainment of a large amount of substantial good, and the promise of better things to come.

In again attempting to work the lode, which on prior occasions has engaged my attention, I offer no apology, deeming it better that in the vast field of observation and research lying before us all, we shall best subserve the general good by each one specially cultivating some particular allotment in that field. There can, moreover, be little doubt that at the present moment, and for some time yet to come, during what is clearly a period of transition, the ethics of pharmacy will claim no small share of our attention, and this Conference will deepen its hold on the constituency it represents by giving them a prominent place in its debates.

The field of pharmaceutical ethics, we have said, is a large one; some portions have been already well ploughed up, and good seed sown therein, destined to ripen into valuable results. Other portions await their turn, which assuredly will arrive when those immediately engaging our attention are disposed of. There are, however, three questions of primary importance at the present juncture, which I desire once more should engage the attention of Conference.

It will be only in harmony with natural selection in the order of time, if we start with the matter of—

The Preliminary Examination.—A real, though gradual improvement, has been already effected. Candidates are presenting themselves in better condition for the test: still the proportion of failures is both humiliating and disappointing. Since the Edinburgh meeting I have taken the trouble again to write to valued correspondents in different parts of the kingdom, tabulating a series of questions on this subject, and their kindness in procuring and furnishing me with valuable information I take this opportunity of publicly acknowledging. The results roughly put, though carefully examined, may be thus epitomized:—Students are better prepared; greater anxiety and sense of responsibility in reference to the examination is producing a healthful stimulus. As might be expected, a larger proportion of "plucked" are amongst the senior candidates; a considerable number of this class not presenting themselves a second time for examination, an important inquiry suggests itself, are they quitting the business for some other avocation, or are they merely deferring their difficulties to the indefinite future? The premium having been paid, the probabilities are that parental pressure renders the latter alternative the real answer to the inquiry.

Again, and yet again, we must enforce the proposition, until it be recognized as a first principle, that the Preliminary examination, or its equivalent, should be passed prior to the commencement of apprenticeship; and I hold that any chemist neglecting to stipulate for this condition, in the face of the overwhelming amount of evidence adduced in its favour, does both himself and his pupil an act of injustice. A compulsory clause to this effect would be a positive boon.

But what can be done for these youths, who, placing their finger on the wax seal, have uttered the binding words, "I deliver this as my act and deed?" It is now generally admitted that to lower the standard of examination would be most impolitic, unjust to those who have gone before, and not an act of real kindness to their successors. Let it be known, for the encouragement of apprentices who have not yet passed, that, assuming they have received a respectable education, the *available leisure* to be secured in three months, if diligently used, is sufficient to enable any lad of fair ability to surmount the difficulty.

With all due deference I submit to the Conference for discussion, and to the Council of the Pharmaceutical Society for their deliberation, whether it would not be desirable entirely to change the practice in regard to this examination; in fact, abolish it so far at least as the provinces and local secretaries are concerned, and accept as the *uniform rule* what is now the *exception* only—the local examinations of the university and the College of Preceptors.

As Local Secretary, I have now for some years been called on to superintend the Preliminary Examination, and whilst I believe the system has worked fairly, I am still disposed to think the university test would be preferable.

Two objections probably will be raised on the student's side—the additional cost in money and study. As to the extra guinea, the Council in consideration of the Society's incidental expenses being lessened, might be disposed to reduce the registration fee to one guinea, and so equalize the cost. The second objection—for undoubtedly the university test is a more stringent one than our own—might be met by prospective legislation: thus, only those youths who were apprenticed after a certain date, to come under the operation of the law.

Apprenticeship.—The important matters of the Preliminary Examination and apprenticeship are, as we have seen, intimately allied, but not always in the order here stated.

Let us now assume that a well-educated youth having passed the initial test, his friends are desirous of placing him in the establishment of some respectable chemist, that he may study pharmacy and become a man of business. The difficulties in finding and selecting a suitable position are at once experienced. The men who in every respect are competent to instruct and guide, decline the responsibility. To this particular fact I desire to call especial attention, for unless the *will* and the *power* are more linked together, the difficulties of the future will be aggravated.

In the instructive though brief debate on this matter at our meeting last year, Mr. Mackay gave us a most lucid and interesting sketch of the Scottish system; Dr. Edwards furnished some valuable details in respect to the Canadian plan. Reference also was made to the views on apprenticeship held by my friend Mr. Giles. That those opinions respectively were argued with ability, it is sufficient to mention the names of the authors; yet I venture to think that neither of the systems will acclimatize on English soil.

I am disposed further to believe that our English method of placing a youth for a term of three or four years under the direct supervision of a practical pharmaceutist and within his family circle, is an immense advantage.

The system of boarding out is open to the grave objection of failing to secure anything like moral control. Parental influence at the age of 16 or 17 should be sustained and continued by the wise and thoughtful discipline of a well-ordered household; every wise man desires as much for his son. I must, therefore, regard as chimerical a scheme which altogether dispenses with these safe-guards, and plunges a lad at the most critical period of life in the midst of temptations, deprived of those aids which in reviewing our own past we must admit to have been valuable.

The additional cost of a pharmaceutical education so acquired, must also be regarded as no trifling difficulty; a cost vastly disproportioned to the net result which can be possibly secured either of social status or moneyed competency—a cost as great as that of a profession without its status, but with a pecuniary reward below that of the average of drapers and grocers.

That the position of a pharmaceutical chemist in this country is an advancing one and destined still further to improve by that process of natural selection established by educational tests, I most gladly recognize. But no estimate, however sanguine, of the lot of the ordinary provincial chemist can warrant an outlay of £250 to £300 on his apprenticeship.

The obstacles in the way of adopting the Scottish system of attending classes are so blended with another subject that it may be better stated under the consideration of the last ethic of pharmacy to which I desire to advert on the present occasion.

Provincial Education.—It is only necessary to point to the voluminous correspondence and frequent debate on this question to demonstrate the interest and importance attaching to it. That something ought to be done, and that something must be done, is a widely-spread conviction. But what, and how? There's the rub. *Quot homines tot opiniones.*

The nebulous condition of the thing at length bids fair to assume definite and substantial proportions under the masterly and comprehensive treatment of Mr. Schacht, who has thus laid us under fresh obligation for the services he has rendered to pharmacy, and so justifying the high position his name commanded at the recent election of Council.

To the analysis of his scheme Mr. Schacht invites the fullest inquiry, and in this respect it would seem he is not likely to be disappointed. A special feature in it is the multiplication of local centres of instruction—the creation of schools of pharmacy subsidized by the Pharmaceutical Society on the important basis of payment on results. This plan is decentralizing as it affects Bloomsbury Square, and centralizing within a given, but limited, radius of the local centre.

It is possible that the enlarged demand in future for technical education may render the formation of these provincial schools a matter of necessity; but I confess I should view with regret any action which would lessen the influence of our admirable school in London. Let us take care that the heart beats vigorously, the extremities must then of necessity be ministered unto.

Our central institution has done, and is doing, good work. Not simply have we a long list of honoured names—household words amongst us—who were indebted to its curriculum for the foundation of their scientific attainments, but we have scattered over every portion of the kingdom, and well-nigh of the world, men who are conducting their business with scientific intelligence and accuracy, who likewise will tell you that they look back with with grateful feelings to the time spent at the Square.

If needs be, and the possibilities of the case admit, let us try and increase the number of such agencies; but let us at the same time take care it is not to the detriment of the parent institution. I do not object to the establishing such schools of pharmacy, but my deliberate and long-cherished conviction is, that such schools must inevitably, and that from no fault of their own, fail to supply the wants of the country. Let us assume as a mere hypothesis, that five schools have been established in the same number of large towns representing a centrally and conveniently as possible the five great divisions of England, north, midland, south, east and west; and, further, that associations are formed in other important places, but of lesser populations than the aforesaid centres, yet containing a sufficient number of chemists to combine. There still remains the difficulty of dealing with smaller towns; and be it remembered it is in these places, in the aggregate so important, is to be found the great bulk of our pupils.

To attend classes at the nearest centre would be impracticable, at least with the regularity requisite for an educational course.

In the shape, therefore, of combined effort, it but remains to form a local association such as I attempted to describe at our last Conference. The history of such association when written will not be so creditable or encouraging as could be desired; a more earnest and resolute spirit for work on the part of our apprentices may alter their complexion,—let us hope it will be so.

Finally, I desire once more to place on record my settled opinion that the only real practicable solution of the many problems, in this transition period, connected with the all important matters of apprenticeship and provincial education, must, in the main, be found in the slow but certain advance in technical knowledge on our own part as teachers.

That there will always be room for combined action there can be no doubt, and I hope to see the day when every considerable town will possess its flourishing association of pharmaceutists. but let us not forget our individual responsibility. When—and not until then—the entire body of chemists are technically trained will these questions be set at rest. Patience is needed; the good work is progressing more surely than some of us imagine. May we return to our homes and separate spheres of action from these annual gatherings with the resolve to contribute our personal share to the advancement of the general good.

Salisbury.

The Conference then adjourned for a short time.

On its reassembling shortly after two o'clock,

Professor ATTFIELD read as a "postscript" to his paper, the following letters which he had received on the subject of Pharmaceutical Education.

LETTER FROM MR. EDWARD SMITH, OF TORQUAY.

"My dear Doctor,—At the outset let me say that I consider every pharmacist in the country is deeply indebted to you for your exceedingly interesting and suggestive paper on Pharmaceutical Education. The firm and determined manner in which you have handled the subject is, to me, an especial source of satisfaction, whilst the value of your paper is greatly enhanced by the fact of your being practically engaged in the work of education; it seems to me that this distinct enunciation of an opinion by so eminent a professor of the Pharmaceutical Society is precisely the one thing hitherto wanting to enable those who, like myself, have had little or no practical experience in teaching, so to focus, as it were, their ideas as to approach the subject with much less diffidence, and with much more clearness, than has before been possible. Your paper will doubtless tend to draw present divergencies of thought into a common groove, and thus be the means of more speedily enabling us to devise some wise and permanent settlement of this all-important question.

"I must confess that I have been startled beyond measure at the picture so vividly drawn, so eloquently put before us, in your description of that wretched and pernicious system of 'cramming.' Although it was well known to me that 'cramming' establishments existed, I had not conceived the possibility of the 'fact that within the past ten months more students have been crammed than have been legitimately prepared for the Minor examination.' This is not only a terribly humiliating fact, but it is highly discouraging to those who are, and have been, conscientiously striving and working hard to disseminate sound instruction amongst the rising generation of pharmacists, and is, moreover, unquestionably a state of things that cannot possibly be suffered to exist if our examinations are to be other than a huge sham.

"Whether this 'cramming' is encouraged most by an unfortunate selection of examiners, or by the present system of examination, may possibly be a point open to argument. For my own part I see no possibility of materially improving the *personnel* of the examiners, for, supposing there is at any time a 'weak brother' on the Board, this could not really affect the general result of an examination. On the other hand, I think you have made out a strong case against our present imperfect system of examination, and heartily concur in your observations both as to the imperative necessity of compulsory education, as well as to the method propounded of supplementing the Minor examination, by requiring candidates to produce certificates of attendance at some recognized school of pharmacy.

"But whilst thus acquiescing generally in your propositions, I am not unmindful of the difficulties that surround them. I think the Society has not at the present moment the necessary powers to insist upon such attendance. There may be comparatively little difficulty in obtaining such powers if we can make our aim clear and induce Government to help us. This accomplished, the very difficult question as to the number of schools confronts us.

"I certainly do *not* agree with your opinion that 'there will be room for three or four or five schools,' and that it is 'impossible to establish a school of pharmacy in every twentieth town.' The number of schools must depend upon the number of pupils, and this must depend upon the length of time each shall be required to attend a school. I gather from your paper generally that it is supposed that a pupil will attend for one session only. But why for one only? If we are to do the work thoroughly, three sessions (certainly not less than two) would be insisted upon. Now if three sessions were adopted, you would have three times the number of pupils; there would be the 1st, 2nd, and 3rd years' men. The advantages of this would be manifold. A greater number of more conveniently situated schools would be established, and a much larger proportion would be self-supporting; and thus, whilst all the larger towns would require little or no subsidy, the parent Society would be enabled to give greater help to smaller schools, *i. e.*, precisely the schools requiring most help. So far from twenty schools being impossible, I should hope to see fully that number in a flourishing condition.

"Of course, the compulsory attendance of an apprentice for three sessions would involve a complete revolution in the relation between master and apprentice, a revolution I, for one, would rejoice heartily to see brought about. The duty of the master should be limited to practical training; the duty of schools of pharmacy to supplementing this by theoretical and systematic teaching, with practical laboratory work of a higher character than can be taught in an ordinary business establishment.

"But in my opinion, all our labours in this direction will be of very little avail, unless the Preliminary examination is maintained at a good standard. Euclid and algebra ought eventually to be included, and Greek as well as Latin authors.

"I regard this examination as the grand corner-stone on which all our hopes rest. It is the entrance gate that should be most jealously guarded. We must rely absolutely upon this examination to provide suitable material for our educational efforts to thrive upon. If a youth is fundamentally weak in elementary education, if he is deficient in rudimentary knowledge, then he has not the mental power to assimilate the intellectual food of the character that ought to be provided by schools of pharmacy.

"The Preliminary examination not only tests the previous training and actual knowledge of a youth; but if the character of the examination is kept up to a suitable standard, it gives us reasonable grounds for assuming that the boy who can pass has been trained to habits of study, and has acquired a desire—a sort of appetite—for further information. A boy who cannot pass is, in no sense, worthy of our consideration. One may as well sow corn on a turnpike road as to anticipate any good fruit from such a source.

"With many apologies for so discursively criticizing your paper—you will no doubt easily separate the rubbish.—Believe me, faithfully yours,

"EDWARD SMITH."

LETTER FROM MR. JOHN MACKAY, OF EDINBURGH.

"*Dublin, 7th August*, 1872.

"My dear Attfield,—Just as I was leaving Edinburgh on Monday morning a proof copy of your paper on Pharmaceutical Education was put into my hands, and, in case my silence in the face of your invitation to criticize might be construed into concurrence with your views, I venture to send you one or two lines, to say I cannot agree with you on this important question.

"I have not time to discuss point after point wherein I disagree, and my few remarks must, therefore, be very general.

"Let me say with such a communication as yours before the meeting on the 13th, how much I regret my unavoidable absence from Brighton on this occasion, as I feel certain the discussion will be a very interesting and important one!

"From the very nature of existing things Pharmaceutical Education must, I submit, be looked on as compulsory up to a certain point, because we know that without a certain amount of education no one can for the future become a dispensing chemist. With your horror at cramming (in the true sense of the word), I quite agree, but such a system has existed, does exist, and will continue to exist. You have the highest authority for its existence; and go where you will, even in your Oxford and Cambridge, as well as in our own universities in Scotland, you will find such a course pursued, if not in all, certainly in connection with several subjects. I hold there is no Royal road to becoming a pharmacist, and the allusion you make to the public announcement that an ignoramus may be transformed into a chemist and druggist in a month is simply absurd.

"But your ideas are, I conceive, for the future education of our young men, far a-head of the present condition of things. Excuse me saying, you point rather to the *Pharmaceutical millennium*, than to the plodding weary days of the ordinary dispensing chemist. In other words, you take the aristocratic view of the matter, apparently forgetting the hundreds, nay the thousands, of those having the will, but lacking the power to take advantage of the teaching you would have all our young men have. That there should be, and probably always will be, centres in large towns, where the few, I would say the *very few*, may go and study with a satisfaction to themselves and a credit to us as a body, I at once admit; but I also think such schools should not be supported as centres of education by the funds of our Society.

"Again, regarding present examinations for the Minor and Major, I believe that these fairly represent what young men ought to undergo. No candidate for the former gets through under a minimum of three hours close examination, while the latter extends to more than double that time, having the written as well as oral to go through. Remember that with all our desire to become *Professionals*, we still belong to *trade;* and, if you doubt my statement, go into the country and even some large towns and see the curious admixture of articles the chemist and druggist keeps, and is obliged to sell, otherwise he and his family would very possibly starve. Take a glance also at the manner in which assistants as a body are paid. I will venture to assert that, in many instances, good workmen, ordinary clerks, and even letter-carriers are as well if not better paid than some who are educated and highly responsible assistants, with the actions of whom life and death frequently hang in the balance; for we know the deadly poisons which have to pass through their hands.

"Want of opportunity during an apprenticeship, and deficiency of funds after that has expired, will militate against many attending courses of lectures; and though it is an easy thing to say, well, such lads should not join us, I would ask where are you to get recruits, and from what sources are you to fill your ranks? Glance at the inducements you offer in after-life. Can you not easily count those who have been what the world calls *successful?* and, if so, can you not count the thousands who make a living and nothing more?

"I will, however, close, not without adding how much I shall feel interested to read the discussion.—I remain yours truly, "John Mackay."

Letter from Mr. William Gilmour, of Edinburgh.

"11, *Elm Row, Edinburgh,*
"9*th August*, 1872.

"Dear Sir,—Before making a few remarks on 'Pharmaceutical Education,' a proof sheet of which you so kindly forwarded, allow me to express the regret I feel in being unable to attend the meetings of the Conference this year, the more especially as I think it promises to be one of the most important as well as interesting yet held.

"I am glad the all-important question of Pharmaceutical Education is to be brought forward, and brought forward in so able and practical a manner. Doubtless it is in every way the question of questions to young and old alike at the present time, for assuredly, as contained in your paper, a thousand times wrong are they who think that compulsory examination means also compulsory education.

"I intend not to enter into that elaborate criticism of your paper which you so courteously ask, for it were folly to attempt doing so without having more leisure both to collect and write down my thoughts than I can well spare at present. The general question of education is too important and fraught with too many difficulties to be lightly written or spoken about; and it is the general question on which I would only feel inclined to write about, or, indeed, as I take it, you would only have me reply upon, rather than cavilling at every sentence or statement which did not entirely dovetail with mine. I promise, however, if some one abler does not do so, to bring the subject up at one of the earliest of our scientific meetings here in the coming winter, when, if you will allow me, I will return the compliment by you of sending me a proof of your paper by forwarding you one containing a few thoughts on the same subject from a Scotch point of view.

"Now I hope you don't think this last expression an unhappy one? I only mean that some of your principal arguments for a compulsory education cannot and do not apply to Scotland since the passing of the Pharmacy Act, 1868. Notably is this so in your argument proving the deterioration not only in the character, but also in the extent of the knowledge taught in the chemistry class of the Society's school. Here the arrangement is such that those who accept the Society's conditions, not only for the chemistry class, but for every other—botany, materia medica, etc.—get the same instruction as those who graduate in our university, and this from the very nature of the arrangement; and as one of the examiners I can speak confidently not only in the great superiority in the character of the knowledge, but also in the very tone of those candidates who now present themselves both for the Minor and Major examinations.

"Did time, however, permit, I would not simply rest content with this assertion. I would put it yet more forcibly and show that it applied equally to those who had attended no classes at all, but simply depended on their own unaided exertions. Neither would I be averse to take you on your own ground, and debate your own statements regarding the point.

"But not less does your argument fail in its application to Scotland, regarding 'cramming.' I take it upon me to say that cramming—I mean the systematic procedure by public crammers to which you refer—is totally unknown in any part of Scotland. As for private cramming, that is, mere mental effort on the part of the candidate, I cannot see that you will ever get beyond it. I know of no system of examination into which it does not enter, or no theoretical system into which it is not possible to enter. I am *not* going to put in a word of apology for such, but after all, is there not the possibility of a word of sympathy for the 'poor fellow' with mental beyond intellectual attainments? The former may be his one talent, and he has laid it out and cultivated it to the best of his ability, and who knows but it may prove more valuable and be laid out to more advantage both for the world and himself than the five talents of intellect?

"Now, coming more immediately to the question of compulsory education, holding, as I do, that the Compulsory Examination Act has raised the moral as well as intellectual tone of the young men coming forward for their examination, can I refuse to support the further movement for compulsory education also? I answer this question by asking another, viz., is it expedient? Is it expedient to drive all our young men of promise and otherways from, or out of the profession? For this I hold is the point mainly or greatly to be considered. Would a compulsory education such as you foreshadow not simply drive all the young men from the field of pharmacy? I hold it would, and for the very simple reason that it would not pay. Nay! do not start at what may at first appear such a low, grovelling, unworthy consideration. I may have put the point bluntly, but I am convinced that I have put it correctly; for the idea, I suspect, is thoroughly exploded now-a-days of following a profession from the mere love of it without respect also to the pecuniary consideration. Now, to impose further restrictions on the young men would simply drive them into other pursuits requiring either less time or money to prepare them for it, or which would prove more remunerative for the outlay. I am not going to enter into any arguments in support of this idea, but I am thoroughly convinced it is correct, unless you provide a free or a cheap education at the expense of the Society's funds; and this I would oppose more than anything else, as I have ever found that a pauper education is the worst possible.

"I hope you will excuse these few hasty thoughts and criticisms, strung together quickly and unsystematically, but I could scarcely refuse your kind invitation on so important a subject and on so important an occasion.

"I am, dear sir, yours truly,

"Wm. Gilmour."

Letter from Mr. David Kemp, of Portobello.

"*Portobello,*

"*9th August*, 1872.

"Dear Sir,—Your paper on 'Pharmaceutical Education' has given me great satisfaction, on account of the thorough and exhaustive manner in which the subject is treated, and the conviction that it furnishes the true solution of a most important and difficult question.

"Having believed all along that the Pharmaceutical Society was really desirous and honest in its endeavours to promote pharmaceutical education, not only in London but also in the provinces, I am greatly pleased with the explanation you have given of its position, and your very complete vindication of its conduct in regard to it from its commencement to the present time. With reference to the Minor examination, I am inclined to think that after the present exceptional and transitional period has passed, it might be abolished with advantage, if the rights of those who were apprentices prior to 1868, and those who have entered the business since to be examined under the present regulations, be reserved. If this were done, there would be only the Preliminary and Major examinations left, the latter of which, with education made compulsory by proof of attendance at lectures on the various subjects being required from each candidate for examination, would go far to destroy the system of cramming of which you so justly complain.

"I fully agree with you in thinking that until education is made compulsory, the demand for a thorough pharmaceutical education will not be sufficiently urgent or extensive to warrant the Society in incurring much expense in providing it out of London. In the meantime, however, the desire, such as it is, for it, should be fostered and encouraged in every legitimate way, by all who are interested in the advancement of Pharmacy and as far as practicable and just, by substantial aid from the Society, but I do not think it would be wise to provide it or right to ask it much below its fair value.

"I feel satisfied that a school such as you propose in each of three or four of the great centres of population would be sufficient to meet the demand for it when it arises, and that it ought not to be provided on any extensive or expensive scale till then.

"My answers then to the questions you proposed, namely:—

'1. Is it desirable to make pharmaceutical education compulsory? If so,

'2. By what method should it be made compulsory? and

'3. What means should be adopted for providing students with the means of obtaining pharmaceutical education?'

"Are:—

"To the first, Yes.

"To the second, By requiring proof of systematic study.

"To the third, by the present school in London, and by organizing schools elsewhere when really required and likely to be entirely or nearly self-sustaining.

"I am, dear Sir, yours truly,

"David Kemp."

Letter from Mr. Peter Squire, of London.

"277, *Oxford Street, London, W.*

"*10th August*, 1872.

"Dear Dr. Attfield,—Your very elaborate paper seems to have exhausted the subject, and left little room for criticism; but if cram does exist to the extent you say it does, and if, as I suppose, it may be possible that Examiners are insensibly led to adopt set questions, then it does appear that some means should be devised to ensure a good curriculum of education.

"Thirty years or more ago, when my opinion had weight in the Society, I ruled at the Board of Examiners that if the candidate possessed the amount of knowledge necessary to carry on his business with safety to the public, we ought not to demand from him even his indentures of apprenticeship. But vast changes have taken place since then; my ideas are too antiquated for the present generation, nevertheless, my opinion still is, and always will be, what I stated in the House of Lords, that educated intelligence is by far a better safeguard than the best devised Act of Parliament against poisoning.

"Yours truly,

"P. Squire."

Mr. G. W. Sandford, of London, fearing that he might not be able to attend the Conference had forwarded the following remarks to Professor Attfield, but being present was requested to read them:—

Professor Attfield has indeed rightly stated in introducing the important subject of Pharmaceutical Education to this meeting that no apology was necessary. I am sure every member of the Conference will thank him for so ably describing the condition of pharmaceutical education *past* and *present*, and receive with all respect and attention the opinion of one so well qualified to form an opinion on the best means of promoting it in the *future*. The advancement of pharmacy seems to me to be the special province of this Association, and though professedly we meet to exchange notes of the doings of the past year for our mutual edification and improvement, I think the education of the future pharmacists of Great Britain must be a matter of the deepest interest to us all. In the few words defining pharmaceutical education, the chief requirements of a pharmacist are forcibly expressed; and if we succeed in instilling into the minds of the rising generation these ideas, England, although last in starting, may not be the least among nations in pharmaceutical honour.

Professor Attfield proposes two questions, and they are perhaps the two leading questions on the subject now occupying the minds of most men present.

1st. How to supply the demand for knowledge which compulsory examination has called forth.

2nd. The future relation of the Pharmaceutical Society to pharmaceutical education.

For certain reasons it seems to me that these two questions should change places, and I would therefore at once offer a few remarks on the relationship of the Society to education. It is rightly asserted that the Society was originally founded for the purpose of advancing chemistry and pharmacy, and promoting an uniform system of education of those who should practise the same, but I must dissent from the opinion I have so frequently heard and seen expressed of late that the founders intended it to be *ultimately* an *educating* establishment.

We know that their object was to *enforce* education by rendering examination compulsory; but at the time the current of 'Free-trade' was running so strongly in this country that questions not purely of trade were drawn into the stream, and the efforts even of Jacob Bell and his fellow-labourers were unequal to the task of extricating this particular one. But Jacob Bell was a man not easily daunted, and, although defeated for the time, not to be turned from his purpose. His determination then was to convince the public of the advantage which would arise from the better education of chemists and druggists. But there were no means in existence—I mean no public means—to advance that education, and he rightly decided that the funds which had been gathered together by the infant Society, could not be better employed than in forming such a school as was needed—a school, which in the first place would send abroad throughout the land a better class of chemists—a school, the success of which financially should encourage the establishment of other schools in various parts of the kingdom, to be assisted also in the beginning by grants in aid; he felt that if these establishments could be made self-supporting, his work would be done. I cannot for one moment suppose that he ever intended to found a vast charity for the education—not of the children of chemists—but of those lads whose parents might in future desire to make them chemists!

Coming to Dr. Attfield's report under '1846,' he describes the difficulty of the Council when seeking to render examination compulsory by Act of Parliament; rather than relinquish its mission of education, he says it would have given up its examining powers. I do not put exactly the same interpretation on the records of the period. It seems to me that the Council were then, as now, bent on making examination compulsory, but that having established themselves as teachers, and there being in fact no other public teachers, they felt a very reasonable fear that when no man should be allowed to perform certain duties and possess certain rights until he had passed the examinations, and no other school than their own was in existence, the Legislature would naturally say, it is contrary to sound wisdom to make you, the proprietors of the school, the examiners of the pupils; such a course would be open to abuse, and consequently a public danger.

I am strengthened in this view by the opening of the leading article in the very same journal to which Dr. Attfield refers, and that article was in all probability written by Jacob Bell himself; it runs thus:—

"The main feature of the proposed Pharmaceutical Bill is the establishment of a compulsory examination for future chemists and druggists. The machinery of the Bill consists merely of an arrangement for constituting a competent Board of Examiners, and the penalty clauses are introduced for the purpose of making the examination compulsory.

"All the other parts of the Bill are matters of detail subservient to the one grand object, namely, the establishment of an efficient and compulsory examination."

A little further on, when Parliament saw no objection to the Society exercising the two functions, it seems to me the reason was that the Act in which the power of examination was given to the Society gave no exclusive rights, save those of certain titles, to the examined men; and so no hardship would virtually be suffered by rejected candidates.

And this naturally brings us immediately to the relationship of the Society to education now that the Act of '68 forbids a man even calling himself a "chemist and druggist," and virtually precludes him from practising as one by rendering it penal for him to deal in certain "poisons" which, as a dispenser, he must require daily. Even now the main appointment of examiners is left with the Pharmaceutical Society, subject to the approval of the Privy Council, and the addition of a Government assessor, and I therefore think—indeed, have publicly stated from time to time for the last three or four years—that the relationship stands in danger of being what Dr. Attfield calls an "unholy alliance." I am glad to be supported in this opinion by so able a man as Mr. Mackay.

Turning now to the first question,—"How to supply the demand for knowledge which compulsory examination has called forth?" I by no means think that although in my opinion the Pharmaceutical Society should cease to *keep a school*, it should cease also to be the *schoolmaster abroad*, aiding, and to some extent guiding, other schools.

In its early days it took the only possible means of supplying the requirement of the time—the establishment of one great model centre of pharmaceutical education—necessarily *in* the metropolis, but not, as some most unreasonably tell us, *for* the metropolis. Everybody knows that the chemists' assistants in London are mostly countrymen; that the common course of events is for country apprentices to become London assistants, and such are the men who, according to the Professor, have availed themselves of the advantages offered at Bloomsbury Square. That establishment has various facilities for education; some of them must remain and be augmented from year to year. I mean the library, museum, and perhaps the lectures. I say '*perhaps the lectures*,' because I feel that professors are an appropriate appendage to any learned society. But two great objects have now been attained. Examination is compulsory, and therefore education necessary, and the schools in London have established the fact that they may be self-supporting. Can we not then leave the School of Pharmacy mainly to its own resources? Housing, and so far helping it perhaps, but depending on proper fees from its pupils for its support. Would not such a school be in reality in more healthy and wholesome condition if so left? I have said that because the Society examines, it should not also teach; and although that may be an argument for leaving the established central school to itself, it is no argument against helping to sustain other schools in large provincial centres until they too are able to stand alone. But herein we must not be led away. There are very few provincial centres where this would be done successfully, and, as I said before, it would be monstrous to set up huge charity schools for boys who, in selecting pharmacy as their future, have done so without possessing sufficient means to carry them through their education. To aid these efforts in the country would be legitimately carrying out the intentions, and following in the steps of the founders of the Society. Much has been said about the way in which aid should be given. One man is shocked at the idea of paying lecturers; another would contribute nothing for rent. To me it has always seemed that where an association has been proved to be working in the right direction, and needs assistance, there pecuniary aid should be given to the general fund of that association, and the directors on the spot should apply it as best they could. The Pharmaceutical Society could never be hampered by the machinery required to make all such associations 'branches' or 'in connection,' and would have no further authority over them than to discontinue its assistance instantly on being satisfied either that it was misapplied or no longer needed. Fettered with details many difficulties might arise. Even paying for results might lead to that which Professor Attfield so earnestly and justly denounces—'cram.'

We know that wherever an examination has to be passed, a door is opened for 'cram.' From the 'Senior Wrangler' to the lowest clerk in a Government office 'cram' is resorted to. It is not as the Professor has stated that the Pharmacy Act has not created a demand for education. The very fact of this superficial teaching being advertised is an evidence of the demand for education; and it seems to me somewhat unjust to say the principals in pharmacy residing in provincial towns are basing their appeal to the Council to aid them, on a demand which does not yet exist. When the School of Pharmacy in Bloomsbury Square was started, no demand for it existed; but its founders desired to create a demand, and we may give our provincial friends, who know that *sound education* is required, credit for a like desire, and a desire to render the superficial system both unnecessary and distasteful to students. To correct this deplorable state of things, another power than the Act of Parliament must be employed. The Board of Examiners could do much if they had time to make the examinations more practical. They would, I know, be glad to enforce on the candidates the requirement of a period of actual service in a chemists' shop. Dr. Attfield would have a period of study in some particular school, but he must not blame the Pharmacy Act for not requiring this, because when that Act was passed there was no such school in existence except that of the Society itself.

As bearing on this question, I may just allude to the report of Dr. Greenhow, which appears in the last PHARMACEUTICAL JOURNAL. Among other good things, he says there, "It would, in my opinion, greatly conduce to the advantage equally of masters and apprentices if a general understanding could be arrived at, that no young men should enter on employment either as apprentices or assistants, who had not previously passed the Preliminary examination."

You cannot make men perfect by Act of Parliament; you may restrain them from evil, you may even keep them in a straight line of conduct by the letter of the law; but if you imbue all concerned, masters as well as apprentices, with the spirit of the Pharmacy Act—and I know no organization more powerful to do so than this Conference—you will have done much to promote the objects for which the Pharmaceutical Society has so long laboured.

NOTES READ BY MR. ROBERT HAMPSON, OF LONDON.

Owing to the zeal—I will not say over zeal—of the friends of pharmaceutical education, there has arisen something of the nature of a crisis on this question, which it is desirable to tide over, without taking false, or injudicious steps.

The very suggestive paper contributed by Professor Attfield is deserving of thorough discussion, and as he asks for free criticism upon it, and the general question, I will very briefly comment upon the "situation."

I regretfully agree with the statement that there is *not* "a wide-spread demand by assistants and apprentices for pharmaceutical education," although I believe the demand has slightly increased since the passing of the Pharmacy Act of 1868.

Whilst dwelling upon this fact, I have a lively recollection of the recent zealous efforts of the Manchester Chemists' Association in the very laudable endeavour to found a school of pharmacy in connection with Owens College. These efforts were considered to be well-timed, and necessary, and were very cordially supplemented, by the managers of the important institution to which the school was attached. Notwithstanding that Manchester is the centre of a notably wealthy district, including many thriving towns, the aggregate population equalling London in number, these very hopeful efforts ended in comparative failure. *Funds were abundant in this instance, but the students were not forthcoming.* In the face of this discouraging experience, and experience of a like character in other important places, to attempt to establish a comprehensive scheme of pharmaceutical education, however ably the scheme may be planned, is simply to court defeat, to jeopardize the interests of the school at Bloomsbury Square, which does not flourish to our satisfaction, and to spend money fruitlessly.

In trying to discover the cause, or causes, accounting for this evident want of demand for pharmaceutical education, no great distance, in the way of research, need, I think, be traversed.

The chief cause is a very palpable one, if we open our eyes to look for it, and not live in a maze of 'great expectations.'

It is simply this. The very limited, and slowly-growing demand on the part of medical men, and consequently on the part of the public also, for improved, or even passable pharmacy.

If the medical profession, or the public, were loud, or only gently pressing in their demands for improved pharmacy, or for *pharmacy at all* in the majority of places, there would be no lack of zealous students, willing, yea eager, to pay the *full value* for instruction received, —no subsidies being required—whether in metropolitan, or provincial schools of pharmacy.

When this demand shall have grown, and this demand is the only safe basis on which to build, and the labourer in pharmacy is considered to be more worthy of his hire, then, and not till then, will pharmaceutical education flourish.

We must not therefore be so irrational as to expect a rapid growth in the demand for pharmaceutical education. The improvement we so much desire, will be gradual, and in exact proportion to the demand for genuine pharmacy.

I think there is no doubt, that the unsatisfactory relationship, or rather *want* of relationship, which exists between the medical profession and those who practise pharmacy, is the most constant, and influential cause of the deficient demand, for pharmaceutical education.

An abiding interest in pharmaceutical education and progress is not to be expected, when, in many towns and whole districts, a physician's prescription is almost a novelty, and the Pharmacopœia processes are unpractised, as their is absolutely no use for any but the most simple pharmacopœia preparations.

Is the much-to-be-deprecated process of cramming a very venial offence, when the student is aware that ordinary practical knowledge, with the possession of the legal entrance into the trade, is all, in the majority of cases, that is likely to be required from him by his client when in business?

The examination-room is the place to check cramming.

Compulsory attendance at lectures will not remedy the want of demand for pharmacy. The time is not ripe for the proposed change of compulsion—a change that would press so severely upon the hard-working self-reliant student, who, in spite of all difficulties, passes the examinations with credit and honour.

The ordinary but imperious laws of demand and supply rule this question, and we must not wilfully ignore them.

Can nothing therefore be done, to bring the physician, and the pharmaceutist, into more intimate mutual relationship? Cannot this Conference, as it assembles year, by year, do something in this direction?

Much more depends upon the removal of this defective relationship, than the *premature* establishment of schools of pharmacy; for when the demand comes, the supply will follow, 'in good time.'

I would say in reference to provincial pharmaceutical education, that I think the Pharmaceutical Society would willingly aid, in the establishment of central schools of pharmacy, according as a *genuine demand* for these schools arises. This aid being given, only tentatively, as these institutions should be self-supporting.

The scheme adopted by the Pharmaceutical Council in November of 1870, had it been carried out, would have been an excellent one for the purpose.

I object to grants being given to pay lecturers and class-teachers. The students' fees ought to cover these expenses. We have no right to unjustly cheapen pharmaceutical education.

There is no prospect of establishing a large number of efficient schools of pharmacy. It is better to have *one or two* situated in important centres, well supported and conducted, than a great number of small evanescent schools, which may be here to-day, and gone to-morrow.

We must bear in mind, that if aid be given to establish schools and classes in a *diffusive manner*, central schools of pharmacy will never be formed, as a diffusive pseudo-philanthropic scheme, will prevent the requisite aggregation of students into educational centres.

I have confidence in the ultimate future of pharmaceutical education, and this confidence is mainly based upon an improving national and scientific education; the controlling influence of the legal tests required under the Pharmacy Act; and a more just recognition of pharmacy on the part of the medical profession and the public.

Parliamentary and Law Proceedings.

Important Decision against a Medical Man.

At the Sheffield County Court the Judge (T. Ellison, Esq.,) has delivered a decision of considerable importnace to medical men. A surgeon in the town had entered about forty cases, and when the first, which was to recover the sum of 12*s*., was called on, his Honour asked him whether he was a surgeon or an apothecary, or both. The plaintiff replied that he was a surgeon only. His Honour then asked him whether he claimed the 12*s*. for surgical operations or for medicine. The plaintiff replied that the claim was for medicine, and not for surgical assistance. His Honour told him that he had no qualification as an apothecary to supply medicines, and the Act of Parliament said he could only sue according to his qualification. He held the qualification of a surgeon, and he could sue for nothing but what came within his surgical practice. The plaintiff said if that were so he would withdraw the case. In going through his list of plaints he withdrew all those for medicine supplied; and where the plaint was for surgical assistance and for medicines, he had to abandon the latter. Another medical practitioner was in court who only held a diploma as an apothecary, but in his case no questions were asked, and he was allowed to prove his claims.

Accidental Poisoning by Laudanum.

On Wednesday, August 21st, an inquest was held by Mr. J. Makinson, the deputy coroner for Manchester, touching the death of Oscar Henry Cutler, the infant son of an ironmonger living in Oldham Road. A servant of the deceased's parents, named Barratt, said that the deceased was unwell on Sunday morning, and she gave it, by mistake, a dose of laudanum. She thought the bottle contained paregoric, which was the deceased's proper medicine. A sister of the deceased said that shortly after the deceased had taken the laudanum, Barratt said to her, "See what I have done; I have given the child laudanum. Don't tell your mother; I will let her know when she comes down." Witness's mother did not come down till about an hour and a quarter afterwards, when the deceased, who went to the bottom of the stairs to meet her, seemed sleepy. Barratt then told her mistress what had happened, and the deceased was taken to a doctor. He appeared to be recovering from the effects of the poison, but on Monday evening was seized with fits and died. A verdict of accidental death was returned; and the jury censured Barratt for not immediately mentioning the mistake she had made to her mistress.—*Manchester Guardian.*

Suspected Poisoning by Arsenic.

On Saturday, August 24th, Mary Ann Cotton was brought up at the Bishop Auckland Police-court, charged with the wilful murder of Charles Edward Cotton, her step-son, at West Auckland, on the 12th of July last.

Mr. Thomas Scattergood, of Leeds, surgeon (lecturer on forensic medicine and toxicology at the Leeds School of Medicine), said: On the 26th of July last I received from my pupil, Mr. Lockwood, six jars and two paper parcels. They were all well secured and labelled. The bottles were numbered 1, 2, 3, 4, and 7, and beneath the seal of each was a slip of paper with the name of W. B. Kilburn written on it. One of the paper parcels was numbered 6, and securely sealed and labelled, and secured to the bottle. The other parcel was also sealed and labelled, but not numbered. The jar No. 1 contained some fluid drachms of a liquid purporting to be part of the contents of the stomach of the late Charles Edward Cotton. The jars numbered 2, 3, 4, 5 and 7, contained the stomach and part of the bowels, the spleen, kidneys, heart, and portions of the lungs and liver purporting to be those of the late Charles Edward Cotton. The parcel numbered 6 contained a napkin purporting to have on it the last evacuation from the bowels of the late Charles Edward Cotton. I have analyzed these, and found the stomach and upper portion of the smaller bowel for the length of 18 or 20 inches presented marks of inflammation of such a kind as are produced by an irritant poison. The redness was in patches, and in one or two places there was blood effused beneath the mucus membranes. I carefully examined the small intestine to see if there were any of those appearances which are met with in cases of enteric fever, but there were no such appearances. The stomach and small intestine were well preserved, so that the appearances of inflammation were quite distinct. I found arsenic in the contents of the stomach and in the contents of the bowels, in the substance of the stomach and of the bowels, in the liver, the lungs, the heart, and the kidneys. I did not find any in the spleen. There were brown stains of fæces on the napkin, and on it also I found arsenic. The amount contained in the nine fluid drachms of stomach contents was rather more than half a grain of white arsenic or arsenious acid. The amount contained in the other parts submitted to me I estimated at about one-fifth of a grain. I found no morphia in the contents of the stomach, but I found traces of bismuth. The remaining parcel, purporting to contain articles found in prisoner's house by the police, contained, first, a paper of arrowroot; second, a powder wrapped up as by a surgeon or chemist, which weighed above two grains, and consisted chiefly of borax, with a little morphia, and a little oily matter which might have been dropped on the outside of the paper cover; third, a tin canister containing a quantity of red lead; and, fourth, a box of pills. None of these articles contained any arsenic. After hearing the evidence of Dr. Kilburn and Mr. Chalmers, and taking into account the appearances I observed in the stomach and bowels, and the result of my analysis, I am of opinion that death resulted from poison by arsenic. The prisoner was formally committed for trial at the next assizes at Durham on a charge of wilful murder.—*Leeds Mercury.*

Poisoning by a Preparation of Cantharides.

Mr. William Emsley, the deputy-coroner of the borough of Leeds, held on Saturday afternoon an inquiry respecting the death of Charlotte Lavinia Bee, two years of age, the daughter of a labourer. It appeared that on Friday morning Mrs. Bee went to Holbeck to assist the wife of Mr. Clough, and took with her the deceased. Shortly after ten o'clock, while engaged in playing, the child ran into an outhouse, and taking up from the floor a bottle containing a preparation of oil of cantharides, drank a portion of the corrosive liquid. She was badly blistered about the face and mouth, and suffered very much. Mr. Mann, surgeon was summoned, and after a remedy had been applied, the child was, by his advice, removed to the infirmary. She remained in an insensible condition throughout the day, and her death occurred in the evening. It seemed that the occupants of the premises were ignorant of the bottle and its contents, but it transpired that the liquid had been obtained some years ago for the purpose of blistering horses. The verdict was "Accidentally poisoned."

Obituary.

FELIX ROBERT GARDEN.

We regret to record this week the death of a former member of the Council of the Pharmaceutical Society of Great Britain. Mr. Felix Robert Garden, late of 372, Oxford Street, died at Ventnor, August 2nd, 1872. Mr. Garden was educated at the London University College, where he received a good classical education. When a youth he selected the church for his future career. After a brief sojourn, however, with a clergyman in the country with whom he was placed to go through his preparatory studies, he changed his mind, and decided on following his father's calling as a chemist and druggist. Mr. Garden was for many years a member of the Pharmaceutical Society, and was elected a member of the Council. In consequence of delicate health, Mr. Garden was for several years unable to apply himself closely to business, and in January, 1863, he retired from it altogether. The name of his firm, however, was continued as Garden and Robbins until January, 1865. We believe that Mr. Garden's father was at one time a partner with the celebrated Mr. Accum, with whom he carried on business for some years in Compton Street, Soho. When Mr. Accum left the country, Mr. Garden settled in Oxford Street.

WILLIAM HUSKISSON.

The Pharmaceutical Society has lost another of its founders by death, in the person of Mr. William Huskisson, who died on Saturday last, August 24th. Mr. Huskisson was born in 1793 at the Old Bath House, Cold Bath Fields, Clerkenwell (since pulled down), and after leaving school, went into the chemical business of his father and cousin (Huskisson and Towers). On the commencement of the Pharmaceutical Society he became a life member, and always felt the warmest interest in the welfare of the Society. He was of a quiet and retiring disposition, and, though he enjoyed the private friendship of most of the distinguished chemists of the last generation, he rarely mixed with society. He joined heartily, however, in the scheme of his friend Dr. Birkbeck to establish the London Mechanics' Institution, and was a member from its commencement to the time of his decease. He lived for many years and died in the same house, in Mecklenburgh Square, which his old friend, Mr. Samuel Parkes (author of the Catechism), had occupied previously.

ALFRED UTLEY.

On August 26th, at Ryde, after a lingering illness, borne with great patience, Mr. Alfred Utley, Pharmaceutical Chemist, of Mount Vernon Road, Liverpool. Aged 32.

Notice has also been received of the following deaths:—

On the 22nd July, Mr. John Nicholas, pharmaceutical chemist, of Narberth, Pembrokeshire. Mr. Nicholas had been a member of the Pharmaceutical Society since 1853.

On the 17th August, Mr. John Beaton, pharmaceutical chemist, of 6, St. George's Terrace, Kilburn. Mr. Beaton had been a member of the Pharmaceutical Society since 1851.

On the 7th July, Mr. H. Miller, chemist and druggist, late of Battersea.

On the 9th August, Mr. G. H. Ellcome, chemist and druggist, late of Fareham.

On the 15th August, Mr. C. Goodbarne, chemist and druggist, of Brighton.

Correspondence.

EXAMINATION FEES.

SIR,—Three subjects of great importance are at the present time before the Pharmaceutical Council, and will beyond doubt receive the most careful and ample consideration of our representatives, viz., Provincial Education, Minor Examinations, and Examination Fees.

Upon Mr. Schacht's proposed scheme for provincial education on which you have invited and received many criticisms and suggestions, I will not at present enter. So far as I have been able to look into it, I confess myself but little enamoured with it, believing it will require very material alteration before it can possibly be made applicable to the work of our Society.

The wider scope of subjects for the Minor examination, to which I ventured to refer in my remarks at the last annual meeting, has now been officially brought before the Council by Dr. Greenhow in his report presented at the late meeting of Council, and this will, therefore, at once receive the attention it demands. The necessity for that examination being more searching will, I feel sure, be acknowledged by most persons, when it is considered that instead of its being looked upon as the stepping-stone to the Major, as was invariably the case in days gone by, it is now accepted as the legal evidence of full qualification; the result being that not only do those who go through the ordeal deceive themselves, but the real benefit intended for the public good by the compulsory examination is reduced to its very lowest degree.

But the point to which I more particularly desire to direct attention is that of examination fees. It is one of great importance, and I believe at present stands as a serious barrier to our progress as a Society, and to the real improvement of pharmacists generally. Mr. Mackay, in a letter lately addressed to this Journal, p. 118, remarks that "the time may come when such a course (lessening fees) might be deemed advisable for the interests of the Society; but a change such as this would require very great consideration before a step so serious could be safely taken." Mr. Frazer in the same Journal tells us he has already given notice of certain resolutions upon the subject to be considered at the September meeting of Council. With regard to Mr. Mackay's fears, I question whether, when an error has been discovered it is not better at once to face, and, if possible, remove it rather than to delay; but, on the other hand, whether the resolutions proposed by Mr. Frazer do not go too far, and would not be fraught with untold difficulties and inconveniences to the Board of Examiners I seriously doubt; to say nothing of the almost pauper class of students implied by the conditions suggested. These are, however, questions on which we must expect differences of opinion; but however widely we may differ therein, I cannot help thinking it a pity and want of good taste, to give expression to such uncalled-for sneers and personalities as have been seen of late in the correspondence column. Such utterances add no weight to the argument, and reflect no credit on the writer.

My earnest desire is to see the whole trade as far as possible united into one body, each member as such holding a responsible position, to be used for the benefit of the whole. It has been with this desire that I have ever advocated the adoption of a liberal policy towards those we are in the habit of regarding as outsiders; and it is for the furtherance of the same object that I desire now to see a radical change brought about in the examination fees.

Educational qualification has always been held as the *sine quâ non* of membership; upon due evidence of its possession (either assumed, as in the case of those who are admitted by virtue of having been in business before a certain date, or proved by examination), membership alone has been obtained. In future, those only who pass the Major examination will be eligible for election as members, but unfortunately the advantages of membership, as viewed by outsiders, are so few that a very small proportion only, of those who aspire to the higher grade of pharmaceutical chemist, deem it necessary or desirable to join themselves to the Society as members; the result being that our strength as a society is yearly decreasing, whilst the numerical and therefore political strength of outsiders is largely increasing, and the feeling of estrangement, instead of being wiped out, is perpetuated and extended to an untold extent, and must ultimately, if not removed, be productive of immense difficulty and evil.

The plan which suggests itself to my mind is *not* the reduction of examination fees, but such an alteration in them as shall present a substantial gain to those who, by persevering study, show their appreciation of the higher qualification and title, and shall thereby at the same time secure to the Society a body of enlightened and influential members. To this end I would propose the following scale:—

Fees.	£. s. d.	Annual Subscriptions on becoming connected with the Society.	£. s. d.
First or Preliminary (Registered as Apprentices or Students)	2 2 0	Eligible on application to the Council, to be elected Apprentices or Students of the Society	0 10 6
Minor (Registered as Chemists and Druggists)	5 5 0	Eligible, on application to the Council, to be elected Associates of the Society	1 1 0
Major (Registered as Pharmaceutical Chemists and Associates of the Society without extra fees) . .	10 10 0	Registered as Members of the Society on entering business on own account without extra fee	

by which it will be seen that all who pass the Major examination would not only be registered at once as Pharmaceutical Chemists, and as members of the Society, without any extra fees, upon going into business as masters, but would at once be put into possession of a tangible gain, by being henceforth free from fees of any kind whilst retaining their connection with the Society as Associates.

Here would be provided what I believe is now greatly needed, a substantial stimulus to the Major examination, something worth a little extra study and expense, something to encourage the rising generation to persevere in the path of learning.

One or two objections to this step I would at once very briefly meet. It will doubtless be argued that such a sacrifice would be ruinous to the Society financially, and a serious injustice to those who have paid or are paying their subscriptions.

Financially I believe it would be found a direct advantage, and that the Society would be enriched thereby, many being induced to pass the Major who are at present deterred from so doing by the fact, that, although they succeed in passing the examination, they would yet gain no further advantage without the payment of extra fees. As to injustice to old members, I believe the objection more imaginative than real, and that experience would prove the willingness of such to forward the general good, whilst those who have passed since the Pharmacy Act came into operation might fairly be admitted on payment of a five-guinea commutation fee.

Another, and perhaps more difficult, although not insurmountable, question would arise upon the supply of the Journal. This would probably require a complete change from the present free circulation. The Journal account has always formed a sore point in the annual statement, showing a considerable loss to the Society; that such should be allowed to continue is of itself highly improbable, and would, beyond doubt, independently of any such alterations which I have ventured to suggest, be a subject for the consideration of the present or future Councils; any alteration such as I suggest would but accelerate the step which is considered by a large number of our members to be inevitable, viz., the abandonment of the free issue of the Journal, letting it stand upon its own intrinsic merits. That such a step would be alike advantageous to the Society as proprietors, and to the readers as such, is the generally expressed opinion of most with whom I have spoken upon the subject.

I must apologize for the length of my letter, but trust the thoughts expressed may commend themselves to the serious consideration of the Council; believing that some such action is really called for in the interest of the Society.

Edwin B. Vizer.

63, *Lupus Street, Belgravia South,*
August 27th, 1872.

Chemists' Club.

Sir,—The letter in the Journal, published a few weeks since suggests an idea which, if adopted, would, I think, conduce more to the unity and concord of our fraternity than any institution which has hitherto been proposed.

The convenience and comfort of a "Chemists' Club" in London, to all who are connected with the trade, either in town or the provinces, must, on consideration, be manifest to all, at the same time, it would, being established, be inexpensive and self-supporting. Much may be said of the advantages which would attend it, and I hope much more will be said, and the subject well discussed and ventilated. With your correspondent, I also shall be glad to become a member, and if any of your readers approve of the suggestion, and will convene a meeting on the subject, I have no doubt a satisfactory result would be arrived at. Hoping to have the opinion of your correspondents on the subject.

One who will Attend the Meeting.

Appeal: Mrs. Stockman and Family.—The following subscriptions have been received in response to an advertisement which appeared in last month's Journal on behalf of Mrs. Stockman and family:—E. H. Matterson, £2; Lunar Caustic, 10*s.*; Mr. Berry, 2*s.* 6*d.*; A Poor Clerk, 3*s.*; F. H. Charles, 1*s.*; R. Rowe, 10*s.*; For Pity, 1*s.* 6*d.*; a Manchester Member, 2*s.* 6*d.*; E. Worth, 5*s.*; W. W. Clark, 10*s.*; Collected by Mr. John Wavell, Local Secretary for Ryde, £3. 3*s.* 6*d.* Mr. Wavell, in his letter says, "I should suggest if the local secretaries for other districts would kindly exert themselves in this matter, a very useful and serviceable amount could be raised for the bereaved family." A more distressing case was never submitted to the public. Mrs. Stockman and her eight children, through the suicide of her husband (a chemist at Gosport), under very painful circumstances, are entirely dependent on charity for support. She has been brought up to the drapery business; and if a sufficient sum can be raised, it will be invested by the trustees in the purchase of a small business of that description, as Mrs. Stockman is an active business woman. More than £100 have been already subscribed by friends in the neighbourhood and others, including £20 from the Benevolent Fund of the Pharmaceutical Society. A still larger amount is needed to carry out the above object; and it is thought it only requires the attention of the benevolent and well-to-do among the large number of chemists to assure such amount being received. The money will be judiciously invested by the trustees, G. Perfect, Esq., Havelock Park, Southsea, and Charles Mumby, Pharmaceutical Chemist, 47, High Street, Gosport, by whom subscriptions will be thankfully received.

"*An Assistant to a Physician.*"—The gentleman referred to has not only passed the Minor examination, which is compulsory, but also the Major, which is voluntary.

"*Not Happy.*"—Yours appears to be a case which unfortunately occurs too frequently of the improper apprenticeship of youths destitute of all elementary fitness for becoming qualified druggists. We are utterly at a loss to understand the latter portion of your history, or to reconcile your statements that you had served nearly four years "in a first-class West-end shop where there was nothing but dispensing," and that subsequently you failed to pass the Preliminary examination. In answer to your question what you should turn your attention to if you again fail to pass the Preliminary examination, we are unable to make any suggestion.

"*Quinia.*"—The sale would not be strictly legal, but we believe no objection would be raised to it.

R. G. H.—(1) You will find an article on the subject in the Calendar of the Pharmaceutical Society. (2) Apply at Stationers' Hall.

Z.—A description of the test may be found in almost any handbook on chemistry.

R. & J.—The colouration is probably due to some impurity dissolved by the naphtha.

Communications, Letters, etc., have been received from Mr. G. F. Schacht, Mr. W. Wilkinson, Mr. Pollard, Mr. Reynolds, Mr. Tichborne, Mr. Langridge, Mr. Harrison, Mr. Deane, Mr. Squire, Mr. Minett, Dr. C. Kidd, Mr. Treves, Mr. S. T. Severs, "Assistant to a Physician," "An Unqualified Assistant," "Ratæ," A. M. A. P. S., R. J. N.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from page* 161.)

SASSAFRAS RADIX.—*Medulla.*—When present, the medulla is composed of irregular sub-globose cells, unpitted, containing small quantities of starch and usually also a dark red-brown colouring matter.

Wood Zone.—The wood is very light and porous, and is composed of pleurenchymatous cells, of vascular vessels, and the parenchymatous cells of the medullary ray. Viewed in cross section, the vessels are oval or circular, and in duplicate usually; the wood cells are irregularly shaped polyhedrons, the medullary rays composed of sub-cylindrical cells.

Wood Cells.—These when viewed longitudinally are seen to be of the true pleurenchymatous type, are long with pointed ends, and are intimately coherent. The vascular vessels are very large and clearly discernible by the unaided eye if a thin section be held up to the light. They are distinctly pitted, and have but moderately thick walls, which are very rarely completely perforate. The size, shape and arrangement of the pits are very varied. The larger vessels are somewhat minutely pitted, the pits being arranged with great regularity in close proximity with each other; are oval, their long axis being transversal to that of the vessel. These vessels form a very pretty object. Other vessels are coarsely pitted, the pits being "bars" rather than pits. The gradations between these extremes are gradual. The vessels are not reticulate, but certain of them manifest a disposition to tear longitudinally, as though they were formed by the adhesion of contiguous pitted wood cells.

The cohesion of the vessels in linear series is usually oblique, the septa is usually partially absorbed, a hernoid annulus remaining. When the septum has not been absorbed, it is pitted like the vessel.

The cells of the medullary rays are sub-cylindrical, and contain small quantities of starch and colouring matter. The starch is somewhat difficult of examination. The granules are rather small, ovate, and intensely doubly refractive.

A well-executed longitudinal section mounted in Canada balsam, after a prolonged soaking, forms a very beautiful polariscope object when viewed with a neutral violet, a cyanogen blue, or a purple selenite. When the selenite, polarizing, and analysing prisms are properly adjusted, the variety of colours seen will surprise any one but a very *blasé* polariscopist.

Cortical layers.—The presence of great quantities of colouring matter and other cell contents renders the examination of the cortical layers somewhat difficult. The sections must be carefully boiled, and then allowed to macerate, in alcohol before examination, if a close examination be desired. The parenchymatous cells of these layers do not present special features of interest. In shape they are irregularly modified sub-cylindrical cells; their walls are thin and unpitted.

Medullary rays are present in the innermost layers. The outer cells, the sub-epiblema are cubic, uncompressed cells with rigid walls and stained a dark brown, almost black. The flat cells of the exterior have no special features. The liber cells of the bark are cord-like, very long, and very tough. A cross section of them is not easy of accomplishment; they are then seen to be tubes almost wholly filled with sclerogenous deposits.

Canada balsam or dammar is the best medium in which to mount transverse sections. Longitudinal sections should be mounted in dammar and in glycerine. Before mounting them in balsam, they must be dried very gradually and carefully from the water in which they were immersed after being cut, and soaked in turpentine for some days.

THE RELATION BETWEEN THE ODOUR OF GASES AND THEIR POWER OF RESISTING LIQUEFACTION.

BY F. TREVES.

With regard to this singular and marked relation, it is, in the first place, to be noted that those gases alone have odour that can be reduced to liquids or solids by the application of pressure or great cold. And reviewing this relation in another aspect, it will be found also that every gas that is inodorous is likewise quite irreducible by either cold or pressure. In the second place, the intensity or strength of the odour of any gas bears a marked relation to the power required to reduce that gas to a liquid or a solid state, the strength of the odour being always in inverse ratio to the amount of force requisite for condensation. These relations—to which attention is now for the first time called—I have found to exist (with very few exceptions) in the case of all known gases. Of the four elementary gases—omitting fluorine—three, viz., oxygen, hydrogen and nitrogen, are quite inodorous, and at the same time, quite irreducible by either pressure or cold. Whilst the fourth gas, chlorine, which is possessed of a most suffocating smell, is easily condensed to a liquid. To take the case of some of the more common compound gases, it will be noticed that carbonous oxide, which is inodorous, is also incondensible, whilst carbonic oxide, which has a faint, pleasant and pungent odour, can be brought not only to a liquid, but also to a solid state. Nitrous oxide again, which possesses a very faint yet decided smell, can be liquefied and also solidified, but nitric oxide, which is an odourless gas, has never yet been reduced by any known means. Methyl hydride is not possessed of smell, and is not to be liquefied, whilst ethylene, with its faint garlic odour, liquefies at a temperature of 110° if under pressure. Acetylene, on the other hand, forms one marked exception to this general rule: it has a most distinct and far from pleasant smell and has as yet proved incondensible. In noticing, secondly, the ratio between the strength of the odour and the power required to reduce the gas, it will be seen that sulphurous acid, which possesses a smell more intense, perhaps, than that of any other known gas, being quite irrespirable, requires only a pressure of two atmospheres at 15°, or a temperature of 17·8°, to reduce it to a liquid, whilst, on the other hand, no less than fifty atmospheres at a temperature of 7·2° are required to reduce nitrous oxide, a gas almost inodorous, to a liquid condition. Again chlorine is easily liquefied under about five atmospheres, whilst hydrochloric acid, the odour of which is very much less intense than that of chlorine itself, requires the application of at least forty atmospheres for proper reduction. Ammonia and sulphuretted hydrogen require a temperature of 6·5° and 17°, respectively, to produce liquids, while ethylene, with other faint smelling gases, is only reduced under high pressure at 110°. A few gases—and strangely those in particular that are described as having a "fœtid" or "garlic" odour—present some slight exceptions to this singular ratio, but it holds good so generally, that a list of gases arranged in order according to their reducible properties, and a list arranged according to their properties of smell will show a rough but most marked coincidence.

ON THE CULTIVATION OF THE OLIVE, NEAR VENTIMIGLIA.

BY MR. L. WINTER.

(From a letter addressed to Mr. Daniel Hanbury, F.R.S.)

As you wish for a little information on the propagation of the olive in this part of Italy, I have drawn up a few remarks which, though not containing much that is new, may yet serve to complete or to confirm your own observations.

The different kinds of olive-tree we have in this country may be classed under three divisions:—

1. *Olivastro*, the Wild Olive, *Olea europæa, L.*, grows quite spontaneous, reproducing itself by seeds and suckers; leaves on young trees small and oblong,—on older trees a little larger and lanceolate; branches sometimes spiny; fruit small, oblong, and very bitter. This kind may be regarded as the parent of all the varieties.

2. Varieties reproducing themselves truly by seed, but not so freely as the *olivastro*, and having the fruit less bitter. Under this head may be placed the following:—

- α. *Pignuole.*—Branches greyish; leaves lanceolate, acute; fruits when ripe almost round, affording an oil of rather strong flavour. There are hundreds of these trees on the Capo Martino, near Mentone, quite wild.
- β. *Columbaïre* (Genoese dialect). — Branches brownish; leaves varying in shape, but mostly obtuse; fruit large, somewhat pointed.
- γ. *Spagnuole.*—Fruit more elongated than the preceding. These forms, α. β. γ., vary more or less *inter se.*

3. Varieties not reproducing themselves truly by seed, but returning to the *olivastro*. That these varieties degenerate when propagated by seed is the general assertion among the people here; but regular experiments have never, I think, been carried on, for raising the plant by seed is not advantageous, suckers being of more rapid growth. In this division I would place two varieties, viz.:—

- α. *Nilane.*—Fruit large, oblong. This occurs in abundance as far west as Cannes, whence along the whole French coast of the Mediterranean, another olive with still larger fruit is cultivated.
- β. *Punginaïre.*—This is another variety which we have in this country. It has long willow-like leaves, and produces a very large pointed fruit, chiefly preferred for salting.

The propagation of olive-trees belonging to this third division is effected by cleft-grafting on the stem of the *olivastro* at about six inches above the ground. When the scion has taken, earth is heaped around it, so as to stimulate it to shoot out roots. After three or four years the little tree begins to fruit, and arrived at an age of about 20 to 25 years, the roots which have been thrown out by the graft send up suckers, any which come from those of the parent *olivastro* being of course extirpated. These suckers, when about two years old, will be strong enough to bear separation from the parent-root and to be planted as independent trees. Such young trees fruit in three to five years after planting. When a sucker is thrown out from a large naked root, it may be surrounded by a heap of earth into which it will strike roots, and in due time may be separated as already explained.

The quality of the oil obtained from the cultivated olive very much depends on the degree of maturity of the fruit. The riper the latter, the better will be the oil it yields.

Near Marseilles the olives are gathered in October and November, while they are still unripe, and the oil is consequently of very inferior quality. This plan of anticipating the crop is adopted on account of the cold *mistral*, which spoils the olives sometimes completely, freezing them and rendering them nearly worthless for oil. To make the trees thicker in foliage, and thus capable of affording a natural shelter to their fruits, the peasants prune the tops every year after the gathering. In this district of Italy comparatively little pruning is needed, the trees on many properties being allowed to grow quite *au naturel.*

About La Mortola and the adjoining district of Latte, as well as on all the lower slopes of the Riviera, the olives are frequently attacked in the month of July by an insect called *moschino*, which lays its eggs in the berry.* The caterpillar developes itself in August, finding its nourishment in the pulp of the fruit. Olives thus infested drop from the trees while not yet fully ripe, that is, in October, November and December. On the mountains at some distance from the sea, the olives are scarcely at all affected by these insects; the fruits in consequence attain their perfect maturity, the crop being gathered between December and May. The oil yielded by such olives is very clear and of superior flavour, and it commands a high price. In proof of this latter fact, I may remark that the value of the oil produced at Latte contrasted with that of the mountain village of San Michele at the head of the valley is ordinarily as three to four, sometimes even as two to three.

THE AIMS AND INSTRUMENTS OF SCIENTIFIC THOUGHT.†

BY PROFESSOR CLIFFORD.

(*Continued from p.* 166.)

I said there were two ways in which a law might be inexact. There is a law of gases which asserts that when you compress a perfect gas, the pressure of the gas increases exactly in the proportion in which the volume diminishes. Exactly; that is to say, the law is more accurate than the experiment, and experiments are corrected by means of the law. But it so happens that this law has been explained; we know precisely what it is

* It appears not to lay more than one egg in each,—at least I have never found more than a single caterpillar in an olive.

† Lecture delivered before the British Association at Brighton, Monday, August 19th, 1872.

that happens when a gas is compressed. We know that a gas consists of a vast number of separate molecules, rushing about in all directions with all manner of velocities, but so that the mean velocity of the molecules of air in this room, for example, is about 20 miles a minute. The pressure of the gas on any surface with which it is in contact is nothing more than the impact of these small particles upon it. On any surface large enough to be seen, there are millions of these impacts in a second. If the space in which the gas is confined be diminished, the average rate at which the impacts take place will be increased in the same proportion; and because of the enormous number of them, the actual rate is always exceedingly close to the average. But the law is one of statistics; its accuracy depends on the enormous numbers involved; and so, from the nature of the case, its exactness cannot be theoretical or absolute.

Nearly all the laws of gases have received these statistical explanations; electric and magnetic attraction and repulsion have been treated in a similar manner; and a hypothesis of this sort has been suggested even for the law of gravity. On the other hand, the manner in which the molecules of a gas interfere with each other, proves that they repel one another inversely as the fifth power of the distance; so that we have found at the basis of a statistical explanation a law which has the form of theoretical exactness. Which of these forms is to win? It seems to me again that we do not know, and that the recognition of our ignorance is the surest way to get rid of it.

The world in general has made just the remark that I have attributed to a fresh student of the applied sciences. As the discoveries of Galileo, Kepler, Newton, Dalton, Cavendish, Gauss, displayed ever new phenomena following mathematical law, the theoretical exactness of the physical universe was taken for granted. Now when people are hopelessly ignorant of a thing, they quarrel about the source of their knowledge. Accordingly many maintained that we know these exact laws by intuition. These said always one true thing, that we did not know them from experience. Others said that they were really given in the facts, and adopted ingenious ways of hiding the gulf between the two. Others again deduced from transcendental considerations sometimes the laws themselves, and sometimes what through imperfect information they supposed to be the laws. But more serious consequences arose when these conceptions derived from physics were carried over into the field of biology. Sharp lines of division were made between kingdoms and classes and orders; an animal was described as a miracle to the vegetable world; specific differences which are practically permanent within the range of history, were regarded as permanent through all time; a sharp line was drawn between organic and inorganic matter. Further investigation, however, has shown that accuracy had been prematurely attributed to the science, and has filled up all the gulfs and gaps that hasty observers had invented. The animal and vegetable kingdoms have a debatable ground between them, occupied by beings that have the character of both and yet belong distinctly to neither. Classes and orders shade into one another all along their common boundary. Specific differences turn out to be the work of time. The line dividing organic matter from inorganic, if drawn today, must be moved to-morrow to another place; and the chemist will tell you that the distinction has now no place in his science except in a technical sense for the convenience of studying carbon compounds by themselves. In geology the same tendency gave birth to the doctrine of distinct periods, marked out by the character of the strata deposited in them all over the sea; a doctrine than which, perhaps, no ancient cosmogony has been further from the truth, or done more harm to the progress of science. Refuted many years ago by Mr. Herbert Spencer, it has now fairly yielded to an attack from all sides at once, and may be left in peace. When, then, we say that the uniformity which we observe in the course of events is exact and universal, we mean no more than this, that we are able to state general rules which are far more exact than direct experiment, and which apply to all cases that we are at present likely to come across. It is important to notice, however, the effect of such exactness as we observe upon the nature of inference. When a telegram arrived stating that Dr. Livingstone had been found by Mr. Stanley, what was the process by which you inferred the finding of Dr. Livingstone from the appearance of the telegram? You assumed over and over again the existence of uniformity in nature. That the newspapers had behaved as they generally do in regard to telegraphic messages; that the clerks had followed the known laws of the action of clerks; that electricity had behaved in the cable exactly as it behaves in the laboratory; that the actions of Mr. Stanley were related to his motives by the same uniformities that affect the actions of other men; that Dr. Livingstone's handwriting conformed to the curious rule by which an ordinary man's handwriting may be recognized as having persistent characteristics even at different periods of his life. But you had a right to be much more sure about some of these inferences than about others. The law of electricity was known with practical exactness, and the conclusions derived from it were the surest things of all. The law about the handwriting, belonging to a portion of physiology which is unconnected with consciousness, was known with less, but still with considerable accuracy. But the laws of human action in which consciousness is concerned are still so far from being completely analysed and reduced to an exact form, that the inferences which you made by their help were felt to have only a provisional force. It is possible that by-and-by when psychology has made enormous advances and become an exact science, we may be able to give to testimony the sort of weight which we give to the inferences of physical science. It will then be possible to conceive a case which will show how completely the whole process of inference depends on our assumption of uniformity. Suppose that testimony, having reached the ideal force I have imagined, were to assert that a certain river runs up hill. You could infer nothing at all. The arm of inference would be paralysed, and the sword of truth broken in its grasp; and reason could only sit down and wait until recovery restored her limbs and further experience gave her new weapons. I want in the next place to consider what we mean when we say that the uniformity which we have observed in the course of events is *reasonable* as well as exact.

No doubt the first form of this idea was suggested by the marvellous adaptation of certain natural structures to special functions. The first impression of those who studied comparative anatomy was that every part of the animal frame was fitted with extraordinary completeness for the work that it had to do. I say extraordinary, because at the time the most familiar examples of this adaptation were manufactures produced by human ingenuity; and the completeness and minuteness of natural adaptations were seen to be far in advance of these. The mechanism of limbs and joints was seen to be adapted far better than any existing ironwork to those motions and combinations of motion which were most useful to the particular organism. The beautiful and complicated apparatus of sensation caught up indications from the surrounding medium, sorted them, analysed them, and transmitted the results to the brain in a manner with which at the time I am speaking of no artificial contrivance could compete. Hence the belief grew amongst physiologists that every structure which they found must have its function, and subserve some useful purpose; a belief which was not without its foundation in fact, and which certainly (as Dr. Whewell remarks) has done admirable service in promoting the growth of physiology. Like all beliefs found successful in one subject, it was carried over into another; of which a notable example is given in the speculations of Count Rumford about the physical properties of water, to which the President has already called your attention. Pure water attains its greatest density at a temperature of about 39½° Fahr.; it expands and becomes lighter whether it is cooled or heated so as to alter that temperature. Hence it was concluded that water in this state must be at the bottom of the sea, and that by such means the sea was kept from freezing all through; as, it was supposed, must happen if the greatest density had been that of ice. Here then was a subtance whose properties were eminently adapted to secure an end essential to the maintenance of life upon the earth. In short, men came to the conclusion that the order of nature was reasonable in the sense that everything was adapted to some good end. Further consideration, however, has led men out of that conclusion in two different ways. First, it was seen that the facts of the case had been wrongly stated. Cases were found of wonderfully complicated structures that served no purpose at all; like the teeth of that whalebone whale of which you heard in section D the other day, or of the dugong, which has a horny palate covering them all up and used instead of them; like the eyes of the unborn mole, that are never used, though perfect as those of a mouse until the skull-opening closes up, cuttting them off from the brain, when they dry up and become incapable of use; like the outsides of your own ears, which are absolutely of no use to you. And when human contrivances were more advanced it became clear that the natural adaptations were subject to criticism. The eye regarded as an optical instrument of human manufacture, was thus described by Helmholtz; the physiologist who learned physics for the sake of his physiology, and mathematics for the sake of his physics, and is now in the first rank of all three. He said, "If an optician sent me that as an instrument, I should send it back to him with grave reproaches for the carelessness of his work, and demand the return of my money."

The extensions of the doctrine into physics were found to be still more at fault. That remarkable property of pure water, which was to have kept the sea from freezing, does not belong to salt water, of which the sea itself is composed. It was found, in fact, that the idea of a reasonable adaptation of means to ends, useful as it had been in its proper sphere, could yet not be called universal, or applied to the order of nature as a whole.

Secondly, this idea has given way because it has been superseded by a higher and more general idea of what is reasonable, which has the advantage of being applicable to a large portion of physical phenomena besides. Both the adaptation and the non-adaptation which occur in organic structures have been *explained*. The scientific thought of Dr. Darwin, of Mr. Herbert Spencer, and of Mr. Wallace, has described that hitherto unknown process of adaptation as consisting of perfectly well-known and familiar processes. There are two kinds of these; the direct process, in which the physical changes required to produce a structure are worked out by the very actions for which that structure becomes adapted—as the backbone or notechord has been modified from generation to generation by the bendings which it has undergone; and the indirect processes, included under the head of Natural Selection—the reproduction of children slightly different from their parents, and the survival of those which are best fitted to hold their own in the struggle for existence. If the naturalists here were able to talk to you for weeks, they might give you some idea of the rate at which we are getting explanations of the evolution of all parts of animals and plants, the growth of the skeletons, the nervous system and its mind, of leaf and flower. But what, then, do we mean by explanation? We were considering just now an explanation of a law of gases; the law according to which pressure increases in the same proportion in which volume diminishes. The explanation consisted in supposing that a gas is made up of a vast number of minute particles always flying about and striking against one another, and then showing that the rate of impact of such a crowd of particles on the sides of the vessel containing them would vary exactly as the pressure is found to vary. Suppose the vessel to have parallel sides, and that there is only one particle rushing backwards and forwards between them; then it is clear that, if we bring the sides together to half the distance, the particle will hit each of them twice as often, or the pressure will be doubled. Now it turns out that this would be just as true for millions of particles as for one, and when they are flying in all directions instead of only in one direction and its opposite; provided only that they interfere with each other's motion. Observe now; it is a perfectly well-known and familiar thing that a body should strike against an opposing surface and bound off again; and it is a mere every-day occurrence that, what has only half so far to go should be back in half the time; but that pressure should be strictly proportional to density is a comparatively strange, unfamiliar phenomenon. The explanation describes the unknown and unfamiliar as being made up of the known and the familiar, and this, it seems to me, is the true meaning of explanation. Here is another instance. If small pieces of camphor are dropped into water, they will begin to spin round and swim about in a most marvellous way. Mr. Tomlinson gave, I believe, the explanation of this. We must observe to begin with that every liquid has a skin which holds it; you can see that to be true in the case of a drop, which looks as if it were held in a bag. But the tension of this skin is greater in some liquids than in others; and it is greater in camphor and water than in pure water. When the camphor is dropped into water, it begins to dissolve and gets surrounded with camphor and water instead of water. If the fragment of camphor were exactly symmetrical, nothing more would happen; the tension would be greater in its immediate neighbourhood, but no motion would follow. The camphor, however, is irregular in shape; it dissolves more on one side than the other; and consequently gets pulled about, because the tension of the skin is greater where the camphor is most dissolved. Now it is probable that this is not nearly so satisfactory an explanation to you as it was to me when I was first told of it, and for this reason. By that time I was already perfectly familiar with the notion of a skin upon the surface of liquids, and I had been taught by means of it to work out problems in capillarity. The explanation was therefore a description of the unknown phenomenon which I did not know how to deal with as made up of known phenomena which I did know how to deal with. But to many of you possibly the liquid skin may seem quite as strange and unaccountable as the motion of camphor on water. And that brings me to consider the source of the pleasure we derive from an explanation. By known and familiar, I mean that which we know how to deal with, either by action in the ordinary sense, or by active thought. When, therefore, that which we do not know how to deal with, is described as made up of things that we do know how to deal with, we have that sense of increased power which is the basis of all higher pleasures. Of course, we may afterwards by association come to take pleasure in explanation for its own sake. Are we then to say that the observed order of events is reasonable, in the sense that all of it admits of explanation? That a process may be capable of explanation, it must break up into similar constituents which are already familiar to us. Now, first, the process may itself be simple, and not break up; secondly, it may break up into elements which are as unfamiliar and impracticable as the original process.

It is an explanation of the moon's motion to say that she is a falling body, only she is going so fast and is so far off that she falls quite round to the other side of the earth, instead of hitting it; and so goes on for ever. But it is no explanation to say that a body falls because of gravitation. That seems that the motion of the body may be resolved into a motion of every one of its particles towards every one of the particles of the earth, with an acceleration inversely as the square of the distance between them. But this attraction of two particles must always, I think, be less familiar than the original falling body, however early the children of the future begin to read their Newton. Can the attraction itself be explained? Le Sage said that there is an everlasting hail of innumerable small ether-particles from all sides, and that the two material particles shield each other from this and so get pushed together. This is an explanation; it may or may not be a true one. The attraction may be an ultimate simple fact; or it may be made up of simple facts utterly unlike anything that we know at present; and in either of these cases there is no explanation. We have no right to conclude, then, that the order of events is always capable of being explained.

There is yet another way in which it is said that nature is reasonable; namely, inasmuch as every effect has a cause. What do we mean by this?

In asking this question we have entered upon an appalling task. The word represented by *cause* has sixty-four meanings in Plato and forty-eight in Aristotle. These were men who liked to know as near as might be what they meant; but how many meanings it has had in the writings of the myriads of people who have not tried to know what they meant by it will, I hope, never be counted. It would not only be the height of presumption in me to attempt to fix the meaning of a word which has been used by so grave authority in so many and various senses; but it would seem a thankless task to do that once more which has been done so often at sundry times and in divers manners before. And yet without this we cannot determine what we mean by saying that the order of nature is reasonable. I shall evade the difficulty by telling you Mr. Grote's opinion. You come to a scarecrow and ask, what is the cause of this? You find that a man made it to frighten the birds. You go away and say to yourself, "Everything resembles this scarecrow. Everything has a purpose." And from that day the word *cause* means for you what Aristotle meant by *final cause*. Or you go into a hairdresser's shop, and wonder what turns the wheel to which the rotary brush is attached. On investigating other parts of the premises you find a man working away at a handle. Then you go away and say, "Everything is like that wheel. If I investigated enough, I should always find a man at a handle." And the man at the handle, or whatever corresponds to him, is from henceforth known to you as *cause*, and so generally. When you have made out any sequence of events to your entire satisfaction, so that you know all about it, the laws involved being so familiar that you seem to see how the beginning must have been followed by the end; then you apply that as a simile to other events whatever, and your idea of cause is determined by it. Only when a case arises, as it always must, to which the simile will not apply, you do not confess to yourself that it was only a simile and need not apply to everything, but you say, "The cause of that event is a mystery which must remain for ever unknown to me." On equally just grounds, the nervous system of my umbrella is a mystery which must remain for ever unknown to me. My umbrella has no nervous system; and the event to which your simile did not apply has no cause in your sense of the word. When we say then that every effect has a cause, we mean that every event is connected with something in a way that might make somebody call that the cause of it. But I at least have never yet seen any single meaning of the word that could be fairly applied to the whole order of nature. From this remark I cannot even accept an attempt recently made by Mr. Bain to give the word a universal meaning, though I desire to speak of that attempt with the greatest respect. Mr. Bain wishes to make the word *cause* hang on in some way to what we call the law of energy; but though I speak with great diffidence, I do think a careful consideration will show that the introduction of this word *cause* can only bring confusion into a matter which is distinct and clear enough to those who have taken the trouble to understand what energy means. It would be impossible to explain that this evening; but I may mention that *energy* is a technical term out of mathematical physics, which requires of most men a good deal of careful study to understand it accurately.

Let us pass on to consider with all the reverence which it demands, another opinion, held by great numbers of the philosophers who have lived in the brightening ages of Europe; the opinion that at the basis of the natural order there is something which we can know to be *unreasonable*, to evade the processes of human thought. The opinion is set forth first by Kant, so far as I know, in the form of his famous doctrine of the antinomies or contradictions, the nature of which I will endeavour to explain to you. Kant said then that space must either be infinite or have boundary. Now you cannot conceive infinite space; and you cannot conceive that there should be any end to it. Here, then, are two things, one of which must be true, while each of them is inconceivable; so that our thoughts about space are hedged in, as it were, by a contradiction. Again, he said that matter must either be infinitely divisible, or must consist of small particles incapable of further division. Now you cannot conceive a piece of matter divided into an infinite number of parts; while on the other hand you cannot conceive a piece of matter, however small, which absolutely *cannot* be divided into two pieces; for however great the forces are which join the parts of it together, you can imagine stronger forces able to tear it in pieces. Here again, then, are two statements, one of which must be true, while each of them is separately inconceivable; so that our thoughts about matter also are hedged in by a contradiction. There are several other cases of the same thing, but I have selected these two as instructive examples. And the conclusion to which Kant was led by the contemplation of them was, that on every side when we approach the limits of existence a contradiction must stare us in the face. The doctrine has been developed and extended by the great followers of Kant; and this unreasonable, or unknowable, which is also called the absolute and the unconditioned, has been set forth in various ways as that which we know to be the true basis of all things. As I said before, I approach this doctrine with all the reverence which should be felt for that which has guided the thoughts of so many of the wisest of mankind. Nevertheless I shall endeavour to show that in these cases of supposed contradiction there is always something which we do not know now, but of which we cannot be sure that we shall be ignorant next year. The doctrine is an attempt to found a positive statement upon this ignorance, which can hardly be regarded as justifiable. Spinoza said, "A free man thinks of nothing so little as of death;" it seems to me we may parallel this maxim in the case of thought, and say, "A wise man only remembers his ignorance in order to destroy it." A boundary is that which divides two adjacent portions of space. The question, then, "Has space (in general) a boundary?" involves a contradiction in terms, and is therefore unmeaning. But the question, "Does space contain a finite number of cubic miles, or an infinite number?" is a perfectly intelligible and reasonable question, which remains to be answered by experiment. The surface of the sea would contain a finite number of square miles, if there were no land to bound it. Whether or no the space in which we live is of this nature remains to be seen. If its extent is finite, we may quite possibly be able to assign that extent next year; if, on the other hand, it has no end, it is true that the knowledge of that fact would be quite different from any knowledge we at present possess, but we have no right to say that such knowledge is impossible. Either the question will be settled once for all; or the extent of space will be shown to be greater than a quantity which will increase from year to year with the improvement of our sources of knowledge. Either alternative is perfectly conceivable, and there is no contradiction. Observe especially that the supposed contradiction arises from the assumption of theoretical exactness in the laws of geometry. Now the other case that I mentioned has a very similar origin. The idea of a piece of matter, the parts of which are held together by force, and are capable of being torn asunder by greater forces, is entirely derived from the large pieces of matter which we have to deal with. We do not know whether this idea applies in any sense to the *molecules* of gases even; still less can we apply it to the *atoms* of which they are composed. The word force is used of two phenomena; the pressure which, when two bodies are in contact, connects the motion of each with the position of the other; and attraction or repulsion; that is to say, a change of velocity in one body depending on the position of some other body which is not in contact with it. We do not know that there is anything corresponding to these phenomena in the case of a molecule. A meaning can, however, be given to the question of the divisibility of matter in this way. We may ask if there is any piece of matter so small that its properties as matter depend upon its remaining in one piece. This question is reasonable; but we cannot answer it at present, though we are not at all sure that we shall be equally ignorant next year. If there is no such piece of matter, no such limit to the division which shall leave it matter; the knowledge of that fact would be different from any of our present knowledge, but we have no right to say that it is impossible. If, on the other hand, there is a limit, it is quite possible that we may have measured it by the time the Association meets at Bradford. Again, when we are told that the infinite extent of space, for example, is something that we cannot conceive at present, we may reply that this is only natural, since our experience has never yet supplied us with the means of conceiving such things. But then we cannot be sure that the facts will not make us learn to conceive them; in which case they they will cease to be inconceivable. In fact, the putting of limits to human conception must always involve the assumption that our previous experience is universally valid in a theoretical sense, an assumption which we have already seen reason to reject. Now you will see that our consideration of this opinion has led us to the true sense of the assertion that the order of nature is reasonable. If you will allow me to define a reasonable question as one which is asked in terms of ideas justified by previous experience, without itself contradicting that experience, then we may say as the result of our investigation, that to every reasonable question there is an intelligible answer, which either we, or posterity, may know.

We have, then, come somehow to the following conclusions. By scientific thought we mean the application of past experience to new circumstances, by means of an observed order of events. By saying that this order of events is exact, we mean that it is exact enough to correct experiments by, but we do not mean that it is theoretically or absolutely exact, because we do not know. The process of inference we found to be in itself an assumption of uniformity, and that as the known exactness of the uniformity became greater, the stringency of the inference increased. By saying that the order of events is reasonable, we do not mean that everything has a purpose, or that everything can be explained, or that everything has a cause; for neither of these is true. But we mean that to every reasonable question there is an intelligible answer, which either we or posterity may know by the exercise of scientific thought. For I specially wish you not to go away with the idea that the exercise of scientific thought is properly confined to the subjects from which my illustrations have been chiefly drawn to-night. When the Roman jurists applied their experience of Roman citizens to dealings between citizens and aliens, showing by the difference of their actions that they regarded the circumstances as essentially different, they laid the foundation of that great structure which has guided the social progress of Europe. That procedure was an instance of strictly scientific thought. When a poet finds that he has to move a strange new world which his predecessors have not moved, where nevertheless he catches fire from their flashes, arms from their armoury, sustentation from their footprints,—the procedure by which he applies old experience to new circumstances is nothing greater or less than scientific thought. When the moralist, studying the conditions of society and the ideas of right and wrong, which have come down to us from a time when war was the normal condition of man, and success in war the only chance of survival, evolves from them the conditions and ideas which must accompany a time of peace, when the comradeship of equals is the condition of national success,—the process by which he does this is scientific thought and nothing else. Remember, then, that it is the guide of action; that the truth which it arrives at is not that which we can ideally contemplate without error, but that which we may act upon without fear; and you cannot fail to see that scientific thought is not an accompaniment or condition of human progress, but human progress itself. And for this reason the question what its characters are, of which I have so inadequately endeavoured to give you some glimpse, is the question of all questions for the human race.

GLYCEROLE OF ASSAFŒTIDA.

The following formula for the above preparation is published in the 'American Journal of Pharmacy,' by Mr. A. Robbins. He states that he has used it many times during the last ten years and always found it to give a good article of milk of assafœtida:—

℞.	Assafœtida	℥ ij.
	Glycerine, q. s., ft. . . .	f. ℥ viii.

Select the best assafœtida and cut it quite fine; put it into an eight-ounce bottle, and add five fluid ounces of glycerine; cork well and suspend in a can of water, which place on the stove where the heat will be very moderate; let it remain so a day or two, shaking the bottle frequently; then strain through a coarse cloth, and return the residue to the bottle with three fluid ounces of glycerine; let stand as before, and then strain into that first obtained, and make up to eight fluid ounces by adding glycerine.

One fluid drachm of this added to seven drachms of water will make milk of assafœtida containing the proper quantity of the drug.

The author has also used glycerine with gum ammoniacum, and while the solution was not as perfect as that of assafœtida, he found upon examination that the amount of ammoniacum taken up is about the same as when the mistura ammoniaci is made by the officinal U.S. formula. With myrrh he did not succeed well, but still obtained a passable preparation which he has no doubt could be, by continued experiment, much improved.

Oil of Cloves for Microscopical Preparations.—Dr. Webber, of Boston, recommends the use of oil of cloves in preference to turpentine, as it is not so volatile, and allows of preparations being kept a day or two for examination. It also allows the Canada balsam to be used without the previous washing of the preparation, which is necessary if carbolic acid be used.

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 7, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

DISPENSING AND DRUG-DEALING SURGEONS.

Not unfrequently our medical contemporaries are very much exercised respecting the conduct of those whom they are pleased to describe as "prescribing druggists." On such occasions there is a great deal of respectable horror expressed at the wickedness of the man who, with no more qualifications than are necessary to secure him a place on the Register of Chemists and Druggists, presumes to supply a customer with a bottle of mixture or a box of pills for the cure of a passing stomach-ache, or a cold in the head. Of course, it would be mere affectation on our part to pretend to be ignorant of the fact that such a practice is sometimes carried to a point where it encroaches seriously upon the domain of the medical man. But the next time that any of our medical friends feel disposed to rush into print anent this question, we would recommend them to discuss the subject under two heads, and if they devote the first part of the treatise to the fustigation of the "prescribing druggist," then, in a second part to treat with impartial zeal an analogous offender, we mean the "dispensing and drug-dealing surgeon."

Towards the satisfactory accomplishment of so desirable an object, we call attention to the present state of the relations between medical men and pharmacists in some of the towns of Scotland, as disclosed in a letter to the 'Glasgow Herald' for August 28th. We are there informed that in Glasgow there are two shops for the sale of salts, senna, seidlitz powders, etc., kept by medical practitioners for every one kept by a chemist and druggist. "In "Airdrie and Coatbridge, I believe, there is only "one druggist to some eighteen or twenty surgeons "keeping open shop; in Paisley there are some "seven druggists to between twenty and thirty "surgeons' shops," and so on. Notwithstanding the writer's statement that "in England no such thing as an open surgery is known," we are sorry to say that the custom also obtains, and that extensively, in this country. In many a district any inclination that a chemist and druggist might have to avoid poaching on the medical man's preserves, is severely tried by the knowledge that the medical man is his closest competitor in his more proper business.

Now we do not wish to depend upon the *tu quoque* argument, but it must be evident that if a man is unfairly and severely pressed in competition, his ethical views will probably be blunted, and he will be induced to do that which under more favourable circumstances he would not have countenanced. This remark applies to both sides of the question; and therefore we think it would tend to the elevation both of the medical man and the chemist and druggist if, instead of competing with and scolding each other, some neutral ground could be found for the rectification of their grievances.

But what is to be said with respect to the *vexata quæstio* of dispensing? It is notorious that the greater part of the dispensing of medicines in this country is done by medical men themselves. But how far this is from the proper upholding of the dignity of the profession may be estimated from the fact, that in this custom Great Britain stands almost alone. How frequently it transgresses the spirit of the law of this country is shown by a case recently before the Sheffield County Court, and reported at p. 178 of last week's issue, where a decision of the Judge caused the abandonment of numerous claims made for the supply of medicines by a gentleman who was a surgeon, but not an apothecary. To this legal decision may be added a quotation from an "Abstract of the Principal Laws Affecting the Medical Profession," by R. G. Glenn, Esq., LL.B., Barrister-at-Law, which is prefixed to the "Medical Directory" for 1872.* "A medical "practitioner, not being a qualified apothecary, is "prohibited from selling, or keeping an open sur- "gery for retailing, dispensing or compounding "poisons, under penalty of £5, unless he was either "registered before August 11th, 1869, or has been "registered since that date, after passing an examina- "tion in pharmacy, in order to obtain his diploma "for such registration."

Every year that passes weakens the old plea that the medical man is unable to depend upon his prescriptions being correctly dispensed, in consequence of the heterogeneous nature of the body of chemists and druggists. The uneducated chemist and druggist is becoming every day more and more a thing of the past. And we believe that if those medical men who are able to appreciate how useful and intelligent a handmaiden to medicine pharmacy may become, would, by example and precept, use their influence to obtain for her votaries that fair share of the work for which they are specially trained, the result would go far towards extinguishing both the "prescribing chemist" and the "dispensing and "drug-selling surgeon."

We learn from the *Times* that the University of Munich, at its recent 400th anniversary, conferred upon Mr. Simon the honorary diploma of Doctor of Medicine, "propter præclarissima de sanitate publicâ tuenda atque augendâ merita."

* See Pharm. Journ. [3] ii. 572.

THE BENEVOLENT FUND ELECTION.

It will be seen in another part of this page that a *third* candidate for an annuity from the Benevolent Fund was placed on the list at the meeting of the Council this week. As there are but two annuities to be given, there will necessarily be a contested election, which will take place on Friday, October 25th. It should be remembered that the benefits of this fund are not confined to members of the Pharmaceutical Society, but are equally extended to necessitous registered chemists and druggists. We hope, therefore, that not only those who usually subscribe, but also many who have not hitherto done so, will send subscriptions in time to take part in the forthcoming election.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

September 4th, 1872.

MR. T. H. HILLS, TREASURER, IN THE CHAIR.

Present—Messrs. Betty, Bottle, Greenish, Hampson, Schacht, Savage, Urwick, and Williams.

The minutes of the last meeting were read and confirmed. A former member of the Society having paid up the arrears of his subscriptions, and subscription for the current year, was restored to membership.

Elections.

MEMBERS.

The following Pharmaceutical Chemist was elected a Member of the Society—

Beasley, Frederick ....Clapham.

The following Registered Chemists and Druggists were elected Members of the Society—

Hughes, John Griffith........Thornbury.
Ker, Richard ....Stranraer.
Oldham, William ....Burslem.
Robson, John Binnington ....Filey.
Ruston, Joseph ....Maryport.
Snowdon, George Walker ....Thornton Heath.

Associates.

The following, having passed their respective examinations, were elected "Associates in Business" of the Society—

Minor.

Smith, Edward ....Brighton.

Modified.

Clark, Simon Prince..........Glasgow.
Oldham, James...............Hull.

The following, having passed the Modified examination, was elected an Associate of the Society—

Insull, Edward Samuel ....Shelton.

Jacob Bell Memorial Scholarship.

A letter was read from one of the recently-elected Junior Bell Scholars, stating that his engagement with his employer did not terminate until Christmas, and asking to be allowed to commence his laboratory instructions at that time.

Mr. Williams said he had received a communication from the young man's employer to the same effect, and stating that it would be very disadvantageous to himself to relinquish his assistant's services.

After referring to the regulations bearing on the point, it was

Resolved unanimously—That the gentleman elected must conform to the conditions imposed, and attend the laboratory through the entire session, or resign the Scholarship.

Finance Committee.

The report of the Finance Committee was received and adopted, and sundry payments were ordered.

Benevolent Fund.

The report and recommendation of the Benevolent Fund Committee were received and adopted. The name of Elizabeth Wilkes, of Bromyard, the widow of a member, was placed on the list of candidates for election as an annuitant in October next.

Vermin Killers.

Mr. Betty stated that a little difficulty had arisen with regard to the carrying out of the resolution passed at the last Council meeting, authorizing the issue of a circular of amended regulations with regard to vermin killers. The difficulty had arisen in consequence of the use of the word "Preparation" in the schedules, and he suggested that the matter should be further considered by the Parliamentary Committee before the proposed circular was issued. A resolution to this effect was passed unanimously.

Lady Pharmacists.

The Secretary read a letter from a lady asking if ladies were admitted to the lectures of the School of Pharmacy and to the laboratory. He stated that some years ago Miss (now Dr.) Garrett applied for admission to the lectures, and the professors, seeing no objection, she paid the fees and attended the course. On the matter, however, being brought to the attention of the Council, some members thought such a proceeding was irregular, and a resolution was passed prohibiting the admission of ladies to the lectures in future He did not know whether the present Council would be inclined to reconsider the matter.

Mr. Hampson said he was very glad such a letter had been received, and gave notice that at the next Council meeting he would bring forward a resolution for rescinding the one referred to by the Secretary.

British Pharmaceutical Conference.

Mr. Savage, on behalf of the Local Committee of the Pharmaceutical Conference at Brighton, presented the Council with a photograph of the members attending the Conference, suitably framed.

A resolution of thanks to the Local Committee, both for the photograph and for their kind reception of members was, on the motion of the Chairman, passed unanimously.

BENEVOLENT FUND.

Subscriptions and Donations Received during July and August, 1872.

SUBSCRIPTIONS.

London.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Tuesday, August 13th, 1872.

(*Continued from page* 178.)

Election of an Honorary Member.

The President: Before we begin the discussion of the Education question I wish to repair an omission which was made this morning. Owing to the want of precise information the Executive Committee were not aware, until Professor Markoe stated it, that we had present here another American pharmacist of eminence—Professor Wayne, of Cincinnati. I am about to ask you to elect Professor Wayne an honorary member of this Conference, and to express some regret that we were not so well informed beforehand of his movements as to be able to bring his name forward at the first sitting of the Conference. I do not think I need say more. Professor Wayne is not merely the professor of pharmacy in the Cincinnati College of Pharmacy, but he is widely known as a chemist and mineralogist. These facts of themselves, even were it not for his presence here at our meeting, would be sufficient to absolve us from going through our usual custom of recommendations of this sort coming up from the Executive Committee; I ask you, therefore, to elect Professor Wayne, of Cincinnati, an honorary member of this association.

Mr. Schacht said that he had been requested, as a matter of form, to second the nomination of Professor Wayne, though the acclamation with which that gentleman's name had been received rendered unnecessary any further comment on the subject.

The motion was then carried by acclamation.

Professor Wayne said: I cannot but thank you for the honour you have just conferred upon me in electing me a member of the association. It was a matter I was not prepared for at all. Further, I would say, it gives me great pleasure to meet the pharmacists of Great Britain in convention.

Discussion on Pharmaceutical Education.

The President then invited a discussion on the subject raised in Professor Attfield's paper, requesting the gentlemen who spoke to condense their remarks so far as consistent with free expression of opinion. There were present two or three gentlemen well versed in questions affecting education and scientific examinations who were not accustomed to attend these meetings. The Conference would gain much by hearing the views of Professor Michael Foster, of Cambridge, for instance, as well as some others he saw present, on the matters in debate.

Mr. Schacht: Mr. President and gentleman, my views upon this question are, I hope, pretty well known; I have already taken means, and others have taken means, to make you acquainted with them, and I came here with the resolution to take no part in your proceedings, *de novo*, but to listen to the views of others, and confine any remarks I might have to make to what might be suggested by them. I candidly confess that although I have made an effort to handle well the threads of the matter which has been introduced, and to keep them distinct, I feel myself somewhat bewildered by the many different views which have been put forth. But there are two or three words which help me considerably to arrange the matter in my mind, and those words you will all remember to have heard frequently uttered. They are, examination, education, cram. Perhaps these three words will serve to direct the discussion. But before even I venture to follow the suggestions which those words afford, it seems to me that there is one consideration above all others which we should take into account. There has been hinted the idea that the Pharmaceutical Society has nothing to do with education. Now if that be an idea which prevails generally among the members of the Pharmaceutical Society, it seems to me that there is an end of the necessity of any discussion as to methods and processes. It lies at the root of the whole question, whether it is worth while to entertain any scheme whatever, or whether it would be better to leave the whole subject to the commonplace process of supply and demand. A portion of Professor Attfield's paper goes very largely, as it appears to me, in this direction: rather to compel education, but not to supply it. Now, if this doctrine has a general echo in the minds of those who constitute the Society, I say once more, let us discuss the matter no more. It must be left then to individual effort, and as far, at least, as the Pharmaceutical Society is concerned, collective effort is useless. That, however, is not my opinion. I oppose it absolutely and *in toto*, and heartily echo that other portion of Professor Attfield's paper which hardly seems to be in accordance with the one to which I have alluded, and which has traced the action of the Pharmaceutical Society from its commencement to the present time, and proved that that action has been identical with the theory that it is a part of the duty of the Pharmaceutical Society to promote pharmaceutical education. Holding, then, that view, I enter upon the consideration of the three questions suggested by the three words I have named. In the first place with regard to the examinations of the Pharmaceutical Society, I should like simply to make this remark—that possibly they may not be perfect. We will even admit that they are largely capable of improvement, though whether by each of the two processes that have been indicated, or by any other, does not materially signify. It is possible that by ejecting our twelve present examiners, and substituting twelve individuals of that impossible character imagined, but never seen, by Mr. Tait, we might improve the quality of our examination. If we had twelve perfect examiners, it is possible that we might have a perfect examination. But the Professor in candour admits that this is almost an impossibility, and, therefore, does not encourage us to hope that much change will take place by modifying the Board of Examiners at present existing. But he leads us rather to hope that improvement would be effected if we adopted the other alternative, of supplementing the present condition of examining by making it necessary that each candidate should bring with him a certificate of attendance at certain courses of lectures. I am not quite sure whether he includes the fact of his having been apprenticed for a certain number of years in the trade.

Professor Attfield: Yes.

Mr. Schacht: Now, I ask you just to observe this fact—that in proportion as you make it necessary by Act of Parliament, or by the procedure of the Pharmaceutical Society, that that examination should be difficult to pass, and that the candidate should have attended certain lectures, in that proportion do you act the part of an arbitrary tyrant;—you put the man in the difficulty and dilemma in which you would place a beggar, supposing that you were to pass a law that none but those who wore velvet gowns should be considered citizens, and be entitled to the privileges of citizens; unless at the same time you give the beggar, in the one case, or the pharmaceutical student in the other, the opportunity of fulfilling these conditions which you say shall be necessary before you bestow the privilege which he seeks. It seems to me that in that part of his argument, the writer is simply strengthening the position of those who are claiming for pharmaceutical students, wherever they may be, some sort of opportunity for systematic instruction. It is very little use to say that they must have a certificate, if they have had no opportunity of attending lectures as to which certificates are required.

Well, then we are brought to face the question, How shall these courses of lectures be supplied? If you make them compulsory, and admit that it is part of the duty of the Pharmaceutical Society to assist in the promotion of this all-important matter, the question is narrowed to —How shall these various courses of lectures be supplied? You have had that scheme which we now have a fair right to attribute to Mr. Reynolds; or, without going so far as to attach an individual name to it, you have had offered to you that scheme which was presented two years ago by the committee appointed by the Pharmaceutical Society. By recent references we believe that that was mainly the work of Mr. Reynolds. You had that suggestion put before you, and that has been echoed by several gentlemen lately, not simply at the present meeting, but by writers in the PHARMACEUTICAL JOURNAL within the last few months. Broadly speaking, it consists in the recognition of a few schools throughout the country. Professor Attfield limits the number to about five, and whether it is five, six, or seven, it is a limited number. The doctrine supposes a limited number of schools to be distributed in a few centres throughout the country. You have had also a proposition to which is attached my name; and though I felt some hesitation in allowing that to appear, and to be especially alluded to as Mr. Schacht's scheme at first, I have certainly less hesitation now, seeing that it has come in for a good share of rough handling, which, at any rate, makes it less bad taste for me to father it. The principle of this scheme is, instead of limiting the schools, to make them as far as possible numerous. Well those are two very opposite doctrines. For my own part I suppose it will not be deemed very wonderful that I should adhere to the idea which I deliberately adopted, that it is the duty, if we do anything in the direction of promoting education, we should do it as broadly and not as narrowly as possible. I am aware that one opinion is as good as another opinion if merely uttered in words, uncorroborated by any proof, but I ask for proof the other way, and I have a fair right to ask for proof the other way if the assertion is made that it will be money thrown away, and that the effort will be so much waste of energy. I have a right to ask on what ground those conclusions are arrived at. I have not heard them stated further than the one general ground that few schools of science are remunerative and self-supporting. I am quite prepared to admit it. Further than that, I wish to make a very strong observation upon that point, because there has been more than once during to-day a kind of idea uttered that those who accept aid from the Pharmaceutical Society are degrading themselves into the position of paupers or charity boys, a view which I oppose most vehemently and emphatically, and I think with good right, for I would like to ask any gentleman here to tell me what large educational establishment does not place its students in a similar predicament, and yet no one accuses a senior wrangler of Cambridge with being a charity boy, although it is more than probable that he has had a very large proportion, if not the main part, of his education paid for by other people. He is no charity boy for having earned the benefit of those endowments which enthusiastic people, and philanthropists, and large-hearted people (I will not use the disagreeable word charitably-minded people) have left for his benefit. It is not to be thrown at him that he has adopted and absorbed the charity of others for the purpose of his own aggrandizement. He has simply availed himself of those opportunities which are given for the great cause of education, and the fostering of learning, which was really and truly the purpose which those great men of old had in founding their endowments. Sir, I am myself a pupil of the Pharmaceutical Society, and am delighted to remember the fact. Moreover I rejoice to acknowledge an obligation to those who organized the school at Bloomsbury Square. I paid my fees, well-knowing those did not represent the money value of the education I obtained. Yet I decline to admit myself either a pauper or a charity boy. It is only at small private schools in which the students pay for what they get, and they do pay for what they get, and precious poor stuff it is. Where there is anything like good education, it is always in the great establishments where the munificence of founders has enabled the governors of those institutions to provide means of education vastly superior to any that could be obtained if current fees paid for the entire expenses of the establishment. One word more with reference to the subject cram. Now I must ask you to observe—or, rather, to remember, those of you who have read my scheme,—that the whole process adopted there is to avoid the possibility of cram. Professor Attfield having been very vehement, as he was perfectly right in being, against the atrocities of cramming, after using the emphatic words he did, naturally felt that he was bound to put a limitation on the word against which he had launched those invectives, and he wished us to understand that the word cram did not apply to the process of private tuition which we all know more or less about. Now let me ask you also to remember that in the sense in which other people may use the word cram, every process which is short of a thorough systematic and complete course of education is cramming. Of course, it has more or less degree of darkness this ugly black thing; and in some manifestations it presents a more ugly colour to look at than in others. Now, remember, I do not use any such vehement expressions about this as some do; but let me remind you that in your own establishment at 17, Bloomsbury Square, cramming is quite possible. I was lately looking over the number of students who had systematically attended, or who had for any portion of the time attended the instruction at Bloomsbury Square, and I was not a little surprised to find that the number who had fulfilled a complete course was very far short of the number who were registered as students. They varied in the time of their attendance, from a complete course of ten months to a very far less complete course of one month. Now, if it is attempted to thrust into one month that amount of study which is understood naturally or ordinarily to occupy ten months, I cannot help thinking that that is cramming; and as we know that it will not fulfil its purpose, this establishment at 17, Bloomsbury Square more or less lends itself to the process of cramming. Now, I do not wish to make more of this fact. I do not point to it angrily or disagreeably; I merely point to the fact that it is possible. But I ask you whether, on the other hand, the scheme suggested in the report bearing my name is not pointed in a diametrically opposite direction? It offers not one single sixpence of the Society's property in return for anything which is not absolutely performed. Not one single penny is asked on speculation; not one single penny is asked to be given for a promise; not one single penny is given ultimately except for results earned by legitimate processes. It is required not simply that a man can pass an examination, but that he shall pass that examination as the result of a regular systematic training on the subject on which the examination takes place. I think that that is a point really and truly deserving of consideration. Following, as my observations do, upon the reading of papers that have been especially aimed to point out that the fundamental error of the present system is that it becomes, in point of fact, a premium for imperfect education, I think that the process which is exactly the reverse of that deserves special consideration. My purpose to-day, as it has been ever since the publication of my own few ideas, was rather to take the opinion of others. I wish not to enforce my own in the smallest degree. I only wish that it should stand fairly upon its own merits, and that it should come in for a fair and judicious criticism and not a hasty one. As you know, this scheme bears some comparison and some relationship to the Government scheme of aiding scientific education throughout the country. Indeed, I am quite free to admit that it is founded upon the Government scheme; but it is not the Government scheme, and those who suppose that I have adopted it because it is the Government scheme are making a strange and foolish blunder. It is not the same, but the principle is identical with it; and I am quite willing to admit that I owe everything to the suggestions which that scheme has given. And allow me to add that I do not consider it at all an argument for the weakness and uselessness of the scheme, as it stands, that it has stood the test of a great many years' trial at the hands of the Government authorities. As I have said two or three times, any one who is in the smallest degree interested in this subject can find the whole details in the volume issued by the department year by year, for the price of sixpence. I really do not like to allude to charges which are unsubstantiated by a name, for anonymous charges are things which one would rather leave alone; but there have been assertions made that the scheme of the Government has only just escaped a collapse, that every one who knows anything of it is disgusted—pupils and teachers alike, and that there is this year only one sixth of the number of pupils there was in recent years. I ask any one who has seen those assertions to be kind enough, in simple candour, to look at that book. If he does not feel disposed to take the trouble, I can tell him that I have gone carefully over the numbers, and though I do not claim a right to defend the Government scheme, I think it is only fair that I should take this opportunity to state that there have been more classes in the last year than in any year that has preceded it,—that there are something like 34,000 students in the classes now, and that there were 7600 more in the last year than in the year before. Those are figures which are as easily as possible ascertained by any one who will take the trouble to turn over the pages of that book. Be that as it may, sir, the question for us to consider is, of course, what will suit our purposes the best. I should myself be very glad indeed to adopt the best process whatever it may be. I mean to advocate it as far as my power on the Council will enable me to do so. Mr. Reynolds is here, and several gentlemen who endorse his views are here. Let us by all means gather why we should expect so much better results to show themselves, when our schools for scientific culture are limited to a few, rather than when we endeavour, if possible, to extend the aid of our Society generally and systematically throughout the country.

Mr. Stoddart said: Both the proposed schemes hinge upon the same thing, namely, that we who are in the country should aim to give our younger friends the benefit of a good education so far as regards pharmacy. If we were about to make a commercial speculation, we should count the cost, and would rather seek a real basis to work upon than an imaginary one. Therefore, if we have this money to spare in Bloomsbury Square, I should prefer spending it in the way by which I should get the most reliable results. I think, and have often thought, that we make two errors, and those errors are very common I know, because I hear them expressed very frequently as I am moving about the country. There is this first of all—that we ought to, as it were, make everything straight for a lot of young men to enter into our profession. Now, once for all, I am diametrically opposed to that. I say it is not correct. We want to make our profession a good profession. We want to raise the status here as well as in other parts of the country. We who are now in business will probably never reap so much benefit from this as our sons and grandsons will; but, nevertheless, we want to leave them a good heritage, and I do not see at all, if we make pharmacy a good profession worth having, why we should collect all the young men we can and coax them into it. If they wish to come, let them come, but they must prove themselves good enough to come, because it is self-evident that if we take just anybody we never shall improve our status. It will continue to be like what it is in the present day, when we have all sorts of people with us. But, if a hundred young men were to come to me and say to me, "We do not want to shirk the examination; will you help us?" I would help them with the greatest pleasure in the world, but I would not make these examinations so low and so easy that they could not help passing them. I hope that no person here or elsewhere will ever take a pupil or an apprentice who has not passed the Preliminary examination. In the city in which I live I am frequently called upon to go into the different schools to examine the boys, and it is an invariable practice with me when I go there never to ask them anything difficult. For instance, if I am going to examine them in arithmetic I know very well that if I were to ask them an abstruse question, it would be answered in a moment; but, I say, "You go into the market and buy so many pecks of potatoes, and I will give you a £5 note—what is the change?;" and, I will wager, I should not get a correct answer. I assure you such is the fact. Only last week a gentleman came and gave me a suggestion. I said, "Really, I can hardly credit it." He said, "Come with me into a school where there are 200 boys—boys that have passed an examination in the most wonderful way." They were able to answer difficult questions which, perhaps, I should have made a mistake in. First of all my friend gave them a question to solve, which they did without the slightest hesitation. Then I said, "Buy me a dozen apples at so and so, and a dozen pecks of potatoes, and here is a five-pound note; what will be the change?" and there was not one that could tell me. It is the same with our Preliminary examinations. I appeal to anybody here who is a local secretary, and he will say that it is in the simple things, the ground-work of education, that neglect occurs. Now, I say, let us never take a pupil unless he has passed a Preliminary. Say to him, "When you have done that, come, and we will take you, and we will do our best to help you along." Now comes what I consider to be the basis of the scheme we ought to adopt. I do not care at all, as Mr. Schacht says he does not care, whether it is his scheme or Mr. Reynold's scheme or anybody else's. Like him I simply want the best. Now Mr. Schacht's scheme I like excessively. It is that we must not do the work for them. Let those in the country help themselves, and then we will help them along afterwards, but we must not go and found a school for them. Mr. Schacht knows as well as I do the work we have done in Bristol, and he knows very well that we have been very successful. Mr. Giles will tell you the very same thing; and he will tell you that the plan we go upon there is to make every one do the best, and then we help him; but we do not help them to take any illegal step. Now, with regard to this horrid word "cramming," it sets one's teeth on edge to hear it so many times. It is a very disagreeable word, and the thing is one not to be upheld for a moment. But I understand the word in a somewhat different sense from that in which it has been used by Mr. Schacht. I do not think that cramming in the practical sense is putting three months knowledge into one month. I may have a pupil to whom I give two lessons a week, the course extending over three months; but suppose he is a hard-working pupil, and says, "I will work every day; I will do it all in a month:" that is not the kind of cramming which Professor Attfield means. What he speaks of is an illegitimate way of doing it, which is cheating and nothing else. I should have thought the examiners could easily find out whether a boy was taught properly or not. Having been in the business for nearly a third of a century, I would not hesitate to say that if any young man in the world were to come to me, and I gave him a pestle and mortar and a pair of scales to dispense a prescription, before he weighed out the very first item I should know whether he had been properly instructed. The very way he would hold the scales would be sufficient for me. If you have put a pair of scales into a tyro's hands, you have noticed that he laid hold of the scales in the wrong place, and instead of weighing accurately he could not weigh a drachm within five or six grains, because he would destroy the balance of the scales by holding the top of it; and before such a young man had put the first part of the ingredients into the mortar I should say, "You know nothing about it." Therefore, whether there are two schools or a dozen, if they set to work in a legitimate way to teach young men in their neighbourhood, I think they will have a claim on the Pharmaceutical Society. I think Mr. Reynold's scheme is perfectly right. I never understood him to say for a moment that he would send down to such and such a place a certain sum of money to begin a school. They must begin for themselves legitimately and fairly, and then we will help them. I was one that took part in the committee that formed that scheme, and I don't think that it has failed at all. The difficulty was this—that in a large town where we had a lot of pupils, we did not want exactly the same that a small town did. It was wanted in a different manner, and we treated each one on its own individual merits. Now, that will answer very well, but the cry has been that we want something that will apply universally; and that is where Mr. Schacht's scheme answers; or if it does not answer—if it is impracticable—it is because the people have not done sufficient to help themselves. I heard it asked this morning, "What is a village to do which has not more than five pupils in it?" Well, I say that young men ought not to go there to learn their business. They go with a full knowledge of the opportunities which the place affords; therefore, I do not see that we should have any blame for it. I, for one, will take part in making this a profession really of some value, and not simply a money-making business. Of course we must have one as well as the other; but still there is no reason at all why we should not have as high a status as we possibly can. There is one thing which I would very strenuously insist upon, and that is a proof that the young man who comes has had experience in the business. Our Transatlantic friends will tell us that that is a *sine quâ non* with them.

Professor Markoe, of Boston, U.S., said: Mr. President, and gentlemen of the British Pharmaceutical Conference,—I have come altogether unprepared to speak before you, and all that I can say with regard to the American system, is simply to give you a detail of the practical working of the Massachusetts College of Pharmacy, which I will take as a type of the rest of the American Colleges of Pharmacy, inasmuch as all the Colleges of Pharmacy in the United States have adopted the same standard. There is usually one College in each of the States where pharmacists have sufficient influence to start a college. The various pharmaceutical colleges have generally three chairs—Chemistry, Materia Medica and Pharmacy, and Botany. The lectures are almost always in the evening. Lectures in the day time have sometimes been tried, but, in general, that time has not been suited to the American system of doing business. There is no preliminary examination required in either of the schools, but there is one basis upon which all the American colleges are in union, namely, in exacting an apprenticeship of at least four years to some practical pharmacist. Mere service in a wholesale store will be of no avail at all. It makes no difference how long or how many lectures a student may attend, for, if he cannot bring to the Examining Board his certificate, signed by some respectable pharmacist, he will not be admitted to the examinations. A practice has prevailed also which has acted somewhat as your Minor examination, if I may term it so,—that at the end of the lectures each of the professors submits his class to an examination on the subjects treated in the course of lectures. This examination is now pretty uniformly a written examination, and consists of about fifty questions, of course the character of the questions being unknown until the evening of the examination. The whole class is examined in each of the departments, and in our own school we require 66 per cent. of correct answers in each of the professorial examinations. Those young men who have passed this examination successfully, are then required to deposit with the Dean of the Faculty a certificate from their respective employers certifying that they had served the proper amount of apprenticeship. They are also required to produce a thesis, or dissertation, upon some subject of pharmacy, materia medica, or some related subject. This must be written neatly; and if the thesis gives evidence of insufficient English education, even if the other examinations are satisfactory, we reject the candidate. So much for the preliminary or professors' examinations, as we term them. The young man then, after having brought a written certificate, goes before the directors of the College of Pharmacy. He goes before the Committee of Trustees in the Massachusetts College, and in the Philadelphia College they have an Examining Board which takes the place of the other bodies. He is then subjected to an examination, part of which is written and part oral, and he is required to recognize specimens of pharmaceutical substances, and also of materia medica; but what we insist upon is that he shall have had four years behind the counter. In addition to that the student must attend the lectures. We generally keep a check list. One great advantage that we derive from the professors' examinations is that we sift out all the weak men, so that it is very rarely that one who has passed the professors' examinations fails to pass the other; but even then some of the weakest ones are sifted out at the second examination. There were at the completion of our last session last spring eight young men who passed the junior, or professors' examination, and, out of that number, two were rejected at the last examination. A word or two with respect to pharmaceutical education. The subject of pharmaceutical education in the States I think has taken a very promising turn indeed. We have now in full operation a college of pharmacy in the city of Philadelphia, at which last year something like 250 pupils attended, and the number is likely to increase. In the Maryland College of Pharmacy they have 75 pupils. At Chicago the session would have started with quite a full class, had not the unfortunate disaster there broke up the school for a time, but, with the wonderful enterprise of that city, the managers have got organized again, and they already announce a course for next session. The New York College of Pharmacy has for many years been very inefficient, having very small classes of from 25 to 50, but after the passing of the Irving Act, which resulted from the Tammany Ring, by which a most unjust measure was put upon the New York pharmacists, they united and succeeded in defeating it, and now they have got a very excellent Act. In Philadelphia the Pennsylvania legislature passed an Act which is also satisfactory, and the practical execution of that Act is in the hands of the College of Pharmacy. In Massachusetts the legislature has endeavoured to pass two Acts, and both have been lost by a small majority, but there is every reason to hope that next year a Pharmacy Act will be passed in Massachusetts. Similar Acts have been passed at Ohio and Illinois. Our Acts are all remarkable for their brevity. They are not so complicated as the English Pharmacy Act. It would be impossible to pass anything so long as that in the States, and we find that we practically gain all the good, although we have very much shorter Acts. Now the first Pharmacy Act of any value at all was for the city of Baltimore, which was passed by the Maryland legislature. The circumstances were these: an effort was made to pass an Act for the entire State of Maryland, but the petition asking for it was mainly signed by the city of Baltimore, and it was lost. Profiting by that experience, the Baltimore pharmacists got a petition signed by all the pharmacists of Baltimore—the good, bad, and indifferent—and another from all the leading physicians, and a third from all the influential citizens, and those petitions asked for the passing of a Pharmacy Act for the city of Baltimore alone. All the country members of the legislature who opposed the previous Act said, "If the city of Baltimore wants this Act only for itself, let it have it." That measure passed without any trouble, and the Act has only about five sections. The principal points were that on and after the passing of the Act no person should be allowed to open a pharmacy unless he had observed a regular apprenticeship of four years and passed an examination before the Examining Board, or unless he could produce a certificate with the degree of graduate in pharmacy from some recognized college of pharmacy, that certificate being dependent on a four years' apprenticeship. By that means they effectively killed off the diplomas given by some of the cheap colleges, who, finding it profitable, had given their diplomas to some persons who had merely attended lectures and never had anything to do with the practical work of pharmacy. Furthermore, the different Pharmacy Acts do not recognize the right of a person holding the degree of M.D. to practise Pharmacy. They consider both professions perfectly distinct. Most of our schools, successful as they are, have relied mainly upon the intelligence of the community and on moral influence. We have not in Massachusetts now—we would rather not have—legislation. If it comes we simply take an interest in it. We have influence enough in the legislature to defeat any Act that would not suit us, and we have done so already several times, when political hucksters were going to make capital out of pharmacy.

Mr. Haselden said: I had no intention to offer one word upon education, because I came here more with the idea of listening, in order that I might obtain a knowledge of the wishes of the community at large connected with pharmacy, and also because I was afraid that anything that I might say, being President of the Pharmaceutical Society, would be taken as a *dictum*. Now I hope that the few words that I say will be taken in my capacity as a private member of the Conference, and not as President of the Pharmaceutical Society. I rise more particularly to speak upon the subject of the examinations, because I have heard the word "examination" a great many times, and I have heard no gentleman say a word either in favour of the examinations or against them, except in so far as they have been mentioned in our Professor's paper. I believe, and it is the opinion also of Dr. Greenhow, that for the present our examinations are sufficient. The Doctor has stated that they are conducted in as satisfactory a manner as they could possibly be conducted. Indeed, to use his own words, he said they are as near perfection as human nature can arrive at, and yet I am told to-day that they are a long way off perfection. I was for some time an active member of the Board of Examiners, and, of course, as President of the Society I am now *ex officio* Chairman of the Board of Examiners. I have paid great attention to the examinations and great attention to the examiners and their capabilities, and I must say that I am quite of opinion that for the present they are sufficient for all our wants. Doctor Greenhow says that the Minor examination which turns a gentleman out fully qualified to commence business, and consequently, to a certain extent, having the lives of Her Majesty's subjects in his hands, should be a little more practical. There I quite agree with him; but he also says, "before you carry that out give twelve months' notice, and let the candidates know what they will have to undergo." I think the Doctor is right there also. I am very sorry for what Professor Attfield says as to the standard of the examination, because I cannot agree with him. He says that it has been lowered enormously. Now I maintain that it has not been lowered at all. The printed directions for the examiner's guidance are what they were formerly when the examinations were voluntary, but with this addition, that in the Minor examination for pharmacy the candidates are required now to know something about the decimal system of weights and measures in accordance with the Pharmacopœia. That portion of the examination being carried out, the standard cannot be lowered. It is rather increased than otherwise. In practical chemistry candidates are required now in the Minor examination to give proof that they are acquainted with the system of testing. I cannot, therefore, agree that there is any diminution in the examination. I go further, and say that in practical dispensing and reading prescriptions I am certain that the examination is quite stiff enough for any of those who come up. If I were to bring forward anything to support this opinion, I might simply mention that in the last examination for the Minor there were, I believe, 38 candidates, and no less than 24 of them were plucked. As regards the qualifications of an examiner, which have been specially pointed out, I suppose, in some measure for our guidance, I must say that I think they are very good as far as they go, and that it is not merely necessary that an examiner should know his subject to its fullest extent, but he should also have a certain amount of discernment and discretion in working the candidates that come before him. It is also said that we should have special examinations, and that the subject should be carried out to a greater extent over a large area. Well, gentlemen, if we were to go much further than we do, or at least if we were to occupy much more time than we do, we should never get through the examinations, unless you gave us fewer candidates and many more hours to deal with them. Now there are two classes of candidates who always obtain a larger amount of time. I know that a botanical examiner does now, and he did on former occasions, when he finds a young gentleman well up in his subject, carry him on for the pleasure of the thing, to see how far he can go. And then there is another class of candidates not well up, and the examiner says, "I must have a little patience with this man, and I must give him five or ten minutes longer than the ordinary men, in order to find out what he has any doubt about, and to make an allowance for nervousness, or something of that kind." Then it has also been said that the School of Pharmacy in Bloomsbury Square should be separated from the examinations. I know there is a disposition to separate them, but the examinations are conducted by quite a different party of gentlemen from the educational portion. The educational portion is conducted by professors: the examination is conducted by ourselves. You may call pharmacy a profession if you like; I call it a business at present. We are men in business, and who is better qualified to examine candidates to become chemists and druggists than a man who is in the business and knows the business? Well, it has also been stated that it is not a good plan that the education should be picked up here, there, and everywhere. Now, I believe that it is a good plan. I do not care myself where a man has been educated, if he has only the knowledge which I wish him to have. If you educate your young people by a certain routine, and by a set class of professors, and by those professors alone, what will the consequence be? They will know these professors' books by heart, and they will know no other. It was stated formerly in the examination regulations that the candidates should be acquainted with 117 pages of Bentley, as regards the vegetable kingdom, and also three other pages as regards reproduction. Well, what was the consequence? When you asked a candidate any question not in those 117 pages, he said, "That is not in Bentley's 117 pages." Such is the result of compelling your young men to be educated by a certain class of men only. Now, with regard to Bloomsbury Square, and what Bloomsbury Square has done. I have said it before, and I say it again, that it took a long time to do what has been done. It took 30 years to establish Bloomsbury Square properly. But look at the gentlemen on the platform. Two-thirds of them were students at Bloomsbury Square, and you tell me that the examination was not strict enough. The regulations put down in the paper could be made so strict that nine men out of ten could not pass them. I have had a good many gentlemen pass through my hands. I have had some who are in this room now; and I would ask them whether, although I was tolerably good-natured, if I did not at the same time give them quite as much as they wished to have. But to come back to Bloomsbury Square and compulsory education. It is said that Bloomsbury has done nothing to make education compulsory. Why, Bloomsbury has done the only thing that could make education compulsory. Bloomsbury passed your Act of 1868; and without that Act pharmaceutical education never would have been compulsory. That Act compels examination; examination enforces education. How can a man be examined, with a hope of success if he is not educated? But there is also another point which should be borne in mind. Our Professor quotes our examination, and he compares it with the examination and the rules of the examiners of the other scientific bodies—the Colleges of Physicians and Surgeons. But then he forgets this one circumstance: that the examinations of physicians and surgeons have been compulsory more than half a century, whereas ours have been compulsory only for four years; therefore, you should not compare our regulations with their regulations. And then there is another point which you must bear in mind. Although the Act could render the examination compulsory, the Act could not alter the character of the men or boys who were already in the business. There are men in the business who had these boys in their care previously; and there must be time allowed to work out all that. We are all agreed about the Preliminary; and I have no doubt that that will come as a matter of course. But when we speak of the Minor examination, I believe that in a few years, and a very few years, too, the youths will come up from their apprenticeship in a condition to pass that examination. Their masters, or the gentlemen taking apprentices, will improve with the times; and if they cannot give them all the information necessary, they will give them all that they can, and they will advise them to go to other sources to finish their education, and to get all the extra knowledge which is necessary to pass the Minor. You will thus get in time good practical men of business, who have learnt the practical part of their business in the shops and not at the lectures. I will not trespass on your time any longer, gentlemen, because I did not intend to occupy it in any way whatever. I approve of Mr. Reynolds's scheme with the amendment which the Council added to it at the end of the session. I also approve, to a certain extent, of Mr. Schacht's scheme. I do not care which system you adopt. You might even employ both systems so long as you adopt something which will help young men to get qualified; but if you attempt to supply the education which the parents should give in the first instance, and the master in the second, it will be a failure.

Mr. M. Carteighe said: I fancy that Mr. Haselden has been somewhat hard upon Professor Attfield, because he has to some extent misinterpreted him, but at the same time I must honestly say that the tone of this communication and the strong language used justify some of us in thinking that it merits strong condemnation; but the real question in Professor Attfield's paper is, assuming cram to exist, can it be prevented? He states so positively throughout that cram does exist, that I presume we must take his *ipse dixit* for it. His statements read to me so superlative and so innocent that I really began to wonder whether there be cram in Civil Service examinations—whether there be cram in other departments of the State—whether indeed there be cram at South Kensington about which Dr. Foster can tell us anything. The fact is that cram has been rampant ever since examinations have been in existence. You cannot get rid of it, but the Professor has very kindly educated us to day as to the best way of reducing it to a minimum. Well, he has initiated three propositions. The first is Preliminary examinations. Well, we have had them for some time. The next is a certificate that the candidates have been for four years with a duly registered chemist and druggist. Well, I apprehend that this suggestion has occurred to many over and over again. If there be one defect in our examinations that is just the crucial one. We do not insist upon that particular practical knowledge which represents, after all, the *summum magnum* of our examinations. Examinations at the best can only be tests of a certain amount of knowledge, and if we were to extend the time from twenty minutes to two hours, it would be impossible for any professor, be he Professor Attfield or Professor Tait, to state precisely that man's value in the science in which he was being examined. You must take a certain amount of knowledge for granted on the facts before you, and it is quite possible that in some cases, nay even in many cases, you may be mistaken; but in all examinations of this kind, there is always a large margin allowed for nervousness and irritability of temper either on the part of the examiner, or on the part of the candidate. Well, now we may admit, as I said before, that there is cram, although I am not at all prepared to admit a large part of what is here written without the evidence which should have been brought forward to convince us that the Board has been passing inefficient men for so long a time. But as the Professor's object is one which we all have at heart, that is, to make the examination as useful as possible, it is not worth while to cavil about the evidence. The remedy is the point to which we come, and that remedy is obtaining a certificate of having been four years with a duly registered chemist and druggist, and of having attended certain lectures. Well, as regards the first, the certificate from the chemist and druggist. Perhaps Professor Attfield is not aware that this subject has been discussed over and over again both at the Council table and at the Board of Examiners, and that resolutions have been proposed and submitted that arrangements to that effect should be carried out. The Board have sent up recommendations to the Council on more than one occasion, and as lately as last year they sent up a statement that it would strengthen their hands very much if they could get certificates from chemists and druggists that a candidate had been engaged for four years in daily preparing himself and accustoming himself to the routine of his business. But there have been difficulties in the way. Now if the Professor's paper should help us to get over them he will, in my judgment, be amply rewarded. Besides the four years, the Board desired to insist upon every candidate's being 20 or 21 years of age. Well, as a matter of expediency, the Council gave us to understand, although I do not believe any resolution was passed that it is not desirable to insist upon a four years' certificate or a fixed age. The age is very important, because the cram which I have found is that *which is obtained as the candidates pass through the Society's own laboratory.* We have found it among those young men who have tolerably well-to-do parents or guardians, and who go to a shop for six months, get rather above it, and are then sent to the School of Pharmacy. These young men come to us very fair chemists and botanists, but they know next to nothing about the particular part of the business by which we gain our daily bread, and they fail to pass. We are ordered by the Act under which we conduct our examinations to examine in half-a-dozen subjects, but I presume the Professor alludes more particularly to chemistry. I repeat that we have found the cram to be most rampant in those young men, otherwise brilliant, who have never been in a shop for any lengthened period of time, and the Board was and is of opinion that it would be of immense advantage to insist upon 20 or 21 years as the minimum age at which a candidate should come up for the Minor examination. It was conceived that in all probability such an one must have obtained a certain amount of practical experience, and that the errors which must necessarily occur in every examination would be, to some extent, reduced. Well, this question was also remitted to the Council, as already mentioned, and their solicitor's opinion was asked, and he reported on the subject. I do not know what the final report to the Council was, but I have made an appeal to more than one member of the Council since, to take the bull by the horns, and interpret the Act in a liberal spirit, and insist upon the age of twenty or twenty-one (twenty-one I prefer) as the minimum of age at which a candidate shall acquire the legal privilege of a chemist and druggist. It does seem to me that to insist upon this is essential in the interests of the public as well as ourselves. In the Act itself it states that a man to be eligible for the Modified examination shall be of full age, and have been three years engaged in business; but for the Minor examination we have no guarantee, and candidates come up at the age of sixteen or seventeen deficient in practical knowledge, but full of cram. This proposition then is a safeguard that would tell in the Professor's direction. Well, the last thing he proposes —and that is the only new proposal in the scheme—is that there shall be a certificate of having attended lectures, and he says, "I am of opinion that thus 95 per cent. of the cramming now practised will be prevented." I was brought up in a medical school. There was an attendance-book, and it was necessary for every candidate to send in his schedules to the examining body. Where the candidates were by nature idle or stupid, they had ample opportunity to, and very often did, walk out of the room immediately after they had signed the book, or within a few minutes. I have myself seen as many as twenty students get up from a lecture immediately after signing the book. Wherever there is an inducement for moral fraud, it is very difficult indeed to control it, and I do not think that the certificates proposed by Professor Attfield would materially prevent cram. You would get some excellent men, but others would still sidle out of the room, and, when the time came for examination, seek any man who would assist them, ON A NEW PRINCIPLE, for money. The fault, the Professor thinks, does not rest with the examiners. Well, I must say, in spite of what the President of the Pharmaceutical Society has told you, that I do not think the examination for the Minor by any means perfect. It is quite capable of improvement, and I believe it to be possible for the board to correct some of the evils of which Professor Attfield complains. Any process by which that would be brought about would involve a complete change in the system of our examinations, and I think it could be done without increasing the stringency. In opposition to the statements in the paper, I may mention that not long ago the Board had an opportunity of meeting with a gentleman who had been in Professor Attfield's laboratory for one or two years. He was an excellent chemist, a very good botanist, and well up in materia medica. In fact, he possessed all the knowledge that could be obtained by work in a laboratory or by reading. Well, he had to appear no less than twice for the Minor, and three times for the Modified, before he could pass in prescriptions and practical dispensing. But we all know that crammers are very skilful, and it is necessary to vary the mode of examination and the questions. I think it would be an immense gain if the examinations, instead of being monthly or oftener, were held once a quarter, and conducted from day to day. It would give us then only four examinations in the year, and it would, I think, prevent the frequent recurrence of stock questions, some of which it is almost necessary in certain subjects to put to every candidate. It would also present an immense advantage—an advantage of which some of my colleagues as well as myself would avail ourselves, viz., that of resigning our seats to some of our provincial friends. I ought in justice to the Board to rectify one omission on the part of Mr. Haselden. He forgot to mention that about three months ago a committee was appointed to consider the question of cram at these examinations, and to decide whether anything could be done in the way of checking it. That committee is actually extant. There is a scheme drafted for the consideration of that committee, and I think this fact shows that the examiners are really alive to the evil, and that, so far as they are concerned, they are disposed to do all they can to check it. But it is very important that the examiners themselves should bear in mind the particularly transitional state in which we are. I hear complaints about the number of failures. If you were to see the hands and faces of those who have come up for the last three years for the Minor examination, you would say that most had just been shut out from the Modified. These are men who became registered under that inefficient Preliminary which was extant before the passing of the Pharmacy Act; and who only want just that modicum of knowledge which is necessary to ensure registration as chemists and druggists. As soon as that class is got rid of, and you get men who have passed a respectable Preliminary, I am sanguine enough to believe that fewer persons will resort to the cramming establishments alluded to by Professor Attfield, and therefore I think it would be far better to let the whole of this question stand over until this transitional period is passed.

The question of provincial *education* is essentially a political one. It is said that we have no objection to assist those who are assisting themselves. But there is this enormous divergence of opinion—that while, on the one hand, some say that you should only assist temporarily because the circumstances require it; on the other, say they, you should do it in perpetuity. I have not read the scheme of Mr. Reynolds in the latter sense, but if Mr. Schacht in his scheme means that we are to continue to carry on this process of examination and payment for results as part of the regular system of the Society, I for one decidedly object to it, and would oppose it. I object altogether to being taxed to educate apprentices for whose education means should be found by their friends. I think it would be wrong altogether in principle to ask a master to take money out of his pocket to educate his own apprentice. The shoe pinches just where pointed out by Mr. Schweitzer. If a man has passed the Minor examination, and takes an apprentice, he ought to be able to prepare his pupil in the ordinary course of business, so that at the end of his time, without going to any professor, he could pass the Minor examination of the present time. Some of the very best men who pass, some of the men who know the principles of chemistry best, are just the men who have not learned their pharmacy. If they have learned chemistry pure and simple, I do not think that we actually want what is called pharmaceutical chemistry, but we *do* want pharmacy, which should in all cases be taught by the master.

Professor MICHAEL FOSTER: I should have preferred having the opportunity of listening to the remarks of speakers to saying anything myself, because what I have to say can only be said from the general points of view. I will confine myself, if you please, to two observations. One is that it seems to me as an outsider that many of the questions that you have discussed to day have very decidedly a financial aspect. One sympathizes entirely with all your efforts to raise, as you have done, the status of the chemist and druggist, but you must remember that however high you may become by efforts of that kind, you can only become powerful and numerous as your occupation becomes more and more remunerative. I speak now not as a representative of the profession to which I belong, but entirely as an individual. I rather wonder that your efforts have not become more unanimously and strenuously directed towards taking away from the profession to which I belong that practice of medical men of dispensing their own medicines, which certainly does not properly belong to them. It seems to me that when that is thoroughly established, a great many of these problems with which you are dealing today will meet with their solution tolerably readily. And now for one other remark about examinations. As your President said, I have had recently and for some years past, a great deal to do with examinations. I have never had the pleasure of meeting Professor Tait, and if I had I am sure I should not be a third to add to those two with whom he has already had to do. But I have made my observations as I have gone along, and I tell you plainly that the more I examine, the less secure and the less safe and the less satisfied do I become with the task of examining. The word cram, which was introduced with an apology by your President to-day, is a word which is before me always. It is a nightmare to me and worries me all my life long. From day to day, and from week to week, and from month to month, I find myself doing nothing but fighting against this fearful system of cram. I have no doubt Professor Attfield thinks very badly indeed of the cram, which is manifested at your pharmaceutical examination. I do not know; it may be worse than the cram which manifests itself at the Civil Service examination. Very certainly that same spectre is to be seen at South Kensington; and, alas! I meet it again and again even in those wonderful walls of the London University. You have no idea of the energy which is spent by a certain number of men in cheating the examiner—energy which might be far better bestowed. The process of cramming means that you send up a lad, and you make him appear to the examiner as if he knew that which he does not know. The first thing that the cram-man or grinder does is to make himself acquainted with the mind of the examiner—acquainted with all his little foibles and peculiarities. For instance, if a cram-man had to prepare a pupil for the gentleman at the other end of the platform [Mr. Stoddart], he would say to the pupil, "Be very careful how you hold your scales." They understand all those little means by which the examiner arrives at a conclusion. You may depend upon it that if you only have a short examination or a hurried one, the cram-man, the grinder, will beat you. If you give the examiner time enough, and allow him, especially, a practical examination, then he will have a greater power over the candidate. I cannot at all understand Professor Attfield saying, in his paper this morning, that it is easier to cheat at the practical examination than at the theoretical one. I know of no examination at which it would be easier to cheat than at the examination in chemical riddles, as they may be called, which, to my mind, afford no examination in chemistry at all. But a real practical examination, depend upon it, puts greater difficulties in the way of the grinder than anything else. The great element, however, is time, whether it be an examination with written papers, or a *vivâ voce* examination. If you have a *vivâ voce* examination, half your time has to be spent in putting the candidate into a comfortable position. You have two things to do. You have to cheer up the nervous man. He may possess the knowledge you are seeking, or he may be putting on the nervousness in order to cheat you. You do not know, and you have to wait and see whether it is real nervousness or not; and you require a very great deal of time in order to conduct the examination thoroughly and satisfactorily. I cannot say what your arrangements may be —whether they are such as to admit of your examinations being lengthened very considerably. I have heard something about a quarter of an hour or ten minutes. That seems to me gone at once in an examination. I want hours; I want days; nay, if I were to speak my whole mind, I should say I required weeks of examination before I should say that a man was fit to pass. You say that is impracticable, and it is to a very large extent. And here comes another opinion, which certainly has been growing up in my own mind with increasing force for some time past; that is, the necessity of having some evidence before the lad comes up of his having been taught. I do not mean attending lectures. I was a medical student, and I am perfectly aware of the ridiculous folly of attending lectures. I attended lectures with a kind of official conscience, which was common at least in my days in various hospitals, and I know myself I have been signed for attending lectures which I could not possibly have attended, except with the destruction of my medical education. Very frequently the students occupy the time of the lecture in drawing caricatures of the lecturer and reading books, and so on. You cannot do any good by simply requiring attendance on the lectures; but this you can do. Suppose a boy has been taught for a length of time by a conscientious man who loves the subject which he is teaching. There is no man better fitted to tell the worth of that boy's knowledge than the man who has taught him for such a length of time; but you cannot trust the man alone, because men will put a little strain on their conscience, and give their friends a certificate. How can you get over this? It is practicable to join together the examiner and the teacher. Let every lad have a testimony from a teacher in whom you have confidence of his having studied the subject well and thoroughly for a certain length of time. If you do that, you can then give him a far shorter examination at the hands of a technical examiner; and if the two results agree, I would put any amount of money on the result that he is a fit boy who knows the subject on which he has been examined. But then you must have a certain number of recognized teachers. And here allow me to make one observation, and that is, that it seems to me, with regard especially to schools of pharmacy, that it is not necessary that you should establish big schools like that in Bloomsbury Square. Do not take yourselves away altogether from the efforts which have been made to establish science schools in various parts of the country. You require botany and chemistry. I am not aware that the chemistry which belongs to the pharmaceutist is different from that chemistry which a chemist himself possesses, or which a medical man possesses. Why not let your lads get their chemistry from recognized chemistry teachers? And the same with botany. I was very glad to hear one gentleman say that he did not believe in pharmaceutical chemistry. No more do I. Surely you will achieve the end in view, if you have chemistry and botany taught thoroughly by teachers upon whom you can depend in all parts of the kingdom.

Mr. R. W. Giles: In common with every one in this room I have listened to that address of Dr. Foster with the greatest pleasure and satisfaction, and I have found that he has entirely and eloquently expressed those opinions which have long influenced my mind upon this subject. I am not proposing now to discuss this question thoroughly, but I wish to call attention to a point which appears to me to be an essential point lying at the origin of our discussion, and which has been rather slightly treated of to-day. I fancy that, practically, the question which we have to consider is really, what are our relations, as a corporate body in another place, to this question of education? I apprehend, sir, that there is no difference amongst us about the fact that education is essential for the rising generation of pharmacists; and I imagine also, that there is no difference of opinion amongst ourselves as to our readiness and our desire to promote education, although it may not be an absolute obligation which we have undertaken. But we feel personally anxious to co-operate in affording those facilities which are essential for those who enter the business, whether before entering the business they have claims upon us or not. That question of our corporate relations to this question of education appears to me not to have received the attention which it deserves. I think it would be a mistake if we were here to discuss the financial affairs of Bloomsbury Square at great length. That would be decidedly out of place. At the same time we know that we are intimately related in our individual capacity with that institution, and we can speak of scarcely any question affecting pharmacy without involving the position and relations of Bloomsbury Square. In saying this I am saying that which is highly eulogistic of that institution. I deny that the institution at Bloomsbury Square has ever charged itself with the task, or is properly chargeable with the task, of providing the education of future pharmacists. And, I not only say that it is not properly chargeable with it but I say that it is utterly impotent to discharge such an obligation. At the same time it can do much in the way of co-operation, and much in the way of sympathy and encouragement. I am the man who made the foolish blunder of supposing that the scheme which Mr. Schacht propounded had some connection with the Government institutions for the promotion of science; and therefore I was specially delighted to hear the good advice independently offered by Professor Foster that we should adopt that education which is sown throughout the land in diverse establishments.

Professor Foster: I did not mean that exclusively. I meant that for general teaching.

Mr. Giles: Well, it appears to me that that is the best source of pure scientific teaching which is extant; and is within our reach, and has been made available for us, and that generally throughout the country. We should rely upon that, but we cannot rely upon it for the complete education which we find in Bloomsbury Square, and which I hope we shall find before long elsewhere. Now I have been delighted to hear observations in the papers and from previous speakers as to the propriety of establishing certain other leading schools of pharmacy; and I do think that, having regard to the financial position of Bloomsbury Square, the time has arrived when we should think of establishing a school of pharmacy in North Britain. I think that is the place where we should commence; and I consider that in contemplating an extension of a system of pharmaceutical education it would be unwise to proceed *per saltum*, and that we should proceed more gradually, not committing ourselves to any risks and disastrous expense. By observing this we should test the amount of demand for pharmaceutical education which is existing about the country, and we should then see whether the want of students at Bloomsbury Square is caused partly as a matter of locality, and through the difficulty of youths finding homes in London which may be remote from their own homes, and whether they might not be more conveniently accommodated in a centre nearer themselves. The result of that experiment would certainly influence us in our future proceedings. We should be able to judge whether it was desirable to establish a school in the Midland counties or elsewhere. But I think we should certainly foster or encourage some means for preliminary scientific education, and I do think, as I have thought ever since our experience in Bristol has taught me so, that the schools of science and art founded by the Government are most available means for our purpose. Although that instruction has not been specifically referred to, yet I find that Mr. Schacht has admitted that his recommendations are largely influenced by his experience in Bristol. I think I understood that, and there we certainly have acted upon those opportunities. We have availed ourselves of them, and however encouraging our experience there may have been, certainly it depends upon the facilities which these institutions have afforded us. I think that is as much as we could wisely do now instead of at once undertaking a national system of education throughout the length and breadth of the country. I think that the time has probably arrived when we may contemplate the institution of another important school of pharmacy, but I think we should make a mistake if we undertook to start at once, in centres not metropolitan, extensive schools of pharmacy at all like that in Bloomsbury Square, or at all capable of affording such a high standard of education.

Mr. Reynolds: Mr. President and gentlemen, you would feel it more unnatural were I not to wish to claim your indulgence for two or three minutes, than that I should now rise. The task of defending what was brought forward in 1870 as a proposition for meeting the wants which we all acknowledge would be in very bad hands were it left to me alone to defend what was then done. The able testimony of such experienced educators as Mr. Proctor and other gentlemen has been given in favour of what was then brought forward. I may state that the scheme of 1870 is by no means to be regarded as the work of myself or of one individual, for a great deal of consultation took place amongst the members of the Provincial Education Committee, and it is the contribution of various persons; so that whilst for a matter of convenience I would not protest against my name having been connected with it, it is only just that that this explanation should be given. I do hope that very great good will result from our devotion of to-day to this subject. I think that we can see our way somewhat more clearly than we did when Professor Attfield introduced the matter by his paper in which two salient points were brought before us, and we had the alternative of whether our Board of Examiners should be relied on for checking this system of cram, or whether we should be compelled to go to the other serious alternative of requiring schedules of attendance on lectures. I dare say that the opinion in this room is almost unanimous that we need not take that latter alternative, and that we have both the disposition on the part of the Board of Examiners and also the power in their hands to do a great deal towards what we all wish to be done. There are one or two things to be noticed in connection with setting up any additional schemes of education, or I may say aiding them, because it is a question of aiding rather than of initiating these schools. The question whether this is to be a permanent thing or not ought not to be shirked by the present Council nor by anybody concerned. In 1870 we did not hesitate to give a direct expression of our opinion that the transitional condition of the students who had been caught in 1868 in an unprepared condition justified the help which was given; and this is consistent with the feeling which I believe is general in this meeting—that we ought not permanently to tax the existing body of chemists and druggists in order to bring up those who are to supply their ranks. Now, Mr. Schacht concluded with the challenge to those who preferred the scheme of 1870 to his own, to show why it was better that money should be given to a few places rather than that it should be distributed and produce more good. I will say that there is nothing remarkable in the fact that many persons should think that the more concentrated use of that money would do the greater good. We know that we are acting in a more conservative spirit. We are following the example which was laid down by a previous generation when they established one school in Bloomsbury Square; and we have been satisfied as long as that has seemed sufficient for our requirements. But it is a revolutionary change to endeavour to spread the aid in a very diffuse manner over the country, and although it is not a task which I am anxious to go deeply into, I must take exception to Mr. Schacht's scheme that it does not carry out what the phrase "payment for results" would indicate. Now, Mr. Schacht would give sums of money to schools that were able to send up students who could pass in chemistry and in botany. Well, these are two subjects, and one of the examiners told us that no less than six subjects are required by the Board. I do not call it a "result" to pass only in chemistry and botany. If you pay for that you are getting only a third of the result that is asked for by the Board. I know it is extremely tempting, and I make this public confession that I started with the impression in 1870—the full belief that the payment-for-result system was the ground that we had to work. The result of consultation with various other members of the Society led me to the conviction that, whilst very tempting in appearance, it was not the soundest basis for giving us permanent schools in the country. I hold that opinion very strongly still.

Dr. Edwards: I shall detain you but a very few minutes, Mr. Chairman; but there are some matters which have presented themselves to my mind in a light which I think will enable me to indicate two or three of the strong points, and perhaps some of the weak points of the discussion. In the first place, in reference to our friend Professor Attfield's excellent paper. It has evidently conveyed to us the result of a very great deal of careful thought, and it is also a very interesting history of the progress of pharmaceutical education. I think that one strong point is conveyed in a word used by yourself on another occasion, and that is the insistance upon the word *thorough*. I read in it, and I read in that expression by yourself, the pith of Professor Attfield's strong point. The value of the education given in Bloomsbury Square may be appreciated rather by its thoroughness than by the number of students And, therefore, it is with very great regret that I find that the average of attendance which used to be some ten months, in the case of the larger number of students who entered, has been reduced to such a very small period. Regarding the present value of the education given there, it is certainly unfortunate that the education should be distributed over so large a number, and the thoroughness be so very obviously reduced in proportion. Then, I think, the weak point of Professor Attfield's paper is his reliance upon lecture certificates. I remember my experience as a professor in a medical school of some years' standing. I must say that I can place no reliance whatever upon the production of lecture certificates. Perhaps, also, as a teacher of pharmacy for some years I may say the same thing. I have really found that attendance for considerable periods of time upon lectures, or merely upon oral instruction, has very much less value than it appears to have on paper; and I estimate as of the very greatest importance in pharmaceutical education the practical work in the laboratory. I place this practical work in the laboratory, manipulative chemistry, far beyond oral instruction. As regards what fell from my friend Professor Markoe on the American system of education, there is one point which is a strong point, and which might be with advantage added to the examination at Bloomsbury Square, and that is the preparation of a thesis; I believe in requiring from every man who comes up for the Major examination some attempt at mastering a subject, especially such a one as manipulative chemistry. He might write on some substance, giving all the information he can from his own experiments on the matter. It is of immense advantage to the man, besides which it would be the opening of future research, and gives the man the opportunity of expressing to his own mind the way in which he arrived at information which would afterwards be valuable to the whole community. It would enrich not only the Society, but the body of pharmaceutists at large and such institutions as the Pharmaceutical Conference, if every one of the students who had to pass a Major examination were required to produce a thesis—to give some account which he has composed himself, and which is founded, to some extent, upon researches he has made in his laboratory. And then for the weak point. I am quite satisfied that mere evening instruction, whether it be in the laboratory or lecture-room, is extremely weak. A man can never feel upon his legs in learning such a subject as chemistry unless he can afford some portion of the time—two or three or five months—in which he will devote his whole energies to the science of learning. A man who is occupied entirely by the business of the day, and simply comes to a night school of chemistry, never acquires that kind of information which will thoroughly fit him for his future duties in life as a pharmacist. That is, I think, the weak point of the College of Pharmacy at Massachusetts. We have had a little experience of that kind in Canada. We endeavoured to sweep away the absurdity of a medical curriculum for our students which required a two years' attendance and a six months' course of chemistry and two years and three months of botany and Materia Medica, which were all required in the province of Quebec. The chemists having taken it in hand, endeavoured to substitute something else for it. They took the principle of the Pharmaceutical Society that they would not require attendance on lectures, and only required certain standards of examination. When those standards of examination were discussed I felt it incumbent upon me to retire entirely from this voluntary association, because I could not subscribe to their terms of examination. The idea was to push a man through a purely commercial examination, and with so little previous education, that I felt compelled to throw up my appointment on the Board of Examiners, and declined to sit any longer and sign their certificates. This I did out of justice to my *alma mater*. Now, we ought to go a little beyond the ranks of our profession with regard to this question of apprenticeship, and endeavour to educate the public mind on the subject. I think we do not sufficiently avail ourselves of a frank and open press. I think we give all the information we can in the Pharmaceutical Journals, but we do not give sufficient information to the public, who, as parents and guardians, have young men for whom they have to provide instruction. As to the requirements of the body of pharmaceutists, occasional articles appear here and there; but we might follow up such meetings as this, and such as we have from time to time in different parts of the country, by interesting a portion of the press, and giving them from time to time information from the secretaries as to what is passing in the pharmaceutical world. There is frequently something that is really interesting to the public in such facts. In this manner the way might be prepared for a better class of young men to come in and pass a preliminary examination. The public, as a whole, are not sufficiently aware of the necessity for this preliminary examination for entrance into the business. I would also offer as a suggestion that, in addition to the knowledge of classics, it is very desirable in the Preliminary examination that the subject of accounts and bookkeeping should take a larger place. In our Preliminary examination, it should not be merely a question of arithmetic; but I think that even in our Minor examination we ought to require a higher standard of bookkeeping and accounts than is at present required. We overlook that matter, but I think it is one of the sciences which it would be desirable to increase in stringency in the examination. As to apprentices, I rather disagree with Professor Attfield. I think that the day for paying premiums for apprentices is past, and you have to look at that as one of the old customs of the country which have passed away like the curfew.

The President intimated that it would now be necessary to close the discussion, unless the Conference decided to sit on Thursday.

Professor Attfield said that he had no intention of replying to the discussion under the present circumstances, for by doing so he should be bringing himself far too prominently forward in connection with the subject. This paper on the subject had been only one among many contributions to the discussion of the matter. He should probably reply through the Pharmaceutical Journal to some of the views which had been adduced.

The Conference then adjourned to the next day.

Correspondence.

Pharmaceutical Education.

Sir,—May I, as a member of the rising generation of pharmacists, venture to give brief expression to some of my opinions and experiences anent the question of the hour.

In the first place, sir, experience has taught me that nine months of steady, systematic work in a small country village, where no help but self-help is obtainable, will enable one, with ease, to pass the "Minor" in honours; and out of my experience there has grown up an opinion that the cry for help which comes up with so doleful an intonation from our young men is not deserving of the tender consideration it receives. Ever since examination became compulsory they have been making this plea of inadequate educational appliances an excuse for lazy inaction, and if they are so deficient of brain and so wanting in energy as to be unable to obtain the legal qualification of a chemist and druggist without special organizations and pecuniary aid, I cannot but think that it will be for their own comfort and our credit if they decide to retire to the nearest eligible crossing, in which case they will probably ask a grant for besoms. Now it is doubtless true that under Mr. Schacht's scheme very many of these gentlemen might be dragged through the Minor wicket-gate, and left to swell the number of the rather motley company already to be found within the fences which the Act of 1868 has raised, but I think it behoves us to ask whether their presence is likely to "advance the interests of the sciences of chemistry and pharmacy;" and whether men of good education and active brain are likely to be attracted to our ranks when we beat up for recruits in the back lanes and casual wards. I once lived in a town where there existed a small but very efficient and admirably disciplined volunteer corps, which numbered among its members the best men of the neighbourhood. But some enthusiastic gentlemen, whose generosity exceeded their judgment, subscribed amongst themselves a fund sufficient to establish in the corps a very liberal system of "payment by results." In a very short time the discipline and efficiency had wofully decreased, and the uniform was so disgraced that no gentleman would wear it.

I am only "a young man from the country," and ought not, perhaps, to speak so strongly, but I cannot help feeling that we are in present danger of inaugurating a most suicidal policy. Does it not seem absurd that we should allow our subscriptions to be used in furtherance of a scheme which will glut the labour market and tend to multiply the number of small druggists, cloudy in their notions of pharmaceutical ethics, and untrustworthy in the matter of prices? If our status is to be raised, it must be done by the increase among us of men to whom the "grand old name of gentleman" is not a "mere attraction," and who will not be likely to treat the Queen's English with that careless freedom in which the authors of some of our trade circulars seem to glory. We are assured, however, that the country members of the trade are now thoroughly roused. I rejoice to hear it, and would humbly suggest that, as soon as they have had time to recover from the novelty and suddenness of the great change which has come upon them, they shall, as you, sir, have said, "come forward and zealously co-operate with the Society in the endeavour to make the necessity of education more generally appreciated." Such a pharmaceutical revival is our great want, and would prove of far greater value than any attempt to multiply the number of small associations, deficient, as I believe they must be, in spirit, system and teaching power.

Let the Pharmaceutical Society organize branches in one or two of our great trading centres, and maintain the highest standard of efficiency in all its departments; and let all our masters, assistants and apprentices once become fully alive to the absolute necessity of education and the possibility of effort, and then, sir, I venture to think that pharmacy, as a science and as a profession, will be in a more hopeful condition than it can be under any system of eleemosynary nursing.

Newton Chifney.

Tooting, S.W., August 13*th*, 1872.

Sir,—I have read Professor Attfield's paper with great interest, and cordially agree with many parts of it, but one suggestion I must confess staggers me, viz. "that every candidate for the Minor should produce a certificate of having attended a course of instruction at some recognized school of pharmacy." This would suit a select few no doubt, but how many men from remote country places would be able to comply with this regulation? Living miles from any of the great centres of pharmaceutical instruction, they must endeavour by their own exertions to pass the ordeal. Now the expense of a three months' course of training at Bloomsbury Square, or elsewhere, might represent £50 or £60; an outlay which many young men can ill afford; and what is the business after all? Does it pay even now for the trouble and expense? Let us, therefore, maintain a bold front, and resent any further encroachment upon our liberty. I have been myself a student at Bloomsbury Square, and am able to speak in the highest terms of Professor Attfield's system of teaching, and the kindliness and patience invariably manifested to the most backward as well as the more advanced students, so it is evident I am no advocate for cramming or I should have gone to the nearest establishment and been coached for the occasion.

An Ex-Student at Bloomsbury Square.

August 21*st*, 1872.

Another Side to the Educational Question.

Sir,—For a long time the educational question seems to have been an all-absorbing one to those whom we are accustomed to look up to as leaders in the ranks of pharmacy. It is no doubt one of vast importance, and in its proper solution must lie the grand secret of future prosperity and success.

At present, so many new plans and individual schemes are ventilated week after week through the medium of the Pharmaceutical Journal, that he must indeed be a far-sighted individual who could give a satisfactory answer to the question—how will it end? One thing seems certain, and it is, that all are agreed on the point of a "higher standard," the cry has gone forth "Upward! onward! excelsior!" and therefore the question at issue is, "How is this to be done? It is not my aim for a single moment to grapple with it, for I am merely one of those who are looking on, and waiting with curious interest the result of this most important discussion. I am a student, and, as it is for our especial welfare that so much concern is manifested, I feel that it will not be out of place to pen a few thoughts from a student's point of view, and as I am certain that in doing so I shall be only writing those of hundreds of my fellow-students, there can be no need of apology.

With men of such high intellectual capacity and professional standing as we have at our head, there ought not perhaps to be the shadow of a doubt but that all will be ultimately settled for the best. We are proud to have such men to emulate, but we also know that their position in life is gained, and our only fear is that, for this reason, they will treat as a secondary consideration what after all is to us the primary, viz., pecuniary affairs. However high it may be their intention to raise us as body by a raised system of education, there is still a question which must inevitably occur, Will it pay to do so? Yes; we must come to the sober reality; we have chosen pharmacy as the means by which we may be enabled to gain a livelihood, and to do so honestly and creditably must be our chief concern. Even now the outlay necessary to bring up a youth as a chemist is something considerable, and methinks it is for this reason that apprentices are already being regarded as a scarce commodity. I take it that to a large majority the question of increased outlay is a serious one, to some, I fear, a complete barrier; and, in the event of an alteration, some allowance ought certainly to be made to those who have already embraced the study of pharmacy as existing under the present regulations.

A higher system of education means increased outlay; for increased outlay we must demand increased remuneration; for higher mental power, less of physical must be expected. Will employers be willing to meet these demands? Will the public be willing to pay for them? if so, then I, in common with very many more, will be only too glad to do my utmost, in order to attain to that standard which will enable me to reap these benefits; but if not, the advanced educational scheme must be treated as a house with no foundation —it must surely fall to the ground.

Penzance, September 2*nd*, 1872. C. B. A.

Examination Fees.

Sir,—I was very pleased on reading Mr. Frazer's excellent letter in a recent Journal on the above subject. That he will be successful in reducing the fee for the Major I feel confident, if the Council will take into consideration the expenses we as assistants voluntarily incur in order to pass; such as paying for laboratory instruction, chemical apparatus, lectures and examination fees, books, board, lodging, and the whole of our time for about four months.

Mr. Urwick's resolution, "That all registered chemists and druggists be admitted members of the Pharmaceutical Society without paying even the entrance fees," is, to say the least of it, a very partial business indeed. What have these gentlemen done for the welfare of pharmacy that they should be dealt with so leniently?

Should Mr. Urwick succeed, "members" will be so general, that comparatively few will think it worth their trouble to present themselves for the Major, unless prompted by the love of extra knowledge to do so.

Much is said just now about provincial education. I say, in the first place, help those who try to help themselves by reducing the examination fees; then let them do what they can for the provinces. If you will insert this I shall feel obliged.

Wales. Machaon.

Pharmaceutical Chemists and Members of the Pharmaceutical Society.

Sir,—Permit me to express my humble disapproval of the proposed plan of admitting Registered Chemists to be Members of the Pharmaceutical Society by payment of an annual subscription.

I admit that it would considerably increase the funds of the Society, and this pecuniary benefit is all that I can see in the adoption of such a method. This, however, I think is completely overbalanced by a pecuniary advantage of the Major Associate, which might be proved by asking almost any respectable and even educated person, unassociated with the regulations of the Society, the following question:—What is the difference between a Pharmaceutical Chemist and a Member of the Pharmaceutical Society? The majority of people imagine that the word Pharmaceutical implies or signifies that the person to whose name it is attached has obtained it by passing stringent examinations; they think such a man will be perfectly competent to make up prescriptions, and so he obtains their patronage. Seeing, then, that a member by examination and a member by payment are viewed in the same light by the public, we shall be placing a thoroughly competent Chemist on the same footing with a man who knows little, or next to nothing about his business. Can a surgeon become a member of the College of Physicians by payment?

In conclusion, I think it would be well if candidates for the Modified examination were allowed to present themselves for the Major without passing the Minor. J. L.

Vermin Killers.

Sir,—In the Journal for August, I read, in the case of "Poisoning by a Vermin Killer," that the Coroner for Leeds would consider it his duty to order the prosecution of any chemist who should sell "Battle's Vermin Killer" without entering it in the 'Sale of Poison's Book' in accordance with the 17th section of the Act of Parliament. Before we can obey the law we must know its meaning, and I cannot see how a "Vermin Killer" (though it may contain "Strychnine or any of the poisonous vegetable alkaloids and their salts," as stated in Schedule A, part 1, or "The preparations of strychnine," as stated in the Additions to Schedule A, can be deemed a poison, requiring to be registered in accordance with Schedule F of the same Act. "Battle's Vermin Killer" is a proprietary article, and as such we sell it. We are not supposed to know its contents; and if we were supposed to know the formula, I think even then it would come under the second part of Schedule A. If it does not, I think the words "Vermin Killer" might be properly struck out, for the majority are made with strychnine, as being the most concentrated and surest poison for vermin we have.

But even supposing it is necessary in accordance with law to register all "Vermin Killers" containing strychnine, why are not our sheep-dipping compositions, our fly powders, and our maggot lotions entered in accordance with Clause 17, when it is well known they contain respectively arsenic and bichloride of mercury, and yet are sold by the hundred-weight? Or, to come more closely home, why are not our cough stuffs, sold in bottles at 1*s.* 1½*d.* and 2*s.* 9*d.* (which so frequently contain morphia, emetic tartar, or prussic acid) obliged to be registered in our poison book?

I apologize for trespassing on your time and space, but should be glad if you would kindly give publicity to this, as I think if the Coroner for Leeds was to consider himself a chemist, and look at it in this light, he would then see that a "Vermin Killer," though it may contain strychnine, is not required to be registered any more than a cough elixir which contains emetic tartar, or a maggot lotion which contains corrosive sublimate. E. S. Balchin.

Sir,—There appears much doubt respecting the sale of poisons, and various opinions given, and from the observations of the Coroner in the case of death from Battle's Vermin Killer, reported in a recent Journal, it appears requisite for purchasers of Vermin Killers to sign for the same. If that be correct, will you have the goodness to inform me if the same applies to Sheep Dressing containing arsenic, also Brown's Chlorodyne, and other preparations containing articles in the first part of the Poison Act; also if cough mixtures, lozenges, etc., containing morphia or poppies, must be labelled "Poison?" I think, for the satisfaction of the trade, some plain rule should be laid down, and not subject parties who are desirous of obeying the law to be censured in the way they frequently are. Inquirer.

August 3rd, 1872.

Sir,—In reference to your note on page 94 of the Pharmaceutical Journal, I would beg to ask whether you have seen the "Regulations" issued by the Council, and a copy of which is now before me, in which "Vermin Killers" (every compound containing a "poison" and sold for the destruction of vermin)" are distinctly placed in part 2 of the Schedule? I have always considered that they were so defined, and have acted upon that supposition, and I can say such is the universal practise in this district.

As, however, your definition seems to clash so decidedly with the generally received interpretation of the matter, it would be very desirable to have an authoritative statement by the Council upon the question, that the chemists throughout the country may know what to do.

Carlisle, August 3rd, 1872. W. Moss, Local Secretary.

R. I. N.—The opacity may arise from the cinnamon and cloves in the vin. opii rather than from the tinct. kino. The manner of mixing would also have somewhat to do with it. If the tinct. kino, vin. opii, and mucilage be added separately one after the other to the cinnamon water, the mixture will be fairly bright and reddish; but if the tinct. kino, vin. opii, and mucilag. acaciæ are mixed briskly, and the cinnamon water added to them, the mixture will probably be turbid. In the P. B. 1864, the aromatics were omitted in the vin. opii, and restored in 1867. Does our correspondent make his own tincture and wine, and thus ensure uniformity in them?

Mr. J. Gamgee.—We consider the substance of your letter more suited for an advertisement than as a satisfactory decision of the question referred to in our issue of last week. The testimonial that you enclose from Professor Wanklyn has been forwarded to the writer of the article.

G. Cathcart.—The solution ought not to deposit any sediment. We should advise you to analyse the white sediment you speak of, in order to ascertain what it consists of.

W. H. Dingle.—The practice is much to be deplored, but we do not think it advisable to give it publicity by referring to it more particularly.

Communications, Letters, etc., have been received from Mr. C. Fryer, Mr. M. Elwood, Mr. G. A. Keyworth, Mr. R. W. Giles, Mr. D. Jenkins, Mr. J. Barker, Mr. Barton, Mr. Atkins, Mr. Ekin, Mr. Deane, Mr. Haffenden, Mr. Sutton, Mr. Groves, J. A., T. G. S., A. C., "One of the Laity."

The following journals have been received:—The 'British Medical Journal,' August 31; the 'Medical Times and Gazette,' August 31; the 'Lancet,' August 31; the 'Medical Press and Circular,' August 31; the 'Chemical News,' August 31; 'English Mechanic,' August 31; 'Gardeners' Chronicle,' August 31; the 'Grocer,' August 31; the Journal of the Society of Arts,' August 31; the British Journal of Dental Science' for September.

MONOBROMATED CAMPHOR.

BY JOHN M. MAISCH.

Monobromated camphor was discovered by Th. Swarts, in 1861,* who obtained it by heating Laurent's bibromide of camphor ($C_{20}H_{16}O_2Br_2$), in a sealed tube, to 100° C. After several hours, the colour of bromine disappears, hydrobromic acid is formed, and a brownish oil, which gradually becomes crystalline, and contains the new compound. If bromine and camphor, in the proper proportions, are heated in a sealed tube for three hours, in the water-bath, the same compounds are formed. The crystalline mass is washed with water, recrystallized from alcohol after treatment with animal charcoal, washed with an alcoholic solution of potassa, to free it from hydrobromic acid, then with much water, and finally recrystallized from a mixture of alcohol and ether.

After the publication of Professor Deneffe's account† of the medicinal properties of this compound, I attempted to prepare it, at the request of Professor Wm. A. Hammond, of New York, and followed at first the above process, not being aware at the time of the researches of W. H. Perkin, to which I shall presently refer.

Laurent prepared bibromide of camphor by dissolving camphor in cold bromine, and freeing the crystals, which form after some time, by rapid expression between bibulous paper. Gerhardt states that these crystals decompose on the application of heat into bromine and camphor, which, however, has been refuted by Perkin. I can confirm this observation of the latter, and have also satisfied myself that Laurent's statement, that camphor crystallizes unaltered from its warm solution in bromine, is incorrect, as the copious evolution of hydrobromic acid proves.

Monobromated camphor is formed according to the following equation: $C_{20}H_{16}O_2+2Br=C_{20}H_{15}BrO_2+HBr$. If prepared in a closed tube, it is evident that at all stages of the process the pressure must be very considerable; at first, in consequence of the volatile nature of both camphor and bromine, and subsequently on account of the presence of the gaseous hydrobromic acid. When operating on a small scale, with suitable precautions, there was little difficulty in obtaining the compound. But when using several ounces of bromine at once, the tubes were usually shattered, and it became evident that this process could not be used with advantage on a large scale. The observation that on slightly heating the mixed camphor and bromine, the heat increases after the withdrawal of the fire, and the vessel contains considerable quantities of hydrobromic acid, suggested the idea that the camphor might be bromated without using closed tubes, simply by digesting the bibromide at an elevated temperature, or by allowing bromine to act upon camphor at a higher temperature, with the precaution to return into the retort any bromine and bromide of camphor which might be volatilized, while the disengaged hydrobromic acid might be absorbed by a solution of an alkali.

The neck of the retort was raised and connected with a reversed Liebig's condenser, which being found unnecessary, was afterwards substituted by a glass tube. If the reaction was not allowed to become too violent in the beginning, no bromine volatilized, but a yellowish-brown substance condensed in the neck, flowing back into the retort like oil; gradually this became lighter in colour, and golden-yellow needles were observed in the upper part and neck of the retort after cooling. Whether these needles are a bromide of camphor or a hydrobromate of monobromated camphor has not been determined.

The heat was raised after the first reaction was over to a temperature varying in the different experiments between 100° and 132° C. (212° and 270° F.). The higher temperatures were found better adapted for rapidly generating the monobromated camphor; but in all cases a considerable quantity of an oily compound was found in the mother-liquor from which the monobromated camphor had crystallized. This oil contained more or less of the latter compound in solution, which was obtained by reducing it to a low temperature. The mother-liquors containing the oil, in consequence of the frequent application of heat, turned black and left, after the evaporation of the menstruum, a black oil, which, in the course of several weeks, became granular; the oil still present in the magma could not be removed by different solvents which would also dissolve the crystallized granules. On being expressed between bibulous paper a grey solid mass was left behind, which was permanent in a temperature of 32° C. (90° F.), but became soft and oily when exposed to the direct heat of the sun, which was above 38° C. (100° F.) This compound is not monobromated camphor; its composition has not yet been investigated.

Attempts to separate the whole of the monobromated camphor from this oily substance by sublimation were not successful; the whole mass, after a slight white sublimate had been obtained, near 132° C. (270° F.), turned black, and after cooling sometimes did not separate any crystals, but remained liquid and oily, while at other times dark blackish-grey crystals were obtained.

It was noticed that the mother-liquors of the first crystallizations of monobromated camphor contained considerable hydrobromic acid, which also adhered to the crystals. The endeavour to remove it by washing with hot water was not entirely successful, and necessitated the drying of the solid portion previous to recrystallization from alcoholic solvents. To avoid these difficulties, the removal of the acid by means of a weak alkali (carbonate of lime) suggested itself, and, instead of alcohol, petroleum benzine was experimented with as a suitable menstruum for recrystallization.

The first crystallizations, whether obtained from alcohol or from petroleum benzine, contained notable quantities of the oily matter mentioned above, in consequence of which bromine was liberated on exposure to the light. The greatest portion of this oil could be removed by pressure between bibulous paper, and the remainder by subsequent recrystallization; but the loss of monobromated camphor was considerable, owing to its being partly absorbed by the paper with the oil, and to its remaining to some extent in the mother-liquor with that portion of the oil not absorbed by the paper. Gasoline or petroleum naphtha was found to be a good solvent for this oil, and to dissolve at the same time much less of the monobromated camphor than alcohol, ether, or petroleum benzine. Accordingly, when the crystals as

* 'L'Institut,' 1862-63. Kopp and Will's 'Jahresbericht,' 1862, 462.

† American Journal of Pharmacy, 1872, 84.

first formed have been drained in a funnel, they may be obtained nearly pure simply by washing them with gasoline, and require then one crystallization from alcohol or petroleum benzine to be entirely pure and unaltered in the light. The monobromated camphor dissolved by the gasoline may be recovered by evaporating most of the solvent spontaneously, washing the crystals with a little gasoline and re-crystallizing. The remaining mother-liquors, if not used as solvents in subsequent operations, may be worked up with the oil left by the first crystallization.

While experimenting with bromide of camphor, W. H. Perkin,* in 1865, obtained monobromated camphor by treating the oily matter obtained from the action of bromine and camphor with hot solution of potassa, and subsequently heating the product in a retort, collecting that portion of the distillate separately which comes over above 364° C. (508° F.).

T. Swarts,† however, prefers the process suggested by him to that of Perkin, regarding the former as more satisfactory; he also states that when moist monobromated camphor is distilled, or it is left in contact with hot water, bromine and hydrobromic acid are evolved, and camphor free from bromine is separated. The regeneration of camphor under these circumstances has never been observed by me; on the contrary, when the monobromated compound is boiled in a retort of water, a white crystalline sublimate resembling snow-flakes is slowly formed in the neck of the retort, and these crystals contain bromine, and have all the behaviour of monobromated camphor.

Perkin observed that monobromated camphor, treated with alcoholic ammonia in a sealed tube, at 180° C. (356° F.), undergoes a slight decomposition, with the formation of an organic base and of ammonium bromide. Fearing that the prolonged action of hot potassa solution upon the oil which already contains monobromated camphor might induce its decomposition, and my time not permitting to investigate it, I had resort to carbonate of lime (white marble), which, as previously observed, was found to answer the purpose well, as far as the removal of hydrobromic acid was concerned. On heating the remaining oily matter gradually, it was found to turn blackish when nearing 150° C. (300° F.), the colour became darker as the temperature rose, and a little oil distilled over, which solidified after a while and turned red from the liberation of some bromine. Meanwhile, the flake-like sublimate in the neck of the retort increased considerably, and the hot liquid boiled actively between 260° and 261° C. (500° and 502° F.), disengaging considerable quantities of hydrobromic acid, and separating also so much charcoal that the retort cracked. Eight ounces of bromine had been used in this experiment, the black residue of which, when dissolved in alcohol and filtered, yielded white crystals, requiring to be re-crystallized once, while the mother-liquor had a strong acid reaction, due to free hydrobromic acid.

Although this experiment was not very favourable for Perkin's process, in its application to the prepation of this compound on a large scale, it suggested a method of utilizing the oily residue which had accumulated from the mother-liquors of the first crystallization of monobromated camphor prepared at a lower temperature. The grey granular mass, left by expressing a portion of the solidified oil, as stated above, was slowly heated to 260° C. (500° F.), and after the disengagement of most of the hydrobromic acid, was dissolved in petroleum benzine, treated with marble and filtered, when monobromated camphor crystallized. The oily residue, containing some of the granular compound, was next treated in the same way, with a similar result. In both cases some of the oily mass was left in the mother-liquor, which may undoubtedly be utilized in a subsequent operation.

(To be continued.)

LABORATORY NOTES.*

BY EDWARD SMITH, F.C.S.

Bromide of Potassium.—This salt is generally found in commerce of a high degree of purity. This is not, however, always the case, a sample sent to me proved to be contaminated with chloride of potassium. The amount of chloride was estimated as follows, iodides, iodates, and carbonates having been previously ascertained to be absent:—

·0640 grains of the dry salt were titrated with $\frac{n}{100}$ solution of silver nitrate, potassium chromate as indicator, 55·5 c. c. of $\frac{n}{100}$ silver were required to complete the reaction, and

55·5 × ·00119 = ·0660; the volume of silver solution used is therefore in excess of that required for pure potassium bromide, for ·0640 (amount taken) should require 53·78 c. c., since ·0640 ÷ ·00119 = 53·78 and

51·0 c. c. $\frac{n}{100}$ silver × ·00119 = ·06069 K Br.

4·5 c. c. $\frac{n}{100}$ silver × ·000745 = ·00335 K Cl.

55·5 c. c. = ·06404 K Br + K Cl.

and ·00335 ÷ ·0640 × 100 = 5.20

·06069 ÷ ·0640 × 100 = 94·80

The sample, therefore, contained 5·2 per cent. of chloride and 94·8 per cent, of bromide of potassium.

Acetic Acid.—Iron is not usually mentioned in the text-books as an impurity in this acid. A small amount of iron proves very tiresome, since, if the acid be used for preparing mindererus, the iron is constantly and gradually depositing. On examining some acid which had been partly used in making mindererus, I found it to contain iron and manganese, the proportion of the former metal was 2·67 grains to an imperial pint. The manganese was not estimated, but was very readily detected in the iron sulphide (thrown down by ammonia sulphide from the neutralized acid) before the blow-pipe. In every other respect the acid was satisfactory.

Glycerine.—The high price of English glycerine has encouraged the introduction of foreign supplies. English glycerine, as a rule, stands the Pharmacopœia tests of gravity, etc., well. Continental samples, although professedly pure, and "equal to Price's," are not always reliable; either the gravity is low, or they are not odourless, or perfectly free from metallic impurity. One specimen, apparently pure, I found to contain a notable amount of some sulphur compound (not determined) probably arising from H_2S having been used to free the glycerine from metals. It had a sp. gr. = 1·250, without odour, free from metallic impurity, and generally stood the usual tests. On warming gently with dilute acid,

* Read at the Brighton meeting of the British Pharmaceutical Conference, August 14, 1872.

H_2S was given off in sufficient quantity readily to react upon lead paper, and to discolour metallic solutions.

A mixture composed of dilute acid and this glycerine and water became highly offensive within a couple of hours at the ordinary temperature. As glycerine and dilute acid frequently enter into the composition of mixtures and lotions, the occurrence of sulphur in the former is a possibility which dispensers should bear in mind. Its presence may readily be detected as above indicated.

Bismuth.—The common impurities of metallic bismuth are arsenic, antimony, copper, and lead. I have very rarely met with lead, but my experience is perhaps somewhat limited. The amount of arsenic and antimony is generally small, and will not require here any especial attention, since the greater portion (if not quite all) of these two metals is eliminated during the subsequent treatment for the removal of copper, which latter is the most difficult metal to get rid of.

In the purification of commercial bismuth, instead of following the B. P. method of fusing with nitre, I have adopted the process of Hugo Tamm,* which has proved in my hands exceedingly efficient and satisfactory. The treatment consists simply in fusing the coppery bismuth with potassium sulphocyanide. Tamm says, "The sulphocyanide which I use is prepared by mixing eight parts of cyanide of potassium and three parts of flowers of sulphur. One part of this mixture is thrown over sixteen parts of the metal melted at a low temperature." A bright red heat is sufficient, such as may be readily obtained by almost any Bunsen burner.

In order to satisfy myself of the thorough elimination of the copper by this process, a sample of coppery metal and the resulting purified button were carefully examined as follows:

3·2585 grains of the impure bismuth were dissolved in dilute nitric acid, ammonium chloride added, and the bismuth precipitated as oxychloride by the addition of a large volume of water, excess of ammonia was now added, the precipitate thrown in a filter, well washed, and the acidified filtrate divided into two equal portions, α β.

Through α, H_2S was passed to excess, the precipitate so formed collected, washed, and ignited. The residue thus obtained is a mixture of copper sulphide, oxide, and sulphate. To remove the latter, it was again carefully ignited with ammonium carbonate, and the resulting mixture of copper sulphide and oxide weighed. The weight $=$ ·0115 grains, this $\times 2 =$ ·0230 grains in quantity taken (3·2585 grains) and ·0230 gr. $=$ ·01836 grain copper $=$ ·563 per cent. copper in sample examined. As the percentage of copper in copper sulphide and oxide is identical, a mixture of the two is of no consequence in estimating the amount of metallic copper.

The portion β of the filtrate was treated in a similar manner, by passing H_2S through, but the resulting precipitate was dissolved in nitrohydrochloric acid, evaporated to dryness, and the residue dissolved in dilute hydrochloric acid. From this solution the copper was precipitated as metal by zinc in a platinum dish in the usual way. The weight of metal obtained was equal to ·558 per cent. of quantity taken. The mean of the two experiments $=$ ·563 $+$ ·558 $\div 2 =$ ·560 per cent.

48·45 grains of impure metal were then fused with a mixture of 2·5 grains pure K Cy, and 1·0 grain S for fifteen minutes. The fire was then removed, and after a few moments, to allow the slag to separate, the crucible being gently tapped to agglomerate the metal, the latter was poured out, and the button when cold weighed:

Weight of button $=$ 44·25 grains, the loss was therefore 4·20 grains $=$ 8·6. per cent.

This loss is, however, much too great, the fact being that I did not succeed in obtaining the whole of the metal in the button, brilliant metallic specks being visible after cooling, disseminated through the slag. A second fusion of the latter yielded a small button, but on examination it was found to be contaminated with particles of slag, and consequently gave evidence of the presence of copper.

Subsequent operations have proved that the loss should never exceed five per cent.

I must here remark, that the proportions laid down by Tamm work well if *pure* cyanide be used, but if ordinary commercial fused cyanide be employed, then a larger proportion is necessary. Practically, I have found that 50 parts of impure metal required from 3·5 to 4 of cyanide with 1 of sulphur. If a deficiency of cyanide be used, sulphide of bismuth is formed, thus involving a second fusion, or entailing a serious percentage loss of metal in the button, but this need not happen if the above precautions be observed.

A weighed portion of the button first obtained was dissolved, and after the separation of Bi. as before, treated with H_2S, but *not a trace* of Cu. was revealed. Excess of ammonia to the acid solution did not produce the slightest coloration, nor did any of the usual specific tests for Cu. indicate the slightest trace of that metal. The coppery bismuth had, therefore, been completely freed from the Cu. by the very simple process of Tamm.

Since writing the above, I have met with a paper by Mr. Schacht,* wherein he gives the results of some of his experiments in removing Cu. from Bi. by fusion with nitre. It is stated that the whole of the Cu. cannot be removed by the B. P. process. This statement is doubtless correct, repeated fusions are certainly necessary. The process of Tamm, so far as my experience goes, is unquestionably by far the more perfect, and I think leaves nothing to be desired, A little sulphur may be left with the metal, but this is practically of no consequence. With regard to percentage loss, Mr. Schacht states "that the loss varies with the duration of the process from 7 to 17 per cent." In his experiment, 1000 grains of coppery bismuth, after three fusions with nitre, lost 170 grains, and "still yielded abundant evidence of copper." In this respect, therefore, as well as in the more thorough efficiency, the process of Tamm may well supersede that of the present Pharmacopœia.

NEW DERIVATIVES FROM MORPHINE AND CODEINE.†

BY C. R. A. WRIGHT, D.SC. LOND.

Lecturer on Chemistry in St. Mary's Hospital Medical School.

During the past year further experiments have been made on the derivatives of these two alkaloids, in continuation of the results briefly described at the last meeting of the Conference. The principal results are as follows:—

It was shown previously that compounds are obtainable from codeine (by the action of hydrobromic acid) which may be regarded as formed by a polymerizing action, the resulting products containing four times as much carbon in their formulæ as the original base; and that analogous substances are formed by the action of hydriodic acid in presence of phosphorus, hydrogen being also added on in this case. Further examination has confirmed these results in the main, with this difference, however, that the action of hydrochloric acid on codeine and morphine appears to indicate that the formulæ of these bases are double of those usually ascribed to them; while polymerides exist containing respectively twice, three times, and four times as many atoms in their formulæ as the original bases; so that the following series may be written:—

† Read at the Brighton meeting of the British Pharmaceutical Conference, August 4, 1872.

Codeine	$= \overline{C}$	$= C_{36}H_{42}N_2O_6$
Dicodeine	$= \overline{C}_2$	$= C_{72}H_{84}N_4O_{12}$
Tricodeine	$= \overline{C}_3$	$= C_{108}H_{126}N_6O_{18}$
Tetracodeine	$= \overline{C}_4$	$= C_{144}H_{168}N_8O_{24}$
Morphine	$= \overline{M}$	$= C_{34}H_{38}N_2O_6$
Dimorphine	$= \overline{M}_2$	$= C_{68}H_{76}N_4O_{12}$
Trimorphine	$= \overline{M}_3$	$= C_{102}H_{114}N_6O_{18}$
Tetramorphine	$= \overline{M}_4$	$= C_{136}H_{152}N_8O_{24}$

Each of these bases is apparently capable of giving rise to a large number of derivatives. In the codeine series both the polymerides themselves and many of their derivatives have been obtained. In the morphine series, the polymerides themselves have not been formed as yet; nor have the derivatives of trimorphine been obtained with certainty; but derivatives of tetramorphine and dimorphine have been obtained, some being formed by the removal of the elements of water from the polymerides themselves; the dehydro- or "apo-" derivative of the latter polymeride is apparently the *apomorphine* examined some few years ago by the late Dr. A. Matthiessen and the author.

When hydriodic acid and phosphorus act on codeine, methyl is eliminated as iodide and a series of substances are obtainable, all of which are expressible by the general formula—

$$(\overline{M}_4 + H_{16}) + nHI \pm p\,H_2O$$

By pushing the treatment further, other substances are formed having the general formula—

$$(\overline{M}_4 + H_{16} - O_8) + nHI \pm p\,H_2O.$$

When morphine is subjected to the same treatment, products are formed which are apparently absolutely identical with the corresponding codeine products. Much fewer derivatives are, however, obtainable from morphine, the fact of their being no methyl to eliminate and thus place the substance in a quasi-nascent state, being probably the reason for this difference. Thus the morphine derivatives hitherto obtained all belong to the first series—

$$(\overline{M}_4 + H_{16}) + nHI \pm p\,H_2O,$$

none of the other series containing less oxygen having been obtained as yet from this base. These derivatives have no marked physiological action, considerable doses (up to eight grains) being given to an adult she-terrier without producing any result other than a purging action lasting for a few hours.

It is noteworthy that both from morphine and codeine the same compound $(\overline{M}_4 + H_{16}) + 9HI - 4H_2O$ is derivable. The formula of this substance ($C_{136}H_{161}IN_8O_{20}$, 8HI) is incapable of being halved, and indicates that the iodized bases are really C_{136} compounds, and not C_{68}, as was supposed at first. On account of the similarity in physical properties between these iodized derivatives and the bromotetracodeine, chlorotetramorphine, etc. obtained by the action of hydrobromic acid on codeine, the formulæ of these latter substances are also considered to be double of those formerly attributed to them, *i.e.*, they are viewed as $C_{136} - C_{144}$ compounds and not $C_{68} - C_{72}$ bodies. Inasmuch, however, as they still contain four times as much carbon as the codeine and morphine (when these two are doubled as above explained), the old names are still applicable; and this class of bodies, which are characterized by the property of being amorphous and insoluble in ether, may be conveniently alluded to as the "*tetra bases.*"

To obtain the polymerides of codeine themselves without alterations by further secondary reactions, the action of acids other than hydracids was examined. Phosphoric acid when heated to about 200° (by boiling down the aqueous solution of codeine in excess of glacial phosphoric acid) yields *dicodeine* soluble in ether, amorphous, but forming crystalline salts, and *tetracodeine*, much resembling in its properties all the other "tetra bases" examined, being insoluble in ether and amorphous, and forming amorphous salts. These two bases appear to be identical respectively with the "isomer of codeine" of Armstrong, and the "amorphous codeine" of Anderson, both prepared by the action of sulphuric acid on codeine. On examining this reaction, a third polymeride was also found to be formed, which is amorphous and soluble in ether, but which forms amorphous salts. On account of this body being in many properties and respects intermediate between dicodeine and tetracodeine, it is considered to be *tricodeine.*

The proof of the correctness of the formulæ attributed to dicodeine and tetracodeine is as follows: when dicodeine is treated with hydrochloric acid it undergoes the following reaction:—

$$C_{72}H_{84}N_4O_{12},4HCl + HCl = H_2O + C_{72}H_{83}Cl\,N_4O_{11},4HCl.$$

The resulting body is soluble in ether and gives *amorphous* salts, whereas dicodeine hydrochloride is crystalline. Hence this body is not a tetra base, and hence the inference is that dicodeine has a C_{72} formula. When codeine itself is similarly treated, the first product of the reaction contains chlorine and carbon in the ratio 1 to 36, whence codeine is a C_{36} body. Tetracodeine evidently belongs to the same general group as the substances termed "tetra bases;" and as these have been shown to be C_{144} compounds, it follows that tetracodeine has double the formula of dicodeine, which again is double that of codeine: whence the names. Tricodeine is considered to be such on account of its properties, which are intermediate between those of dicodeine and tetracodeine; the action of sulphuric acid on dicodeine does not give rise to tricodeine, but does to tetracodeine, so that tricodeine is formed directly from codeine. The action of hydrochloric acid on tricodeine is, however, quite different from that on codeine and dicodeine; the elements of water are removed, and the product contains *no chlorine at all.* Tetracodeine, on the other hand, undergoes no change when heated for a long time with hydrochloric acid.

The action of hydriodic acid on codeine, dicodeine and tetracodeine is again very different, as exemplified in the following reactions:—

Codeine $4\overline{C} + 36HI = 8CH_3I + 4H_2O + I_{16} + (\overline{M}_4 + H_{16} + 12HI - 4H_2O)$.

Dicodeine $2\overline{C}_2 + 25HI = 8CH_3I + 4H_2O + I_8 + (\overline{M}_4 + H_8 + 9HI - 4H_2O)$.

Tetracodeine $\overline{C}_4 + 18HI = 8CH_3I + 2H_2O + (\overline{M}_4 + 10HI - 2H_2O)$.

With the codeine H_{16} is added on to $\overline{M}_4$; with the dicodeine H_8 only; and with the tetracodeine no H at all; a tetra base results in each case. The product from dicodeine has the formula $C_{136}H_{153}IN_8O_{20}$,8HI, which contains C_{136} and is incapable of being halved. Sulphuric acid converts dicodeine into tetracodeine, no tricodeine being produced thereby; hence tricodeine is a polymeride formed directly from codeine, and is not produced by the metamorphosis of dicodeine previously produced; the reverse being true for tetracodeine.

Dr. Stocker finds a considerable difference in the physiological actions of these different polymerides; the higher polymerides usually produce vomiting or diarrhœa (in cats and dogs), while codeine produces a peculiar hypersensitiveness and cerebral congestion not noticeable with the others.

When morphine is treated with phosphoric acid, two products are obtained corresponding in properties to dicodeine and tetracodeine; these are not, however, the polymerides themselves, but are derivatives therefrom derived by abstraction of the elements of water. One is soluble in ether, and forms crystalline salts, though amorphous itself. This is produced only in small quantity, and appears to be identical with apomorphine, which is accordingly viewed as a derivative of dimorphine.

$$2\overline{M} = 4H_2O + (\overline{M}_2 - 4H_2O) = 4H_2O + C_{68}H_{68}N_4O_8.$$

The other is a tetra base, and is formed by this reaction—

$$4\overline{M} = 2H_2O + (\overline{M}_4 - 2H_2O) = 2H_2O + C_{136}H_{148}N_8O_{22}.$$

This latter base gives rise to new derivatives when treated with hydrochloric or hydriodic acid; it is quite as powerful an emetic as apomorphine, and being obtainable in much larger quantity, may possibly come into use in medicine. According to the experiments of Dr. Stocker it does not seem to produce so much after-depression as apomorphine. Hitherto it has been administered by hypodermic injection, but it could probably be conveniently given as a pill.

A large number of the compounds examined have not yet been named, on account of their complex compositions. The term *diapotetramorphine* has been given to the last described base, on account of its having the composition of tetramorphine minus two proportions of water, $\overline{M}_4 - 2H_2O$. Adopting the same kind of nomenclature, ordinary apomorphine would be termed *tetrapodimorphine,* having the composition of dimorphine minus four proportion of water $\overline{M}_2 - 4H_2O$.

A large number of other products have also been partially obtained, and are now in course of examination; it is hoped to extend the investigation of the opium alkaloids to some of the lesser known ones, such as narceine and papaverine. In reference to this point, the author cannot conclude without acknowledging the extreme kindness and liberality of Messrs. Macfarlane and Co., of Abbey Hill Chemical Works, Edinburgh. During the course of these researches these gentlemen have furnished gratuitously large quantities of several alkaloids, including the rarer ones, and amounting in the aggregate to several pounds weight of materials of the highest degree of purity; without the help thus liberally bestowed, the investigations would have been impossible.

KOEGOED.*

BY MR. GEORGE ALEXANDER KEYWORTH, HASTINGS.

A plant growing very abundantly in Bushmanland, on the borders of Namaqualand, South Africa. Mules and horses there, through drinking brackish water, have inflammation of the stomach. The remedy is a pint of decoction of this plant (made by boiling a handful of it in a quart of water to a pint) with half a teacupful of brandy. It acts as a slight purge. The natives chew it for the same purpose. Chopped up and mixed with oats, etc., for cattle, it serves as a condiment. Koegoed is pronounced Koukwood; "goed," in Hottentot Dutch, means "wood."

The specimen exhibited was brought to this country last year by C. J. Small, Esq. The plant has been examined by B. J. Austin, Esq., member of the Reading Microscopical Society, whose report is added. I am not aware that the plant has previously been much noticed. Its therapeutical value also remains, I believe, to be ascertained.

Mr. Austin says, "After looking carefully, and more than once, over the specimen you sent, in hope of finding a blossom that would assist in determining the relation of the plant, I could find none; and, indeed, have found but one leaf, which it would be rather presumptuous to set down as belonging to the plant just because it was met with among fragments. The pieces seem to me to have been soaked in salt water;† the taste is saltish, and, indeed, crystals of salt form in the distilled water in which I softened some of the root fibres.

"The fibrous nature, too, of the root—for the specimen seems to consist wholly of roots*—may be due to this. The wood zones are quite separated, and so also is the cortical exterior. This has made it very difficult to cut sections. All the leaf-fragments too are completely skeletonized. I have, however, made the best sections possible, and find the usual pitted ducts in the wood. The chief peculiarity is the thickened margin of the wood cells in the outer portion, similar to what is seen in woody fibre of root of ginger, and a delicate spiral structure exists in some of the cells. There appear to be no definite starch granules, although there are some cells which appear to be of an albuminous character. These are numerous, but show no trace of striæ, nor does polarized light produce any effect. These cells are probably the remains of a milky juice, and to them I attribute the readiness with which the root tinges water of a brownish-yellow.

"Raphides abound in the central part of the root, and they vary in shape, some being acicular, others prismatic with flat ends, and others with oblique ends.

"The only leaf I found presented no very marked feature, the venation showing it to be exogenous, which, of course, guides but little."

* Read at the Brighton meeting of the British Pharmaceutical Conference, August 14th, 1872.

† This arises from the brackish soil of Namaqualand, impregnated with nitrate of soda, which whitens it.

* Mr. Small does not remember seeing any leaves or flowers. The roots are creeping and matted upon the surface of the ground. He considers the effects to be "slightly narcotic or sedative, slightly stimulant, stomachic and carminative."

ORGANIC CHEMISTRY AND THERAPEUTICS.†

BY A. W. HOFMANN.

(Continued from p. 163.)

I will here trace some of the advantages which have accrued to therapeutics from the study of chemical metamorphoses. There is an entire series of bodies which formerly could only be obtained in small quantity, often in an indifferent state of purity, and which were extracted with more or less difficulty from natural sources. But the study of chemical metamorphoses has revealed methods for now preparing these substances in a state of perfect purity, in considerable quantities and at a moderate price. Some of these discoveries belong to the most interesting episodes in the history of the development of organic chemistry.

During the last thirty or forty years a great proportion of chemical labour has been devoted to the study of alcohol; it might be said, that during this period the progress of organic chemistry has been principally represented by the study of alcohol and its derivatives, and there are two names, those of Liebig and Dumas, honourable mention of which must not be omitted in speaking of this epoch. In conjunction with Peligot, Dumas discovered in wood spirit a new alcohol, possessing properties analogous to those of spirit of wine or ethylic alcohol, and which he classed by the side of the latter under the name of methylic alcohol. Then chemists commenced to realize that in ethylic and methylic alcohols they had the prototypes of a vast class of substances, the most important among organic compounds. This idea gave a new direction to research, and the chase was commenced with an ardour that has not relaxed to the present day; every part of organic chemistry has been explored with the greatest care, but it was principally from the saccharine bodies, whence was derived the alcohol of wine, that it was hoped to obtain new alcohols. Research so energetic did not long remain without result. In an oily liquid obtained in distilleries as

† Lecture delivered at the Medical Chirurgical Institute of Berlin.

an accessory to the fermentation of sugar, and which, in consequence of its bad odour, the manufacturer carefully separated from the spirit of wine, Cahours discovered a third alcohol; and thus a substance which hitherto had taken much trouble to get rid of, acquired at once a great scientific importance. This body was amylic alcohol, contained also in potato spirit. It was soon found that it presented all the properties of the alcohols already studied, and that under the influence of oxidizing agents it produced an acid, just as methylic acid was converted into formic acid and ethylic alcohol into acetic acid. But what was the astonishment of chemists when it was recognized that this acid, obtained for the first time by Dumas and Stas, was identical with the substance which the study of valerian root had superficially made known! So long as valerianic acid was extracted from valerian, as that root contained only very small quantities, it was not possible to use it generally in consequence of its high price; but no sooner had science demonstrated that it could be prepared from potato spirit than it became an object of manufacture, and its salts, especially the valerianates of zinc and bismuth, were employed in medicine.

Among the organic acids which were best known to chemists was lactic acid. First observed in sour milk by Scheele, this acid was afterwards found in a series of acid liquids, in the gastric juice, in sour krout, and in the juice of cucumbers. But it was only when the relation which existed between lactic acid and sugar was discovered, when it was demonstrated that it was formed in the majority of cases at the expense of saccharine matters, and when the conditions under which sugar is transformed into lactic acid were determined; in fact, only when the chemist had given a method which allowed of its fabrication industrially, that the use of this acid was introduced into therapeutics, where now, under the form of lactate of iron, it plays so important a part.

I ought to mention here succinic acid, although its employment in medicine is not to be compared with that of lactic acid. The former method for the preparation of succinic acid by the dry distillation of amber yielded but a small quantity of acid, and it was difficult to rid it from the impurities with which it was contaminated. But no one would think now of preparing it by a method so costly. Analysis has demonstrated that the molecule of succinic acid only differs from that of malic acid by having one atom of oxygen less. Dessaigne has demonstrated that the berries of the mountain ash (*Sorbus aucuparia*) will give an abundant supply of malic acid, which can be transformed into succinic acid by a simple process of fermentation. All the succinic acid of commerce is prepared in this manner.

No less remarkable and important for the progress of chemical research is the revolution which has been effected in the manufacture of benzoic acid. The existence of this acid had been indicated from the fourteenth century, but it was not till the latter years of the last century that its nature was ascertained. It was first obtained from benzoin. Although it had been met with in other resins, and especially in balsam of tolu, benzoin was until the last few years the chief material from which benzoic acid was manufactured; to-day only a small portion of that used in pharmacy and in the arts is prepared in this manner. In 1829 Liebig discovered in the urine of herbivorous animals hippuric acid, a peculiar nitrogenized acid, which by fermentation is transformed into benzoic acid. Later, Dessaigne showed that the same transformation could be effected by boiling hippuric acid with concentrated hydrochloric acid, a reaction in which a most interesting secondary production is formed, viz. glycocol. The present manufacture of benzoic acid is based on these reactions.

Formic acid is another acid meriting notice, although less important therapeutically. It is scarcely necessary to say that in the distillation of oxalic acid, chemists have a source which furnishes the acid much more easily and in a state of greater purity than the organism of the insects from which it takes its name.

I needly hardly speak of glycerine, the marvellous properties of which are every day utilized in some fresh way in pharmacy. Glycerine is, however, properly speaking a pharmaceutical conquest; for Scheele discovered it in 1783 while preparing lead plaster. But it is only since science has demonstrated its nature, and the classic labours of Chevreul upon the fats have enabled us to understand in all its simplicity the mechanism of saponification, that the industrial manufacture of the fat acids and of glycerine could be undertaken with success. It was reserved for our time to be a witness of the great modification which the introduction of saponification by water has caused in the fat industry, the conception of that process having been impossible before the development of organic chemistry. Since the adoption of aqueous saponification, glycerine has become very easily obtainable, and as it is found in the market in a state of purity which leaves nothing to be desired, it is not easy to assign any limit to its employment.

(To be continued.)

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION AND SCHOOL OF PHARMACY.

The Council of the above Association, desiring to meet the expressed requirement of increased accommodation, have taken and furnished rooms at 37, Blackfriars Street, Manchester, in the centre of the city, and within easy distance of all the railway stations. The reading-room and museum are supplied with an excellent collection of materia medica specimens, book of autograph prescriptions, and a valuable library of works on pharmaceutical subjects. The class-room is capable of accommodating a large number of students. The rooms are to be open for study and reference on Tuesdays and Fridays, from 5 till 10 p.m., and on Mondays, Wednesdays, and Thursdays from 7 till 10 p.m. The following courses of lectures and classes have been arranged for the coming session:—

Pharmaceutical Chemistry.—Twenty-five lectures, by Mr. Louis Siebold, on Tuesdays, from 8 to 9.30 p.m. Fee 12*s.* 6*d.* To commence October 8th.

Materia Medica.—Twenty-five lectures, by Mr. Louis Siebold, on Fridays, from 8 to 9 p.m. Fee, 12*s.* 6*d.* To commence October 11th.

Pharmaceutical Botany.—Fifteen lectures, by Mr. Louis Siebold, on Fridays, from 9 to 10 p.m. Fee, 7*s.* 6*d.* To commence October 11th.

Pharmaceutical Latin (*Elementary*).—Ten lessons in elementary Latin, by Mr. J. J. Smith, B.A., on Wednesdays, from 7 to 8 p.m. Fee, 5*s.* To commence October 9th.

Pharmaceutical Latin (*Advanced*).—Ten lessons in more advanced Latin and reading and translating prescriptions, by Mr. J. J. Smith, B.A., on Wednesdays, from 8.30 to 9.30 p.m. Fee, 5*s.* To commence October 5th.

Students willing to attend the three first courses (viz., Chemistry, Materia Medica, and Botany), may do so for a reduced composition fee of 30*s.*

Tickets may now be obtained of Mr. F. Baden Benger, Hon. Sec., 1, Market Place, or of Mr. Louis Siebold, Oxford Street, Manchester.

In addition to the above lecture courses, monthly meetings will be held from October to March, for the reading of papers on, and discussion of, subjects interesting to the trade.

A very considerable outlay having been made in preparing for the coming session, the committee earnestly invite the co-operation of masters, assistants and apprentices, without which the facilities now offered to pharmaceutical students in Manchester and district cannot be maintained.

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 14, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE VALUE OF PHARMACEUTICAL EDUCATION.

IT speaks well for the hopefulness and good feeling of Manchester pharmacists, that while yet the statement of Mr. HAMPSON, as to a former effort to found a school of pharmacy in that city having ended in comparative failure, is yet fresh in our recollection, such an announcement should be possible as that on the preceding page. Not the less so, since we are told, that on the former occasion funds were abundant, but the students were not forthcoming. While ready, however, to recognize to the fullest degree the persevering kindness shown, we are not altogether prepared to admit that the new prospectus is free from liability to criticism.

Scientific and technical lectures at sixpence each may be very desirable from a student's point of view, in certain cases, though we believe such cases are exceptional. But whether the proffer of lecture instruction at such a rate would conduce to the elevation of pharmacy is, we think, quite another question. It is true that in one notable instance even this degree of cheapness has been surpassed. But if it be desired to make any scheme of provincial pharmaceutical education permanent, it is evident that there must be some correspondence between the expenditure involved by the delivery of a course of lectures and the fees to be paid by the students. We are sorry to say experience has shown that if a qualified teacher is to be fairly paid for his labour —as he certainly should be—no town in this country, not even excepting London, would under existing circumstances supply a sufficiency of students to pay the bare expenses, if the fee for twenty-five lectures were no higher than 12*s.* 6*d.* The result would be either that a deficiency would have to be made up from some outside source, or there would be insufficient funds to command the services of a properly qualified lecturer. Gratuitous or partially paid teaching—even if effective—there is no right to expect.

Four years have now elapsed since the passing of the Pharmacy Act. The claim which certain classes of persons in the trade then seemed to have for assistance in passing the compulsory examinations is fast diminishing with the lapse of time. In the discussion at Brighton, as well as in these columns, there has been a decided opinion expressed, that those who in future wish to enter the pharmaceutical ranks should be prepared to pay adequately for their technical education. This appears to be a healthy sign, indicative of good for the pharmaceutical community of the future as well as for the public.

The argument is often heard that the cost of education for entering the business is not repaid by any profits which are afterwards made in it. No doubt there is too much ground for this complaint. But the remedy for this state of things we believe to be very much in the hands of pharmacists themselves; and for confirmation of our opinion we would refer to Professor MICHAEL FOSTER's remarks recently at Brighton. Lightly won, lightly prized, is old experience. So long as persons entering pharmacy are led to expect that they will be provided with technical education far below cost price, so long will there be a class, with whom others will have to compete, who will be ready to throw in their experience with the wrapping paper, and supply the public with their wares at a percentage of profit not higher than the ordinary huckster. An illustration of what we mean is furnished in the persistency with which is urged by certain chemists and druggists, that in a shop full of customers the time required for registering the sale of vermin killers could only be given to the detriment of the vendor. With a public willing—nay, anxious—to restrict the sale of such poisons to the qualified pharmacist, surely it would be better policy to find time for such an operation, and to charge for it too.

THE CHICAGO COLLEGE FUND.

IN accordance with the intimation given when the subscription list to this fund was closed, the Committee consulted the Council of the Chicago College respecting the disposition of the balance in hand. It was found that all chemical and galenical specimens would be presented by American manufacturers; that glassware and other containing vessels would be provided by themselves; and that German books would be sent from Germany; but that chemical and physical apparatus of any kind would be acceptable. Professor ATTFIELD, therefore, as Treasurer and Secretary of the Fund, and with the consent of the Committee, has purchased a selection of optical, electrical, thermal, pneumatic, and chemical apparatus, the manufacturers of which have, in all cases, granted liberal reductions. This collection of apparatus, added to the collection of books (partly presented and partly purchased), will constitute the offering of British pharmacists to their Chicago brethren; the estimated value when safely housed in Chicago will be about five thousand dollars.

The gratifying duty of announcing the completion of the Committee's labours to the members of the Council of the Chicago College fell to Professor

Attfield, and on the 11th July he forwarded a letter containing a list of the apparatus, with a notification that it would be sent off in a few days. To this letter he has now received the following reply:—

Chicago, Illinois, United States,
August 17, 1872.

Prof. J. Attfield, Ph.D.,
Treasurer and Secty. of the Chicago College Fund.

Sir,—We have the honour to acknowledge the receipt of your letter of July 11th, announcing the result of the subscription which has been contributed by British pharmacists and now so generously presented to the Chicago College of Pharmacy.

As officers and trustees of the College we have observed from time to time the great efforts and the untiring zeal our friends in England and elsewhere have manifested in the endeavour to aid us in re-establishing our College, so the receipt of your communication was not an absolute surprise, but, sir, the perusal of the letter, showing, as it does, the extent of the donation, the peculiar care and judgment that has been exercised in its selection, and the large number of contributors, comprising not only pharmacists and scientists, but even their assistants and apprentices, from every part of Great Britain and Ireland, combine to excite in us feelings of profound amazement and gratitude.

May we hope, sir, that all who have contributed to this Fund will believe that we duly value and appreciate the sacrifices they have made for us, and all be pleased to receive, in the name of the Chicago College of Pharmacy, our sincere acknowledgments and thanks; although we would not have one contributor feel that we underestimated the service he had rendered us, we should think our duty incomplete did we not specially thank you, sir, the various members of Committees, and all who took the initiatory steps in this matter; you have indeed cause for congratulation that such marked success should have attended your efforts.

We accept your munificent gift as a valued trust, to be carefully and sacredly administered for the benefit of all who shall seek improvement within the walls of our College. We hope to hand it down to our successors complete and unimpaired, except as time and good usage shall cause them to decay; and when the student, as he seeks or follows the inspiration of knowledge now dwelling upon the page of lettered science, or holding, with unpractised hand, the instrument that shall unfold wonders to his full, eager mind, he, and all, shall know that these aids to knowledge were placed within his reach by brother pharmacists of Great Britain and Ireland, and given in the holy names of sympathy and brotherly love.

Reciprocating these sentiments—
We have the honour to remain, sir,
Your obedient servants,
George Buck, President,
formerly M.P.S.G.B.
T. H. Patterson, 1st Vice-President.
Jas. W. Mill, 2nd Vice-President.

Albert E. Ebert,
Corr. Secty.

We understand that the second edition of Professor Attfield's Manual of Chemistry, published in this country, as well as the third edition, published in America, having been exhausted, it is intended to issue a new English edition in October, and a new American one as soon as possible after the issue of the new United States Pharmacopœia.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Wednesday, August 14th, 1872.

(Second day.)

The proceedings were resumed this morning at about ten o'clock.

Election of Honorary Members.

The President said that the Executive Committee had just determined to bring forward the name of Dr. Carl Schacht as an honorary member of the Conference. That gentleman was the chairman of the German Pharmacopœia Committee, and also a member of the technical commission appointed to assist the German Government in matters connected with pharmacy.

The name of Dr. L. A. Buchner, of the University of Munich, was submitted by Mr. Hanbury. Both gentlemen were unanimously elected honorary members.

Sixty candidates for election as members of the Conference were then submitted to the meeting, and their election was unanimously agreed to.

A paper on "Calabrian Manna" was then read by Mr. Daniel Hanbury, F.R.S. At the request of the author, the publication of this paper is delayed for a short time.

The next paper read was—

On the occurrence of Manganese in Plants, especially in Drugs of the Zingiberaceous Order.

by professor flückiger, bern.

Black oxide of manganese was known to the ancients, but considered to be an ore of iron; that it is a compound of a peculiar metal was one of the splendid discoveries of the most eminent pharmacist who ever lived. The laboratory of the small pharmaceutical establishment at Upsala, where in 1774 the great Scheele first pointed out the existence of manganese, was probably of the most humble character. There he not only traced the prominent characters of that metal, or at least of its oxygenated compounds, but he was already aware that it is in some instances a constituent of the ash of vegetables. He says that some chemists before his time had frequently observed that the ash of what they called *alkaline salts* assumed a bluish or greenish colour. But they were unable to explain the reason, whereas Scheele, in his famous paper on peroxide of manganese, devoted to this fact a chapter entitled "Presence of Brunsten, or Magnesia nigra (as he called the peroxide), in the Ash of Plants." He showed that the green ash yields an aqueous solution of the same colour, which, on addition of any acid, turns red, and after some time deposits a brown powder. Scheele was quite correct in attributing these reactions to the presence of manganese; he observed very little of it in the ash of *Serpyllum*, more of it in the ash of wood.*

Since Scheele's time, manganese has been very frequently met with in plants, most commonly in company with iron. The latter metal is one of the indispensable elements of vegetable life, at least in phanerogams, whereas manganese is wanting in many plants. No plants, however, have ever been proved to perish by want of manganese which they actually do so soon as iron is absolutely excluded. Whether, on the other hand, the iron in plants can or cannot be replaced by manganese has likewise not yet so far as I know been determined.

In numerous instances, the amount of manganese in the ash is exceedingly small; in several plants belonging to various natural orders, however, it has been met with

* C. G. Scheele, *Opuscula chemica et physica*, i. (1778) 227 ad 281.—German translation by Hermbstädt II. (Berlin, 1793) 85–87. Cap's 'Biographical Notice on Scheele,' in *Journal de Pharmacie et de Chimie*, 43 (1863), 337.

in a somewhat larger quantity. Among these latter the order *Zingiberaceæ* claims a prominent place, as the following experiments will show.

All the *Cardamoms* at my command afforded ashes of distinctly green colour even by incineration of the smallest quantity of the drug. This is also most striking in Grains of Paradise where the manganate of potassium is so largely formed, that I deliberated whether an accidental admixture of some compound of manganese had not occurred. I therefore examined the *fruits* of *Amomum Melegueta*, Roscoe, from Sierra Leone, with which I had been presented by my friend D. Hanbury. A single seed taken from this fruit and incinerated in a platinum capsule is sufficient to yield a green residue, the colour of which becomes much more intense if the seed is burnt in a loop of thin platinum wire and then fused in the oxidizing part of the flame with a little sodium carbonate. For this purpose a small spirit lamp is better than a gas light, the flame of which causes a current of air which would blow away the small amount of ash. The burning of the seed on the platinum wire succeeds much better with the flame of spirit of wine; the heat is quite sufficient to fix the ash in the loop of the wire. It is then moistened with a little water in order to attach a particle of dried carbonate of sodium. Sometimes the carbonate fused with the ash is but little coloured at first, but assumes an intense green hue if it is moistened and again kept in fusion for some time in the oxidizing flame. In the interior reducing part of the flame the manganate is destroyed, and the bead becomes almost colourless, and *vice versâ*. The coloration becomes more distinct by addition of nitrate or chlorate of potassium; borax is not preferable to the carbonate.

The thin paper-like pericarp of *Amomum Melegueta* affords not more than 7·7 per cent. of ash; this is, however, much more than the percentage yielded by the seeds, and the ash of the former is evidently richer in manganese. The smallest fragment of the pericarp yielding a scarcely visible quantity of ash will produce an intensely green bead with carbonate of sodium.

Elettaria Cardamomum, Maton, the mother-plant of the Malabar Cardamom, as contained in my herbarium, from Canara, fully confirmed the above statements. Every part of it, the thinnest rootlets, the stalks, the leaves, the pericarp as well as the seeds, furnished a green bead.

The fruits of *Elettaria Cardamomum*, Var. *β. major*, the *Ceylon Cardamom* of trade are likewise rich in manganese, especially their pericarp. All the drugs derived from zingiberaceous plants which I had the opportunity of examining, were proved to contain manganese, viz., the rhizomes of *Cassumunar* (yellow Zedoary), *Curcuma*, *Galanga*, *Zedoaria*, *Zingiber*. The same remark applies to the smallest fragments of the leaves of *Amomum Cardamomum*, L., grown in Java, *Curcuma longa*, L., from Java, *Curcuma leucorrhiza*, Roxb., from Mangalore, *Zingiber officinale*, Roscoe, from Java. Among *Cannaceæ* I have examined the leaves of *Maranta indica*, Tussac, cultivated in Java, which afforded an exquisite green bead. Yet in *Maranta arundinacea*, L., grown in the Botanic Garden of Bern, I failed to ascertain the presence of the metal under notice.

These experiments speak sufficiently in favour of the suggestion, that manganese is widely and constantly distributed throughout the said natural order, although it would be desirable to have further confirmation with regard to other *Zingiberaceæ*, which I had not at hand. This I hope will be performed by some other chemist.

I was desirous to make a quantitative estimation of manganese in Ceylon Cardamoms, which according to their behaviour on platinum wire are likely to be the richest in that metal. As to the incineration of the drug, the usual attention is requisite to avoid loss, which can easily result by the sudden evaporation and inflammation of the volatile oil. A low red-heat is sufficient to burn away the organic matter. The cold ash must then be moistened with water, dried in the steam bath and again gently heated. By repeatedly performing this process without using a strong heat, the ash can be at last obtained free from carbon. A very high temperature would, on the contrary, melt the phosphates and thus protect the organic matter. The ash is finally to be moistened with carbonate of ammonium, which restores the full amount of carbonic acid to the carbonate of calcium. Thus,

I. 4·597 air-dried Ceylon Cardamoms yielded 0·743 ash = 16·16 per cent.; and

II. 11·027 air-dried Ceylon Cardamoms yielded 1·525 = 13·88 per cent., or, on an average, = 15·02 per cent.

The drug when exposed for 30 hours to the heat of boiling water loses 10·73 per cent. of moisture; the above number of 15·02, with reference to dried Cardamoms is consequently to be increased in the reverse proportion. The real percentage of ash then amounts to 16·8 (III.) The two estimations I. and II. are rather discrepant, but could scarcely be expected to agree very closely, inasmuch as the drug exhibits great variation in the comparative amount of pericarp and seeds, and the latter yield less ash.

The ash was subsequently moistened with dilute hydrochloric acid and, as soon as the carbonates were decomposed, warmed with the same yet concentrated acid. After the complete evolution of chlorine I added acetate of sodium, in order to replace the hydrochloric by acetic acid. The warmed liquid was now saturated with chlorine gas, and the peroxide of manganese thus separated was collected twelve hours later and weighed, after due calcination, in the form of mangano-manganic oxide or brown oxide, Mn_3O_4, intermediate between protoxide and peroxide. This was performed according to the usual rules of analysis; I ascertained moreover that the portion of the ash insoluble in hydrochloric acid contained no more manganese, and that, on the other hand, the brown oxide of manganese, which the ash had furnished, did not alter red litmus paper.

Of ash, 0·743 as obtained in the above experiment I., afforded 0·0082 manganoso-manganic oxide = 0·0059 of manganese. 100 parts of the ash consequently contain 0·79 of it; that is to say, the dried Cardamoms contain of that metal 0·16 per cent. In a further experiment I incinerated 25 grammes of the same Cardamoms, which would have corresponded to 22·31 of dried, and, according to number III., would have afforded 3·75 ash. I obtained now 0·0515 of the oxide Mn_3O_4 = 0·0468 of manganese. The ash consequently contained 1·28 per cent.; that is to say, the dried drug 0·209 per cent. of the metal. The portion of the ash, which had not been dissolved by hydrochloric acid, yielded still a slight green coloration on platinum wire; but I ascertained that no more peroxide of manganese was to be obtained from it by means of chlorine.

As in the case of the ash, the two experiments do not quite accord, owing, I am inclined to think, to the same reason.

Numerous instances are recorded in chemical literature of plants or their parts affording nearly as much or more manganese as I observed in these Cardamoms. Reichhardt* detected in the ash of cinchona barks from 0·10 to 4·1 per cent. of Mn_3O_4, corresponding to 0·07 to 2·8 of metal. The latter amount was furnished by flat Calisaya bark yielding not more than 1·22 per cent. of ash. This bark itself contained therefore only 0·03 per cent. of manganese.

Calluna vulgaris, Salisb., according to Thielau,† furnishes 3·3 per cent. of ash, from which he obtained 4·77 of

* 'Chemische Bestandtheile der Chinarinden.' Braunschweig, 1855, p. 77.

† Wittstein's 'Vierteljahresschrift für praktische Pharmacie,' iv. (1855) p. 525.

the intermediate oxide = 3·44 of manganese. The plant itself would therefore afford 0·11 per cent. of the metal.

Eriophorum vaginatum, L., yielded when dried 2·8 per cent. of ash, from which Willing* obtained 3·74 per cent. of oxide of manganese. Supposing it was the intermediate oxide, I calculate 2·7 per. cent of the metal; that is to say, 0·075 per cent. of the plant itself. Ramdohr's analysis of *Secale cornutum*† enables me to calculate that its ash contained 2·14 per cent. of metal or 0·06 per cent. with regard to the drug.

Yet the most striking accumulation of manganese ever observed in plants has been pointed out by Gorup-Besanez in *Trapa natans*, L.‡ If we calculate the analysis performed in his laboratory, we find that that plant, as collected in a tank near Nuremberg, contains no less than 1·61 to 1·68 of manganese; the hard pericarp of the fruit only 0·53 per cent. Wittstein's analysis of the ashes of several plants § may be reckoned to afford the following percentages of manganese as contained in the dried plants or their parts, viz., *Usnea barbata* Hoffm., grown on pines 0·05; leaves of *Betula alba*, L., 0·16, wood of the same tree only 0·018. In Wittstein's laboratory the seeds of the beech (Fagus) were proved to be rich in manganese; || the shells contain 0·13, the kernels 0·28 per cent. of it. This has been corroborated by qualitative estimation by Braun** and De Vry.††

Hops, according to Wheeler's researches,‡‡ furnish an illustration of the variability of the amount of manganese in one and the same drug. Among 12 sorts of hops of English, German, and Bohemian origin, he met with that metal only in the English specimen, which contained 0·09 per cent. of the metal. It is in accordance with these results, that I found the *lupulinic glands* (Lupulin) devoid of manganese.

Padina Pavonia, Lamour, is said §§ to contain the astonishing amount of 8 per cent. of manganese, a statement which certainly requires further investigation; the small specimens of that sea-weed in my herbarium yielded me no very sure traces of manganese, when examined on platinum wire. The same must be said with regard to *Padina*, collected for me at La Mortola, near Mentone, on the Mediterranean. In another fine specimen of the same seaweed, kindly sent by Mr. T. B. Groves from Weymouth, South of England, the presence of manganese was more evident. Yet on incineration of from 5 to 10 grammes of it, the amount of that metal proved to be so insignificant, that I altogether failed in estimating it quantitatively. I cannot, therefore, reckon *Padina Pavonia* among the plants rich in manganese.

The ash of another sea-weed, the officinal *Carrageen*, did not at all colour carbonate of sodium in the oxidizing flame.

Some other analyses of ashes, containing manganese, in which the quantities of this metal were estimated, are to be met with in a recent very exhaustive work—Wolff's 'Aschenanalysen,' etc., Berlin, 1871; 4to.

The above numbers will be found sufficient to illustrate my estimation of manganese in cardamoms. This metal has moreover been shown qualitatively to be present in numerous plants, although all these facts do not as yet enable us to trace clearly the part it plays in the vegetable kingdom.

I examined, nevertheless, some other parts of plants by means only of the qualitative test. As to *Cinchona* barks, I can fully confirm the statement that they contain a small amount of manganese, but I was unable to find it in the seeds of several species, or in the isolated liber-fibres, as for instance of *Cinchona boliviana*. *Secale cornutum* furnished a green bead with carbonate of sodium. *Trapa natans*, collected by myself in Switzerland (where it is a very rare plant) corroborated the above statements of Gorup-Besanez; a small fragment of it, which furnishes a microscopic residue of ash, is sufficient to demonstrate brilliantly on platinum wire the presence of manganese.

Pepper, both black and white, *hemp* fruits, *Lycopodium* (the officinal spores), the leaves of *Lobelia inflata* contain manifestly some manganese. *Lichen islandicus* is less evidently provided with it.* *Kamala* of unusual purity is not to be mentioned with certainty among the drugs containing manganese. I was not able to prove its presence in a specimen affording no more than 1.3 per cent. of ash. Commercial kamala is usually contaminated with a large amount of inorganic matter;† to such contamination may be attributed the circumstance that Leube found 0·14 per cent. of manganese in the ash of kamala which he analysed.‡ One of the small capitules or a fragment of the pedicel of *Wormseed* is sufficient to demonstrate the presence of that metal.

Manganese being so widely diffused throughout the vegetable kingdom, it is of some interest also to point out those plants or drugs in which it is wanting, or at least occurs only in quantities so extremely small that the test which I made use of fails in revealing it. The following are examples of this class furnishing no manganese, viz.: *Allspice* (*Fructus Pimentæ*), *Semen Colchici*, *S. Cydoniæ*, *S. Lini*, *S. Psyllii*, *S. Sesami* (both black and white), *S. Sinapis albæ*, and *S. Sinapis nigræ*, *S. Stramonii*. *Tinnivelly Senna* leaves as well as well as *Guaiacum wood* are also free from manganese. Lupulin has already been stated to be so likewise.

It would be desirable to have a full list of drugs stating where manganese is present or not. This investigation will, I hope, be performed by some zealous student of pharmacy; it would form at the same time a valuable contribution to the history of that metal. I need scarcely say, that great care must continually be taken for most perfectly cleaning the platinum before every experiment. This, however, is easily done by shaking off the fusing bead of sodium carbonate and repeating this process till no trace of green is to be observed—not only on the loop but on the entire piece of wire used.

Mr. EKIN (Bath): Is it not probable that the presence and quantity of manganese is much more determined by the strata on which the plants are grown, than by any peculiarity of the natural orders? Professor Church some two or three years ago examined the vegetation of the lias, which contains a quanity of manganese, and he found that the forest trees, the herbage, and, in fact, all the vegetation contained a very appreciable quantity of manganese also. There was not much variation. It seemed to be regulated more by vigour of growth than by natural orders, and this is rather at variance with the views of the author of the paper. He thinks that certain natural orders have greater affinities for taking up this metal than others.

Mr. Hanbury: The suggestion just made is well worthy of attention. The same idea occurred to me. I fully intended to provide Professor Flückiger with specimens of some of these plants grown in England. I will do so, in order that a comparative examination may be made. It seems exceedingly probable that the soil has something to do with the matter. On the other hand, we must observe this striking fact, that here we have cardamoms from Malabar, and grains of paradise from West Africa, and ginger from the West Indies, and they all seem to have picked up manganese somehow. Whether plants raised from seed and grown in an English hothouse would likewise yield the metal, is a point to be looked at.

Mr. Stoddart: I may call to the recollection of those who met me at Liverpool that I mentioned a circumstance corroborating Mr. Ekin's observations. At the top of a hill near Bristol I found the presence of strontium in all the plants by means of a spectroscope. That is far easier than any other method of detecting it. It is, however, an astonishing fact, that you find strontium in the plant when growing on the celestine beds of the new red marls, but not elsewhere.

Mr. T. B. Groves: I believe the same experiments were made on an extensive scale by Dr. Daubeny, of Oxford, but Dr. Flückiger does not appear to be aware of them. He cultivated a considerable quantity of garden, and watered the plants with various saline solutions, and observed whether the saline matter was taken up or not. The occurrence of manganese in plants does not seem to have much importance at the first blush, but perhaps it has something to do with the health of plants, and it has struck me that the occurrence of hop disease might be owing to a deficiency of manganese where the plant is cultivated.

Mr. Sutton: Dr. Daubeny's paper is a very valuable one. It was published in the Transactions of the Chemical Society. I think that if Mr. Hanbury would take the trouble to send Dr. Flückiger a copy of that journal, he would feel very much interested in it, because it bears a great deal upon the matter in question.

The President: I think the suggestions which have been made will prove very valuable every way. I confess that very much the same line of thought occurred to me whilst the paper was being read. Dr. Flückiger, however, does not commit himself to limiting manganese to a certain natural order. He speaks very guardedly throughout. There are certain water plants which he names in connection with the subject as containing manganese. My impression is that, of course, the manganese is derived from the ground, or it could not appear in the plants. But the question is whether certain plants will grow on ground where there is no manganese.

Note on Succus Scapi Taraxaci.

BY MR. HENRY BARTON, BRIGHTON.

Dissatisfied with the variable character of the usual preparations of dandelion, in 1862 I collected some flower stalks with the flower in full bloom, and expressed from them the juice. Gratified with the appearance, taste and effect, the next year the experiment was resumed, rejecting the flowers and crushing only the stalks. Our notes for 1863 may be thus condensed: — From 75 lb. 12 oz. flowering stalks as gathered, 12 lb. 6 oz. flower heads were picked off and rejected; and allowing about $1\frac{1}{2}$ lb. for drying and waste, from the remaining 62 lb. stalks by crushing and pressure were obtained 31 lb. 8 oz. of juice, to which we added 25 per cent. by measure of spirit, and stored in glass bottles; after some weeks it was filtered from the very small deposit, the resulting liquor remaining bright and retaining its characteristic taste.

From that time to this we have operated in much the same way, with the exception that on one occasion we added the spirit to the crushed pulp, and allowed it to remain 24 hours before submitting it to pressure; in the resulting liquor there was no appreciable difference from the former preparation either in odour, taste or colour. Our note for the present year gives similar results: from 237 lb. of the stalks were obtained 123 lb. 4 oz. of the juice, also from 63 lb. flower heads we pressed 24 lb. 3 oz.; this latter we consider inferior and have kept it separate.

The yield would be greater if the plant came in direct from the collectors' hands; as it is, they gather it one day and forward it by carrier the next.

The stalk juice is not so rich in solid constituents as is that from the root; but if I may be permitted to quote Professor Bentley, who, when speaking of the juice from the latter collected in the summer months, remarked that "its value as a medicine most certainly did not depend solely upon the amount of solid constituents it contained, but principally, if not entirely, upon the presence of a bitter principle, which had been termed taraxacine. One of the best evidences therefore of the value of taraxacum and its fitness for medicinal use would be its taste, etc." If then we may be allowed to admit taste as one of the evidences of value, it will certainly be favourable to stalk juice, and judging from the frequent remarks of our friends in the medical profession and others who have taken it, I have reason to believe that, if not the best, it is certainly one of the best, most uniform and readily obtainable preparations of taraxacum, and one that can be kept for almost an indefinite period without changing.

I will only now remark that if required in quantity, there would be little difficulty in meeting the demand; we once gave *carte blanche* to our collectors, the children of a parish some miles hence, and they sent in in three days 1258 lb. How much they would have sent it is difficult to say, as we were compelled from an accident to our press to countermand the order. At first we were at a loss as to the best means of effectively breaking up the stalk, the pestle and mortar process being ineffectual and tedious, but upon trial found a Kent's mincer, set in the direction for cutting coarse, answer admirably, feeding our press as readily and rapidly as could be desired; indeed so well does it bruise and divide succulent roots, leaves, stems, etc., that I can recommend our friends to give it a trial under similar circumstances.

Mr. Deane: I have been in the habit for many years of preparing the juice of the flowers of taraxacum, and it has proved a very useful preparation, and very uniform in character. I have generally succeeded in obtaining the flowers overnight, and working them the next morning, crushing them through rollers. I think Mr. Squire many years ago first drew attention to a preparation of the kind. I think some particulars about it will be found in one of the early volumes of the Transactions of the Pharmaceutical Society. Whether he continues to make it at the present time I do not know. It is tolerably certain that it is not so bitter as the preparation from the root, but it is more uniform. It is by no means made out, however, whether the active principle of taraxacum depends on the bitterness or not.

Mr. Giles: Taraxacum is an article in the Materia Medica which has interested me very much, and certainly we do find a very considerable want of uniformity in the succus taraxaci, which I think arises from the very large latitude given in the Pharmacopœia for collecting it. It says October to March. That covers too large a period. Mr. Deane, with that accuracy of observation which always characterizes every remark he makes, has referred to the greater uniformity of the flowers. The reason appears to me to be that the time is more limited. My experience is that if you take the root in the month of January, you get a much better product, totally different in appearance. The extract which you obtain is much less in quantity. It is almost black, extremely sapid, and very bitter. My observation is that the time for taking the root, in order to get the best medicinal effect, is the month of January.

Mr. Ekin: Mr. Giles's explanation can hardly be the true one, if we remember that dandelion flowers from early spring to late autumn. You have quite as large a range in the flower as in the root.

Mr. Williams: The flower would not vary as much as the root.

Mr. Barton: We have found that the admixture of the flower takes away from the bitterness.

Mr. Ekin: No doubt there would be a succession of flowers during the flowering season, which would be of the same age in point of development at the time of gathering.

Mr. Smith (Edinburgh): In our experience in the cultivation of taraxacum we found a very decided result, owing to the manuring of the ground. Probably the reason for the great discrepancy that occurs in the quality of the ordinary root depends on where it is obtained from and how it is cultivated and attended to. On one occasion we got a most remarkable result. The bitter principle was intense like aloes, and the root was collected immediately after the flowering. The weather happened to be particularly calm, and the whole field was several inches deep with the most lovely snow-white carpet which could be conceived. Our neighbours were so annoyed by the continual escape of the seed that we gave up the cultivation of it. A deal depends on the manuring of the ground, and I believe that if the plant were cultivated, instead of being plucked wild, its character would be much more under our control.

Mr. Umney: A large supply of taraxacum root for the London market is obtained from Cambridgeshire. It is collected wild about the month of November. To obtain it in the month of January would be almost an impossibility, at any rate, on the large scale, for the ground would then be too hard to be turned up on account of frost. I am of opinion that the latter part of the autumn is by far the best time for the expression of the juice. Having expressed juice in the early spring, and compared its flavour, depth of colour, and density, with the autumnal juice, I have always given the preference to the latter, the spring juice always appearing to me to contain more water and less flavour than that of the autumn. I should like to ask Mr. Barton whether he has compared the relative amount of extractive by evaporating the juice.

Mr. Barton said that the density was decidedly less in the flower stalk.

Mr. Carteighe: I should like to ask Mr. Umney what pharmaceutical principle is involved in the conclusion at which he has arrived,—that the density acts in any way as an indication of the quality of taraxacum juice. It is a new theory to me. I was under the impression that juice made from spring taraxacum was far better than that of the autumnal plant. That is my own experience. I have made it several times at different periods of the winter, spring and autumn. I think with Professor Bentley, that the spring juice is the better. The principle is that the value of taraxacum is due to its bitter principle. If Mr. Umney knows of any other quality which modifies that, I shall be glad to hear of it.

Mr. Umney: As we know of no definite principle that can be isolated, we must rely upon the taste. Colour, flavour, and density I have always looked upon as indicating quality. The specific gravity is less in April than in December, and I also think that the flavour of the juice expressed in November is far superior to that which is expressed in April, notwithstanding what Professor Bentley says on the subject. We have no means of estimating the active principle in taraxacum; I presume, therefore, that taste is the only test upon which we can rely.

Mr. Barton: In consequence of the difficulty of obtaining the root in the spring, I always found it better to use the flower stalks.

Pill Coating.

BY T. HAFFENDEN.

Many expedients have been tried and suggested for coating pills. The first requisite, of course, is a perfectly round, dry, hard pill, that will not run, and then to secure a coating, tasteless, elegant in appearance, insoluble for a moment or two in the mouth, and yet sufficiently soluble to allow the active ingredients of the pill to commence operations as soon as it reaches its post of duty.

Gilding and silvering are very common and useful modes of disguise, the great objection is that if kept any time, they are so liable to tarnish, besides, there is a strong and, I must own, well-founded objection by many to a pill which inwardly or outwardly has any metallic ingredient in its composition.

There is a mode of coating recommended by some, viz., sticking the pill on the point of a needle, dipping in a solution of gelatine or isinglass, and sticking the other end of a needle into a pad, for the pill to drain and dry. I have never tried this process myself; even if successful, which is possible, it involved too much time and finessing for ordinary purposes.

I frequently use myself the solution composed of

Balsam of Tolu	1 part.
Sulphuric Ether	4 parts.
M.	

and am very successful in getting a tasteless varnish or coating, which disguises the taste perfectly, but, I find sometimes the dark natural colour of the pill as seen through the varnish, is objected to; this, to some extent I have obviated by rolling the pills before the varnish is dry in powdered French chalk. I find after a few times, to acquire the necessary manipulative dexterity, I can get a good-looking covering on "the pill." One note here: the tolu used for the solution, and which seems to answer best, is that which has been used in preparing syrup of tolu, so that I use what I formerly threw away, and the methylated ether answers very well for the purpose, reducing the cost of materials to a mere fraction.

Many chemists used to get their pills coated with sugar in the same way as sugar plums, by wholesale confectioners; I believe confectioners now decline to do it; at all events the old and respectable firm with which I do business, though most obliging on all other points, totally decline helping me here.

Another method I have fairly succeeded with, has been to mix powdered tragacanth, precipitated chalk, and powdered French chalk together, damp the surface of the pills, get them nicely-coated with the powders, transfer them to a hair sieve, and agitate them over the steam of boiling water; I find the steam sets the gum tragacanth, and forms a nice coating which fulfils my requisites of pearly appearance, tastelessness, sufficient insolubility, and is besides not brittle, liable to chip off. It requires to be done with great care, otherwise in drying the coating cracks away and is unserviceable. I have turned out a nice sample of pills coated in this way after being previously varnished and made waterproof with the tolu solution. I have tried unsuccessfully to introduce plaster of Paris into the composition of the coating, but, owing to its greediness and great fondness for water, have not been successful.

I am now turning my attention to the use of yolk of egg, to brush the pills over with, and then roll them in

French chalk, or powdered starch and French chalk mixed. I also fancy something may be done with glue made liquid, after the French fashion, with nitric acid, and some combination of powders.

Of course, the powders used could, with cochineal, saffron, etc., be variously coloured if wished, according to the taste of patient or dispenser.

The Writer added that since preparing the paper he had spoken to a medical friend who objected to tragacanth, on the ground that it would be insoluble in the stomach. His own opinion was that, even if that body were insoluble, the coating of the pill would crack in the stomach and allow the pill to act.

The President remarked that coated pills were much more in vogue on the other side of the Atlantic than here. He would ask the two American gentlemen what they had to say on the subject of the paper.

Professor Wayne: Sugar-coated pills in the last few years have become quite an institution of America. In fact, no drug shop is without them. We not only coat them when made from prescriptions, but a whole list is kept constantly at hand ready coated, and we buy them from the wholesale manufacturers. We have found very little objection to these pills, because of the improved process by which we manufacture them, and the low temperature that is used in the sugar-coating. They are perfectly soluble, and answer all the purposes of pills. In extemporaneous sugar-coating our method is to make the pill as dry and hard as possible, coat it with a solution of tolu, and then cover it with a powder containing equal parts of milk-sugar and ordinary sugar, and dry it. It is perfectly protected by the tolu, and has a complete coating of sugar. It has not the pearly appearance which a machine-made pill has, but it answers every purpose; the coating serving to disguise the pill and make it pleasant to take. We have a small apparatus for extemporaneous coating of pills. It has a revolving cylinder and a spirit lamp. The pills are rotated in the machine, and in a very short time a perfect coating is produced. But by far the larger portion of the sugar-coated pills are manufactured by the manufacturing pharmacists, and sold at the dispensaries, and prescribed by our physicians.

Mr. Andrews: As a pill-taker, unfortunately, as well as a pill-maker, I should very much prefer a thin coating either of silver or of gold to *Creta præcipitata*, or French chalk, or plaster of Paris. With respect to the American plan, that appears to me perfectly simple and easy to carry out, and entirely unobjectionable, but the practice of buying pills from wholesale houses, I think, would never suit the English pharmaceutist.

The President: When I was in Philadelphia a year ago I was allowed, by the courtesy of Mr. Wiegand, to see the whole manufacture of sugar-coated pills by the large firm of Burke and Trinshow. I think it was quite by an extension of courtesy that I was allowed to see it. But although I had the very strongest objection to buying pills from wholesale manufacturers on a large scale, I certainly cannot bear too high a testimony to the excessive care in that establishment, and I would as soon take a pill out of their place as one I made myself. The enormous scale on which this thing is done in America surprised me more than anything else in connection with American pharmacy.

Professor Markoe: I only want to say a word with regard to the positive objection in America to the introduction of anything of a mineral or inorganic character in the pill coatings. If any manufacturing pharmacist were once detected in that practice, and it were exposed, it would be pretty sure to kill the sale of his preparations. I may mention that I have seen a sugar-coated sulphate of quinine pill broken after two years, and the interior of the pill-mass has been quite soft. The coating used in that case was inspissated honey.

Mr. Atkins: There could be no more appropriate place for the discussion of pill-coating than Brighton, where it is successfully carried out. There is no great difficulty, I imagine, in coating pills in large quantities. If you have to make a large quantity at a time, processes are pretty well known and practised for the purpose. What we want to ascertain is a good method of extemporizing a coating or rapidly coating pills. I believe that pharmacists will say that the tendency is growing for coating; and if any one present is able to contribute to us any method by which we can rapidly and successfully coat a box of pills, he will confer a very great boon. That I think is a yet undiscovered boon.

Mr. Bottle (Dover) asked why their Transatlantic friends used milk as well as cane sugar.

Professor Wayne said that he had found by experience that the mixture of two gave a much more uniform coating than simply cane sugar.

The Tinctures and Wines of the British Pharmacopœia.

BY W. W. STODDART AND R. L. TUCKER.

The solutions which we call by the doubtful appellation of "tinctures" form no insignificant item in the stock of a pharmaceutist. They have repeatedly been the subject of comment, and an apology is probably necessary for bringing them forward in the present paper. Why are they introduced into our Materia Medica? Is it because they are used by the physician as mere flavouring or preservative ingredients in their prescriptions? Or is it because they are really valuable and true solutions of the active principles of plants, and having specific powers as medicinal agents? We think the latter to be the case, and have tried to find out the most exhaustive method of preparation, and for the elimination of a product similar in all respects to that of the recognized Pharmacopœia.

The following notes are the results of an extensive series of analyses and experiments made for the attainment of this object.

Some prefer the old process of maceration, others the more recent one of percolation, while the compilers of the present Pharmacopœia generally recommend a quasi combination of both.

At our first meeting at Bath, a very interesting paper was read by Mr. Savage on some of the tinctures of the last edition of the Pharmacopœia, and a table of results appended. His plan of examination seemed good in many respects, and we have taken it as our guide in compiling a complete epitome of the tinctures and wines, each of which has, with few exceptions, been prepared in three ways for the purpose of comparison, viz.:—

1. By the maceration (marked in the table M).
2. By the Pharmacopœia formula (marked P).
3. By the same, as modified by the authors (marked S).

They have all been made with the greatest and most scrupulous care, and the sp. grav. of the spirit or wine ascertained and adjusted before being used.

There are 65 tinctures and 10 wines ordered in the Pharmacopœia; of these, 10 are simple solutions, 24 are prepared by maceration, and 40 by a combination of maceration, and so-called percolation. Our table gives the results of an examination of all, except 26, which have no relation to the methods in question, and is arranged in columns in the following manner:—

1. The method of preparation employed.
2. The weight per ounce of ingredients ordered.
3. The sp. grav. of solvent.
4. Ths sp. grav. of the resulting tincture.
5. The total contents, per ounce, of the tincture.
6. The percentage of ingredients dissolved.

Preparation by maceration.—This is the oldest process, and consists in bruising or coarsely powdering certain roots, barks, seeds, etc., and placing them in spirit or other menstruum for a specified time. After the time for maceration has elapsed, the fluid is strained off, and the remainder submitted to the action of a powerful press. Filtration completes the process.

Many persons still strongly advocate maceration, because it gives tolerably uniform results which they cannot so easily obtain by other means. The objections are the length of time required, the great waste from evaporation, and from the marc left in the press being still rich in active principles. It is in our opinion the last method that ought to be adopted by the careful and economically inclined pharmacist for the perfect extraction of the soluble matters of any herb or plant. There have been many suggestions for improving the process and saving the time, such, for instance, as that recommended by Dr. Burton, where the ingredients were suspended in the upper part of the solvent. The spirit, as it becomes saturated, and therefore of greater density, falls to the bottom of the vessel, its place being taken by more spirit, to be in its turn saturated and deposited. By this means exhaustion is attained with considerable rapidity, and saving more than half the time.

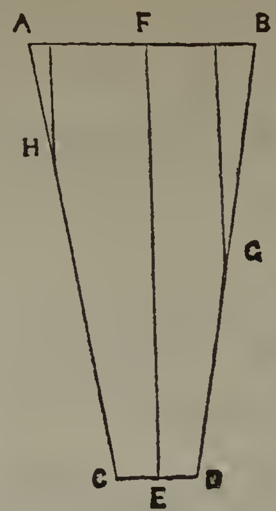
Preparation by percolation.—This method is comparatively a recent one, and was introduced some years ago, and strongly recommended by our friend Mr. Deane. When properly conducted, there is no doubt that percolation is of all methods the most perfect, and accompanied by the least waste. The resulting tincture is ready for use, quite bright, and independent of the press and filtering paper.

Probably why percolation is not more generally in use is on account of the difficulty attendant on "packing." A satisfactory percolation can only be performed by an absolutely perfect and uniform arrangement of the ingredients, and which is often an impossibility. It is imperative that the spirit should pass through equally and horizontally, or else one portion would permeate much faster than another. Each layer of the solvent as it passes downwards should be *displaced* by a fresh one, but a *mixture* of the two should not be allowed, which would entirely alter the *modus operandi* of the whole process.

Tincture making is generally placed in the hands of the apprentice or junior assistant, and of course a want of experience only makes matters still worse. The consequence is, that the proprietor of the establishment is startled at the thin bodied laudanum, the washy tincture of gentian, or the tasteless Vin. Ipecac.

It is surprising how constantly the meaning of the word percolation is misunderstood. It is so in the Pharmacopœia itself; for instance, in the directions for making Tinct. Chiratæ, Capsici, Colchici, Conii, Gentianæ, etc., what is there by inference termed percolation is not percolation but simply washing, and a large waste of spirit unnecessarily entailed. To obviate this waste is the object of our experiments, and of the process which we now recommend, the adoption of which an experience of twenty years will fully justify. There are two essentials for success in the operation, namely, the *proper form of percolator;* and secondly (strange as it may seem), *no direct packing.*

The form of percolator.—These are sold of every possible variety, according to the fancy of the manufacturer, but all are referable to two kinds, cylindrical and conical. Repeated trials have proved that the perfect cylinder is the only one on which dependence can be placed. A little reflection will at once point out the error of recommending the conical form. The well-known laws of hydrodynamics show that the pressure of a column of fluid on the bottom of a containing vessel is invariably equal to the weight pressing on the area of the base. It will, therefore, be evident that a percolator, having the form of an inverted cone, must have an unequal pressure from the contained fluid, and, as a consequence, the materials being exposed to an unequal pressure, must be unequally exhausted. The fluid will pass most rapidly through those parts where the force from behind is the greatest.



The diagram represents the form of percolator, ABCD, prepared by Mr. Deane (PHARM. JOURN. 5.533) having the sides inclined to the base line at an angle of 82°. If the vertical height be 24 inches, a column of water at EF would exert a pressure on the base CD, equal to 12·384 ounces for every square inch. But at the point G the pressure would be only 6·192 ounces, and at H only 3·096 ounces, or one-fourth of the whole.

Lateral pressure also causes a diagonal current in the direction of the central column, and exercises a considerable mixing force, which is of the greatest consequence when water is employed to displace spirit. Instead of true displacement, a combination of the two fluids will take place, and very much heighten the sp. grav. of the tincture.

Professor Redwood alluded to this fact when he said, "The conical form is most used, because the liquid aggregates towards the middle of the column, so that near the bottom more liquid runs than at the side * * * *spirit not to be driven out with water because it mixes.*"

Our experiments, as detailed in the accompanying table prove, we think, that the Professor's warning may be rendered unnecessary. We also differ from the opinion of Dr. Burton (PHARM. JOURN. 5, 1845,) when he affirmed that percolation is more expensive, more difficult, and less generally applicable than maceration. Our investigations and general practice prove just the contrary, and show that, with the exception of Tinct. Limonis (when fresh peel is ordered), percolation is by far the best and most economical method of preparing the tinctures and wines.

The most satisfactory work was done when the percolator had a diameter about one-fourth the length, and when the ingredients occupied one-fourth the interior.

Spontaneous packing.—As we before mentioned, any one who has worked much in the tincture department must be aware of the almost total impossibility of so regularly placing the ingredients with the requisite uniformity. The method which we venture to recommend is to allow the ingredients *to pack themselves,* and we think that so great a simplicity and completeness are attained that the veriest tyro may be entrusted with the operation without the risk of failure. Our mode of procedure is to powder the ingredients and pass them through a sieve having from 20 to 30 apertures to the inch, and put into the *whole of the spirit* and macerate for 48 hours, with occasional agitation. At the expiration of the time, the supernatant spirit is poured off, the dregs stirred up and poured into the cylindrical percolator, and allowed to drop until the liquid passes away clear and bright. It is then placed in the receiver, and all the spirit gradually poured on and allowed to percolate in the usual way. When all has passed through, an equivalent proportion of water is carefully poured on the residue to displace the spirit absorbed. If properly conducted, the water will not mix with the spirit, but by its gravitating force, will drive it forward. The process thus proceeds with great uniformity, and the materials are perfectly exhausted. No waste is incurred, and the tincture is made with a rapidity equal to the method of Dr. Burton, identical with that of the Pharmacopœia, and without the necessity of using the extra quantity of spirit or the aid of pressure. We give two examples to explain more clearly our made of proceedure, one where there is an excess of the material to the spirit, and another where the quantity of spirit is greatly in excess of the materials. To exemplify the first we would instance Tinct. Zingib. fort.

Four pounds of ginger are stirred up with one gallon of rectified spirit and left for 48 hours. The supernatant spirit is put aside, and the deposit poured into the percolator. As soon as the tincture passes through bright, which it does in the course of three or four minutes, the percolator is placed in the stand, and allowed to stay till all the spirit has been poured on. In this case 88 ounces will have passed through, while 72 will have been absorbed by the ginger. A considerable quantity of water is then gently poured on the top of the ginger, and allowed to displace the spirit till the gallon of tincture is obtained. If only a few drops more are allowed to go through, the resin will be deposited, showing that the water has made its appearance.

For the second instance let us take Tinct. Colchici sem. Two and a half pounds of the powdered seeds are mixed with two gallons of proof spirit and allowed to macerate for 48 hours. The supernatant liquid is then poured off, and the dregs placed in the percolator as before described, and the spirit displaced by water. With this quantity 32 ounces will have been absorbed by the seeds.

It will thus be seen that we dispense with the use of the press or the extra quantity of spirit by allowing the ingredients to settle spontaneously, or, in other words, to *pack themselves.*

To show you that such is the case, Mr. Tucker and I have made nearly all the tinctures and wines of the Pharmacopœia, and drawn up the following table of results. The only ones omitted are the following 26, because they have no relation to the point at issue.

Tinct. Aloes	Tinct. Kino
,, Assafœtida	,, Limonis
,, Benz. Co.	,, Myrrhæ
,, Camph. Co.	,, Opii Am.
,, Cannab. Ind.	,, Quiniæ
,, Cantharid.	,, Tolut.
,, Castorei	Vin. Aloes
,, Chlorof. Co.	,, Antim.
,, Cocci	,, Aurant.
,, Ferri Acet.	,, Ferri
,, Ferri perchlor.	,, Ferri Citrat.
,, Guaiaci Am.	,, Opii
,, Iodi	,, Quiniæ.

All the experiments were conducted in the following manner:—The sp. grav. were taken by the ordinary bottle, or by Regnault's modification, or by Mohr's hydrostatic balance. The evaporation was first conducted in a Griffin's hot-air bath at a temperature which never exceeded 212° F. till a soft extract was obtained. The capsule was then removed and placed on an air-pump over sulphuric acid, and dried *in vacuo* till no further loss was sustained, and instantly weighed by an Ortling balance. This method was thought preferable to that employed by Mr. Savage on a sand bath, or that recommended by Dr. Burton, which was at the temperature of 230° in an American oven. For, in many instances, it was found that partial decomposition was produced before complete desiccation.

To measure the tincture for evaporation a cylindrical narrow measure was first used, but the measurement was not found to be sufficiently accurate for comparison where the difference was small. A narrow glass tube graduated into $\frac{1}{50}$ cubic inch was substituted, and found to give a satisfactory and uniform result.

Before commencing, the sp. grav. of the proof and rectified spirits were carefully adjusted to 920° and 838°. The ingredients were weighed and sifted. The proper quantity for half a pint of each tincture was taken and placed in a stoppered bottle with the proof, rectified or ammoniated spirit, as the case may be. One lot was allowed to macerate for seven days and the other for 48 hours, preparatory to percolation. When the tinctures were finished the sp. grav. were taken, and a fluid ounce evaporated.

No.	Name.	Method.	Grs. per oz. of ingred. used.	Sp. grav. of solvent.	Sp. grav. of Tinct.	Total contents per oz. in grains.	Per cent. of ingred. dissolved.

Mr. Haselden: I have listened with attention and great satisfaction to this paper. I admire very much Mr. Stoddart's patience and ingenuity in carrying out this matter. At the same time it is gratifying to me to hear what he has said, because I have myself come to the same conclusion that the cylindrical is the best form for percolators. You will perhaps remember that in 1864, soon after the appearance of the first British Pharmacopœia, I exhibited at Bloomsbury Square an apparatus which I had had made in order to carry out the Pharmacopœia process of maceration and percolation; and this percolator and macerator was cylindrical. The only objection made to it at the time was that it was rather large (holding four gallons) and that it was expensive. The percolator has rests inside it for fixing a diaphragm about one sixth of its length from the bottom. When the ingredients are large in quantity I use the diaphragm and allow the liquor to pass through, having liquid above and below the ingredients. When I do not think proper to use the diaphragm there, the quantity being small, I have a perforated plate, which covers over the opening of the percolator, which opening is connected with a tap, so that I can turn off or on at will. In using this vessel there is no necessity for another vessel in which to macerate the ingredients with the spirit first of all, and certainly there is no waste in transferring from one vessel to another. I put the ingredients in as Mr. Stoddart directs, and pour upon them the quantity of spirit. I allow them to macerate until all the material is well acted on by the spirit. I then well stir it up, and allow it to settle and pack itself down just as Mr. Stoddart has described. After a certain number of hours (say 24) I turn on the tap very gently and allow the percolation to commence. In that way I always get satisfactory preparations. Towards the end of the process (perhaps this may be superfluous) before I displace the spirit that remains, I take the precaution to press the ingredients to pack them down more. My cylinder is large enough to admit a couple of 28 lb. weights. I cover the ingredients with a metal plate, place one weight on the top of it. After a certain time I increase the pressure by putting another weight; and when I find that I can get no more droppings by means of these weights I remove them, and place over the top a thin piece of blotting-paper which prevents certainly any immediate mixture of water and spirit; and upon that I pour the water. I have seldom failed, I believe, to get a satisfactory preparation. There is another precaution which I take, when pressure and not displacement finishes the process, and which I mentioned on a former occasion. It was published in the Pharmaceutical Journal; but things are forgotten, and, though I am sorry to intrude myself upon you, I find that it is only by doing so again and again that it is remembered that the same thing has been told previously. The other precaution which I take in order to get all I possibly can out of the ingredients, and with as little waste as possible, is this: the Pharmacopœia permits and directs you to add sufficient of the menstruum after pressing to make up the quantity originally ordered. Instead of doing that, after the work is finished I pass the proper quantity through before pressing. I can tell pretty well from notes and experience how much will be lost in preparing one or two gallons, or even a quart. Thus, if there is anything left in the marc I have an extra chance of getting it out if I add at once the supposed loss. I think that is a little improvement. There are several tinctures in the Pharmacopœia which require particular manipulation. I am not going into all the particulars to-day. I may mention tincture of senna, for instance, with raisins in it; and compound tincture of cardamoms. Tincture of orange-peel also. This requires a little management to get not only a satisfactory preparation, but one which is not wasteful; because in the ordinary way the orange-peel absorbs a great quantity of the menstruum, and there is a difficulty in getting it out. However, I have a paper in hand upon tincture of orange-peel, and embracing the question whether it is prepared better from fresh peel or dried.

Mr. Savage: The percolator mentioned by Mr. Haselden has its objections. It is a metal percolator, and metal has an effect upon the tinctures, sometimes turning them much darker. I suggested some time ago a percolator whereby you might attain all the objects that you desired, and most effectually in any small quantity. It was one of Loysell's percolators by which ordinary coffee is made. It is a decided improvement compared with anything we have. A tube runs down the centre, and about two inches from the bottom is a double diaphragm. Betwixt the diaphragms you put your ingredients. A funnel is screwed on the top. The menstruum passes through the ingredients, and then repasses again, so that the substance is always surrounded with the menstruum. Thus you get a capital result with very little trouble. With respect to the observations of Mr. Stoddart, there is one thing which cannot be too strongly impressed on my brother pharmacists; that is, with reference to the measures. You will find that in dispensing and ordinary selling in small quantities, by having the two

* These determinations include the total contents per ounce of the wine.

dram measures cylindrical, you will save a great deal in the course of the year.

Mr. Giles: Mr. Stoddart has referred to the preparation of the tincture of ginger. I have been troubled with the puffing which takes place in the marc when you place on the water. I have always been obliged to put on a certain amount of water which displaces the spirit, and then it forms a muck, and this I have to take off with a spoon, then putting on more spirit.

Professor Markoe: The remarks made by the last speaker express the American idea. That is the practice we have been following a long time. Percolation alone is practised in the United States. We consider that maceration is a thing of the past, and that percolation is the process for every drug. Of course with tincture of tolu and resin guaiacum, and so forth, maceration is used, but for everything else percolation. We insist in every case on having a perfectly uniform powder, be it coarse or fine. We take the position that the mixture of a fine powder with ligneous particles is entirely wrong. We consider that to turn back a portion of the tincture into the percolator is exceedingly bad practice, and we make it a practice that the first drops shall be as clear as the last. We always carry the percolation to exhaustion. We employ fine powders sifted through a sieve of 20 meshes to the inch, and never use the English method of saturating the drug with the menstruum. Suppose we are working with a pound of the drug, we moisten that in the hand with about one-fourth of the menstruum. This will give a damp powder that will slightly cohere, but will never become pasty. A pasty mass will never properly pack; cylindrical percolators we think the best, but there are many cases in which the conical percolation is used because of certain advantages. For instance, in making fluid extract of gentian which is liable to swell, it would be totally impossible to percolate through a cylinder. If we use a conical percolator, as the substance swells, the slanting sides of the funnel allow it to relieve itself, and it is not a difficult matter to percolate gentian with a powder as fine as 50 or 60 meshes to the inch. Percolation has been carried in the United States to a degree of refinement that is scarcely known in Great Britain, for the reason that the most popular class of preparations are those known as the fluid extracts; these liquids being made of such a strength that each minim shall represent the soluble active principle of one grain of the drug, and one wine ounce shall represent one troy ounce of the drug. As many drugs are injured by heat, our aim is to avoid subsequent evaporation. We consider it poor work on the part of a pharmacist if, taking 16 ounces, we are not able to practically exhaust it by the time we have got three wine pints of the menstruum. We use the finest powders we can get. The tendency has been to use a menstruum as strongly alcoholic as possible, and to push through whatever remains of the drug. Merely to make up the measure with water, displacing all the contained menstruum is very easily done. When the percolation is done, you just scrape off the pulpy mass. The moment the water is added, it swells up into a mucilaginous mass, and after a little time the percolation stops. It is the practice of several large manufacturers who work on a large scale to go on percolating and exhausting with alcohol, trusting to the use of pressing to press out as much of the menstruum as possible, and keeping it to be used next time the preparation is made. Then, in order to recover what alcohol remains after pressure, the mass is thrown into a large steam-still, mixed with plenty of water, and the alcohol recovered that way.

Professor Wayne: I have very large percolations to make, and it is very necessary to obtain all the alcohol that has been used in percolation. By the use of water you obtain very readily a mucilaginous mass which it is very difficult to percolate, and which gives you an immense amount of trouble. My method is to use an alcoholic menstruum until my substance is completely exhausted. I afterwards distil the magma, using the alcohol in the next percolation of the same substance. I find by that means great economy of time. It requires a very long time if water is used; and long before the point has arrived the root becomes mucilaginous, and water will no longer pass through it; or in warm weather fermentation will set up and acetic acid be formed.

Mr. Umney: Mr. Stoddart remarked in his paper that the contact of the water when put upon the marc to displace the alcohol was merely skin deep. This is contrary to my experience. Let it be required for instance to recover alcohol of 56 over proof (·838) from a marc by displacement with water. It will be found upon examining the products after rectification that the strength will range from 56 to 40 or 20 over proof, to considerably under proof (·920), therefore, I imagine, to say that the mixing is *only skin deep* is incorrect.

Mr. Stoddart: In replying to what has been said, I can only say that facts are stubborn things, and the tinctures have been made twice over this way, therefore it can be done. With regard to Mr. Haselden's tincture of senna, tincture of cardamoms, and tincture of orange-peel, they are all three substances which do not easily powder. The raisins were, of course, the difficulty, but they were smashed up in a mortar; and you will find there is sufficent of the dry ingredients to suck up the menstruum, and you can actually sift them through a coarse sieve about twenty meshes to the inch. If you repeat these experiments, do not use any diaphragm whatever. I would wish that if anybody in the kingdom intends to repeat my experiments he should use nothing but a tube, and tie over a bit of muslin at the bottom. As to what Mr. Giles has said about the ginger, all I can say is that I get the ginger into a measure, put on the spirit, and stir it up with a spatula, and then put it on the muslin and wait till the ginger has settled, I then have a clear liquid.

Mr. Giles: Don't you find that water put on the powder forms a mucilaginous magma?

Mr. Stoddart: I am coming to that. You first of all stir up the ginger with the spatula and then pour it into the percolator. Let the spirit run through, and leave the top dry. Then you put on exactly the quantity of water that is deficient, and leave it and go to sleep if you like. It does not disturb the top at all; but there will be a dark brown ring, which is the skin-deep mixture which I mentioned. Tincture of myrrh is one of the 26, which are simple solutions. We made it by percolation. As to Professor Markoe, he must forgive me if I disagree with him altogether. He says, first of all moisten the powder, and if there is a swelling of the magma, use a conical percolator. Now, if you let it loose into a conical percolator, you undo my experiment. It has been said that it is impossible to make tincture of gentian in the way I have described. Well, I have done it. I will give you a very easy experiment which any one may try. Get some ground coffee and stir it up with water till it comes into a "muck," as Mr. Giles calls it. It must be just so liquid that the muck, when put down into the percolator, will run of its own accord. Then if you put a pint of water you will have your extract of coffee in magnificent style, and if you are economical, put another pint of water on the top, and you will get a liquid of about a third of the strength of the first.

The Bell and Hills' Fund.

The President then said that the question of the appropriation of Mr. Hills' last gift to the Conference had occupied the attention of the Executive Committee at a meeting held that morning, and they had instructed him to place before the Conference their view. The Executive Committee recommend to the annual meeting that the following be laid down as the general financial plan for the appropriation of the generous donation of Mr. Thomas Hyde Hills, viz., "That it be added to the existing 'Bell and Hills' Fund,' and that the discretionary power of granting a sum of £10 for books to any local association in towns where the Conference has met be continued. Further, that the principal sum of £200 be retained until the Executive Committee decide that one bond of £50 be sold out, and that such scale of the stock be not repeated until an interval of three years from the last sale. The Executive Committee for the current year to decide upon the appropriation of such income from principal and interest, by granting sums in aid of original research, or for the cultivation of pharmaceutical science."

Mr. T. H. Hills: Mr. President, with your permission I beg to say that it will afford me much pleasure to be allowed to move the resolution recommended by the Executive Committee. I gave the money without conditions more than it should be used for pharmaceutical education; to give money with conditions takes away more than half the value of the gift, and I feel that which the Committee now recommend is for the purpose I intended. I, therefore, have great pleasure in moving the resolution.

Mr. Deane: Gentlemen, I think there is little necessity for me to add many words on this occasion. We all of us know and feel the great generosity and warm-heartedness of Mr. Hills, and his zeal in the cause of pharmacy and the well-being of this association. Whatever I might say would be only a repetition of that which is in your own minds; and as we have a great deal of business on hand, I would simply beg to second the resolution so nobly put forward by our friend Mr. Hills.

The following resolution was then put to the meeting and carried:—

"That the recommendation of the Executive Committee relative to Mr. Hills' donation of £200, having been submitted to that gentleman and approved by him, be adopted by this meeting,"

The meeting then adjourned until two o'clock.

Parliamentary and Law Proceedings.

Poisoning by Laudanum.

An inquest was held at Sunderland on Monday, September 2, to inquire into the death of a Dutch gentleman, named Heemskirk, who had died after having been found insensible in bed, with a bottle that had contained laudanum by his side. Evidence was given that the deceased had suffered severely from "tic," and had been in the habit of rubbing his face with laudanum to ease the pain.

William Henry Barker, assistant to Mr W. B. Harrison, chemist, of 6, Bridge Street, said that on Thursday afternoon, between two and three o'clock, Mr. Heemskirk came into the shop and asked for some pure laudanum to apply to the face as a liniment for "tic." On witness inquiring how much he would require, deceased asked him to show him some bottles. He showed him a one fluid ounce bottle, but deceased said as he wanted to use it often, he would require a larger bottle. He then showed him the two ounce bottle produced, and he said it would do. Witness went to get a blue glass bottle, in which they generally put poison, when he said he would prefer the plain bottle, and witness labelled it poison and put on the name of the seller. He said he wanted to take the bottle home, so that it might not get into the hands of the servants. Witness told him repeatedly it was poison, and he said he knew that—he had been in the habit of taking it—(witness intimated that he understood him to mean that he had had it before for the purpose of using externally). He asked him (witness) what dose to take to induce sleep, and witness told him he would not recommend that it be taken internally at all. He recommended something simpler, and told him it was not safe for any person to take laudanum unless they were in the habit of doing so. He, however, told deceased that twenty drops was the medium dose, and on no account to take more; and he said he had had it through his hands before. He told him that a larger dose ought not to be taken without the advice of a medical gentleman. The two ounce bottle produced was full. He had known the deceased for several years, and for the last two years as a customer. He had not bought laudanum before to witness's knowledge; the other assistant was away. He bought things for "tic," and nervine, which witness believed contained laudanum, although he did not say he was suffering from "tic." On Thursday, there was nothing exceptional in his manner. Witness looked upon him as an intelligent, steady, and respectable gentleman, and would have felt confidence in giving him a larger quantity; although he would not sell it to one person in a hundred who asked for it incidentally, nor to any person whom they did not know.

A Juryman: I think your confidence will be shaken for the future?

Witness: Well, yes.

A Juryman thought that there needed some alteration of the law.

The Coroner remarked that persons would then endeavour to purchase it in smaller quantities at different shops.

Mr. Dixon detailed the efforts made to restore Mr. Heemskirk to consciousness, and said that death had been caused by an overdose of laudanum, which he thought deceased had swallowed during temporary unconsciousness caused by excruciating pain.

The jury returned a verdict to the effect that deceased died from an overdose of laudanum, obtained on the statement that it was to be used as a liniment for "tic," and that the laudanum was administered by his own hand, but that there was no evidence to show the state of his mind at the time of administration.—*Sunderland Times.*

Suicide by a Vermin Killer.

At Sheffield, an inquest has been held by the Deputy Coroner, Mr. Wightman, respecting the death of Mary Walker. Evidence was given tending to show that the deceased had committed suicide by taking some vermin killer, from motives of jealousy.

Mary Ellen Bishop, 13 years of age, deposed that she bought the vermin killer for the deceased, who said it was to kill mice. When she gave it to her she was sitting in a chair, crying.

George Corry, assistant to Dr. Robinson, had attended deceased on the day named. She died in about five minutes after he was first called in. From the symptoms he judged that she had been poisoned with strychnine.

Mr. Spurr, chemist and druggist, said that his assistant had sold the powder to the girl Bishop. Vermin killers are not placed under the restrictions of Part 1 of Schedule A of the Poisons Act.

The Coroner thought that they ought to be, for it was a mere farce to pass an Act of Parliament to prevent the sale of strychnine and then allow it to be bought in the form of a vermin powder. He thought it would be better if it were mixed with a strong emetic. It was a well-known fact that rats and mice could not be made sick, and if a human being took any with a felonious intent, sickness would supervene, and the evil would be obviated. In summing up the Coroner said that if the jury thought fit to append anything to their verdict with reference to the sale of poisons he would forward it to the proper authorities.

Mr. Spurr said if it were thought well to take into consideration the question of adding vermin killers to the list of poisons to be registered when sold, another side of the question would have to be looked at. It would be rather a serious tax upon the time of druggists when there was a pressure of business, to have to leave off three or four times, perhaps, on a busy morning or evening, to register the sale of a 2*d*. or 3*d*. packet, each registration, with inquiries, explanations, and entry, taking up some ten to fifteen minutes. Still, if it were thought wise and prudent to add these articles to part 1 of schedule A., the trade, he thought, would not object; but it appeared to him reasonable and just that a small registration fee should be paid for every entry, as a compensation for the trouble.

The Coroner said no amount of trouble should be allowed to stand in the way when a human life was at stake.

Mr. Spurr further said that it was not Battle's Vermin Killer with which deceased had been poisoned, but a preparation by another firm.

The Coroner was sorry to hear that any one else was in the business, as he was firmly of opinion that Battle's preparation had been the means of causing the death of more persons than any other poison. He thought that if greater precautions were used in the sale of the article, the deaths from poisoning would be less frequent.

After some further conversation the jury returned a verdict that deceased had committed suicide whilst labouring under a fit of temporary insanity.

Obituary.

JOHN CARGILL BROUGH.

At Esher, on Sept. 7, 1872, this man of the large heart and intense human sympathy passed away, aged 38.

If it be true that

"He prayeth well that loveth well"

John Cargill fulfilled to the letter the divine command, "pray without ceasing."

The end was not unexpected: for years he was a reed shaken by the wind, a lamp flickering in its socket—one Saturday morning at the break of day, the reed was broken, and the light expired. *Then* he entered into—life.

It is very difficult to say anything about him or about any brave and gentle spirit when he is gone—*Good things* appear so meagre in cold print; whimsical fancies; the infinite pleasantry of a passing hour, alike with the unstudied pathos of the moment, bear no repeating.

Mr. Brough, (if his friends will pardon the use of any term but Jack) was not known as a writer to the readers of this Journal; before his strength began to fail he was the Editor of the Chemist and Druggist—He was essentially a London literary man—circumstances led him into the domain of Pharmacy—but from his boyhood his fingers were smeared with printer's ink and the press claimed him for its servant. Why he was not legally qualified as a Pharmacist is explained in one of his most mournful and most exquisite notes. His was a hand to hand fight with Time the result of constant physical weakness—the res angustæ domi pressed heavily upon him and we are acting on the dearest wish of his heart in quoting "There are two friends, whom to know, is in itself an honour, who have spent themselves in turning my sick couch into a bed of roses."

Mr. Brough was born at Pontypool in Monmouthshire; his father was a brewer and suffered severely in the chartist riots the events of which will be found narrated in a work called "Hidden Fire." We need hardly state that he was a younger brother of the Brothers Brough, well known to literature and to the stage. He was first we believe employed on the Illustrated London News, and subsequently was connected with the Morning Star. He passed through strange apprenticeship, Type being usually the master, and thus he was thrown in contact with all sorts of people and intimately knew so many who have made their mark and become distinguished. This period must be passed over though it supplied him with an inexhaustible fund of anecdote—he never lost his interest in the geography of Fleet Street and the Strand or as he himself expressed it "I hope I may never be so respectable as not to be able to show a fellow creature the way to Covent Garden."

The first undertaking that brought him into notice was the Editorship of the Journal already mentioned, the prosperity of which he strove his utmost to secure. He was also the Editor of the Ironmonger writing the technical details of machinery; Sub-editor of Nature which he soon had to relinquish—Editor of a scientific periodical called the Laboratory one of the ablest that has ever been issued and patronized by our most celebrated contributors, English and Foreign—yet commercially it was a failure and lasted only six months. He was elected as the first Editor of the Year Book of Pharmacy—great hopes were entertained that his remarkable knowledge of his subject and skill in abstract and arrangement would have produced an authoritative compendium—these hopes were never destined to be realized—as always sickness gave its inexorable veto and forbade the attempt.

There is a little book of his which may strongly be recommended to the young—it is called Fairy Tales of Science—the style is throughout delightful, while the chapter devoted to an Atom is particularly good—he prepared for the press the last edition but one of Cooley's Encyclopædia of Practical Receipts: he undertook various literary work, reported lectures, wrote articles and spoke the truth when he signed himself a *Journalist.*

There had been a long and bad quarrel in Pharmacy some time since, the particulars of which need not be recalled. The Society, supposed to favour science and education—on the one hand, and outsiders supposed to exalt trade interests on the other—there were two Journals—the official and the opposition. One thing is certain that both parties knew very little of each other. Mr. Brough with a tact beyond praise endeavoured to effect a reconciliation or rather a mutual understanding, which amounted to the same thing—"I am convinced" (he writes) "that the proposed extension of the Pharmacy Act meets all the requirements of the trade and I have been working day and night to bring about a settlement of the question." [Feb. 16, 1867]. Again—"You may be quite sure that I shall not sneer at the Pharmaceutical Society for I am convinced that the reform of British Pharmacy can only be worked out by that body." Never surely was there a better peacemaker—his amiability assumed the shape of genius, and he is fairly entitled to be chronicled amongst us if only for his devoted and successful endeavours when his aid was most urgently required.

Let him not pass however without a word respecting his marvellous social influence. No other adjective will do. It was a gain for one's entire after-life to have enjoyed his companionship—he was so utterly unselfish—"so purposeless in his friendships" he loved his neighbour better than himself—How many of us can recollect the broader atmosphere we breathed when in his society—how we learnt with him to make large allowance; how instinctively we began to covet the excellent gift of charity—nor is it too much to say that his childlike and guileless character, bright with habitual cheerfulness, rippling over with quaint humour, softened and spiritualized by the peace of God, has left behind it an effect for which hundreds of us rejoice.

Less we cannot, more we dare not say. We may turn for an instant to the lighter shades of character—hoping that some who may read this, need not be told that Mr. Brough not only was wonderfully well versed in the lore of books but that he had a special gift in letter writing—his pen talked—that is the explanation of the secret: there was simply a mechanical difference between his notes and his conversation. Both were the revival of Charles Lamb, with too often a pathetic tinge of Hood. He was best in amusement when he had no definite subject, and positively nothing to say. The ability displayed in his serious communications was rare, and in the power of hinting compliment, he has scarcely been surpassed. One of his cleverest public efforts was the introduction at the meeting of the British Association in 1869 to a jeu d'esprit called "Exeter Change"—the appearance of which stimulated not a little the curiosity as well as the admiration of the leading scientific men to some of whom it proved his first introduction. That brochure contained besides the "Ode after Tennyson" which was unique—nothing was in sprightlier taste than his verse and pencil sketches which tempted the Fellows of the Chemical from their severer studies—nor must it be forgotten that the one title of honour of which Mr. Brough was justly proud was that of F.C.S.

Quitting the editorial chair and general literature in 1870, he became Librarian of the London Institution, a post for which by nature, training and all his antecedents he was specially qualified. Some may not be aware of the continuance of that noble library, nor pleasurably acquainted with the courtesy of its officers; nor yet know by experience the large resources it has to offer in the way of reference. Here Jack, (he was never recognized by any other name) was in full glory. Surrounded by books which found themselves in an unusual position close to the Bank, and beaming placidly upon his visitors. The old personal fascination followed him to his City home. He wore it like a charm. Soon he gathered round him distinguished helpers — conversaziones and excellent sets of lectures were commenced and the spacious rooms were filled with listeners and readers. A mysterious Providence summoned him from the very midst of his labours. The decree makes us wonder, but we are silent—his work was done faithfully and to the uttermost—with scarcely a vestige of what is termed health he literally took up his bed and walked—and as we stood round his grave at Norwood, thinking of his orphan children, there was this strong consolation, that we knew assuredly that *his* name was written in the Lamb's own book; and we rejoiced that his bright example had led others to share that perfect peace which was his blessedness in the life that now is, waiting only for its full accomplishment in that which is to come.

J. I.

Pharmaceutical Examinations.

Sir,—It is much to be regretted that more time was not available for discussing the subject of Pharmaceutical Education at the recent meeting of the Conference at Brighton, for though it is sufficiently notorious that many incompetent men do manage to pass the Minor examination, yet, until the reading of Dr. Attfield's paper, few persons would have imagined that the vigilance of our examiners was so constantly and systematically evaded.

Men advertise "that an ignoramus may be converted into a chemist and druggist in a month," or, as I would rather say, into a resemblance sufficiently specious to deceive the examiners, and the Professor says, "what is very terrible, these crammers keep their word in most cases;" if this be true—if it be only partially true—the evil is of the greatest magnitude, and it is impossible to resist the conviction that we must make an alteration in our present system of examination.

The great evil of the present mode is, that some of the examiners have been on the Board for many years, their style of examination is well known, and, unless I am misinformed, the very questions they are likely to ask are, in many cases, anticipated and prepared for; Dr. Attfield in his paper corroborates this, for he says, "The successful legitimate candidate knows his subjects, the successful illegitimate candidate *knows the questions that will be put to him.*"

The remedy is not difficult nor far to seek; make the examination longer in the practical portion, and *have a frequent and total change of examiners,*—or, better still, have two or three examiners in each subject, and decide by ballot a few days previous to examination who shall take the various subjects, thus would cramming be almost entirely done away with, but, as a still further precaution, each candidate should be compelled to produce a certificate of having served an apprenticeship of at least three years' duration.

A *compulsory* attendance upon any particular course of lectures, though strongly recommended by some, is, I think, objectionable, nor is it necessary, for some of the best pharmacists I have ever known have acquired their knowledge (while working for their support) by diligent study during the hours not engaged in active business; no obstacle should be placed in the way of such as these, we ought rather *laudare pleno ore.*

Frederick Andrews.

23, *Leinster Terrace, London,*
August 20th, 1872.

Sir,—In the majority of letters from your correspondents on the subject of study, there seems to be ignored the one thing needful—Time. In a recent issue of the Journal, your correspondent Mr. Ekin alludes to both the Major and Minor examinations as being easy, and I am far from refuting his opinion; for with plenty of time, and opportunities for study, I think any average-witted fellow could pass both at the age of 21. Recently a gentleman gave us an account of the way in which he prepared for the Minor, and how he passed. But he said nothing about the length of time he was able to devote to study during the day. Perhaps he had a good deal, for he was in a village, where, I am afraid, he would not be dispensing the whole of the day. Of course, I am speaking of those departments of study that we cannot pick up behind the counter. We may obtain a fair knowledge of dispening and materia medica during "shop-hours;" but as for chemistry, botany, and so forth, they must be acquired at other times, if the shop be opened at 7 A.M. and close at 8 or 9 P.M., leaving at the very most eleven hours out of the twenty-four of which eight must be devoted to rest, and certainly part of the remaining three hours to health and recreation. I do not complain of the difficulty of the examination; all I ask is more time.

Syrupus.

August 6th, 1872.

Mrs. Stockman and Family.—The following sums have been thankfully received in aid of the above family:—Mr. F. McCulloch, per Mr. J. Wavell, Local Secretary, Ryde, £1. 1*s.*; Mr. W. Matthews (Rouse and Co.), £1. 1*s.*; A Friend, 5*s.*; Chemist Assistant, 1*s.*; Emily Lloyd, 5*s.*, ; Mr. R. O. Rippon, £1,; Mr. W. R. Harvey, 2*s.* 6*d.*, Mr. and Mrs. B. Humpage, 10*s*, 6*d.*; Mr. Noad, 2*s.* 6*d.*; Mr. M. Mitchell, 10*s.*; W. J. T., 10*s*. Collected by Mr. J. C. Pooley, Local Secretary, Bath: Mr. Barnett, 10*s.*; Mr. Ekin, 10*s.*; Mr. Tyler, 10*s.*; Messrs. Commans and Wilson, 10*s.*; Mr. J. C. Pooley, 10*s.*—in all, 50*s*. Further contributions are much needed, and will be received with many thanks by G. Perfect, Havelock Pork, Southsea, and Charles Mumby, Pharmaceutical Chemist, Gosport, Trustees.

"Justice."—We do not think the subject worth pursuing any further. The titles referred to had their origin in a compromise, the effects of which are becoming less every year.

A. Barron.—Apply at the office of the Registrar of the University of London, Burlington Gardens.

"Inquirer."—Dr. Cobbold's Cantor Lectures on "Our Food-Producing Ruminants and the Parasites that Reside in Them," was published in the 'Journal of the Society of Arts' for July 7, 1871, and following numbers.

"Ignorance," "An Old Chymist," and *J. C.* are referred to the rule as to anonymous communications.

Communications, Letters, etc., have been received from Mr. G. Cathcart, Mr. Jenkinson, Mr. A. Barron, Professor Redwood, Mr. Macdowell, "Inquirer," "A Major in Business," "Spofforth," "Medical Dispenser," "Local Secretary in an Eastern County."

MONOBROMATED CAMPHOR.

BY JOHN M. MAISCH.

(*Concluded from page 202.*)

To recapitulate the results of these experiments, before giving the process which, in my experience, is best adapted to obtain monobromated camphor on a more extensive scale for medicinal purposes, it may be stated that the process is divided into three distinct operations: 1, the combination of bromine with camphor (bibromide of camphor), which takes place at the ordinary or slightly elevated temperature, particularly in the presence of a trace of alcohol; 2, the formation of the substitution compound (monobromated camphor), which may be effected at a temperature of 100° C. (212° F.), or in a much shorter time at 132° C. (270° F.); and 3, the utilization of the oily residue, the greatest part of which is converted into the substitution compound at 260° C. (500° F.). The product of the second part is at once white, requiring, if decomposition has been avoided, no filtration, but simply recrystallization. The use of the cheap petroleum benzine and naphtha, in preference to alcohol and ether, will also commend itself for the sake of economy. The yield is probably larger than by Perkin's process, and the entire absence of all danger by the bursting of apparatus recommends this method as more practical than that of Swarts. Although more time is required for finishing the process completely, the different reactions will not require much supervision, except the careful attention to the temperatures.

The combining weight of camphor $C_{20}H_{16}O_2$ is 152; that of 2Br=160; equal weights of the two substances, therefore, give a slight excess of camphor. I have found it advisable to use about one-twelfth more of camphor, the excess of which remains in the mother-liquor, and very likely serves to prevent the formation of bibromated camphor ($C_{20}H_{14}Br_2O_2$), if the oily residue previous to its final treatment has liberated bromine on exposure to the light. A greater increase of camphor is unnecessary, since even in the proportion of two to one bromine, the formation of the oily compound and the liberation of bromine on subsequent exposure is not prevented, while the difficulty of obtaining the substitution compound free from camphor is considerably increased.

In regard to the quantity that may be conveniently worked up at a time, the manipulation described below renders it possible to use 12 oz. of bromine in a retort of the capacity of a quart, in which even 14 oz. have been operated upon by me at once.

Regarding the necessary apparatus, I have found the following most serviceable, and well adapted for the purpose.

A quart retort is placed in such a position that, the neck being sufficiently raised, any liquid condensing therein may readily flow back into the retort. To the neck is joined a glass tube, eighteen inches to two feet in length, bent downwards at the further end, and by means of india-rubber and glass tubing connected with a bottle of about 8 oz. or more capacity; the glass tube is cut off immediately beneath the cork, while another glass tube, running nearly to the bottom of the bottle, is bent twice at right angles, and dips with the other end into an open bottle containing about 8 oz. of water and an alkali for the absorption of the hydrobromic acid. The intervenient bottle, which is empty, serves merely as a receptacle for the bromide solution, which is drawn over on the cooling of the contents of the retort, and pressed back again into the last bottle on the reapplication of heat; the liquid is thereby prevented from running into the retort, but the bottle may be replaced by a Welter's safety-tube inserted into the tubulure. Since, theoretically, one half of the bromine employed is converted into hydrobromic acid, its saving is a matter of some importance; it may be collected in water, or combined with any salifiable base or its carbonate. I have found the employment of white marble very convenient; the resulting solution of bromide of calcium is nearly pure; traces of iron present are removed by hydrosulphate of ammonia, after which the solution will, on evaporation, yield the pure salt.

The retort is charged with 13 oz. of camphor broken into pieces of convenient size, with which the neck is completely filled, while the balance is given into the retort. For this quantity, 12 oz. of bromine are used, which is introduced in four or five portions in quantities ranging from 2 to 4 oz. at a time, the larger quantity being used in the beginning, the smaller afterwards. If a funnel tube is used for this purpose, and the last drops of the bromine are washed down with a small quantity of alcohol (about ½ drachm), the reaction usually commences in from 15 to 20 minutes, or it may be brought on by the careful application of heat, which should be at once withdrawn as soon as gas bubbles commence to rise in the retort; the reaction will then proceed without any further attention, the heat increases, some bromine and bromine compounds volatilize, the latter being mostly condensed in the upper part of the retort, while the former condenses in the neck, forming with the camphor an oily liquid which returns to the retort. The next addition of the bromine should not be made until the contents of the retort have cooled down almost or quite to the ordinary temperature: and this precaution should be particularly observed, if, perhaps, in consequence of too violent reaction, all the camphor has run into the retort. The contents of the latter will usually solidify when cooling, after such a reaction: but sometimes they remain quite fluid, and congeal on the subsequent addition of the requisite bromine. If the bromine is added in too large quantities, the heat will become so high, and the reaction so violent, that a large quantity of bromine may distil over uncondensed; if added in fractions, with the precautions stated, the temperature rises generally to from 60° to 65° C. (140° to 150° F.), with at first slow, but gradually brisk extrication of hydrobromic acid gas. It follows from the latter phenomenon, that the mass must contain some monobromated camphor, or perhaps combinations of it with hydrobromic acid and bromine.

Up to this stage the tubulure of the retort may be kept closed with the glass stopper; now a thermometer is inserted, and the retort slowly heated; a rapid, but regular evolution of hydrobromic acid gas takes place as the temperature increases; the golden yellow needles, mostly condensed in the neck, fuse and run back, and when the temperature has gradually reached about 120° C. (241° F.), the liquid boils somewhat and the evolution of gas slackens. From and above 90° C. (194° F.), the deep red colour of the liquid becomes much lighter, and if the heat is raised to about 132° C. (270° F.), the colour will not deepen. At a somewhat higher temperature, particularly when nearing 150° C. (302° F.), the liquid soon becomes darker and finally black.

When the temperature has reached 132° C.—which should require not less than three hours—the fire is withdrawn and the retort allowed to cool to about 50° or 55° C. (120° to 130° F.); the contents are dissolved in 12 oz. of petroleum benzine, and the solution is poured into a beaker glass containing some warm water and pieces of marble to neutralize the free acid still present. While cooling, the benzine solution is occasionally stirred to disturb the crystallization. On the following morning, the liquid matter is poured off, the benzine mother-liquor separated from the aqueous solution of bromide of calcium, and the crystals drained upon a funnel, the neck of which is loosely stopped with some cotton. Petroleum naphtha or gasoline is poured upon them until they change but little in colour when exposed to the direct sunlight. When dry the crystals will weigh about twelve ounces; for complete purification they require to be recrystallized from alcohol or petroleum benzine.

More crystals may be obtained by evaporating the benzine mother-liquor to one-half and washing them first with the naphtha solution and then with some fresh naphtha. The mother-liquor, not yielding sufficiently pure crystals, is evaporated, heated in a retort to 260° C. (500° F.), when it boils again, evolving hydrobromic acid. When the evolution of the latter slackens, the black mass, after cooling sufficiently, is taken up with benzine, the solution treated, as before, with warm water and an alkali (marble) and set aside to crystallize; the black crystals are redissolved in alcohol or benzine, the solution filtered and crystallized. The crystals require to be washed with petroleum naphtha, and on recrystallization are obtained pure. The remaining mother-liquors which on concentration do not yield any crystals, are evaporated, and the oily matter reserved for a subsequent operation.

Monobromated camphor crystallizes from alcohol in thin white or colourless prisms or needles; from petroleum benzine, it may be obtained in long, flat prisms, which are perfectly transparent and hard, and assume the appearance of shining scales when crystallizing rapidly from a very concentrated solution. It is entirely insoluble in water, but readily and freely soluble in alcohol, ether, and in less than its own weight of hot petroleum benzine, from which solution the greater portion crystallizes on cooling. It is permanent in the air and is not affected by the direct sunlight. Boiled with water it evaporates very slowly, condensing in the neck of the retort in fine white interlaced needles. Its odour is somewhat camphoraceous, not very strong, but persistent, and reminding of Borneo camphor; the taste likewise reminds of camphor, and is terebinthinate and scarcely bitter. It fuses at about 67° C. (170° F.), and boils with partial decomposition at 274° C. (525° F.) According to Swarts, it forms with hydrochloric and hydrobromic acids, oily compounds, crystallizing after having been warmed for some time, in soft scales. This is very probably the oil-like matter remaining in the first mother-liquor, and requiring for its decomposition a temperature of 260° C. (500° F.) But even then the decomposition is not complete, and Perkin found that the product obtained by his process at 274° C., required to be freed from oil by pressing between bibulous paper. Long continued application of heat (260° C.), and treatment with potassa may perhaps effect it. Its decomposition by the action of light and air may probably be expressed thus: $C_{20}H_{15}BrO_2$, $HBr = 2\,Br + C_{20}H_{16}O_2$.

When boiled with a solution of nitrate of silver in nitric acid, monobromated camphor is decomposed and bromide of silver precipitated. From this he amount of bromine was calculated, and the following results obtained:—

	Theory.		Found. I.	II.	III.
20 C	120	51.95	—	—	—
15 H	15	6.49	—	—	—
Br	80	34.63	34.59	34.57	34.64
2 O	16	6.93	—	—	—
	231	100.00			

No. I. was monobromated camphor crystallized from petroleum benzine; II., crystallized from alcohol, and, III., obtained by heating the oily compou of the first mother-liquor to 260° C. and crystalliz nd from petroleum benzine.

ON A METHOD OF DETERMINING THE EXPLOSIVE POWER OF GASEOUS COMBINATIONS.

BY JAMES DEWAR.

In a paper recently read before the Royal Society of Edinburgh, the author describes an apparatus by means of which the explosive power of gaseous combinations can easily be determined, and from this, by Bunsen's process, the temperature may readily be calculated. The essential feature of the apparatus is the registration of the "compression volume" of a given initial volume of air, on which the gaseous explosive mixture has been allowed to act. As the duration of the pressure is all but instantaneous, the well-known formula

$$\frac{P_2}{P_1} = \left(\frac{V_1}{V_2}\right)^{1\cdot 4}$$

may be employed to ascertain the final pressure, more especially as the sudden rebound prevents any great loss of heat. In order to test the apparatus many experiments were made with mixtures of hydrogen and oxygen, and the mean result arrived at was a condensation to one-fifth the original volume of air (the initial volume being measured at 30 in. bar), when pure electrolytic gas was employed. This is equivalent to a pressure of 9·5 atmospheres, and therefore agrees with Bunsen's previous determination. The author hopes to be able to execute a series of determinations under varying conditions of temperature and pressure.

ORGANIC CHEMISTRY AND THERAPEUTICS. *

BY A. W. HOFMANN.

(Continued from p. 206.)

Not only has the direct employment of glycerine resulted in advantage to therapeutics, but also the investigation of its metamorphoses, a study which has been followed with great zeal by chemists. It has long been known that the remarkable irritant properties of pow-

* Lecture delivered at the Medical Chirurgical Institute of Berlin.

dered mustard are due to a volatile oil obtained in distilling black mustard with water. But it fell to Will to determine the nature of this oil. He showed that the essence of mustard contained, combined with sulphur and cyanogen, an organic radical known under the name of allyl, and already met with in other substances; for instance, in essence of garlic, where it is combined with sulphur under the form of sulphide of allyl. While studying the action of iodide of phosphorus upon glycerine, Berthelot observed the formation of a substance in which this radical was united with iodine to form iodide of allyl; this quickly gave rise to the idea of the synthesis of the essence of mustard by the reaction of a metallic sulphocyanide upon the iodide of allyl. In fact, by distilling the iodide of allyl with sulphocyanide of potassium, essence of mustard was produced possessing all the properties characteristic of that obtained from the plant, and a large proportion of commercial essence of mustard is made in this manner.

In connection with this subject I would briefly mention another synthesis which has some interest, although but a slight one for therapeutists. In the organism of the *Cochlearia Armoracia* is produced an oil which the pharmacist utilizes to a certain extent in the spirit of horseradish. This oil has been ascertained in recent researches to have a constitution analogous to that of essence of mustard. It is sulphocyanide of butyl, a compound which it is easy to prepare artificially.

In the presence of these conquests, are we not right in expecting that the more important medicaments, which at present can only be extracted from the plants, will soon be prepared synthetically by chemists, and that even if they are not produced directly from the elements, at least it will be possible to obtain them by the modification of other substances, so that they will be procurable more easily and in larger quantity than by the present methods? However this may be, the foregoing examples are sufficient to indicate in how many cases the study of the changes undergone by organic bodies has been the origin of new, simple and less costly methods for the preparation of substances of which the curative properties have been demonstrated by experience. It would have been singular if, in traversing these tortuous paths in the domain of chemistry, the searcher had not also encountered some new compounds of which it sufficed to study the properties and recognize in them valuable therapeutic agents.

It is not necessary to seek far for examples of the progress of therapeutics in this sense due to the development of organic chemistry. The products of dry distillation vary not only with the nature of the substance distilled, but also with the temperature used in the operation. The decomposition is thus very varied, especially when the substances employed are complex mixtures of different compounds. Among the numerous products so obtained from wood, creasote, discovered by Reichenbach in the products of distillation of beechwood must be mentioned first. That chemist did not fail to appreciate its strongly antiseptic properties, as is indicated by the name he assigned to it. The antiputrescent action of creasote was so indubitable that, from the time of its discovery, it has been the object of an active manufacture; nevertheless, it has not been much employed in medicine, it being used principally for the the sake of its antiseptic properties. By the side of creasote was soon placed carbolic acid, an analogous body discovered by Runge in coal-tar. Possessing the same properties as creasote, carbolic acid has the advantage of being crystalline and presenting more definite chemical properties; it is easily prepared in a pure state and its purity assured, especially when, as is frequently the case, the well-crystallized sulphocarbolates derived from this acid are used. Besides the price of carbolic acid is relatively moderate, being chiefly obtained as an accessory product in other industries, such as the manufacture of coal gas and that of coke. But it is not only for the sake of the gas and the coke that the distillation of coal is now carried on; tar, the mixture of solid and liquid products so obtained, has already become an important article of commerce, supplying the materials for an entire group of industries. Tar yields benzine, the primary matter in the manufacture of the aniline colours; anthracene, by the aid of which is produced artificially the colouring principle of madder; and, lastly, a nearly inexhaustible quantity of carbolic acid, which, besides its hygienic applications, serves as the primary matter for the making of a magnificent red colour—coralline. We cannot here deal with the coloured derivatives of this acid, but its disinfecting properties are well worthy the attention of medical men. Its name cannot be pronounced here without recalling the important services rendered by it during the late war. If the frightful calamities which, under the form of epidemics of every kind, ordinarily succeed to the horrors of the fight, during this campaign made less victims than in preceding wars, doubtless this fortunate result is due to various causes; but impartial observers agree that among these causes must be reckoned the use of disinfectants, and chiefly carbolic acid.

In order that by the side of products so important, those possessing less striking properties may not be forgotten, I will here say a few words concerning collodion. The methods of investigation of a science are necessarily modified by the object pursued at a certain period. While chemists were devoted to the study of products of decomposition of organic bodies, nitric acid with its oxidizing properties was naturally one of their favourite agents. But nitric acid not only acts as an oxidizer, in many cases its nitrogen enters into the molecule of the products of decomposition, and bodies were so produced that were termed nitrated compounds. Then commenced an epoch which might be called the period of the treatment by nitric acid; chemists treated by this reagent everything that fell into their hands, obtaining thus a number of combinations, for some of which an application was quickly found. In so treating benzine, Mitscherlich obtained nitrobenzine, the first and also the most important of the nitrated compounds, which, for a long time, has, under the name of essence of mirbane, supplied a want of the perfumers, and more lately has formed the groundwork of the aniline colours industry. By the action of nitric acid upon phenol, Laurent obtained the yellow colouring matter known as picric acid. Again, by the aid of nitric acid, Pelouse obtained nitrated starch, or xyloidin, the explosive properties of which are utilized in pyrotechny. Schönbein in his turn treated cotton in the same manner, and discovered pyroxylin, or gun-cotton, for a long time a rival to gunpowder. But this powerful agent of destruction has also a more peaceful application; dissolved in ether, under the form of collodion, it becomes at the same time the indispensable auxiliary of the photographer, and the faithful aid of the surgeon; instead of causing wounds it heals them.

In analogous circumstances, but in another department of organic chemistry, was produced a substance more important still to surgery, and therefore to medicine in general. As an agent of decomposition, chlorine is no less energetic than nitric acid, and the time came when chlorine in its turn secured the preference of chemists. In the important researches upon the nature of alcohol during the last thirty years, chlorine has played a most important part. Under the action of this element, with its affinity for hydrogen, Liebig saw alcohol transformed into a series of remarkable products, differing from each other in the proportion of chlorine which they contained. Among these substances there was one that had escaped the researches of Soubeiran, and which Liebig first submitted to analysis. This was the body now known as chloroform. Among the same products of the chlorination of alcohol, the great chemist also met another substance, the name of which has for some years been in every mouth, chloral. Chemists could not at first agree as to the nature and composition of these two bodies, and then commenced the great controversy between Liebig and Dumas, which chemists of that day followed with so much anxiety, and we read with so much interest, not knowing which most to admire, the ardour that filled the two champions, or the admirable logic of their arguments. We cannot deal here with this controversy, in which the views of Dumas ultimately triumphed, but it is interesting to note what researches originated in these two bodies, to which was reserved so brilliant a future. The history of chloroform and chloral is a proof of the general axiom, that every fact seriously and disinterestedly studied, with the sole object of arriving at the truth, however far off the possibility of its practical employment may seem, will sooner or later find an useful application. For many long years chloroform was only an object for theoretic speculation; but when, thirty years since, the American Jackson discovered the anæsthetic properties of ether, the hour sounded for chloroform also. At the commencement of 1847, Flourens showed that the vapour of chloroform exercised upon animals an action analogous to that of ether; and at the end of the same year, that is to say fifteen years after its discovery, James Simpson, of Edinburgh, used chloroform for the first time as an anæsthetic. Nor was it a mere lucky chance that introduced this important agent into medicine. Simpson sought systematically for a substance possessing the anæsthetic properties of ether, but not exercising like it an injurious influence upon the system, and it was only after having carefully compared a long series of organic compounds that he decided in favour of chloroform. Since then, notwithstanding numerous attacks and many propositions to substitute it by other bodies, chloroform has victoriously held its place among the best auxiliaries of the surgeon and the accoucheur.

The history of the introduction of hydrate of chloral into therapeutics is, perhaps, even more interesting. Its discovery preceded that of chloroform; for it was in 1832, while studying chloral which he had just discovered, that Liebig for the first time met with chloroform. It is singular, that nearly forty years elapsed before the marvellous physiological properties of chloral were suspected. Although at the time of its discovery chloral attracted the attention of all chemists, and its discovery was of great importance in the solution of various questions, for a long period it was only the object of rare researches. And this was not without reason, for in a field that had been explored by Liebig there is generally but little probability of making a rich gleaning. Thus chloral fell into oblivion, being scarcely known from personal study to the younger generation of chemists; therefore, the astonishment was the greater when suddenly it reappeared upon the scene in a most unexpected manner. Again, it was not by chance that the physiological properties of chloral were discovered; if ever a discovery responded to that which was expected by its author, it was the marvellous action of chloral upon the organism discovered by Liebreich.

One of the most remarkable reactions of chloral is the transformation which it undergoes under the influence of alkalies. In 1832, Liebig demonstrated that in the presence of alkalies the molecule of chloral seizes the elements of water and breaks up into chloroform and formic acid. In 1868, Liebreich asked this question, "How does this reaction affect the system if, instead of taking place in the retort of the chemist, it occurs in the living organism?" The transformation of chloral into chloroform and formic acid takes place even under the influence of extremely dilute alkaline solutions. Chloral is soluble in water, and consequently easily absorbable by the organism; once absorbed, it comes into contact with the blood which has an alkaline reaction. So that here there was a question fairly put to Nature; and never does she refuse to reply to such questions.

We cannot here trace the progress of the employment of chloral, but it will give some idea of it to say that all the chloral prepared for the requirements of science from 1832 to 1868, scarcely amounted to one kilogram, while to-day the manufacturers of Berlin alone send one hundred kilogrammes into commerce daily. As to the manner in which chloral acts upon the economy, physiologists are not yet agreed, but no medical man of the present day doubts that in it he has always a practicable means of producing a more or less profound anæsthesia, and that therein organic chemistry has furnished to therapeutics one of its most valuable agents. But one need not be a physician to appreciate the value of this service; one need only experience its marvellous properties, or see them exercised upon others. Science, especially, has reason to rejoice concerning them, for during the severe illness which recently menaced the life of the great chemist who discovered chloral, he was able by its use to obtain beneficial and reparative sleep.

If I have dilated somewhat upon the introduction of chloroform and chloral into medicine, it is because this introduction was the commencement of a new phase in the relations between organic chemistry and therapeutics. As long as the researches of organic chemistry were confined to the domain of analysis, therapeutics was content to receive, with thankfulness, the fruits of those labours, and even when the study of the metamorphoses of organic bodies commenced, its *rôle* was scarcely changed. In the first case it accepted gladly indications as to the nature of the substances it used; in the second, it was happy to enrich itself with the discoveries due to the progress of chemistry. But the relations between the two sciences quickly changed: therapeutics was no longer content only to receive; already it stretched out a hand towards the treasures which incessant labour had acquired for organic chemistry. It was in the presence of a well-defined want that it examined these treasures, searching and trying, and finishing by placing its hand upon chloroform, which answered so well to its expectation. But as chemistry discovered fresh reactions, therapeutics made them the objects of remarkable speculation, and it was thus that the action of chloral was discovered. This is a method that ought incontestably to offer to therapeutics an immense field for development. He who examines this field, who knows with what ardour, perseverance, care and love, chemists have cultivated it; he who has seen this field, in the first decades of this century a waste, and now a verdant oasis, transformed by the cares of indefatigable workers into a flourishing garden; he who knows the fruits already produced by this garden, will have no doubt that therein is a rich harvest for therapeutics to gather; and as formerly the problem chemists had to resolve was to determine the composition of substances used as medicines, so it is now for the physician to examine the physiological properties of the numerous substances that have had their origin in systematic chemical research and to seek to profit by them. In such researches it is necessary that a choice should be based upon an intimate acquaintance with the substance; to ascertain the facilities existing for procuring it; and never to lose sight of the relations which exist between it and substances already tried. Often the study of a single compound will suffice to give an idea of the physiological action of all the bodies of a series; but always investigations conducted in this manner will exercise an important influence upon the development of therapeutics.

There is still another direction in which organic chemistry has rendered services to therapeutics. It is well known what singular modifications may occur in the physiological properties of a substance when it unites with one or more elements to form a more complex body. Thus, arsenicum, combined with oxygen or hydrogen, under the form of arsenious acid or of arseniuretted hydrogen, constitutes a deadly poison. If besides the oxygen and hydrogen, it unites with carbon to form such a compound as the oxide of cacodyle or the compounds of tetræthyl-arsenium, it loses its poisonous properties. It is not only the introduction of other elements which influences the physiological properties of a body, but they depend sometimes upon the manner in which these elements are combined. United with carbon, hydrogen, and oxygen, as tartarated antimony, antimony acts as an emetic; in another compound where it is united with the same elements, it has no longer such action. The group of cyanogen compounds present examples still more striking. Anhydrous prussic acid may be mixed with fifty times its weight of water, and even more, without losing its poisonous properties. Combined chemically with one or two molecules of water, as formic amide or formiate of ammonia, the molecule of prussic acid loses its poisonous properties. Again, add to the molecule of prussic acid a group formed of one atom of carbon and two atoms of hydrogen, that is to say, introduce the radical methyl, and according to the place occupied by that radical, according to the manner in which it is combined, we shall have two bodies of the same composition, but with different properties; one by its suffocating odour and poisonous properties recalling prussic acid; the other, with a strongly aromatic odour, but not having the slightest injurious effect upon the system. We thus have a method of modifying the physiological action of a substance by the addition of a certain number of atoms of carbon and hydrogen, by the introduction into its molecule of the radical methyl. How could such a discovery remain long unutilized? Already therapeutists have sought to profit by it, and with this object have been produced the extensive researches of Crum Brown and Fraser upon the changes which occur in the physiological properties of strychnine, brucine, thebaine, codeine, morphine and nicotine, when the radical methyl is introduced into these bases, and in the same direction, the labours of Jolyet and Cahours upon aniline and its methylic derivation.

The limit to which I am confined will not allow me to indicate all the results of these researches. But there are some indubitable facts to which I would call your attention. It has been found that the reflex cramps produced in a frog by the administration of morphine are reduced to a simple paralysis when the base has been methylated; and that the more or less sudden action of strychnine, brucine and thebaine are nearly extinguished in their methylic derivatives. The latter only present the action upon the extremities of the motor nerves, which characterizes the Indian arrow poison curarine. If the beginning of research discloses such modifications in the powerful properties of well-known substances, it cannot be doubted that in the future active researches will be prosecuted in this direction.

Perhaps it is reserved for us to see a revolution take place in therapeutics like that which has recently been accomplished in the dyeing industry. The modern dyer disdains, more and more, to produce the different shades by the mechanical mixture of many colouring matters; it is the same colouring principle which, according to colour desired, undergoes a definite chemical modification. This same methylic radical which we have seen deprive prussic acid of its dangerous properties can work in colouring matters an infinite variety of modifications. Let it be introduced into the molecule of rosaniline, the base to which we owe fuchsine, and this magnificent red is converted into a splendid violet. The introduction of two or three methylic radicals causes this red violet to pass into a blue violet and then into blue. Two more methylic groups and we obtain the magnificent green, which rejoices the heart of the fairer half of the human race. The modern dyer is not content with the methyl radical; there are other radicals, compounds of carbon and hydrogen, carbon and oxygen, and oxygen and nitrogen, which he utilizes with the most marvellous results. This remarkable revolution which, in dyeing, is now an accomplished fact, is, in therapeutics, scarcely in its first stage. But he who observes with an attentive eye and reflectingly the powerful influence that to-day chemistry impresses upon every science and industry with which it comes into contact, will not doubt that, however varied these sciences and industries may be, the changes brought about by this influence will all be in the same direction, and that just as now the dyer no more has recourse to mechanical mixtures, but to chemical compounds to attain his object, so the therapeutist will follow in the path traced out, and apply himself more and more to modify the physiological properties of his medicaments, no longer by means of mechanical mixtures in the phial of the pharmacist, but by the aid of chemical modifications of the molecule of the active principle itself.

IGNITION OF COTTON BY SATURATION WITH FATTY OILS.*

BY JOHN GALLETLY.

The following experiments have been made with the view of giving greater precision to our knowledge of the kindling of cotton or other open combustible materials which happen to have imbibed animal or vegetable fatty oils. Graham mentions† that "instances could be given of olive oils igniting upon sawdust, of greasy rags from butter, heaped together, taking fire within a period of twenty-four hours." The danger of fire from this cause is familiar to those manufacturers who coat any textile fabric with varnishes containing drying oils, and also to Turkey-red dyers from the olive oil employed in their process. Generally, it is stated in Watts's Dictionary that this combustion "may take place in intervals varying from a few hours to several weeks, when considerable masses of lamp-black, tow, linen, paper, cotton, calico, woollen stuffs, ships' cables, wood ashes, ochre, etc., are slightly soaked in oil and packed in such a manner that the air has moderate access to them." (Watts's Dict. ii. p. 880.) Nevertheless, there is great vagueness about the exact conditions in which actual ignition of the mass would take place, what size of a heap might be necessary, and the various powers of different oils to produce this result. Graham states, in the report already quoted, that the ignition of heaps of the materials under discussion "has been often observed to be greatly favoured by a slight warmth, such as the heat of the sun. This is a very important observation. I shall only, however, mention in the meantime that the first of my experiments was made at a temperature of about 170° Fahr., but I have some made at a heat a little over 130° or about the temperature a body acquires by lying perpendicular to the sun's rays; the former temperature might represent the heat attained in the neighbourhood of a steam pipe, or in front of an open fire. For completeness, I shall repeat in this paper, along with later results, some observations published a few weeks ago in the 'Oil Trade Journal.'

Boiled Linseed Oil with Chamber kept about 170° Fahr.—A handful of cotton waste, after being soaked in boiled linseed oil and removing the excess of this by wringing, was placed among dry waste in a box 17 in. long by 7 in. square in the ends. Through a hole in the cover of this box a thermometer was passed with its bulb resting amongst the oily cotton. Shortly after reaching the temperature of the warm chamber the mercury began to rise rapidly, viz., from 5° to 10° every few minutes, and in 75 minutes from the time

---

* Read before the Chemical Section of the British Association, August 21st, 1872.

† Report on the Fire in the 'Amazon,' 'Journ. Chem. Soc.,' 2 v. p. 34.

the box was placed, in the chamber the heat indicated was 350° Fahr. At this point smoke issuing from the box revealed that the cotton was now in a state of active combustion, and on removing it to the free access of air, it burst into flame. In another similar experiment the temperature rose more slowly, but reached 280° Fahr. in 105 minutes, when, from the appearance of smoke, it was plain that the cotton was burning, and the whole mass was soon in a flame on being placed in a current of air. On a smaller scale I tried a quantity of the oiled cotton that just filled a common lucifer match-box; within an hour it was on fire, the temperature of the chamber being 166° Fahr.

Raw Linseed Oil, as generally supposed, does not so readily set fire to cotton as the boiled oil, but in two experiments where the size of the box employed was 6½ in. by 4½ in. square in the ends active combustion was going on in the one case in five and the other in four hours.

Rape Oil, put up as in first experiment on boiled linseed, resulted, in two trials, in the box and cotton being found in ashes within ten hours. The box being put up at night, the result was only observed in the morning. In one trial I did not get the cotton to ignite in six hours; the chamber in the cases of this oil and raw linseed was kept about 170° Fahr. With the five following oils, at a little over 132° Fahr., the quantity of waste used was loosely packed in a paper box holding about the sixteenth of a cubic foot.

Gallipoli Olive Oil.—The two trials made with this oil gave closely similar results; in one case rapid combustion was going on in a little more than five, and in the other within six, hours.

Castor Oil.—I found the oxidation of this oil to proceed so slowly that only on the second day I found the interior of the box to be a mass of charred cotton. Its sp. gr. (·963) is remarkably high, and its chemical nature very distinct from the other vegetable oils I have tried, which, no doubt, has some intimate connection with its slow oxidation.

I have tried three oils of animal origin with effects very distinct and instructive.

Lard Oil, an oil of an ordinary sp. gr., viz., ·916, produces rapid combustion in four hours.

Sperm Oil, which has a sp. gr. of only ·882, and is not a glyceride, showed its unusual chemical character by refusal to char the waste.

Seal Oil, which has a strong fish-oil odour, not unlike the sperm, but a sp. gr. of ·928, produced rapid ignition in one hundred minutes. Comparing raw linseed with lard and seal oils, it would appear that the statement is not altogether correct, that drying oils are more liable to spontaneous combustion than non-drying oils. I have also some reason to believe that the rate at which oxidation takes place does not chiefly depend on the presence of small quantities of oxyotized or other easily putrefiable matters, but rather on the particular olein. However, further inquiry on this point is necessary. I have made at least two experimenta with each oil, and have got remarkably uniform results. The ignition of the cotton can be calculated on for any oil, with about the same certainty as the point at which sulphur or other combustible material takes fire when heated in the air. So that the term spontaneous combustion may be objected to for the same reason that Gerhard objects to spontaneous decomposition produced by oxidation. The heavy oils from coal and shale, being chiefly the higher olefines, have a remarkable effect in preventing this oxidation, undoubtedly by giving a certain protection from the air. Mixtures of these oils with 20 per cent. rape gave no indication of heat whatever at 17° Fah.; and even seal oil, with own bulk of mineral oil added to it, did not, at 135°, reach a temperature sufficient to char the cotton. The author hopes that these remarks will lead to a more elaborate inquiry into this subject, both for scientific and practical purposes.

PRELIMINARY NOTE ON "GUARANINE."

BY JOHN WILLIAMS, F.C.S.

The fruit of the *Paulina Sorbilis* is made up into rolls by the Indians of Para, in South America, and is by them called "Guarana." Its infusion is used as a beverage, and within a few months has been introduced into medical practice, and recommended as a remedy for sick headache.

Dr. Stenhouse some years back examined guarana, and isolated the crystallizable principle, which he named guaranine, but considered it to be identical with caffeine or theine.

I considered it a matter of interest to prepare some of this substance, and first proceeded to do so by the process given by Stenhouse, but found it troublesome, and the result not so satisfactory as might be desired. This led me to adopt the following process, which I found in every way satisfactory.

Guarana reduced to a fine powder, is mixed with one-third of its weight of hydrate of lime, and moistened with water. After an hour or two it is placed in a drying closet, and completely dried at a moderate heat. This is exhausted with boiling benzole, filtered, and the benzole distilled off, when a small quantity of light-coloured oily matter is left. This is treated with boiling water, and the whole digested over the water-bath until all traces of benzole have been dissipated, then filtered through a wetted filter so as to keep back the oil; the aqueous portion evaporated to a small bulk, and set on one side for 24 hours, yields the guaranine white and pure, in fact requiring no further purification of any kind. I have tried the process upon tea, and it appears to answer, but have not yet finished my experiments in that direction. As far as appearance goes, guaranine appears to be identical with theine and caffeine, but the author suspects it will be found to be rather more soluble in water, and not quite so bitter in taste as the above-mentioned bodies.—*The Chemical News.*

THE BRIGHTON ASSOCIATION OF PHARMACY.

At an adjourned meeting of the chemists and druggists of Brighton, W. D. Savage in the Chair, held at the Town Hall, on Friday evening, September 13th, it was resolved that the balance from the Pharmaceutical Conference Fund of £25, held by Mr. Glaisyer, the Treasurer, be a reserve fund, to be applied (as contingencies may arise) for Pharmaceutical purposes.

Mr. Brew, as President, Mr. Schweitzer, as Secretary, and Messrs. Cornish, Gwatkin and Savage, members of the old Chemist and Druggists' Association, resigned their respective offices, having first assigned over the sum of £20 for the safe keeping of the Treasurer, Mr. T. A. Brew, and Mr. Thos. Glaisyer, and to be used in such way as they and the old Sub-Committee may from time to time determine.

It was then moved by Mr. Mathews (at Mr. Colby's), and seconded by Mr. W. H. Smith:—That a new Association be formed, to be called "The Brighton Association of Pharmacy," consisting of an Executive Committee of twelve (six principals and six assistants); and ballot for names having been taken, the following was the result:—Messrs. Brew, Colby, jun., Cornish, Ettles, Savage and Schweitzer, principals; and Messrs. Gwatkin, jun., Higham, Mathews, Pick, Purvis, and W. H. Smith, assistants, who on the motion of Mr. Barton, seconded by Mr. Higham, were elected the first Committee.

It was further resolved that Mr. W. D. Savage be President, and Mr. Mathews, Secretary.

The sum of £2. 2*s*. was voted by the old Committee to meet a few preliminary expenses. A vote of thanks to the Chairman concluded a very satisfactory meeting.

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 21, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PHYSIC AFLOAT.

WE took occasion at the commencement of the current year, to comment upon ships' medicine chests, and the reputed quality of the drugs contained therein. There is, however, another aspect of the question, interesting alike to the doctor who is to prescribe, and to the druggist who has to furnish the physic required for the voyage. We will state a case, example being better than precept. A druggist, say at Shields, Sunderland or Newcastle, receives an order from a shipowner to furnish a medicine chest for a complement (including passengers and crew) of 500 persons. He may or may not be an adept at nautical work, but we may safely say with no slight to our readers, that not one man in fifty would be able to commence work with a clear perception of what was required. He may or may not be informed as to the destination of the vessel, and the probable duration of the passage. He will have, in all probability, no opportunity whatever of consulting the ship's doctor, inasmuch as that functionary, with a perverse but ever-recurring constancy, seldom turns up before the ship is just on the eve of getting under weigh. And so the druggist is cast adrift on his own resources. The 'Medical Guide' and 'Scale of medicines' authorized by the Board of Trade, give little or no assistance, as they apply only to ships' crews. We believe that a list of medicines and medical stores required in such a case may, after some official correspondence, be obtained from the Emigration Office, and the person concerned can of course, if he chooses, obtain and consult such of the Army regulations as relate to this subject in connection with the transport of troops to foreign stations. But all these means of gaining information are roundabout, incomplete and eminently unsatisfactory. Transport by water is now practised so often on a large scale, whether under the auspices of the Emigration Commissioners, or as a matter of private enterprise, that some sort of official list of medicines and medical stores ought to be issued and sanctioned for the information of druggists who are called upon to furnish medicine chests. A very eligible opportunity now occurs for the adoption of such a plan, as the Board of Trade have, by an Act that has just become law, taken over all the duties that formerly appertained to the Commissioners of Emigration, and so have, or should have, the materials for the compilation of these lists close at hand. They should, of course, be as simple as possible, and if distinct indications were given as to the proportion of drugs, etc., required in accordance with the duration of the voyage and the number of persons carried, the information would prove a most invaluable boon to many of our readers who now perforce flounder about, and have to glean the requisite knowledge in a "scrappy," and, therefore, incomplete manner.

THE report of Mr. HOWARD on the Jamaica-grown cinchona barks, which we published in a recent number, is so very satisfactory that it cannot fail to inspire the colonists with renewed energy in the cultivation of those species which appear to be the most productive of quinine. From St. Helena we have hitherto had good accounts as to the suitability of the climate and the prosperity of the plants under cultivation; but a recent number of the 'St. Helena Guardian' now before us contains grave charges of the neglect of these valuable plants for the growth of common vegetables. It is proved beyond doubt that cinchonas are easily cultivated in St. Helena, for we are told in the same paper that the plants already established "are in perfect good health, showing the most vigorous growth. Some are 8 feet 6 inches in height, and from 8 to 9 inches in circumference; about 600 vary from 5 to 6 feet, showing a most rapid growth." The question then is very reasonably asked why, when there is plenty of room for some thousand more plants at Diana's Peak, the cultivation is not proceded with?

WE read in a report from the British Consul at Aleppo that "a profitable trade" might be carried on in Storax from Mount Amanus, where the *Styrax officinale* grows abundantly, but none of this rare and precious gum is gathered. It is well known that the *Styrax officinale*, L., is the source of the original Storax of the ancients, and it has always been more or less scarce and valuable, and in recent times has quite disappeared from commerce. The question may well be asked, why is this, if the plant grows so abundantly that the Consul, who ought to know the capabilities of the country, sees the means from whence might spring "a profitable trade?"

THE practice of early closing appears to be steadily extending, and a recent instance of its adoption is reported by Mr. EVE, in the case of the Hampstead pharmacists, who have issued a circular requesting the co-operation of the public.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Wednesday, August 14th, 1872.

(Second day.)

The Conference reassembled at two o'clock. The first paper read was on—

Kamala.

BY THOMAS B. GROVES.

The few remarks I have to make on this substance refer exclusively to the moot point whether it contains the crystallizable principle Rottlerine.

The botanical history of the drug, its pharmaceutical preparations, and its medicinal uses have already been so fully and conscientiously treated by Mr. D. Hanbury that I need do no more than direct inquirers to volume XVII. p. 405 of the Pharmaceutical Journal, where all the facts then known are amply set forth.

The chemistry of the drug had previously been investigated by Dr. Anderson, and reported on by him in an elaborate paper first published in the Edin. New Philos. Journ. (new series) 1, 300, wherein was announced the discovery of Rottlerine, a crystalline principle obtainable in yellow silky crystals by allowing an ethereal tincture of Kamala to evaporate slowly and spontaneously. This substance is by no means of an interesting nature. It is not believed to have much to do with the activity of Kamala as a vermifuge, and moreover its chemical relations are not noteworthy. It is indeed doubtful whether its formula has as yet been correctly ascertained. The experiments of Anderson were some four or five years subsequently repeated by G. Leube, jun., the results being published in several German publications devoted to pharmacy, and in the Pharm. Journ. vol. II., second series. He described several resins more or less closely allied in character and composition, and assigned to them formulæ more or less doubtful. The remarkable point of his work was that he altogether failed to obtain Anderson's crystalline principle Rottlerine. Since then various samples of Kamala have been examined by competent observers (by Mr. D. Hanbury more especially), and still with the same negative result. In consequence of this clashing of opinions, Dr. Attfield in 1867 obtained from Dr. Anderson some further details respecting the extraction of Rottlerine, and a probable explanation of the cause of Leube's failure. The latter chemist had evidently been supplied with an impure specimen of Kamala. It had yielded no less than 28 per cent. of ash, whereas the pure article should give less than four per cent.; and although the mineral constituents were unlikely to be found in the ethereal tincture, it was not unlikely that a specimen so largely adulterated would also contain foreign organic bodies that would prevent the crystallization of a substance so intractable as Rottlerine. It was also explained that the crystals obtained were small in quantity, variable in amount in different experiments, and recognizable as crystals only by means of the microscope.

It came to pass then, that, up to last year, Anderson's results had received no confirmation from other experimenters. In December, last year, however, Mr. D. Hanbury was good enough to send me a large quantity of a thick solution of Kamala in ether, in which were imbedded numerous feathery crystals of an orange colour and not a few whitish semi-crystalline granules. The chemical inactivity of the Kamala crystals rendering their extraction a question of solvents and filtration only; this demanded a greater amount of care and perseverance than the subject, in my opinion, merited. I proceeded thus. Having ascertained that the crystals were not re-dissolved when the ethereal solution was thinned with alcohol, it was in that way rendered sufficiently fluid for the mother-liquor to pass through paper, and then thrown on a filter contained in an air-tight arrangement. After a week or so the orange-coloured pasty mass was removed from the filter, and subjected first to simple draining on bibulous paper; next, to the same assisted by the pressure of weights. Evaporation of ether was as before carefully prevented. The mass so obtained was boiled with alcohol, and the operation several times repeated until the sparingly soluble residue retained but little colour. The spirit deposited on cooling a sufficient quantity of what I have termed Kamala wax to render the filtrate semi-solid. When completely cold it was again filtered, and the solid residue washed with cold spirit. This substance proved to be the same as that which had remained undissolved in the previous operation. They were, therefore, subsequently treated together, and after being several times dissolved in boiling spirit were allowed to deposit therefrom. Thus obtained, the substance presented the appearance of a yellow powder of no great intensity of colour, and in all probability would if pure be perfectly white. The intensity of the colour imparted by the Kamala dye would make such a purification exceedingly wasteful, and perhaps altogether impossible to effect.

The filtrate being a cold spirituous solution of what may be termed crude Rottlerine was next evaporated quickly to dryness, and the residue, dissolved in ether, was placed aside in a deep beaker loosely covered, to evaporate spontaneously. As it approached a syrupy consistence, I could perceive a layer of an orange colour slowly making its appearance at the bottom of the vessel. This layer I was not slow in recognizing as caused by a multitude of microscopic crystals, but owing probably to difference of circumstances, not feathery as before, but consisting chiefly of aggregated needles. At the proper moment this stratum was separated from the supernatant fluid, cautiously thinned with ether, and thrown on a filter supported in an air-tight funnel. To remove the syrupy mother-liquor it was lightly washed, and then subjected to draining on bibulous paper with and without pressure. It was, however, far too readily soluble to admit of being completely purified in that way.

Dried spontaneously by exposure on a glass plate to the air, it formed after some days (for it retained the ether tenaciously) a dry substance of orange colour, which, when powdered and examined microscopically, showed no appearance whatever of crystalline structure. Treated with solvents, it was evident that its solubility had much diminished, and moreover I was completely unsuccessful in my attempts, in many ways varied, to induce it to resume the crystalline form. I am, therefore, of opinion that when exposed to the air undefended by their mother-liquor, the crystals of Rottlerine undergo a change (probably by absorption of oxygen) that prevents one from regarding the amorphous product as the same thing as the well-defined body that was subjected to desiccation. This explains, I think, the fact that various experimenters have obtained results so discordant.

Rottlerine, as stated by Anderson, *does exist*, but being easily modified by exposure to air, a *new* as well as pure specimen of Kamala should be taken for its extraction.

In testing my own specimen of Kamala, which must have been four years old, I avoided the interference of the waxy substance by thoroughly washing out the colouring matter with *cold* spirit. That substance is then left on the filter out of harm's way. When the spirituous tincture thus obtained was evaporated to dryness, and the ether solution of the solid residue was set aside to concentrate itself by slow evaporation, not a symptom of crystallizing was observable, thus confirming the anticipations derived from my knowledge of the age of the specimen.

Mr. Hanbury: This substance was very circumstantially described by Professor Anderson, of Glasgow. He describes the occurrence of a mass of crystals filling an ethereal solution of Kamala when the latter is in a tolerably concentrated condition; and I may say that it has struck me as a very extraordinary circumstance that this fact which he observed many years ago has not been distinctly observed by any subsequent chemist. I myself have tried it repeatedly; examining strong ethereal solution of Kamala even in a condition in which it was almost like thin mucilage. I have examined it on a plate of glass, and in other ways, but I never could detect any crystalline structure whatever until on a recent occasion, when, to my great astonishment, some ethereal tincture which had been drying up in a bottle for some time exhibited a considerable abundance of crystals. But why other specimens of the drug failed to afford it, is by no means, in my opinion, satisfactorily explained by the fact of the Kamala used having been impure, because the impurity in this drug is merely earthy matter, and the presence of earthy matter would only diminish the amount of soluble matter which the drug might afford. One does not see at all why it should destroy or alter the chemical principle. It seems rather, from the explanation which Mr. Groves offers, that the age of the drug has something to do with it; but without close examination we are really hardly able to say whether that is the fact or not. I rather think that the Kamala which was the subject of his observations was some of a recent parcel that was collected in the north of India; and probably it was not more than a year old, if so much.

Florentine Orris.

BY HENRY GROVES.

Florence has not always borne its present distinction for the produce of orris root. Anciently that of Illyria was the most famous, and even Italians gave the preference to that of Dalmatia, which would almost lead one to suppose that some of the species at present cultivated may have been introduced in like manner as some of the numerous tulips which now adorn the cornfields around the City of Flowers, and which are supposed to have escaped from garden cultivation. The negative evidence of Micheli (A.D. 1720) would seem to support this view; he having simply mentioned the occurrence of *T. sylvestris*, whereas we have now some ten or twelve forms of that genus, four of which are exceedingly common. In any case the introduction of Iris must have been at a very early period, as Andrea Cesalpino, in 1583, mentions two of our present species — *Iris florentina* (Linn.) and *I. Germanica* (Linn.) as occurring in the neighbourhood of Florence; the former he describes as "Iris cujus flos ex toto candidus," and the latter as "Iris" simply. Later we find much confusion of nomenclature, and the synonym of "Iris florentina" has been given to both *I. germanica* and *I. pallida*, the former in Savi's 'Botanicon Etruscum,' and the latter in Santi's 'Viaggi,' both of which are of the present century. Santi, however, describes his plant as a variety of florentina. It was thus that it became usual to quote the Florentine iris as the source of all orris root, whereas it is now known that three species are capable of yielding the sweet-scented rhizome, and are called in common "Giaggiolo" or Ireos, the latter being considered the more refined term, and adopted by perfumers, whereas the former is always used by the country people. The employment of these words gave great offence to Antonius Musa Brasanolus as far back as 1545, for in his 'Examin. omn. simpl. Medicament,' published at Venice, he contended that they should be simply "Iris," and asserts that at Ferrara many druggists collected the rhizomes of a species of Gladiolus (?) instead of the true drug, and from this he argues that the word "Giaggiolo" was derived, it having a sound somewhat similar to Gladiolo. This author advised the use of Illyrian orris; which, although perhaps not a distinct species, owed its superiority to a suitable soil and climate, which caused it to flourish abundantly in that region. Illyria was visited by him in company with the Duke Alphonso, and especial attention was paid to the various irides. They were collected with flowers of various colours, some being white or variegated, others pale or yellow, purple or blue; in fact, so great was the variety, that it was customary to separate them, not by their flowers, but by their rhizomes, of which two kinds were noted in Illyria, one called Rhaphanitis (from its similitude to Rhaphanites), being considered the best, while the less esteemed bore the name of Rizotomos, and had a sub-rufous colour.

Although the three species of Iris already mentioned, are found in the orris growing districts of Tuscany, the *Iris florentina* (Linn.) is by far the most rare, and is very seldom found beyond the precincts of the country villas, where, in common with the two other species, it is used to ornament the wall and gardens. From this it will be seen that the Florentine orris root is almost entirely the produce of *Iris germanica* (Linn.) and *Iris pallida* (Lam.), these two species being at present about equally cultivated. In the neighbourhood of Genoa, the *Iris florentina* is much more frequent than at Florence, and it is planted, together with one of the other species, around the roots of the fig-trees, which are said to flourish better when thus surrounded, possibly on account of the moisture retained in the soil by the shelter of leaves. The cultivation of Iris as a commercial product has very much increased during the last sixty or seventy years, since the establishment of a manufacture of orris peas at Pontasieve in 1806, under the auspices of the Marquis Strozzi. This establishment is situate in the centre of the orris district, which is very extensive, and embraces many communes on the right and left banks of the Arno, perhaps the greatest yield being from the neighbourhood of Rignano and Pontasieve, although Grassina, Greve and Panzano on the left bank, and Compiobbi on the right contribute largely to the general sum. The rhizomes are frequently collected from the peasants by mezzani or middlemen, and sent to some centre, such as Pontasieve or Leghorn, from which latter port it is sent in large quantities to England and other countries. The rhizomes are picked over and sold either as "scelti" or selected, or as "in sorte," or sorts, and vary very much in price in different seasons. This year the prices are advanced. Besides the whole rhizomes, the Pontasieve manufactory sells pieces or "frantumi," and raspings or "raspature" for the use of perfumery, the prices of which are of course ruled by the price of the whole rhizome. There is also a considerable trade in powdered orris, which, under the name of "ireos," is much sought for by strangers. The pharmacy of S. Maria Novella, at Florence, sells enormous quantities of the powder either plain or scented, so that the combination of perfumery with drug vending is by no means as English as we suppose, for in Italy it is of very ancient date; the same may be said of the manufacture of liqueurs, of which industry the Grande Chartreuse of Grenoble offers a striking example, which has served as a model to many a similar establishment throughout Europe. All the species of Iris are very hardy, and are cultivated chiefly on the wall sides of the terraced stony hills so frequent in Tuscany, or on the otherwise waste ground separating plots of ground in hilly districts, sometimes also it establishes itself on the waste ground contiguous to cultivated land or even in thin woods. The irides are by no means confined to Tuscany, but as a branch of industry their cultivation is not well known beyond it. On an excursion to the lake Thrasimene, I noted a large extent of an iris, which, although out of flower, appeared to me to be *I. germanica*, on the east end of the Isola Maggiore; and on remonstrating with the people for not turning it to account, they informed me the rhizomes were once collected, but could not be sold for want of the proper trimming. The plants flower in April; the *I. florentina* (which is some days later than the other two species), the tall *Iris pallida* with its pallid blue, and the more lowly *I. germanica* with its deep azure flowers, conspicuously gladden the springtide. It is in August that the rhizomes are harvested. They are so superficially set in the soil as to require little labour in uprooting, and, as they are dug up, a sufficient quantity of offshoots are selected each with a small portion of rhizome attached—a mere fragment suffices. These are set aside in the cellar or other convenient damp place, and kept until the cooler and more rainy month of October sets in, when they are planted in the cleared places, and speedily take root. It requires, at the least, two years for the plants to form another crop of rhizomes sufficient for removal. As soon as the rhizomes are taken up, they are deprived of their outer integuments either by peeling or scraping, and the denuded wood is carefully laid out in the sun, great attention being used to avoid bruising, which discolours the product when dried. The odour of the drug developes itself as soon as the rhizomes are thoroughly dry, and it is said that it continues to improve up to a couple of years, but this does not prevent the country people from selling the crop at once. Although the iris crop is comparatively a side product, it is of sufficient importance to be shared by the landowner according to the Tuscan system, which provides that the owner of the soil shall find the plant, and the contadino, or labourer, his toil,—the profit to be divided equally between them. A group of these small farms or poderi is overlooked by a fattore, or bailiff, on behalf of the owner, all purchase of implements or cattle being managed by him; happy is the man on whom he smiles, so great is his influence on the farm.

The severe frosts of last winter, whereby perished many thousands of olive-trees, besides other fruit and ornamental plants, have given us a clue to the present distribution of the orris plants, for on a visit with Mr. D. Hanbury, to one of the few spots where the three enumerated species flourish without cultivation, we found *Iris florentina* so nipped by the frost that the upper buds were entirely rotten, and the plants themselves so backward and puny as to present a lamentable contrast with the *Iris pallida*, whose tall, flaunting inflorescence, unlike the other two species, was quite double the height of the leaves. I have remarked that this species is to be seen planted higher up on the mountain side than the *I. germanica*, and this would seem to give it the preference for hardiness. The white papyraceous bracts of the *I. pallida* are very conspicuous, and offer a distinctive character in comparison with the *I. germanica*, which has the bracts less developed and of a green colour. The bracts of the Florentine orris would seem to have a texture between those of the other two, but are not larger than those of *I. germanica*. It is very difficult, perhaps impossible, to distinguish the fresh rhizomes of the different species, although, as Mr. Hanbury pointed out to me, the lobes of Florentine orris root, seem more cylindrical than the other species; moreover, it appeared to me, that the rhizomes were less forked than with the other species. In conclusion, I may state my belief that in some future time *Iris pallida* will become more extensively cultivated, as being the most hardy of the three species, and the one best suited to resist the cooler air of the mountains, or the scorching heat of the lower clevations.

Mr. Hanbury: I may be allowed just to say that I had the pleasure last spring of visiting, partly in company with Mr. Groves and partly by myself, many spots in the neighbourhood of Florence where these plants were growing. I also observed the distribution of the plant, and noticed how it was restricted to the neighbourhood of Florence. On going southward, or on going towards Ancona, one was very soon out of the district of iris cultivation. In fact, it appears quite confined to a comparatively small area of which Florence may be taken as the centre. What Mr. Groves says about the species is borne out by my own observations. He says that these three species are distinct, and that *Iris florentina*, which we have been accustomed to regard as the chief source of commercial orris root, is that which affords least of it. In fact, orris root may be said to be derived more from *Iris pallida* and *Iris germanica* than from *Iris florentina*.

Mr. Haselden: I cannot add anything to the history of the *Iris florentina* or *Iris germanica*; but I may make a few practical observations upon the rhizome of the iris which is supplied to us in the course of business. The employment of the orris root, as we commonly call it, is chiefly in the form of powder for tooth powders. Also it is largely employed by chemists and perfumers for making tincture and used as an adjunct, or, as it were, a vehicle for, other perfumes. There is this peculiarity about orris root—that, like some other perfumes that I may mention, musk, ambergris, and vanilla, it is almost impossible to exhaust it of its odour. Orris root contains, as far as my experience goes—(I have not gone into the matter very minutely)—a resinous gum, a mucilaginous gum, a large amount of starch, and, authors say, an essential oil. I have tried, but without success, to obtain that essential oil. An oil has been introduced from Germany as the essential oil of orris root, and at a very large price, but I am inclined to think that it is not the pure essential oil. In order to obtain the essential oil of orris root, distillation with water is the process. The difficulty with it is that it contains so much mucilage and so much starch that it is necessary to keep it constantly stirred before it arrives at the boiling-point, at which point the oil would come over. Unless it is kept constantly stirred, before it comes to the boiling-point it is almost sure to stick to the bottom of the still and become spoilt, or else it boils over. By making a tincture of orris root a strong perfume is obtainable by the employment of rectified spirits; but when distilled in order to get a colourless tincture, a large amount of the perfume remains behind along with the resin. The odour of the distillate is very faint. Water extracts a large amount of the perfume; but it is useless except as a substitute for common water in distilling for the oil. Orris root is used very much by fashionable people, as a preservative or, rather, as a corrective masticatory; and the custom, with those who are particular about it, is to have the orris root soaked in water and cut into very fine pieces and then dried; they carry it in the pocket, and use it as they require it. But I find that it is possible to get the odour of the orris root if distilled with some essential oil. I obtain a combination of the oil with which it is distilled with a strong odour of the orris root at the same time. It appears that some essential oils have the power of not only dissolving, but of positively extracting, and carrying over in the process of distillation, the odour of the orris root. There is, of course, a waste of the original oil in the operation, but still for any one who is curious in the perfume of orris, it is really one of the best ways of obtaining it. Macerate the orris root well in water, first of all; then slice it, and in that way the starch which abounds is less troublesome. There is no oil I know of which answers the purpose better than that commonly known as oil of geranium, the article used to adulterate otto of roses. In that way, with care, you may get over the original oil of geranium very strongly impregnated with the flavour of the orris root. That is the only way in which I have been able to obtain anything like oil of orris root. There is this peculiarity about orris. Like musk, it never seems to lose its odour entirely.

Mr. Umney: I rise not to make any remarks upon Mr. Groves's paper, but merely to set at rest the doubt which Mr. Haselden seems to have of the existence of essential oil of orris root. Having distilled during the past eight years several tons of the root, I can assure him such a body is to be met with in commerce, very much resembling in appearance cacao butter. The proportion of essential oil obtained is about one part from one thousand of the root. Professor Attfield will remember that some years ago he saw several ounces of it.

Mr. Hanbury: Is that the substance that is described as orris camphor in Gmelin?

Mr. Umney: It may be. I may remark that it is a very expensive oil, more so, perhaps, than otto of rose.

Professor Wayne asked whether the essential oil contained all the odorous principle of the orris root.

Mr. Umney: The essential oil dissolved in spirit has a very powerful odour.

The President: The question is whether there is any oil left in the residue after distillation.

Mr. Umney: I should say not, as distillation would be continued until the root no longer yielded oil.

Professor Wayne: I thought the odorous principle of orris root depended upon the soft resin more than upon the essential oil. I think it will be found that the soft resin contains the odorous principle, and that the odour of the essential oil depends upon its containing some of the soft resin accidentally.

Professor Attfield: Although I have every intention of examining into this question I have not done so at present. From what I remember I think the substance shown to me by Mr. Umney was probably a mixture of definite chemical substances.

Note on Guaiacol.

BY JOHN WILLIAMS, F.C.S.

In a recent number of the Pharmaceutical Journal (No. 92, third series, page 788) attention was drawn to the statement that creasote consisted mainly of a body called "Guaiacol" and which was a product of the destructive distillation of gum guaiacum. As this appeared to be a fact of some interest I determined to prepare a little of the substance and compare its properties with those of the ordinary creasote of commerce.

The process of preparing it is as follows:—Gum guaiacum reduced to powder is exposed in a shallow iron pan to considerable heat, sufficient to cause the commencement of charring, and until every trace of water is driven off. We thus avoid the frothing, which otherwise renders the distillation of the gum a very difficult matter. When the mass has been thus heated for some time it is transferred to an iron retort, furnished with a long iron tube, to act as a condenser. The heat must be increased gradually to low redness, and continued as long as any tarry matter continues to distil. In this way a product is obtained amounting to about one-third the weight of the gum employed.

This tar is again placed in an iron retort and distilled, when it yields about one-third of its bulk of a light brown oily liquid. This brown oil is treated with a solution of caustic soda, which dissolves a part of the oil, but leaves a considerable quantity which must be separated and rejected. The alkaline solution of the oil is now placed in a retort and subjected to prolonged distillation, water being added from time to time, to make up for that which distils over. In this way a quantity of light oily matter passes over, having a very offensive smell, and floating on water. This is to be rejected, and when no more oil is observed to pass over, the alkaline solution in the retort is diluted, and a slight excess of sulphuric acid added, by which means a dark coloured heavy oil is separated. This is distilled, and the oily product again treated with caustic soda and distilled as before, by which means a further small quantity of the light oil is separated. This alkaline solution on exposure to air soon turns of a very dark brown, almost black colour, and when an acid is added after a few days a very dark purple coloured oil is deposited. This oil distilled gives a light yellowish oily liquid, which after several distillations yields a colourless heavy oily liquid, which is the pure or nearly pure guaiacol.

Guaiacol is an oily liquid, considerably heavier than water; it is quite white when first distilled, but soon assumes a pale straw colour. Its smell is characteristic of creasote, but not so disagreeable as some of the samples of that body found in commerce. The sample I have made begins to boil at 200° C, and soon rises to 210°, at which point eight-tenths distil over, and the remainder comes over at 215°. Pure creasote is stated in the books to boil at 210°. Guaiacol refracts light strongly, and has the taste as well as the general physical properties of creasote. It is soluble in glacial acetic acid, but insoluble in pure glycerine.

It appeared interesting to compare this body with creasote as found in commerce, more especially as some attention has lately been drawn to the fact, that creasote is sometimes sold consisting mainly of carbolic or crysylic acid, or other products of the distillation of *coal* instead of, as it ought to be, of *wood*.

In commerce we find two kinds of creasote, said to be derived from wood, one well known in England, manufactured by Messrs. Morson and Son,—which I shall call "English" creasote—is said to be made from Stockholm tar, and if so, is the product of pine-wood probably. The other, of German manufacture, is said to be the product of beech-wood. Of the common German coal-tar creasote, I have made no especial note, but have employed pure carbolic acid in all cases to represent the coal tar or phenylic product.

English creasote commences to boil at 100°, but almost immediately rises to 213°, at which about six per cent. passes over; the temperature then rising to 216°, at which about 34 per cent. passes over; then to 222°, when about 34 per cent. again distils, and then rises to 231°, when 16 per cent. is obtained, the remainder distilling at a still higher temperature. We thus find that this is a hydrated product, and that its boiling-point is considerably higher than the proper boiling-point of creasote as represented by Guaiacol.

German creasote commences to boil at 200°, gradually rising to 220°, 40 per cent. comes over under 203°, 34 per cent. at 210°, and 16 per cent. under 220°, thus boiling rather lower than it should for pure creasote, but apparently not containing much of the higher homologues.

Carbolic acid boils at 180°, and, when pure, its boiling-point is quite constant.

English creasote is insoluble in pure glycerine, as stated by Mr. Morson, in the Pharmaceutical Journal, No. 99, page 921.

German creasote is soluble in glycerine.

Carbolic acid dissolves in glycerine in all proportions.

As I have before stated, guaiacol is not soluble in glycerine; it therefore became of great interest to find out, if possible, why the German creasote should be soluble, and thus differ from the guaiacol and English creasote, more especially as I found that the addition of, say 50 per cent. of carbolic acid to either guaiacol or English creasote, causes them to become perfectly soluble in glycerine. It thus becomes very important that we should, if possible, devise a mode of detecting the presence of carbolic acid in pure creasote.

For this purpose recourse was had to Professor Flückiger's process as described in Pharmaceutical Journal, No. 103, page 1008. It consists in adding creasote (or carbolic acid) to a very small quantity of perchloride of iron in solution, then adding alcohol and afterwards diluting considerably with water. If carbolic acid alone is employed a beautiful blue colour is produced, but if creasote, a dingy brownish liquid is the result. Now this test distinguishes between pure creasote and pure carbolic acid perfectly, but when I attempted to use it as a means of detecting the presence of carbolic acid in creasote it quite failed, the brown creasote reaction quite masking the blue produced by the carbolic acid. I tried various proportions, and in no instance could I obtain a reaction I could depend upon, 50 per cent. and even 100 per cent. of carbolic acid mixed with English creasote or guaiacol being quite undistinguishable. Professor Flückiger distinctly states that his test enables us to detect the presence of carbolic acid in creasote, but I cannot agree with that statement; in my hands, at least, it does not answer.

In a recent number of the 'Chemical News' a test was given by means of bromine. When bromine water is added to an aqueous solution of carbolic acid, a white oil is speedily deposited, but when it is added to an aqueous solution of pure creasote or guaiacol, a brown oil is the result. This test, however, fails, as might be expected, to distinguish carbolic acid when mixed with creasote; in all cases a brown oil is deposited, which is useless for the purpose we have in view.

Strong solution of ammonia dissolves carbolic acid readily (the solution turning blue after a few hours' exposure to the air) while guaiacol and creasote (both English and German) are only partially soluble, or at any rate would require a very large quantity of ammonia to effect complete solution. I found German creasote to be much more soluble than either guaiacol or English creasote, namely, one-half dissolving without much difficulty, when treated with about six times its bulk of strong liquor ammonia.

The English creasote so treated did not lose above one fourth of its bulk.

The portion of creasote insoluble in the ammonia was separated; the ammoniacal solutions being diluted and neutralized with acid, also deposited the creasote which had been dissolved. These different samples were examined carefully.

The English, which had dissolved in ammonia when distilled, smelt better and more like guaiacol than the original sample of creasote before treatment; it also boiled nearer 210°, all distilling under 220°.

The portion which did not dissolve in ammonia when distilled, yielded a liquid which had a much more offensive smell and appeared to contain more of the impurities of the original creasote than the soluble portion; its boiling-point was, however, lower and almost identical with the first portion. Both samples were insoluble in glycerine. The German creasote, which did not dissolve in ammonia, retained its old boiling-point, but no longer dissolved in glycerine. The portion soluble in ammonia was carefully examined; its boiling-point was found to be almost the same as the normal creasote. Its smell was good; almost identical with guaiacol, but it was soluble in glycerine. Attempts made to detect the presence of carbolic acid quite failed.

Other means were then tried to procure evidence of the presence of carbolic acid in creasote.

It is stated in the paper first referred to (Ph. Jour. No. 92, p. 789), that while the phenol series yields with nitric acid trinitrophenol or picric acid, guaiacol or creasote yields only oxalic acid. If this were true, we might hope to detect the presence of picric acid, and thus prove that carbolic acid had been contained in the creasote.

To determine this point, the creasote to be examined was first dissolved in about twice its weight of glacial acetic acid, and then added to an equal bulk of strong nitric acid, sp. gr. 1500. (If the creasote to be examined is added direct to the nitric acid, the action is so violent and unmanageable that no definite result can be arrived at). The capsule containing the mixture must be placed on a sand bath, and evaporated almost to dryness. When pure carbolic acid has been used, the product is a bright yellow crystalline mass (pure picric acid), but in the case of guaiacol or creasote (both English and German), the product is a brown, sticky, semi-resinous mass. This product, treated with a little hot water, is transferred to a large test tube or small retort, and a gramme or so of ordinary bleaching powder added, and a gentle heat applied, the result being the production of chloropicrin if picric acid is present, which can be distinguished without doubt or difficulty by its most peculiar and repulsive smell, or can be separated by distillation if thought necessary; but if oxalic acid is the product of the reaction, no chloropicrin is produced, but simply a liberation of chlorine. I am sorry to say that in all my trials I obtained chloropicrin, and not a trace of chlorine, and all other attempts made to isolate oxalic acid from the product of the reaction of nitric acid upon guaiacol or creasote having quite failed I have come to the conclusion that the statement respecting the different products obtained from creasote and carbolic acid by oxidation is incorrect. Picric acid, or some isomer of that body, is the product of the reaction in all cases, irrespective of the source of the creasote (or carbolic acid) being from coal-tar or from wood.

Attempts were made to distinguish between carbolic acid and creasote by the production of sulpho-conjugated acids. But the acid produced by creasote appears to be too much like the sulpho-carbolic acid for anything like a distinguishing test to be founded upon that reaction.

I regret that the results of my experiments are of a negative rather than of a positive nature, but I trust, unsatisfactorily as they confessedly are, they may prove of service to any one who may wish to follow up the examination of the true nature of creasote.

There is, I think, no doubt that the English creasote is a genuine product of wood tar. It is, however, not a homogeneous body, but probably consists of several isomeric substances; while the fact of the German (beech-wood) creasote dissolving in glycerine led me to suspect the presence of carbolic acid, but all my attempts to demonstrate its presence have quite failed, and I can only conclude that beech-wood tar yields a creasote to a certain extent different to that yielded by either guaiacum or pine-wood tar. In some of its chemical properties German creasote much nearer approaches guaiacol than the English; its smell is almost identical, and its boiling-point very much nearer and more constant.

When English and German creasote are dissolved in strong caustic soda, and then diluted, the English becomes milky, and yields, when distilled, an appreciable quantity of light oil; the German, on the contrary, remains bright and yields no oil, which would tend to prove the German to be in some respects a purer article than the English.

The fact of the German creasote dissolving in glycerine ought to be explained, either by proving that beech-wood creasote really possesses this property, or has obtained it from some peculiarity in the mode of manufacture.

It would be very interesting to examine some of Reichenbach's original creasote, if an authentic sample could now be obtained; perhaps some member of the Conference may be able to assist in this matter.

To Mr. Myles Smith, our chemical assistant, I must express my best thanks for many of the suggestions, and nearly the whole of the experiments here detailed have been performed by him with great care and accuracy.

Mr. Morson: Our attention has naturally been called to the extensive sale of carbolic acid under the name of creasote; and we are very well satisfied to find that by the mixture of glycerine we have had some chance of detecting it. We have examined some specimens from German sources, and we have invariably found them to dissolve in glycerine, and we have also found that there is a peculiar coloration in all the creasote so prepared—a tendency to a red coloration, whilst in all pure creasote, or what we consider to be so, the tendency is to become brown. This is excessively remarkable; for some which is designated as pure white creasote, and which I obtained from an excellent source in Paris, though perfectly white became perfectly red in the course of about three months, and is perfectly and entirely soluble in glycerine, even in a diluted form. In an American journal some observations are made on the short notice written by my son on the subject; and they state that no doubt our experiments are made with diluted glycerine. Such, however, is not the case. They were made with Price's glycerine, which, I think, can hardly be called diluted glycerine. You have only to add a few drops of this substance to find out that carbolic acid in all its forms is perfectly soluble in glycerine, and that most readily. Creasote we have prepared for 40 years. We take the heavy oil of tar, and separate the light oils by frequent saponification with oil of vitriol, and ebullition. We distil it in a concentrated form. We do not distil it in glass, for it breaks the retorts very readily, until you get rid of the whole of the water, and requires a very high temperature for the process. We have constantly pursued one process, and never had difficulty. Of course, the introduction of carbolic acid has interfered with it. It is strange that Gerhardt was perfectly acquainted with it. He says, "Le substance qu'on vend dans le commerce sous le nom de créosote n'est souvent que l'acide phénique plus ou moins impure. Mais le véritable créosote, extrait de goudron de bois par M. Reichenbach, est un corps parfaitement distinct, et c'est à cette créosote que le vinaigre de bois, l'eau de goudron, la fumée de bois, doivent leurs propriétés antiseptiques." It is a curious thing that carbolic acid and creasote act very differently as preservatives of animal matter. There are instances in which that will be found to be the case. Creasote preserves in a very different way from carbolic acid. There is another fact which should not be lost sight of, and that is, that if you mix carbolic acid with creasote, the mixed body is perfectly soluble in glycerine, and even in comparatively diluted glycerine. When it contains half its weight of water, it will still dissolve carbolic acid. Consequently, the observations made in the American journal as to diluted glycerine do not in the slightest degree apply. Professor Flückiger speaks of anhydrous glycerine. That is a body I am not acquainted with; but I suspect—in fact, I know—that much that is described as beech-wood creasote is nothing but carbolic acid, and is not derived from wood. I make this observation because some of the so-called beech-wood creasote becomes red, and that is quite a characteristic of carbolic acid.

Mr. Stoddart: I should like to ask Mr. Morson a question which I have not been able to get solved. Some few years ago, a naturalist, who was going to Australia, went into a shop in London to get some creasote; and all the things that he put into the bottle and brought back from Australia were preserved admirably. You could dissect them, or do what you like with them, and they did not disintegrate. He then took them out, and put them into fresh creasote, and, to his utter astonishment, all the things disintegrated.

Mr. Morson: He got pure creasote first, and carbolic acid afterwards.

The President: The fact is, that pure creasote has a very different sort of antiseptic power from carbolic acid. That is very well known amongst zoologists and anatomists, who I find generally prefer pure creasote for preserving specimens of animal tissues.

Mr. Morson: When creasote is distilled with water and so perfectly saturated, this solution is very efficient in preserving objects of natural history.

Tincture of Perchloride of Iron.

BY MR. T. H. HUSTWICK.

So many complaints having been made as to the unsatisfactory character of this preparation, and so many alterations suggested in its formula, is proof enough that considerable revision is needed to make it an acceptable article to those who have to do with it.

Of the suggestions that have appeared in the Pharmaceutical Journal for improvements in the formula, one was an addition of a certain proportion of glycerine, another, a reduction of the quantity of spirit; the objection to the first of these is too patent to call for remark, and to the second, it is that the reduction is not carried far enough, for so long as alcohol is left so long will there be a liability to change.

Now the spirit being useless, either chemically or medicinally, for no medical man orders the tincture from any therapeutic value possessed by the spirit, but simply, as I believe, from pure force of habit; and it also having been pronounced by competent authority to be "useless, unnecessary and detrimental," I think we are justified in expunging the tincture from our Pharmacopœia and abolishing it in our practice.

Acting on this idea, for two years past I had completely abandoned the use of tincture, the liquor being invariably substituted in its place. Prescriptions wherein tincture was ordered, and which had been previously dispensed at other establishments, were prepared by me with the liquor, the substitution in no case giving rise to any difference either in taste, appearance, or any other particular, while, for retailing, it also has completely taken the place of the tincture.

I do not exactly like tampering with official formulæ, but would prefer, where they are unmistakably objectionable, if possible, to ignore them altogether.

As to the legality of such a substitution as this, though it cannot be held to be exactly and strictly correct, still I think an educated pharmacist who thoroughly understands what he is about, should not be tied down by a Medo-Persian law in such a case as this, where an elegant, stable, and inexpensive compound is made to displace one that is inelegant, unstable and costly; such a change causing no difference whenever used.

These are my own opinions strengthened by experience, and I should like to elicit an opinion from those who have had more experience than myself, and if anything said here to-day on this subject can induce our medical friends to prescribe a good article in the place of a bad one, I, for one, shall be abundantly satisfied.

Mr. Schacht: I think some of the difficulties which are supposed to surround this preparation are more fanciful than real, and can be very easily indeed surmounted. I think the changes that sometimes annoy us in the tincture are limited to one cause, and that is the absence of chlorine in the preparation in sufficient quantity, and that that arises very likely from the fact that the quantity of nitric acid ordered in the Pharmacopœia is beyond what is necessary, and consequently after the oxidation process is completed, during the evaporation which follows, a large proportion of chlorine is naturally driven off. I certainly take this liberty with the Pharmacopœia process, that instead of adding the whole quantity of nitric acid there ordered, and heating until there is the exhalation of red fumes, the acid-protochloride is heated and the nitric acid added gradually. The evolution of red fumes in that case occurs long before the nitric acid is all added. After that, I cease to add further nitric acid and the evaporation is then not attended with so much loss of the chlorine element. Since I adopted that plan some three years ago, I have never found any trouble arising from change in tincture made from liquor so prepared.

Mr. Giles: It appears that one gentleman who has spoken has taken a liberty with the Pharmacopœia, and I have taken another. I think it is very important that the formula should exist in a form in which it can be practised. I made the tincture according to the new Pharmacopœia one day, and I have never repeated it. I did not try to find out the why and the wherefore.

Mr. Umney: I was about to confess that I also have taken a liberty with the Pharmacopœia. The excess of nitric acid is about 25 per cent. over the theoretical quantity that should be required; and I have used about 5 per cent. in excess of that required by theory, and I have reduced to a minimum the chief complaint—that of sending out the tincture on a large scale with the smell of hyponitrous ether by the action of a large quantity of nitric acid on spirit of wine. When the smell is so prevalent, I have noticed the peculiar appearance described by Mr. Glaisyer. Perhaps it is that some of the salt is reduced into the ferrous state. It certainly has that peculiar colour which we notice in testing for nitrous acid.

Professor Attfield: Irrespective of the presence of nitric acid or nitrate of iron, there is an action between the perchloride of iron and the alcohol. That action commences as soon as the tincture is made, and goes on slowly, varying in rate according to the position occupied by your specimen in relation to light, until ultimately, after some years, in many cases, the whole of the ferric salt is reduced to ferrous chloride. And inasmuch as this always takes place, though the rate varies, I conceive that we should prefer to use, wherever we can legitimately do so, the aqueous solution of perchloride of iron, rather than the spirituous one; and as I have never heard, though I have made many inquiries amongst medical men, that the tincture is really supposed to be of any great therapeutic value over the liquor, we may hope that in time we may produce such an impression upon medical men that they will use the liquor.

Mr. Hanbury: But so long as there is a tincture ordered in the Pharmacopœia, I hold that we are bound in honesty to use it.

Mr. Sutton: I quite agree with Mr. Hanbury. Only last week I had brought back to me a bottle half full of tincture of perchloride of iron. It had become thick and disagreeable in appearance; and, in fact, the change had taken place by its standing six weeks. The customer said that she could not take it. I have no doubt that the real effect produced is similar to that of the reducing action of alcohol upon chromium salts, only in the case of iron it is very much slower.

Professor Attfield: The body produced is a chlorinated ethereal body. I am not quite sure which, but it is an ethereal body.

Mr. Groves: I believe there are two classes of action which take place. If the liquor contains too small a proportion of chlorine, a very speedy reaction occurs, and a sub-salt is thrown down. If the liquor contains an excess of acid which it ought to have in order to be permanent, then, after a lapse of greater time, an ethereal action occurs, and you get quite a different affair. In either case the result is unfortunate. I suppose every one here is in the habit of doing what I do, of keeping the *liquor ferri*, and mixing it when required.

Professor Markoe: The practice of the United States provides for a proportion of muriatic acid, added purposely with the intention of gradually developing or forming muriatic ether. We all take especial pains not to dispense the tincture of chloride of iron until it has acquired the distinct odour of muriatic ether. I have forgotten what is the percentage in excess of muriatic acid, but it is added purposely; and we have two preparations—the simply watery solution and the tincture—which are used distinctly by physicians.

Professor Attfield: I should say that the remarks which have fallen from Professor Markoe seem to suggest that an important agent introduced into pharmacy and the practice of medicine would be the old German tincture, which is, I believe, a solution in which the per-salt of iron has disappeared altogether. It is a light green liquid, which you may obtain quite easily by putting your bottle of tincture of perchloride of iron out in the sunlight for a few months. You will then get the maximum instead of the variable proportion, which, I suppose, would always be present according to the practice of pharmacy in America.

Mr. Reynolds: This preference for the ethereal flavoured tincture is not confined to America. I have standing instructions from one physician always to use such a tincture in preference to one that has not the flavour of ether. I suppose we must regard the reason to be not that the physician considers the ethereal flavour to have any special medicinal quality, but that it makes it a somewhat more elegant remedy. If it be not stable and permanent, it is quite desirable, of course, that we should have a tincture free from that objection.

Mr. Haselden: I have never, I believe, taken a liberty with the Pharmacopœia, but I have taken a liberty with my customers. When the present form of tincture of perchloride of iron was first introduced, it was quite impossible (at least I found it so) to make the preparation, or to buy a preparation that was suitable for those who before had been used to the tincture of perchloride of iron, or muriate of iron of the London Pharmacopœia. Well, having no new preparation which was satisfactory, what was to be done? I could only supply that which had been supplied before, and which was perfectly satisfactory to the patients and the medical men with whom I came in contact. Having found this old preparation approved of by both these parties, and not being able to get a good preparation from the new Pharmacopœia, I have continued to use, up to the present day, the old tincture of muriate of iron. That, I believe, is an efficient preparation. If made according to the London Pharmacopœia, a saturated solution is obtained, and the addition of the spirit really makes no difference either in appearance or effect. It has, as far as I know, always been a satisfactory preparation to my customers. We talk about an aqueous solution. I dare say the solution might be better adapted for some cases, but medical men sometimes order two drachms of tincture of perchloride of iron, or muriate of iron, and at the same time 14 drachms of tincture of cinnamon. If simple tincture of cinnamon and tincture of muriate of iron are mixed, a tolerably fair mixture is obtained; but if water were used, decomposition of the tincture of cinnamon would result. Therefore, before recommending very strongly an aqueous solution, I think the matter should be well thought over and well tested, and it should be tried whether that would be really a better product than the old preparation.

Researches on the Constituents of Aloes.

PART I.—BY WILLIAM A. TILDEN, D.SC. LOND., F.C.S.

On a former occasion I had the honour of presenting to the Conference the results of some experiments which I had made upon the constituents of aloes, and an investigation of the action of alkalies upon those substances, chiefly with regard to the changes which have been observed in several pharmaceutical preparations. The object of the present paper is to bring together all the facts that have been established with reference to the chemical composition and properties of the proximate constituents of aloes, including some new experiments which I have been assisted in carrying out by the able co-operation of Mr. Edward Rammell.

The various kinds of aloes met with in commerce are, of course, well known to consist of the inspissated juice obtained from a peculiar stratum of vessels in the leaves of different species of *Aloë*. It is said that the juice which exudes from a freshly cut leaf is comparatively pale in colour, but that it speedily becomes brown by exposure to the air. There can be little doubt that this change which commences thus early in the aloetic liquid advances much further before the inspissation is complete, whether that operation is performed with the aid of artificial or solar heat, or whether the evaporation proceeds spontaneously. In the peculiar semi-fluid, socotrine aloes, frequently met with in commerce, the alteration is less marked than in the other solid varieties, for this substance may be looked upon as consisting mainly of crystallized aloïn and the resinoïd matter; and these two substances may, I think, be regarded as the two primary constituents of all the varieties of aloes.

My own experiments have been conducted chiefly with the Barbadoes variety, because I have found that practically that is the best source from which to prepare in quantity the crystalline principle which I venture to call for the sake of distinction "Barbaloin." The process I employ for that purpose has been already described. (Year Book of Pharmacy, 1870).

The researches of Flückiger, which were communicated last year to the Conference, have shown that the crystalline substance met with in Natal aloes, and probably also that of the Zanzibar variety, is totally different from "Barbaloin," which occurs not only in Barbadoes but in Socotrine and Cape aloes. Though the composition of these crystalline bodies is not representable by the same formula, there can, however, be no doubt that they are analogous in constitution.

All the different varieties of aloes then may be represented as consisting of mixtures in various proportions of the following proximate constituents:—

1. Aloïn and products of its decomposition or change.
2. Resinoïd matter.
3. Accidental ingredients, *e. g.*, gum, albumen and salts, to which there will be no necessity to allude further.

Aloïn.—The barbaloin, isolated originally by Messrs. T. and H. Smith, and examined by Dr. Stenhouse, possesses the formula $C_{34}H_{36}O_{14}.H_2O$, but in the water-bath loses the molecule of water. It is characterized by its comparatively ready solubility in alcohol, from which it crystallizes in tufts of yellow prisms; by giving, when moistened with strong nitric acid, a transient red colour; by furnishing, with excess of bromine water, a yellow precipitate of brom-aloïn; and by giving, by prolonged digestion with nitric acid, a large quantity of chrysammic acid. I have recently found (Journ. Chem. Soc. [2] x. 204) that by acting upon barbaloin with chlorine in the presence of concentrated hydrochloric acid, a chloro-derivative may also be obtained, which crystallizes readily in tufts of beautiful prisms. It has the formula $C_{34}H_{30}Ce_6O_{14}.6H_2O$.

No attempt has been made so far as I am aware to explain the constitution of barbaloin. It seems to me, however, to possess all the characters of a complex phenol. Thus it gives with ferric chloride a dark olive coloration; it furnishes a sulpho-acid, the barium salt of which is soluble, though not crystallizable. It also gives the chloro- and bromo- substitution derivatives just alluded to, and when acted upon by nitric acid it yields two nitrated acids, viz., picric and chrysammic acids. The latter is evidently a derivative of anthraquinone, inasmuch as it is the sole product of the nitration of chrysophane from rhubarb, and from that body anthracene has been obtained. Hence barbaloïn most probably contains two groups each containing C_{14} and one C_6.

The action of acetyl chloride has not yet been tried, but so soon as the number of hydroxyl groups in barbaloïn is known it will be possible to write for it a constitutional formula.

The products of the alteration of barbaloïn existing in ordinary crude aloes comprise anhydrous, non-crystalline aloin and oxidation products. These have already been fully described in my former paper.

Nataloïn is obtained from Natal aloes, and was first discovered by Professor Flückiger, and described in his paper last year. I have found that when previously purified by crystallization from alcohol, it furnishes large and distinct crystals by deposition from water; and I am indebted to Mr. F. J. Hanbury, at present studying in the Laboratory of the Pharmaceutical Society, for valuable assistance in preparing beautiful specimens of this body. I have submitted nataloïn to combustion, and obtained numbers which lead to the formula $C_{25}H_{28}O_{11}$.

		Theory.		Experiments.
C_{25}	300	59·52	(I) 59·59	(II) 59·53
H_{28}	28	5·55	6·07	5·86
O_{11}	176	34·92	———	———

And this formula is supported by the composition of the acetyl derivative $C_{25}H_{22}(C_2H_3O)_6O_{11}$ which I have also succeeded in obtaining.

		Theory.	Experiments.
C_{37}	444	58·73	58·54
H_{40}	40	5.29	5·38
O_{17}	272	———	———

Nataloïn is characterised by its crystalline form, rectangular plates, by its comparatively limited solubility, and by giving with nitric acid a blood-red coloration which does not fade unless heat be applied; also by giving no definite bromo-derivative, and lastly by furnishing, under the influence of nitric acid, no chrysammic, but only picric in addition to oxalic acid.

It was formerly stated that aloes contained a glucoside. I can only say that my own experiments contradict this. This matter was referred to in my former paper. I have only now to add that the experiments there described of boiling pure aloïn with sulphuric acid and water, has been extended to Barbadoes and Cape aloes with the same negative result. Sugar could in no case be detected in the liquid by the fermentation test.

PART II.—BY WILLIAM A. TILDEN, D.SC. LOND., AND EDWARD RAMMELL (*Bell Scholar*).

Resin of Aloes—When almost any kind of aloes is exhausted by successive treatments with cold water, a curdy yellowish-brown substance remains as a residue, which is commonly known as resin of aloes. In preparing extract of aloes according to the directions of the Pharmacopœia, the same substance is deposited in a fused state as the solution is allowed to cool. It then has the aspect of a soft, dark-brown, elastic, sticky matter, which gradually hardens and becomes brittle in the course of time. It is obvious from its solubility in water that it is not a resin in the usual sense of the word, and it will be found in fact that, by repeating the action of hot water once or twice, a considerable portion of it may be taken up and rendered permanently soluble so as to resemble very closely the rest of the extract. We have made some experiments upon this substance, the material operated upon being the "resinoïd" from a very fine sample of Barbadoes aloes and a second specimen from Socotrine aloes, for which we are indebted to Mr. T. B. Groves, whose valuable experiments on aloes are well known.

The resin in both cases consisted of the matter which had been deposited in the course of preparing extractum aloes B. P., and which had further been subjected to a washing with warm water.

This resin was exhausted by repeated boiling with distilled water, acidified by a few drops of acetic acid; the solution was filtered through paper in a funnel surrounded by boiling water, and the filtrate which had a clear sherry-colour was then acidified more strongly by the addition of hydrochloric acid and set aside in a covered vessel. In a few hours the resin which had been deposited was collected, drained from the mother-liquor and washed with cold water. In this way we had effected the analysis of the original resin into two portions, one of which, A, was soluble in hot water; the other, B, insoluble. The latter was much darker in colour than the former. They were both further purified by dissolving in rectified spirit, filtering, and evaporating to dryness, a temperature of about 220° Fahr. being maintained until the substance ceased to lose weight.

We had conceived the idea that the so-called resin of aloes was a product of the condensation of the crystalline principle, generated by the abstraction of the elements of water from that substance.

This view was supported by the undoubted fact already alluded to, that by repeated washings a portion is rendered permanently soluble, and, on the other hand, that pure aloïn heated for a long time on the water-bath is partly resinified.

Experiments with the soluble resin A.

Three combustions were made in oxygen gas, the substance being weighed in a platinum boat which was introduced into the combustion tube behind a long column of granular oxide of copper.

1. From Barbadoes aloes—
   ·2968 of substance dried as in all the following experiments at 220° Fahr. left ·0003 ash, and gave ·670 CO_2 and ·1510 H_2O.
2. The same.
   ·3162 gave ·0005 of ash, and ·7115 CO_2 and ·154 H_2O.
3. Socotrine.
   ·3275 gave ·7260 CO_2 and ·1680 H_2O.

These data correspond respectively to the following percentages:—

	(1)	(2)	(3)
C	61·60	61·46	60·46
H	5·65	5·42	5·69

Considering the nature of the substance analysed, these numbers agree with each other satisfactorily.

A portion of the resin to which the analyses (1) and (2) refer was dissolved in rectified spirit, and the solution deluged at once with bromine water in excess, A precipitate formed which was collected, washed, and dried in *vacuo* over sulphuric acid. The bromine in it was determined by heating in a sealed tube with nitric acid and silver nitrate.

·3145 gave ·302 Ag. Br.

corresponding to

40·85 per cent. of Bromine.

Now, assuming this resin A to have the constitution which we believe we have a right to assign to it, its formula would be

$$C_{68} H_{70} O_{27}.$$

That is to say two molecules of aloïn *minus* a molecule of water.

$$2 (C_{34} H_{36} O_{14}) - H_2O = C_{68} H_{70} O_{27}$$

The percentages of carbon and hydrogen required by this formula are given below, together with the experimental numbers—

		Theory.	Experiment. 1	2	3
C_{68}	816	61·91	61·60	61·46	60·46
H_{70}	70	5·31	5·65	5·42	5·69
O_{27}	432	—	—	—	—

And the formula of the brominated body would be $C_{68} H_{58} Br_{12} O_{27}$.

	Theory.		Experiment.
C_{68}	816		
H_{58}	58		
Br_{12}	960	42·36	40·85
O_{27}	432		

From this comparison it will be seen that, so far as composition is concerned, our view is completely confirmed.

Further evidence which seems to be conclusive was obtained by heating a portion of the resin with water in a sealed tube to 300° F. for several hours; when cold the tube was opened, the solution filtered from the undissolved residue and evaporated to a syrup. It could not, however, be made to crystallize.

This was perhaps to have been expected, contaminated as it was with a considerable quantity of resinous impurity. But by adding bromine water to a part of the solution a yellow precipitate was obtained, which, when dissolved in alcohol and left to spontaneous evaporation, furnished crystalline tufts which were visible under the microscope.

By boiling a portion of the same substance for several hours with dilute hydrochloric acid in a flask from which the air was excluded, a larger portion was rendered permanently soluble. The solution was strongly bitter and gave a precipitate with bromine water.

We also found that when resin A was boiled with nitric acid, a large quantity of chrysammic acid was formed, together with picric and oxalic acids and carbonic anhydride. It yielded the same products, in fact, as are obtained from barbaloïn under the same circumstances.

We thought it likely that, conversely, crystallized barbaloïn would be readily converted into resin by the action of dehydrating agents, but we found that on heating it with chloride of zinc, or with concentrated hydrochloric acid in sealed tubes, till on gradually raising the temperature a change was visible in the contents of the tube, the condensation seems to proceed at one step too far, and the result is a black insoluble pulverulent matter which we have not yet examined further.

The previously recounted experiments appear, however, to establish the view that that portion of the resinoïd matter of aloes which is soluble in hot water is a kind of anhydride of aloïn standing in the same relation to the crystalline substance that ether does to alcohol, or, as recently shown, that tannic acid bears to gallic acid. In both cases a crystalline body is converted by condensation and the loss of the elements of water into an uncrystallizable body.

$$\underset{\text{Gallic Acid.}}{2 (C_7H_6O_5)} - H_2O = \underset{\text{Tannic Acid.}}{C_{14}H_{10}O_9}$$

$$\underset{\text{Barbaloïn.}}{2 (C_{34}H_{36}O_{14})} - H_2O = \underset{\text{Aloe Resin A.}}{C_{68}H_{70}O_{27}}$$

One practical conclusion that may be drawn from these experiments is, that in preparing extract of aloes, the quantity of product may be much augmented, probably without deterioration of its quality, by treating the deposited resin several times with water.

Experiments with the insoluble resin B.

This substance purified in the manner already described was analysed by combustion in oxygen gas as in the last case.

1. Barbadoes
   ·2980 gave ·6795 CO_2 and ·1520 H_2O.
2. Barbadoes
   ·3225 gave ·7410 CO_2 and ·1635 H_2O.
3. Socotrine
   ·3410 gave ·0015 ash, and ·7710 CO_2 and ·1670 H_2O.

Calculating from these data, the percentages of carbon and hydrogen are as follows:—

	1.	2.	3.
C.	62·18	60·27	61·94
H.	5·66	5·63	5·46

It will be seen in these analyses that the numbers obtained are not perfectly concordant, and this might in fact be almost expected from the indefinite and changeable character of the substance operated upon. Moreover, it is possible that we may not have been wholly successful in removing from it traces of foreign matters soluble in rectified spirit. Nevertheless, we incline to the belief that the composition of this substance is more nearly represented by the numbers obtained in the first and third analysis than by those of the second. And we regard it as not improbable that this insoluble part of the resin may result from the simultaneous oxidation and condensation of crystallizable barbaloïn. Suppose, for instance, two molecules of barbaloïn to lose a molecule of water, and at the same time four atoms of hydrogen:

$$2 (C_{34}H_{36}O_{14}) - H_2O - H_4 = C_{68}H_{66}O_{27}.$$

The formula to which such an hypothesis would lead would be

$$C_{68}H_{66}O_{27},$$

and would require percentages of carbon and hydrogen, which in the following table may be compared with those obtained experimentally:—

	Theory.		Experiment. 1.	2.	3.
C_{68}	816	62·10	62·18	60·27	61·94
H_{66}	66	5·02	5·66	5·63	5·46
O_{27}	432	—	—	—	—

We by no means consider this view established, as in the nature of the case it would be very difficult, if not impossible, to indicate by any analysis of a substance of this kind, a change so small as would be represented by the loss or gain of a few equivalents of hydrogen. But the few facts we have at our disposal seem to show certainly that the insoluble part of aloe-resin is not a product of simple condensation. Thus, when heated with water to a high temperature as described in the former case, a portion is rendered soluble, but it differs in appearance and character from the soluble substance into which resin A is converted by the same treatment. Moreover, when treated by nitric acid the amount of chrysammic acid produced is very much smaller than in the case of resin A.

It is somewhat interesting to observe that if the mean of the numbers obtained in our analyses of these two be compared with the mean of the numbers obtained by Stenhouse in the analysis of anhydrous barbaloïn, we find them approach each other so nearly as almost to coincide. The theoretical numbers calculated from the formulæ exhibit the same relation. It is, however, to be noticed that taking them in the order in which they stand, there is a gradual increase in the proportion of carbon. The reason of this has been already pointed out.

Experimental Numbers.

	Aloin, average Stenhouse.	Resin, A, soluble in hot water.	Resin, B, insoluble in hot water.
C	60·63	61·17	61·46
H	5·57	5·58	5·58

Theoretical Numbers.

Calculated from the formulæ.

	$C_{34}H_{36}O_{14}$	$C_{68}H_{70}O_{27}$	$C_{68}H_{66}O_{27}$
C	61·07	61·91	62·10
H	5·38	5·31	5·02

The President: I am sure, gentlemen, it must be a cause of great satisfaction to every one here that one of the Bell scholars should, in conjunction with Dr. Tilden, bring this valuable contribution to our pharmaceutical work. This increases my regret that the time does not permit us to do justice to work so excellent.

Mr. Smith: It might enhance the value of the paper just submitted that there should be an expression of the opinion of one who has worked up a very large quantity of aloes. The results which we have arrived at in the manufacturing thoroughly corroborate the character of the resin just referred to. We have not gone into the analysis as exactly as the gentleman who has read the paper, but our practical experience on a very large scale thoroughly corroborates his observations.

A Cheap Disinfectant.

BY E. C. C. STANFORD, F.C.S.

Some of the popular disinfectants have such an offensive odour of their own that an odourless substance will generally secure the preference for ordinary household purposes. We have several harmless, cheap, and odourless disinfectants amongst the alkaline and other chlorides. I have recently experimented on several of these to ascertain which is the most powerful, and, at the same time, the cheapest. That highly popular substance known as Chloralum was used also for the sake of comparison. The experiments lasted thirty days, and the times noted were those when mildew and offensive odour first appeared. The chlorides were each mixed in the proportion of 2 per cent. and 5 per cent. with urine. In the second experiments a mixture of equal parts of blood and water with the clot removed was used, and the chlorides added in the same proportions.

Mixtures with Urine, 2 per cent. Salts.

	First appearance of mildew.	First appearance of offensive odour.
Chloralum	4 days	6 days
Chloride Iron	none	none
„ Calcium	15	none
„ Sodium	4	8
„ Potassium	4	5
„ Ammonium	4	23

Mixtures with Urine, 5 per cent. Salts.

Chloralum	4 days	6 days
Chloride Iron	none	none
„ Calcium	25	none
„ Sodium	4	8
„ Potassium	12	none
„ Ammonium	none	7

Mixtures with Blood and Water, 2 per cent. Salts.

Chloralum	11	none
Chloride Iron	26	none
„ Calcium	18	none
„ Sodium	5	6
„ Potassium	5	6
„ Ammonium	none	12

Mixtures with Blood and Water, 5 per cent. Salts.

Chloralum	11	none
Chloride Iron	none	none
„ Calcium	18	none
„ Sodium	4	5
„ Potassium	4	5
„ Ammonium	none	13

It will be seen that the most powerful of all is the Chloride of Iron; the simplest and least powerful is the Chloride of Sodium. The cheapest, in proportion to its power, is the Chloride of Calcium. This substance is a waste product in all alkali works, and the quantity at present thrown away is enormous; I now propose it for general household use as a convenient, colourless, harmless, and cheap disinfectant. I propose to use it in the form of solution containing 25 per cent. of the solid salt, and acidified with 12 per cent. of Hydrochloric Acid. This increases its power and is a harmless addition. I found about the same proportion in liquid Chloralum. Compared with liquid Chloralum in deodorizing sewage it was found to be about four times the strength, and it can certainly be produced for half the price.

The sample of powdered Chloralum used in the urine and blood experiments was found to contain about 3 per cent. of Chloride of Iron, which accounts for part of its deodorizing property. I was first led to notice the disinfecting power of Chloride of Calcium by using it in urinals. There is always great difficulty in keeping urinals in houses free from offensive odour; this is entirely obviated by putting a lump of Chloride of Calcium in the urinal; it lasts a long time, as it dissolves very gradually, and keeps the urinal perfectly free from odour.

For general household purposes, however, the liquid form is more convenient, and I propose to give the combination I have described the name of Chloricalcium, which is shortly and sufficiently descriptive of its composition.

Mr. Schacht inquired whether the author considered it necessary that the article should be so strongly acid for commercial use as it was described to be. The reason he asked the question was, that in his endeavours to keep portions of his own house sweet and odourless, he had used materials which had tended to destroy the pipes. It appeared to him that the presence of a very large proportion of free muriatic acid in the disinfectant would make it rather difficult of application for closet purposes.

Mr. Groves expressed the same opinion.

Mr. Stanford, in reply, said: My experience is confined principally to the use of the soluble chloride of calcium. It may surprise many when I tell them that such an extremely deliquescent substance as chloride of calcium will stand for months when it is put in a large lump. The acid is added to this disinfectant because it is an advantage to have an acidified solution, as most of the odours contain ammonia or some volatile alkaline body. It is not in the least necessary, for chloride of calcium alone is a far better disinfectant than chloride of aluminium alone, and is by far the most powerful and the cheapest.

The President: You use the fused chloride of calcium of course?

Mr. Stanford: Yes.

Election of Officers.

On the motion of Mr. Giles, seconded by Mr. Allchin, the following officers were elected by ballot for the ensuing year—

President.

H. B. Brady, F.L.S., F.C.S., Newcastle-on-Tyne.

Vice-Presidents who have filled the office of President.

H. Deane, F.L.S., Clapham Common, S.
Professor Bentley, F.L.S., M.R.C.S., 17, Bloomsbury Square, W.C.
D. Hanbury, F.R.S., F.L.S., Clapham Common, London, S.W.
W. W. Stoddart, F.C.S., F.G.S., Bristol.

Vice-Presidents.

T. H. Hills, F.C.S., London.
J. Williams, F.C.S., London.
R. Reynolds, F.C.S., Leeds.
F. M. Rimmington, Bradford.

Treasurer.

G. F. Schacht, Clifton, Bristol.

General Secretaries.

Professor Attfield, Ph.D., F.C.S., 17, Bloomsbury Square, W.C.
F. Baden Benger, 1, Market Place, Manchester.

Assistant Secretary.

John Moss, F.C.S.

Local Secretary.

R. Parkinson, Ph.D., Bradford.

Editor of the Year Book.

C. H. Wood, F.C.S.

Editor of the Transactions.

Professor Attfield.

Other Members of the Executive Committee, 1872-3.

M. Carteighe, F.C.S., London.
T. B. Groves, F.C.S., Weymouth.
F. Sutton, F.C.S., Norwich.
C. Ekin, F.C.S., Bath.
T. Greenish, F.C.S., London.
W. D. Savage, Brighton.
C. Umney, F.C.S., London.
F. C. Clayton, Birmingham.
M. Rogerson, Bradford.

Auditors.

Mr. Collins proposed, and Mr. Husband, of Exeter, seconded a motion appointing Mr. Brew, of Brighton and Mr. Hick, of Bradford, as auditors.

Carried unanimously.

Mr. Morson moved—"That the cordial thanks of this assembly and the non-resident members be given to Mr. Savage, Mr. T. Glaisyer, and the other members of the Local Committee for their most successful efforts in organizing the present meeting." He said that the non-resident members of the Association would be unanimous in returning their thanks to the members of the committee who had provided for them so handsomely and treated them so well.

Mr. Bamford: The uniform kindness that I have met with at Brighton has led me to accept the duty of seconding this vote, which I do with great pleasure. I am sure that you all feel it to be well merited, and I can say no words which would present that view more clearly to you.

Professor Attfield: I should like just to support the resolution. In previous years I have had to state to the Conference how greatly I have been helped in my office of secretary by the local committee, more especially by the permanent officers of the local committee, in the town where we have met. I can say nothing of the kind this year, simply because the local committee have had the whole of the arrangements, and I have had nothing whatever to do with them. To the local committee is due the whole credit.

The motion was carried unanimously.

Mr. Savage, in reply, said that these members of the local committee, whose names had not been mentioned in the resolution had taken an active part in the arrangements.

Mr. Ince: Gentlemen, I have very great pleasure in moving a vote of thanks to the Town Council of Brighton and the Pavilion Committee for the use of this room. I am sure I need say nothing further about this, because it is a resolution which commends itself to you all. I do not recollect that we have ever been under equal circumstances as far as accommodation is concerned, though, I believe, at Bath we were under similar circumstances as to architectural beauty.

The resolution was seconded by Mr. Schacht, and carried unanimously.

Mr. Savage said that as there was no member of the Town Council present, he might state that the Pavilion Committee had most readily, upon his application, placed one of the best rooms of the building at the disposal of the Conference, both for the meetings and the supper.

Mr. Betty moved that the thanks of the Association be presented to Mr. H. B. Brady for acting as President at the present gathering. He said that he felt unable to do justice to the urbanity of manner and the talent which had been displayed by the President in the discharge of his onerous duties.

Mr. Greenish seconded the motion.

Mr. Hanbury, in supporting it, said that he was sure that the chair could not have been filled in a more able manner than on the present occasion.

Carried by acclamation.

The President: Gentlemen, for some weeks past this meeting has been upon my mind like a night-mare. If ever there was a decision of this Association which I felt disposed to question, it was that of the meeting at Edinburgh, when the election of officers was under consideration. I felt my inability to do what the president of this large Conference ought to do, and during the course of its proceedings the same thing has been constantly in my mind. So far from feeling that the meed of praise which my friend Mr. Betty has awarded me is my due, I tell you honestly that I was prepared to apologize for the apparently arbitrary way in which I have been compelled on one or two occasions, especially to-day, to conduct the business of the meeting. In many ways it is a painful thing to find good papers before you, and gentlemen present capable of thoroughly discussing them, and then to have to give a mere *résumé* of the paper, and forego the discussion altogether in consequence of the want of time. If I have seemed in any way discourteous in this respect, I assure you that it has been only with a view to geting through the business in something like reasonable time. For those personal expressions which you have used I can only thank those who have utterred them and those who appear to have endorsed them. It seems to be your pleasure that I should continue another year in this office; I should have been glad to have been excused from the duty, not on account of any indisposition to serve the Conference, which I have loved from the beginning, but from the feeling that you have so many amongst you who are so much better able to undertake the somewhat onerous duties which fall to the lot of yonr president.

The proceedings then terminated.

ERRATUM.—In the President's remarks on Pill Coating at p. 213 in last week's Journal, *read* Bullock and Crenshaw *for* Burke and Trinshow.

Parliamentary and Law Proceedings.

A Fatal Mistake.

An inquest was held on Thursday evening at the Cambridge Hotel, Woolwich, on the body of an infant named Mary Dixon, who was accidentally poisoned.

Rose Dixon, widow of James Dixon, tailor, of 3, Mary Ann Cottages, Frances Street, said that deceased was her daughter and her age was seven weeks. She was bringing her up by hand, as she had to take a situation in service, but had not yet transferred her to the care of any one else. She only arrived from Ireland on Sunday week, and the journey made the child ill and feverish. She therefore sent for a James's powder, as a cooling medicine, and the messenger returned saying that the druggist had none, but had given another little powder, which she was to give the baby. She administered it on Monday afternoon, and on the middle of the next day the child was very ill. Five minutes after she had given the powder she saw printed on the inside of the powder "Stedman's teething powder," and Mrs. Styles went directly to the druggist, who advised her to give the child plenty of warm water to make it vomit, and also gave her a dose of medicine for it, and told her to keep it awake. She did so, although it was very drowsy, and next morning the child seemed better, but got worse during the day. She saw the druggist several times with the child, and paid him 2*s.* 6*d.* for a visit and his services to the child. When she found on Tuesday that the druggist was not a doctor, she taxed him with being not qualified, and he referred her to Dr. Hughes, who came on Wednesday. She did not tell him what the child had taken, thinking that the druggist had informed him, and the same night the child died. The druggist charged her nothing for the medicine he gave the child.

Margaret Styles, the wife of an artilleryman living in the same house, said the last witness was acquainted with her in Ireland, and came to her at Woolwich. Witness had often been to the druggist, Mr. Shipman, in Frances Street, for her child, and on Monday went for a James's powder for Mrs. Dixon and a Stedman's powder for her own child. He said he had not a James's powder, but gave her one which he said was of a cooling nature. Her own baby was nine months old, and she told the druggist its age. She had always used Stedman's powder, because she had been told that it kept away little fits. He gave her the powders in separate packages, and told her to be sure not to make any mistake by exchanging them. They were both in the same coloured paper, and there was no label or writing outside either. After the baby had taken the one powder they saw "Stedman's powder" printed on the inside wrapper, the outside paper being white.

Mr. Geo. Virgo Shipman, chemist and druggist, of 2, Frances Street, said he was registered by the Pharmaceutical Society. He served the last witness with the two powders, pointing out the printed label on the Stedman's powder and cautioning her to be most careful not to make a mistake. The baby's powder was not labelled at all, and both were in outer wrappers of white paper, but he had told the woman expressly that the one with the printed label on was for the elder child.

The Coroner said it would have been better to label both the powders. And there was another serious question affecting Mr. Shipman. How came he, being a non-qualified practitioner, to attend the child and treat the case.

Mr. Shipman said he went in a friendly way.

The Coroner said the law was now very stringent on the subject. A druggist might give advice as a friend, but he must not undertake the management of a case.

Mr. Shipman said in that case if he saw a fellow-creature bleeding to death, he supposed he must not stop the bleeding.

The Coroner: Every case must be judged by itself, and in that case it would be inhuman to refuse any help in your power; but here you have been attending upon a patient for two days like a qualified doctor, treating the case yourself and charging a fee; and not until the child was dying did you recommend any other assistance.

Dr. Hughes said he attended the child on Wednesday afternoon between two and three o'clock, under an order from the parish. Nothing was said about the urgency of the case either when he was sent for or when he got to the house. He saw that the child was dying from severe narcosis—as he supposed from opium; but the women said it was only diarrhœa. He was not told anything about the mistake which had occurred, and asked where they got their medicine. They told him Mr. Shipman's, and he went there, where he learned for the first time what had happened. The case was hopeless, and the child died the same night. He had since made a *post-mortem* examination, and found the child very badly nourished—in fact, he might say starved. It had been brought up on a feeding-bottle—the greatest curse for babies that ever existed. ("Hear, hear," from the jury). He did not think the child would have survived the dose even if it received the best attention, for its life was on the flicker, and the least thing was enough to put it out. Stedman's teething powders were composed of calomel, opium, sugar and starch. No child under a year old ought to take opium, except under very extraordinary circumstances. Stedman's teething powders were altogether a different thing from Steedman's soothing powders, which were an old-established and harmless medicine.

Mr. W. F. Smith, of 280, Walworth Road, said he appeared for the proprietor of Steedman's Soothing Powders, a tried preparation of fifty years' standing, prepared by Mr. Steedman, of Walworth. The powder given to the child was not one of these, but a different preparation called Stedman's Teething Powder—the two being entirely different.

Mrs. Styles, re-called, said she asked for Stedman's Teething Powder, and got it.

The Coroner pointed out that the Stedman's Teething Powder administered to deceased was only printed on one side, and Mrs. Styles might have opened it from the plain side without turning it over. The child having been brought up by hand, was very weakly, and very little would kill it, especially after a sea voyage. He believed that Mr. Shipman duly cautioned Mrs. Styles; but he thought he did wrong in charging 2*s.* 6*d.* for attending the child, the Act being strict in that respect. He also thought it would have been better to have got a doctor the moment the mistake was discovered. It would also have been better to have put one powder in blue paper and the other in white.

The jury considered the administration to have been accidental, and returned a verdict to that effect.

Correspondence.

Examination Fees.

Sir,—I have read the communication from Mr. Vizer, which appeared in the Journal for August 31st, under the above title; and, while ready to acknowledge that Mr. Vizer evidently wishes to advance the best interests of the Society, I am, nevertheless, of opinion that some of the recommendations put forth in that letter are founded on fallacies. I will, therefore, examine a few of his statements by the test of published official documents, as I am confident that if I succeed in showing them to be incorrect or imperfect, no one would be more ready than Mr. Vizer to acknowledge the service.

Passing over matters of opinion, which it is not my object to discuss; it is sufficient to remark that Mr. Vizer says he desires now "to see a radical change brought about in the examination fees," the object being to induce persons to join the Society who at present hold themselves aloof. In developing his argument, he says, "unfortunately the advantages of membership, as viewed by outsiders, are so few that a very small proportion only of those who aspire to the higher grade of pharmaceutical chemist deem it necessary or desirable to join themselves to the Society as members; the result being that our strength as a Society is yearly decreasing, whilst the numerical, and therefore political, strength of outsiders is largely increasing." To this I take exexception, first, as to pharmaceutical chemists; and, on reference to the Registrar's Reports, as to members, associates and apprentices for the years 1870 and 1871, it will appear that there is here a series of mistakes. We learn from these reports that in 1870* only 63 persons passed the Major examination, but that 84 persons were elected to membership as pharmaceutical chemists for the first time, besides 13 who were restored, giving a clear increase on the year, after deducting deaths, secessions, etc., of 19. In 1871† the number passing the Major was 50, while the number elected to membership as pharmaceutical chemists for the first time was 63, and 6 were restored. So that in these two years there were 166 pharmaceutical chemists elected to membership, against 113 persons who passed the Major examination. Nor must it be forgotten that of this 113 some probably are connected with the Society as Major Associates, and are not reckoned in the 166.

Next, as to whether it be true that "our strength as a Society is yearly decreasing, whilst the numerical, and therefore political strength of outsiders is largely increasing." In 1870 the number of persons who passed the Minor examination, and therefore the total number by which the numerical strength of outsiders could have been increased, was 199; a number insufficient to fill the vacancies in the Register caused by death, even if none had joined the Society. On the other hand, the clear increase in the numerical strength of the Society was,—pharmaceutical chemist members, 19; chemist and druggist members, 179; associates in business, 60;‡ associates not in business, 170; total, 428.

In 1871, again, 234 passed the Minor, but the net increase to the strength of the Society—excluding apprentices as before—was 269. So that while the additions to the entire body of chemists and druggists during the two years were only 433, insufficient to maintain a *statu quo*, the numerical strength of the Society was increased by no less than 697, that of the outsiders being at least equally decreased.

If we take the statistics another way, the result is no more favourable to Mr. Vizer. In 1870 there was a net increase of associates of the Society amounting to 230. Deduct from these 150, as representing those who had only passed the Modified examination, and we still have not only all the vacancies filled, including those among Modified men elected associates, but a clear increase of 80 men with the Minor qualification, showing that a large proportion of the 199 who in that year passed the Minor compulsorily also joined the Society voluntarily. Again, in 1871 the net increase, after deducting 141 Modified men, was 46.

I will not discuss here the probability of Mr. Vizer's theory, that men not induced to seek the title of "pharmaceutical chemist" by the possible benefits attached to it, would be overcome by the offer that they should be excused paying subscriptions, especially if that privilege were purchased by an increase of seven guineas in fees and loss of the Journal. This, and the anticipated financial benefit to the Society, are fair matters of opinion that could be discussed at another time; and I pass on to the next statement put forward as one of the facts upon which Mr. Vizer's theory is founded. He says that "the Journal account has always formed a sore point in the annual statement, showing a considerable loss to the Society." I am aware that there is an impression to this effect in the minds of a few persons, but there is not the least foundation for it. In fact, there have been years when the Journal has been a source of revenue to the Society. If Mr. Vizer will refer to the annual balance sheets, he will find in proof of this, that in 1865 the cost of furnishing free copies to members, which had been decreasing for some years, was extinguished, mainly through the exertions of Mr. Mackay, and there was an actual surplus of £50. 10*s.* 8*d.* In 1866 this surplus was increased to £218. 5*s.* 5*d.*; in 1867 to £296. 14*s.* 7*d.*; in 1868 to £332. 4*s.* 7*d.* In 1869, by the great increase in the number of members, after the passing of the Pharmacy Act 1868, and the issue of an index to twelve volumes, which cost £99 13*s.* 6*d.*, there was a charge incurred of £31. 18*s.* 8*d.* In 1870, when the present weekly series commenced, the balance sheet showed a large sum against the Journal; but apart from the inevitable expense and loss attendant upon such a change, that was due principally to the fact that a large sum on the advertisement account did not become payable from the publishers until after the close of the year.

In the balance sheet for 1871 there is a sum of £164. 9*s.* 7*d.* charged against the Journal, and I expect to see this sum reduced to a nominal amount if the Council will, as in former times, leave the management as far as possible to those who, taking a real interest in the Journal, understand it best. But I maintain it to be wrong altogether to regard that deficit as a loss, for it represents the actual cost of some 6000 Journals weekly, including about £500 a year for *postage*, and if the Journal account were credited with a proportion, say only half, of the publishing price for each copy supplied free, as, I believe, is done in the case of the American 'Journal of Pharmacy' by the Philadelphia Society, the apparent deficit in the balance sheet would be transformed into an apparent gain of more than two thousand pounds. In the face of these facts, and considering that the proceeds of the Journal are actually sufficient to pay for 6000 copies weekly and more than two-thirds of the postage, while the Society's announcements are thus made *gratis*, and the Society's interests promoted without expense, it cannot fairly be said that the Journal account shows "a considerable loss to the Society."

As to the benefits which Mr. Vizer thinks would result from making a charge for the supply of the Journal, his statements before being discussed would require to be supported by detailed explanations as to the way in which the abandonment of the free issue of the Journal would be advantageous to the readers or to the Society as proprietors. Speaking generally on this point, my conviction, is that even if the balance against the Society were very much larger than £164 per annum, the members would not sacrifice so powerful an engine for the defence of our interests, as a weekly journal must necessarily be.

‡ Doubtless Mr. Vizer is aware that a person who has passed the Minor examination is eligible to join the Society as an associate, and to exercise, when in business on his own account, all the privileges appertaining to membership, except that he cannot hold office as a councillor or examiner.

Dr. John Muter, Ph.D., F.C.S., writes to declare that in the school under his direction no such process as that described by Professor Attfield is in operation. Dr. Muter also expresses his approval of the Society's examiners.

Communications, Letters, etc., have been received from several correspondents, but owing to want of space we are compelled to defer the replies until next week.

PHARMACEUTICAL EDUCATION AND EXAMINATION.

BY PROFESSOR REDWOOD.

I am unwilling to allow the discussion of the subject introduced by Dr. Attfield at a meeting of the British Pharmaceutical Conference to pass without offering some remarks which I had no opportunity of making at the meeting. I consider the subject one of the deepest interest and importance to the Pharmaceutical Society—one, in fact, which more perhaps than any other affects the prosperity of the Society, and the interests of British pharmacy. The Pharmaceutical Society occupies a position with reference to the education and examination of those who are legally authorized to carry on the business of chemist and druggist, which, while it constitutes its highest function, invests it with considerable power and influence, and imposes upon it great responsibility. The complaints which have been so frequently, and not unjustly, expressed from time to time during the last thirty or forty years, of the low state of pharmacy in this country, of imperfect qualification among those engaged in its practice, of increased competition, small returns, and diminished profits, may find a practical remedy for the evils complained of in the judicious exercise of the influence and control which the Society can exert over the future members of the trade. But with the powers conferred upon the Society there are corresponding responsibilities. The primary object of legislation is the good of the public, not merely of a section of it, excepting as this may result indirectly or without detriment to the mass. Happily the interests of the pharmaceutical body, as a section of the public, and of the public at large, have points of coincidence enough to render the furtherance of one consistent with that of the other, and this is especially the case with reference to questions of pharmaceutical education.

The new features introduced into the discussion at Brighton, in connection with those on which the opinions of pharmacists had been previously asked by the Council, give to the subject-matter a wide and comprehensive range, which appears to be favourable to the successful and judicious disposal of the various propositions that have been made.

The whole subject may be comprised within the scope of the following questions :—

1. What is the nature of the education required for the qualification of those to whom the practice of pharmacy is entrusted ?

2. By whom and in what way should the education we require be provided ?

3. What is the best method of testing the qualifications of those to whom certificates giving the right to practice pharmacy are granted ?

The first question appears to demand something more than the mere consideration of means by which a qualification for the practice of pharmacy may be supplied. It would be easy to suggest a curriculum of education that would furnish the knowledge required for such qualification, but there are circumstances surrounding the question that must be taken into account—conditions that have to be fulfilled, and obligations that are due to those directly affected and to those indirectly affected by the law. In fact, we must consider the requirements of the law, the obligations moral as well as legal of the existing race of students, and the interests of the public.

The requirements of the law are pretty clearly defined in the Pharmacy Acts and the bye-laws of the Pharmaceutical Society. There are two compulsory examinations to be prepared for and passed —the Preliminary and the Minor—the Major examination being optional. I entirely agree with those who urge the importance of the former of these, and of its being passed at the commencement of pharmaceutical pupilage. No part of the ordeal to which students are subjected is more calculated than this to exert a beneficial influence on the future condition of the pharmaceutical body. It may be used as a lever by which to raise the status of the chemist and druggist without inflicting hardships or entailing disappointments, which are otherwise liable to occur. The amount of scholastic knowledge indicated by this examination should be a sufficient guarantee of ability, both mental and financial, to pursue the subsequent studies with effect. The law does not indicate at what period of pupilage this examination should be passed, excepting that it shall precede the Minor examination, but probably a bye-law making the fee proportionate with the time that has elapsed after the commencement of technical studies might accomplish the desired object.

The Minor examination indicates the nature of the knowledge required by law for the chemists' and druggists' certificate. It is not a high qualification, but it is a thoroughly practical one. It was not originally intended as the qualification of a man engaged in business on his own account, and the Pharmaceutical Society is not responsible for its having been made so. This was an act of the Legislature, and on several occasions a strong feeling has been manifested in Parliament that the qualification for this certificate should not be raised above that of the Minor examination. It would, I conceive, be inconsistent with the duty of the executive body to deviate from the spirit of the law while this remains as it is.

The subjects involved in the Minor examination and the extent of knowledge implied by the description of it given in the bye-laws, appear to me to be such as a young man of average ability, with the scholastic acquirements indicated by the Preliminary examination, ought to be able to acquire in a three or four years pupilage with a competent master, and attendance during part of the time at lectures or classes for systematic instruction. Even without lecture attendance, if the pupil be properly guided in his studies, he may, as many do, successfully prepare for this ordeal. I hope, however, as increased advantages are offered, and brighter prospects presented to those who pass, that a greatly increased proportion of our students will be induced to aim at a higher distinction than that of barely fulfilling the requirements of the law. It should be the aim and desire of all to go beyond this, and many do so, but many also, I am sorry to say, from want of zeal, ambition, prospective advantage or means, do just as much as the law requires and no more.

There are obligations of an ethical nature by which students should be induced to consider, not merely the requirements of the law, but the interests of the profession to which they belong, and, could they discern it, their own interests also, which are involved in the efficient performance of their professional duties. These obligations cannot be too strongly insisted upon; but it must at the same time be admitted that there are circumstances affecting many of the present race of students which claim for them a special indulgence. Many of these have been induced to enter upon the study of pharmacy with little school knowledge, and unprepared for the necessity of incurring further expense than that of their appenticeship to enable them to pursue the business of a chemist and druggist as their future livelihood. They have found themselves suddenly placed in a critical position not previously contemplated, with examinations to pass for which they were unprepared, and the preparation for which involves expenses they can ill afford. Is it matter of surprise that many of these should seek to bring themselves within the requirements of the law by the easiest process? The moral obligations of this class can hardly be measured by the standard we may hope to see applied to those who shall succeed them.

Then with regard to the interests of the public; these seem to demand that there should be to some extent a gradation of qualifications among chemists and druggists. The conditions are so different under which the business has to be conducted in different places, that it would be unreasonable to expect the same qualification in all those who are engaged in it. There are many country towns and villages the inhabitants of which are supplied with the medicines they require by men who rarely, if ever, see a prescription, and to whom a knowledge of analytical chemistry would certainly be unremunerative if not useless, but who, like Lord Elcho's dealer in mousetraps, may be profitably applying a kind and amount of knowledge such as their position requires, and which is not inconsistent with that position. It is from this view of the subject, no doubt, that the objection has arisen which has been urged against fixing a higher standard than that which is comprised in the statutory qualification of a chemist and druggist.

The law defines the minimum qualification, and it certainly is not very exacting. It leaves much to voluntary effort, to the influence of public opinion and combined action, by which so much has already been effected.

It might have been expected that our educational arrangements would require some modification to meet the altered circumstances resulting from recent legislation. That the means which, during the last thirty years, have been employed, under an exclusively voluntary system, for promoting and providing pharmaceutical education, should prove insufficient, and should be considered unsuited in charactrer as well as extent, for the accomplishment of what is now required, does not necessarily imply that those means were inappropriately or unwisely devised at the time when they were called into operation. That they have been incomplete, and in some respects insufficient, has resulted from conditions under which they were established; but they have nevertheless been productive of much good which could hardly have been effected in any other way.

It cannot be denied that existing arrangements, as applied to the whole body of chemists and druggists, are defective, and very insufficient for the accomplishment of what could be desired, or indeed, of what the law demands. This may be admitted without detracting from the credit due to those who have provided and those who are using such means as the course of events has called into requisition. Whatever has been done, and is now doing, in the way of systematic education, is so much in advance of what was done thirty years ago. During that period we have made steady progress, and I cannot admit that there has been within the interval anything like a retrograde movement. Yet, looking to the future, it is obvious that much remains to be done.

It appears to me that the circumstances affecting the future are so far different from those of the past, that it will be necessary to entirely remodel our educational arrangements. I look to the application of the Preliminary-examination-lever, together with the *esprit de corps* which our association in Bloomsbury Square is calculated to promote and maintain, for the means of establishing a system of education, both central and provincial, more adequate to the wants of the student-class, more conducive to the advancement of the interests of pharmacy, and more consistent with the principles upon which such a provision ought to be founded, than any now existing in this country.

A sound pharmaceutical education should be both practical and systematic. Much of the former can only be acquired at the retail and dispensing counter of a pharmaceutical establishment. The latter is best acquired through lecture instruction and systematic laboratory work. The education should commence with apprenticeship or pupilage with a pharmaceutical chemist or chemist and druggist, capable of imparting a general knowledge of the mode of conducting business, and the special knowledge of medicines, their preparation and the art of dispensing them. During this period of pupilage opportunities will be afforded of studying chemistry, botany and materia medica from books, and probably in some instances, to a greater or less extent from attendance at lectures. But the instruction thus acquired is often fragmentary and incomplete. A few lectures on chemistry or botany may tend to create a taste for scientific study, and may communicate valuable matter for which lecture illustration is necessary; but the student will find it difficult by mere reading, with occasional attendance at short courses of lectures, to acquire a sound and general knowledge of subjects so comprehensive as those of chemistry and botany. Hence the importance of having schools with extended and well illustrated courses of lectures, in which the subjects in a connected, systematic and sufficiently complete form, are explained and illustrated, the matter being as far as possible made applicable to the particular uses to which the students intend to apply it.

In establishing such schools there are two objects, the fulfilment of which should be especially aimed at. One is, that in every case provision should be made for complete and thorough instruction in all departments of knowledge required for the highest qualification in pharmacy; and the other is, that the schools should be self-supporting.

All the objections that are urged against the sort of superficial teaching called cramming, may with equal justice be applied to any attempt at teaching chemistry and the allied branches of physics, botany and materia medica, as these should be studied by qualified and accomplished pharmacists in short courses of lectures with imperfect means of illustration. It must not be understood, however, that I object to such lectures, which are often the only ones available; neither do I object to the use by students at a certain period of their studies, of short condensed treatises, sometimes called cram books; nor, under certain circumstances, to the services rendered by qualified tutors in guiding the pupil in the path he should pursue, and testing his knowledge as he proceeds. It is not the use of these means that is justly subject to condemnation, but the abuse of them; and what I think should be particularly guarded against is that such teaching should be represented and considered as anything more than partial aids to the furtherance of a more comprehensive and complete system. I would not honour with the name of a school, for our purpose, any establishment that was not provided with the means of giving complete and thorough instruction to pharmaceutical students. Let such schools be established wherever they can be maintained, or rather, I should say, wherever they can maintain themselves, in an active and efficient state. I see no reason why they should not be self-supporting and very good reasons why they should not be mere sucklings of the Pharmaceutical Society.

Then, it may be asked, is the Pharmaceutical Society to be exonerated from all charge and responsibility with regard to pharmaceutical education? I should be the last to make such a proposition. But this brings me to the consideration of the question,

By whom and in what way should the education we require be provided?

With reference to this question it is important to notice that the contemplated education is not merely for the apprentices and pupils of members of the Pharmaceutical Society, but for all future practitioners in pharmacy, including the pupils of those, three-fourths of whom are unconnected with the Society. Neither is the education referred to the whole, but only a part, of that which is required for the qualification of a chemist and druggist. It is the part supplementary to that which for a money consideration is stipulated for in the apprenticeship or pupilage, which should, if it does not, always form the commencement of a complete pharmaceutical education. To the extent to which the knowledge obtained during apprenticeship is deficient, that which is supplied by class or school teaching must be capable of filling up what is wanted to complete the statutory qualification. One part of this education is as necessary as the other. The whole as indicated by the test examination is the guarantee of proficiency given to the public in return for exclusive privileges.

It is no longer a question as to whether scientific knowledge is requisite or not. The time has been when it was not so, when all the druggist thought it necessary for him to do was to satisfy an imperfectly informed public that he knew enough to enable him to supply them with what they wanted in his line of business. But that time is passed. Enlightened and disinterested members of the trade, desirous of elevating the position of their calling, and at the same time of furthering the interests of medicine and the safety and welfare of the public, initiated a new era in which a more complete education was provided. Hitherto the Pharmaceutical Society, with whom the proposition originated, has been almost exclusively chargeable for the establishment and maintenance of the supplementary education thus offered. It was a new and untried experiment in this country, the predicted advantages of which were disbelieved in by many, nay, by most, even of those immediately and directly interested in it. This education has been supplied at a merely nominal charge to those who have partaken of its benefits, the Society defraying the principal part of the expenses from its own resources. The circumstances under which this system was first introduced rendered this mode of offering it at a discount the only one by which it was thought that a full and fair trial of it could be ensured. It has now been tried and approved. That which at the commencement was a speculative and not a popular system, is so far sanctioned and demanded by law, that without it the requirements of the law cannot be fulfilled.

The education for a qualification to practice pharmacy, with its contingent expenses, is the premium imposed by Parliament upon the privileges it has conferred on those to whom the practice of pharmacy is entrusted. Parents who propose to train up their sons to this occupation have no more right to expect relief from the expense of the latter or supplementary part of the education than they have from that of apprenticeship itself. The Pharmaceutical Society has not yet been asked to subsidise apprentice fees, but hitherto it has to a great extent subsidised the supplementary education supplied in its own school, and it is now called upon to extend the same or some equivalent assistance to other schools.

I agree with those who think that the subsidising of our schools, under existing circumstances, is not the method best calculated to ensure their maintenance in a healthy, vigorous, efficient, and permanent condition.

I would not exonerate the society from all responsibility with reference to our school arrangements. The great and important educational work which the society originated, and by the accomplishment of which it has acquired a well-merited reputation, the real basis of its present power and influential position, will continue to claim from it the fostering care of a parent. The society has obtained the means of making educational establishments independent, and it cannot confer a more important benefit upon them than by rendering those means available through the judicious exercise of its influence.

The principal cause of weakness and dependence in our school arrangements is the insufficiency of the fees charged for lecture attendance. The practice of charging such low fees arose from a desire to encourage education and to extend as far as possible the influence of the means so laudably provided at the expense of promoters, not partakers, of these benefits. At one time pharmaceutical students had free admission to the lectures and even a bonus offered in addition, in the shape of prizes. That was the time of hottest competition between the supporters of ignorance and indifference on one hand, and a combination of good men seeking to improve the position prepared for their successors on the other hand. We have heard of competition between rival stage coaches, the proprietors of which have lowered the fares until at last they have carried their passengers for nothing, and I have even heard of a spirited competitor, who, in such a case, has offered to give a bottle of wine into the bargain. The promoters of pharmaceutical education and advancement have acted upon a somewhat similar principle, but with a much better motive to justify their conduct.

Now, is it necessary to perpetuate the system of subsidising our schools? Can we not make them independent? Treating them as the offspring of the Pharmaceutical Society, would it not be the natural solicitude of a parent to see them capable of taking care of themselves? Yet a just and judicious parent, after petting and spoiling a child, and making it dependent on home for all its resources, would not at once cast it off without capital to start with on its own account, or any remunerative occupation on which to depend for its future support. The society under the pressure of circumstances has made the business of pharmaceutical education an unprofitable one. It has spoilt the education market, and it owes it as an imperative duty alike to teachers and students, to endeavour to put the process of school teaching on a more satisfactory footing before withdrawing the support it has hitherto so liberally afforded.

Why should pharmaceutical students expect to have expensively illustrated lectures provided for them at a charge of 2½*d.* a lecture while the usual charge for similar lectures elsewhere is about two shillings? At the Government school of Mines, a school established at considerable cost to the Government, and conducted on terms not illiberal to students, the fee for attendance at forty lectures on inorganic chemistry is £4, or at the rate of two shillings a lecture; whereas the fee for attendance at more than a hundred lectures delivered in the school of the Pharmaceutical Society on chemistry and pharmacy and the physics relating thereto, is twenty-one shillings, or at the rate of two pence-halfpenny a lecture.

It may be questioned whether at any time it was sound policy to depreciate in this way the value of lecture teaching, by charging fees which are so utterly at variance with those usually charged, and so disproportionate even to the bare cost of their production. Our two-penny lectures are no doubt often estimated at the value we attach to them, and the society that provides them at considerable sacrifice and expense is barely thanked for its liberality. But admitting that there was sufficient justification for the course originally adopted in providing lectures at a cost to the students which left them no excuse for not availing themselves of such means of instruction, the same thing cannot be said with reference to the future. The law now renders education necessary, and those who provide it are entitled to be paid a fair value for the benefits conferred in meeting the demand thus created.

It is neither just nor fair, since the occasion for it has ceased, that we should continue the practice of underselling in the lecture-market. We have not done so with our practical classes, and it has been shown that as regards mere current expenses, *they* can be made self-supporting. May we not hope to see the lecture classes put, perhaps not suddenly, but gradually, upon an equally satisfactory footing?

I think it is the duty of the Society to endeavour to accomplish this object. It would be a manifest injustice to throw the burden of an unprofitable undertaking on to the professors, and to expect them to take the responsibility of providing education for a class of students who have been led to believe that it would be supplied to them at merely nominal fees.

I do not even think, if the Society could and should bring about such a change in regard to lecture arrangements as would assimilate the fees with those charged for similar lectures in other schools, that it would be practicable to meet all expenses from this source, that is, to pay for premises, and stock-in-trade, as well as to meet current expenses, out of the fees paid by students. Something must be done in the way of endowment. Our practical school in Bloomsbury Square was liberally endowed by Jacob Bell, in addition to what has been done for it by the Society. The lectures in the same school may also be said to be endowed, by the stock of apparatus and specimens in the museums and elsewhere, and the premises, the use of which is supplied by the Society. Without these where and what would the school be?

But here a question presents itself. It may be asked, how can we approve of endowment, and at the same time condemn subsidisement? I think there is a wide difference between them which justifies our doing so. Endowment gives strength, while subsidisement represents and engenders weakness. The one is capital indicating power, and the other is pension indicating dependence, and implying deficiency of energy or renunciation of effort. All our best schools are endowed, but not subsidised.

I cannot conceive it possible to establish schools such as we require without endowment. What have we been doing for the Chicago College of Pharmacy? And have we not stronger claims at home, for the endowment of schools for our own students?

It appears to me that there are two objects the Society ought to aim at, namely, first to establish a scale of lecture and class fees sufficient to meet the current expenses of the central school, over which it has complete control, and when the change involved in the accomplishment of this object has been fairly tested and found to be effectual, to proceed in the next place to the endowment of the school to a sufficient extent to ensure its permanence and efficiency, without further aid from the Society.

In carrying these objects into effect, increased facilities would be given for the starting of provincial schools with some prospect of success. If a scale of remunerating fees were adopted at the central school, a similar system would naturally follow and could be more easily maintained in the provinces. Means would thus be afforded of ascertaining to what extent and where further school accommodation was required and could be creditably and efficiently supported. Such schools in due course would claim, and no doubt receive assistance from the Society, as well as from those more immediately connected with them, who would be required to contribute in some way to their endowment.

It has been represented that any attempt to establish and maintain schools affording complete and thorough pharmaceutical education, must fail while the prevailing system of coaching or cramming pupils is allowed to exist. I do not agree with this opinion, but of course if the cost of attending our recognised schools should be increased, the difficulty they would experience in contending against the inducements to adopt a short and easy process of preparing for examination would be augmented.

Dr. Attfield thinks that the pernicious system of cramming pupils for examination can only be suppressed, either by requiring candidates for examination to show that they have studied for a specified time in a specified way, or by altering the character of our examinations. We shall no doubt all agree that if any thing could be done to encourage the lengthening within certain limits, or to discourage the undue shortening, of the time occupied in acquiring the knowledge of which evidence is to be given at the examinations, it would be an important point gained. I must say, however, that I doubt the practicability of enforcing the adoption of a fixed curriculum of education for all pharmaceutical students, and I should be sorry to see any material alteration made in the constitution of our Board of Examiners. But this brings me to the consideration of the next question,

What is the best method of testing the qualifications of those to whom certificates giving the right to practice pharmacy are granted?

With reference to this question we must not lose sight of the legitimate object of our examinations, which is to protect the public from the injurious effects of ignorance in those who would undertake the exercise of important duties affecting the public health. Our examinations are not intended for the discovery of the extent of a candidate's knowledge so much as of his want of knowledge. They are designed rather as a test of his weak points than of his strong points. The knowledge to be tested is of a varied but special and technical nature, involving an acquaintance with drugs, their natural sources, their commerce, composition, and properties, the uses to which they are applied in medicine, the methods by which they are prepared for such uses, the physical agencies employed in the preparation of medicines, the chemical changes which occur in their production, and the means of distinguishing them from each other, the good from the bad, the genuine from the spurious or adulterated.

It is not a high degree of scientific attainment in any of the branches of knowledge comprised in this carriculum that is most wanted, but a general proficiency in all, and great ignorance in none.

The examiners by whom the required qualification will be best ascertained are those who possess the full qualification themselves, and whose practical experience enables them to determine where and what allowances may be admitted without detriment to the interests of the public.

If the object of the examinations were the testing of the extent to which candidates had carried the acquirement of knowledge in the higher branches of the departments of science included in the curriculum, it might be desirable to have men on the Board of Examiners who were devoted exclusively to the cultivation of those sciences; but as such an object is not and ought not to be contemplated, any alteration in that respect in the constitution of the Board would, I believe, be detrimental to its usefulness.

I am not aware of our examinations having in any respect failed to accomplish what is required of them. The examiners consist of the best men that can be found willing to undertake the duties, and belonging to the class most capable of making a judicious selection of those to whom the practice of pharmacy may be safely entrusted. As the system of compulsory examination proceeds, and students present themselves who have commenced their pharmaceutical education with a full knowledge of what they have to pass through and prepare for, some modifications, will, no doubt, be made in the method of testing the qualifications of candidates. Without going to the extent that has been suggested, I think something might be done to encourage legitimate study, and to discredit cramming. At the examinations of the University of London, although candidates for degrees are allowed to get the required knowledge in any way they please, they have to state in general terms how their studies have been conducted. This, no doubt, serves as a guide to the examiners. With a similar object, when the practical class of the Pharmaceutical Society was under my direction, I latterly always obtained from every student on entering, a statement of the opportunities for study that he had previously availed himself of, by which I was better able to judge of the further studies best suited for him. Information thus obtained would probably prove useful at our examinations.

The weaknesses and defects which are associated with particular kinds of education are most easily discovered by methods of examination having that special object. If candidates were required to state where, when, and how their education had been conducted, the information thus furnished would enable the examiners to conduct the examinations with better effect. And thus, without imposing any particular programme of education upon all students alike, encouragement would be given to such as afforded the best results, while imperfect and superficial teaching would be subjected to its merited discredit, whatever that might be.

I would not in any respect alter the constitution of the Board of Examiners. The introduction into it of men exclusively devoted to the pursuit of science would be calculated to weaken the feeling of responsibility of the non-professional members of the Board, and to lower the importance of the position occupied by them. Such a change would also be likely to induce the adoption to some extent of a different style of examination from that hitherto pursued. It would I conceive be a great mistake to endeavour to suppress superficial teaching by giving to the examinations a higher and more scientific character.

It is not by putting questions on abstruse or difficult subjects, or highly scientific but practically unimportant subjects, or questions the meaning of which is not easily comprehended, or which relate to subjects not generally known to persons well informed in the department of knowledge to which the examination relates, that the legitimate objects of examination are most fairly and effectually realized. Questions belonging to one or other of those classes may give an air of learning to the operations of the examining board, and may increase the appearance of superiority of the examiners over the examined; but they are not calculated to elevate the character of the examinations in the estimation of those most capable of forming a just and impartial opinion with reference to them.

In examinations such as those entrusted to our Society, none but plain, simple, and I may almost say, common-place questions, need ever be used; and if, to the extent to which the examinations are carried in any department of knowledge, the examiners be well informed and practically familiar with the subject-matter referred to, and time enough be allowed for the testing process, there will be little to fear from the effects of any mere process of cramming, Time, however, is an important element in a trustworthy examination ; and it is, I believe, by extending and economising its employment that improvement will be effected, more perhaps than in any other way, in this department. One method of economising the time of the examiners would be by making the Minor, as well as the Major examination, to a great extent a written one. But even then the *vivâ voce* examination would admit of extension with advantage, so that the effect of these changes would be not to lessen but to increase the work of the examiners. A great augmentation of this work seems in fact to be inevitable, on account, not only of extension of the time devoted to each candidate, but also of increase in the number of candidates for examination. To meet the demand thus made on the Board of Examiners, I would suggest the appointment of assessors rather than additional Examiners. There is a good deal of work connected with the examinations which might be advantageously assigned to competent assessors, and the examiners would thus be spared much of their labour. Should the Society be relieved of the charges hitherto incurred for education, it would be able to devote more of its resources to the establishment of a thoroughly efficient system of examination.

The work of examination is the all-important work of the Pharmaceutical Society to which the best energies of its best men may be honourably and beneficially devoted. The provision for education which the Society has made, and by the establishment of which it has laid the foundation of its power, and obtained the confidence of all classes, both in and out of Parliament, will be a lasting evidence of disinterested zeal and generous devotion in a cause, the carrying out of the objects of which has been so far accomplished, that the Society may now prepare to apply its available means in another direction, in support of what has become its great and primary object.

CHEMICAL NOMENCLATURE.*

BY PROFESSOR A. CRUM BROWN.

Setting aside in the meantime "trivial" or "proper names" (names which are simply arbitrary words or marks, each indicating, in virtue of a convention applicable to each individual case, a particular substance), there are two systems, or kinds of systems of chemical nomenclature. These may be distinguished as 1st, the composition system, and 2nd, the functional or relational system, or class of systems. In the first the name of a compound indicates the elements or radicals contained in it, and sometimes their proportions. Thus Chlornatrium, Chloriod, dreifach Chloriod, Siliciumwasserstoff, etc. In English we have few names so distinctly compositional in form (we have, indeed, zinc methyl and all the other allied names), but many of our names, although functional in form, are really compositional. Thus, chloride of A means with us nothing more than, or different from, a compound containing the elements chlorine and A; and chloride of sodium, chloride of iodine, ter-chloride of iodine, siliciureted hydrogen not only represent the same substances as the German names just quoted, but tell us neither more nor less about the substances than these German names do. On the other hand, functional names indicate the chemical relations between substances. We may take as examples such names as the anhydride, the amide, the aldehyde, the nitrile of acetic acid. These derivatives of acetic acid contain no acetic acid, but they stand in certain definite relations to that substance, and the anhydrides, amides, aldehydes, and nitriles of other acids stand in the same relation to them. What is still, notwithstanding the efforts of modern chemists, the common popular nomenclature of salts, although originally intended as a compositional nomenclature, might with perfect consistency, be retained as a functional nomenclature. The objection to the term "muriate of soda" was that the substance so named contains no soda. But the amide of benzoic acid contains no benzoic acid. Soda contains oxygen; muriate of soda contains none (unless chlorine be an oxide), but the nitrile of benzoic acid contains no oxygen, although the acid itself does. The name muriate of soda originally meant the *compound* of anhydrous muriatic acid, $2HCl-H_2O$, and anhydrous soda Na_2O, $(2HCl - H_2O) + Na_2O$. We may now, if we please, use the name to mean the result of the action $2HCl + Na_2O-H_2O$. If we do so, the name becomes a functional one, and the phrase "muriate of," or, what is neither better nor worse, "hydrochlorate of," expresses the complex operation—addition of hydrochloric acid and simultaneous separation of water. Similarly, in the case of such names as sulphate of potash, nitrate of oxide of silver, etc., the phrases "sulphate of," "nitrate of" express the complete operations, addition of sulphuric, or nitric acid, and simultaneous separation of water.

While the old view that salts are compounds of anhydrous acids and anhydrous bases is now abandoned by most theoretical chemists, a relic of this view still remains in the most advanced systems of nomenclature, producing an inconsistency really inconvenient to the teacher and student.

The objection taken to the name hydrochlorate of soda was not only that the substance contains no soda, but also that it contains no hydrochloric acid ; this objection is perfectly valid against the name as a compositional one, but does it not equally hold against the words sulphate, nitrate, acetate, etc.? If we are to have hydric sulphate and hydric acetate for sulphuric and acetic acids, why not hydric muriate for muriatic acid? That this question is not altogether an absurd one will be obvious if we consider that all chlorides are not muriates. Those substances which are by general consent called salts stand in a definite genetic relation to the correponding acids (or the hydric salts of the series), and it is inconvenient to have the same general name—chloride—applied to substances which do stand in this relation to hydrochloric acid, and also to those which do not. We may divide the chlorides into two groups, very different in character in their extreme members, and gradually shading into one another. We may take chloride of sodium as a representative of the one, and the chloride of phosphorus as a representative of the other. Chloride of sodium is a muriate; the chloride of phosphorus might be better described as the double anhydride of muriatic and phosphorous acids. We may call the acids and acid anhydrides negative, the hydrated bases and anhydrous bases positive ; arranged in a series, we find the series a continuous one from the most positive or basic oxides or hydrates to the most negative ; it is, however, convenient to have a zero point, and it is no disadvantage if this zero point be an arbitary one. When we come to express numerically the amount of positiveness or negativeness of those oxides and hydrates, it will be necessary to have a zero point, and a very convenient one is that which corresponds pretty nearly to the generally understood limit between bases and acids, and depends upon the direction in which the action $A + \text{water} = B + \text{hydrochloric acid}$ takes place; where A is a chloride and B a hydrated or anhydrous oxide.

* Paper read before the Chemical Section of the British Association at Brighton.

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 28, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PHARMACEUTICAL EDUCATION.

IT is with much pleasure that we call the attention of our readers to a paper on this subject from the pen of Professor REDWOOD, in which he deals with the various points that have been raised not only in the discussion at Brighton, but also by correspondents in this Journal. The Professor's long, and we may say special, experience of this subject, enables him to speak of it authoritatively, and we think few will fail to acknowledge that he does so likewise with a thoroughly catholic appreciation of the various interests involved.

It is with especial satisfaction that we find the Professor decisively urging opinions which we have on several occasions ventured to suggest when referring to the subject of pharmaceutical education. In the first place, while recognizing the necessity that has arisen for extending the scope of our educational arrangements, the important fact that the former action of the Society is incompatible with the altered conditions now existing is not lost sight of; the incomplete, and, in some respects, insufficient nature of the Society's past efforts is fully admitted, as well as the necessity for entirely remodelling our educational arrangements. This important fact has been too much overlooked by many who have expressed their opinions on the subject of late, and we think Professor REDWOOD has done good service by urging it upon the consideration of those who take an interest in the future welfare of pharmacy in this country.

At the same time, those who have been active in advocating the support of pharmaceutical education by the Society, will no doubt rejoice to find Professor REDWOOD in no degree disposed to exonerate the Society from responsibility in this matter, especially during the present period of transition; but we would strongly urge upon the consideration of those who, as we have been told, by Mr. PICKERING, and others, are thoroughly roused in regard to the aid to be given to education, the clear and forcible manner in which the essential characters of pharmaceutical education are set forth and insisted upon by the Professor. Those who fairly consider this aspect of the matter will, we believe, fully agree with him in his pleading for the practical and thorough nature of any educational work that is to be undertaken, and for the self-supporting action of any schools that may be established. The efforts hitherto made by the Society in the cause of education have done their work in establishing the present requirements of the law, and whether the system adopted with that object was politic or not, we think there is little doubt that it is now an anachronism: its continuance indeed, under existing conditions would tend to depreciate rather than promote education, and we entirely agree with Professor REDWOOD in thinking it the duty of the Society to endeavour to make every department or branch of the School of Pharmacy satisfactorily self-supporting.

THE NEW ADULTERATION ACT.

THE question raised by our correspondent "Pharmaceutist" as to the eligibility of pharmaceutical chemists for the office of public analyst under the New Act is, we fear, one that can scarcely be answered satisfactorily for them, if the wording of the Act be strictly interpreted. The specified requirement is the possession of "competent *medical*, chemical and microscopical knowledge," and it would appear to restrict these appointments to medical men. At the same time we agree with our correspondent in thinking, as we have repeatedly stated in this Journal, that there is no class among which more competent persons could be found to hold the office of public analyst than the pharmaceutical chemists. Indeed, we would go further than our correspondent, and say that however well-qualified medical men may sometimes be to fill this office, the nature of their occupations is such as to render them far less able to perform its duties satisfactorily than would be the case with pharmaceutical chemists; and we trust some steps will be taken to afford them an opportunity of rendering the services for which we believe they are frequently so well fitted.

THE OPENING OF THE SESSION.

WE have to remind our readers that the next evening meeting of the Society will be held on Wednesday, the 2nd of October, and that on this occasion the Address to Students will be delivered by Mr. STODDART, of Bristol. Ladies are invited to attend this meeting; and the distribution of sessional prizes and certificates will take place then. The Council also invites for this evening and the following day the exhibition of any articles of novelty or otherwise especially interesting to pharmacists, and for this purpose intending exhibitors should communicate at once with the Secretary.

THE LIBRARIANSHIP OF THE LONDON INSTITUTION.

We understand that it is not the intention of the Board of Managers of the London Institution to fill up the vacancy occasioned by the decease of Mr. J. C. Brough, F.C.S., until after November. The salary is £200 per annum, with apartments, coals and light, and payment for whatever lectures may be delivered by the librarian. He is expected to reside in the house, and superintend as representative of the Board.

INDIAN OPIUM.

With regard to the blight which has seriously attacked the poppy crops in the opium agencies of Behar and Benares, and which has been the subject of some anxiety amongst the authorities in India, there seems to be great fears that it will prove to be of fungoid origin. At first it was thought more than probable that the blight might be attributed to the exhaustion of the soil, consequent upon constant poppy crops without any change or rotation, coupled with insufficient manuring. Dr. King's recommendations on these points, which are contained in a letter addressed to the Secretary to the Board of Revenue, Lower Provinces, are well worth the attention of the opium cultivators, as there can be no doubt that a careful system of tillage would much enhance the value of the crops. He says, "If starvation be the cause, the remedy lies in manure, and by far the best manure and one universally obtainable is cow-dung. This, however, is at present the chief fuel of the people in the drier districts, and little of it reaches the fields, except possibly in the form of ashes, the value of which, as compared to that of the unburnt dung, is but small. Whether this 'blight' be really a special disease or not, it could do no harm were the local opium offices to be instructed to exhort the ryots to burn as little cow-dung as possible, in order that they might save it for manure, and also to collect the filth and sweepings of their villages and put them on their fields. Natives have a great many fancies about the application of manure. They think, for instance, that only rotten cow-dung is of any use, and that if applied fresh to the fields this manure will burn up the crops. They should be disabused of such notions. It may not be quite out of place to draw the attention of the Board in this letter to the progressive exhaustion of the soil which is going on in the drier parts of the country. An Indian field has little rest. In the rotation of cultivation there is no intervention of a fallow year, or of one or two years in grass, as in England. In fact there is really no rotation. Mixed crops are grown in one field, and that often for years in succession. Efficient manuring is unknown, and many fields are never manured at all. The best manure is used as fuel, and, I fear, must to a great extent continue to be so until cheap firewood is supplied to the people. Trees of all sorts other than fruit-bearers, are ruthlessly cut down, and none are planted in their places, natural reproduction being relied upon. But natural reproduction is impossible as long as goats and buffaloes are allowed without let or hindrance to browse down any seedlings that may by chance appear. From the rapid disappearance of all timber, the dependence of the people on dung for fuel is daily increasing. It is, I think, obvious to any one looking carefully into the matter that this state of things cannot last very much longer. The only wonder is that it has lasted until now, and that the soil has not long ago refused to yield. The poppy plant being a gross feeder, its cultivation is one of the first that may be expected to fail from the cause above indicated. As has already been mentioned, I do not say that this 'blight' is really the result of exhaustion, but I do not think it unlikely, and until the cause of it can be settled, I think it would be wise to insist on higher cultivation, and on every ground I consider it is advisable for Government to delay no longer the establishment of fuel plantations in all the barer dry districts."

Notwithstanding Dr. King's excellent advice, as we before said, we fear there is too much reason to believe that the blight is referable to a fungoid growth. Some poppy leaves which have been sent home and submitted for examination to an eminent mycologist have been proved to be attacked by *Cladosporium herbarum* and a species of *Peronospora*, perhaps *P. arborescens*, which attacks *Papaver Rhœas* in this country.

THE COLLAPSE OF CUNDURANGO.

Whether this plant be a species of *Gonolobus Marsdenia*, or any other genus of Asclepiadeæ, it seems nearly to have run its course in a pharmaceutical point of view. From a report of the British Vice-Consul at Guayaquil we learn that it has caused a great amount of speculation in its native country. The Government, having received favourable reports of cures effected by it from medical men in the interior, hastened to send samples to Europe and the United States in order that its curative properties might be tested by competent men. Several speculators, and orders to buy it arrived from the United States, and the price was quickly run up to 100 dollars per quintal. The reports of its use in the hospitals of Europe and the United States proved that, unfortunately, it is not the much desired specific for curing cancer, and its value consequently fell to almost nothing. Several commercial firms in New York have declined to receive consignments of it unless the freight is prepaid, as they cannot sell it for enough to cover the cost of its carriage from Guayaquil to New York.

Provincial Transactions.

NORTHAMPTON CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The Monthly Meeting of this Association was held August 30th, 1872. The President, Mr. H. J. Masters, said he was very pleased the question of provincial education had been considered so fully at the meeting of the Pharmaceutical Conference, and hoped they would be able to discuss Dr. Attfield's paper at their next meeting. He then congratulated the Secretary, Mr. Druce, upon having obtained the prize of books which was open to all who had passed the Minor in honours during the year.

Mr. J. Tutton read a paper on "The air we breathe," in which he explained the composition of the atmosphere, described the physical and chemical characters of the gases of which it was composed and the impurities it contained, and explained in a lucid manner the law of gaseous diffusion, the production of ozone, and the phenomenon of lightning.

After the discussion a hearty vote of thanks was passed to Mr. Tutton. The President said he was glad they were now able to carry out the plan of a circulating library, and the Committee would meet at the earliest opportunity to draw up a code of rules for its management, and also to arrange for the commencement of the winter session.

HALIFAX CHEMISTS AND DRUGGISTS' ASSOCIATION.

Sept. 19, 1872.—Mr. Stott, President, in the chair. A report from the Treasurer was read, showing a balance in favour of the Association of £4. 9*s*. 7*d*., after which the Secretary brought before the meeting the sale of vermin killers. A free discussion took place, particular stress being laid upon the recent remarks of the coroner at Leeds with respect to the non-registering of them. In order to be on the safe side it was resolved, "That no packets of vermin killer be kept in stock of less value than 3*d*. for the future, and that all sales be duly registered."

The system of early closing adopted by the trade last winter was the next subject discussed. The feeling was unanimous in favour of continuing the same plan for the ensuing winter months, viz., putting up the shutters at 7 o'clock, and finally closing at 8. Mr. Dyer trusted that before long the Society would make an attempt at closing somewhat earlier on Saturdays now that the 11 o'clock Publicans Act was in force. He thought if the shutters were put up at 9 o'clock, and the shop door finally closed at 10, it would prove a great blessing to the trade in many ways. After a few remarks on the Food and Drug Adulteration Bill as affecting our interests, the President called the attention of the meeting to the proceedings of the managers of the Civil Service Stores. They were about extending the chemical department, and he thought it was time that something should be done. He saw a few days ago at the station a hamper of medicine from the stores directed to one of his customers, and he was informed that not only members of Parliament but a Cabinet minister in this neighbourhood were supplied by the company. Mr. Dyer quite agreed with the President in his remarks as to the injury this company is inflicting upon the retail trade. A friend of his the other day was quoting to him a list of prices of articles in the fancy and perfumery line, most ruinously low. What steps did the President think could be taken under the circumstances? The President said that public opinion ought to be brought to bear upon it by means of the press, drawing the attention of members of Parliament to the illegality of servants of the Crown engaging in trade on their own account, and by meetings such as these. The Secretary thought that other trade organizations, such as the drapers, grocers, etc., would have to take the matter up, and thus a powerful support might be given to the National Chamber of Trade. He thought it was the duty of the Pharmaceutical Council to test the legality of the company dispensing prescriptions. The subject was adjourned till the next meeting.

THE BRIGHTON ASSOCIATION OF PHARMACY.

At a meeting of the Committee, held at the Town Hall on the evening of Thursday last, the proposed rules were considered, amended, and ordered to be printed, and a copy to be sent to each principal, assistant, and apprentice in the town; and in order that all may have an opportunity of joining the association, it was thought desirable that a personal application should be made, and that the following be deputed to call on the members of the trade in their respective district:—Messrs. Savage and W. H. Smith for the east; Messrs Gwatkin, jun., and Ettles for the north; and Messrs. Cornish and Mathews for the west.

Proceedings of Scientific Societies.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Address of the President of the Chemical Section.

One of my fellow-students in the laboratory of the late Professor Graham began the study of chemistry because he wanted to be a geologist, and he had read in some Geological Catechism that, in order to be versed in that science, it was necessary, as a preliminary step, to gain a knowledge of chemistry, mineralogy, zoology, botany, and I know not what besides. My friend became a chemist, and found that enough for the exercise of his faculties. Yet the catechism had truth on its side; for so intertwined are the various branches of observational or experimental research, that a perfect understanding of one can only be obtained through an acquaintance with the whole cycle of knowledge. Yet, on the other hand, who can survey the whole field even of modern chemistry? There was a time doubtless, in the recollection of the more venerable of my auditors, when it was not impossible to learn all that chemists had to teach; but now that our 'Handbook' has grown so large that it would take a Briareus to carry it, and it requires a small army of abstractors to give the Chemical Society the substance of what is done abroad, we are compelled to become specialists in spite of ourselves. He who studies the general laws of chemistry may well turn in despair from the ever growing myriads of transformations among the compounds of carbon. We have agricultural, physiological, and technical chemists; one man builds up new substances, another new formulæ; while some love the rarer metals, and others find their whole souls engrossed by the phenyl compounds. How is this necessity of specialization to be reconciled with the necessity of general knowledge? By our forming a home for ourselves in some particular region, and becoming intimately conversant with every feature of the locality and its choicest associations, while at the same time we learn the general map of the country, so as to know the relative position and importance of our favourite resort, and to be able (when we desire it) to make excursions elsewhere. To facilitate this is one of the great objects of the British Association. The different sections are like different countries; and, leaving the insular seclusion of our special duties, we can pass from one to the other, and gain the advantages of foreign travel. From this chair I must of course regard chemistry as the centre of the universe, and in speaking of other Sections I must think of them only in their relation to ourselves. There is that rich and ancient country, Section A, which, according to the Annual Report, comprises several provinces, Mathematics, Astronomy, Optics, Heat, Electricity, and Meteorology. It was when the idea of exact weight and measures was projected into it that Alchemy was transmuted into Chemistry. As our science has become more refined in its methods its numerical laws have become more and more significant; and it may safely be predicted that the more closely it is allied with general physics, the greater will be the mathematical knowledge demanded of its votary. But till lately the chemist and the astronomer seemed far asunder as the heavens and the earth, and none could have foretold that we should now be analysing the atmospheres of the sun and stars, or throwing light on the chemical composition of planetary nebulæ and the heads of comets. There is in this, too, as in other things, a reciprocal benefit; for we are encouraged to hope that this celestial chemistry will reveal to us elements which have not yet been detected among the constituents of our globe. Light, Heat, and Electricity: how intimately are these associated with the chemical force, or, rather, how easily are these Protean forces transformed into one another! The rays of the sun coming upon our earth are like a chemist entering his laboratory: they start strange decompositions and combinations not only in the vegetable kingdom, but also among the inorganic gases and salts! they are absorbed selectively by different bodies which they penetrate, or are refracted, dispersed, and polarized according to the chemical composition and structure of the substance. All this has been the subject recently of much scientific research; and I need scarcely remind you of the beautiful art of photography as one of the results of photo-chemistry, or the benefits that have arisen from a study of circular polarization, indices of refraction, and especially spectrum-analysis. In regard to the latter, however, I would remark that while the optical examination of the rays emitted by luminous vapours has yielded most brilliant results, there is another kind of spectrum-analysis—that of the rays absorbed by various terrestrial gases, liquids, and solids—which has already borne valuable fruit, and which, as it is far more extensively applicable than the other, may perhaps play a still more important part in the Chemistry of the future. The dispersion of the rays of the spectrum is certainly due to the chemical nature of the body through which they pass; but this is yet almost unbroken ground waiting for an explorer. As to heat, it has ever been the tool of the chemist; and it would be difficult to over-estimate the significance of researches into the specific heat or the melting and boiling points of elements and their compounds. The laws of chemical combination have been elucidated lately by thermo-chemical researches; it has been sought to establish a connection between the absorption or radiation of heat and the complexity of the chemical constitution of the active body; while the power of conducting heat, or of expanding under its influence, offers a promising field of inquiry. As to electrical science, one department of it (Galvanism) is strictly chemical; the electrolytic cell does our work: and indeed we claim half the electric telegraph; for while the needle may oscillate in Section A, the battery belongs to B. Last in Section A comes meteorology; and there are chemical questions concerning the constitution of the atmosphere, its changes, and the effect of its occasional constituents upon vegetable and animal life, which merit the deepest attention of the physiologist, philanthropist and statesman. If we turn to Section C, there is an outlying province belonging to us—namely, mineralogy, which lies on the frontiers of geology. A vast and very promising region is the origin and mode of formation of different minerals; this has attracted some explorers during the past year; but in order to investigate it properly, the geologist and the chemist must travel hand in hand. Geology, in demanding of us the analysis of earths and ores, rocks and precious stones, repays us by bringing to our knowledge many a rare element and strange combination. When we pass from C to D (that is, from the crest of the globe to the organized beings that inhabit and adorn it) we are introduced into new regions of research. When organic chemistry was young, Cuvier said of it, "Dans cette nouvelle magie, le chimiste n'a presque qu'à vouloir; tout peut se changer en tout; tout peut s'extraire de tout;" and though we have now learnt much of the laws by which these magical transformations proceed, they far transcend the dreams of the French philosopher; there is yet no visible limit to the multitude of products to be derived from the vegetable and animal world, and their changes seem to afford boundless scope for chemical ingenuity. The benefit here also is reciprocal; for the physiologist enters by our aid into the wonderful laboratory of the living plant or animal, and learns to estimate the mode of action of different foods and medicines. There have lately been some good researches of this character. The difficulties are great; but the results to be achieved are worthy of any effort. There may be little intercourse between us and the geographers in E; but we stand in no distant relationship with many of the subjects discussed in F. Economic science embraces the chemical arts, from cookery upwards; such imperial questions as that of the national standards, or the patent laws, interest us greatly; the yield of our corn fields is increased through our knowledge of the constituents of soils and manures; and upon many of the chemical manufactures depend in no small degree the commerce and wealth of Britain. In this most important branch of technical chemistry we need the skill of the mechanician; and this introduces us to Section G. One of the questions of the day illustrates the connection between these varied departments of study. Statistics prove that the consumption of coal is now advancing, not at the gradual pace which recent calculations allowed, but at a rapidly accelerating speed; and they make the householder anxious about rising prices, and the political economist about the duration of our coal-fields. It is well known that there is a great waste of fuel throughout the country, as the maximum of heat produced by the combustion is very far from being ever utilized; and it will be for the combined wisdom of the chemist, physicist and mechanician to devise means for reducing this lavish expenditure, or to indicate other available sources of power. While this correlation of the natural sciences renders it desirable that the votary of one should have some general acquaintance with the rest, the correlation of all knowledge shows that no education can be complete which ignores the study of nature. A mind fed only on one particular kind of lore, however excellent that kind may be, must fail of proper nourishment. I am not going to say a word against philological studies; I am too fond of them myself for that; I could wish that the modern languages were taught more, and the classic languages were taught better, than they are at present. But what I contend for is, that chemistry (or some cognate branch of science) should have an honoured place in the education of every English lady and gentleman. I say purposely "an honoured place;" for at present where chemistry is introduced we too often find the idea latent which was expressed by one principal of a lady's college, who told a friend of mine that he was to give the girls a course of pretty experiments, but that she did not expect him to teach them any thing; and we know that when boys repeat chemical experiments at home it is looked upon as an amusement, a philosophical one no doubt, but rather objectionable, inasmuch as they spoil their mother's towels and singe their own eyebrows. Of course, some knowledge of chemistry is indispensable for a large number of our manufacturers, and for members of the medical profession, while it is extremely valuable to the farmer, the miner and the engineer. It will also be readily granted that information about the air we breathe, the water we drink, the food we live upon, the fuel we burn, and the various common objects we handle, must be of service to every man. But we are met by the advocates of the old system of education with the remark that the value of school-teaching does not depend so much upon the information given as upon the mental training. This I admit—though it seems to me that if the same training can be secured by two studies, the one of which (like the making of Latin verses) gives no information at all, while the other (like chemical analysis) imparts some useful knowledge, we should prefer the latter. But I hold that, as a means of educating the mental faculties, chemistry, faithfully taught, has in many respects the advantage over literary studies. There is superabundant scope for the exercise of the memory: the powers of observation are developed by it to a wonderful degree; the reasoning powers may be well disciplined on the philosophy of chemical change, or the application of the laws of Dalton, Mitscherlich, and Avogadro; while the imagination may be cultivated by the attempt to form a conception of the ultimate particles of matter, with their affinities and atomicities, as they act and react upon one another under the control of the physical forces. And I might speak of higher considerations than mere intellectual culture; for surely the works of the Allwise and Bountiful Creator are a more truthful and a purer subject of contemplation for the opening minds of youth, and more in accordance with Christian ideas, than are the crude notions of a past stage of civilization, and the ignorant and gross fancies of a defunct paganism. There is another requirement in education—the training of the mind to the discovery and recognition of truth. For this purpose, philological studies have no fitness; mathematical studies, though peculiarly adapted for it, apply only to cases where demonstrative proof is possible; but the study of physical science is remarkably well fitted for teaching the proper methods of inquiry, and the strict relations between theory and fact. Now, the historian, the politician, the mental philosopher, the theologician, or any one else who desires to influence the thoughts of his fellow-men, should be in a position to distinguish between truth and error in his own department; and his mind may be well disciplined for this by a study which is less liable to be disturbed by human passions, predilections, or wishes, and where the conclusions are more readily brought to the test of observation or experiment. Our Government insists on a certain standard of education for all who are allowed to teach in our elementary schools. In those schools which receive no State aid, it is only public opinion which can insist that the teacher shall be duly qualified himself. Such bodies as the British Association form this public opinion, and will deserve well of their country if they demand that these masters and mistresses shall know something of the material universe in which they move, and be able to impart to every child such scientific knowledge as shall afford him an interesting subject for thought, give him useful information, and discipline his mental powers. Among the many services rendered by the monthly reports of the progress of chemistry which the Chemical Society publishes, and the British Association helps to pay for, there is one which is rather salutary than pleasant. They bring prominently before our notice the fact that in the race of original research we are being distanced by foreign chemists. I refer not to the quality of our work, about which opinions will probably differ, but to the quantity, which can be determined by very simple arithmetic. This is a matter of no small importance, not only for the honour of England, but still more for the advancement of science, and the welfare of man. From the Physical Chair of this Association last year, a note of warning was uttered in the following words, after a reference to the sad fate of Newton's successors who allowed mathematical science almost to die out of the country:—"If the successors of Davy and Faraday pause to ponder even on *their* achievements, we shall soon be again in the same state of ignominious inferiority." The President of the Chemical Society also, in the last Anniversary Address, drew attention to the diminished activity of chemical discovery, and to the lamentable fewness of original papers communicated. He traces this chiefly to the "non-recognition of experimental research by our universities," and suggests that in the granting of science degrees every candidate should be required, as in Germany, to prove his ability for original investigation. Concurring in this, I would remark that other causes have also been assigned, and other suggestions have been made. There is the small recognition of original research even by our learned societies—at least such recognition as will come home to the understanding of the general public. It is true the Fellowship of the Royal Society is awarded mainly for original discoveries, and there are two or three medals to be disposed of annually; but these distinctions fall to the lot of the seniors in science, often men who are beyond the need of encouragement; and though they doubtless are serviceable as incentives, there is many a beginner in the honourable contest of discovery who is too modest even to hope for the blue ribbon of science. While the Victoria Cross is awarded to few, every soldier who has borne part in a victory expects his clasp; and so might every man who has won victory over the secrets of nature fairly look for some public recognition. It has been suggested, for instance, that the Royal Society, in addition to the F.R.S., might institute an associateship, with the letters A.R.S., designed exclusively for those younger men who have shown zeal and ability in original research, but whose discoveries have not been sufficient to entitle them already to the fellowship. It is suggested, too, that the Chemical Society might give some medal or diploma, or some similar distinction, to those who contribute papers of sufficient merit. But beyond this is the non-recognition of scientific research by society in general. We can scarcely expect the average enlightened Englishmen to be anything but scared by a graphic formula, or a doubly sesquipedalian word containing two or three compound radicals; still he need not continue to talk of the four elements, or of acids being neutralized by sugar. But, indeed, the so-called educated classes in England are not only supremely ignorant of science; they have scarcely yet arrived at the first stage of improvement—the knowledge of their own ignorance. Then again there is the excessive preference of practical inventions over theoretical discoveries—or rather, perhaps, the inability to appreciate anything but tangible results. Thus, a new aniline compound is nothing unless it will dye a pretty colour; if we speak of the discovery of a new metal by the spectroscope, people simply ask, What is it useful for? and the rigorous determination of an atomic weight has for them no meaning, or interest or beauty. The general appreciation of science must be of gradual growth; yet there are wealthy men who know its value, and who might well become the endowers of research. There are, indeed, at present funds available for the purpose—such as the Government grant, and the surplus funds of this Association; but the money is given simply to cover actual outlay; and this, though very useful, scarcely meets the case of those young philosophers who have no balance at their bankers, and yet must live. Will not some of these wealthy men endow experimental scholarships, or professorships, in connection with our colleges, institutions or learned societies? As an instance of the good that may be effected in this way, the Fullerian professorships may be cited; and, as a very recent example, worthy of all honour, may be mentioned the purpose of Mr. J. B. Lawes, not only to continue his elaborate experiments at Rothamsted throughout his lifetime, but to place his laboratory and experimental fields in trust, together with £100,000, so that investigations may be continued in the wider and more scientific questions which the progress of agriculture may suggest. The Government of our country, through the Science and Art Department, renders good assistance to the teaching of science; and if the recommendations of the Royal Commission on Scientific Instruction and the Advancement of Science be adopted, the introduction of practical examinations for the obtaining of certificates for a superior grade of science-master will certainly foster a spirit of research. It has generally been held that the promotion of research is within the legitimate scope of Government; and where, as in the case of Aristotle and Alexander, genius and industry have been sustained by princely munificence, the happiest results have ensued. Yet this question of Government aid is a delicate one; for genius, when put into swaddling clothes, is apt to be stifled by them; and were science to depend on political favour or imperial support it would be a fatal calamity. Still I think it will be everywhere admitted that science might with propriety be subsidized from the public funds in cases where the results may be expected to confer a direct benefit upon the community, and where the inquiry, either from its expense, its tediousness, its uninteresting character, or the amount of co-operation required is not likely to be carried out by voluntary effort. The astronomical work which is paid for by Government bears upon navigation, and answers both these requirements; and it is easy to conceive of inquiries in our own science that might equally deserve the assistance of the State. Some of these might also more than repay the outlay, though perhaps the profit would not fall into next year's budget. I believe that this diminution of original research, which we deplore, is partly due to a cause in which we rejoice—the recent extension of science-teaching. The professorships of chemistry are scarcely more numerous now than they were twenty gears ago, while the calls upon the professor's time in conducting classes or looking over examination papers have greatly augmented. Thus, some of the most capable men have been drawn away from the investigation of nature; and in order to afford sufficient leisure for the purpose, means must be found to multiply the number of the professorships in our various colleges. While the rudiments of science are being infused into our primary education, now happily becoming national, while physical science is gradually gaining a footing in our secondary and our large public schools, and while it is winning for itself an honoured place at our universities, it is to be hoped that many new investigators will arise, and that British chemists will not fall behind in the upward march of discovery, but will continue hand in hand with their continental brethren thus to serve their own and future generations.

Parliamentary and Law Proceedings.

AN ACT TO AMEND THE LAW FOR THE PREVENTION OF ADULTERATION OF FOOD AND DRINK AND OF DRUGS.

(10*th August*, 1872.)

Whereas the practice of adulterating articles of food and drink and drugs for sale, in fraud of Her Majesty's subjects, and to the great hurt of their health and danger to their lives, requires to be repressed by more effectual aws than those which are now in force for that purpose.

Be it therefore enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

Penalty on persons adulterating articles of food or drink or drugs.

1. Every person who shall wilfully admix, and every person who shall order any other person or persons to admix, with any article of food and drink, any injurious or poisonous ingredient or material to adulterate the same for sale, and every person who shall wilfully admix, and every person who shall order any other person or persons to admix, any ingredient or material with any drug to adulterate the same for sale, shall for the first offence forfeit and pay a penalty not exceeding fifty pounds, together with the cost attending such conviction, and for the second offence shall be guilty of a misdemeanour, and be imprisoned for a period not exceeding six calendar months, with hard labour.

Penalty on persons selling articles of food or drink or drugs which they know to have been adulterated.

2. Every person who shall sell any article of food or drink with which to the knowledge of such person any ingredient or material injurious to the health of persons eating or drinking such article has been mixed, and every person who shall sell as unadulterated any article of food and drink, or any drug which is adulterated, shall for every such offence, on a summary conviction of the same before two justices of the peace at petty sessions in England, or before two justices of the peace in the justices of the peace court, or before the sheriff substitute of the county, or before any magistrate acting under any general or local Police Act in Scotland, or before justices at petty sessions or a divisional justice in Ireland, forfeit and pay a penalty not exceeding twenty pounds, together with such costs attending such conviction as to the said justices, sheriff substitute, magistrate, or divisional justice shall seem reasonable; and if any person so convicted shall afterwards commit the like offence, such justices, sheriff substitute, magistrate, or divisional justice shall cause such offender's name, place of abode, and offence to be published, at the expense of such offender, in such newspaper or in such other manner as to the said justices shall seem desirable.

Vendor to declare mixture at time of sale.

3. Any person who shall sell any article of food or drink or any drug, knowing the same to have been mixed with any other substance with intent fraudulently to increase its weight or bulk, and who shall not declare such admixture to any purchaser thereof before delivering the same and no other, shall be deemed to have sold an adulterated article of food or drink or drug, as the case may be, under this Act.

Pharmacy Act, 1868, *and* 23 *&* 24 *Vict. c.* 84. *incorporated with this Act. Proviso*, 33 *&* 34 *Vict. e.* 26.

4. The Pharmacy Act, 1868, and the Act twenty-third and twenty-fourth Victoria, chapter eight-four, for preventing the adulteration of articles of food and drink, shall be deemed to be incorporated in this Act: Provided always, that in the application of this Act to Ireland the Act passed in the session of Parliament held in the thirty-third and thirty-fourth year of the reign of Her present Majesty, chapter twenty-six, intituled "An Act to regulate the sale of poisons in Ireland," shall be deemed to be incorporated in this Act instead of the Pharmacy Act, 1868.

Appointment of Analysts.

5. In the city of London and the liberties thereof, the commissioners of sewers of the city of London and the liberties thereof, and in all other parts of the metropolis the vestries and district boards acting in execution of the Act for the better local management of the metropolis, in England the court of quarter sessions of every county, and the town council of every borough having a separate court of quarter sessions, or having under any general or local Act of Parliament or otherwise a separate police establishment, in Ireland the grand jury of every county, county of a city, and county of a town, and town council of every borough, and in Scotland the commissioners of supply at their ordinary meetings for counties, and

the commissioners or boards of police, or, where there are no such commissioners or boards, the town councils for boroughs, within their several jurisdictions, may, and when required so to do by the Local Government Board in England, or by one of Her Majesty's Principal Secretaries of State in Scotland, or by the Lord Lieutenant or other chief governor or governors in Ireland, shall, for their respective city, districts, counties, or boroughs, appoint and remove one or more persons possessing competent medical, chemical, and microscopical knowledge as analysts of all articles of food, drink, and drugs purchased within the said city, metropolitan districts, counties, or boroughs, and shall pay to such analysts such salary or allowances as they may think fit; but such appointments and removals shall at all times be subject in England to the approval of the Local Government Board, in Scotland of one of Her Majesty's Principal Secretaries of State, and in Ireland of the Lord Lieutenant or other chief governor or governors.

Inspectors of nuisances, etc., may submit articles to be analysed.

6. The inspector of nuisances or the inspector of weights and measures, or the inspector of markets, one or all of them, as the local authority appointing them shall think fit to determine, in every district, county, city, or borough, shall procure and submit samples of articles of food or drink and drugs suspected to be adulterated to be analysed by the analyists appointed under this Act, and shall, upon receiving a certificate stating that the articles of food or drink or drugs are adulterated, cause a complaint of an offence against this Act by the party selling or adulterating such articles of food or drink or drugs to be made before a justice of the peace, and thereupon such justice shall issue a summons requiring the seller or the adulterator to appear before two justices of the peace at petty sessions in England, or before two justices of the peace in the justice of the peace court, or before the sheriff substitute of the county, or before any magistrate acting under any general or local police Act in Scotland, or before justices of petty sessions or divisional justices in Ireland, to answer such complaint, and such summons shall be served by delivering the same, or a true copy thereof, upon the premises where such samples were obtained or sold, and the expense of such prosecutions, if not ordered to be paid by the party complained against, shall be deemed part of the expense of executing this Act.

Analysts to make reports quarterly to local authorities.

7. The analysts appointed under this Act shall report quarterly to the local authorities appointing them the number of articles of food, drink, or drugs analysed by them under this Act during the foregoing quarter, and shall specify the nature and kind of adulterations detected in such articles of food, drink, and drugs, and all such reports shall be read at the meetings of the local authorities appointing such analyists.

Proof of identity of articles submitted to analysts.

8. On the hearing by the justices, sheriff substitute, magistrate, or divisional justice of any complaint under this Act in any district, county, city, or borough wherein analyists shall have been appointed under this Act, the purchaser, or inspector of nuisances, or the inspector of weights and measures, or the inspector of markets, as the case may be, shall prove to the satisfaction of such justices, sheriff substitute, magistrate, or divisional justice that the article of food or drink or drugs alleged to be adulterated was delivered to the analysts in the same condition as regards its purity or impurity as it was when received from the seller.

Purchaser of articles of food, etc., may require same to be analysed.

9. Any purchaser of any article of food or drink or drugs in any district, county, city, or borough where there is any analyst appointed under this Act shall be entitled, on payment to the inspector or inspectors appointed under this Act of a sum not less than two shillings and sixpence nor more than ten shillings and sixpence, which shall be accounted for to the local authority appointing such inspector or inspectors, to have any such article analysed by any analyst who may be appointed for such district, county, city, or borough, and to receive from such analyst a certificate of the result of his analysis, specifying whether, in his opinion, such article is adulterated, and also whether, if it be an article of food or drink, it is so adulterated as to be injurious to the health of persons eating or drinking the same, and such certificate, duly signed by such analyst, shall, in the absence of any evidence before the court to the contrary, be sufficient evidence of the matters therein certified, and the sum so directed to be paid for such certificate shall be deemed part of the costs.

Articles of food, etc., ordered for analysis to be received, and samples retained by inspectors.

10. All articles of food, drink, or drugs to be analysed by the analysts appointed under this Act shall be received by the inspectors appointed by the local authorities, and from all such articles of food, drink, or drugs samples shall be taken and sealed in the presence of the analysts by the inspectors, to be retained by them and produced in case the justices, sheriff substitute, magistrate, or divisional justice shall order other analyses to be made.

As to expenses of executing Act.

11. The expense of executing this Act shall be borne, in the city of London and the liberties thereof, out of the consolidated rates raised by the commissioners of sewers of the city of London and the liberties thereof, and in the rest of the metropolis out of any rates or funds applicable to the purposes of the Act for the better local management of the metropolis, and in counties out of the county rate, or out of the grand jury cess in Ireland, and in boroughs out of the borough fund, and in Scotland out of the police money in counties and boroughs respectively.

Proceedings by indictment, etc., not to be affected.

12. Nothing in this Act contained shall be held to affect the power of proceeding by indictment, or to take away any other remedy against any offender under this Act.

MEDICAL ATTENDANCE BY DRUGGISTS.

Yesterday Mr. Richards held an inquest at the White Hart, Vine Court, Commercial Street, on Joshua Charles Salmon, aged one year and five months. The child had been attended by Mr. Stubbs, druggist, Commercial Street, from the 11th to the 15th instant (when it died suddenly). Mr. Richards animadverted severely upon the fact of druggists usurping the functions of qualified medical men. Verdict "Death from natural causes."

Mr. Richards held another inquest yesterday afternoon at the Knave of Clubs, Club Row, Bethnal Green, on Margaret Elizabeth Hughes, aged three months, who had died from want of her natural aliment. In this case the deceased had also been attended by a druggist named Mr. Swire. As in the previous case, Mr. Richards indulged in some rather severe strictures. A similar verdict was returned.

Review.

SCIENCE PRIMERS. CHEMISTRY, by Professor ROSCOE, F.R.S. PHYSICS, by Professor BALFOUR STEWART, F.R.S. London, Macmillan and Co., 1872.

Every teacher of science must at times have felt the want of sound elementary text books on science, suitable for quite young boys. The science-primers before us admirably supply this want, so far as regards the elements of chemistry and physics. We are glad to observe further that Mr. Huxley is engaged on a similar primer, introductory to the study of natural science. The series is published at a wonderfully cheap price, a shilling each; the type is excellent, the cuts are numerous and useful, and the binding seems to be strong. The fact that the authors are such men as Professors Roscoe and Balfour Stewart is a sufficient guarantee that they have been carefully compiled and thoughtfully adapted for the purpose intended.

We are glad to notice that in the chemistry primer, Professor Roscoe has departed from the unphilosophical method of beginning with a study of the elements. To start, as is usual, with oxygen or hydrogen, perplexes a child with something totally new to him, which he cannot, therefore, connect with his previous knowledge; and, further, in dealing with an element as distinguished from a compound, it introduces the conception of an abstract idea, of which a child is incapable. With great wisdom Professor Roscoe begins as follows:—"Here are four things which we all know well—fire, air, water, earth,—let us try to learn what science teaches us about them;" then the author goes on to explain that we come to know about these things by handling or examining them, and that we call this examination experiment, describing what kind of experiments properly belong to the study of chemistry. The following headings to the sections under the first division, fire, will show how the book proceeds. "What happens when a candle or a taper burns?" "Besides carbonic acid gas, there is another substance formed when the candle burns, viz., water;" "When a candle is burnt, nothing is lost;" "Heat is felt when chemical union goes on." In the next division we are told about the air: "What the air contains;" "What goes on when we breathe air?" "What sort of action have plants on the air?" and so on. At the end of each division the lesson is summed up under the head of "What we have learnt." After dealing with the elements of the ancients and broadly explaining their nature in the light of the present day, the author leads the learner up to the elements that modern science has revealed. The properties of the principal elementary bodies are then described, and the book ends with an explanation of the meaning of combining proportions and chemical equations, so lucid as to be quite within the comprehension of the average boy. We remark in passing a little inaccuracy that called forth a letter in the pages of a contemporary. On page 26 hydrogen is said to burn with a pale *blue* flame. Mr. Barrett has shown that a flame of pure hydrogen, of any tint, is slightly brown; the blueness so commonly noted being due to the presence of sulphur, usually derived from the decomposition of the spray from the sulphuric acid employed in generating it; the presence of carbonic acid in the breath of the operator, or in the air of the room, also often leads to a deceptive appearance of the flame.

The primer by Professor Balfour Stewart on physics follows the same general scheme as the chemistry primer. It is, perhaps, not quite equal to its predecessor, but then Professor Roscoe has had the advantage of many years' experience in teaching both young and old boys, and also the aid derived from noting the weak points in the host of elementary books on chemistry that have been published. Professor Stewart is the first to write in the English language a simple and sound primer on physics, and we anticipate much good from its publication. The section on the "Use of certain Forces," p. 10, is capital, and will excite that wonderment and interest in a boy which urges him on to learn more. But the Author will allow us to make one or two suggestions that struck us on looking through his work. We think that occasionally the language or illustrations are a little too childish, young boys are apt to resent this more than many writers imagine. Again, we think it is a mistake to explain a thing too fully in a schoolbook; if every difficulty is made laboriously clear in his text-book, a lad gets into a habit of reading without care, and expects to be pushed up every round in the ladder of knowledge. The business of a teacher is to help his pupil out of the difficulties he gets into, and stimulate him to fresh exertion. We rather expect a teacher will find some little difficulty in using this physic primer as a class-book; we may be wrong, but we should be glad if the author could at some time make the experiment. Then in explaining the electrical machine, there is a serious but very common error, which will puzzle the learner, as the reverse statement is made in the next sentence. On p. 116, after describing the prime conductor of the electric machine and how it is armed with points, the Author goes on to say, "Now you have already been told that points have a great tendency to draw off electricity. The consequence is, that these points draw off, or collect, the positive electricity of the glass and carry it to the conductor, where it remains, since the conductor stands upon glass supports." This is incorrect. The points discharge on to the machine the negative electricity induced upon them by the positive of the excited glass, and then the prime conductor remains positively electrified by its loss of negative. That the Author's rendering is not put for the sake of simplicity is evident from the next sentence, where, in explanation of why we get a spark by putting our knuckle to the prime conductor, we read, "The reason is that the positive electricity of the conductor separates the two electricities which are together in my finger, driving away the positive, which is of the same kind as itself, to the earth through my feet, but, on the other hand, attracting the negative itself. The two electricities then rush together through the air and unite with each other, and in so doing they form a spark."

Even this latter paragraph is open to the objection that a lad gets an idea from such a statement that the two electricities are something substantial, always indulging in the bad habit of knocking up against each other and thereby splintering off sparks. Is any notion more common than that lightning is some sort of Greek fire poured out of a charged cloud, which relieved of its burden, furiously rushes to its neighbour and hitting it a terrific blow, makes the subsequent thunder. Now we think a child should be taught that when we see lightning we do not see electricity but only one of the results of that force, namely, air made to glow fearfully hot along all the devious track of the discharge. Then he might be shown how gases can be made white hot, having previously learnt how platinum gets incandescent, owing to the resistance it presents to the discharge. Another point in the primer we think capable of improvement is an enlargement of what is said on magnetism. The same objection exists in Professor Stewart's larger text-book on 'Physics,' where this subject is treated in rather a meagre way; here only two or three lines are devoted to it, and the fundamental law of magnetism is not even alluded to. There is, of course, much to be said about the impossibility of dwelling on everything in a primer, but every boy has seen a compass and ought to know something about it; and such instruction would not be forgotten from the law of the association of ideas.

There can be no doubt that the essence of all effective teaching is to fasten each additional link in the chain of knowledge on to that which preceded it; thus by rising from what is already familiar to that which is less familiar, the child, and the man too, gets a firm hold of facts and a just view of phenomena. It is because this method is followed so largely in these primers, admirably so in the chemistry primer, that we believe they will be found a powerful means of diffusing elementary scientific instruction.

Adulteration of Food and Drugs Act.

Sir,—The "Adulteration of Food and Drugs Act" passed last month provides that persons to be appointed as analysts must be possessed of "competent *medical*, chemical and microscopical knowledge."

The word "medical" was also in the Act last year, and attention was called to it, I think, sir, by yourself, in the Journal. I communicated at the time with the members representing the town in which I live, and they gave notice of an amendment to have the word altered or omitted, sending me down the printed clause as they proposed it should stand, which would have been quite unobjectionable. After all, however, the word has crept in again this year.

As a rule, I venture to say that a man who is a pharmaceutist, and possesses, as many do, the requisite chemical and microscopical knowledge, is much more fitted to be an analyst under this Act than most medical men, but is he legally eligible? I am afraid that he is not, and if this be so, has not the Parliamentary Committee of the Council of the Pharmaceutical Society been caught napping?

There are a good many pharmaceutists interested in this matter, and I think it would be well if the Council ascertained from their legal adviser exactly how we stand.

Pharmaceutist.

Pharmaceutical Chemists and Members of the Pharmaceutical Society.

Sir,—J. L. is not the only person who protests against admitting registered chemists to be members of the Pharmaceutical Society by payment. I consider it would be a step in the right direction to discontinue granting membership to any except those who pass the Major.

A complaint has been made that few present themselves for the Major degree. If the practice now condemned be continued, will preparing for the Major be of use to any one? The public do not, or will not know the difference between the Major and the borrower of his plumes. Moreover, the Major gets no substantial recompense either from the medical profession or the public.

I could show that the Major degree is at present useless, but perhaps I need not.

Professor Attfield, some time since, stated that the Bell Scholarships profited any profession but that of pharmacy; and the same may be said of the Majors,—many of whom even if they go into business leave it for another.

Although the Society may have got a larger return by the adoption of the practice complained of, yet, by the same means, she has been drained of her best blood—her best men have left her.

The claims of the Majors upon the Society are very great, perhaps greater than those of the apprentices now entering. For the former have been induced to work hard, to invest much capital, to think highly of their calling; and for what? Nothing worth the labour and money expended.

The Majors ought to be a body of chemists well known to the public—as distinct as physicians are from surgeons instead of being totally disregarded by the Society. Many means might be suggested, not only of keeping the Major, but also of improving his position. The Major on leaving Bloomsbury Square and commencing business generally buries his talents under a bushel. This should not be; and as I believe it to be the duty of the Society to encourage her past students I suggest that the Society institute a series of money prizes for the Majors in business. That the prizes be substantial and remunerative, and be given for original investigations or compositions on subjects connected with any branch of pharmacy. We are behind hand in this country in such a matter.

A Major in Business.

Disinfectants and Antiseptics.

Sir,—When discussing this subject in your impression of August 31st, you justly expressed regret that there was no *ex cathedrâ* utterance as to the true merits or demerits of chloralum as a disinfectant. The chief difficulty in obtaining such utterance would appear to me to lie in settling the value of the qualifications of the occupant of the oracular chair. It is to be presumed, for instance, that to many, the utterances of the 'British Medical Journal' are of cathedral importance. Nevertheless, on the very same day whereon you published your remarks, that periodical, relying on a statement of Mr. Stanford, that "Chloride of calcium is the most practicable, cheap and powerful of all disinfectants," favoured the proposal to introduce £200,000 worth of that substance into the London sewers, with the object of preventing the evolution of sewer gases! This is the result of the combined wisdom of a pharmacist and a medical editor!

Such *ex cathedrâ* utterances would certainly be no improvement on the resolutions of the Board of Trade relative to disinfectants. The latter body, when the Shipping Medical Scale of 1867 was drawn up by them, ordered carbolic acid to be the only disinfecting substance on it, although it was well known that, owing to its peculiar odour, it was so little suited for trading vessels, that many shipowners made a rule of refusing to take it on board, even on freight. Urged, however, by the Shipowners' Association to substitute some inodorous substance for the offensive carbolic acid, the Board at length ordered the addition to the Medicine Scale of chloride of zinc. But after a year or two they suddenly discovered that the latter substance, on account of its poisonous character, was too dangerous to be longer retained in the Scale—not seeming to be aware that carbolic acid, which still occupied, and even now occupies, the place of honour on the Scale, was quite as deadly a poison—and not having apparently sufficient knowledge to think of anything better, and being no doubt importuned by the publicity department of the Chloralum Company, thereupon directed it to be displaced by the preparation of the latter concern. Nevertheless, foolish as all this is, it is wisdom itself when compared with the chloride of calcium proposal of the 'British Medical Journal.'

One of the Laity.

London, September 4th, 1872.

[*** We are glad to insert the above letter, but take leave to demur to some of the statements contained therein. In the first place it was not so much the absence of *ex cathedrâ* utterances as to the value of chloralum that we deplored, as the absence *even* of that too readily attainable recommendation. The 'British Medical Journal' is doubtless perfectly competent to take up cudgels as to the "Chloride of Calcium" question, but as a matter of fairness in quotation, we must point out that the favouring of the proposal by our contemporary was distinctly subject to the proviso "if the salts were as effectual as Mr. Cooper imagines them to be." Lastly, the Shipowners' Association or the public have as yet failed to prove that carbolic acid injures either the cargo, the gear, or the hull of a ship, if the acid be properly packed and secured, and used as directed in the 'Medical Guide.' The solution of chloride of zinc was not, according to our own knowledge and belief, restored to the Scale on the petition of the Shipowners' Association, and it is very properly considered more dangerous than carbolic acid, because it is colourless and inodorous.—Ed. Pharm. Journ.]

Displacement.

Sir,—After the reading of Messrs. Stoddart and Tucker's paper at Brighton, a discussion took place (as reported in your Journal of Saturday the 14th) which turned chiefly on the subject of preparing essence, or strong tincture of ginger. It is a well-known fact that when the essence is displaced with water after the process has proceeded a short time, it stops, and even sleeping over it, as suggested by Mr. Stoddart, does not surmount the difficulty. A magma or "muck" (as Mr. Giles terms it) is formed, which it is presumed stops the progress of the water—but does it? The two following observations rather shake one's faith in this orthodox belief:—1st, The displacement proceeds pretty rapidly at first, until the "brown ring" mentioned has thoroughly formed. 2nd, If you remove the "muck" with a spoon and place it in another percolator, water will pass through it there.

The fact then is evident—it is the brown layer, consisting of precipitated resinous matter, which, forming a waterproof diaphragm, necessarily stops the process; remove this, and it proceeds until another similar layer is formed.

Now it seems clear to my mind that Mr. Stoddart's process, as applied to essence of ginger, is not nearly so satisfactory as that of the Pharmacopœia, as regards mixing the whole of the spirit with the ginger in the first instance; for on displacing with water, the dark layer of precipitated resinous matter would form much earlier, and the loss from its more frequent removal would be greater.

CHARLES SYMES.

York Place, Birkenhead,
September 16th, 1872.

PHARMACEUTICAL EDUCATION.

Sir,—The criticisms that have been lavished on Mr. Schacht's scheme for provincial pharmaceutical education, and on its predecessor, that of Mr. Reynolds, have, perhaps, been numerous enough, yet it seems to me that from this multitude of counsellors, not wisdom, but rather confusion has resulted. I cannot see that we are one step nearer the mark than we were last year at this time.

Then, as now, it was universally admitted to be necessary, in order to raise the status of the pharmacist and improve the character of his work, that he should receive a good general and a thorough scientific education, and that with the latter only should the Pharmaceutical Society concern itself,

Men of a certain stamp of mind can scarcely be expected to understand the disinclination for study evinced by so many young men. They seem to believe that a desire for knowledge and the power it confers would of themselves be sufficient to put every one on the alert, and that the complaint of employers ought rather to be, "my employees are devoting so much time to study that my interests are being neglected," instead of the, alas! too prevalent cry, "my employees won't learn, and think themselves injured if the necessity for study is urged upon them."

It is certain, however, that every one who aspires to an independent position as proprietor of a pharmacy must somehow acquire enough to satisfy the Board of Examiners; and as the requirements of that body are not likely to grow less, while the capacity for imbibing knowledge by the young does not improve with age, it seems to me a cruel thing to hesitate any longer in providing a sufficient stimulus to exertion.

I think it may be assumed that the offer of cheap instruction has failed in almost every case; and I am glad of it. It convinces me that in pecuniary matters things have not come to the pass that arrangements need be made for half-a-dozen young men to read out of the same Manuals, or for providing science lectures at a mere fraction of their actual cost. The real difficulties are *time*, which must be conceded by employers, and *disinclination for study*, which must be overcome by employees.

I will take the latter first, and commence by stating that I have not the slightest sympathy with the idle young man who prefers smoking his pipe and sipping his beer to improving his mind and securing his future prospects, nor would I consult his feelings in any arrangement to be made. On the other I cannot see that the diligent young man should to be regarded as one so very meritorious that he ought to be petted and caressed. The tendency to that sort of thing has already, I fear, made some who would otherwise have cast in their lot with the diligent, hesitate and conclude that after all study cannot but be a very disagreeable process. The stimulus that I would provide is, the by no means "clever" expedient of an "Act of Parliament," one that shall exhibit as little as possible of that "management" which finds favour in so many eyes. I should like to see that muddling compromise of 1868 (I am happy to say that I had nothing to do with it except in the way of denunciation) superseded in most, if not all, its provisions relating to examination by one strictly logical and to the purpose. Is it not absurd, that while so much pains has been taken about the qualifications of the master, no restriction has been placed upon his choice of a subordinate? According to the present state of the law a youth may enter a pharmacy and continue in it till grey-headed, dispensing to the public the most delicate and dangerous remedies without ever coming before an examiner to prove his competency. Can this be for the good of the public or even of the unqualified dispenser?

The examinations that I would insist on are three,

1st. Before entering a pharmacy as apprentice or student, a youth should be compelled to pass a Preliminary examination to test his general educational qualifications.

2nd. Not less than, two years say, after this he should be permitted to present himself for the "Assistants" examination, and without first passing this he should not be permitted to "dispense poisons."

3rd. Before commencing business on his own account, he must pass either the Minor examination (giving the title of Chemist and Druggist) or the Major examination (giving the title of Pharmacist). I would not allow a choice of appellations, nor would I permit a druggist's shop to be called a pharmacy.

It will be observed that the Minor and Major examinations are to be alternative, not consecutive, and as the passing of either would enable one to assume the responsibility of conducting a business, care should be taken to make each a sufficient test of capability.

Another most necessary provision would be one compelling the present employees within a definite period (one or two years after the passing of the Bill) to present themselves for either the Preliminary, Modified, or Assistants examination, as the case may be. Those failing to pass should without hesitation be remitted to occupations better suited to their abilities.

This proceeding will of course be denounced as harsh, unjust, nay, positively cruel. I affirm, on the contrary, that it would be an act of great kindness to let those unfitted for the trade know the fact as early as possible. It would be, in my opinion, an act of cruelty to allow a young man to continue in a position of subordinacy from which it would be hopeless for him to expect to emerge. As for giving an extension of time, that would merely render his chance of passing still more problematical.

I think, then, that on every ground we are justified in taking some such step as that I have indicated. The knot we have contrived with so much pains is not to be unpicked, it must be cut. Don't let us stand shivering on the brink of the stream, but resolutely take a header and have done with it.

Well, then, suppose a legitimate and general demand for pharmaceutical education to have arisen, and superseded the penny and even sixpenny lectures of the present, how is the demand to be met? Clearly by the establishment of additional pharmacy schools. Not all of them to be necessarily permanent, but all to be efficient and receiving substantial pecuniary aid from the Pharmaceutical Society. I should be prepared to spend in this way a large portion of the invested funds of the Society. The employment of peripatetic lecturers as advocated by the 'Chemist and Druggist' would tend much to reduce the cost of the scheme, and further its efficiency. The cases of certain young men (there are very few of them I expect) who find themselves injured by the passing of the Pharmacy Act of 1868, would have to be treated individually.

Little need be said as to the concession of time by employers. Should any prove so cantankerous as to decline to afford reasonable facilities for study, the persons injured will have to resort to the same plan that has proved so successful in other humble callings. A monster meeting of chemists' assistants would at least be as permissible as one of bakers, lamplighters, wood-cutters, etc., and doubtless not less successful.

Mr. Hampson has truly remarked, that the general public does not demand high pharmacy, and it is equally true that when it is supplied to them, they are unwilling to pay for it. Neither do provincial medical men as a rule apprehend the advantage that would result to the sick, from the division of labour between the prescriber and the dispenser. But we are all advancing together, and it is to be hoped that some day the British Philistine will become wise enough to perceive that the character for encyclopædic learning credited to, if not assumed by, his medical attendant is not always strictly merited, and will act accordingly.

It must be understood that I would not assent to spend any sum whatever on class teaching in the provinces (except perhaps, in two or three district centres) unless with the definite object of winding up our affairs and putting things straight for the future.

I do not believe in tiding over the difficulty. Ten, twenty, thirty years hence, it would still face us or more probably our successors.

THOS. B. GROVES.

Weymouth, September, 1872.

Sir,—In that part of Mr. Schacht's address which apparently refers to me, I am puzzled by the following statement: "It is not the same" (as the Government system), "but the principle is identical with it; and I am quite willing to admit that I owe everything to the suggestions which that scheme has given." "Not the same," yet identical. "Not the same," yet everything copied from it. Different, yet identical! How funny! I should rather think that if it is "identical with the Government system," and if he owes everything to it, that it certainly is the Government scheme; must be it, and cannot be anything else. Mr. Schacht further states that the scheme has "stood the test of many years' trial at the hands of the Government authorities." To have spoken fully and fairly he ought to have mentioned the growlings the Government has received during the same time; but, I fear, Mr. Schacht's tendency is to describe the bright side of a picture.

Were the eighteen-penny book worth the money I should immediately get it; but as I know its contents, I prefer not to open my purse.

The next paragraph I am sorry to see. I do not know whether Mr. Schacht is disposed to treat me with silent contempt or not, and I do not know why he should mention anything of "the anonymous charges." (?) Although I write anonymously, it is not that I am ashamed of my name. I do so because my first letter was signed anonymously, and then I did not think I should be obliged to write more than that letter. I regret not putting my name to my first letter, because I disqualified myself from reading a paper on the subject to the British Association; but I have consoled myself that I may still be allowed to use my pen in the Journal. "The scheme of the Government has only just escaped a collapse." This I still stick to. At the time I wrote, that the chemistry classes were foremost in my mind, whence proceeded all the growlings and dissatisfaction; and if I had said "the chemical section of the department has all but had a collapse," I should have better expressed my meaning.

The next sentence, "That every one who knows anything about it is disgusted, pupils and teachers alike," was corroborated by the newspapers a few weeks ago. Perhaps Mr. Schacht would very gladly keep this corroboration in the background. "At Brighton the Science Department got a very severe handling," and again, Dr. Wood stated "that the less teachers and pupils had to do with the Government the better." This, sir, was before the British Association. I am sorry I was not there. I should vastly have enjoyed the sight of Mr. Schacht stepping into that company of experienced men with his paper.

In stating "there is this year one-sixth the number of students there was in recent years," I referred to the students of chemistry classes; if Mr. Schacht's point be carried he will teach chemistry chiefly, not physical geography or human physiology, etc. Why, then, should he show statistics of these subjects, or of all the subjects together, and not of those he wishes to teach? Will Mr. Schacht confine his remarks to the chemical students? It is they who have growled and who have diminished in numbers; not any others.

Now, I will tell Mr. Schacht that I am a teacher of science teachers; that I have trained more than thirty teachers, and that all of us, three years since, were fully employed. Last session, however, instead of their being about forty classes and hundreds of students, there was only one teacher, one class, and about twenty students, in a thickly-populated district of nearly half a million of people. If the same feeling pervaded the whole body of teachers as those under my wing—which I have no doubt of, for I am one of 200 science teachers still "on strike"—it amounted practically to a collapse, for chemistry at any rate.

Mr. Schacht is a very funny arguer. "I am not a defender of the Government scheme at all," says he; yet he sticks to it tenaciously, and will hear nothing against it. A practical teacher, who can speak of all the objections, is, in his eyes, of less importance than the 'Blue Book' "got up" to appease "My Lords." A writer with sound reasons at his back, who was accidentally drawn into the debate, but who unfortunately signed his first letter anonymously, is "to be left alone." Under the circumstances, sir, I consider that neither I nor my anonymous charges (?) ought to be left alone. I have a right, I believe, to express my views, to ask Mr. Schacht any question as to why he does this thing or the other, and also a right to expect him fully to answer me; and if he be a lover of truth, if he desire a full and fair criticism, he will welcome me and my anonymous charges (?) and not "leave me or them alone."

A Country Major Associate.

Sir,—Yesterday I read with great pleasure the very interesting report of the discussion at Brighton on the all-important scheme of Provincial Pharmaceutical Education.

Certainly it is one of such magnitude that I am afraid nothing can ever come out of it that could in any way do good to the future position of the Pharmaceutical Society.

As a Local Secretary, I naturally keep a sharp look out for any movement that might either be beneficial or detrimental to the Society,—and more especially—to the whole body of chemists and druggists, both metropolitan and provincial. And in looking (with a provincial view) at the very efficient working of the Pharmacy Act, I cannot help thinking there are many amongst us who are crying, "What is this new scheme?" I can assure you, sir, that many of us in this part of England feel bitterly the effects of the Pharmacy Act, not only in loss of sale, but also in the difficulty we have even now of getting assistants to help us to gain our daily bread. And what is the cause of the latter effect? Simply this. Since the compulsory examinations have been established young men prefer taking situations in large towns where there are already facilities for obtaining the benefit and instruction of duly qualified teachers; many politely informing us that "Salary is no object!"

But the remedy proposed for this state of affairs is, in fact, that which has been in a great measure our ruin, viz., schools in large centres. If this scheme comes to pass, we, in small towns, who cannot by any means support a local association, will be left to drudge through the daily routine of our business as well as we can by the aid of porters.

Now, my remedy for the want of general education would be as follows:—

1st. Make the Preliminary examination the first step into the trade by making every youth pass it before he is bound an apprentice.

2nd. When the lad is out of his time compel him to pass the Minor, so as to qualify him as an assistant.

3rd. Finally let him undergo the ordeal of the Major for his final certificate to enter business on his own account.

For it is well known that the present standard of the Minor examination is by no means a qualifying test of a man's abilities to take up a position as a chemist and druggist. By the plan above given, we should be provided with a well-educated apprentice; assistants able to instruct the apprentices; and, lastly, you would have in the trade men of scientific attainments who could do more by individual instruction throughout the length and breadth of the land than any 8, 10 or 20 schools spread over England.

It must not be thought that I wish to deny any youth his chance of education, but let him find it himself: if he is able let him have his session or part of a session at Bloomsbury, as many of us have had in years gone by; and a better laboratory, museum, etc., cannot be wanted, than those now existing at 17, Bloomsbury Square.

The time has not, I think at all events, yet come for us to do anything beyond trying to perfect our present educational arrangements in London and endeavouring to raise our status by steady industry and self-enlightenment.

I should never have troubled you, sir, on this subject, but I fear that the few are legislating for the many (not in an improper spirit, for I believe they have the matter at heart), to the detriment of the smaller branches of the trade in small towns. It is merely a work of time; and until we get a larger number of examined Major men as masters in the trade, we should not find much reward for our labours; we must remember that "Too many branches weigh down the tree."

I would also in conclusion add that, in my opinion, the mere good or bad attendance at lectures would be perfectly valueless, for I well know the ridiculous farce played by many at such places, not excepting our own under Professors Redwood and Bentley.

A Local Secretary in an Eastern County.

September 11th, 1872.

Sir,—I have read with very much interest the various articles and letters which have appeared lately in the Journal on the above subject, and should have been well satisfied to have left the question in the hands of those able men who have taken it up, and are fully capable of carrying it to a successful issue; but the paper read by Professor Attfield at the late meeting of the Pharmaceutical Conference has raised some fresh points which are worthy of discussion, and a few remarks from a student's point of view may not be altogether out of place if you can find room for them in your next week's number.

The Professor has drawn a gloomy picture indeed of the present state of pharmaceutical education; and from his stand-point I can see that it may be hopeless, inasmuch as he would have every pharmacist to be prodigiously clever; but I maintain that though there may have been fewer prodigies of genius developed of late years, there has certainly been a larger amount of knowledge more widely diffused among the great bulk of employed assistants. They have awaked to the fact that they are no longer mere machines capable of grinding out so many pills per diem, but are in the majority of cases earnestly striving to gain that intelligent information with regard to the drugs they are every day handling, which they feel is required of them. And if, in isolated cases, resort is had to a "coach" to get them through the examinations, though I would condemn it in a man of average ability as damaging to that spirit of self-reliance which is the great secret of success, still it is often advantageous (to prevent waste of energy and constant diminution of the chances of success) to be directed just into those particular channels of information wherewith our present enlightened Board of Examiners think it necessary that the thirsty student of pharmacy should be refreshed.

In sober earnest the remedy for undue "cramming" lies with the examiners, in so varying the questions which they put to the students as to make it impossible for one set to "get up" those which have been put to their predecessors in the examination room. And here I would just wish to have a definition of this "cramming" which seems to be Professor Attfield's nightmare. If it is a fact that those who undertake to prepare youths for examination, manage to obtain knowledge of what questions are likely to be put, and only instruct their pupils in the answers to these in the shortest time possible, then I am fully prepared to join the Professor in wholesale condemnation of such dishonest conduct. But if the epithet be applied to the endeavour to store the mind with those facts from the Pharmacopœia and other sources, which (in addition to satisfying the Board of Examiners) will be useful to the student in after life, then I maintain that this form of "cramming" is commendable even though it may result in the outstripping of a lazy student of considerable genius by an industrious one of somewhat lower ability. And if, in the few weeks preceeding the examination, the young pharmaceutist's mind is frequently too well charged with information to retain it all for a very lengthened period, still a large amount of useful knowledge is stored up for future use; and the effort of mind is good for the student himself, especially if he is afterwards called upon to undergo any competitive examinations, in which the man with the best-trained memory is almost sure to bear the palm.

I must protest strongly against any artificial test being put to students as to their having attended any lengthened period at a recognized school of pharmacy. For, though I fully appreciate the advantages to be gained from association with other earnest minds under proper and efficient guidance, and would heartily recommend such a course to those who, having completed their apprenticeship, and passed the Minor examination, are not content to remain mere undergraduates, but aspire to taking their degree in pharmacy by passing the Major with credit, still the fact must be borne in mind that there are many who in after years will become the backbone of the Society who are not able at that period to afford the necessary outlay of money, and still less, at a later period, of the necessary time, to secure such a privilege. And yet many of these have bravely struggled against adverse circumstances, and even while engaged in active business, have steadily set to work in their few hours' leisure time in the day, and qualified themselves for the "Major." Shall we, then, by any artificial tests, throw stumbling-blocks in the way of intelligent industry, which the possession of a good degree of wealth alone can overcome? Shall we not rather stimulate and encourage it in every way possible? I may safely appeal to Professor Attfield which class of students have mostly turned out best under his instruction,—those who have been sent by their friends well provided with cash to spend *ad libitum*, or those who have exercised some self-denial and saved up in order to obtain the benefit of a few months' systematic training. The revelation of this fact, if it could be arrived at, would be interesting, and I feel sure it would be a sufficient answer to some of those who are inclined to make pharmacy a profession only open to the wealthier classes. Indeed, the failure of artificial tests in the medical profession is sufficiently demonstrated in the Professor's own paper, from which I will quote a clause or two. "The medical students who support the 'medical crammers' are chiefly those whose friends, having driven them into medicine against their will, have bribed them by a too full purse. These men take care to be present in the body at lectures, and hence get their schedules signed, but at other times follow their own foolish ways, and at last have to seek the aid of the crammers." I confess to fearing that a somewhat similar state of things will prevail in pharmacy if we arbitrarily attempt to make it too professional.

Then what is the remedy for the present defects? Surely in endeavouring to keep out of the body altogether those who have no taste for science, and in endeavouring, by every means in our power, to encourage those who are bent upon improving themselves in their hours of leisure, and placing efficient means within their reach for such improvement. Much may be done by employers, I am confident, in this respect. Before taking an apprentice I would suggest some such questions as these—

1. Have you any decided taste for natural history and chemistry, and how have you shown it in your hours of leisure at school?

2. Have you a fair knowledge of mathematics, such as working simple algebraic equations, and a problem from the first book of Euclid?

3. Have you passed the "Preliminary examination" with a fair knowledge of the rudiments of Latin?

With regard to the second of these questions, I am quite sure that the standard of arithmetic in the Preliminary examination is too low. The questions are often such as a boy at the top of the lowest form of a middle-class school of the present day ought to have no difficulty in answering; and I have frequently noticed that, in demonstrating a chemical reaction upon the board, persons much above the school-boy age, who attempt to instruct others in chemistry, disregard in a most painful manner that simple rule that "two sides of an equation should always be equal."

It seems to me that another important step might be gained by making the Minor a written examination instead of a *vivâ voce* as at present, with the exception of a short time for each student to show his familiarity with practical dispensing. This would prevent altogether the getting up of those catch-questions so frequently given by examiners of the old school, and would give the nervous student sufficient opportunity to recover his self-possession and do himself justice, whilst the barefaced ignoramus would be discomfited.

CHAS. FRYER.

Alexandra Road, Croydon,
September, 1872.

Sir,—At the present time the position of the Pharmaceutical Society, with regard to giving aid to education, and also the best method of education, are being very warmly, almost fiercely, discussed—and it is the duty of every one connected with pharmacy to contribute his quota towards solving this difficult problem; and certainly, since the passing of the Pharmacy Act in 1868, no question has been discussed which so much concerns the well-being of pharmacy as these, for, not only are those affected who are at present in business, but also those who will be masters at a future time. Professor Attfield's paper, read before the Conference, discloses a state of things which is fearful to contemplate, which is a disgrace to every man calling himself a chemist and druggist. The Pharmacy Act, which was to have done so much for pharmacy, has, in this matter, done no end of harm; it has created a demand for counterfeit chemists; for a class of impostors, and has supplied it, too. How can we expect to raise the status of the trade, or expect the public to respect the title of chemist and druggist, when a system of deception and of falsehood is fostered amongst our ranks, and almost legalized by Act of Parliament? Clearly such a system requires to be dealt with at once, and with an unsparing hand. But now the question comes up how to do so. As pointed out by Professor Attfield, the only remedy is compulsory education, and this may be obtained either by increasing the time and area of examination, or by causing the student to attend so many sessions of a school of pharmacy. Of these two methods, I think the latter the most practicable, and it might be carried out in the following manner.

According to the May report, the Pharmaceutical Society derives an income of £7000 from all England in the form of subscriptions and examination fees. Now, there are in round numbers fifty counties in England which gives £140 as the sum annually drawn from each county by the Society in the form of fees and subscriptions. The Society annually has a surplus of about £2000, and with this might be established 25 schools of pharmacy, one for each two counties, and placed in the most central city, and having each an annual grant of £80. Then let the Board of Examiners demand from each candidate for Minor or Major a certificate that he has attended two or more sessions, either at the local school or at Bloomsbury Square. Let the local association have lectures and classes on botany, chemistry, and materia medica, and also a dispensing counter; in fact, a regular session. By these means will that usurper, "cram," be done away with at once and for ever.

It may be urged that local associations should be supported by the surrounding locality; under this scheme such would be the case, for the annual grant of £80 would be a share of the money drawn from the county by the Society. Others might urge that local schools are not wanted at all; let the students go up to Bloomsbury Square; but they do not consider the expense of attending two or more sessions there. Others again profess that no local school is of any use unless self-supporting, and they point with pride to Bloomsbury Square, but omit to state that it costs them £600 per annum. If this scheme were adopted, we should see no more of the indifference of students; they would know that they must attend either the Square or the local classes, and would buckle to it with the best face possible under the circumstances, instead of wasting their apprenticeship as at present, and trusting to a month at a "cram shop" to get them through the Minor when their time is out. And can they be blamed for preferring a month so spent to spending their time for three or four years over dry books? By this scheme, instead of having about one-tenth of the apprentices at study, we should have at least nine-tenths, and the London "crams" might shut up shop at their earliest convenience. The indifference of the masters would also disappear; the country members and associates of the Society would know that they got something for their money besides the Journal in the form of aid to their own district. Another objection might be raised, that if, for instance, a school were established in Norwich, it would be unfair to Lynn and to Yarmouth; but it should be remembered that neither Norwich, Yarmouth, nor Lynn could separately support a school; yet under this system, by combined effort, they could support one in the most central place for all.

Another argument in favour of this scheme is its inexpensiveness. The Society need have no "back-bone of gold" to carry it on, for the annual surplus would be amply sufficient for all purposes, while in two or three years many of the schools would be self-supporting, owing to the large number of students attending them. £80 per year at first sight seems a small income for an association; but it must be remembered that there would be the fees of the students. Norwich, for instance, contains between 40 and 50 assistants and apprentices, and taking all Norfolk at about 60 more, and reckoning subscriptions at £1 per session, gives an income of nearly £200 per annum.

There are often heard complaints of the trade, owing to the large number of men with little or no capital in it. Were this scheme to be adopted, it would, to a great extent, do away with this, for when a man went to place his son to the trade he would find that it required such an expenditure, both of time and money, that only those who could well afford it would place their sons to it. As things stand at present, it is said, and with a great deal of truth, too, that this trade is a refuge for all men with a little more brains and much less capital than the ordinary trader. Make the obtaining of the Minor certificate more difficult, fewer will enter the trade, and those who do will come with more capital. And it is in this particular that Mr. Schacht's scheme, beautiful as it is in many respects, would do more harm than good; it would still further lower the status of the trade and throw it open to every one. And it must be remembered that even when backed up by Government, it has proved a signal failure. During the last two or three weeks I have made inquiries as to the working of the Government scheme with regard to the student, and the result is anything but gratifying. Even at the Teachers' Training College, the students have to learn by rote about one hundred equations; and the chances are that the equations required at the examinations will fall amongst them. Not one student in ten understands them. This, with a little smattering of chemistry from any elementary text-book, and a trifle more of graphic formulæ from the examiner's own book, and they are sent forth to teach others chemistry (?). Then, again, unless a student belongs to a registered class, every disadvantage is offered him, and even if he passes the examination he obtains no prize. Clearly such a scheme was formed for the teacher, not for the student. If Mr. Schacht takes a rotten scheme like this for his model, he will find in practice that he has committed a grave mistake. No scheme would so foster "cram" as this; and it would do even worse; it would cause the studies of an honest student to run in one groove, so that students would not learn chemistry or botany, but merely a a botanical or chemical catechism. With regard to the other systems proposed, the majority are practically worthless, on account of one grand flaw, viz., that of coaxing and petting and paying the student to study. No one ought to expect technical education for a mere nothing; like every other commodity, it has its price; but by the tone adopted lately by many leading pharmacists, many students have inferred that education is to be provided for them gratuitously just when it is their sovereign will and pleasure to study.

T. G. S.

Norwich, Sept., 1872

Sir,—So much has been written advising chemists to reject all youths as apprentices who have not passed the Preliminary examination, that it has become a pharmaceutical aphorism, and one must be rather of an antediluvian cast of mind who ventures to think differently.

Let us see what the result of the new dogma will be. We may assume that the only candidates for examination are those who have some knowledge of Latin, and think they will pass it. Fifty per cent., or more, of these likely ones fail, the others who don't try we need not consider, but their number must largely exceed the former. The consequence will be that soon there will be very few apprentices to choose from; they will go up in the market, and correspondingly their premiums will go down.

Some of us have been bold enough to think that an apprentice should be something more than a drudge, and that time and opportunity should be allowed for attending classes for qualifying for a responsible position, but all this means expense and must be paid for in the premium, which cannot be the case if my first position is correct. A certain amount of commiseration has been expressed for assistants and a "Modified" examination provided for their benefit; a little, I think, might be reserved for all the youths who hope to be druggists and are just leaving school. I would not by any means do away with the Preliminary, but I would not shut the door in their faces, as we are advised, till this be passed, for the reason I have already stated; and for another and weightier one, namely, this,—we are punishing these youths and their parents for the sins of our middle-class schoolmasters, on whose heads the punishment ought to fall, and whose manifold shortcomings will, I hope, ere long come under the discipline of some middle-class Forster, who will reserve some of his energy and the nation's money for them and not spend it all on the over-much sympathized with working classes.

Actual experience beats a great deal of theory. I will trouble you with mine; it will doubtless find a parallel with others. In the last few years I have had five apprentices—all respectable youths—all sent as their parents supposed to good schools, and all paid a premium of £100 or more. I merely mention this to show that their parents were not poor, so as to seek cheap schools. All these youths were sixteen; all had learned Latin, and all were intelligent well-conducted lads. Two only could translate a single line of Cæsar, and, strange to say, they had been educated at the Ripon Grammar School, now being remodelled, owing to its not satisfying the requirements of the Endowed Schools'

Commissioners. Whatever its faults it did one thing well—it taught Latin. Would that all other schools, not being disintegrated, could say the same.

The other three would have found it difficult to construct the simplest sentence of nominative verb and object without mistake, and their Latin education is consequently all to begin, though one of them had done the first book of Cæsar. How boys are taught in such slipshod fashion I cannot make out; it seems to me that the foundation is badly laid, and there ought to be more time spent over the five declensions and conjugation of verbs than there is. One step should be made sure before another is taken; for want of it we have these failures. We want some stern supervision of these private schools; then schoolmasters would not dare to let such work pass muster, and the parents' money and the boys' time would not be so wrongfully wasted. We want some guarantee from every schoolmaster that he can and will do his duty. There's the rub, and till this is done there will be these failures. The question is then, how best to meet existing difficulties and patch up the schoolmaster's miserable work. The only plan and the merciful one is to take these lads as they are, and either teach them Latin ourselves or send them to night classes to learn, and give them all the help we can. In this way I got one of my three aforesaid through the Preliminary; the other two are yet to be passed. Of course I wish it was done, and think it a great shame I should give my time to teach these lads what their school ought to have done; but under existing circumstances I see no other plan. Feeling one's own deficiencies in Latin, and knowing also that there are hundreds no better, who nevertheless read prescriptions daily, and having also some doubts as to the profundity of the Latin of the prescribers, one is tempted now and then to doubt whether it is absolutely necessary to be able to translate a passage of Cæsar without a dictionary before one ought to be allowed to be a chemist. This is, however, such a heresy that one scarcely dare say all one thinks; nevertheless there may possibly be something in it.

26 & 27, *Commercial Street, Leeds*, W. SMEETON.

Pharmaceutical Education.—"Reformer" writes expressing surprise at the objections urged against the increased outlay incurred by a higher class of pharmaceutical education. He is of opinion that the remuneration would be increased in greater proportion, since the stringency of the examinations would exclude those not sufficiently intellectually trained, thereby diminishing competition. He thinks that for the full development of pharmaceutical education it will be necessary to comprize such subjects as Euclid, algebra, and natural philosophy.

Mr. J. C. Coles, of Chippenham, writes to say that it is with country members of the trade that the majority of young men pass their first year of study, and he thinks this proves that any aid the Society can afford should be general rather than central.

DISPENSING AND DRUG DEALING SURGEONS.

Sir,—I was much gratified upon reading the article in the Journal for Sept. 7th, concerning the question of medical men keeping retail shops and dispensing their own medicines; it is one of vital importance to the chemist, and I trust the subject will be fully ventilated. If the existing antagonism between medical men and druggists is to be removed, it must be by both parties making concessions, which would prove mutually advantageous, each restricting themselves to their proper and legitimate functions—the chemist confining himself to the dispensing of prescriptions and the retailing of drugs and chemicals, and the medical man visiting his patients, and sending his prescriptions to the druggist for preparation, thereby removing to a great extent the present temptation for the chemist to trench on his prerogative by prescribing across the counter; a certain amount of counter prescribing would of necessity still exist, for the chemist is and must remain the "Poor Man's Doctor;" they (the poor) will come to us for advice and medicine for minor ailments, and I presume the medical man would consider it rather *infra dig.* to supply either for the small remuneration the druggist receives for his trouble.

As the chemist of the future is to be something higher and more worthy of the title than in the past, provision must be made to enable him to keep up his dignity by furnishing the means to live out of the proceeds of his business, a matter which, as things exist at present, he finds somewhat difficult,—the closing of the surgeon's retail, and the transfer of his dispensing to the chemist would go a long way towards this desirable object, while, on the other hand, the medical man would get a *quid pro quo*, and a fertile cause for the present jealousy and ill-will now existing between the two parties would be removed. Trusting you will do your utmost to bring about this desirable consummation.

Newport, Isle of Wight, CHEMIST.

MAJORS AND MEMBERS.

Sir,—In Mr. Carteighe's letter to you, published last week, extracts are made from the Registrar's Reports as to Members elected in 1870 and 1871, and by which it appears that more pharmaceutical chemists were elected than passed the Major in these years.

The following extract therefore, supplementing the Reports referred to, may be somewhat explanatory and perhaps useful:—

Passed the Major in

1852	53	56	60	61	63	65	66	67	68	69	70	
1	1	1	1	2	1	1	2	3	9	38	19	= 79

Associates before August 1st, 1842 5

Elected Members in 1870 . . . 84

Passed the Major in

1853	59	64	67	68	69	70	71	
1	1	3	3	8	8	20	17	= 61

Associates before August 1st, 1842 2

Elected Members, 1871 63

ELIAS BREMRIDGE, Secretary and Registrar.

17, *Bloomsbury Square, September 26th*, 1872.

Mrs. Stockman and Family.—The following sums have been thankfully received in aid of the above family: Mr. J W. Britain, Hampstead, 2*s.* 6*d.*; Amicus, 1*s.*; Messrs. Robbins and Co., Oxford Street, £1. 1*s.*; Mr. T. Hodsoll, 5*s.*; Pharmacist, 10*s.*; Friends, per Mr. Spurling, Brompton, £1. 3*s.*; Mr. Tylee, Bath, 10*s.* Further contributions are much needed, and will be received with many thanks by G. Perfect, Havelock Park, Southsea, and Charles Mumby, Pharmaceutical Chemist, Gosport, Trustees.

W. B. Clark.—We have handed your letter to the Board, who, in framing their new regulations, will doubtless take your suggestions into consideration.

The Editor of the 'Grocery News.'—The paper you refer to was read in the Chemical Section of the British Association at Brighton, and was published *in extenso* in the 'Brighton Daily News.' Our report was derived from the same source.

Mr. James Stedman writes in reference to a case reported at page 239 in our last number to state that the composition of his powders was not correctly given by Dr. Hughes.

A. B. C.—By simple solutions is intended those in the B. P. and others in common use in medicine and Pharmacy, but *not* in that volume.

T. Hugh Jones.—We refer you to the number of the journal in which the recipe appeared.

X. Y. Z.—Formulæ for this preparation have repeatedly been given in the journal.—*Vide* I. 857.

D. Jenkins.—We do not know of any authorized form: 3 grains of the scales in one fluid drachm of syrup make a nice preparation.

Z. (Dulwich).—The plant is *Erigeron canadense.*

"*Justice.*"—(1) It would certainly be unlawful to keep a druggist's shop under the conditions you mention. (2) We do not quite understand this question. (3) You had better communicate with the Registrar on the subject.

P. J.—(1) The sale is legal. (2) The case you mention would not come under the Adulteration Act, we think, unless the salt were sold as medicine.

COMMUNICATIONS, LETTERS, etc., have been received from "Inops," Mr. P. L. Simmonds, "Justitia," Mr. G. J. Cutcliffe, S. W. W., Dr. J. Leon Soubeiran, Mr. E. B. Vizer, Professor Attfield, Mr. S. K. Bennett, G. L., A. P. S., Mr. Jas. Copley, Mr. R. G. Mumbray, Mr. D. B. Sharp, Mr. C. Fletcher, "An Apprentice," Mr. J. Mackay, "A Student," Mr. J. Farr, Mr. W. H. Hayward, Dr. Cameron, Mr. G. W. Stephens, Mr. H. Minett, Mr. H. J. Whitred, Mr. J. Hutchinson, Mr. J. Archer.

PHARMACEUTICAL EDUCATION.

BY PROFESSOR ATTFIELD.

At the close of the prolonged discussion on Pharmaceutical Education which I had the honour of introducing at the Brighton meeting of the British Pharmaceutical Conference, time forbad a reply to the remarks I had invited. A report of the proceedings having now appeared in the PHARMACEUTICAL JOURNAL, I proceed to reply to some questions that have been raised, and make one or two additional observations.

The want of a succinct statement of what has already been done for pharmaceutical education in Great Britain must have been felt by every one interested in the present position of the subject. Such an account was offered in the first and chief part of my paper. The labour involved in the production of that portion was considerable, but is more than rewarded by the testimony given to its faithfulness and usefulness.

Respecting the present and prospective aspects of pharmaceutical education some dissent from my opinions was expressed; but this, I think, mainly because what was meant by education was not defined by me with sufficient fulness. By pharmaceutical education, pure and simple, I understand that knowledge which a man desires and acquires to fit him thoroughly for his calling, irrespective of any examination, voluntary or compulsory, or any title, legal or honorary. Having such knowledge, full in amount, but not more than is sufficient for the purpose just stated, a student necessarily, that is as a matter of course, passes the Minor and possibly the Major examinations of the Pharmaceutical Society; afterwards retaining that knowledge, together with all mental culture its acquirement has afforded. The Pharmacy Act of 1852 stimulated education of this kind. Such education demands the expenditure of a considerable amount of time on the part of the student; but the Council of the Society has always set before pharmacists a course of study of this nature as a standard, and education of this character is what has been aimed at by the promoters, managers and officers of the various schools of pharmacy which have been started from time to time throughout the country, more or less in connection with, or aided, or countenanced by the Society. But there is a method of obtaining knowledge—that is, short-lived knowledge—occupying far less time than that necessary for the acquirement of the kind of education just described. Barristers and others sometimes have occasion rapidly to work up a subject for the temporary purposes of debate, argument, or advocacy. It produces no sort of culture as respects the subject itself, and passes from the memory as rapidly as it entered; but it accomplishes its object legitimately enough. Persons possessing it are for the time well *informed*, not *educated*, in the subject. When, however, such information is acquired and employed for the purpose of passing such an important public examination as our "Minor" or "Major," I maintain that its use is in an ordinary sense of the word illegitimate, to be deprecated by every right-minded pharmacist, and, if possible, prevented. This is the kind of ephemeral knowledge which is confessedly taught and notoriously employed in England (not at present, apparently, in Scotland) to what many besides myself know to be an enormous extent to enable men to pass the examinations mentioned. I find that in imparting such information methods are employed other than the one mentioned in my paper —a process, "cheating" Mr. Stoddart and Professor Foster term it, involving downright violation of the spirit of the eighth commandment, and under which I include (and only under such) any variation in the mode having for its object the ascertaining what questions an examiner may get into the habit of asking. Questions of this kind—"stock questions," as Mr. Carteighe calls them—some of which, as every examiner knows, must in the nature of things be put to almost every candidate, are those to which I alluded in my paper as being commonly asked, and which I mentioned as those the crammed candidate knows will be asked before he enters the room. I repeat that I think no language used in denunciation of the process can be too strong. Whatever be the process, however, it is the practice of giving and receiving mere information, and that of an ephemeral character, to which I wish to draw serious attention; a practice, the adoption of which by so large a number of students goes far to explain the cause of failure of all such more recent attempts to establish provincial schools of pharmacy as that described by Mr. Hampson; a practice which, by keeping so many students out of the classes, would, in my belief, prevent the success of the plans of education proposed by Mr. Reynolds, Mr. Schacht, or even that which "comes from Jötunheim;" and a practice which is already damaging, and which, if allowed to develope at its present rate, will sap the foundation of that true pharmaceutical education which the Pharmaceutical Society fosters and promotes, and has ever fostered and both directly and indirectly promoted in the metropolis and provinces.

With regard to the means of preventing this "coaching," the principle of the proposal which was stated during the discussion as emanating from the examiners themselves, deserves, in my opinion, the cordial support of all pharmacists of influence or in authority. It is that of requiring documentary evidence of lengthened education in at least one, and that the most important subject of examination. I have little doubt that if this plan were carried out, it would be found to work so successfully that it would be extended to the other chief subjects of examination. This is the plan advocated in my paper. My cherished ideas are apparently identical with those already entertained by the examiners, and hence, by the way, the contributor to the discussion whose remarks seem to indicate that he thinks my ideas involve a low estimate of the powers of our examiners, must please extend his censure to the examiners themselves. I repeat, that so far from attacking the examiners, I support them, and give little countenance to the adoption of the method employed at the London University of examination by special experts in each subject. It is not the examiners, but the system which the examiners have to carry out, that I venture to criticize—a system, the weak point of which is, a point in which it differs from that of all other Boards, that it does not at present possess as a guarantee against excessive cramming either documentary evidence of education, or the special searching powers of professional questioners having plenty of time at their disposal. Nay, if there is one subject in which our examiners might already be said to be professional examiners, it is in that termed "pharmacy," yet this is precisely the one in which the Board is asking the co-operation of the Council respecting power to require external evidence of education. I say that if in the subject in which the examiners are most likely to detect superficial information, they desire to have their hands strengthened by certificates of attendance for a certain number of years in a pharmacy, then any proposal that in the other chief subjects similar certificates of attendance for a stated time in a recognized school should be required, cannot logically be considered as uncomplimentary to the Board. Dr. Edwards thought that while the strong point of my paper was advocacy of thoroughness in education, its weak point was support of this schedule system. I submit that my friend's remarks only touched the abuse of the method, and not the method itself. I can speak from eight years' personal experience of its working in a large medical school; and while I know how formerly in some schools it was inefficiently carried out, I also know how easily its abuse can be and is now generally prevented. Professor Redwood's suggestion that candidates should be required to state where, when, and how their education had been conducted, would be useful to the extent to which it were made effective. The plan might be anything between a mere form and the recognition of certain schools, or rather certain modes of education to the exclusion of superficial teachers and teaching. Effectively carried out, it would end, I believe, in the system I have urged for adoption. Under any circumstances its tentative value is considerable.

A few sentences on the question, "Does the prospect of remuneration warrant much outlay for pharmaceutical education, or, briefly, does it pay?" Listen to Professor Markoe, himself a pharmacist engaged in trade. "What you, Professor, want to see done in England we have already accomplished in America. In the States a man is prevented either by law or the force of public opinion from opening a shop unless he can pass an examination *and* has attended a certain length of time in a recognized school of pharmacy, as well as worked practically at dispensing. You see, we give no opportunity for the rise of 'coaching' or 'priming.' Then the expense of education keeps out of pharmacy the crowd of poor and ignorant men that would otherwise enter; and so we have a smaller number of pharmacists in proportion to population than you have, and each business, consequently, is larger; besides, our pharmacists pull together better than if they were less well educated, and so get more fairly remunerative prices from the public and the confidence and help of the medical men." To my remark that this course seemed to discourage brain-power unless associated with money-power, Professor Markoe answered that a pharmacist received no premium with a pupil, and thus was enabled to turn a lad away if he had no aptitude for pharmacy; or, on the other hand, to keep him, and even, after a time, pay him and in other ways give him the means and opportunity of rising. He also alluded to the system as one under which there was always a good supply of well-paid assistants. I am hoping soon to hear more about pharmaceutical education in the various States of the Union.

I do not see why the system of education I support should not in due time be adopted to the extent suggested by the Board of Examiners, and carried out from year to year at such a rate and in such a manner that existing interests should not in any way be affected.

PRESENTATION TO M. CHEVREUL.

A very interesting episode took place at the *séance* of the French Academy of Sciences of September 2nd, on the occasion of what may be regarded as the academic jubilee of the Dean, the famous chemist, M. Chevreul. The fiftieth year of his membership does not strictly occur till 1876; but it is well know that he would have been elected in 1816, had he not urged the Academy to give the vacant place to M. Proust. M. Faye, as president of the Academy, intimated that the members had resolved, as a token of their estimate of his works, and their regard for his personal character, to present the venerable Dean that day with a medal, without waiting for the arrival of the formal jubilee. M. Dumas, in an eloquent and gracefully-worded speech, recounted the many valuable services rendered by M. Chevreul, and at the same time bore testimony to the personal character of the man. After M. Elie de Beaumont, who had been pupil of M. Chevreul, had added a few words of veneration and respect for his old master, the latter attempted to respond, but had simply to express his inability to do so.

LEEDS SCHOOL OF MEDICINE.

The Winter Session of the Leeds School of Medicine commenced on Tuesday, October 1st, when the Introductory Address was delivered by J. D. Heaton, Esq., M.D.

In the evening the Council, with old students and others interested in the school, dined together at the Great Northern Hotel.

In replying to the toast of "Former Members of Council and Lecturers," proposed by Mr. Wheelhouse.

Mr. R. Reynolds said he was quite sure they were right in having instituted such a gathering as that, and in having recognized the importance of maintaining the *esprit de corps* of their profession. He could not forget that he was there representing pharmacy in some degree, and that they stood towards the medical profession, he supposed, as a sort of poor relation, but they were anxious to maintain the credit of the family. Those connected with pharmacy had before them at present the great problem of how they were to educate their young men. The Pharmacy Act of 1868 had rendered education compulsory. It had provided for examinations, but had made no provision whatever for schools, or a system of education. But in a country like England they must not look to the Government to establish such schools. They must follow the example which the medical profession had set them; they must go through those modest attempts of which the chairman had spoken when the Leeds School of Medicine was satisfied with doing honest work—doing it in rooms which made no pretension as public buildings—and they had now got similar work before them. They would admit, if pharmacy were essential or complementary to the skill of the physician, that it was impossible that work should be done well without the requisite instruction was afforded to those who were to undertake that work; and the very kind way in which those connected with pharmacy were treated by the profession generally gave them much encouragement. They found that a great difficulty existed from the want of previous training in their pupils. Their boards of examiners told them of deficient education, and they had students who translated "*summo mane deglutiendus*" as "to be taken in the morning in jelly," and *lactis vaccini recentis*," as "recent vaccination being calmer." But they were honestly trying to do their best, and as being in charge of the ordnance department of the army, they would certainly try to keep the powder dry.

The Pharmaceutical Journal.

SATURDAY, OCTOBER 5, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE NEW SESSION.

THE ceremony of presenting prizes to the successful scholars of a past session, and offering words of welcome and advice to the intending students in the Society's School of Pharmacy at Bloomsbury Square, is always a very pleasant occasion. And this was truly the case on Wednesday last. Seldom has the assemblage been more numerous; the gratulations which met the recipients of prizes could not have been heartier; while it is no disrespect to his predecessors to say that no more appropriate address has been delivered to the students than the wise and genial words of Mr. WILLIAM WALTER STODDART.

It was only natural that at such a meeting allusions should be made to topics which have special interest at the present time, when the educational arrangements of the Society are the subject of so much discussion, and so great difference of opinion. The remarks of Professor ATTFIELD in reference to the Bell Scholars who studied in the Laboratory during last session, formed an appropriate sequence to the discussion at the Council-table in the morning of the same day. The Committee of the Council in making their report seemed to be of opinion that the abolition of the Senior Bell Scholarship, and the increase of the normal number of Junior Scholarships to two, would tend to ensure the instruction being given to a class of men likely to remain in the ranks of pharmacy, and that so, the immediate object of the Scholarships,—the advance of scientific pharmacy,—would be best attained. But it is very significant that of the three Junior Bell Scholars of last session, one has already entered a medical school, while another appears only to have been restrained from leaving the business by the prospect of a desirable foreign engagement. We are afraid that, under the present conditions of pharmacy, this is only natural on the part of aspiring, intellectual and well-educated young men; and that such cases would continue to occur whether the Scholarships were Senior or Junior. But now that the Council appears to have decided upon abolishing the Senior Scholarship, and instituting two uniform Scholarships under reconstructed conditions, it is doubtless desirable that these conditions should, as far as possible, be framed so as to secure the object in view. To this end we have no doubt that any suggestions from those who have well considered the subject will be cheerfully received by the Committee appointed to report as to the details of the scheme.

One very pleasing testimony of the relations which exist between the teachers and the taught at the Society's School, was the very beautiful balance which the past students have subscribed for to present to the late Demonstrator, Dr. TILDEN. In him the laboratory students have sustained a severe loss, both as a teacher and friend. But we do not doubt that in the gentleman who has been appointed to succeed him, who has for the last three years acted as Assistant Demonstrator, they will find that the Council have provided for them a teacher who to experience adds the desire worthily to supply his predecessor's place.

It is gratifying to be able to add, that up to the present time the number of students entering is highly satisfactory, and there appears to be every prospect of a most prosperous Session.

THE NEW ADULTERATION ACT.

IT will be seen upon reference to the report of the proceedings of the Council at their last meeting, that the doubt expressed by a correspondent and alluded to in these columns, as to the eligibility of pharmaceutical chemists for the office of public analyst under the new Adulteration Act, has been submitted for the opinion of the Society's solicitor. We are glad to find that gentleman is of opinion that the medical knowledge required is not that of the physician as to the cure of disease, but such knowledge of the properties and characteristics of medicines as would be possessed by those who are in the daily habit of handling and dispensing them. We hope that so reasonable and desirable a reading of the words of the Act will be sustained, in accordance with the views we have already expressed as to the special fitness of pharmaceutical chemists to fill offices in which a practical knowledge of chemistry is required.

WE have been favoured by Professor ATTFIELD with two letters relating to his paper on Pharmaceutical Education, which he received too late to allow of their being read at the meeting of the Conference at Brighton. One of these is from Mr. FRAZER, who has taken an active part in reference to education as a member of Council; the other is from Mr. WALKER, who has had considerable experience in educational matters. In order to complete the series we have great pleasure in giving them insertion, and they will be found printed at pp. 278–9.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

October 2nd, 1872.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

MR. W. SCOTT BROWN, VICE-PRESIDENT.

Present—Messrs. Atherton, Betty, Bottle, Frazer, Greenish, Hampson, Hills, Mackay, Owen, Radley, Sandford, Savage, Schacht, Shaw, Stoddart, Sutton, Urwick and Williams.

The minutes of the previous meeting were read and confirmed.

Elections.

A former member of the Society having paid up his arrears of subscription, together with his subscription for the present year, and a nominal fine of one shilling, was restored to membership.

Two members who had paid their subscriptions for the current year, together with a nominal fine of one shilling, were restored to membership.

Members.

The following Registered Chemists and Druggists were elected Members of the Society:—

Heathcote, Henry Charles......Winster.
Langford, Charles...............King's Lynn.
Lowe, Walter....................Manchester.
Rowe, Sampson Taylor ....Redruth.
Thorpe, Joseph..................Blackley, near Manchester.
Wright, William Frederick ....Leamington.

ASSOCIATES.

The following gentleman having passed the Modified Examination, and being in business, was elected an "Associate in Business" of the Society:—

Friend, William.............Thornton Heath.

The following, having passed their respective examinations, were elected Associates of the Society:—

Minor.

Bishop, Charles Edward........Bristol.
Court, George Frederick ......Worcester.
Evans, Gwilym..................Swansea.

Modified.

Snook, Joseph John............London.

FINANCE.

The report of this Committee was received and adopted, and sundry payments were ordered to be made.

LIBRARY, MUSEUM AND LABORATORY.

The report of the Library, Museum and Laboratory Committee was received and adopted.

DEMONSTRATOR OF PRACTICAL CHEMISTRY.

Mr. John Moss, F.C.S., who has for the past three years filled the office of Assistant-Demonstrator of Practical Chemistry, was appointed Demonstrator of Practical Chemistry, *vice* Dr. Tilden, resigned.

RESIGNATION OF AN EXAMINER.

A letter was read from Mr. Augustus Bird, tendering his resignation of the office of Examiner on the ground that he had retired from business for some years, and that he felt that a gentleman actively engaged in the duties of the profession was better fitted for such a position.

"Resolved—That the resignation of the office of Examiner by Mr. Bird be accepted, and that the Secretary be instructed to write to him, to express the regret of the Council at the dissolution of the connection."

THE JACOB BELL MEMORIAL SCHOLARSHIPS.

The following recommendations of the Special Committee appointed to report upon the Jacob Bell Memorial Scholarships were taken into consideration, according to notice:—

1. That the Senior Scholarship be abolished.
2. That there be two Junior Scholarships of the value of thirty pounds each, and that the Council, when granting free laboratory instruction, do also grant free attendance to the lectures.
3. Eligibility.—Candidates must be Registered Apprentices of the Society under twenty-one, and have passed not less, or been engaged for not less, than three years in the pharmacy of a Registered Pharmaceutical Chemist or Chemist and Druggist.
4. Subjects of Examination.—*Latin*:—Virgil; the three first books of the Æneid; Latin prescriptions; translations of Latin into English and English into Latin; translations from any Latin pharmacopœia, and parsing. *English*:—Composition and parsing. *Arithmetic*:—The four first simple and compound rules, fractions, and decimals; the British and metrical systems of weights and measures.

The examinations to be wholly in writing, and in case of candidates unable to attend No. 17, Bloomsbury Square, to be conducted under the same conditions as the "Preliminary," and such safeguard as the Council may from time to time deem expedient, and that the papers written by the candidate be numbered, *not named*.

The examination to be conducted by two members of the Board of Examiners, and the award made (subject to the approval of the Council) by a Committee of the President, the Vice-President, and the two said examiners, who shall take into consideration the means, position, and surroundings of the candidates, as well as the number of marks obtained in the competition, and preference shall, where practicable, be given to those least favoured by fortune.

Notice to be given that the successful candidates will be expected to present themselves for the Minor and Major examinations.

Mr. WILLIAMS moved—

"That the recommendation of the Special Committee appointed to consider the Jacob Bell Memorial Scholarships be received and adopted."

He said the matter had been under consideration for some time, and that it was the opinion of the Committee that giving the senior scholarship was offering a prize to young men who had received a considerable amount of instruction, whereas it did not encourage young men who really wanted to learn their business. It rather acted as a superior prize given for attainments, which really tended to pass the recipients out of the business instead of retaining them in it. This view was so strongly impressed upon the Committee, that they had thought it better to leave out the subject of pharmacy and botany from the competitive examination for candidates. He thought what they wanted was to try and encourage the young members and apprentices to pursue their studies so as to qualify them for worthily filling the position in which they would be hereafter placed when conducting the business of chemist and druggist. It was found that practically the Bell Scholarship was a prize given to the students in the laboratory, whereas they should strive to make it a general prize open to all young men in the country. He only wished they were in a position to recommend that, instead of two, there should be two dozen junior scholarships, and he should be very glad if the funds of the Society could be spent in that way, so that their laboratory might be filled with young men from all parts of the kingdom who had gained the right to study there by their proficiency in the studies they had already undergone. However, they were not able at present to go beyond the sum of money already invested in the name of the Jacob Bell Memorial Scholarships Fund. If, however, that system worked well, the time might come when it might be extended, and in that way he believed they might very much help forward provincial education. He would only add that these recommendations had been well considered by the Committee, who had met many times, and had had the benefit of the opinion of the examiners who had tested the candidates.

Mr. STODDART seconded the motion, saying he was satisfied the committee had well considered the matter, and he was quite willing to fall in with their suggestions.

Mr. SCHACHT said he heartily concurred in the principles laid down by Mr. Williams, and carried out in the resolution, that the alteration proposed was wise and proper; but he must object to a portion of the last two clauses, namely, that which stated that the examiners should take into consideration the means, position, and surroundings of the candidates, and that preference should be given "to those least favoured by fortune." That was a very generous doctrine to recognize where possible, but not in such a place as the examiners' room. The first condition was, talent should be the criterion of merit in the candidate, and taking into account the primary object for which the scholarships were instituted, that should still be the rule; and the examiners, instead of being directed to favour any one, should not travel out of that strict line of justice, but should simply decide who was the best man. Again, the last sentence he thought should be made more emphatic.

Mr. MACKAY also agreed with the principle of abolishing the Senior Scholarships, but desired to supplement very strongly what had fallen from Mr. Schacht. He suggested that the Council should agree or disagree with the principle of abolishing the Senior Scholarships; and if this were agreed to, he thought it would be wise to let the matter go back to a committee for further consideration as to the details of working out the examination. As to the examiners inquiring into the means and surroundings of the candidates, it would be placing them in a most peculiar position, and would be, in fact, reviving an inquisitive system, such as had last been heard of in Spain some years ago. Such a thing was most objectionable, and especially so when they had seen in days past, and no doubt would see again, that the son of an ordinary baker might become the senior wrangler.

Mr. WILLIAMS said it was only intended that, where the marks were equal, preference should be given to the candidate who had had fewest opportunities of study.

Mr. BOTTLE concurred with the remarks of Mr. Mackay, and added that the elected candidate himself would be placed in a very unfair position if it were understood that he was selected on account of his poverty.

Mr. SUTTON said if they had to choose between two shipbuilders, one of whom had used only an adze, and the other had been provided with all kinds of tools, and the vessels were equally well constructed, they would certainly prefer the man who had accomplished the most with the fewest opportunities.

Mr. OWEN said he hoped that would be borne in mind in awarding marks.

Mr. WILLIAMS said the marks were awarded before such questions came under consideration at all.

Mr. SANDFORD said he was much averse to seeing the Senior Scholarship abolished, though he was not averse to men leaving the profession to go into something better. They had just had an instance in their own institution; Dr. Tilden, who was a Bell scholar, having now left pharmacy to take a higher position, but he would still be a credit to the Society, and advance its interests. In addition to that, very recently one of the best men belonging to the Society had been talking to him about its future; and said he hoped to encourage research and a further prosecution of study by the members of the trade by instituting a sort of senior scholarship. He thought that if six or eight young men every year could be induced to enter the laboratory and work there for a time after passing the Major examination, it would tend greatly to advance the interests of pharmacy. It must also be recollected that when this Fund was first established, a circular was sent round which contained this passage:—"The details, including the extent of the proposed scholarships and the conditions on which they shall be awarded, necessarily depend on the amount o subscriptions obtained, but the Council feel assured tha such a sum will be subscribed as will enable them to establish not only minor scholarships for young men les favoured by fortune than by industry, but also one, at least, for the advancement of high scientific attainmentst so that there may thus be two classes of scholarships tending to advance the reputation and dignity of the Pharmaceutical Society." That was the principle which started the scholarships, and on which the money was raised, and he thought they would be to some extent breaking faith with those who contributed if they abolished the Senior Scholarship. This question of principle should be decided first before going into any detail, and it must not be forgotten that they had the opportunity, which had been used, of giving two Junior Scholarships when there had not been candidates for the Senior.

Mr. BROWN said he intended to propose an amendment:—

"That this Council receives and adopts Clauses one and two of the Recommendations of the Special Committee (omitting the word 'junior' in Clause two), and refers back the details for further consideration and future report to the Library, Museum, and Laboratory Committee."

That would at once bring before the Council the question to which Mr. Sandford was speaking.

Mr. MACKAY said he would second that amendment.

Mr. SAVAGE thought the Senior Scholarship had already been practically abolished, for several times there had been no senior candidates, and unless the system was modified he did not see how they could come in.

Mr. SUTTON said the Society ought to keep its aims as high as possible; and by keeping up the standard of education, they would be able to get a position equal to that of any chemical or medical society, but this could not be done without hard work.

Mr. ATHERTON said by abolishing the Senior Scholarships, they would do away with any reward for proficiency in pharmacy, since by the new code of regulations the scholarship would only be given for proficiency in elementary education. It hardly seemed to him proper that the Jacob Bell Scholarship Fund should be devoted to such purposes. It ought certainly to be so dealt with as to incite extra exertions in young men to make themselves more efficient pharmacists, and therefore he thought they should either retain the Senior Scholarship or modify the proposed examination. In fact, he should prefer doing away with the Junior Scholarship and modifying the Senior.

Mr. URWICK felt greatly in favour of retaining the Senior Scholarship, thinking it must result in good to the Society; for if a man distinguished himself by attaining it, wherever he might go the credit which attached to him would be reflected on the place where he was educated.

Mr. GREENISH thought it would be most injudicious to do away with the Senior Scholarship; and although there had been no candidates for it on some occasions, education was advancing, and probably in the course of a year or two, applicants would be forthcoming. Just at the present time, when they were desiring to advance education in every possible way, it would be most unwise in his opinion, to make this alteration, especially when if there were no competitors for the Senior Scholarship, two Juniors might be given, so that no injustice was committed.

Mr. Hampson said it appeared to him that if the scholarships were given for elementary education alone, it would really defeat the intention of the founders of the Fund, who evidently designed to promote the advance of pharmacy distinctly.

Mr. Hills said he should not like to give a silent vote upon this question, but would only say that he adhered to the view of the Committee of which he had been a member, that the Senior Scholarships should be abolished, and two Junior Scholarships established instead. At the same time, he thought the examination might be so modified as to contain something at least relating to pharmacy.

Mr. Betty said he was glad to hear at least one gentleman come forward and support in the Council the views which he had advocated in Committee, namely, that in the present state of things the Senior Bell Scholarship was not really useful to the Society or to the trade at large. If it were really contended for and awarded, it would no doubt be of great use, but when it appeared the conditions were such that it fell into abeyance, and they had to take refuge in the plan now suggested, common sense seemed to point out that they should do formally what they had to do in reality. He was still of opinion that it was practically of more utility to the Society to diffuse education rather than to confine it, in however brilliant a star, to one or two spots. If every year there were introduced into the business two Junior Bell Scholars who had received such an education as would do themselves credit, it must certainly be more advantageous than having one Senior Bell Scholar, which was about the average.

Mr. Frazer said he should prefer to retain the Senior Scholarship; firstly, because it would be keeping faith with the subscribers—especially as when candidates did not appear, two Junior Scholarships were awarded; and secondly, because as education was advancing, it was to be hoped that in the near future candidates would be forthcoming.

Mr. Brown said he would now move the amendment which he had mentioned, believing it would be much more generally beneficial to the whole trade throughout the country to award two Junior Scholarships every year than to continue the old system. His amendment proposed to abolish Senior Scholarships, but it excepted all that followed; and he certainly did not agree with the conditions, the qualifications of the candidates, and particularly the paragraph with reference to the subjects of examination, which he thought might fairly be extended with great benefit to the candidates themselves.

Mr. Williams said the words "least favoured by fortune" had been introduced into the recommendations simply because they were in the draft deed, and therefore the Committee thought it best to retain them. He, for himself, did not like them. At the same time it simply meant this, that if two men had equal marks the award should be given to the poorer man. It should be borne in mind that it was simply a question of age, and whether they considered it was as desirable to take a man of twenty-four and give him a year's instruction, as to take a young man of eighteen or nineteen. That was the practical way of looking at it. He quite agreed it was desirable to advance science, but they ought principally to advance pharmacy. As to keeping faith with the subscribers of the fund, he could only say they had the solicitor's opinion in their favour, and the original subscribers would have no cause to complain.

Mr. Hills said the deed had never been completed.

Mr. Williams said he had no objection, in order to save needless division, to withdraw his resolution in favour of the amendment.

Mr. Sandford said he looked through the deed from end to end, and could not find any words in it authorizing them to alter the institution of the scholarships; the Council had only power to alter the arrangements for the examinations. He contended that if the deed had been executed, they would not have been able to abolish the Senior Scholarships, and although they might do it legally in consequence of the deed not having been completed, he thought there was still a moral objection.

Mr. Brown's amendment was then put as an original motion, and carried by a majority of 12 to 8.

Adulteration of Food and Drugs Act.

The President said there was in the last number of the Journal an Editorial note headed "New Adulteration Act," referring to a letter in which a doubt had been expressed, as to the eligibility of pharmaceutical chemists to be appointed as analysts under the Act; and the question was raised, whether the wording of the Act should be strictly interpreted so as to exclude pharmaceutical chemists. Now, it having been pointed out to him that if this were not settled, it might deprive some of their members of the opportunity of being appointed as analysts under this Act, he had requested their solicitor to attend and give his opinion as to what was the real legal meaning of the word "medical" in the Adulteration Act. In his view it did not refer to the special knowledge possessed by a medical man, but simply to a knowledge of medical substances, or of materia medica. He would, however, ask the solicitor to state his opinion upon the matter.

Mr. Flux (solicitor) said he had referred not only to the Act in question, but to section 34 of the Medical Act, which bore upon the question, and he had put his opinion into writing as follows:—

"*As to the Appointment of Analysts under the Statute* 35 *and* 36 *Victoria, cap.* 74.

"I consider that appointments of pharmaceutical chemists, or chemists and druggists, who may in the opinion of the appointors be 'persons possessing competent medical, chemical, and microscopical knowledge,' will be within the letter and in accordance with the spirit and intention of the statute.

"Had the intention been to exclude persons not *medical practitioners*, words of description in accordance with statute 21 and 22 Victoria, cap. 90, sec. 34, would have been used.

"'Chemical knowledge' is not in fact and is not by law presumed to be limited to registered 'chemists and druggists,' and likewise 'medical knowledge' is not, in fact or by law presumed to be limited to 'medical practitioners.' Knowledge of materia medica appears to me to be 'medical knowledge;' the statute which defines the examinations of pharmaceutical chemists and chemists and druggists (15 and 26 Vict. cap. 56) speaks of knowledge in materia medica and in pharmaceutical and general chemistry, as essential in the examined persons, and excludes 'the theory and practice of medicine.' The Pharmacy Act, 1868 (incorporated with the 35th and 36th Vict. cap. 74), in sec. 17, speaks of 'medicine dispensed by a person registered under this Act,' and in sec. 24, 'of articles usually taken or sold as medicines,' thus contemplating the dispensing and selling of medicine by chemists and druggists. The law assumes that every man has knowledge of the articles in which he deals, and it must be considered to assume knowledge of medicines or medical knowledge in a recognized dispenser or seller of medicine.

"The competency required is competency 'to analyse;' and I believe that the true intention of the statute is to authorize the appointment of any person whomsoever, who may possess competent microscopical knowledge, in combination with competent medical knowledge and competent chemical knowledge for analyses, and that the competency as to medicine and chemistry is to be ascertained in the same way as competency as to the microscope, viz., as a question of fact and not by reference to any register.

"Wm. Flux.

"3, *East India Avenue Road*,
2nd October, 1872."

After some discussion it was resolved:—

"That this Council thoroughly endorses Mr. Flux's opinion, and entertains no doubt as to the legal eligibility of pharmaceutical chemists, chemists and druggists, and others, possessing the requisite knowledge for appointment as analysts under the Adulteration of Food and Drugs Act, 1872."

PARLIAMENTARY.

The Report of the Parliamentary Committee was read. It included a revised form of circular with reference to the sale of vermin killers, which had been approved of by the solicitor. The Report and Recommendations of the Committee, with a verbal amendment, were received and adopted, and a copy of the amended regulations was ordered to be sent to every Chemist and Druggist and Coroner throughout the kingdom.

It was resolved—

"That the Registrar be instructed, and is hereby authorized, to erase from the Register the name of Thomas Holden, of Burnley."

Mr. SUTTON read a letter which had been sent to him by the coroner for the city of Norwich, calling his attention to the facts of an inquest which had lately been held in that city, on the death of a child which had been poisoned from an overdose of an opiate inadvertently administered, but where the jury had expressed a strong opinion that medicine of sufficient strength to kill a child should not be sent out without a label stating what the proper dose for certain persons of different ages would be. With this letter was sent a phial containing the residue of the medicine. The mixture contained about one-third of its bulk of laudanum, and was simply labelled "Nurses' Drops," with the name of the seller, there being no poison label or caution whatever.

Mr. WILLIAMS said that it was not the duty of chemists and druggists to give scales of doses.

Mr. SUTTON said it was evidently a case in which a prosecution might have been instituted by the police for selling poison without a caution label. The mixture was sold over the counter and not prepared from a prescription.

After some conversation, it was resolved—

"That the coroner of Norwich be informed by the Secretary that the sale to which he had called attention was an offence for which the police or any person might have prosecuted the seller, but that it was not the province of the Society to take action in the matter."

FEES TO LOCAL SECRETARIES.

Mr. SUTTON brought forward the motion, of which he had given notice—

"That Local Secretaries who have to superintend the examination of candidates for the Preliminary examination shall be allowed the sum of five shillings for any single candidate whose examination he shall superintend; if the number of candidates exceeds one, the sum of two shillings and sixpence each shall be allowed."

Mr. SANDFORD seconded the motion.

Mr. BOTTLE said Mr. Hills had also a resolution to bring forward for setting apart a sum of money towards defraying the expenses of local secretaries in coming to London to attend the Anniversary Meeting. He thought the two matters might well be considered together. It appeared to him that it was rather *infra dig.* to give a man five shillings for sitting three hours, and should prefer awarding half a guinea for each examination without regard to the number of candidates.

After some remarks from Mr. WILLIAMS and Mr. SAVAGE,

Mr. MACKAY suggested that the whole matter had better be referred to a committee.

Mr. HILLS said on a previous occasion he had brought forward the idea of making some recognition to local secretaries for their services, which he was desirous should be acknowledged in some way or other. Whether that should be done in the way suggested by Mr. Sutton or as proposed by himself was to him a matter of comparative indifference. He was quite willing that the whole matter should be referred to a committee to devise some plan which should carry out both Mr. Sutton's and his own idea.

It was ultimately determined that it should be referred to the General Purposes Committee to consider and report upon the whole matter.

EXAMINATION FEES.

Mr. FRAZER brought forward the following motion, of which he had given notice—

"That this Council, fearing that the present rate of examination fees forms an obstacle to many young men entering on the studies necessary for passing these, hereby appoint a special committee to examine into the whole question, and this especially, as to the propriety of reducing the fee for the Preliminary examination by one half, and also as to giving all candidates for the different examinations who failed to pass the first to have two other opportunities of passing without the necessity of making further payment. The Committee will further consider the question of giving all candidates who have passed the Preliminary the option of passing the Major, or such a modification of it as will embrace all the essential features of the Minor at once, without the necessity of passing the Minor also. And further that should these Resolutions be adopted, I propose that all who shall have passed the Preliminary examinations before they come into force shall be admitted to pass the Minor on payment of two guineas, and the Major one of four guineas, and that all our present Minors shall be allowed to pass the Major on payment of one guinea, thus securing that all our present students and assistants shall be able to take our highest honours on a payment of six guineas, instead of ten guineas, as at present. But it is to be understood that in the event of these changes being adopted, there shall be no portion of any of the examination fees returned to the non-successful candidates on their failing to pass the various examinations."

Mr. FRAZER said he was convinced in many cases the saving of fees was a matter of importance to apprentices, and when he looked at the fees exacted by other bodies, it did appear that their own scale was fixed rather too high. In Glasgow the fee for passing the Faculty of Physicians and Surgeons was only ten shillings, and having paid that, the student could present himself for a second examination without further charge. In the Pharmaceutical Society of Philadelphia the fee was four dollars, to be paid once for all, and the fee payable in that city on obtaining the highest diploma was only ten dollars. In the London University the fee for the Preliminary examination was £2, but the candidate had two other opportunities of passing without further charge. Their students, however, had to pay four guineas for three examinations. He believed that the loss to the revenue would be very inconsiderable if they adopted the principle of not returning any portion of the fees to unsuccessful candidates. Last year the fees received from 802 apprentices who passed the examination were £1684. Had the fee been one guinea instead of two, the direct loss would, of course, have been £842 but against this must be credited £333 received from 317 students who failed; £144 from 137 Minors, and £21 from 20 Majors, who were also rejected, making in all £498, to be set off against the loss of £842, leaving a net loss of only £344. Besides that he thought they might count on a portion of this loss being made up by an increase in the number of candidates. He had not taken into account those who passed the Modified examination; because as it was only a temporary affair he did not propose any alteration with regard to them. He was more anxious, however, with regard to the portion of his resolution which gave all candidates passing the Preliminary the option of passing the Major or a modification of it at once, without the necessity of passing the Minor also, than he was with regard to the reduction of the fees, because he was satisfied that in many cases young men who were really qualified to pass, did not do so from a dislike to passing these repeated examinations. Only the previous month one of his most efficient assistants left the trade altogether on the double ground of the fees he would be required to pay, and the necessity of undergoing an examination, especially preliminary, at the hands of men, some of whom might be his juniors in point of age and experience. It did not at all follow that a reduction of the fees necessitated a reduction in the standard of education, nor did he think, as had been suggested by some correspondents in the Journal, that it would have the effect of introducing a race of paupers into their ranks.

Mr. Schacht said he should be glad to second Mr. Frazer's motion, but he thought the time would very shortly come when it would be desirable that the whole subject of the examinations and examination fees should be reconsidered. From what he had recently heard, he believed that a report was being drawn up by the Board of Examiners, which would, ere long, be presented to the Council; and he would rather suggest to Mr. Frazer the desirability of letting this subject, which was a very large one, be referred, as he indeed suggested, to a special committee; that it should stand over altogether until the report he had referred to was received from the examiners, so that the whole matter might be considered together.

Mr. Frazer said he had no objection to this course.

Mr. Mackay thought the time had not yet come for any such alteration as was suggested; at any rate, it had better stand over until the examiners' report came forward.

Mr. Frazer said he should be quite content with this course, especially as he had no doubt that in the meantime it would be ventilated in the columns of the Journal, as had been the case with the education question. Indeed, had it not been for that question looming in the future, he should have been prepared with a much more radical proposal with regard to the fees.

The President said it was not unlikely that the examiners would agree upon their report in the course of the present month.

Mr. Williams said he believed that instead of a reduction in the fees for examinations, an increase would have to be made.

Mr. Urwick said the great evil seemed to be that so many persons who passed the Minor acted upon the maxim of "Rest and be thankful;" and therefore the question was, whether they should not make the Minor examination more strict and more practical, making the Major examination more an honorary one.

Lady Students.

Mr. Hampson moved according to notice:—

"That ladies be admitted to attend the lectures and the laboratory of the Pharmaceutical Society."

He said, ten years ago a resolution was passed at the Council to the effect that lady students were not to be admitted to the lectures; but as it was not recorded in any of the transactions, many of the members were probably unacquainted with it. In 1862, perhaps the admission of lady students to the classes and laboratory might appear a step fraught with great danger, and tending to revolution; but in the present day, in remembrance of the social and educational changes that had taken place, he could not for a moment assume that the present Council, elected on a much broader basis, would endorse the decision of their predecessors, which was, in fact, most arbitrary, unjust and impolitic. The doors were closed against lady students during the attendance of Miss Garrett; but he understood that the professors, who were well able to form an opinion on this question, uttered no cry of complaint or alarm, and that the presence of the lady, who since then had risen to a more distinguished position, produced no inconvenience whatever, but on the contrary, had a salutary influence on the order and decorum observed by the classes. By the Pharmacy Act, 1868, ladies were admitted to the examinations, and were legally qualified to practise pharmacy; and two ladies had already passed the Modified examination with considerable credit. The introduction of the word "person" in the Act of Parliament showed clearly to his mind that the framers of the Act did not intend to shut out lady students, and therefore it was manifestly an arbitrary proceeding and diametrically opposed to the spirit of the Act of Parliament to exclude any person of respectability on account of sex from the instruction necessary to enable her to pass the examination. No doubt it was difficult for some persons to leave the well-beaten groove of custom in this or in other matters; but unless there were some solid reasons for denying admission to lady students, he thought they were bound to afford them the same facilities as gentlemen. Since giving notice of the resolution, he had endeavoured to discover any such reasons, but had failed to do so. As to the notion that it was dangerous and unwise to have a mixed instruction in any college, he thought that was unworthy of being discussed. Indeed, he was in favour of mixed education from the earliest age continuing through the whole process of national and scientific education. He admitted there was a feeling against female education in these kind of matters, but so there was against their writing books, and doing a variety of other things which they were now accustomed to do to the advantage of themselves and the community at large; and in these days of relentless competition he, for one, would not stand in the way of opening out any path by which a woman might obtain an honest livelihood.

Mr. Brown seconded the motion, saying he could see no possible harm which could result from its adoption. He certainly considered that ladies were put in an anomalous position with regard to the interpretation put upon one provision of the Act, since, in case of the husband's death, they were recommended to sell their business as quickly as possible, because they were not able to carry it on. If they were allowed to attend the lectures, this unfortunate state of things might, in some cases, be remedied; and he might add that he had known two instances in which a business, which had not prospered very well under the care of the husband, had thriven much better when conducted by the widow. It was quite possible that in the case of medical and anatomical lectures there might be considerations rendering it undesirable that the two sexes should attend such instruction together; but, with regard to botany and materia medica, there was nothing of that kind, and seeing that it would enable a man to train up his daughter, if he thought fit, to take a part in his business, he thought it only just that a needless restriction should be removed.

Mr. Williams said he should be glad to support the resolution if it were confined to attendance at lectures, as he did not think it would be wise just now to include the attendance in the laboratory.

Mr. Hampson said he believed the laboratory course was the most important, and he was quite sure that if any ladies attended it, they would conduct themselves properly, and no harm would ensue.

Mr. Hills said the permission could be rescinded in twelve months if it were not found to act satisfactorily.

Mr. Bottle said he also should object to opening the laboratory to lady students at present, though he had no doubt that would come at a future time. He thought special arrangements would have to be made, which he did not think they were just now in a position to provide. A few years ago ladies were not admitted to the Inaugural Meetings and Conversaziones; and when a resolution was passed for inviting their attendance, it was soon found the building would not accommodate them, and they had to go to South Kensington. The same result would probably ensue if they were admitted to laboratory instruction, and therefore he should ask the Council, as a progressive movement, to pass a resolution at present simply admitting ladies to the lectures. If it were found that they appreciated the advantages offered to them, and that there was really any demand on their part for laboratory instruction, he had no doubt it would be provided.

Mr. Mackay said he should support the same view. In Edinburgh Miss Jex Blake had beaten the whole Senatus, and had obliged them to teach ladies, but she could not compel them to teach in mixed classes, and Dr. Macadam had had rooms fitted up in Miss Blake's own house, where he gave instruction to six or eight young ladies.

Mr. Hampson said he had no objection, in deference to the wishes which had been expressed to modify his resolution, confining it to the lecture classes.

Mr. Brown said he consented to withdraw the word "Laboratory," not from any want of faith in the principle, but simply as a matter of expediency, for he really did think that with their present arrangements, they were not in a position to admit ladies to the laboratory.

It was then resolved unanimously that the resolution passed in 1862, prohibiting ladies from attending the lectures be rescinded, and that ladies be admitted to attend as students the lecture classes of the Pharmaceutical Society.

PHARMACEUTICAL MEETING.

Wednesday Evening, October 2nd.

The Opening Meeting of the Session 1872-3 was held at 17, Bloomsbury Square on Wednesday evening last. There was a very large attendance of pharmacists and students, and several ladies honoured the proceedings with their presence.

The Chair was occupied by Mr. A. F. Haselden, F.L.S., President of the Society.

The Secretary having read the minutes of the preceding meeting, the following donations to the Library were announced, and thanks were voted to the respective donors:—

Mycetoma—the Fungus-foot Disease of India; On Gnats' Scales: from Mr. Jabez Hogg (Author),—The New Patent Relating to the Sewage of Towns: from Mr. J. Brough Pow (Author),—Tenth Annual Report of the Birmingham Free Libraries Committee, 1871: from the Committee,—Portion of MS. of a work on Chemistry, by Guyton de Morveau; L'Eucalyptus, by Raveret—Wattel: from Dr. J. L. Soubeiran,—An Experimental Research on the Antagonism between the Actions of Physostigma and Atropia: from Dr. T. R. Fraser (Author),—Sketch of the Geology of the Neighbourhood of Banbury: from Mr. T. Beesley (Author),—Edinburgh University Calendar, 1872-73: from the University,—Report of the Curator of the Botanical Exchange Club: from Dr. Trimen,—Pharmacopœia Helvetica, 1872: from the "Société Suisse des Pharmaciens,"—Memoir—R. Chambers and W. Chambers: from Mr. T. H. Hills,—Smithsonian Report, 1870: from the Smithsonian Institution,—Glasgow University Calendar, 1872-73: from he University,—Chemistry—General, Medical, and Pharmaceutical, Fourth Edition: from Professor Attfield (Author).

The President said: It is customary upon occasions like the present, for the Chairman to address a few words of welcome to those assembled. To avoid repetition, I will ask you, if possible, to call to remembrance those spoken by myself twelve months ago, more especially the allusion to the pleasure derived from the presence of those kind friends and visitors who take an earnest interest in our proceedings and prosperity. To me an evening meeting like this, the harbinger as it were of the future, carries with it associations of an enjoyable character, which I trust may never be diminished; it connects the past with the future, the Session which has run its course with that which is approaching, the seniors with the juniors, the kind and encouraging words of the Professors (and I expect they will be quite as much so this evening, if not more so, than usual) with their pupils, and the good words of the address with the students new and old. It is a strong link in the chain which binds us together; may it, like a flourishing vine, year by year grow stronger and stronger.

Chemistry and Pharmacy.

The President then called upon Professor Redwood, as the senior Professor, to present his report with regard to the Chemistry and Pharmacy Class.

Professor Redwood said that what he had to submit to them that evening was simply a statement of facts relating to the class which was under his direction in connection with this Society, and had reference to a past Session. But one important object of their meeting was, as their President had very justly stated, to refer not merely to the past but to the future. It was to open a new Session of their school, and in this respect their proceedings would have reference to a future Session. In fact, their meeting there that evening had for its object to bring together the past and the future, and they might say that the past, the present, and the future were all associated in that meeting. They proposed to introduce students of a past to those of a future Session, and to introduce both to those who represented the present existing state of the pharmaceutical body, and to the parents and friends from whom they derived their supply of students, and who had met together with them to do honour to some of the most deserving and successful of those who had studied in the schools of the Society. At the examination which concluded the last Session, in July last, and which was in every respect a perfectly satisfactory Session, fifteen competitors presented themselves in the chemical class for the prizes which were awarded by the Council; of those fifteen, it was his pleasure and gratification to be able to report seven to the Council as having gained a sufficient number of marks by the answers which they had given to the long list of questions which were submitted to them, to entitle them to some distinction. He might here state that fifteen questions were submitted in his class, extending over a very wide area of physics, practical pharmacy, and chemistry, both inorganic and organic, and the answers to those fifteen questions had to determine the claims of the respective parties to recognition and reward. Six hours altogether were appropriated to the answering of these questions—two periods of three hours each; and he might state, as he had already stated to the Council, that, taking the answers as a whole, considering the number of competitors, and the number and character of the questions submitted to them, he had never on any previous occasion, although he had occupied that position now for some thirty years, had more satisfaction in awarding the prizes than he had on this occasion. Of the seven gentlemen who had been successful, the one who stood first—Mr. Robert Higgins Davies—had 90 marks, the highest number which could under any circumstances be given being 100. The one which stood second—Mr. Edward Rammell—had 84 marks. To these gentlemen the Council had awarded the Silver Council Medal and the Bronze Council Medal. Then Mr. Joseph Walker had 76 marks, and Mr. William Ashwell Shenstone 75, to each of whom an honorary certificate had been awarded. And lastly, there were three gentlemen who had 66, 64, and 61 marks respectively—namely, Mr. F. A. Crisp, Mr. A. B. Cortis, and Mr. Hetherington, to whom certificates of merit had been awarded. These were the gentlemen whom he wished to introduce to them, and regarding whom he was sure they would be pleased to ratify and confirm that which he had suggested to the Council, and the Council had determined upon with respect to granting them the marks of distinction to which he had referred.

Chemistry and Pharmacy.

Hours: Ten till One, and Two till Five. Standard number of marks, 100.

1. Define the meaning of the terms "specific gravity" and "density."

2. A specific gravity bottle having a capacity equal to 1000 grains of water when the perforated glass stopper is fixed in its place, is used for taking the specific gravity of alcohol, in an apartment, the temperature of which is 70° Fahr.; explain the probable sources of error in operating under such circumstances.

3. Describe the law, commonly known as Mariotte's law, relating to the effects of pressure on the density or volume of gases, the way in which results have been obtained on which the law is founded, and the limits to the application of the law.

4. What is the principle of hydrostatic pressure in accordance with which the hydraulic press is constructed; and in what way is that principle turned to account in confining the water in the large cylinder of the press?

5. What are the advantages and disadvantages of the hydraulic as compared with the screw press, when used in pharmacy?

6. In distilling water with an ordinary still and worm-tub, how much water is required in the condenser, and what increase of temperature will occur in it, in getting a gallon of distilled water? In what respect would the result differ in distilling spirit? Explain the cause of the difference, and give the data on which the calculations are based.

7. Explain the terms maceration, digestion, elutriation, lixiviation, percolation, and displacement, as used in pharmacy.

8. Describe some of the leading facts which have been established with reference to liquid diffusion. Explain the way in which experiments on this subject have been conducted; the results on which the process of dialysis has been founded; the form of apparatus used for dialysis; and the conditions under which the best results are obtained by it.

9. Describe the production of chlorine from hydrochloric acid and black oxide of manganese; from common salt, manganese and sulphuric acid; and from chlorate of potash and hydrochloric acid. Describe methods of collecting the gas, and what is specially to be observed in applying such methods. Give the specific gravity of chlorine, and the extent of its solubility in water. Describe the nature of its action on vegetable colours, and on infectious matters.

10. Describe the production of sulphurous anhydride from sulphuric acid and mercury, and from sulphuric acid and charcoal; explaining to what extent heat is required to be applied, what the gaseous products will consist of, how the sulphurous anhydride is to be collected, what its specific gravity is, and what the extent of its solubility in water.

11. Describe the action of sulphurous acid as a decolourizing agent, and the difference there is in its mode of action from that of chlorine. Name some of the organic substances to which it is most advantageously applied for depriving them of colour.

12. Describe the effects of different degrees of heat on zinc, and the way in which the metal may be reduced to the coarsely granulated, and also to the finely granulated state.

13. Describe the Pharmacopœia processes for citrate of iron and ammonia, tartarated iron, and phosphate of iron, and refer to any practical points in connection with those processes that you consider important.

14. Define the terms "Alcohol," "Ether," "Aldehyd," "Ketone," and "Olefine," as used by chemists as generic terms, illustrating the application of each term to two or more homologous compounds.

15. Give the formulæ representing the composition of the following bodies:—

Cane Sugar.
Grape Sugar.
Mannite.
Glycerine.
Nitrous Ether.
Oil of Bitter Almonds.

Botany and Materia Medica.

The President then called upon Professor Bentley to state the results of the examination in the Botany and Materia Medica Class.

Professor Bentley said that, although he had not addressed such an audience on thirty or more occasions of a similar character to the present, as his esteemed friend and colleague Dr. Redwood—yet there had been something like twenty-two or twenty-three occasions on which he had had the honour to address an audience at the commencement of a new Session, and he had often said that that day in his life was always a pleasant one. What he had said on previous occasions he could reiterate on this. He cordially endorsed what had been said by Professor Redwood. He had never had a more attentive or more diligent class, or one which exhibited in the whole course of the year a more uniform progress, than that which he had had during the last session. He could say this with perfect confidence, because it had been his practice during the past year to hold weekly examinations, which he found were most conducive to the success of the students. He intended this year to have occasional written examinations, as well as *vivâ voce* ones, and he hoped that the students would avail themselves as far as possible of them, for they brought the Professor more intimately in contact with his pupils; and thus facilities were afforded of testing the progress made and of asking the lecturer himself for an explanation of any particular subject. He felt very strongly upon the subject of examinations; and speaking from experience not only in regard to pharmaceutical education, but also with respect to medical education, he must say that he knew nothing which was more calculated to advance the students than periodical and systematic examinations during the progress of the course. With these few remarks he would proceed to make some observations upon the students of the past Session. He had already spoken of their diligence and good conduct; and when he spoke of their good conduct, he spoke of it not only as regarded that institution but with respect also to the Botanical Gardens, where they had important and rare privileges and opportunities for study,—and he must say as a member of the Council of the Botanic Society that not the slightest breath of complaint had been made during the past year, or, indeed, in previous years, of the conduct of the pharmaceutical students. He might also mention that it was with some satisfaction that he noticed the number of pharmaceutical students was increasing. This was not the time to go into the question of pharmaceutical education, but he might remark that when they considered the numbers of students who attended the classes, it was at all events to some extent a satisfactory test that, even under the present voluntary system, the young men were desirous of availing themselves of instruction. He found on referring to the Secretary's books that in the year 1869-70 there were 111 students attending his lecturers; and they must bear in mind that this was just after the passing of the Pharmacy Act, when there was a great rush of students. In 1870-1, he had 102—a fall of only nine; and in the year 1871-2 there were no less than 113 students attending the class of botany and materia medica. These facts spoke for themselves, and the members could draw deductions from them quite as well as he could. With regard to the terminal examination, sixteen candidates presented themselves. The examination in his class was twofold. It was a test in every respect. There was not only a written but a practical *vivâ voce* examination, and the total marks awarded for the two examinations was 120. Of the sixteen candidates, seven had at his recommendation been awarded prizes or certificates. The first gentleman, the same as obtained the first prize in chemistry, Mr. Davies, obtained 105 marks out of a possible total of 120. The second gentleman, the same again as obtained the second prize in chemistry, Mr. Rammell, got 103 marks. To these two gentlemen had been awarded the silver Council Medal and the bronze Council Medal respectively. The third, who ran exceeding close with the first two, obtained 99 marks, the numbers being 105, 103, and 99, and a certificate of honour had been awarded to the gentleman making these marks, who bore a name which was honoured in connection with that institution—Mr. Frederick Janson Hanbury. The fourth, Mr. W. A. Shenstone, got 93 marks, and was also awarded a certificate of honour. The next three, who got certificates of merit, were Mr. Arthur Brownhill Cortis, Mr. Joseph Walker, and Mr. Charles Harridge Russell. In conclusion, he congratulated these gentlemen on their success, and said that no one ever obtained a medal or certificate in that Society unless he was fairly entitled to it.

The questions for examination were:—

Botany.

Hours: Ten till One.

1. Give a general description of the different kinds of Raphides, and mention the plants and parts of plants where they are respectively found.

2. Describe the internal structure, and external appearance of an Acrogenous or Acotyledonous stem.

3. Define the following:—Phyllode, stipule, crenate, pinnate, pinnatifid, palmatifid, decompound, ligule, tuber, rhizome, corm, and bulb.

4. Define the following:—Involucre, glume, cyme, receptacle, thalamus, follicle, legume, septicidal, syngenesious, primine, testa, and aril.

5. Give the essential characters of the following Natural Orders, and enumerate the official plants which they respectively contain:—*Malvaceæ*, *Rosaceæ*, *Compositæ*, *Scrophulariaceæ*, *Polygonaceæ* and *Liliaceæ*.

Materia Medica.

Hours: Two till Five.

1. Describe the general characters, and botanical and geographical sources of the different varieties of Rhatany. Mention especially how they may be distinguished from one another, and enumerate the official preparations of Rhatany.

2. Describe the mode of extraction, general characters, varieties, and adulterations of guaiacum resin. Mention its botanical and geographical sources, and the means of detecting it when employed to adulterate scammony.

3. Describe the general characters of annulated, striated, and undulated Ipecacuanhas. Mention their botanical and geographical sources, and to what their medical properties are due. Enumerate the official preparations of Ipecacuanha.

4. Describe the botanical and general characters, varieties, substitutions, and adulterations of Chamomile Flowers. Enumerate the official preparations.

5. Describe the general and chemical characters of Dandelion root, and point out especially how it can be distinguished from other roots; also mention the season usually regarded as the best for its collection, and the data upon which such an opinion is founded. Enumerate the official preparations of Dandelion root.

Practical Chemistry.

The President then called upon Professor Attfield for his report in reference to the class of Practical Chemistry.

Professor Attfield said that at the close of the last session, sixteen gentlemen competed for the prizes in the class of Practical Chemistry. Of these sixteen, fourteen continued working during the whole of the two days devoted to that examination; and of the fourteen, ten succeeded in obtaining such a position as to entitle them to the medals and certificates awarded by the Council. Mr. William Ashwell Shenstone obtained ninety per cent. of the standard number of marks. Mr. Shenstone was a Bell Scholar,—one who would remain in, and doubtless be an ornament to pharmacy. The second on the list was Mr. Robert Higgins Davies, who obtained seventy-eight marks. Mr. Davies was also a Bell Scholar, but, the Professor was sorry to say, leaving the practice of pharmacy for that of medicine and surgery: indeed, he had already entered the ranks of medical students in Dublin. Mr. Davies and the third Bell Scholar,—for there were three last year,—Mr. Rammell, had enriched pharmacy with some original investigations during their term of study. These gentlemen had made researches and published papers: Mr. Davies on Sulphite of Magnesium, which would be found in the Pharmaceutical Journal for the 1st June; and Mr. Rammell, in conjunction with Dr. Tilden, on the Resins of Aloes, communicating the results to the Meeting of the British Pharmaceutical Conference at Brighton; they were published in the PHARMACEUTICAL JOURNAL of the 9th September. Mr. Rammell also, like Mr. Davies, gave indications of leaving pharmacy for higher paths of labour, following in that respect the example of too many of the Bell scholars. The Professor took to himself some credit for keeping Mr. Rammell to a certain extent amongst them. He had accepted a situation which, though not in Europe, was in connection with pharmacy, and on the preceding day had sailed for India, to join a large establishment in pharmacy there, so that the bond which bound them together was not snapped, it was only stretched. The third, fourth, and fifth on the list were Mr. Joseph Walker, Mr. Richard Trist, and Mr. F. J. Hanbury, who had obtained respectively, seventy-six, seventy-five, and seventy-five marks. It was due to these three gentlemen to state that through various circumstances they were unable to work at practical chemistry, during every day of the whole Session. They were only able to work for some four or five months each, and, therefore, the position they had obtained was all the more creditable to them. Certificates of Merit had been awarded by the Council to Mr. Daniel Badcock, Mr. Walter B. Bishop, Mr. James Herbert Midgley, Mr. Arthur Brownhill Cortis, and Mr. David Edwards. These gentlemen had gained nearly seventy marks each, and they quite deserved the position they had obtained. With regard to Mr. Bishop, he ought perhaps to say that, like Mr. Davies and Mr. Rammell, he had made some original investigations and experiments during the Session on the commercial purity and impurity of Iodide of Potassium, and had written a paper which would be found in the PHARMACEUTICAL JOURNAL of the 3rd August, and which would be seen to contain evidence of a considerable amount of analytical skill. At the close of the Session, the staff of the laboratory sustained a considerable loss. Dr. Tilden, who had been the senior demonstrator, the senior assistant in the laboratory for some nine years, had succeeded in obtaining the appointment of Lecturer on Chemistry at Clifton College. It would be known to most of those present that the officers of this Society, including the President and Vice-President, the Secretary and the Professors, invited Dr. Tilden to a dinner when he had obtained his appointment, and presented him with a testimonial, showing their regard for him as a colleague and a gentleman. The laboratory students of last Session, and of some previous Sessions, had also, the audience would be glad to know, subscribed a sum of money to show their appreciation of his attention to them, and the result was a present in the shape of the very handsome balance which was then on the table. While congratulating Dr. Tilden most strongly on the appointment he had obtained, he (Professor Attfield) regretted the loss for his own sake, for the sake of the laboratory, and for the sake of the Society. He would add, for the sake of pharmacy, for Dr. Tilden had contributed to pharmacy several valuable papers during the time that he was demonstrator in the Society. It was to be hoped, however, that in this particular respect they had not lost him altogether, for he promised still to give them the results of some investigations. Dr. Tilden had been asked by several of the students to attend there that evening, and had written regretting his complete inability to be present. The letter was as follows ;—

"College Gate, Clifton, Bristol,
"26th September, 1872.

"My dear Dr. Attfield,—My lecture hours are unfortunately arranged in such a way that I find, to my very great regret, I shall be unable to be present at the annual gathering on October 2nd. I shall be glad, therefore, if you will, in my unavoidable absence, kindly offer to those students of the past Session who come up to receive their well-earned honours, an expression of my hearty congratulations on their success and hopes for their future progress and welfare.

"At the same time I should like to say that I hope to hear of the uninterrupted prosperity and usefulness of the School of Pharmacy, and trust the laboratory work in which I have always taken a good deal of interest may long go on as vigorously as heretofore.

"Believe me, my dear Dr. Attfield,
"Yours very sincerely,
"WILLIAM A. TILDEN.

"Prof. Attfield, Ph.D."

The questions for examination were :—

Hours: Ten to Five. Books and Memoranda permitted.
Standard Number of Marks, 100.

1. The substances supplied to you are six pharmacopœial chemicals. Name them.
2. Ascertain the nature of the impurities (if any) present in the two accompanying salts.
3. The paper is supposed to contain arsenic. Ascertain if such is the case.
4. A specimen of urinary deposit is placed before you; ascertain by the microscope the nature of its constituents.
5. Determine volumetrically the amount of carbonate of sodium (Na_2CO_3) in the sample.
6. Ascertain by a gravimetric method the percentage of acetate of lead in the impure specimen before you.

P.S. You are at liberty to select one of the last two exercises, but not to attempt both. The same value in marks is attached to a correct answer in either.

HERBARIUM PRIZE.

The PRESIDENT next called upon Professor Bentley to report respecting the Herbarium prize.

Professor BENTLEY said that amongst the prizes given in connection with the Pharmaceutical Society, he considered one of the best instituted by the Council was that given for Herbaria of British plants. He classed this amongst the best, because it encouraged young men, particularly in the country, to devote some time during their pupilage to the acquirement of knowledge which could not but be essential to them in their future progress. He regretted that on the present occasion only one collection of British plants was sent in for competition; but while he said he regretted there was only one, he need only point to that one to show them that he could not speak in too high terms of the student who had sent it in. When he told them the name of that gentleman, they would be prepared for great things; and when they saw the case opened in which the specimens were contained, they would confess that even he, who was always inclined to encourage students with a good word if he possibly could, had not said all that could be said of the deserts of the gentleman who had collected them. The name of the contributor was Mr. Frederick Janson Hanbury, who had sent in a collection of British plants containing upwards of 700 specimens, nearly half the flora of the British islands. The number was in itself an evidence of the indefatigable industry of Mr. Hanbury. And when he (Professor Bentley) stated that, independently of the number, nearly the whole of England and Ireland had been ransacked for the treasures, he gave an additional reason why they should congratulate Mr. Hanbury. The collection contained not only common plants, but plants of great rarity and interest—of interest even to botanists. Not only had he to take excursions many miles to collect these different specimens, but he had to bring them home, to name them, to select those which were proper for drying, to dry them carefully, to mount them upon paper, and to preserve and arrange them in the systematic and in the beautiful manner in which they now saw them. He (Professor Bentley) need not say any more than that he recommended the Council to give Mr. Hanbury the highest award they were enabled, namely, the Silver Council Medal. The Secretary had mentioned to him, and he wished particularly to speak upon it that day, that several pupils had written to inquire whether plants gathered from botanic gardens were eligible for the herbaria; he (Professor Bentley) replied, certainly not. In large towns the young students could go into the botanic gardens where the plants were all named, but the object of the prize was to encourage the student to exert his own knowledge. The plants for the herbarium prize must be wild plants, collected from native habitats, and named by the student himself; in fact, those conditions constituted the only value of the prize. He thought the Herbaria prizes might be increased; that in different centres, covering, say, an area of twenty miles, prizes might be offered for the best collection of British plants.

The foregoing medals and certificates were then handed to those of the successful competitors who were present, the President congratulating the recipients as they came forward to receive the awards from his hands.

Mr. W. A. Shenstone, one of the successful candidates, the Secretary to the Testimonial Fund to Dr. Tilden, expressed on behalf of the students in the laboratory their thanks to the Council for the encouragements they gave to the students, to the Professors for the able assistance they had rendered the young men in pursuing their studies, and also to the Demonstrators, especially Dr. Tilden, to whom they offered their best wishes on the occasion of his leaving them, and their congratulations on the new appointment he had received.

The Pereira Medal.

The President then said that the highest prize of the year—the Pereira Medal—had been awarded to Mr. William Ashwell Shenstone, to whom he had great pleasure in handing it.

The following were the questions for examination:—

Chemistry.

Time allowed: Two Hours. Standard Number of Marks, 100.

1. How would you separate tin, lead, silver, bismuth, copper, iron, zinc, and magnesia when present together in the form of a powder insoluble in water, and by what tests would you identify each?
2. Describe minutely the process you would employ to determine the percentage of ammonia in spirit of sal volatile.
3. How would you detect the iron in yellow prussiate of potassium?
4. Explain briefly the atomic theory.

Botany and Materia Medica.

Botany.

Time allowed: Two Hours. Standard Number of Marks, 100.

1. Describe various kinds of inflorescence, illustrating each by an example.
2. Give some account of the germination of the seed.
3. What is phu? Name its varieties, and describe the officinal plant.
4. Describe the drupe, utricle, follicle, and siliqua, with examples.

Materia Medica.

Standard number of Marks, 100.

1. State what you know respecting *Hydrastis Canadensis.*
2. On what does the efficacy of *Hyoscyamus niger* depend? State the theories entertained respecting its employment.
3. State the source of the olibanum of commerce, adducing reasons for the assertion.
4. Write a brief account of recent cinchona cultivation.

The Prize of Books.

The President next announced that the Prize of Books had been awarded to Mr. George Claridge Druce, of Northampton.

The following were the questions for examination:—

Prize of Books.

State the best method of dispensing the following prescriptions, assign the reasons for the same, and write the labels in suitable language:—

℞ Potassæ Carb. gr. x.
Potassæ Nitrat. gr. xxx.
Pulv. Sacchari ʒj.
Ol. Amygdal. ʒiij.
Sp. Ammon. Aromat. ʒij.
Aqu. Destill. ad. ℥iv.
M. ft. Mistura.

Capt. quartam partem mane vespereque vel sæpiùs raucitate urgente.

℞ Ferri Redact. gr. iv.
Quinæ Disulph. gr. j.
Ext. Nucis Vomicæ gr. $\frac{2}{3}$.
Ext. Cannab. Ind. gr. $\frac{1}{4}$.
M. ft. pil. j.

bis die sumend nisi cephalalgia superven. dein capt. j. semel in die tantùm.

Mitte xx. in argent involv.

State the proportions of the materials, temperature of the water, and time ordered for preparing the following infusions, and suggest any improvement that might be made:—Buchu, Cusso, Quassia.

Describe and explain the P. B. process for making Acidum Tannicum.

State the ingredients used in and the method of preparing Emplast. Cerat. Saponis.

Enumerate the preparations of the Pharmacopœia which contain lead.

The Bell Scholarships.

The President then said that two Junior Bell Scholarships had been awarded this year, one to Mr. Sidney Plowman, of Boston, the other to Mr. Edward Lawrance Cleaver, of Oxford Street, London. It would be noticed that the honours were equally divided between town and country.

The requisite number of marks was not obtained by either of the competitors for the Senior Scholarship.

The questions for examination were as follows:—

Senior Bell Scholarship.

ARITHMETIC.

Time allowed: One Hour.

1. Reduce $\frac{3}{7}$ of $\frac{2}{9}$ of $\frac{4}{5}$ of $8\frac{3}{4}$ to a simple fraction.
2. What is the cube root of $\frac{1}{2}$?
3. Find two numbers of which the sum shall be 21, and the sum of their squares 225.

LATIN.

Time allowed: One Hour.

1. State where the verb *eo* differs in formation from a regular verb.
2. Give one illustration of the ablative of manner.
3. Put into Latin,—Therefore exercise and temperance can, even in old age, preserve something of pristine vigour.
4. Translate.—Quibus rebus cognitis, Cæsar maturandum sibi censuit, si esset in perficiendis pontibus periclitandum, ut priùs quàm essent majores eò coactæ copiæ, dimicaret.

ENGLISH COMPOSITION.

Time allowed: One Hour.

Write a few remarks on 'Strikes.'

CHEMISTRY.

Time allowed: One Hour. Standard Number of Marks, 50.

1. A litre of carbonic anhydride is passed over red-hot charcoal; what gas is formed, and what is its volume? Explain how the carbon may be separated from carbonic anhydride.
2. A lighted candle burns if placed in oxygen. It will also burn in chlorine. Explain the nature of the combustion in both cases.
3. How would you detect traces of arsenic in potassio-tartrate of antimony?

BOTANY.

Time allowed: One Hour. Standard Number of Marks, 50.

1. How do plants take up food by their roots and leaves?
2. From what plant or plants are the so-called *bay-leaves* obtained?
3. To what natural orders do the common nettle, the white dead nettle, the teasel, and the wallflower belong?
4. Define venation, vernation, and æstivation, and give examples in support of your definition.

Junior Bell Scholarship.

ARITHMETIC.

Time allowed: One Hour.

1. Multiply £27. 19*s*. $9\frac{3}{4}$*d*. by 59.
2. Reduce $\frac{7}{3}$, $\frac{2}{5}$, and $5\frac{1}{6}$ to a common denominator.
3. Divide 9 by ·45.
4. Multiply ·406 by 52.

LATIN.

Time allowed: One Hour.

1. Give the Present, Infinitive, Perfect, and Supine of *sono, deleo, dico,* and *solvo.*
2. Decline *ambo* and *alius.*
3. Put into Latin,—This is what I have to say about friendship.
4. Translate,—Ad hæc Cæsar, quæ visum est, respondit. Sed exitus fuit orationis: Sibi nullam cum his amicitiam esse posse, si in Galliâ remanerent; neque verum esse, qui suos fines tueri non potuerint, alienos occupare: neque ullos in Galliâ vacare agros, qui dari tantæ præsertim multitudini sine injuriâ possint.

ENGLISH COMPOSITION.

Time allowed: One Hour.

Write a few remarks upon one of the following subjects:—

Reading.
Business Habits.

CHEMISTRY.

Time allowed: One Hour. Standard Number of Marks, 50.

1. What is meant by an elementary body? Name six metallic and six non-metallic elements, and explain in what state they exist in nature.
2. Explain the action that takes place when Potassium is thrown into water.
3. How would you prepare Phosphoric and Hydrochloric Acids? Explain the process in each case by equations, and give the tests for distinguishing one from the other.

BOTANY.

Time allowed: One Hour. Standard Number of Marks, 50.

1. What are the differences in leaf and stem between Endogens and Acrogens?
2. Define the following, and give examples of each, tubercule, corm, stipule, bract, perianth, leaflet.
3. Describe the flower of a buttercup, dandelion, and tulip.
4. Whence do plants obtain their food?

MATERIA MEDICA.

Time allowed: One Hour. Standard Number of Marks, 50.

1. How would you estimate the value of a sample of scammony root and jalap?
2. What plant yields common turpentine, and in what manner is the oil of turpentine of pharmacy obtained therefrom?
3. What is the best method for making cherry laurel water, and how would you determine its strength?

The Inaugural Sessional Address.

The President then said: One pleasant duty follows closely upon another. Having distributed the prizes, it remains for me to congratulate collectively the competitors. I am glad to know that more candidates this year have received certificates than usual. Heartily do I rejoice with the successful candidates, and sympathize with the less fortunate, wishing success equally to both in all their future undertakings. To those now entering as students, I will simply say, listen carefully and attentively to the address which will now be delivered by our friend and colleague, Mr. Stoddart.

The following inaugural address was then delivered by Mr. William Walter Stoddart:—

Mr. President, Ladies, and Gentlemen,—

The greatest pleasure any one can enjoy is the companionship of those who are following the same pursuits, or working out the same investigations, whether in the field of science or of literature.

In that position I am placed this evening, having been requested by your Council to address you, with the view of offering a few suggestions as to the best mode of studying the various branches of pharmaceutical education, and thereby ensuring the greatest success. I must confess, however, that I have undertaken the task with very conflicting feelings. On the one hand, I experience some considerable trepidation, lest I fail to fulfil the duty intrusted to my care; while, on the other, I have the satisfaction of knowing that I am in every respect a fellow-student, and therefore can understand and enter into your many difficulties. Whether or not I remove any, will be for you to decide.

I suppose that all of you are anxiously looking forward to the time when, in after life, you will realize the results of the present careful teaching and training.

Proper food is as indispensably necessary for our minds as for our bodies; and the quality of that food will as surely determine the future development of the one as of the other. If you are content to feed your mental lives with worthless literature, you will most assuredly enervate your powers of thought and judgment; but, on the contrary, if strengthened by appropriate reading and a judicious selection of all that is valuable and useful, you cannot avoid ensuring a vigorous intellect. It will enable you to hold your own among your fellow-men, to arrive at the decision of difficult points which will often arise in your daily occupation, and perhaps to guide your brother pharmacists through many a labyrinth which would otherwise end in a disastrous failure.

Everything in this life if neglected will naturally retrograde and decline into sterility and desuetude. God has given us minds, and intrusted them to our care, and if we do not cultivate them, and thereby widen the sphere of thought, we most assuredly neglect a very solemn duty, and prove ourselves unworthy of the gift.

Not one of you is born to live alone, or for yourselves only; nor can you, whether you wish it or not, avoid making some impression on your companions, either for good or evil. I suppose the great majority of pharmacists are obliged to work hard for their daily bread, and to supply the common necessaries of life for those who are near and dear to them. Experience has repeatedly proved that the much-coveted competence—if such a thing be possible for a druggist—will be attained in proportion to the perseverance and to the intelligence evinced by the skill and knowledge of our craft.

Education is very often confounded with teaching, and the error is as great as it is popular. Education is a final result, that is only obtained from a certain amount of labour, especially if facilitated by faithful and able teachers; but do not deceive yourselves in this matter, for it is possible for you to have at your command the most competent professors the world can produce, and yet fail in gaining the least advantage. And why? Because their instructions have not been accompanied by your own individual efforts. You must build your own edifice, and no one else can do it for you; and as with a material building, it is indispensable that you go to a proper quarry, hew the stone with a practised hand, and gradually place layer upon layer, according to a preconceived plan; so it is with your educational structure. The old saying that "what a man sows, that shall he also reap," applies exactly to your case; and just in proportion to the labour bestowed, and the quality of the seed sown, so will the harvest be. There will be no harvest if the seed be not properly sown.
